

MORGAN & CLAYPOOL PUBLISHERS

Chapter #6

MODELING LANGUAGES AT A GLANCE

Teaching material for the book

Model-Driven Software Engineering in Practice

by Marco Brambilla, Jordi Cabot, Manuel Wimmer.

Morgan & Claypool, USA, 2012.

Contents

- DSL vs. GPL
- Example of GPL: UML
- DSL principles and dimensions
- OCL

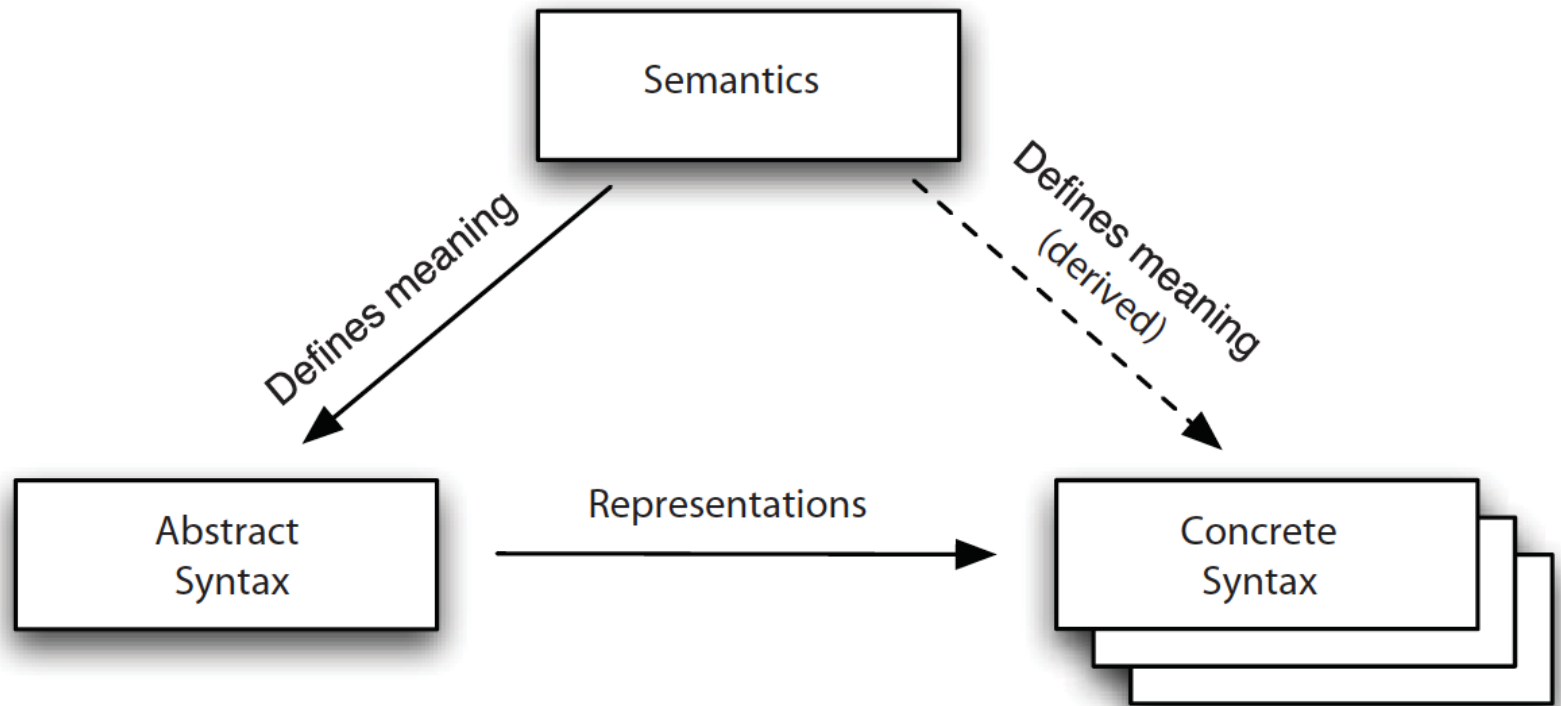

Anatomy of a Modeling Language

- **Abstract syntax:** Describes the structure of the language and the way the different primitives can be combined together, independently of any particular representation or encoding.
- **Concrete syntax:** Describes specific representations of the modeling language, covering encoding and/or visual appearance.
- **Semantics:** Describing the meaning of the elements defined in the language and the meaning of the different ways of combining them.

Anatomy of a Modeling Language

DSL vs. GPL

First distinction is between

- General Purpose languages (GPL or GPML) and
- Domain Specific languages (DSL or DSML)

(already discussed in Chapter 2)

- We take UML as an exemplary case of GPL

UML – UNIFIED MODELING LANGUAGE

Overview of UML Diagrams

- There is no official UML diagram overview or diagram grouping.
- Although UML models and the repository underlying all diagrams are defined in UML, the definition of diagrams (i.e., special views of the repository) are relatively free.

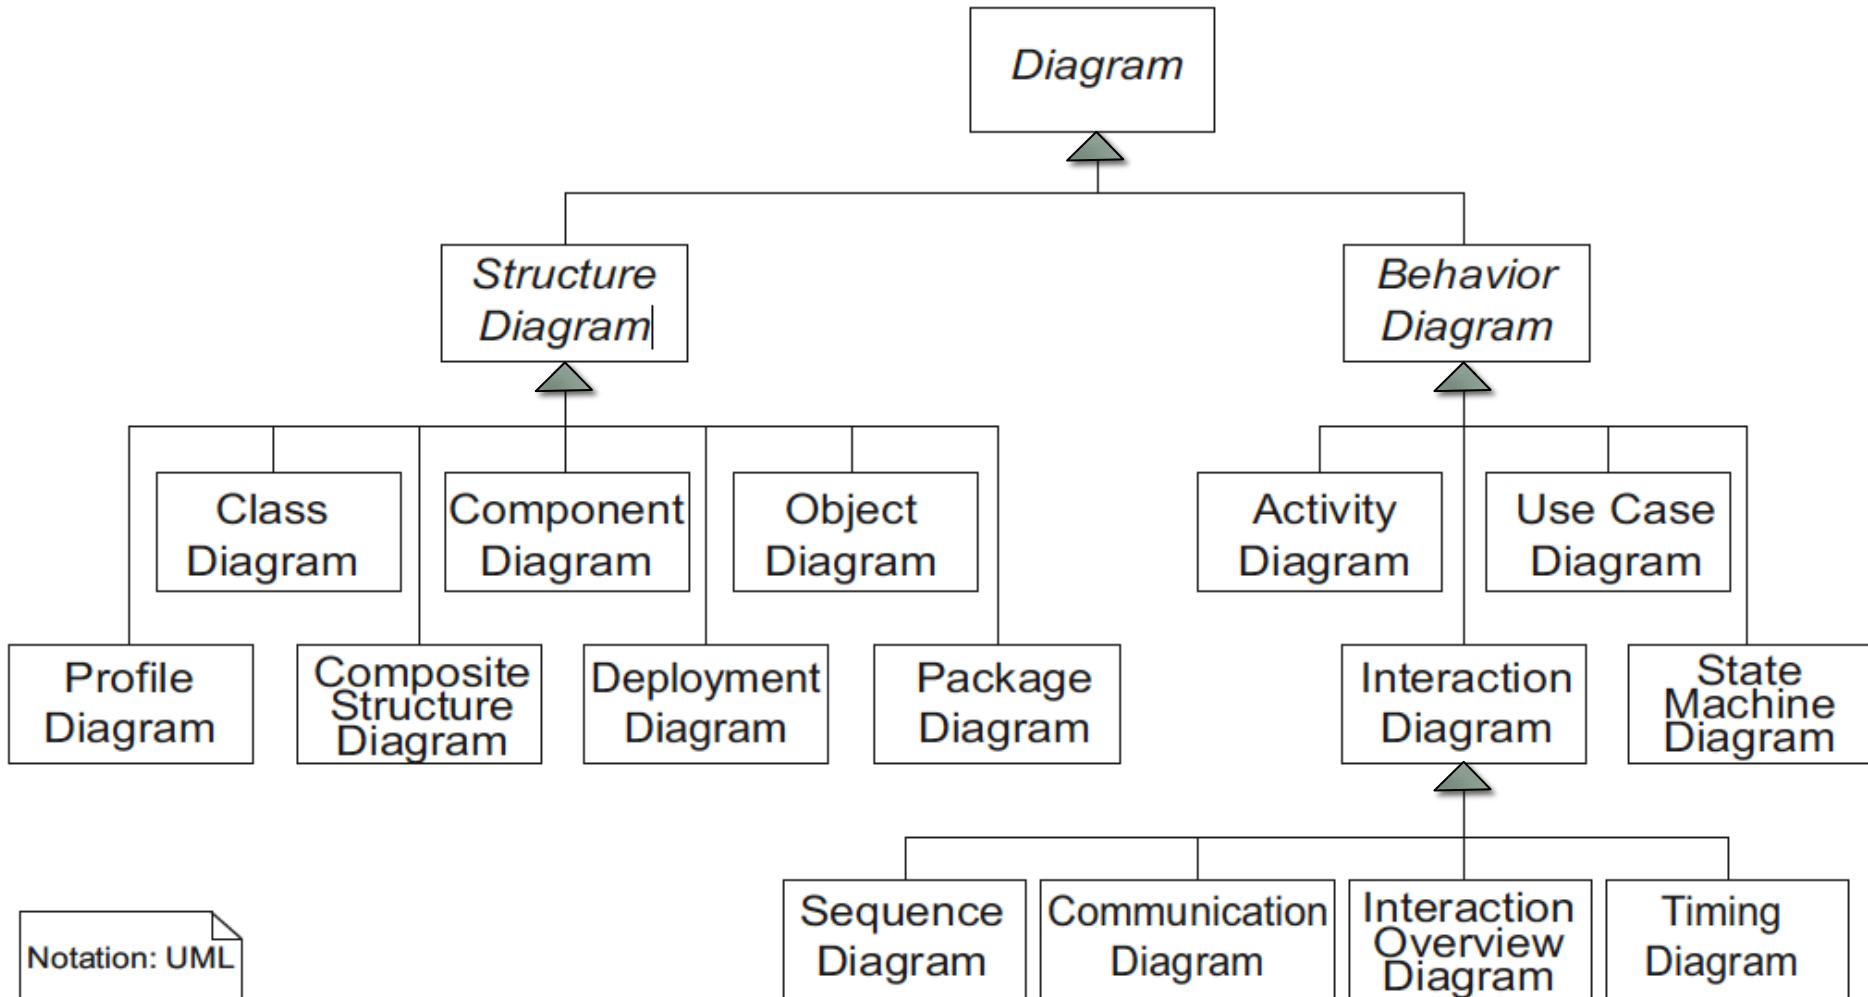

Overview of UML Diagrams

- In UML a diagram is actually more than a collection of notational elements.
- For example, the package diagram describes the package symbol, the merge relationship, and so on.
- A class diagram describes a class, the association, and so on.
- Nevertheless, we can actually represent classes and packages together in one diagram.

Overview of the UML diagrams

UML Design practices

- **Pattern-based design:** A set of very well-known design patterns, defined by the so-called Gang of Four
- **Using several integrated and orthogonal models together:** UML comprises a suite of diagrams that share some symbols and allow cross-referencing
- **Modeling at different levels of detail:** UML allows eliding details in diagrams when needed. Choose the right quantity of information to include in diagrams
- **Extensibility:** UML provides a good set of extensibility features which allow to design customized modeling languages if needed

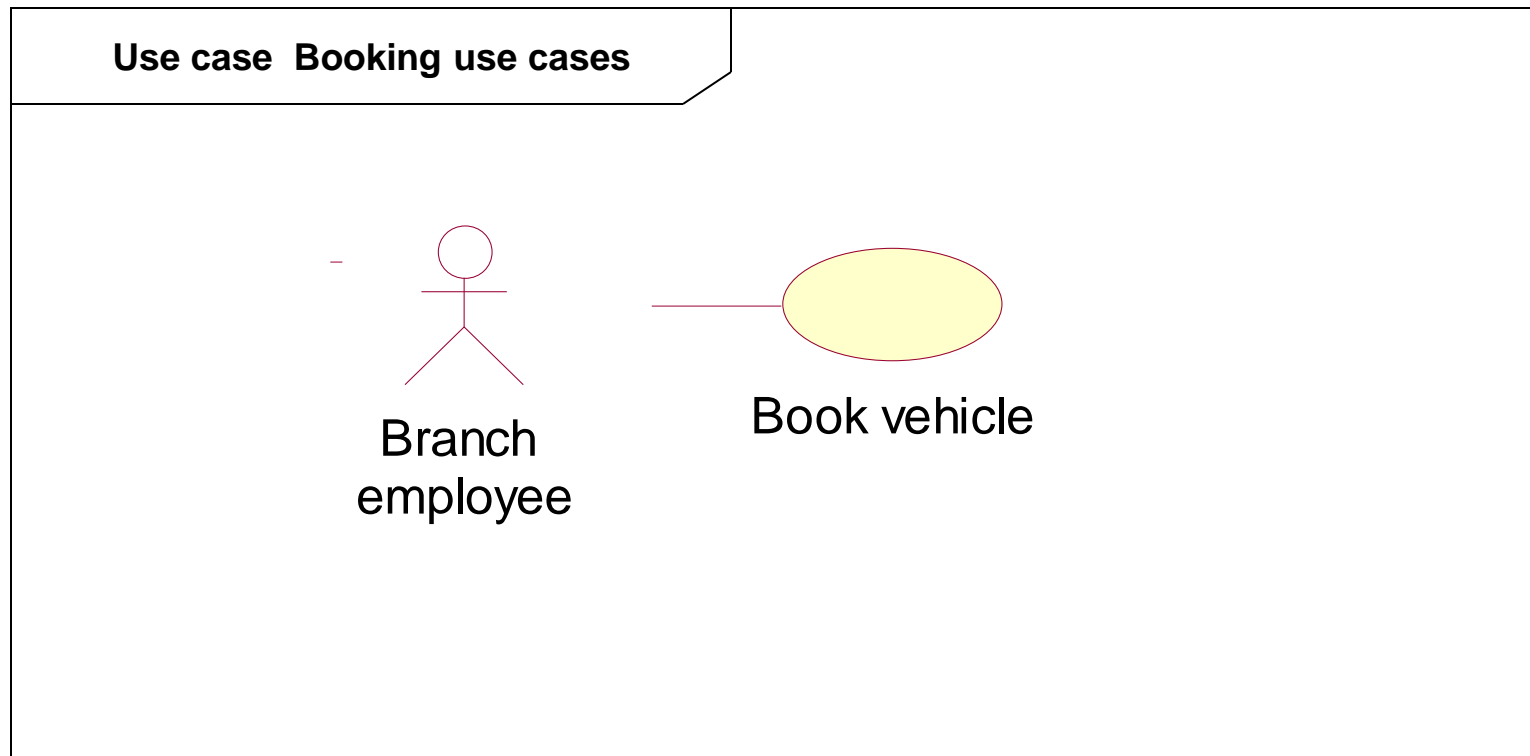

Class vs. instance in diagrams

Basic notation for diagrams

Example of a use case diagram

UML STRUCTURE DIAGRAMS (OR STATIC DIAGRAMS)

Structure diagrams (1)

Emphasize the **static description** of the elements that must be present in the system being modeled:

1. The **conceptual items** of interest for the system
 - **Class diagram:** Describes the structure of a system by showing the classes of the systems, their attributes, and the relationships among the classes
 - **Composite structure diagram:** Describes the internal structure of a class and the collaborations
 - **Object diagram:** A view of the structure of example instances of modeled concepts

Structure diagrams (2)

2. The **architectural organization and structure** of the system.

- **Package diagram:** Describes how a system is split up into logical groupings
- **Component diagram:** Describes how a software system is split up into components
- **Object diagram:** A view of the structure of example instances of modeled concepts

