10A462. Multiply loaded Timoshenko beam on a stressed orthotropic half-plane via a thin elastic layer. - H Bjarnehed *(Div of Solid Mech, Chalmers Univ of Tech, S-412 96 Goteborg, Sweden).* J Appl Mech 60(2) 541-547 (Jun 1993).

The problem of bonded contact between a uniform finite Timoshenko beam and an orthotropic half-plane via a thin elastic layer is considered in this paper. The beam is loaded by distributions of normal and tangential forces, and a uniaxial stress load is applied to the half-plane. The Timoshenko beam theory is extended in such a way that the tangential load is included when the shear contribution to the beam central line deflection is calculated. The layer is formulated as a generalized Winkler cushion including also shear stresses and strains. Governing singular integral equations are stated and numerically solved for the unknown interface stresses. A comparison with a corresponding FE-model is also performed.

10A463. Flexural behavior of fixed-ended channel section columns. - KJR Rasmussen and GJ Hancock *(Sch of Civil and Mining Eng, Univ of Sydney, Sydney, Australia).* Thin-Walled Struct 17(1) 45-63 (1993).

The paper presents a study of the behavior of thin-walled channel sections compressed between fixed ends. The paper emphasises the differences between the behavior of fixed-ended and pin-ended channel sections, arising mainly from the fact that the local buckling induces bending of pin-ended channel sections but not of fixed-ended channel sections. As a result of the different effects of local buckling, the strength of a fixed-ended channel section column exceeds that of a pin-ended column of the same effective length. The increase in strength is quantified for a particular channel section, and is studied through the transition from pinned to fixed-end support by analyzing columns which are elastically restrained against rotations at the ends. The paper also investigates the imperfection sensitivity and post-ultimate behavior of fixed-ended channel section columns. It is shown that fixed-ended columns are less sensitive to local imperfections and that they exhibit greater post-ultimate ductility than pin-ended columns. The study is confined to columns whose overall buckling mode is the flexural mode.

10A464. Elastic wrinkling of a tensioned circular plate using von Karman plate theory. - GG Adams *(Dept of Mech Eng, NE Univ, Boston MA 02115).* J Appl Mech 60(2) 520-525 (Jun 1993).

A circular elastic plate, with a uniform tension field applied at its outer edge, is acted upon by a centrally applied transverse force. As the force is increased, the tension state as determined from von Karman plate theory, changes. In particular for sufficiently large values of the transverse force or displacement, the plate can develop a compressive circumferential membrane stress. When this compressive stress becomes sufficiently large, wrinkling can result. The corresponding value of the transverse displacement is determined by investigating an eigenvalue problem in which wrinkling is indicated by the vanishing of the lowest eigenvalue. The results are the values of the central transverse deflection which induces wrinkling for a range of in-plane tensions and are sensitive to the in-plane boundary support conditions at the outer edge.

10A465. Stress distribution in an elastic perfectly plastic plate subjected to corrosive environmental loads. - A Kadic-Galeb and RC Batra *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401-0249).* Int J Eng Sci 31(9) 1301-1307 (Sep 1993).

We analyze deformations of an isotropic elastic-perfectly plastic plate subjected to environmental effects such as the corrosive forces exerted by the surrounding medium. It is found that for the bounding surfaces of the plate to deform plastically, the corrosion process must propagate to a point whose distance from the outer bounding surface exceeds one third the half-thickness of the plate, and for the central unaffected material to also deform plastically the half-thickness of the corroded layer must exceed five eighths the half-thickness of the plate.

10A466. Instability of a biaxially stressed thin film on a substrate due to material diffusion over its free surface. - LB Freund and F Jonsdottir *(Div of Eng, Brown Univ, Providence RI 02912).* J Mech Phys Solids 41(7) 1245-1264 (Jul 1993).

The configuration of an elastically strained thin film bonded to a relatively thick elastic substrate over a plane interface is considered. The free energy of the system is taken to be the surface energy of the free surface, which is initially flat, and the elastic strain energy. It is assumed that the film material can change the shape of its free surface by means of mass diffusion along the surface, and that this mass transport occurs coherently. As a result of this diffusion process, the free energy of the system changes due to a change in surface shape and due to a change in the elastic energy. If the change in free energy as the surface shape departs from planar is positive, then this change will tend to occur spontaneously and the flat shape is unstable. The stability of a biaxially stressed thin film due to material diffusion over its surface is considered here under both 2- and 3D conditions. The stability condition is derived in the form of a difference between two positive definite quantities, one associated with surface energy and the other associated with strain energy, and the sign of this difference depends on the relative stiffnesses of the materials, the thickness of the film, the surface energy of the film material, and the initial elastic stress in the film. It is demonstrated that the configuration with a flat free surface is unstable under sinusoidal perturbations in the shape of the surface for any combination of parameters, provided that the wavelength of the perturbation is larger than some critical value. Numerical results are presented for the critical value as a function of film thickness for several values of the ratio of elastic stiffnesses of the mterials.

260E. SHELLS (BENDING THEORY)

10A467. Energy-minimizing deformations of elastic sheets with bending stiffness. - MG Hilgers and AC Pipkin *(Div of Appl Math, Brown Univ, Providence RI 02912).* J Elast 31(2) 125-139 (May 1993).

Necessary conditions for energy-minimizing deformations are derived for a theory of sheets in which the strain energy function depends on the second derivatives of the deformation as well as its first derivatives. All of these conditions are extensions of well-known necessary conditions in classical calculus of variations. The interpretation of some of these conditions as material stability conditions is explained.

10A468. FE analysis of multilayered shells of revolution. - MA Rao *(Dept of Mech Eng, Andhra Univ, Visakhapatnam, India),* RV Dukkipati *(NRC, Ottawa, Canada),* M Tummala *(Dept of Mech Eng, Concordia Univ, 1455 de Maisonneuve Blvd, W Montreal, PQ, Canada).* Comput Struct 47(2) 253-258 (Apr 1993).

A FE formulation for the static and dynamic analysis of multilayered shells of revolution is developed. The basis of this formulation is a superparametric curved element having four dof per node including normal rotation. Element stiffness, mass and load matrices are derived for axisymmetric analysis of laminated shells. Static analysis of a multilayered pressure vessel, which has 27 layers in its thickness and a hemispherical cover at one end, is carried out using the formulation and the program developed. Results obtained for the static analysis of the pressure vessel are compared with results obtained by the standard code practices. Natural frequencies of shells of revolution corresponding to axisymmetric modes of vibration are presented.

10A469. Thin shells with finite rotations formulated in biot stresses: Theory and FE formulation. - P Wriggers *(Inst Mech, Tech Hochsch Hochschulstr 1, 6100 Darmstadt, Germany)* and F Gruttmann *(Inst Baumech und Numer Mech, Univ Hannover, Germany).* Int J Numer Methods Eng 36(12) 2049-2071 (30 Jun 1993).

A bending theory for thin shells undergoing finite rotations is presented, and its associated FE model is described. The kinematic assumption is based on a shear elastic Reissner-Mindlin theory. The starting point for the derivation of the strain measures are the resultant equilibrium equations and the associated principle of virtual work. Within this formulation the polar decomposition of the shell material deformation gradient leads to symmetric strain measures. The associated work-conjugate stress resultants and stress couples are integrals of the Biot stress tensor. This tensor is invariant with respect to rigid body motions and, therefore, appropriate for the formulation of constitutive equations. Finite rotations are introduced via Eulerian angles.

10A470. Axisymmetric deformation of varying thickness composite cylindrical shell with various end conditions. - BSK Sundarasivarao and N Ganesan *(Machine Dyn Lab, Dept of Appl Mech, Indian IT, Madras 600 036, India).* Composite Struct 24(4) 345-352 (1993).

A varying thickness composite cylindrical shell subjected to axisymmetric deformation has been analyzed by the FE displacement method. The end conditions considered are clamped-clamped, clamped-free, simply sup simply supported. It is shown that, by properly selecting the thickness variation of the shell wall, both stresses and deflections can be reduced considerably in most cases.

10A471. Differential quadrature for static and free vibration analyses of anisotropic plates. - CW Bert *(Sch of Aerospace and Mech Eng, Univ of Oklahoma, 865 Asp Ave Rm 212, Norman OK 73019)*, Xinwei Wang *(Aircraft Eng Dept, Nanjing Aeronaut Inst, Nanjing, Peoples Rep of China)*, AG Striz *(Sch of Aerospace and Mech Eng, Univ of Oklahoma, 865 Asp Ave Rm 212, Norman OK 73019)*. Int J Solids Struct 30(13) 1737-1744 (1993).

The differential quadrature method is used to analyze the deflection, buckling, and free vibration behavior of anisotropic rectangular plates under various boundary conditions. The roots of Chebyshev polynomials are used to obtain grid-point locations and a new approach is used to apply boundary conditions. Results compare very well with existing numerical data, and less computational effort is required for the problems considered.

10A472. Refined 2D theory of anisotropic plates. - ME Fares *(Math Dept, Fac of Sci, Mansoura Univ, Egypt)*. Mech Res Commun 20(4) 319-327 (Jul-Aug 1993).

The classical theory of plates, in which it is assumed that normals to the midsurface before deformation remain straight and normal to the surface after deformation, overestimates natural frequencies and underpredicts deflections. These errors in deflections, stresses, natural frequencies, and buckling loads are even higher for plates with large ratio of thickness to side, particularly at high frequencies. The plate theories due to Reissner and Mindlin are improvements of the classical plate theory in that they include the effect of transverse shear deformation. Many refined shear deformation theories, in which the assumed displacement field is expanded in powers of the thickness coordinate, are available in the literature. These higher-order theories are cumbersome and computationally more demanding, because, with each additional power of the thickness coordinate, an additional dependent unknown is introduced into the theory. Further, these theories require an arbitrary correction to the transverse shear stiffnesses, and the transverse shear stresses do not satisfy the conditions on the top and bottom surfaces of the plate. Reddy suggested a consistent higher-order plate theory which not only accounts for the transverse shear deformation but also satisfies the zero transverse shear stress conditions on the plate surface and does not require shear correction factors. Because of the simplifications made in Reddy formulation, it is inadequate for the analysis of anisotropic plates subjected to a surface traction field with non-zero tangential components, and for anisotropic plate problems which require the inclusion of the effects of transverse normal strain and stress. The present formulation deals with a generalization of the shear deformation theory. The theory includes the effects of transverse normal strain as well as the effect of transverse shear deformation. Hamilton's mixed variational principle is used to derive the equation of motion and constitutive equations of an anisotropic plate subjected to a surface traction field with tangential and normal components. Therefore, these equations are adequate for the analysis of anisotropic plate problems with general surface conditions for example contact problems involving anisotropic plates with surface constrained. The advantages of applying this theory to the free vibration problems of anisotropic rectangular plates is examined.