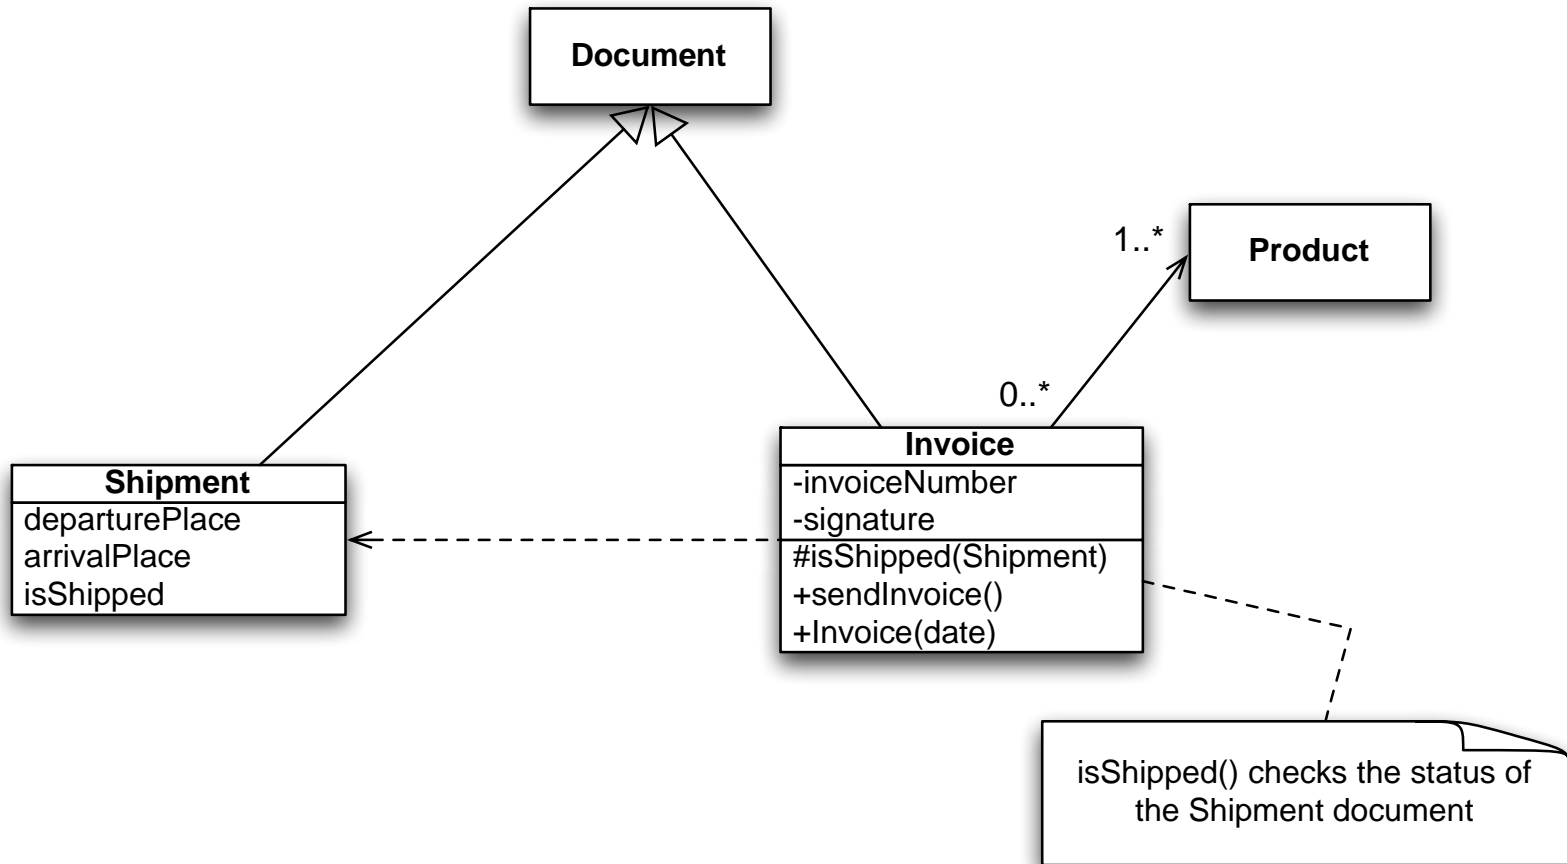

Class diagrams basic concepts

- The basis of UML is described in the **Kernel** package of the UML metamodel.
- Most class models have the superclass ***Element*** and has the ability to own other elements, shown by a composition relationship in the metamodel.
- That's the only ability an element has.

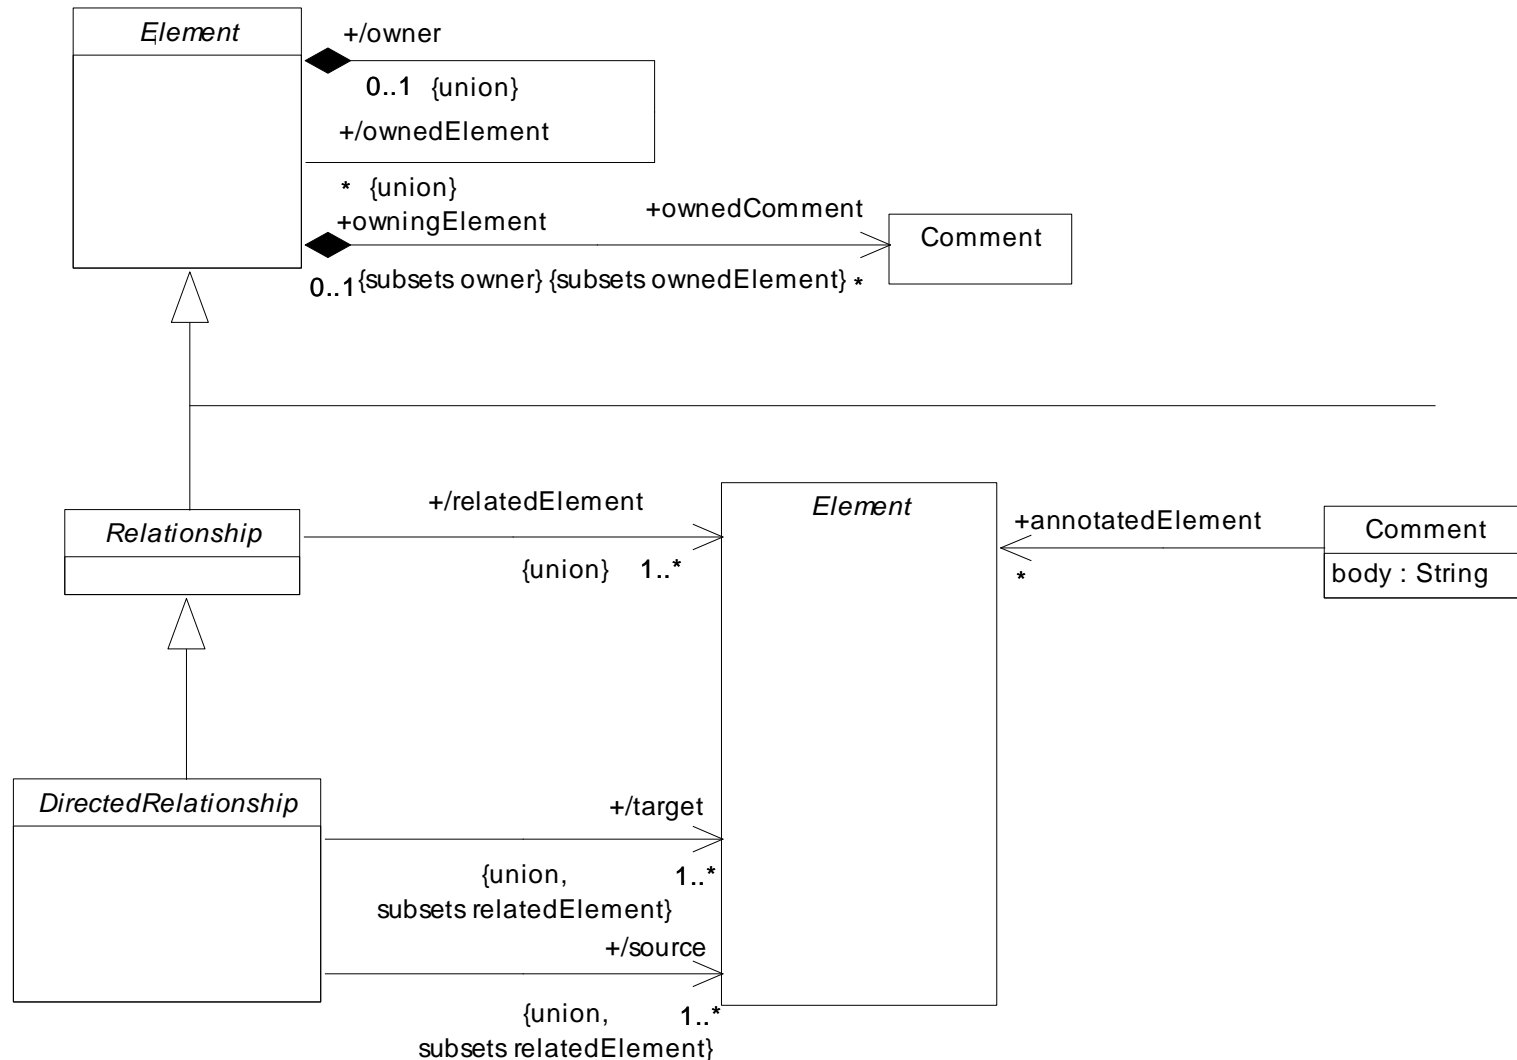

Class diagram example

Component Diagram example

The basic concepts in the UML metamodel for class diagrams

Named elements

- **Def.** A *named element* is an element that can have a name and a defined *visibility* (*public*, *private*, *protected*, *package*):
 - +=public
 - -=private
 - #=protected
 - ~=package
- The name of the element and its visibility are optional.

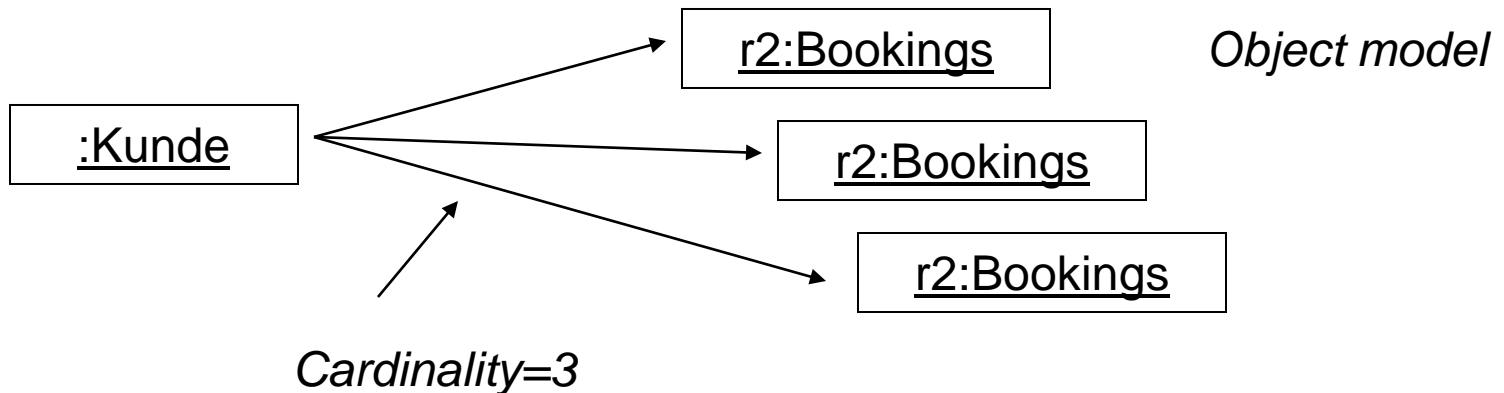

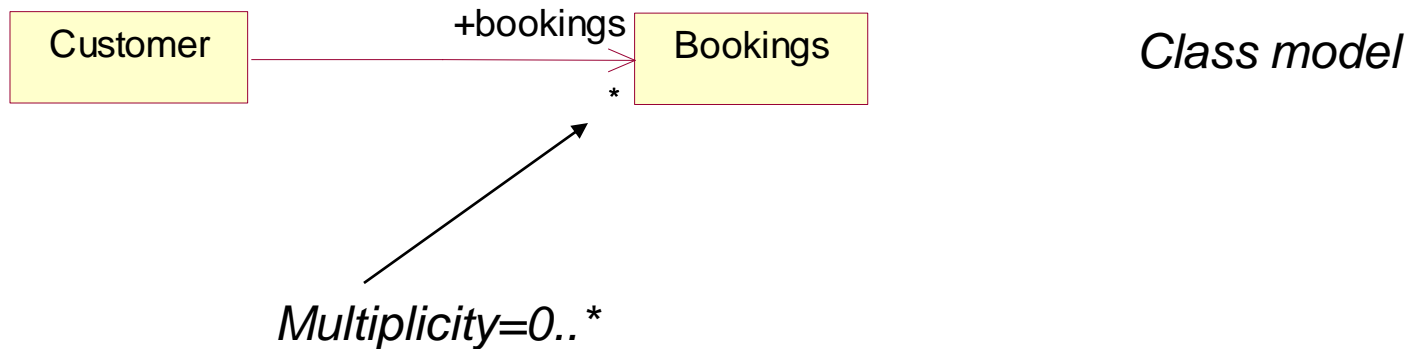

Multiplicities

- A ***multiplicity element*** is the definition of an interval of positive integers to specify allowable cardinalities.
- A ***cardinality*** is a concrete number of elements in a set.
- A multiplicity element is often simply called ***multiplicity***; the two terms are synonymous.

Example Multiplicity & Cardinality

UML BEHAVIOURAL OR DYNAMIC DIAGRAMS

UML Behavioural Diagrams (1)

- **Use case diagram:** Describes the functionality provided by a system in terms of actors external to the system and their goals in using the system
- **Activity diagram:** Describes the step-by-step workflows of activities to be performed in a system for reaching a specific goal
- **State machine diagram (or statechart):** Describes the states and state transitions of the system, of a subsystem, or of one specific object.

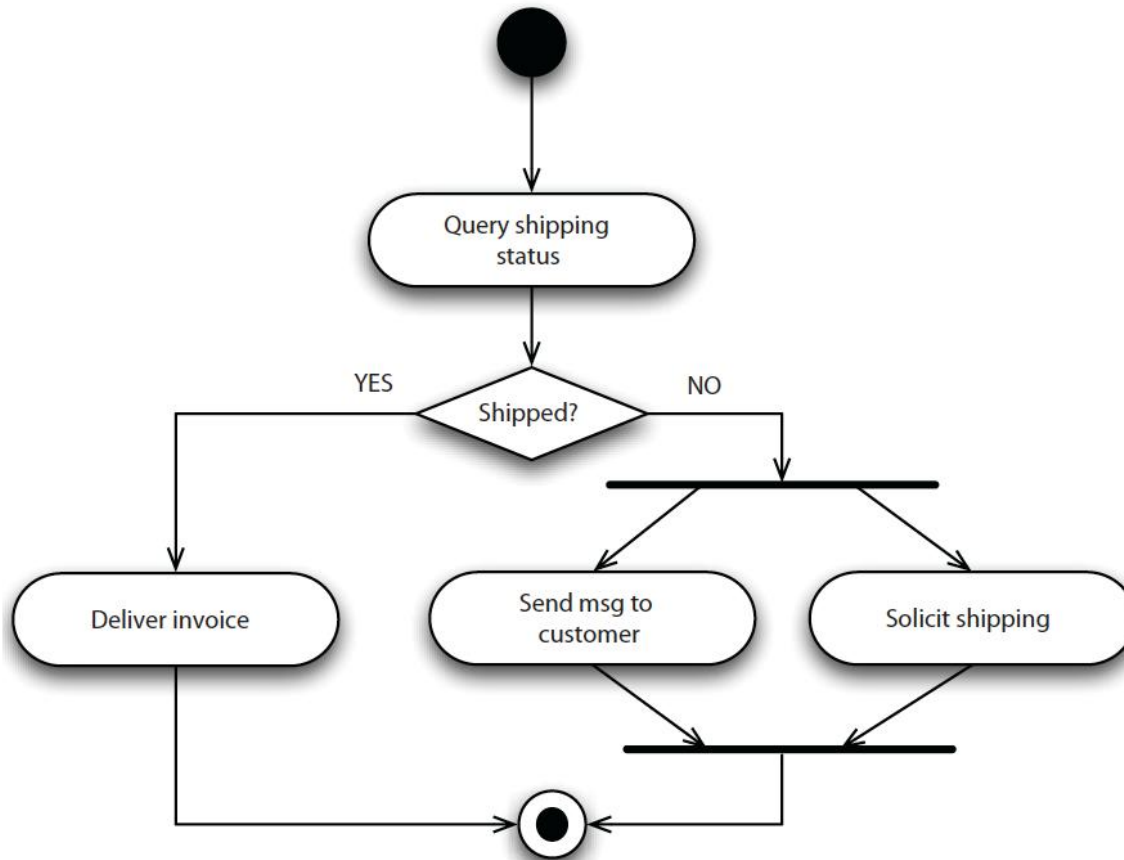

UML Behavioural Diagrams (2): Interaction diagrams

A subset of behavior diagrams, emphasize the **flow of control and data** among the elements of the system.