10A473. Bending analysis of bimodular laminates using a higher-order plate theory with the FE technique. - Yi-Ping Tseng and Kung-Pyng Bai *(Dept of Civil Eng, Tamkang Univ, Taiwan 25137, ROC)*. Comput Struct 47(3) 487-494 (3 May 1993).

The higher-order plate theory is adopted in the FEM to analyze composite plates laminated of orthotropic bimodular materials. The transverse shear deformation can be effectively evaluated where the correction coefficient is not required. The maximum deflections and neutral surface locations of several benchmark problems are determined. The accuracy of the formulation is then established by comparing the numerical results with the analytical solutions.

10A474. FE study of the transverse shear in honeycomb cores. - M Grediac *(Dept Mec et Mat, Ecole Natl Superieure des Mines, 158, cours Fauriel, 42023 St-Etienne Cedex 2, France)*. Int J Solids Struct 30(13) 1777-1788 (1993).

Knowledge of the transverse mechanical properties of honeycomb cores is essential for the design of sandwich panels. This paper deals with the calculation fof the transverse shear moduli of a honeycomb sandwich panel by making a FE study of a representative unit cell. Stress contours inside the honeycomb are also provided. Three cell geometries are studied and the influence of the thickness on the shear modulus and on the homogeneity of the shear stress field is investigated.

10A475. Structural analysis and design of sandwich panels with cold-formed steel facings. - Ken P Chong *(1211 Forestwood Dr, McLean VA 22101)* and JA Hartsock *(619 Sater La, Edmonds WA 98020)*. Thin-Walled Struct 16(1-4) 199-218 (1993).

Superior structural efficiency, ease of erection, mass-production capabilities and thermal-insulation qualities are making sandwich panels with flat or thin-walled cold-formed steel facings and rigid foamed insulating core increasingly popular as enclosures for system buildings. In this paper, the structural behavior – including flexural stresses, deflections, vibration and thermal stresses – is presented, summarizing more than two decades of research. Methods used are analytical (boundary-value approaches), numerical (finite-strip, finite-layer, finite-prism approaches) and experimental (full-scale testing). Key equations are formulated and results by different methods are compared. Design guidelines are also suggested.

10A476. Tests on intermediately stiffened plate elements and beam compression elements. - KH Hoon *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*, J Rhodes *(Div of Mech of Mat, Univ of Strathclyde, UK)*, LK Seah *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*. Thin-Walled Struct 16(1-4) 111-143 (1993).

This paper describes an experimental investigation into the behavior of cold-formed steel intermediately stiffened plates which are subject to pure compression and cold-formed beams with intermediately stiffened compression elements which are subject to bending. Each plate or beam has a central intermediate stiffener. The investigation is concerned with the performance of the intermediately stiffened elements with different degrees of rigidity provided by the stiffener. The ultimate loads are compared with the predictions of BS 5950 Part 5 Code and the first Draft Eurocode 3.

10A477. Correct asymptotic theories for the axisymmetric deformation of thin and moderately thick cylindrical shells. - RD Gregory *(Dept of Math, Univ of Manchester, Manchester M13 9PL, UK)* and FYM Wan *(Dept of Appl Math, Univ of Washington, FS-20, Seattle WA 98195)*. Int J Solids Struct 30(14) 1957-1981 (1993).

A refined shell theory is formulated for the elastostatics of long, moderately thick cylindrical shells in axisymmetric deformation. This theory corresponds to a two-term outer asymptotic expansion of the exact solution for small values of the dimensionless shell thickness parameter. The complexity of the known exact solution for the 3D elasticity problem has stimulated an interest in thin and thick shell theories to provide accurate approximate solutions in the shell interior without any reference (or matching) to the inner asymptotic solution. The principal difficulty in developing a shell theory lies in the determination of an appropriate set of 2D boundary conditions for the shell solution from the prescribed edge data of the 3D theory. The derivations of boundary conditions for the thin shell theory and the refined shell theory constitute a main contribution of this paper. Correct boundary conditions obtained for the first time include (i) displacement edge conditions for thin shell theory, and (ii) stress and two types of mixed edge conditions for the refined shell theory. Several applications of the refined theory are given to show that corrections to the thin shell solution can be important.

10A478. Analysis and shape optimization of variable thickness prismatic folded plates and curved shells Part 1. Finite strip formulation. - E Hinton and NVR Rao *(Dept of Civil Eng, Univ Col of Swansea, Singleton Park, Swansea SA2 8PP, UK)*. Thin-Walled Struct 17(2) 81-111 (1993).

This paper deals with the linear elastic analysis of prismatic folded plate and shell structures supported on diaphragms at two opposite edges with the other two edges arbitrarily restrained. The analysis is carried out using curved, variable thickness, Mindlin-Reissner finite strips. The theoretical formulation is presented for a family of C(O) strips and the accuracy and relative performance of the strips are examined for curved situations. Some variable thickness and elastically supported plates are considered and the interesting phenomenon of the occurence of boundary layers in the twisting moments and shear forces is highlighted for a common boundary condition. Other examples analyzed include box girders and cylindrical shells. In all cases transverse shear deformation effects are included and the contributions to the strain energy from membrane, bending and transverse shear behavior noted. In a companion paper these accurate and inexpensive finite strips are used for structural shape optimization.

10A479. Elimination of self-straining in four-noded plate elements for large deflection analysis. - AK Soh and CK Soh *(Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*. Comput Struct 47(2) 341-342 (Apr 1993).

A method has been proposed to solve the self-straining problem of four-noded plate elements by analyzing large deflection problems. The results obtained by the proposed method for a test example are found to be in good agreement with those of the exact solution.

10A480. Error analysis of FE results on plates with nonuniform grids. - R Sistla *(Anal Services and Mat, Hampton VA 23666)*. AIAA J 31(6) 1075-1076 (Jun 1993).

Discrete Dirac delta functions in 2D and the governing plate differential equations are used to produce continuous approximations from discrete FE data on nonuniform grids. The continuous approximation can be differentiated to compute continuous stresses and moments at any point in the plate and, when substituted in the differential equations, provides a residual error. The paper presents application of examples of the procedure and studies the use of the "smoothed" solution in a Zienkiewicz-Zhu error estimator to assess the performance of the present analysis. In an example involving the linear response of a clamped square plate under uniform transverse load, the present procedure dramatically corrected and smoothed the discrete FE results.

10A481. Research developments in analyses of plates and shells. - KM Liew *(Div of Appl Mech, Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore)*, S Kitipornchai *(Dept of Civil Eng, Univ of Queensland, St Lucia, Australia)*, CM Wang *(Dept of Civil Eng, Natl Univ, Kent Ridge 0511, Singapore)*. J Construct Steel Res 26(2-3) 231-248 (1993).

The results presented in this paper are based on research collaborations between the three institutions, namely: (1) Nanyang Technological University, (2) The University of Queensland and (3) National University of Singapore. A software code named SEPSA, an acronym for super element for plate and shell analysis, has been developed. The software is applied to solve bending, buckling and vibration problems. The formulations and methods of analysis are briefly discussed. Several advantages of the present method over other approximate discretization methods are also addressed. To demonstrate the capability of SEPSA, some plate and shell solutions are presented.

10A482. Single Fourier series solutions for rectangular plates under in-plane forces, with particular reference to the basic problem of colinear compression Part 2. Stress distribution. - N Tahan *(SLP Eng London, Boundary House, Cricketfield Rd, Uxbridge, Middlesex, UK)*, MN Pavlovic *(Dept of Civil Eng, Imperial Col of Sci Tech and Med, London SW7 2BU, UK)*, MD Kotsovos *(Fac of Civil Eng, Natl Tech Univ of Athens, 42 Patission St, Athens, Greece)*. Thin-Walled Struct 17(1) 1-26 (1993).

In this, the second paper of a two-part report on colinearly compressed rectangular plates, a study of the mechanical aspects of the problem is conducted in order to obtain a reasonably general picture of the stress distribution as the relevant geometric and load parameters are varied. Special emphasis is placed on the degree of error inherent in the approximate single Fourier series scheme, and on what constitutes a "long" plate for the sort of systems in question. Finally, a possible practical implication for estimating the tensile strength of brittle materials through compression testing is suggested.

10A483. Two generalized conforming plate elements based on semiLoof constraints. - Zhifei Long *(Dept of Civil Eng, N Jiaotong Univ, Beijing 100044, Peoples Rep of China)*. Comput Struct 47(2) 299-304 (Apr 1993).

In this paper, the merits of both the generalized conforming element and the semiLoof element are utilized to establish nine-DOF triangular and 12-DOF rectangular thin-plate bending elements. The element DOFs are defined with the conventional displacements at corner nodes and the semiLoof constraints are used in the formulation. By using the concept of a generalized conforming element, these elements can pass Irons' patch test and accurate results are obtained with a much lower computational effort.

262. Structural stability (buckling, postbuckling)

262B. NONLINEAR AND FINITE DEFORMATION THEORY

10A484. Finite strip method for the elastic-plastic large displacement analysis of thin-walled and cold-formed steel sections. - PW Key and GJ Hancock *(Centre for Adv Struct Eng, Sch of Civil and Mining Eng, Univ of Sydney, NSW 2006, Australia)*. Thin-Walled Struct 16(1-4) 3-29 (1993).

A large deflection elastic-plastic analysis has been developed using the finite strip method of structural analysis to determine the nonlinear local buckling behavior of thin walled and cold-formed sections in compression. The analysis accounts for plate geometric imperfections, the variation of yield stress around a section, the stress-strain characteristics of the material forming the section and complex patterns of residual stress produced by the cold-forming process. The analysis is verified against reliable solutions for the nonlinear buckling behavior of plates and plate assemblies in axial compression and nonlinear overall buckling behavior of a strut. The analysis is further compared with the results of plates with a rounded stress-strain curve typical of cold-formed steel and aluminium.

262D. IMPERFECTION SENSITIVITY

10A485. Prop-imperfection subsea pipeline buckling. - N Taylor and Vinh Tran *(Sch of Construct, Sheffield City Polytech, Pond St, Sheffield S1 1WB, UK)*. Marine Struct 6(4) 325-358 (1993).

In-service buckling of subsea pipelines can occur due to the introduction of axial compressive forces caused by the constrained expansions set up by thermal and internal pressure actions. Proposed herein is a mathematical model relating to a pipeline, the otherwise horizontal and straight idealized lie of which is interrupted by an encounter with an isolated prop or point irregularity. The overbend produced can serve, in the presence of enhanced topologies involving trenching, burial, discrete or continuous, and fixed anchor points, to trigger vertical or upheaval buckling of the pipeline under in-service conditions. The results of a series of case studies are contrasted with data appertaining to alternative models available in the literature: experimental support is additionally noted. By questioning the implicit stress-free-when-straight assumption present in these alternative models, it is considered that a consistent, imperfection-prone isolated prop formulation is hereby provided, suitable for design application.