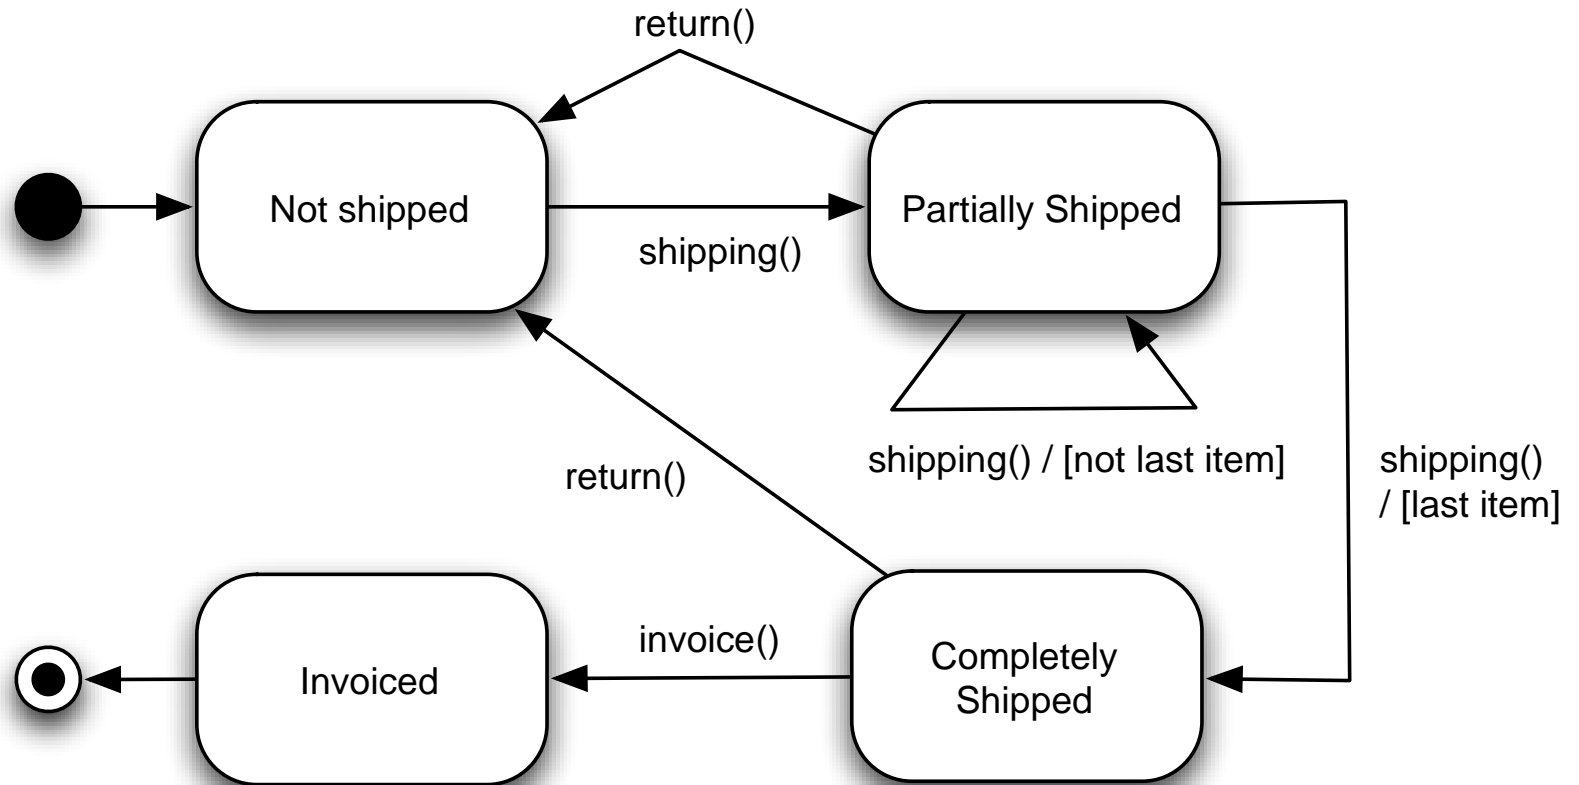

- **Sequence diagram:** Shows how objects communicate with each other in terms of a temporal sequence of messages
- **Communication or collaboration diagram:** Shows the interactions between objects or classes in terms of links and messages that flow through the links
- **Interaction overview diagram:** Provides an overview in which the nodes represent interaction diagrams
- **Timing diagrams:** A specific type of interaction diagram where the focus is on timing constraints

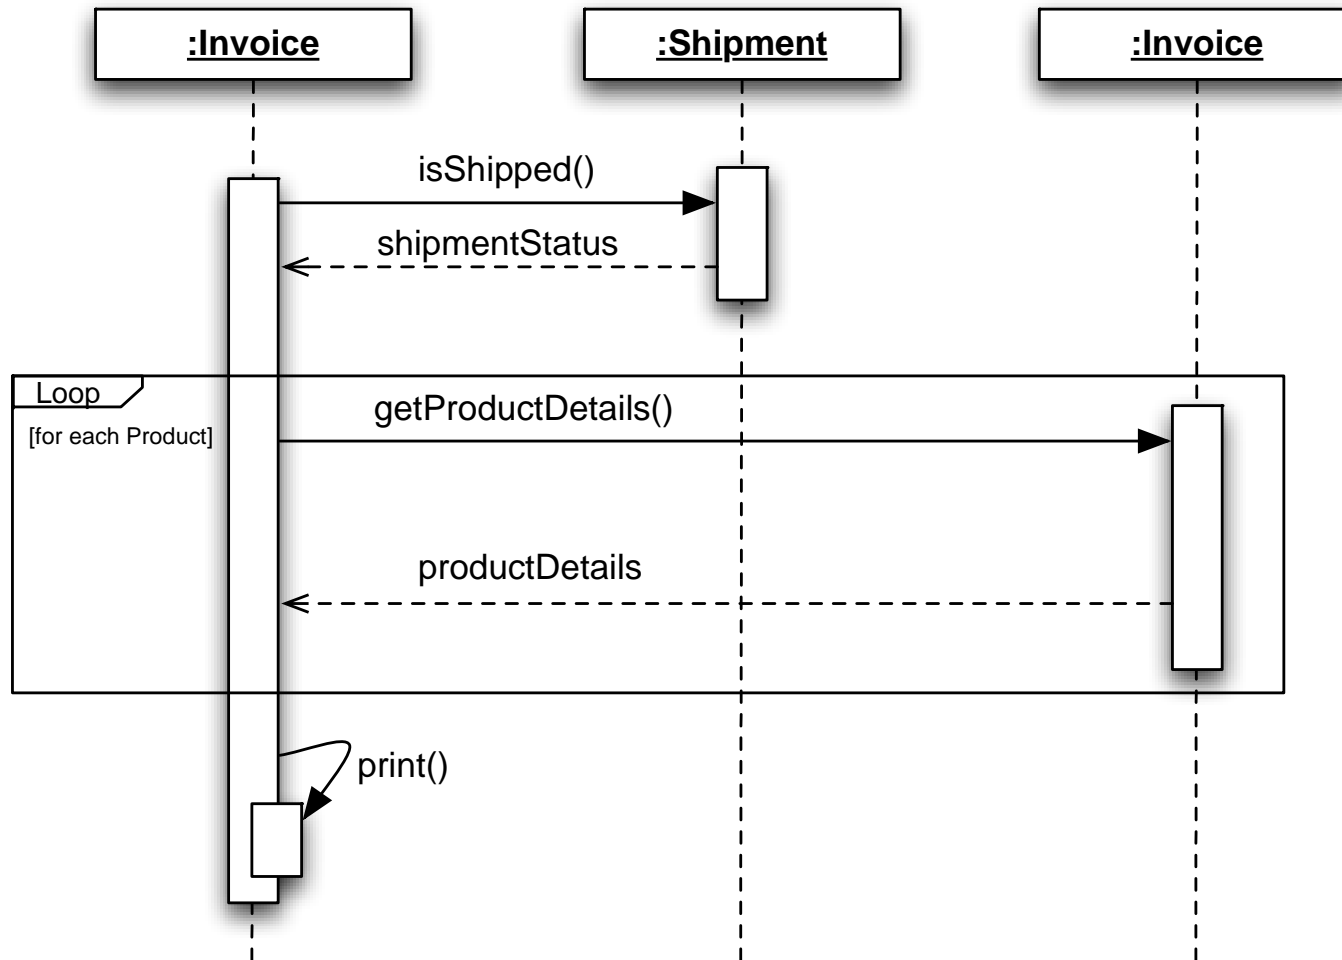

Activity diagram example

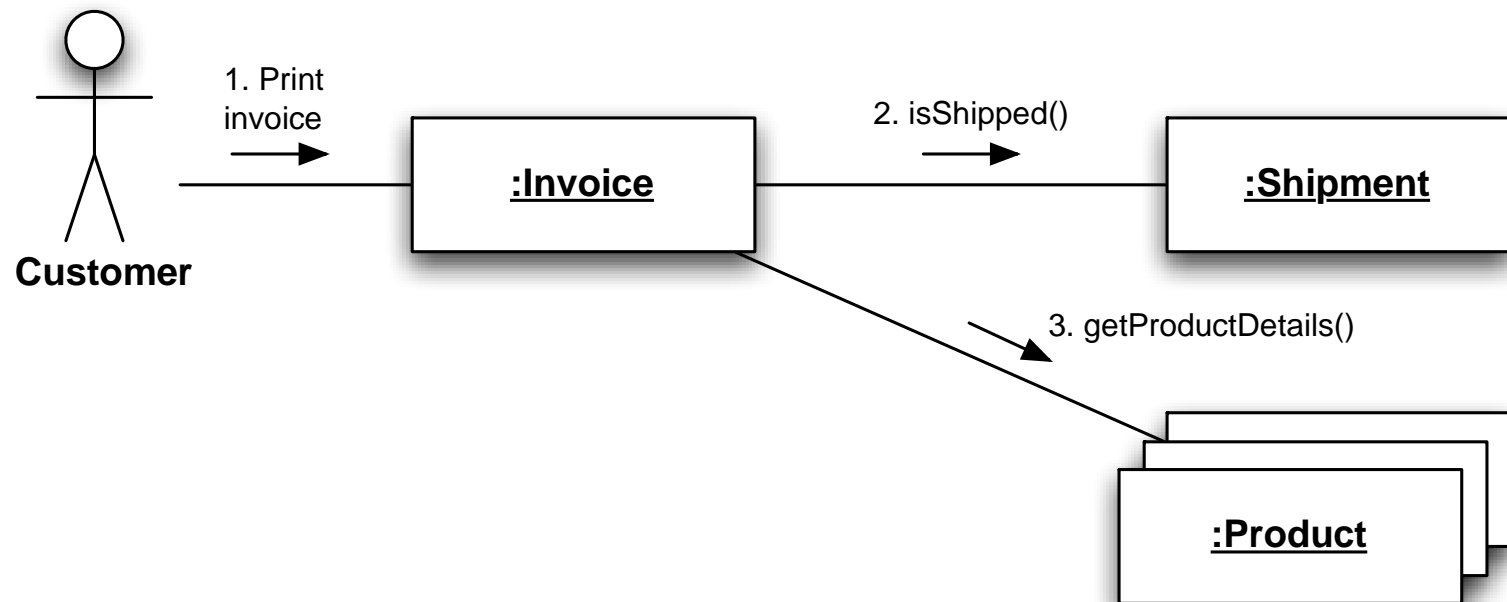

State Diagram example

Sequence diagram example

Collaboration diagram example

UML EXTENSIBILITY

Extensibility: Stereotype definition

- Stereotypes are formal extensions of existing model elements within the UML metamodel, that is, ***metamodel extensions***.
- The modeling element is directly influenced by the **semantics** defined by the extension.
- Rather than introducing a new model element to the metamodel, **stereotypes add semantics to an existing model element**.

Multiple stereotyping

- **Several stereotypes** can be used to classify one single modeling element.
- Even **the visual representation** of an element can be influenced by allocating stereotypes.
- Moreover, stereotypes **can be added to** attributes, operations and relationships.
- Further, stereotypes **can have attributes** to store additional information.

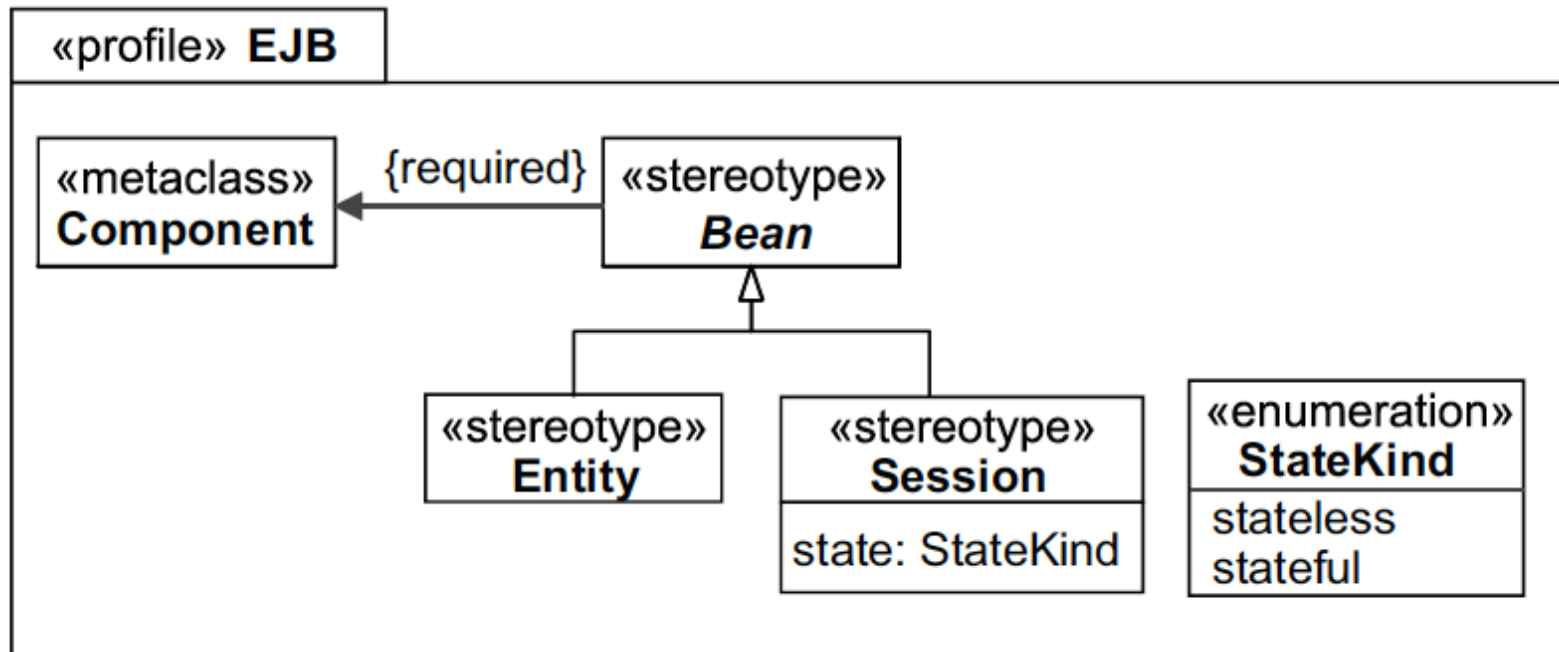

Stereotypes Notation

- A stereotype is placed before or above the element name and enclosed in guillemets (<<, >>).
- **Important:** not every occurrence of this notation means that you are looking at a stereotype. **Keywords** predefined in UML are also enclosed in guillemets.

UML Extensibility: profile example

DOMAIN-SPECIFIC LANGUAGES

Principles for Domain Specific Languages

- The language must **provide good abstractions** to the developer, must be intuitive, and **make life easier**, not harder
- The language must **not depend on one-man expertise** for its adoption and usage. Its definition must be **shared and agreed upon**
- The language must **evolve** and must **be kept updated** based on the user and context needs, otherwise it is doomed to die.
- The language must come together with supporting **tools and methods**
- The language should be **open for extensions and closed for modifications** (open-close principle)

Classification of DSLs (1): FOCUS.

Horizontal vs. Vertical

- **Vertical DSLs** aim at a specific industry or field.
- Examples: configuration languages for home automation systems, modeling languages for biological experiments, analysis languages for financial applications.
- **Horizontal DSLs** have a broader applicability and their technical and cover concepts that apply across a large set of fields. They may refer to a specific technology but not to a specific industry.
- Examples: SQL, Flex, WebML.

Classification of DSLs (2): STYLE.

Declarative vs. Imperative

- **Declarative DSLs:** specification paradigm that **expresses the logic of a computation without describing its control flow.**
- The language defines what the program should accomplish, rather than describing how to accomplish it.
- Examples Web service choreography, SQL.

- **Imperative DSLs:** define an **executable algorithm** that states the steps and control flow that needs to be followed.
- Examples: service orchestrations (start-to-end flows), BPMN process diagrams, programming languages like Java or C/C++.

Classification of DSLs (3): NOTATION.

Graphical vs. Textual

- **Graphical DSLs:** the outcomes of the development are visual models and the development primitives are graphical items such as blocks, arrows and edges, containers, symbols, and so on.
- **Textual DSLs** comprise several categories, including XML-based notations, structured text notations, textual configuration files, and so on.

Classification of DSLs (4): INTERNALITY.

Internal vs. External

- **External DSLs** have their own custom syntax, with a full parser and self-standing, **independent models/programs**.
- **Internal DSLs** consist in using a **host language** and give it the feel of a particular domain or objective, either by embedding pieces of the DSL in the host language or by providing abstractions, structures, or functions upon it.

Classification of DSLs (5): EXECUTABILITY.