262E. COLUMNS AND BEAMS

10A486. Research on elastic buckling of columns, beams and plates: Focussing on formulas and design charts. - CM Wang *(Dept of Civil Eng, Natl Univ, Kent Ridge, 0511 Singapore)*, S Kitipornchai *(Dept of Civil Eng, Univ of Queensland, Queensland 4072, Australia)*, KM Liew *(Div of Appl Mech, Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore)*. J Construct Steel Res 26(2-3) 211-230 (1993).

Although there are many numerical methods which may be used to evaluate critical elastic design parameters accurately, designers still prefer to sacrifice accuracy for simplicity. Approximate formulas or design charts from handbooks and standard texts are used, or conservative assumptions are made to simplify the problems so as to justify their use. Until powerful, user-friendly and inexpensive software becomes readily available to designers, approximate formulas and design charts continue to be used. In recent years, collaborative work between the authors and their research associates has yielded a number of approximate buckling formulas and design charts for critical loads for columns, beams and plates. A review of these research investigations is presented herein, together with some of the newly developed buckling formulas and design charts.

10A487. Static solutions of the Leipholz problem. - W Dmitriyuk *(49a Moshe Sharet St, Kiryat Haim 26260, Israel)*. Int J Solids Struct 30(15) 1997-2008 (1993).

If the external loads on a bar remain in the original direction after buckling, the character of the problem is conservative. When these loads are tangentially-directed the problem is non-conservative and in this case the critical load must be calculated by the dynamic and by the static adjoint method. In this paper the critical buckling load of the strut which is built in at the bottom and compressed by a distributed tangential load is calculated by the static adjoint method.

10A488. Theoretical investigation of the column behavior of cold-formed square hollow sections. - PW Key and GJ Hancock *(Centre for Adv Struct Eng, Sch of Civil and Mining Eng, Univ of Sydney, NSW 2006, Australia)*. Thin-Walled Struct 16(1-4) 31-64 (1993).

An experimental program investigating the column behavior of four sizes of square hollow section was undertaken at the Univerity of Sydney using Australian produced cold-formed square hollow sections. Stub and pin-ended column tests were performed and detailed measurements of the yield stress and residual stress taken around the sections. A large deflection elastic-plastic finite strip analysis including the measured distributions of yield stress and residual stress is used to investigate the behavior of the stub and pin-ended columns. In particular, the influence of the measured through thickness residual stress components on the ultimate load and behavior of the square hollow section columns is demonstrated. The analysis accounts for plate geometric imperfections, the variation of yield stress around a section, the stress-strain characteristics of the material forming the section and the highly complex patterns of residual stress produced by the cold-forming process. Comparison of the analytical results with the test results is provided.

10A489. Thin-walled cold-formed sections subjected to compressive loading. - J Loughlan *(Col of Aeronaut, Cranfield IT, Bedfordshire, MK43 0AL, UK)*. Thin-Walled Struct 16(1-4) 65-109 (1993).

The weakening effects of local buckling on the compressive load carrying capability of thin-walled cold-formed sections is examined and discussed. Theoretical results are presented for the pin-ended support condition and a study is made of the local buckling and overall bending interaction behavior of compression members with different cross-sectional shapes. It is shown that singly symmetric plain channel sections exhibit considerably different interactive equilibrium characteristics to those of I-sections for which the shear centre and section centroid are coincident. The theoretical results given have been obtained through the solution of a differential equation which governs, approximately, the overall bending behavior of a locally buckled compression member. Both local and overall imperfections are considered in the theoretical approach and it is shown that the effect of these is to reduce the ultimate compressive carrying capacity of cold-formed sections. An experimental investigation of the behavior of concentrically loaded pin-ended I-section struts and columns is reported and the findings from this are compared with theoretical predictions. The theoretical predictions of load-deflection equilibrium behavior and stress variations with load are shown to be in good agreement with those obtained from test. The provisions made in the UK Code of Practice and the American Specification pertaining to the design of cold-formed compression members are briefly outlined and compared. It is shown that with regard to I-section struts and columns the American design procedure gives, in general, more conservative estimates of collapse.

10A490. Ultimate strength design of biaxially loaded steel box beam-columns. - NE Shanmugam, JY Richard Liew, SL Lee *(Dept of Civil Eng, Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*. J Construct Steel Res 26(2-3) 99-123 (1993).

This paper is concerned with the analysis and design of box beam-columns subjected to axial load applied at biaxial eccentricities. A spread-of-plasticity method to predict the ultimate strength of box beam-columns of compact cross-sections is proposed. The method is then extended to study the behavior of thin-walled beam-columns in which the effects of local buckling are taken into account in terms of the effective width of the component plates. The analytical results are compared with the corresponding results obtained from experiments carried out by the authors. Design formulae are proposed to predict the ultimate strength of beam-columns of non-compact cross-sections under biaxial loading. Finally, some optimization results for designing thin-walled beam-columns with minimum weights, satisfying the strength limit state and other design constraints relevant to typical conditions in practice, are provided.

262F. RINGS AND ARCHES

10A491. Buckling analysis of steel arch bridges. - AS Vlahinos *(Dept of Civil Eng, Univ of Colorado, 1200 Larimer St, Denver CO 80204)*, JC Ermopoulos *(Dept of Civil Eng, Natl Tech Univ, 42 Patission St, 10682 Athens, Greece)*, Yang-Cheng Wang *(Dept of Civil Eng, Univ of Colorado, 1200 Larimer St, Denver CO 80204)*. J Construct Steel Res 26(1) 59-71 (1993).

Steel arch bridges are analyzed. The shape and the height of the arch are variable and the arch's support are either pinned or fixed. A uniformly distributed load and a moving concentrated load are considered. The location and the magnitude of the minimum elastic critical loads are computed for various values of height to span ratios and load combinations. The influence of arch rib height on the critical loads is studied and the interaction curves between critical concentrated and critical uniform loads are given. Finally the accurate optimum arch heights for all cases are obtained. The results are presented in graphical and tabular form.

262G. FRAMED STRUCTURES

10A492. Design of frames against buckling using a Rayleigh quotient approximation. - RA Canfield *(Dept of Aeronaut and Astronaut, Air Force IT, WPAFB)*. AIAA J 31(6) 1143-1149 (Jun 1993).

A Rayleigh quotient approximation is applied to the design of structures while guarding against elastic instability. It approximates buckling eigenvalues by separately estimating the model strain energy due to the linear and geometric stiffness of the structure. Previously used during structural optimization for the fundamental natural eigenvalue, the Rayleigh quotient approximation is derived for the buckling design problem for the first time. The critical buckling load is found by solving the eigenvalue problem that arises by considering the geometric nonlinearity of the deforming structure. Rayleigh's principle is used to justify the choice of intermediate design variables for approximating terms in the Rayleigh quotient. A truss model illustrates the importance of the design space chosen for approximating the modal strain energy. A beam-column, two plane frames, and a space frame are used to verify the formulation. Special attention is paid to difficult bimodal optima.

10A493. Example of 3D frame buckling. - WR Spillers, A Saadeghvaziri, A Luke *(Dept of Civil and Env Eng, NJIT, Newark NJ 07102)*. Comput Struct 47(3) 483-486 (3 May 1993).

Physical test results are presented to resolve existing disagreements in the literature concerning the collapse load of an L-shaped frame which fails through torsional buckling. Available computer solutions for this problem are compared with particular attention given to the symmetry of the geometric stiffness matrix.

10A494. Modified solution for finding the optimal angle of spacecraft walls under orbital debris impacts. - CP Pantelides and S-R Tzan *(Dept of Civil Eng, Univ of Utah, Salt Lake City UT 84112)*. AIAA J 31(6) 1162-1164 (Jun 1993).

In recent studies it has been shown both analytically and experimentally that orbital debris impact is a hazard to long duration near-Earth space structures. In addition, it has been determined that most space debris impacts will occur at oblique angles to the surface of the space structure. Experimental studies of oblique hypervelocity impact of multisheet structures have shown that there exists a critical debris particle trajectory angle beyond which projectile impacts produce ricochet debris that can cause major damage to orbiting structures.

10A495. Recent research on buckling of framed structures and curved beams. - Yeong-Bin Yang *(Dept of Civil Eng, Natl Taiwan Univ, Taipei, Taiwan 10617 ROC)*. J Construct Steel Res 26(2-3) 193-210 (1993).

Both the buckling of framed structures and the buckling of curved beams have been the focus of intensive research in recent years. However, very few researchers have realized that the problems encountered in the two seemingly independent areas are in effect correlated and can be resolved by the same means. This paper intends to review some of the most relevant works, especially those conducted by the writer and co-workers, on the buckling of framed structures and curved beams, with particular emphasis placed on the implementation of rational procedures for analyzing problems involving 3D rotations. It is recommended that such procedures be adopted in a general computer program for calculating the buckling loads of 3D framed structures.

10A496. Influence of lips on thin-walled sections. - LK Seah *(Dept of Mech and Prod Eng, Nanyang Tech Inst, Singapore 2263)*, J Rhodes *(Dept of Mech Eng, Univ of Strathclyde, Glasgow, UK)*, BS Lim *(Process Software Pte, Science Centre Rd, Unity House, #05-02, Singapore 2260)*. Thin-Walled Struct 16(1-4) 145-177 (1993).

Turning the free edge of an unstiffened flange inwards or outwards to form a "lip", can substantially improve the local buckling resistance of a member. The lip is the most common type of edge stiffener used in cold-rolled, thin-walled sections. In this paper the behavior of plate elements of thin-walled sections stiffened by compound lips (ie, lips which are folded twice to form "lips on the lips") is examined both theoretically and experimentally. An outline of a series of tests on compound edge-stiffened thin-walled sections of various geometries is given and some load-end compression displacement paths are compared with the theoretical predictions. Reasonably good agreement is obtained between the experimental and theoretical results. Comparisons of the theoretical predictions with experimental results of other researchers are also presented in this paper.

10A497. Linear elastic stability analysis of shear-deformable plates using a modified spline finite strip method. - YK Cheung and J Kong *(Dept of Civil and Struct Eng, Univ of Hong Kong, Hong Kong)*. Comput Struct 47(2) 189-192 (Apr 1993).

The stability of shear-deformable plates under constant initial stresses is studied by the spline finite strip method. Third-order plate theory is used as the basis for developing the strip element. The classical B_3-spline function is modified in such a way that the resulting spline finite strip element incorporates the merits of spline interpolation and the versatility of the FEM. A set of demonstration analyses are presented to show the validity of the modified spline finite strip method.

10A498. Antisymmetric bifurcations in a compressible pressure-sensitive circular cylinder under axisymmetric tension and compression. - KT Chau *(Dept of Civil and Struct Eng, Hong Kong Polytech, Hung Hom, Hong Kong)*. J Appl Mech 60(2) 282-289 (Jun 1993).

This paper examines antisymmetric bifurcations of geometric diffuse modes, including buckling and surface rumpling modes, for a compressible pressure-sensitive circular cylinder of finite length under axisymmetric loadings. The analysis includes the effects of nonnormality, transverse isotropy, and confining stress on the appearance of antisymmetric geometric diffuse modes and their relationship to the onset of localization. The long wavelength limit of the eigenvalue equation is found corresponding to the Euler's buckling load; the short wavelength limit corresponds to the eigenstress for the surface rumpling mode if the cylinder is incompressible and satisfies plastic normality. If the lateral stress is nonzero, a finite solution exists for the antisymmetric long wavelength limit; for the cases that the in-plane bulk modulus becomes unbounded, this finite eigenstress equals to the plane-strain results obtained by Chau and Rudnicki (1990). The lowest possible bifurcation stresses are plotted for various constitutive parameters by combining the results of the bifurcation analyses for both the axisymmetric (Chau, 1992) and the antisymmetric modes. This eigenvalue surface also provides a condition that determines whether bulging (antisymmetric) or building (axisymmetric) appears first for a fixed specimen geometry under compression.

10A499. Axisymmetric dynamic buckling of submerged cylindrical shells. - B Mustafa, STS Al-Hassani, SR Reid *(Dept of Mech Eng, UMIST, Sackville St, Manchester M60 1QD, UK)*. Comput Struct 47(3) 399-405 (3 May 1993).

Dynamic buckling response of tubes immersed in water and subjected to an axisymmetric external throughwater pressure pulse is investigated using the FEM. A loading routine describing the hydrodynamic net pressure, incorporating incident and reflected pressure pulses on the structure was developed. This is interfaced with the general-purpose FE code ABAQUS to solve for the structural response which has non-linearity in both material properties and displacements. Idealized geometric imperfections in the radius are used in the FE model to trigger the radial buckling mode. The same numerical procedure was employed to predict the dynamic buckling response of tubes subjected to impulsive loading in air. Comparisons are made with plastic flow buckling theory and experiments reported in literature.

10A500. Buckling and post-buckling characteristics of pressure-loaded cylinders. - Seishi Yamada *(Toyohashi Univ of Tech, Toyohashi 441, Japan)* and JGA Croll *(Dept of Civil and Env Eng, Univ Col, London WC1E 6BT, UK)*. J Appl Mech 60(2) 290-299 (Jun 1993).

Nonlinear Ritz analysis is used to investigate the elastic buckling behavior of pressure loaded cylinders. Careful analysis of the energy changes during the buckling process allows definition of a reduced stiffness theoretical model. This reduced stiffness model provides a convenient means for estimating lower bounds to the imperfection sensitive elastic buckling behavior.

10A501. Influence of local fiber undulations on the global buckling behavior of filament-wound cylinders. - DW Jensen and SP Pai *(Dept of Aerospace Eng, Penn State)*. J Reinforced Plastics Composites 12(8) 865-875 (Aug 1993).

The predicted compressive stiffness and buckling strength of filament-wound cylinders using classical lamination theory is significantly higher than those observed experimentally. This discrepancy is partially influenced by the variation of mechanical properties in the region of fiber undulations. These regions are localized geometric defects intrinsic to the filament-winding, weaving, and braiding processes. In the present work, the average mechanical properties of the fiber undulation region are quantified using the modified models of woven-fabric composites to account for the 3D effects. The mechanical properties thus determined can be incorporated as local element properties into global FE models. Preliminary results from large-displacment analyses of filament-wound cylinders are relatively more accurate when fiber undulations are accounted for.

10A502. Sensitivity analysis in post-buckling problems of shell structures. - H Noguchi and T Hisada *(Res Center for Adv Sci and Tech, Univ of Tokyo, 4-6-1 Komaba Meguro-ku, Tokyo 153, Japan)*. Comput Struct 47(4-5) 699-710 (3 Jun 1993).

In this study, a method to evaluate sensitivities in post-buckling analysis is developed. The gradients of load values obtained under several constraint conditions are discussed. Unlike other methods for sensitivity analysis, the present method can cope with both snap-through and bifurcation problems without eigenvalue analysis. In addition, the load sensitivity at arbitrary points on an equilibrium path can be calculated. Using the MITC4 shell element, several numerical examples, such as a bifurcation buckling and a snap-through analysis of shell structures, are solved to show the performance of this sensitivity analysis method.

10A503. Stability loss in thick transversely isotropic cylindrical shells under axial compression. - GA Kardomateas *(Sch of Aerospace Eng, Georgia Tech)*. J Appl Mech 60(2) 506-513 (Jun 1993).

The stability of equilibrium of a transversely isotropic thick cylindrical shell under axial compression is investigated. The problem is treated by making appropriate use of the 3D theory of elasticity. The results are compared with the critical loads furnished by classical shell theories. For the isotropic material cases considered, the elasticity approach predicts a lower critical load than the shell theories, the percentage reduction being larger than increasing thickness. However, both the Flugge and Danielson and Simmonds theories predict critical loads much closer to the elasticity value than the Donnell theory. Moreover, the values of n, m (number of circumferential waves and number of axial half-waves, respectively, at the critical point) for both the elasticity, and the Flugge and the Danielson and Simmonds theories, show perfect agreement, unlike the Donnell shell theory.

262K. STIFFENED AND ANISOTROPIC STRUCTURES

10A504. Sandwich panels. - JM Davies *(Univ of Salford, Salford, UK)*. Thin-Walled Struct 16(1-4) 179-198 (1993).

In recent years, there has been increasing interest in the use of structural sandwich panels as the cladding of buildings and a good deal of research and development has been carried out. This paper reviews the state of the art with regard to the structural design of elements consisting of two thin metal faces separated by a lightweight core. Various aspects are discussed but two are given particular attention, namely methods of global analysis and the local buckling of compressed face elements. The analysis of sandwich panels under all possible loading and boundary conditions no longer poses any problem. Classical solutions, approximate solutions and numerical methods such as FE all have their place and are reviewed in detail. Local buckling phenomena in sandwich elements are similar to those in other thin-walled metal elements with the added consideration that buckling is resisted by the core material. This leads to some quite complex analysis which requires simplification for practical design. The paper includes a useful bibliography of recent references.

10A505. Stability of continuous composite plate girders with U-frame action. - RP Johnson *(Dept of Civil Eng, Univ of Warwick)* and Shiming Chen *(Inst of Urban Construct, Peoples Rep of China)*. Struct Build 99(2) 187-197 (May 1993).

Tests are reported on two half-scale twin double-cantilever girders with class 4 webs. In one, lateral stability of the bottom flanges was provided by continuous U-frame action; and in the other, by discrete U-frames that included the shear connection and the concrete slab, which was reinforced as the deck of a highway bridge. Four distinct types of lateral buckling failure were observed. They are discussed in relation to three design methods, including that of Eurocode 4: Part 1.1.

262L. DYNAMIC STABILITY

10A506. Stability of spinning shear-deformable laminated composite plates. - R Bhumbla and JB Kosmatka *(Dept of Appl Mech and Eng Sci, UCSD)*. J Sound Vib 163(1) 83-99 (8 May 1993).

A first order, shear deformation plate theory is used to study the buckling speeds and the corresponding deformed shape of spinning, laminated composite plates offset from the axis of rotation. The thoery accounts for geometric nonlinearity in the form of von Karman strains and the effects of rotatory inertia. A displacement FE model is developed to obtain the numerical solutions to this class of problems. The buckling speeds are presented as functions of spin vector location and orientation, and composite ply lay up. The phenomenon of tensile buckling is examined. the buckling speed is seen to decrease with the spin vector offset from the plate clamped root, and increasing pitch orientation. It is shown that laminated plates can be designed to buckle in specific modes and at specific speeds. Nonlinear effects have been shown to be significant for cases where there is coupling between in plane and out of plane deflections of the plate. This coupling is a result of either material anisotropy or the application of forces out of plane of the plate.

10A507. Stability of the damped hill's equation with arbitrary, bounded parametric excitation. - CD Rahn *(Dept of Mech Eng, Clemson Univ, Clemson SC 29634)* and CD Mote Jr *(Dept of Mech Eng, UCB)*. J Appl Mech 60(2) 366-370 (Jun 1993).

The minimum damping for asymptotic stability is predicted for Hill's equation with any bounded parametric excitation. It is shown that the response of Hill's equation with bounded parametric excitation is exponentially bounded. The parametric excitation maximizing the bounding exponent is identified by time optimal control theory. This maximal bounding exponent is balanced by viscous damping to ensure asymptotic stability. The minimum damping ratio is calculated as a function of the excitation bound. A closed form, more conservative estimate of the minimum damping ratio is also predicted. Thus, if the general (eg, unknown, aperiodic, or random) parametric excitation of Hill's equation is bounded, a simple, conservative estimate of the damping required for asymptotic stability is given in this paper.

10A508. Tight lower and upper bounds to first eigenvalues. - R Schmidt *(Col of Eng and Sci, Univ of Detroit, Detroit MI 48221)*. Indust Math 42(1) 1-8 (1992).

Procedures for enclosing the first eigenvalue (such as the bifurcational buckling load or fundamental frequency of free vibrations) by rather tight lower and upper bounds are described in this note. The essence of the approach is to employ the Krylov-Bogolyubov enclosure theorem for the determination of a lower bound to the second eigenvalue and then to use that value in Temple's inequality to obtain a lower bound to the first eigenvalue. Furthermore, an upper-bound formula, based on three successive Rayleigh-Schwarz quotients, is used to calculate a tight upper bound. The bifurcational buckling of a heavy, slender, elastic cone fixed at its base serves as an illustrative and didactic example.

264. Electromagneto solid mechanics

10A509. Rotation of a rigid ellipsoidal inclusion embedded in an anisotropic piezoelectric medium. - Tungyang Chen *(Dept of Civil Eng, Natl Cheng Kung Univ, Tainan, Taiwan 70101, ROC)*. Int J Solids Struct 30(15) 1983-1995 (1993).