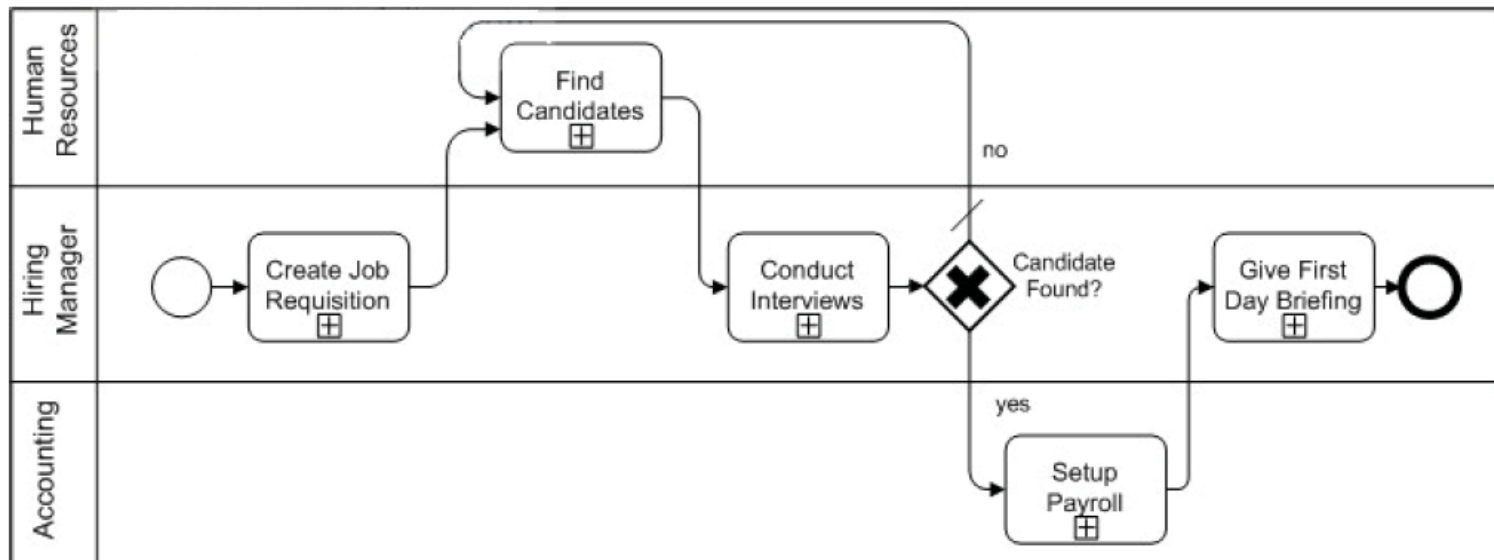

Model Interpretation vs. Code Generation

- **Model interpretation:** reading and executing the DSL script at runtime one statement at a time, exactly as programming languages interpreters do.
- **Code-generation:** applying a complete model-to-text (M2T) transformation at deployment time, thus producing an executable application, as compilers do for programming languages.
- See Chapter 2 for model executability details.

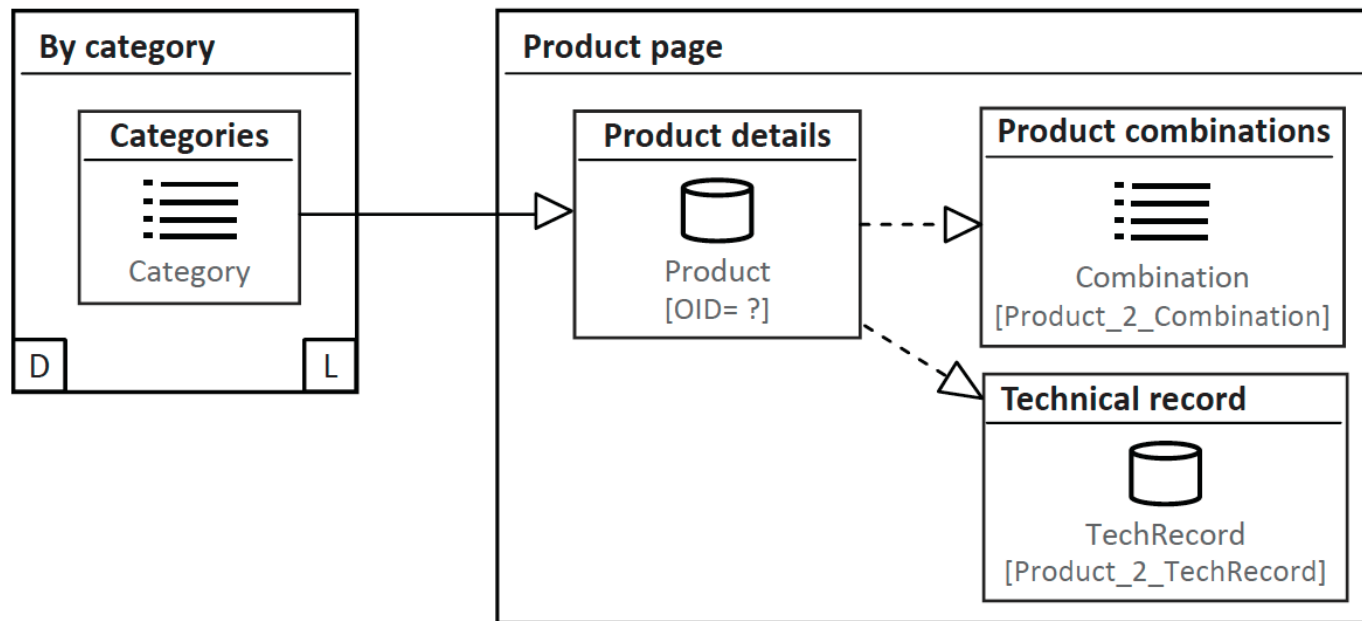

DSL example (1): BPMN process model

- Graphical, external, imperative, horizontal DSL for specifying business processes

DSL example (2): WebML hypertext model

- Declarative, graphical, horizontal DSL for modeling Web navigation Uis. Supporting tool WebRatio applies a full code generation approach for executing the models.

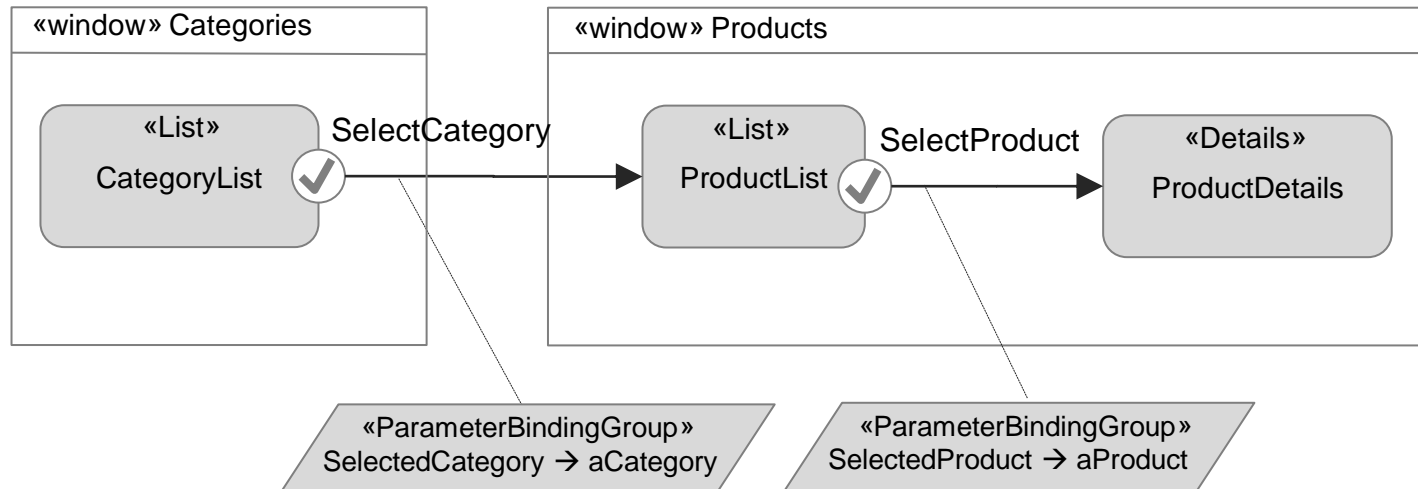

- See also: www.webml.org

DSL Example (3): IFML by OMG

- Interaction Flow Modeling Language
- Defines content and navigation of user interfaces

- See also: <http://www.ifml.org>
and IFML book: <http://amzn.to/1mcgYuo>

DSL example (4): VHDL specs

- Textual, external, declarative, vertical DSL for specifying the behaviour of electronic components.
- Example: definition of a Multiplexer in VHDL

```
entity mux4_to_1 is
    port (I0, I1, I2, I3: in std_logic_vector(7 downto 0);
          SEL: in std_logic_vector (1 downto 0);
          OUT1: out std_logic_vector(7 downto 0));
end mux4_to_1;
```

- Multiplexer (MUX): electronic component that selects one of several analog or digital input signals and forwards the selected input into a single output line.
- See more at: <http://en.wikipedia.org/wiki/Multiplexer>

DSL Example (4): VHDL Cont.d

Alternative representation of the multiplexer, according to different notations (which could be seen as DSLs themselves):

- Electronic block diagram, truth table, output boolean expression

EN'	S1	S0	Q
0	0	0	D0
0	0	1	D1
0	1	0	D2
0	1	1	D3
1	x	x	1

$$Q = S1' S0' D0 + S1' S0 D1 + S1 S0' D2 + S1 S0 D3$$

OCL – OBJECT CONSTRAINT LANGUAGE

OCL Topics

- Introduction
- OCL Core Language
- OCL Standard Library
- Tool Support
- Examples

Motivation

- Graphical modeling languages are generally not able to describe all facets of a problem description
 - *MOF, UML, ER, ...*
- Special **constraints** are often (if at all) added to the diagrams in **natural language**
 - Often **ambiguous**
 - Cannot be validated **automatically**
 - No **automatic** code generation
- Constraint definition also crucial in the definition of new modeling languages (DSLs).

Motivation

- Example 1

Additional question: How do I get all Employees younger than 30 years old?

Motivation

- **Formal specification languages** are the solution
 - Mostly based on **set theory** or **predicate logic**
 - Requires good mathematical understanding
 - Mostly used in the academic area, but hardly used in the industry
 - Hard to learn and hard to apply
 - Problems when to be used in big systems
- ***Object Constraint Language (OCL)***: Combination of modeling language and formal specification language
 - Formal, precise, unique
 - Intuitive syntax is key to **large group of users**
 - No programming language (no algorithms, no technological APIs, ...)
 - Tool support: *parser, constraint checker, code generation, ...*

OCL usage

- Constraints in UML-models
 - Invariants for classes, interfaces, stereotypes, ...
 - Pre- and postconditions for operations
 - Guards for messages and state transition
 - Specification of messages and signals
 - Calculation of derived attributes and association ends
- Constraints in meta models
 - Invariants for Meta model classes
 - Rules for the definition of well-formedness of meta model
- Query language for models
 - In analogy to SQL for DBMS, XPath and XQuery for XML
 - Used in transformation languages

OCL usage

- OCL field of application

- Invariants **context C inv: I**
- Pre-/Postconditions **context C::op() : T**
pre: P post: Q
- Query operations **context C::op() : T body: e**
- Initial values **context C::p : T init: e**
- Derived attributes **context C::p : T derive: e**
- Attribute/operation definition **context C def: p : T = e**

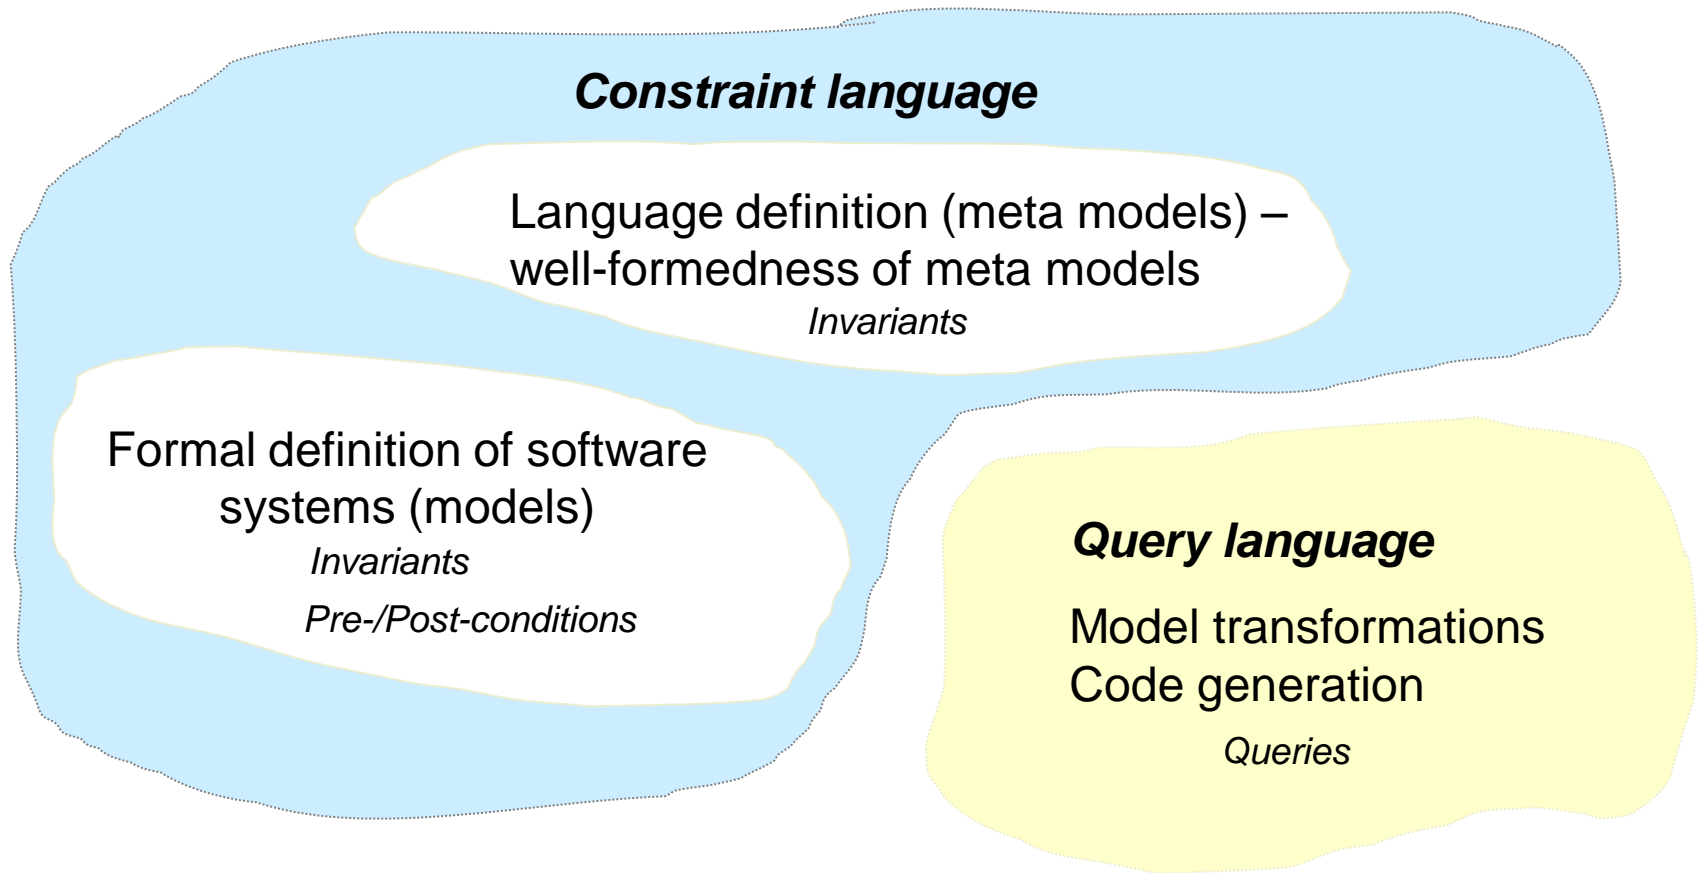

- Caution: Side effects are not allowed!