A rigid ellipsoidal inclusion is embedded in a homogeneous piezoelectric matrix and is rotated infinitesimally, about an axis through its center, by an imposed couple. Without having to solve the governing equations of equilibrium, we find directly the relation between the couple and rotation vectors, together with the stress, strain, rotation tensor, and electric fields just outside the ellipsoidal surface. In addition, we establish boundary integral formulae for evaluation of the fields in the matrix. Gaussian quadrature formulae with variable station points are employed in the numerical computations. Results are presented for a piezoelectric PZT-6B to show the effect of the aspect ratio of the spheroid on the rotational stiffness. This work extends the results of Walpole to piezoelectric media.

10A510. Universal relations in piezoelectric composites with eigenstress and polarization fields Part I. Binary media: Local fields and effective behavior. - Y Benveniste *(Dept of Solid Mech Mat and Struct, Fac of Eng, Tel-Aviv Univ, Ramat Aviv 69978, Israel).* J Appl Mech 60(2) 265-269 (Jun 1993).

Binary composite media of arbitrary phase geometry are considered. The constituent phases have general anisotropic piezoelectric behavior and contain constant eigenstress and spontaneous polarization fields. An electromechanical loading of the composite aggregate is found which results in uniform strain and electric field intensity throughout the solid. The existence of these uniform fields is used to derive exact universal relations between the local fields as well as between the effective constants of the composite aggregate.

10A511. Universal relations in piezoelectric composites with eigenstress and polarization fields Part II. Multiphase media: Effective behavior. - Y Benveniste *(Dept of Solid Mech Mat and Struct Eng, Tel-Aviv Univ, Tel-Aviv Univ, Ramat Aviv 69978, Israel).* J Appl Mech 60(2) 270-275 (Jun 1993).

We consider heterogeneous piezoelectric media in general and multiphase piezoelectric composites in particular. A distribution of statistically homogeneous eigenstress and spontaneous polarization fields is admitted in the solid which is itself statistically homogeneous, and the effective eigenstress and spontaneous polarizaton is sought. The method here is based on the use of virtual work theorems in piezoelectric media and therefore differs from the approach used in the companion paper (Benveniste, 1993). We show that the effective eigenstress and polarization follow from a knowledge of the influence functions related to an electromechanical loading of the composite aggregate in which no eigenstress and polarizations are present. When applied to the special case of binary systems with constant eigenstress and polarization fields in the phases, the above result implies that the effective eigenstress and polarization can be determined in terms of the effective elastic, piezoelectric dielectric tensors of the medium, the constituent properties, and the individual eigenstresses and polarizations.

10A512. Safety analysis of the superconducting magnet system of a next generation tokamak. - N Mitchell, L Bottura, S Chiocchio *(NET team, Max-Planck-Inst fur Plasmaphys, Boltzmannstr 2, W-8046 Garching bei Munchen, Germany).* Fusion Eng Des 22(3) 193-216 (Apr 1993).

A preliminary safety analysis of the superconducting magnet system of a "next generation" tokamak is performed. Such tokamaks must satisfy nuclear class safety standards to permit their operation. Designs are not sufficiently advanced to permit the full safety case to be made. However scoping calculations of the form presented here enable potential problems to be identified or eliminated. With a number of constraints on the design it is shown that "passive" safety could be achieved in such a magnet system ie, the magnets can not cause failure in adjacent nuclear components.

266. Soil mechanics (basic)

10A513. Hydraulic fracturing of soil during laboratory experiments Part I. Methods and observations. - LC Murdoch *(Center Hill Res Facility, Univ of Cincinnati, Cincinnati OH).* Geotechnique 43(2) 255-265 (Jun 1993).

Hydraulic fracturing appears to have useful environmental and geotechnical applications, but the details of fracture morphology and propagation in soil are poorly known. To identify those details, more than 100 hydraulic fractures were created by dyed glycerine injected into rectangular blocks of silty clay confined within a triaxial loading cell. The traces of the fractures were observed directly through a transparent loading plate in the experimental apparatus, and the fracture surfaces were described after they had been exposed by the blocks being split open. Steps and ridges on fracture surfaces, and lobes near the leading edge of a fracture were ubiquitous in silty clay, as they are on the surfaces of hydraulic fractures in rock or other brittle materials. Details of the leading edge, however, depend on the water content of the soil, which is one difference between hydraulic fractures in soil and those in rock. Fluid injected to create a hydraulic fracture appears to penetrate to the leading edge of the fracture when the pressure of pore fluid is less than atmospheric while the sample is under load. At greater water contents when the pore pressure is positive, the injected fluid lags behind the leading edge. It is inferred that this phenomenon occurs because water infiltrates into the fracture tip and prevents penetration of the injected fluid.

10A514. Hydraulic fracturing of soil during laboratory experiments Part II. Propagation. - LC Murdoch *(Center Hill Res Facility, Univ of Cincinnati, Cincinnati OH).* Geotechnique 43(2) 267-276 (Jun 1993).

The propagation of hydraulic fractures in soil was studied in the lab by glycerine injected at a constant rate into rectangular samples of silty clay confined in a triaxial cell. During propagation, the trace of a hydraulic fracture appeared on the side of the cell as a nearly straight, narrow line that tapered from 0-05 mm to negligible aperture at the tip. Pressure of the glycerine was recorded as a function of time and is characterized by a period of nearly linear increase, a break in slope followed by a period of increasing pressure but decreasing slope, a maximum, and then a period of decreasing pressure. Tests terminated early in that sequence of events indicated that the break in slope marks the onset of hydraulic fracturing. The pressure at the onset of the fracturing was predicted from a determination of the fracture toughness of the silty clay. The forms of the pressure records were markedly affected by the water content of the soil: increasing water content decreased the pressure required to initiate a hydraulic fracture (and decreased fracture toughness) and flattened the pressure record during propagation.

10A515. Hydraulic fracturing of soil during laboratory experiments Part III. Theoretical analysis. - LC Murdoch *(Center Hill Res Facility, Univ of Cincinnati, Cincinnati OH).* Geotechnique 43(2) 277-287 (Jun 1993).

A theoretical analysis is developed to explain observations from lab experiments where hydraulic fractures were created in silty clay soil. The analysis is based on a critical stress intensity criterion for propagation. The fracture is assumed to be a 2D slit embedded in an elastic material of infinite extent. It is assumed to be filled with one fluid that is injected at the mid-line of the fracture and another that infiltrates the fracture tip. Other parameters included in the analysis are initial fracture length, elastic modulus, pressure in the fracture tip, growth of the infiltrated region at the tip, fracture toughness, and the rate of the leakoff. Results of the analysis are presented to highlight the effects of a slight change in each parameter. The model is validated by the use of curve-fitting methods to estimate parameters required to mimic pressure records from lab experiments, and then by comparison of the estimated parameters with quantities measured in the lab. The results suggest that pore fluid infiltrating into the tip of a propagating fracture can control many of the details of hydraulic fracture development in soil, confirming a conceptual model postulated earlier based only on lab observations.

10A516. RES: A numerical program for reinforced-soil slopes based on the rigid-plastic theoretical model. - D Lesniewska *(Inst of Hydroeng, IBW PAN, Gdansk, Poland).* Geotextiles Geomembranes 12(5) 435-439 (1993).

A brief description of a rigid-plastic model of reinforced soil is presented with an account of its application – program RES, which may serve for numerical analysis of reinforced slopes. The program is able to solve the classical differential-boundary-value problem of slope-bearing capacity for reinforced and unreinforced soil in a wide range of soil and reinforcement parameters. The solution is obtained with a method of characteristics and contains the slope's bearing capacity (the value of the failure load), a definition of slip line, responsible for construction damage, and the total stresses in the plastic region of the slope.

10T517. Evaluation of a constitutive model for overconsolidated clays. - AJ Whittle *(Dept of Civil and Env Eng, MIT).* Geotechnique 43(2) 289-313 (Jun 1993).

10A518. Analytical interpretation of dilatometer penetration through saturated cohesive soils. - RJ Finno *(Dept of Civil Eng, NWU).* Geotechnique 43(2) 241-254 (Jun 1993).

A 3D numerical solution to the problem of penetration of a flat plate dilatometer through saturated cohesive soil is presented. Axisymmetric stream functions are used with those corresponding to a uniform velocity field to approximate the geometry of the stream lines during penetration. After the source strengths have been determined, velocities and strains are computed. The computed strain fields are compared with those for axisymmetric and plane strain penetrations to show the need to use a 3D analysis. Effective stresses are computed from the strains based on assumed constitutive response (in this case an anisotropic bounding surface model) and total stresses are computed based on equilibrium considerations. The method provides computed horizontal stress indices that compare favorably with field data. The effect of penetration on the horizontal stress index measured by the dilatometer is evaluated. This index is shown to be most sensitive to changes in overconsolidation ratio and at-rest earth pressure coefficient, which reflect the initial in situ stresses.

10A519. Dynamic effects in a saturated layered soil deposit: Centrifuge modeling. - I Krstelj and JH Prevost *(Dept of Civil Eng and Operations Res, Princeton).* Soil Dyn Earthquake Eng 11(8) 485-496 (1992).

The dynamic response of a saturated layer soil deposit was modeled on the Princeton Univ geotechnical centrifuge using various centrifugal acceleration levels. The layered soil deposit consists of a saturated Nevada sand layer overlaid by a slit layer of low permeability. Measured acceleration and pore-water pressure time histories are used to validate the scaling laws used in interpreting dynamic centrifugal modeling test results. Careful measurements of the settlements at the silt surface are performed using a non-contact displacement transducer, and comparisons are made with measurements obtained with standard linear voltage displacement transducer. Finally, the experimental results are used to verify the validity of the numerical procedures encompassed in the computer code DYNAFLOW.

10A520. Rigid-plastic boundary in statically indeterminate problems in the mechanics of granular materials. - D Harris *(Univ of Manchester Inst of Sci and Tech, PO Box 88, Manchester, M60 1QD, UK)*. Quart J Mech Appl Math 46(1) 41-69 (Feb 1993).

A complete formulation for general statically indeterminate boundsry-value problems is presented for a continuum, rigid-plastic, model of granular materials satisfying the stress-equilibrium conditions, the Coulomb yield criterion and the double-shearing kinematic equations. Equations for the velocity field in the neighborhood of a finite stress discontinuity are derived. The calculus of variations is used to formulate a method for obtaining the characteristic curves which separate the rigid and deforming regions and which are subject to a mixed boundary condition containing both stress and velocity variables. The criterion is applied to the region in the vicinity of the exit of a wedge-shaped channel under conditions of converging flow. On the assumptions of radial flow sufficiently far inside the channel, rigid flow on exit and a transitional region which includes a curvilinear fan of characteristic curves it turns out that velocity and stress fields can be found satisfying all the required boundary conditions but that the necessary condition that the work-rate be everywhere non-negative fails to be satisfied.