- Operation `C::getAtt : String body: att` **allowed** in OCL
- Operation `C::setAtt(arg) : T body: att = arg` **not allowed** in OCL

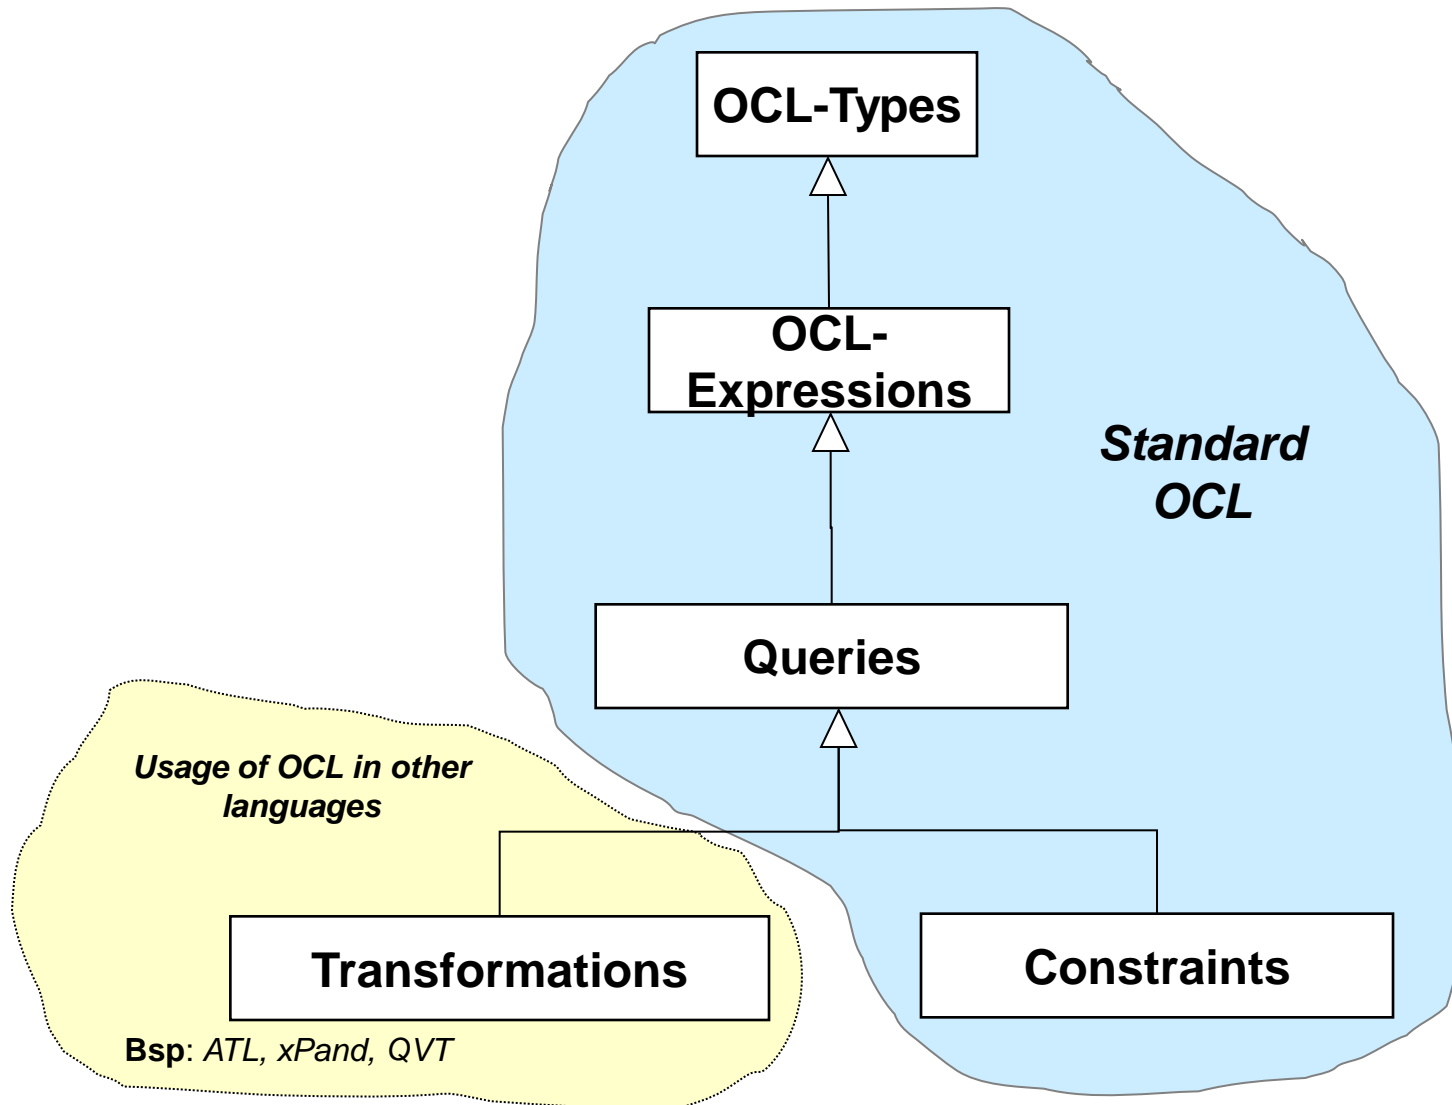

OCL usage

- **Field of application** of OCL in model driven engineering

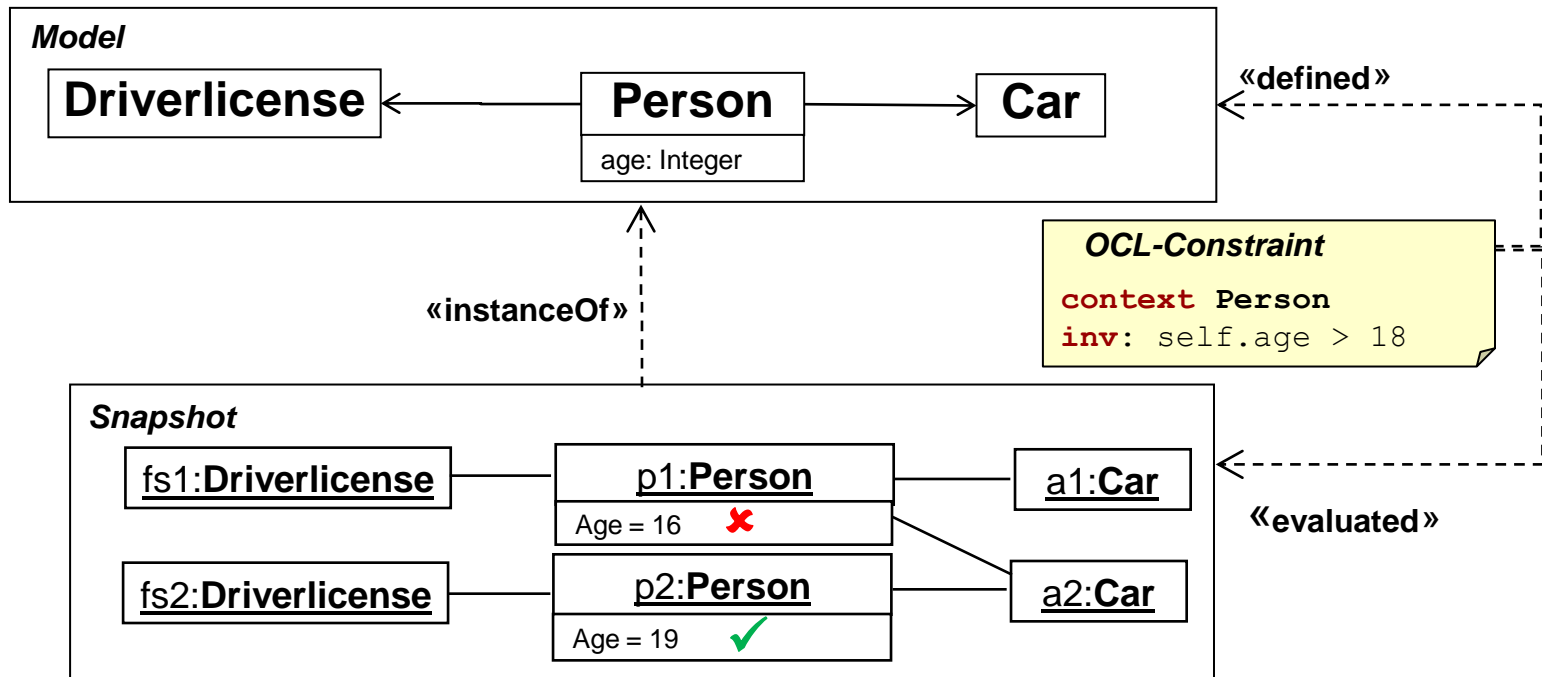

OCL usage

OCL usage

How does OCL work?

- **Constraints** are defined on the modeling level
 - Basis: Classes and their properties
- Information of the **object graph** are queried
 - Represents system status, also called *snapshot*
- **Analogy** to XML query languages
 - XPath/XQuery query XML-documents
 - Scripts are based on XML-schema information
- Examples

Design of OCL

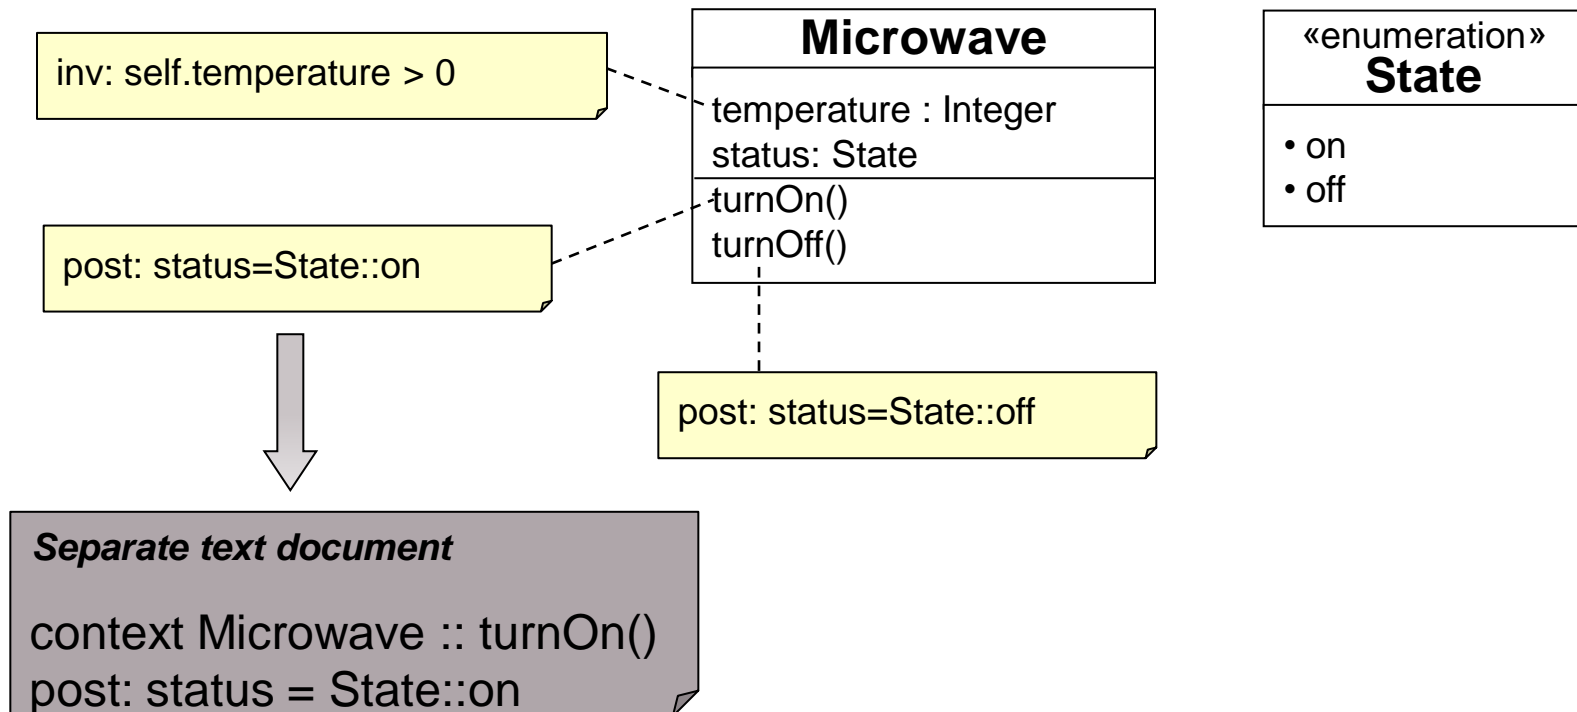

- A context has to be assigned to each OCL-statement
 - **Starting address** – which model element is the OCL-statement defined for
 - Specifies which model elements can be reached using path expressions
- The context is specified by the keyword **context** followed by the name of the model element (mostly class names)
- The keyword **self** specifies the current instance, which will be evaluated by the invariant (context instance).
 - **self** can be omitted if the context instance is unique

▪ Example:

Design of OCL

- OCL can be specified in **two** different ways
 - As a comment **directly** in the class diagram (context described by connection)
 - Separate document file

Types

- **OCL** is a typed language
 - Each **object**, **attribute**, and **result** of an operation or navigation is assigned to a **range of values** (type)
- **Predefined types**
 - **Basic types**
 - Simple types: *Integer, Real, Boolean, String*
 - OCL-specific types: *AnyType, TupleType, InvalidType, ...*
 - **Set-valued, parameterized Types**
 - Abstract supertyp: *Collection(T)*
 - *Set(T)* – no duplicates
 - *Bag(T)* – duplicates allowed
 - *Sequence(T)* – Bag with ordered elements, association ends {*ordered*}
 - *OrderedSet(T)* – Set with ordered elements, association ends {*ordered, unique*}
- **Userdefined Types**
 - Instances of *Class* in MOF and indirect instances of *Classifier* in UML are types
 - *EnumerationType* – user defined set of values for defining constants

Types

Examples

- **Basic types**

- true, false : *Boolean*
- -17, 0, 1, 2 : *Integer*
- -17.89, 0.01, 3.14 : *Real*
- “Hello World” : *String*

- **Set-valued, parameterized types**

- Set{ Set{1}, Set{2, 3} } : *Set(Set(Integer))*
- Bag{ 1, 2.0, 2, 3.0, 3.0, 3 } : *Bag(Real)*
- Tuple{ x = 5, y = false } : *Tuple{x: Integer, y: Boolean}*

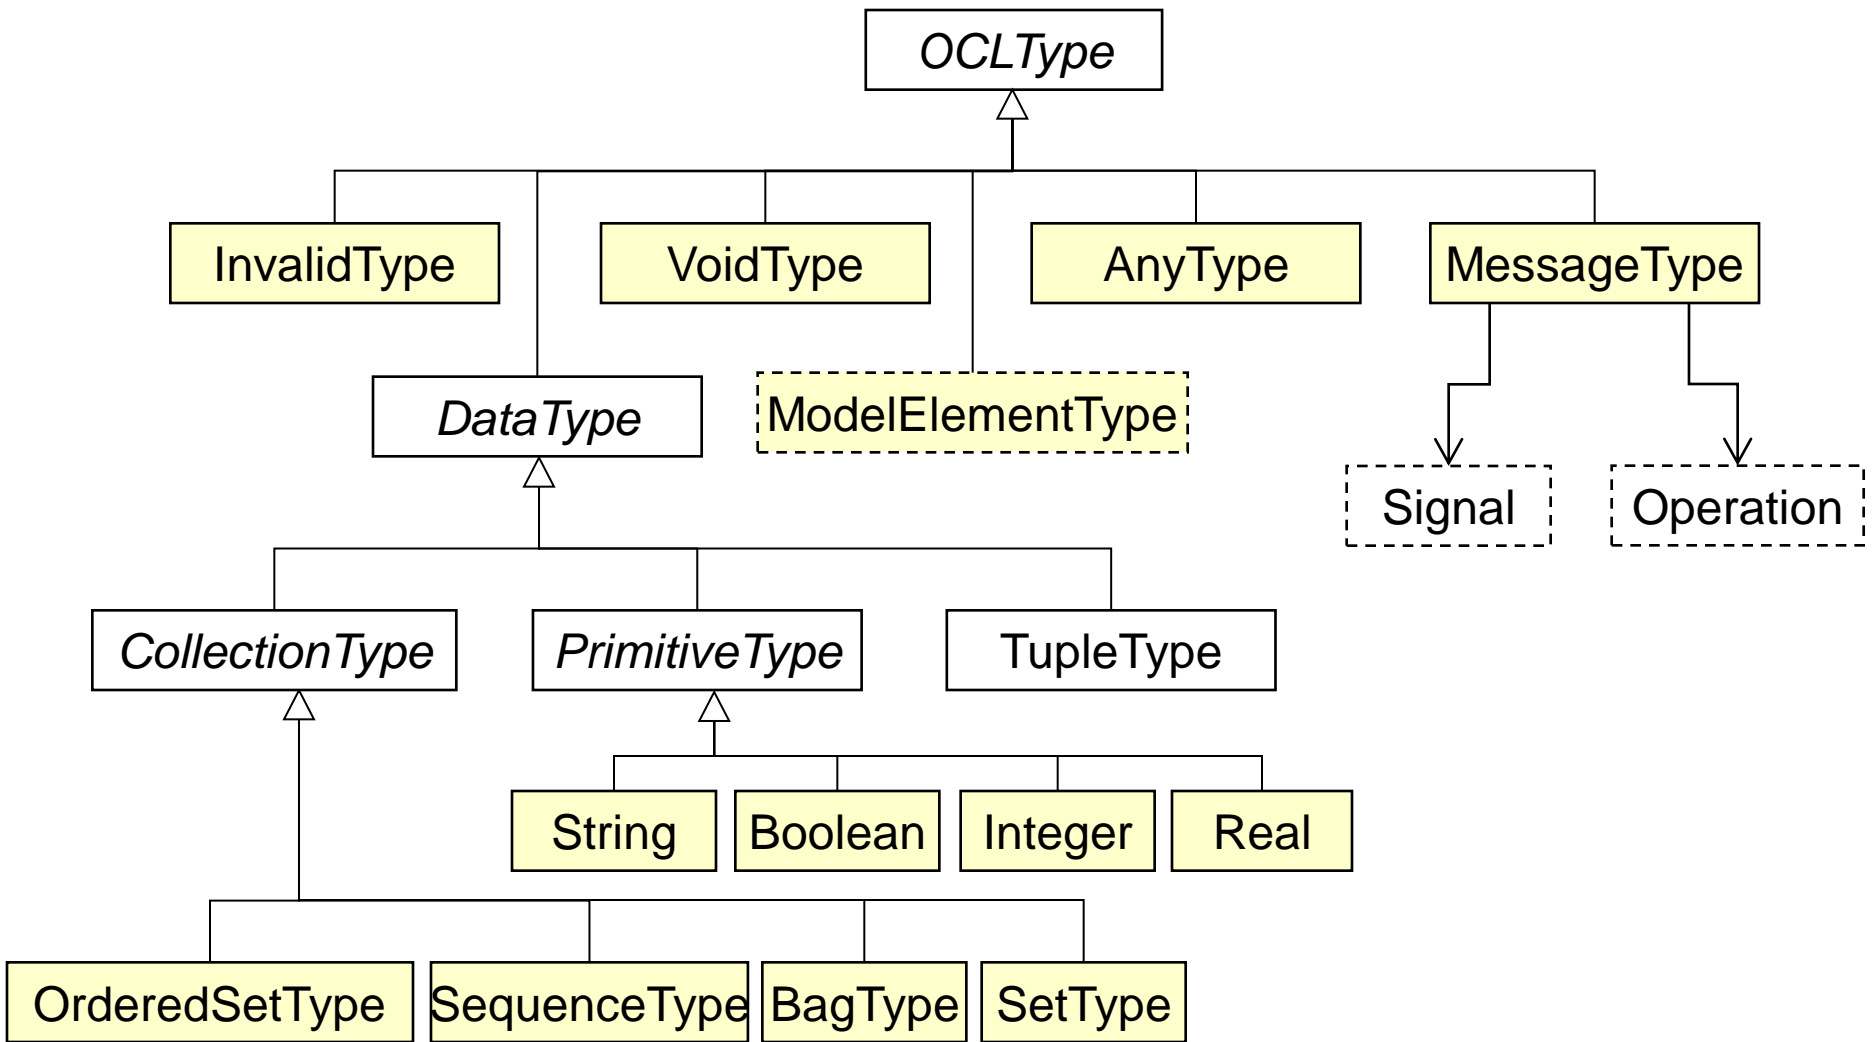

- **Userdefined types**

- Passenger : *Class*, Flight : *Class*, Provider : *Interface*
- Status::started - enum Status {started, landed}

Types

OCL meta model (extract)

Expressions

- Each OCL expression is an indirect instance of *OCLExpression*
 - Calculated in certain environment – cf. context
 - Each OCL expression has a **typed return value**
 - **OCL Constraint is an OCL expression with return value Boolean**
- **Simple OCL expressions**
 - *LiteralExp, IfExp, LetExp, VariableExp, LoopExp*
- **OCL expressions for querying model information**
 - *FeatureCallExp* – abstract superclass
 - *AttributeCallExp* – querying attributes
 - *AssociationEndCallExp* – querying association ends
 - Using role names; if no role names are specified, lowercase class names have to be used (if unique)
 - *AssociationClassCallExp* – querying association class (only in UML)
 - *OperationCallExp* – Call of query operations
 - Calculate a value, but do **not** change the system state!

Expressions

- Examples for *LiteralExp*, *IfExp*, *VariableExp*, *AttributeCallExp*

LetExp

VariableExp

AttributeCallExp

IntegerLiteralExp

```
let annualIncome : Real = self.monthlyIncome * 14 in  
  if self.isUnemployed then  
    annualIncome < 8000  
  else  
    annualIncome >= 8000  
  endif
```

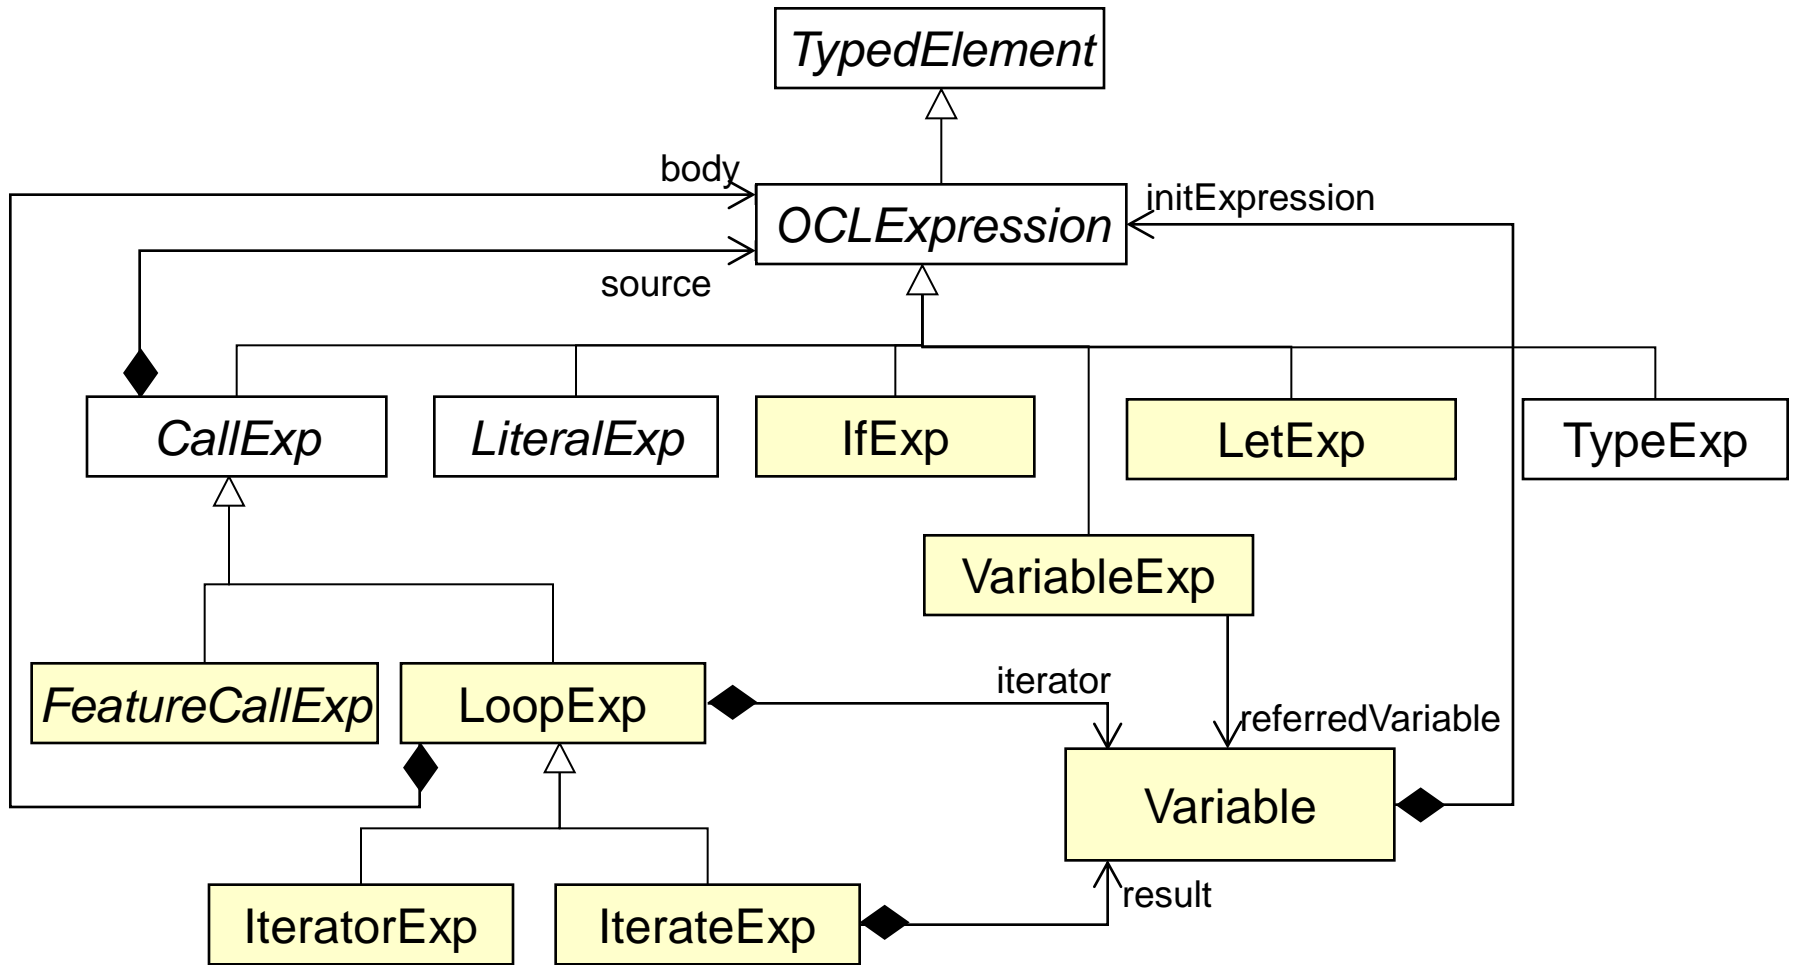

IfExp

- **Abstract syntax** of OCL is described as **meta model**
- **Mapping from abstract syntax to concrete syntax**
 - *IfExp* -> **if** Expression **then** Expression **else** Expression **endif**

Expressions

OCL meta model (extract)

LiteralExp: *CollectionLiteralExp, PrimitiveLiteralExp, TupleLiteralExp, EnumLiteralExp*

Query of model information

- Context instance

- `context Person`

- AttributeCallExp

- `self.age : int`

- OperationCallExp

- Operations must not have **side effects**
 - Allowed: `self.getAge() : int`
 - **Not allowed:** `self.setAge()`

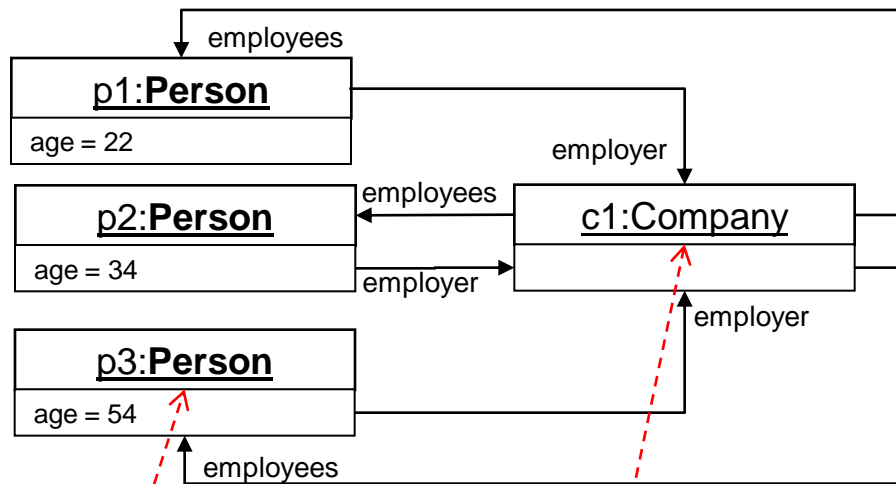

- AssociationEndCallExp

- Navigate to the opposite association end using role names
`self.employer` – Return value is of type **Company**
 - Navigation often results into a set of objects – Example
`context Company`
`self.employees` – Return value is of type **Set (Person)**

Query of model information

Example

context Person
self.employer

context Company
self.employees

$c1 : Company$

$Set\{p1, p2, p3\} :$
 $Set(Person)$

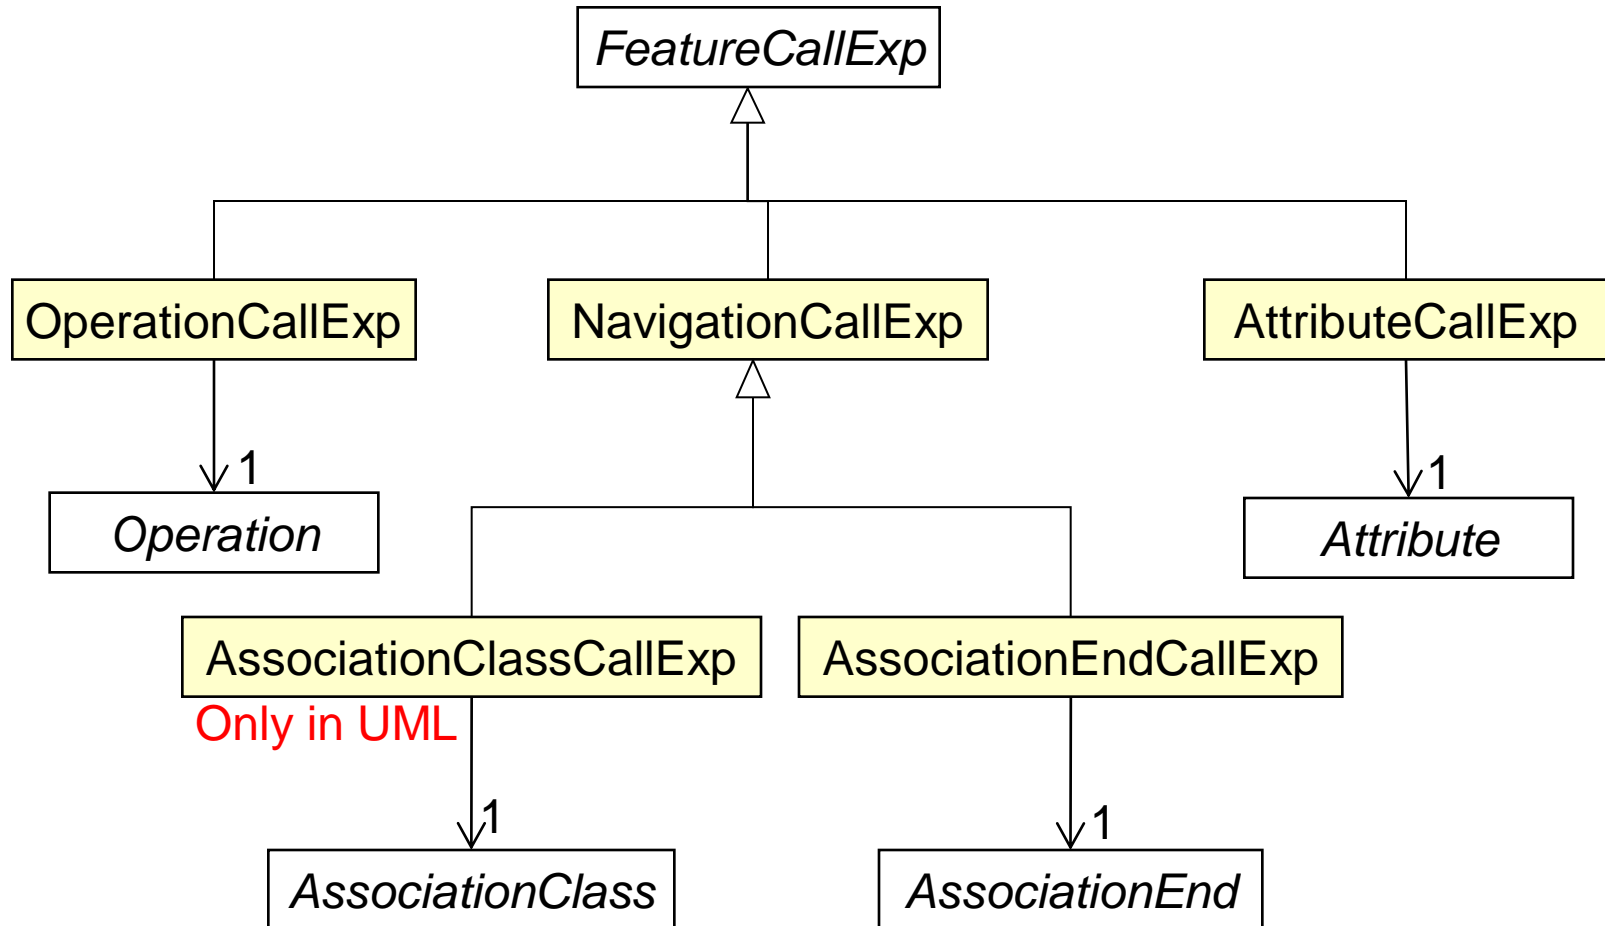

context Company
self.employees

$Set\{p1\} :$
 $Set(Person)$

Query of model information

OCL meta model (extract)