10A521. Molecular dynamical study of granular fluids I. The unforced granular gas in 2D. - I Goldhirsch *(Dept of Fluid Mech and Heat Transfer, Fac of Eng, Tel-Aviv Univ, Ramat Aviv, Tel-Aviv 69978, Israel)*, M-L Tan, G Zanetti *(CRS4, PO Box 488, I-09124, Cagliari, Italy)*. J Sci Comput 8(1) 1-40 (Mar 1993).

Results of a numerical study of the dynamics of a collection of disks colliding inelastically in a periodic 2D enclosure are presented. The properties of this system, which is perhaps the simplest model for rapidly flowing granular materials, are markedly different from those known for atomic or molecular gases, in which collisions are of elastic nature. The most prominent feature characterizing granular systems, even in the idealized situation in which no external forcing exists and the initial condition is statistically homogeneous, is their inherent instability to inhomogeneous fluctuations. Granular "gases" are thus generically nonuniform, a fact that suggests extreme caution in pursuing direct analogies with molecular gases. We find that once an inhomogeneous state sets in, the velocity distribution functions differ from the classical Maxwell-Boltzmann distribution. Other characteristics of the system are different from their counterparts in molecular systems as well. For a given value of the coefficient of restitution, e, a granular system forms clusters of typical separation $L_0 \approx l(1 - e^2)^{1/2}$, where l is the mean free path in the corresponding homogeneous system. Most of the fluctuating kinetic energy then resides in the relatively dilute regions that surround the clusters. Systems whose lienar dimensions are less than L_0 do not give rise to clusters, still they are inhomogeneous, the scale of the corresponding inhomogeneity being the longest wavelength allowed by the system's size. The present article is devoted to a detailed numerical study of the above-mentioned clustering phenomenon in 2D and in the absence of external forcing. A theoretical framework explaining this phenomenon is outlined. Some general implications as well as practical ramifications are discussed.

10A522. Creep response of laterally loaded piles in ice and permafrost. - UGA Puswewala, RKND Rajapakse, L Domaschuk, H Shields *(Univ of Manitoba)*. Geotechnique 43(2) 223-240 (Jun 1993).

A computationally efficient pile element and a time-incremental FE code are developed to model laterally loaded piles in ice-permafrost, by modeling the pile as a beam supported on a spring-dashpot system. A numerical method involving plane strain FE analyses of laterally loaded rigid cores in frozen media is proposed to derive the appropriate spring and dashpot relationships for the pile element. Results of analyses using the pile element agree satisfactorily with experimental findings on laterally loaded rods in ice. Creep response of laterally loaded piles in icy permafrost is analyzed using the code. The deformation behavior of laterally loaded floating piles in ice predicted by the simple pile element is confirmed by rigorous analysis of the identical problem using 3D continuum elements. The computer code incorporating this simple pile element is a valuable predictive tool for practising engineers.

10A523. Two computer programs for the design and analysis of geosynthetic-reinforced soil-retaining walls. - RJ Bathurst *(Dept of Civil Eng, R Military Col, Kingston, ON, K7K 5L0, Canada)* and MR Simac *(Earth Improvement Tech, 100 Mayflower Court, Cramerton NC 28032)*. Geotextiles Geomembranes 12(5) 381-396 (1993).

The paper describes two commercially available programs that can be used to design and analyze soil-retaining walls that are constructed with horizontal sheets of geosynthetic reinforcement. The programs differ in their scope, program interface, and flexibility to optimize design during a user session. Both programs have been written for micro-computers operating under MS-DOS 3.0 or greater and have a graphical interface that allows the user to view the probelm cross-section at any stage in the design process. The analyses that are implemented in the programs are based on current recommended practice in North America. External stability is examined by using a "gravity wall structure" analog, and "tie-back wedge" approach is used for internal stability.

10T524. Expert system for the design of geotextiles. - G Mannsbart and S Resl *(Polyfelt Ges mbH, St Peterstr, 21, A-4021, Linz, Austria)*. Geotextiles Geomembranes 12(5) 441-450 (1993).

10A525. Stability analysis of reinforced slopes. - JR Greenwood *(Travers Morgan, Euribon House, Shortwood Close, Nottingham, NG1 7JF, UK)* and M Zytynski *(MZ Assoc, Llwynhaf, Llanddarog Rd, Carmarthen, Dyfed, SA32 8AR, UK)*. Geotextiles Geomembranes 12(5) 413-424 (1993).

The application of routine stability analysis to reinforced slopes is described. Problems are encountered in introducing reinforcement forces into certain established analytical methods. It is shown that the simple (or simplified) method of analysis lends itself to the inclusion of reinforcement forces. Two computer programs are described (i) SLIP4, a development of a hand calculation for determining the factor of safety of a single slip surface by four different methods and calculating the benefits of reinforcement, and (ii) STABLE, a sophisticated search program for analysis of non-circular or circular slips, including the effects of geotextile or geogrid reinforcement or other anchor forces.

10A526. End restraint in triaxial testing of soils. - J Feda, J Bohac, I Herle *(Inst of Theor and Appl Mech, Acad of Sci, Vysehradska 49, 128 49 Praha 2, Czech Republic)*. Acta Tech CSAV 38(2) 197-220 (1993).

The effect of end restraint of specimens of sand and reconstituted loess on their deformation was investigated. Triaxial CID tests with specimens' diameter 3.8 cm and height-dia ratio 2:1 and 1:1 were carried out to explore the effectiveness of different arrangement of lubrication layers and of quality of lubrication agent. Correlations of the peak angle of internal friction φ'_f, volumetric strain gradient at failure $(d\varepsilon_v/d\varepsilon_a)_f$ and of axial and volumetric strain at failure ε_{af} and ε_{vf} vs the initial porosity and consolidation pressure $\sigma'_r c$ were found and analyzed for effectively lubricated and unlubricated specimens with slenderness 2:1 and 1:1. The effect of lubrication with (dilatant) sand, though unimportant for strength and strain gradient with 2:1 (and lubricated 1:1) specimens, increases strains at failure, especially for 1:1 lubricated specimens. In this case, the stress field is uniform and strains equal about twice the standard value. The respective ratio depends on the initial porosity and can be used to transform the results of standard tests to the tests with uniform stress-strain fields. Loess specimens (contractant) did not show any considerable effect of end restraint. Some abnormities in the behavior were ascribed to the effect of aging.

10A527. State-space representation and optimal control of nonlinear material deformation using the FEM. - RV Grandhi, A Kumar *(Dept of Mech and Mat Eng, Wright State Univ, Dayton OH 45435)*, A Chaudhary *(UES Inc, Dayton OH)*, JC Malas *(Mat Eng, WPAFB)*. Int J Numer Methods Eng 36(12) 1967-1986 (30 Jun 1993).

A state-space model for representing the nonlinear material deformation and an optimal control scheme for obtaining desired process conditions in the deforming material are presented in this paper. The formulation is general for various metal-forming processes including forging and extrusion operations. The state variables selected in the formulation are the die-billet contact nodal velocities and the nodal velocities of the critical FEs of the billet. The control input is the ram velocity, which is determined by using the linear quadratic regulator theory to maintain desired strain rates within the selected FEs. The influence of an optimally designed ram velocity on the deforming material is studied using performance measures. This paper includes the development of the state-space model from nonlinear FE formulation, optimal control strategy and numerical example cases with discussions.

272B. APPLICATIONS OF PLASTICITY THEORY

10A528. Analysis of 3D hexagonal closed-die heading by the FE flow formulation. - PAF

Martins and MJM Barata Marques *(Seccao Tecnologia Mecanica, Inst Superior Tecnico, Avenida Rovisco Pais, 1096 Lisboa, Portugal).* J Mat Processing Tech 38(3) 553-566 (May 1993).

Modeling 3D metal-forming processes with the FE flow formulation based on the Doraivelu et al, constitutive equations is considered. The basic theory is reviewed. Special emphasis is placed on the numerical implementation of such formulation. The authors discuss the substitution of the Gauss by the Irons numerical integration rule for the evaluation of the deviatoric component of the generalized stiffness matrix, and present two criteria for analyzing mesh degeneracy and mesh-die interference. Three-dimensional contact problems are discussed briefly. Three-dimensional closed-die hexagonal heading, starting from a cylindrical aluminium-alloy billet, is reported. Theoretical and experimental results for the punch load-punch displacement evolution are analyzed, good agreement between them being found.

10A529. Constitutive model for cold deformation of aluminium at large strains and high strain rates. - S Tjotta and A Mo *(Senter for Industriforskning, PO Box 124 Blindern, 0314 Oslo 3, Norway).* Int J Plasticity 9(4) 461-478 (May 1993).

A temperature-dependent constitutive model for viscoplastic deformation of aluminium based on a single, scalar internal variable is presented. The model is designed particularly for the strains, strain rates, and temperatures important for cold forging. Special attention is paid to the underlying physical processes that determine the flow stress in the metal. The kinetic constitutive equation is based on thermal activation of dislocations over an average potential barrier from various kinds of obstacles. Strain hardening is modeled through the internal variable which represents the increasing height of these barriers. The model is generalized to three dimensions, and it has been implemented in the FE code ABAQUS. Simulations of simple forging operations are presented.

10A530. Free surface ductility in upsetting. - Hitoshi Moritoki *(Mining Col, Akita Univ, 1-1 Gakuen-cho, Tegata Akita 010, Japan).* Int J Plasticity 9(4) 507-523 (May 1993).

Cold upsetting of a circular cylinder is often used to evaluate the cold forgeability of forming materials. The index of the forgeability is the critical strain at which a crack occurs on the expanding free surface of the upsetting cylinder. The forming limit due to the cracking is analyzed by a method based on the sufficient condition for the collapse of the unique solution. The modes of cracking are determined by comparing the stabilities of deformation from the forming limit to the two modes able to permit strain rate discontinuity on the plane of localized necking. Numerous experiments published in the literature have shown a linear relationship with the slope of -0.5 in circumferential strain vs axial strain at the forming limit. The forming limit and the mode predicted are in very good agreement with the experimental results.

272C. FORGING

10A531. Validation of FE codes for prediction of machining distortions in forgings. - U Chandra *(Concurrent Tech, 1450 Scalp Ave, Johnstown PA 15904).* Commun Numer Methods Eng 9(6) 463-473 (Jun 1993).

When a forging is machined to its net shape, unacceptably large distortions can occur if the final part shape is complex. Such distortions can be predicted with the application of the FEM. However, numerical errors associated with the FE technique can render such predictions unreliable. This paper presents benchmark problems for verifying the accuracy of machining distortions predicted by any prospective FE code. Also, a comparison between two industry-standard general-purpose codes, ANSYS and ABAQUS, is presented.