OCL Library: Operations for OclAny

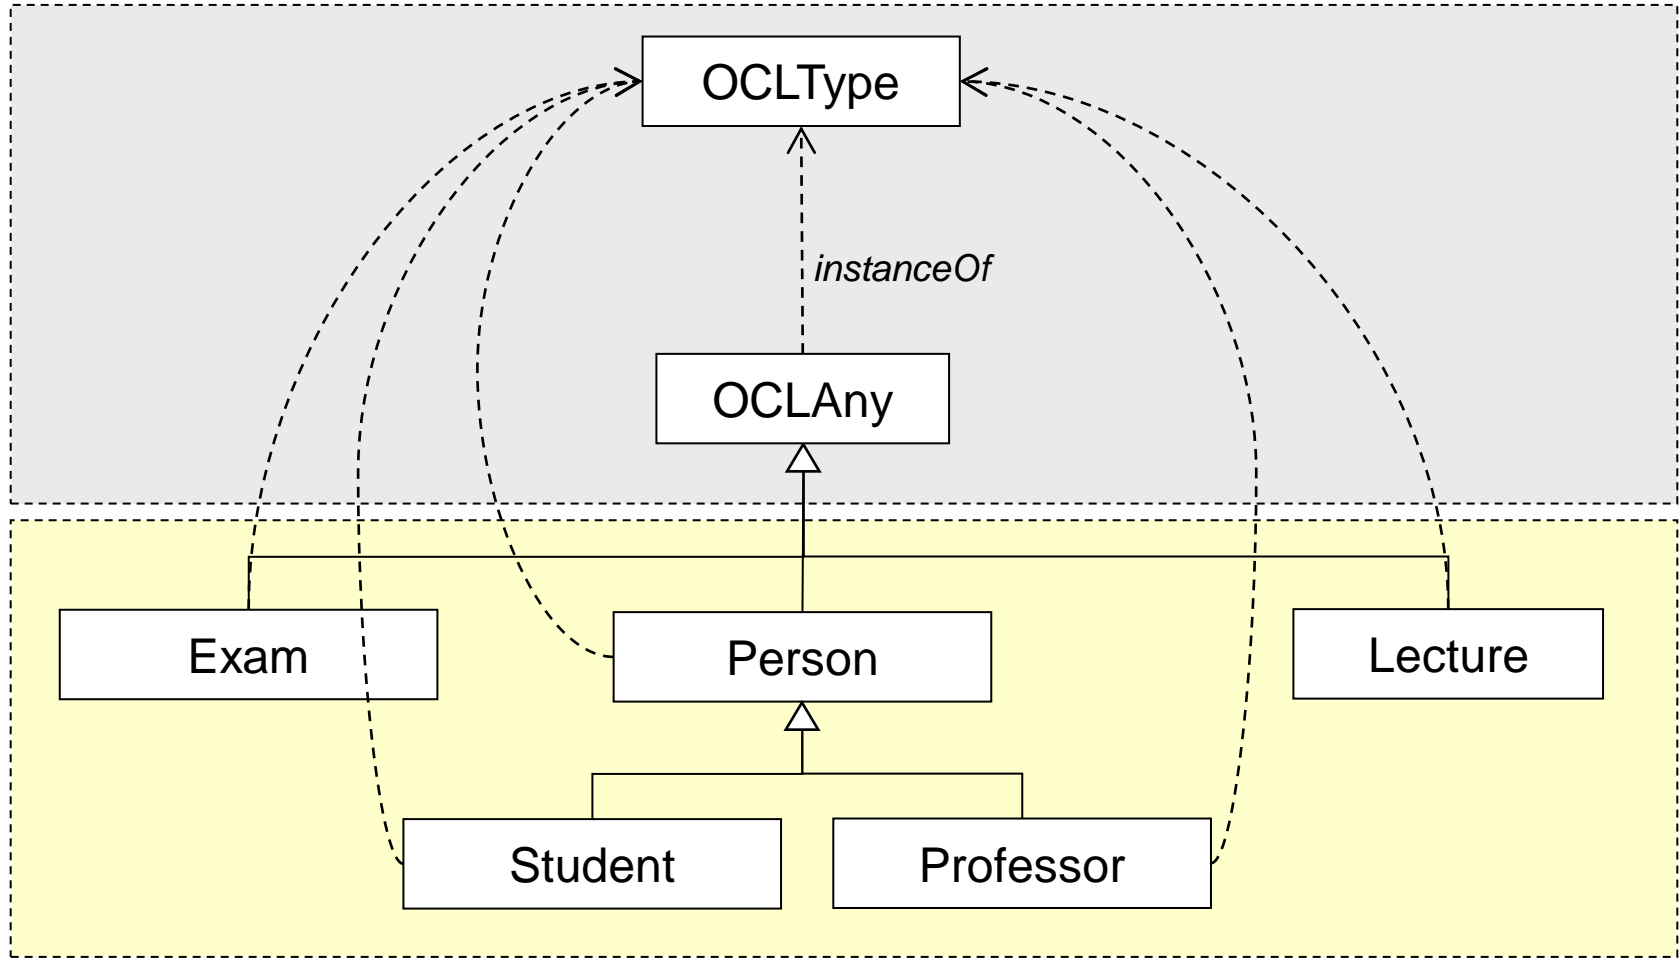

- *OclAny* - **Supertype** of all other types in OCL
 - **Operations** are **inherited** by all other types.
- **Operations** of *OclAny* (extract)
 - Receiving object is denoted by *obj*

Operation	Explanation of result
$\text{=(obj2:OclAny):Boolean}$	True, if <i>obj2</i> and <i>obj</i> reference the same object
$\text{oclIsTypeOf(type:OclType):Boolean}$	True, if <i>type</i> is the type of <i>obj</i>
$\text{oclIsKindOf(type:OclType): Boolean}$	True, if <i>type</i> is a direct or indirect supertype or the type of <i>obj</i>
$\text{oclAsType(type:Ocltype): Type}$	The result is <i>obj</i> of type <i>type</i> , or <i>undefined</i> , if the current type of <i>obj</i> is not <i>type</i> or a direct or indirect subtype of it (casting)

Operations for OclAny

Predefined environment for model types

Operations for OclAny

- ***oclIsKindOf* vs. *oclIsTypeOf***

context **Person**

```
self.oclIsKindOf(Person) : true
self.oclIsTypeOf(Person) : true
self.oclIsKindOf(Student) : false
self.oclIsTypeOf(Student) : false
```

context **Student**

```
self.oclIsKindOf(Person) : true
self.oclIsTypeOf(Person) : false
self.oclIsKindOf(Student) : true
self.oclIsTypeOf(Student) : true
self.oclIsKindOf(Professor) : false
self.oclIsTypeOf(Professor) : false
```

Operations for simple types

- **Predefined** simple types
 - Integer {Z}
 - Real {R}
 - Boolean {true, false}
 - String {ASCII, Unicode}
- Each simple type has predefined operations

Simple type	Predefined operations
Integer	*, +, -, /, abs(), ...
Real	*, +, -, /, floor(), ...
Boolean	and, or, xor, not, implies
String	concat(), size(), substring(), ...

Operations for simple types

- Syntax

- $v.operation(para1, para2, \dots)$
 - Example: “bla”.concat(“bla”)
- Operations without brackets (Infix notation)
 - Example: $1 + 2$, true **and** false

Signature	Operation
$Integer \times Integer \rightarrow Integer$	{+, -, *}
$t1 \times t2 \rightarrow Boolean$	{<, >, ≤, ≥}, $t1, t2$ typeOf {Integer or Real}
$Boolean \times Boolean \rightarrow Boolean$	{and, or, xor, implies}

Operations for simple types

Boolean operations - semantic

- OCL is based on a **three-valued (trivalent) logic**
 - Expressions are mapped to the three values {true, false, undefined}
- Semantic of the operations
 - $\mathcal{M}(l, exp) = l(exp)$, if exp not further resolvable
 - $\mathcal{M}(l, \text{not } exp) = \neg \mathcal{M}(l, exp)$
 - $\mathcal{M}(l, (exp1 \text{ and } exp2)) = \mathcal{M}(l, exp1) \wedge \mathcal{M}(l, exp2)$
 - $\mathcal{M}(l, (exp1 \text{ or } exp2)) = \mathcal{M}(l, exp1) \vee \mathcal{M}(l, exp2)$
 - $\mathcal{M}(l, (exp1 \text{ implies } exp2)) = \mathcal{M}(l, exp1) \rightarrow \mathcal{M}(l, exp2)$
- Truth table: true(1), false (0), undefined (?)

Undefined: Return value if an expression fails

1. Access on the first element of an empty set
2. Error during *Type Casting*
3. ...

\neg		\wedge	0	1	?	\vee	0	1	?	\rightarrow	0	1	?
0	1	0	0	0	0	0	0	1	?	0	1	1	1
1	0	1	0	1	?	1	1	1	1	1	0	1	?
?	?	?	0	?	?	?	?	1	?	?	?	1	?

Operations for simple types

Boolean operations - semantic

- Simple example for an **undefined** OCL expression
 - $1/0$
- **Query** if undefined– `OCLAny.ocllsUndefined()`
 - $(1 / 0).ocllsUndefined() : true$
- Examples for the evaluation of Boolean operations
 - $(1/0 = 0.0)$ **and** *false* : *false*
 - $(1/0 = 0.0)$ **or** *true* : *true*
 - *false* **implies** $(1.0 = 0.0)$: *true*
 - $(1/0 = 0.0)$ **implies** *true* : *true*

Operations for collections

- Collection is an **abstract supertype** for all set types
 - Specification of the **mutual** operations
 - *Set, Bag, Sequence, OrderedSet* inherit these operations
- **Caution:** Operations with a return value of a set-valued type create a new collection (no side effects)
- Syntax: $v \rightarrow op(\dots)$ – Example: $\{1, 2, 3\} \rightarrow size()$

- Operations of collections (extract)
 - Receiving object is denoted by *coll*

Operation	Explanation of result
<i>size():Integer</i>	Number of elements in <i>coll</i>
<i>includes(obj:OclAny):Boolean</i>	True, if <i>obj</i> exists in <i>coll</i>
<i>isEmpty:Boolean</i>	True, if <i>coll</i> contains no elements
<i>sum:T</i>	Sum of all elements in <i>coll</i> Elements have to be of type Integer or Real

Operations for collections

- Model operations vs. OCL operations

OCL-Constraint

context Container
inv: self.content -> first().isEmpty()

context Container
inv: self.content -> isEmpty()

Semantic

Operation *isEmpty()*
always has to return true

Container instances must
not contain bottles

Operationen for Set/Bag

- *Set* and *Bag* define additional operations
 - Generally based on **theory of set concepts**
- **Operations of Set** (extract)
 - Receiving object is denoted by set

Operation	Explanation of result
$union(set2:Set(T)):Set(T)$	Union of <i>set</i> and <i>set2</i>
$intersection(set2:Set(T)):Set(T)$	Intersection of <i>set</i> and <i>set2</i>
$difference(set2:Set(T)):Set()$	Difference set; elements of <i>set</i> , which do not consist in <i>set2</i>
$symmetricDifference(set2:Set(T)):Set(T)$	Set of all elements, which are either in <i>set</i> or in <i>set2</i> , but do not exist in both sets at the same time

- **Operations of Bag** (extract)
 - Receiving object is denoted by bag

Operation	Explanation of result
$union(bag2:Bag(T)):Bag(T)$	Union of <i>bag</i> and <i>bag2</i>
$intersection(bag2:Bag(T)):Bag(T)$	Intersection of <i>bag</i> and <i>bag2</i>

Operations for OrderedSet/Sequence

- *OrderedSet* and *Sequences* define additional operations
 - Allow access or modification through an **Index**
- **Operations of OrderedSet** (extract)
 - Receiving object is denoted by *orderedSet*

Operation	Explanation of result
<i>first:T</i>	First element of <i>orderedSet</i>
<i>last:T</i>	Last element of <i>orderedSet</i>
<i>at(i:Integer):T</i>	Element on index <i>i</i> of <i>orderedSet</i>
<i>subOrderedSet(lower:Integer, upper:Integer):OrderedSet(T)</i>	Subset of <i>orderedSet</i> , all elements of <i>orderedSet</i> including the element on position <i>lower</i> and the element on position <i>upper</i>
<i>insertAt(index:Integer,object:T):OrderedSet(T)</i>	Result is a copy of the <i>orderedSet</i> , including the element <i>object</i> at the position <i>index</i>

- **Operations of Sequence**
 - Analogous to the operations of *OrderedSet*

Iterator-based operations

- OCL defines operations for *Collections* using *Iterators*
 - Expression Package: LoopExp
 - **Projection** of new *Collections* out of existing ones
 - Compact **declarative specification** instead of imperative algorithms
- Predefined Operations
 - select(exp) : *Collection*
 - reject(exp) : *Collection*
 - collect(exp) : *Collection*
 - forAll(exp) : *Boolean*
 - exists(exp) : *Boolean*
 - isUnique(exp) : *Boolean*
- iterate(...) – Iterate over all elements of a *Collection*
 - Generic operation
 - Predefined operations are defined with iterate(...)

Iterator-based operations

Select-/Reject-Operation

- **Select** and **Reject** return subsets of collections
 - Iterate over the complete collection and collect elements
- **Select**
 - **Result:** Subset of collection, including elements where *booleanExpr* is **true**

```
collection -> select( v : Type | booleanExp(v) )  
collection -> select( v | booleanExp(v) )  
collection -> select( booleanExp )
```

- **Reject**
 - **Result:** Subset of collection, including elements where *booleanExpr* is **false**
 - Just *Syntactic Sugar*, because each *reject-Operation* can be defined as a *select-Operation* with a negated expression

```
collection-> reject(v : Type | booleanExp(v))
```

=

```
collection-> select(v : Type | not (booleanExp(v)))
```

Iterator-based operations

Select-/Reject-Operation

- Semantic of the *Select-Operation*

OCL

```
context Company inv:  
  self.employee -> select(e : Employee | e.age>50) ->  
  notEmpty()
```

Java

```
List persons<Person> = new List();  
for ( Iterator<Person> iter = comp.getEmployee();  
iter.hasNext() ){  
  Person p = iter.next();  
  if ( p.age > 50 ){  
    persons.add(p);  
  }  
}
```

Iterator-based operations

Collect-Operation

- *Collect-Operation* returns a new collection from an existing one. It collects the **Properties** of the objects and not the objects itself.
 - Result of *collect* always **Bag<T>.T** defines the type of the property to be collected

```
collection -> collect( v : Type | exp(v) )  
collection -> collect( v | exp(v) )  
collection -> collect( exp )
```

- Example
 - *self.employees -> collect(age)* – Return type: Bag(Integer)
- Short notation for collect
 - *self.employees.age*

Iterator-based operations

Collect-Operation

- Semantic of the *Collect-Operator*

```
context Company inv:
  self.employee -> collect(birthdate) -> size() > 3
```

OCL

```
List birthdate<Integer> = new List();
for ( Iterator<Person> iter = comp.getEmployee();
iter.hasNext() ){
  birthdate.add(iter.next().getBirthdate()); }
```

Java

- Use of *asSet()* to eliminate duplicates

```
context Company inv:
  self.employee -> collect(birthdate) -> asSet()
```

OCL

Set
(without
duplicates)

Bag

(with duplicates)

Iterator-based operations

ForAll-/Exists-Operation

- **ForAll** checks, if all elements of a collection evaluate to true

```
collection -> forAll( v : Type | booleanExp(v) )  
collection -> forAll( v | booleanExp(v) )  
collection -> forAll( booleanExp )
```

- **Example:** self.employees -> forAll(age > 18)

- **Nesting** of forAll-Calls (*Cartesian Product*)

```
context Company inv:  
self.employee->forAll (e1 | self.employee -> forAll (e2 |  
    e1 <> e2 implies e1.svnr <> e2.svnr))
```

- **Alternative:** Use of multiple iterators

```
context Company inv:  
self.employee -> forAll (e1, e2 | e1 <> e2 implies e1.svnr <> e2.svnr))
```

- **Exists** checks, if at least one element evaluates to true
 - Beispiel: employees -> exists(e: Employee | e.isManager = true)

Iterator-based operations

Iterate-Operation

- **Iterate** is the generic form of all iterator-based operations

- **Syntax**

collection -> iterate(**elem** : Typ; **acc** : Typ =
 <initExp> | **exp(elem, acc)**)

- Variable **elem** is a typed *Iterator*
- Variable **acc** is a typed *Accumulator*
- Gets assigned initial value initExp
- **exp(elem, acc)** is a function to calculate **acc**

- **Example**

collection -> collect(x : T | x.property)

-- **semantically equivalent to:**

collection -> iterate(x : T; acc : T2 = Bag{} | acc -> including(x.property))

Iterator-based operations

Iterate-Operator

- Semantic of the *Iterate-Operator*

collection -> `iterate(x : T; acc : T2 = value | acc -> u(acc, x)` OCL

```
iterate (coll : T, acc : T2 = value) { Java
    acc=value;
    for( Iterator<T> iter =
coll.getElements(); iter.hasNext(); ){
        T elem = iter.next();
        acc = u(elem, acc);
    }
}
```

- Example

- Set{1, 2, 3} -> `iterate(i:Integer, a:Integer=0 | a+i)`
- Result: 6

Tool Support

▪ **Wishlist**

- Syntactic analysis: Editor support
- Validation of logical consistency (Unambiguous)
- Dynamic validation of invariants
- Dynamic validation of Pre-/Post-conditions
- Code generation and test automation

▪ **Today**

- UML tools provide OCL editors
- MDA tools provide code generation of OCL expressions
- Meta modeling platforms provide the opportunity to define OCL Constraints for meta models.
 - The editor should dynamically check constraints or restrict modeling, respectively.