272D. EXTRUSION

10A532. Simplified 3D FE analysis of the non-axisymmetric extrusion processes. - Hyun-Woo Shin *(Inst of Adv Machinery and Des, Seoul Natl Univ, 56-1 Shinrim-Dong Kwanak-Gu, Seoul 151-742, S Korea),* Dong-Won Kim *(Dept of Mech Des and Prod Eng, Seoul Natl Univ, Seoul, S Korea),* Naksoo Kim *(Dept of Mech Eng, Hong-Ik Univ, Seoul, S Korea).* J Mat Processing Tech 38(3) 567-587 (May 1993).

In this study a new simplified 3D numerical method and the associated computer program have been developed to simulate non-axisymmetric extrusion processes. To define the die geometry for non-axisymmetric extrusion, the area mapping technique has been used. A stream-lined die surface was used to minimize the total extrusion pressure. The extrusion of square, hexagonal, and "T" sections from round billet has been both simulated and explored experimentally using a model material. The computed results for the cross-sectional grid distortion have been found to be in good agreement with the experimental results. Computational results will thus be valuable for the designing of tool geometries and the corresponding processes.

10A533. Urethane clamp as a metal-forming tool. - S Thiruvarudchelvan *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263).* J Mat Processing Tech 38(3) 491-500 (May 1993).

A clamp making use of a tubular urethane rod was constructed recently and used in the semi-continuous extrusion of aluminium rod of 19.3 mm diameter. Using axial clamping pressures of up to 75 MPa on the urethane, axial compressive forces of up to 45 kN were generated on the aluminium feedstock. Clamps of this type may be designed and used with several other metal-forming processes with beneficial effects, some of these processes being identified in this paper. The advantages and limitations of the use of this clamp in these processes are discussed.

272F. DRAWING

10A534. Stressed-strained state of a blank at the initial stage of hydrodynamical drawing. - VM Popkov and SV Lapin *(Kaluga).* J Machinery Manuf Reliab 6 68-75 (1992).

A mathematical model of the stressed-strained state of a blank at the initial stage of hydrodynamical drawing is proposed. Some results computed using the model, are presented. The theoretical results are compared with experimental data.

272G. SHEET METAL FORMING AND STAMPING

10A535. Analysis of the hydrostatic bulging of an elliptic diaphragm by the energy method. - HS Lee *(Prod Eng, R&D Dept, Kia Motors, Kwang-Myung, S Korea)* and DY Yang *(Dept of Precision Eng and Mechatronics, Korea Adv Inst of Sci and Tech, Taejon, S Korea).* J Mat Processing Tech 38(3) 539-552 (May 1993).

An approach using the energy method is proposed for the analysis of 3D sheet-metal forming. There are some limitations in analysis by the energy method, eg, the analytical expression of the geometric configuration and the construction of a proper kinematically-admissible velocity field are very difficult and the estimation of strain rate at a point on the surface is very complicated. In the method suggested, the principal components of strain increment are calculated directly from the change of geometric profile for an arbitrary triangular element. The corresponding solution is found through optimization of the total energy consumption with respect to some parameters assumed in the kinematically-admissible velocity field and the geometric profile. In order to check the validity of the method proposed, the hydrostatic bulging of an elliptic diaphragm has been analyzed. In comparison of the computed results with existing experimental results, good agreement has been obtained for the pressure curve, the polar membrane strains and the strain distributions and it has thus been shown that the approach is applicable to the analysis of 3D sheet-metal forming.

10A536. Cold-formed thin-walled framework with flexible joint. - Tan Soon Huat *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263, Singapore)* and J Rhodes *(Dept of Mech Eng, Univ of Strathclyde, UK).* Comput Struct 47(3) 451-458 (3 May 1993).

The behavior of symmetrical double storey frameworks of cold-formed thin-walled plain channel members and semi-rigid connections is investigated analytically. A method of analysis, which is based on the matrix stiffness method, is developed and written into a computer program. Generalized relationships between forces and displacements at the ends of an element with semi-rigid connections are presented in a matrix form. The analysis takes account of member local buckling, connection strength and full moment-rotation behavior, axial load effects and shortening due to flexure. Using the theoretical analysis, the elastic critical load of the framework can be established.

10A537. Simulation, control and optimization of the gas-pressure forming of aluminium alloy sheet at elevated temperature. - PS Bate, DC Price, DJ Barrett, WT Roberts *(IRC in Mat for High Performance Appl, Univ of Birmingham, Birmingham B15 2TT, UK).* J Mat Processing Tech 38(3) 589-612 (May 1993).

The superplastic forming of Al-4.5% Mg alloy sheet, using gas pressure at elevated temperatures, has been studied. By using suitable models of material behavior and friction, it was possible to simulate this process with FEM. A rigid-plastic model was used, with the assumption that the material behaved as a membrane, to model axisymmetric forms. Such simulations could then be used to optimize the process, in terms of minimizing the forming time required whilst minimizing the amount of cavitation damage or retaining acceptable material thickness. To apply the optimization in practice, and for the generation of experimental data, a high degree of process control was required. Control of forming pressure is not sufficient for this purpose and volume-rate control was used. Good correlation was found between the predictions of the simulation and results from formed parts, and friction was found to be a very important factor in the process. It was possible to reduce the amount of cavitation significantly by applying an optimized volume-rate cycle.

272H. MACHINING (INCL NM)

10A538. Effects of carbon content and microstructure on the metal removal rate in electrochemical machining. - Ming-Chang Jeng, Ji-Liang Doong, Chih-Wen Yang *(Dept of Mech Eng, Natl Central Univ, Chung-Li, Taiwan 320, ROC).* J Mat Processing Tech 38(3) 527-538 (May 1993).

The present study investigates the effects of carbon content, microstructure and working pressure on the metal removal rate and current efficiency in the electrochemical machining of carbon steels. Four different carbon contents and various heat-treatment procedures (quenching, temperature and annealing) were performed. Some important experimental results are shown, as follows: (1) The removal rate and current efficiency increase with carbon content. (2) The quenched microstructures and tempered microstructures have a greater removal rate and current efficiency than those of the annealed microstructures. (3) The workpiece machined at the low working pressure of 3-4 kg/cm^2 has the greatest removal rate and current efficiency. (4) The machined surface roughness of all kinds of microstructure decreases with increase in the carbon content. (5) The roughness of the machined surface for annealed microstructures is greater than those of the quenched and tempered steels.

10A539. Remote sensing for on-line temperature estimation in machining: A basic framework. - S Raman *(Sch of Indust Eng, Univ of Oklahoma, Norman OK 73019)* and PH Cohen *(Penn State)*. J Mat Processing Tech 38(3) 613-632 (May 1993).

Remote thermocouple sensing (RTS) is a technique that utilizes analytical and experimental evidence to create models for temperature sensing, thus integrating the advantages of both approaches. The remote solution is an inverse problem of predicting the source based on some remote location temperatures. An accurate forward solution should be available that determines the relation between the source and sink, for estimation of the inverse relationship. Extensive simulation has been performed on the forward solution, thus establishing a need for fast and accurate computation.

272J. CASTING

10A540. Analysis of high-temperature behavior of solidified material within a continuous casting machine. - JR Boehmer, FN Fett, G Funk *(Inst of Energy Eng, Dept of Mech Eng, Univ of Siegen, Paul-Bonatz-Str 9-11, D-5900 Siegen, Germany)*. Comput Struct 47(4-5) 683-698 (3 Jun 1993).

The continuous casting of metals is determined by a multitude of dof, the combination of which conditions the quality of the products. To investigate in a theoretical way the principal possibilities that influence the process, an analysis is performed to simulate the high-temperature behavior of the solidified material within the continuous casting machine, ie, within the mould (with respect to contact and shrink gap formation) and the following secondary cooling zone (regarding support rolls and spray cooling). For the simulation of mass transport, solidification and/or remelting, and heat transfer, a finite difference method is applied; for the calculation of the thermomechanical stresses and strains the ADINA program is used as a FEM. Both thermal and stress analysis have been iteratively coupled to consider feedback. Emphasis is put on the highly nonlinear material behavior at temperatures near the solidification temperature as well as on the 3D and transient contact between strand and mould. To guarantee both accuracy and efficiency of computation, there is need for a problem-specific discretization, load history and stress-state formulation, material modeling, and coupling strategy.

10A541. Fluid flow, heat transfer and inclusion behavior in continuous casting tundishes. - Kouji Takatani, Yoshiyasu Shirota, Yoshihiko Higuchi, Yoshinori Tanizawa *(Iron and Steel Res Lab, Sumitomo Metal Indust, Oaza Sunayama 16, Hasaki-machi, Kashima-gun, Ibaraki-ken 314-02, Japan)*. Model Simulation Mat Sci Eng 1(3) 265-274 (Apr 1993).

A mathematical model to represent fluid flow, heat transfer and inclusion separation in continuous casting tundishes has been developed. The influence of tundish depth and length, flow rate, pouring method of molten steel and presence of a dam on the rate of inclusion separation is investigated for slab caster tundishes. A comparison of the present numerical results to simple analytical results has been made.

274B. CRACK INITIATION

10A543. Assessment of data for dynamic crack initiation under shock pressure loading Part I. Experiment. - LH Hernandez-Gomez *(Inst Invetigaciones Electricas, Dept Ing Mec, Dante 36 6o Piso Apdo Postal 5-849, 11590 Mexico DF, Mexico)* and C Ruiz *(Dept of Eng Sci, Univ of Oxford, Oxford OX1 3PJ, UK)*. Theor Appl Fracture Mech 19(1) 75-83 (Jun 1993).

A technique for analyzing crack initiation and growth in polymeric materials is described. The specimen is a circular plate fixed at the edge and subjected to a pressure shock wave loading. The design of the test is shown to reflect the loading history. Static tests can also be performed with the same equipment. The results of both static and dynamic tests are compared in terms of the load intensity required for crack initiation. It is found that this is higher for the static tests than for the dynamic tests, as expected.

10A544. Assessment of data for dynamic crack initiation under shock pressure loading Part II. Analysis. - LH Hernandez-Gomez *(Inst Investigaciones Electricas, Dept Ing Mec, Danta 36 6o Piso Apdo Postal 5-849, 11590 Mexico DF, Mexico)* and C Ruiz *(Dept of Eng Sci, Univ of Oxford, Oxford OX1 3PJ, UK)*. Theor Appl Fracture Mech 19(1) 85-94 (Jun 1993).

Presented in Part I is a shock-tube testing device for assessing the dynamic crack initiation characteristics. Data were found to obtain the critical dynamic stress intensity factor. Part II of this work is considered with the FE dynamic stress analysis to assist the interpretation of the experimental data for a center cracked PMMA specimen. Results are compared with the corresponding static data and show that they are not comparable with the stress intensity factor interpretation because of the dynamic loading rate effect.