OCL Tools

- Some OCL-parsers, which check the syntax of OCL-constraints and apply them to the models, are for free.
 - IBM Parser
- Dresden OCL Toolkit 2.0
 - Generation of Java code out of OCL-constraints
 - Possible integration with ArgoUML
- USE: UML-based Specification Environment
 - <http://sourceforge.net/projects/useocl>
- OCL frameworks are originated in the areas of EMF and the UML2 project of Eclipse
 - Octopus
 - Fraunhofer Toolkit
 - OSLO
 - EMFT OCL-Framework/Query-Framework

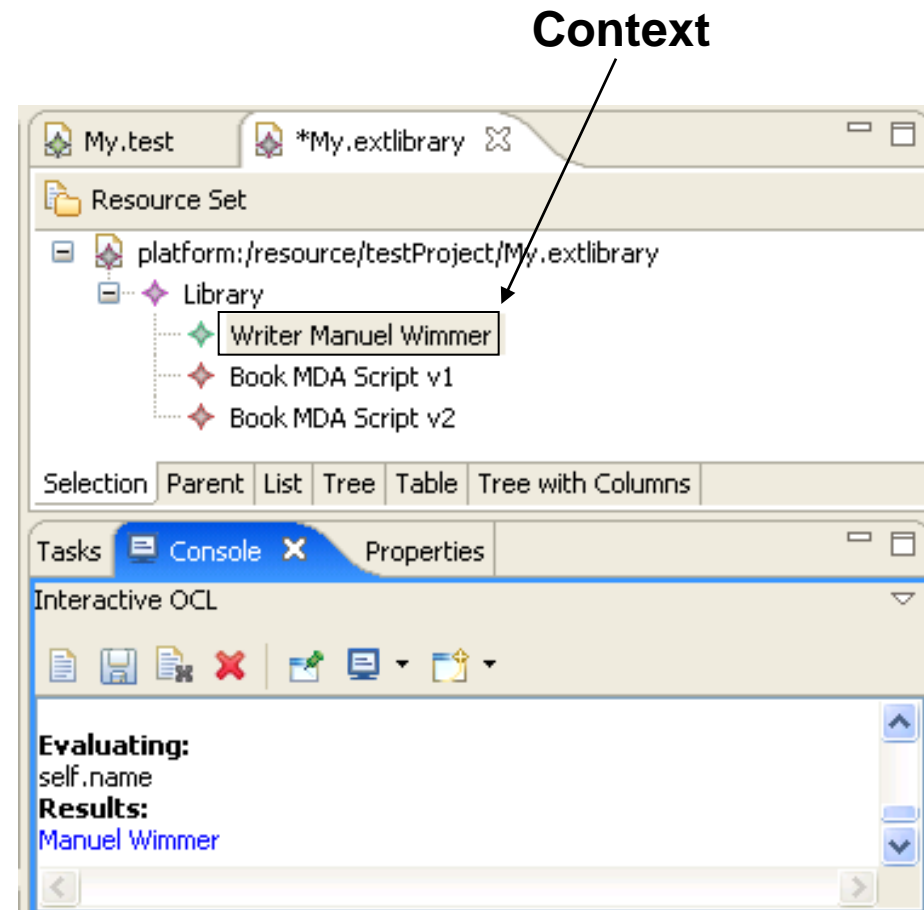

OCL Tools

■ EMFT OCL-Framework

- Based on EMF
- *OCL-API* – Enables the use of OCL in Java programs
- *Interactive OCL Console* – Enables the definition and evaluation of OCL-constraints

■ EMFT Query-Framework

- **Goal:** SQL-like query of model information
- **select** exp **from** exp **where** *oclExp*

Example 1: Navigation (1)

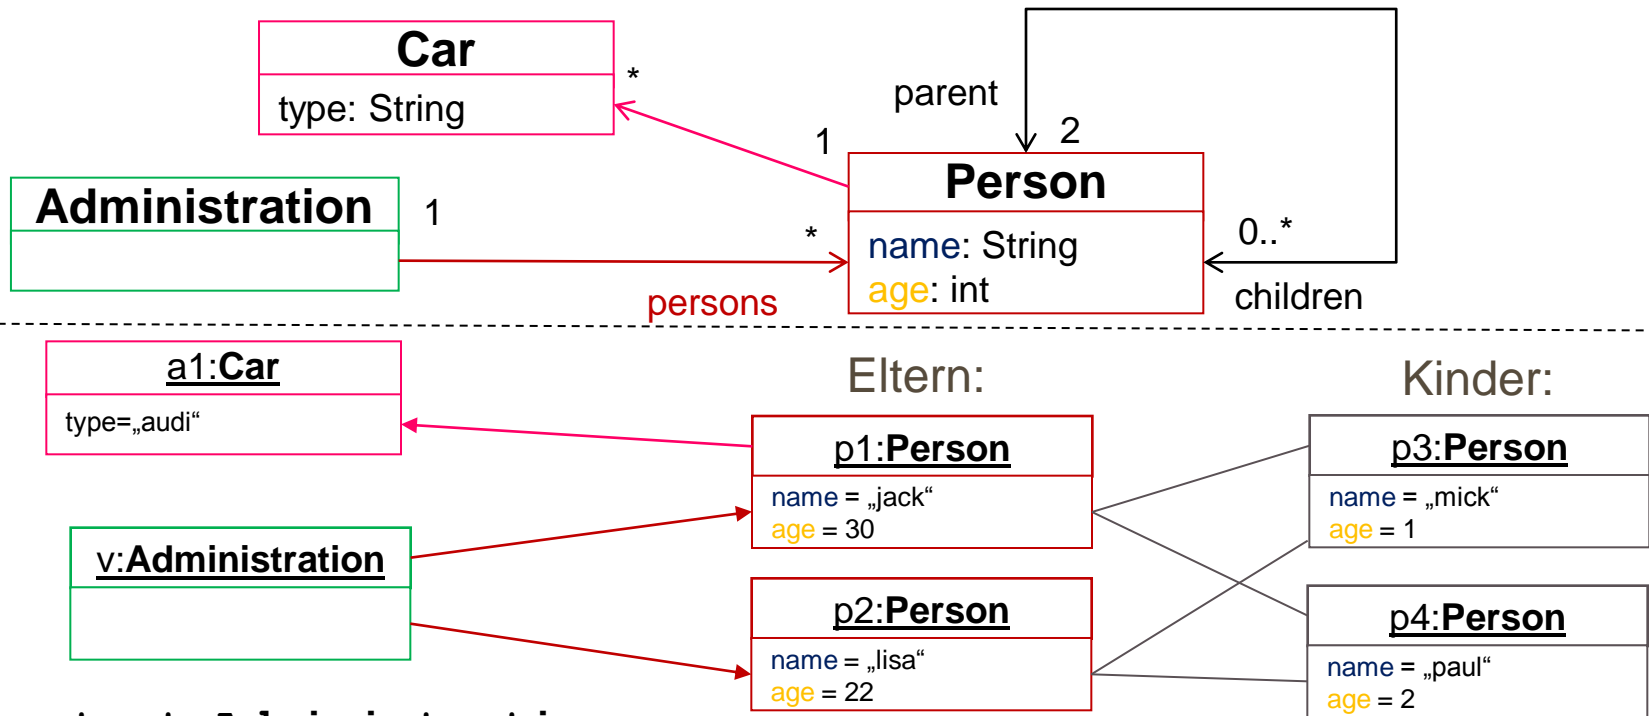

context Administration:

- `self.persons` → { Person p1, Person p2 }
- `self.persons.name` → { jack, lisa }
- `self.persons.age` → { 30, 22 }

Example 1: Navigation (2)

context Administration:

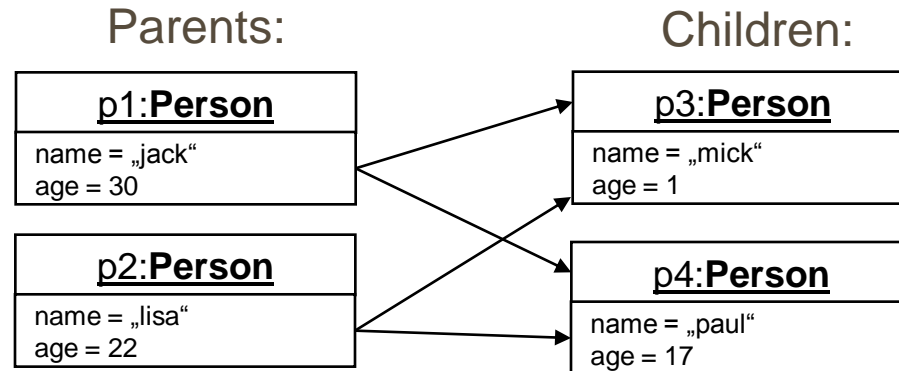

- `self.persons.children` → `{{p3, p4}, {p3, p4}}`
- `self.persons.children.parent` → `{{{p1, p2}, {p1, p2}}, ...}`
- `self.persons.car.type` → `{ "audi" }`

Example 2: Invariant (1)

Constraint: A child is at least 15 years younger than his parents.

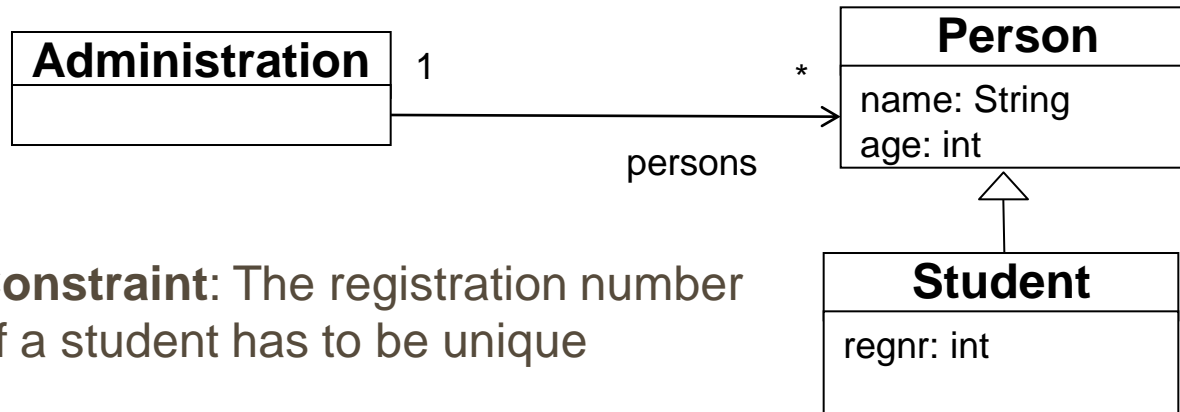

context Person

```
inv: self.children->forAll(k : Person | k.age < self.age-15)
```

Example 2: Invariant (2)

Constraint: The registration number of a student has to be unique

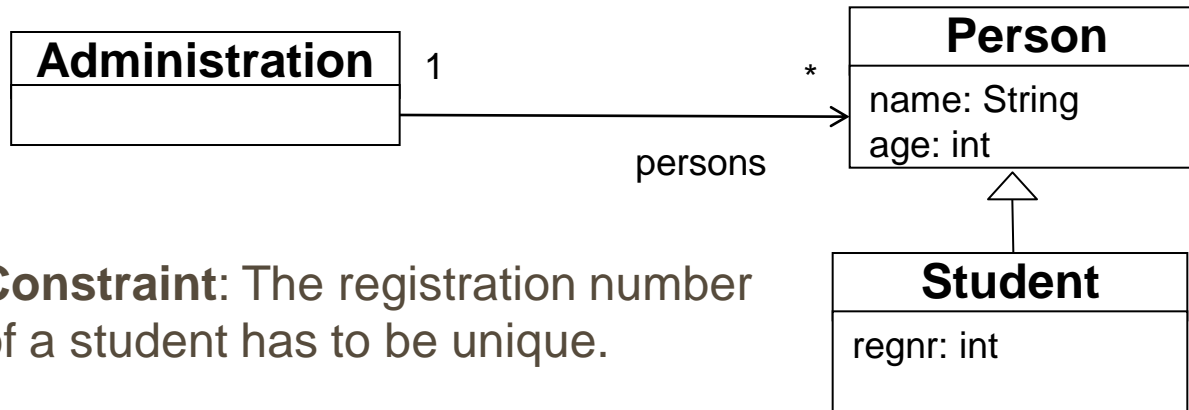

```
context Administration
```

```
inv uniqueRegnr :
```

```
self.persons -> select(e : Person | e.oclIsTypeOf(Student))
    -> forAll(e1 |
self.persons -> select(e : Person | e.oclIsTypeOf(Student))
    -> forAll(e2 |
e1 <> e2 implies e1.oclAsType(Student).regnr <>
    e2.oclAsType(Student).regnr)
```

Example 2: Invariant (2) cont.

Constraint: The registration number of a student has to be unique.

```
context Administration
```

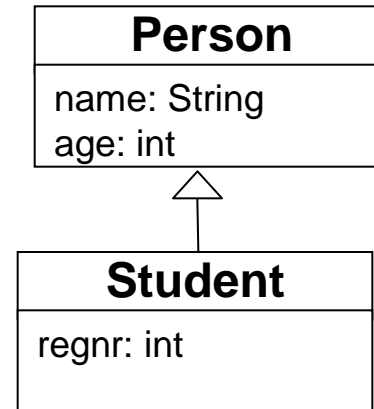

```
inv uniqueRegnr :
```

```
self.persons -> select(e : Person | e.oclIsTypeOf(Student))
-> forAll(e1, e1 | e1 <> e2 implies
e1.oclAsType(Student).regnr <>
e2.oclAsType(Student).regnr)
)
```

Example 2: Invariant (2) cont.

Constraint: The registration number of a student has to be unique.

```
context Student
```

```
inv uniqueRegnr :
```

```
Student.allInstances() -> forAll(e1, e1 | e1 <> e2 implies  
    e1.oclAsType(Student).regnr <>  
    e2.oclAsType(Student).regnr)
```

Example 3: Inherited attribute

A Person obtains family allowance, if he/she is younger than 18 years, or if he/she is studying and younger than 27 years old.

```
context Person::familyallowance
```

```
derive: self.age < 18 or
```

```
(self.age < 27 and self.studies -> size() > 0)
```

Example 4: Definitions

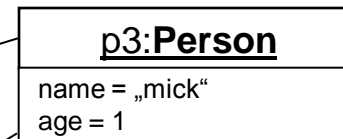

Constraint: A Person is not a relative of itself

Parents:

Children:

kind

```
context Person
```

```
def: relative: Set(Person) = children-> union(relative)
```

```
inv: self.relative -> excludes(self)
```

Assumption: Fixed-point semantic, otherwise if then else required

Example 5: equivalent OCL-formulations (1)

Constrain: A person is not its own child

- `(self.children->select(k | k = self))->size() = 0`

The Number of children for each person „self“, where the children are the person „self“, have to be 0.

- `(self.children->select(k | k = self))->isEmpty()`

The set of children for each person „self, where the children are the person „self“, has to be empty.

Example 5: equivalent OCL-formulations (2)

Constrain: A person is not its own child

- `not self.children->includes(self)`

It is not possible, that the set of children of each person „self“ contains the person „self“.

- `self.children->excludes(self)`

The set of children of each person „self“ cannot contain „self“.

Example 5: equivalent OCL-formulations (3)

Constrain: A person is not its own child

- `Set{self}->intersection(self.children)->isEmpty()`
The intersection between the one element set, which only includes one person „self“ and the set of the children of „self“ has to be empty.
- `(self.children->reject(k | k <> self))->isEmpty()`
The set of children for each person „self“, for whom does not apply, that they are not equal to the person „self“, has to be empty.

Example 5: equivalent OCL-formulations (4)

Constrain: A person is not its own child

- `self.children->forAll(k | k <> self)`

Each child of the person „self“ is not the person „self“.

- `not self.children->exists(k | k = self)`

There is no child for each person „self“, which is the person „self“

Outlook

ATLAS Transformation Language (ATL)

- **Query-part** (**from**) – What has to be transformed?
 - When **selecting** the relevant model elements
 - additionally to the type indication, constraints on attributes and association ends are required,
 - which are specified in OCL.
- **Generation-part**(**to**) – What has to be created?
 - When **creating** the target structure
 - additionally to the type information, derived information is required,
 - which are calculated in OCL.

Transformation rules

Query-part

OCL-expression

Generation-part

```
rule Property2Attribute {  
  from p : UML!Property (  
    p.association.oclIsUndefined()  
  )  
  to a : ER!Attribute (  
    name <- p.name.toUpper(),  
    entity <- p.owningClass  
  )  
}
```