10A545. Two-dimensional cracks at an angle to an interface. - B Chen and TJ Lardner *(Dept of Civil Eng, Univ of Massachusetts, Marston Hall, Amherst MA 01003)*. Int J Solids Struct 30(13) 1725-1735 (1993).

In this paper, we provide additional numerical results for the energy release rate and the stress intensity factors at the tip of a straight 2D crack at an angle to an interface of a bimaterial system. Three cases are considered: a semi infinite crack under a pair of point loads, a finite crack under a pair of point loads, and a finite crack under uniform pressure. The formulations for each of these cases lead to a system of singular integral equations which can be solved numerically. The effects of the orientation of the crack, the distance between the crack and the interface, and the material properties, α, \Beta, are investigated. The results are compared to the corresponding asymptotic results of Hutchinson et al for the subinterface crack (crack parallel to the interface).

274C. SUBCRITICAL CRACK PROPAGATION

10A546. Elevated temperature fatigue crack growth in alloy 718 Part I. Effects of mechanical variables. - H Ghonem *(Mech of Solids Lab, Dept of Mech Eng and Appl Mech, Univ of Rhode Island, Kingston RI 02881)*, T Nicholas *(Wright Lab, Mat Directorate, WPAFB)*, A Pineau *(Centre des Materiaux, Ecole des Mines de Paris, 91000 Evry, France)*. Fatigue Fracture Eng Mat Struct 16(5) 565-576 (May 1993).

In this paper observations concerning the effects of mechanical variables on the crack growth process in alloy 718 are reviewed and analyzed on the basis of the related deformation characteristics in the crack tip region. The variables included temperature, frequency, wave shape, hold time, load ratio and load interaction. These analyses have suggested that the role of each parameter in the acceleration of crack tip damage is governed mainly by their relative influence on the nature of the corresponding plastic deformation and associated slip line density. On the basis of this view (which assumes crack growth damage covers the range from cyclic- to fully time-dependent processes), the interactive effects of loading parameters are discussed when considering the corresponding fracture mode. Conflicting experimental observations under different operating conditions are examined.

10A547. Mixed mode fatigue crack growth with a sudden change in loading direction. - YC Lam *(Dept of Mech Eng, Monash Univ, Clayton, Vic 3168, Australia)*. Theor Appl Fracture Mech 19(1) 69-74 (Jun 1993).

With a sudden change in the maximum load level, there will be a corresponding change in the crack driving force regardless of whether the load is applied monotonically or cyclically. The effective strain energy density factor range $\Delta S_{p,eff}$ has been used to correlate mixed mode fatigue crack propagation where the crack growth direction is not known as in a priori. Examined in this work is a sudden change of load direction on fatigue crack growth while the load level remains unchanged. Yielding is assumed to be localized near the crack tip such that the crack growth behavior can be described adequately by the elastic stress field. Under the conditions investigated, minimal change on crack growth rates is observed. No firm conclusion could be drawn on deviation of crack path for the case considered.

10A548. Review of crack propagation under unsteady loading. - HH Bryan and KK Ahuja *(Georgia Tech)*. AIAA J 31(6) 1077-1089 (Jun 1993).

This paper presents an overview of the theories and research currently available on crack propagation under unsteady loadings, especially those of acoustic origin. Although all efforts have been taken to provide a thorough review of the subject, inadvertent omissions of relevant material are unavoidable.

10A549. Stick-slip in the thin film peel test I. The 90° peel test. - K-H Tsai and K-S Kim *(Div of Eng, Brown Univ, Providence RI 02912)*. Int J Solids Struct 30(13) 1789-1806 (1993).

An analysis of the process of stick-slip in the 90° peel test is carried out using a slender elastic beam theory which considers both stretching and bending of the film. Using an energy based crack propagation criterion, it is shown that the intersection between the energy release rate curve and the interface toughness curve delineates the limit cycle on the interface toughness versus crack-growth rate plane for stick-slip 90° peeling. As a result of this analysis, it has been found that the effects of bending are significant and cannot be neglected in the general case. In addition, the stick-slip period and frequency have been found to depend on Young's modulus, and the thickness and length of the free film, and the dependence differs for the bending-dominant and stretching-dominant peel tests.

274D. DYNAMIC PROCESSES

10A550. Vibration of elastic structures with cracks. - IY Shen *(Dept of Eng Mech, Univ of Nebraska, Lincoln NE 68588-0347)*. J Appl Mech 60(2) 414-421 (Jun 1993).

An analytical algorithm is proposed to represent eigensolutions $[\lambda^2{}_m, \psi_m(r)]^\infty{}_{m=1}$ of an imperfect structure C containing cracks in terms of crack configuration σ_c and eigensolutions $[\omega^2{}_n, \phi_n(r)]^\infty{}_{n=1}$ of a perfect structure P without the cracks. To illustrate this algorithm on mechanical systems governed by the 2D Helmholtz operator, the Green's identity and Green's function of P are used to represent $\psi_m(r)$ in terms of an infinite series of $\phi_n(r)$. Substitution of the $\psi_n(r)$ representation into the Kamke quotient of C and stationarity of the quotient result in a matrix Fredholm integral equation. The eigensolutions of the Fredholm integral equation then predict $\lambda^2{}_m$ and $\psi_m(r)$ of C. Finally, eigensolutions of two rectangular elastic solids under antiplane strain vibration, one with a boundary crack and the other with an oblique internal crack, are calculated numerically.

274E. FATIGUE CHARACTERISTICS OF MATERIALS

10A551. Effect of crack deflection and branching on the R-curve behavior of an Al-Li alloy 2090 sheet. - N Eswara Prasad, SV Kamat, G Malakondaiah *(Defence Metall Res Lab, PO Kanchanbagh, Hyderabad-500 258, India)*. Int J Fracture 61(1) 55-69 (1 May 1993).

The methodology to predict the increase in crack growth resistance due to crack deflection and branching is described. These procedures are discussed with respect to an Al-Li alloy 2090 sheet in T6 condition, the R-curve tests on which revealed that the crack path in L-T orientation was deflected and branched while it remained nominally straight in T-L orientation. The resistance to slow stable crack extension in L-T orientation was found to be significantly higher as compared to that in T-L orientation. Such behavior is rationalized in terms of crack deflection and branching. The observed variation in the crack path morphology and the resulting R-curves in L-T and T-L orientations can be understood in terms of the microstructural features of the alloy.

10A552. Effect of yield strength on the basic fatigue strength of welded joints. - A Ohta, Y Maeda, N Suzuki *(Natl Res Inst for Metals, 2-3-12 Nakameguro, Meguro-ku, Tokyo 153, Japan)*. Fatigue Fracture Eng Mat Struct 16(5) 473-479 (May 1993).

The basic fatigue strength of welded joints in four steels having different yield strengths has been obtained by tests in which the maximum applied stress was held constant and equal to the yield strength, to simulate the tensile residual stress in real large-scale structures. In the long-life region superior properties occurred with a decrease in the yield strength. It is therefore suggested that both low yield strength steel, which can be produced by a thermo-mechanical control process without affecting the tensile strength, and steels or welding consumables which show a low transformation temperature, may have a high fatigue strength.

10A553. Elevated temperature fatigue crack growth in Alloy 718 Part II. Effects of environmental and material variables. - H Ghonem *(Mech of Solids Lab, Dept of Mech Eng and Appl Mech, Univ of Rhode Island, Kingston RI 02881)*, T Nicholas *(Wright Lab, Mat Directorate, WPAFB)*, A Pineau *(Centre Mat, Ecole des Mines de Paris, 9100 Evry, France)*. Fatigue Fracture Eng Mat Struct 16(6) 577-590 (Jun 1993).

Observations concerning the effects of the environments and material variables on the crack growth process in alloy 718 are reviewed and analyzed on the basis of deformation characteristics in the crack tip region. The review of the role of material variables has focused on the effects of chemical composition and microstructure parameters including precipitate size and morphology as well as grain size and morphology. These analyses have suggested that the governing mechanism at the crack tip is the degree of homogeneity of plastic deformation and associated slip density. For conditions promoting homogeneous plastic deformation, with a high degree of slip density, the environmental damage contribution is shown to be limited, thus permitting the dominance of cyclic damage effects which are characterized by a transgranular crack growth mode and a lower crack growth rate. Under conditions leading to inhomogeneous plastic deformation and lower slip density the crack tip damage is described in terms of grain boundary oxidation and related intergranular fracture mode. Considering the crack growth damage mechanism in alloy 718 ranges from fully cyclic dependent to fully environmental dependent, conflicting experimental observations under different operating conditions are examined and a sensitizing approach is suggested to increase the alloy resistance to environmental effects.

10A554. Fatigue life assessment of aluminum alloys with casting defects. - B Skallerud *(SINTEF Struct Eng, N-7034 Trondheim, Norway)*, T Iveland, G Harkegard *(Div of Appl Mech, Norwegian IT, N-7034 Trondheim, Norway)*. Eng Fracture Mech 44(6) 857-874 (Apr 1993).

The fatigue lifetimes of cylindrical aluminum specimens containing shrinkage cavities were measured. The results were compared with those of specimens without macroscopic cavities (DC cast). Two different heat treatments were considered: T4 (naturally aged) and T6 (near peak aged). The pore shape and distribution in the specimens were complex. Pores with a maximum diameter larger than 0.2 mm resulted in a significant reduction of the lifetime. Numerical calculations were carried out to predict the fatigue life, and crack growth model taking crack closure effects into account was used. This model tended to give somewhat nonconservative results when compared with test results. Modification of the model, taking a short crack effect into account, gave conservative results.

10A555. Flexural fatigue characteristics of FRP sandwich beams. - RA Shenoi, S Aksu *(Dept of Ship Sci, Univ of Southampton, Southampton SO9 5NH, UK)*, HG Allen *(Dept of Civil Eng, Univ of Southampton, Southampton SO9 5NH, UK)*. Fatigue Fracture Eng Mat Struct 16(6) 649-662 (Jun 1993).

The flexural fatigue characteristics of FRP sandwich beams are investigated. The skins of the beams are made from hybrid glass-aramid fibres set in epoxy resin and the core material is made from linear PVC foam. The beams under investigation have practical application in marine operations. The applied load is uniformly distributed throughout the length of the beam which is simply supported. From both static and fatigue tests, it is revealed that the failure occurred in the core due to excessive shear, in turn, resulting in large deflections. An empirical expression is derived to postulate a failure criterion.

10A556. Fracture and fatigue of bonded rubber blocks under compression. - AN Gent, TYP Chang *(Univ of Akron, Akron OH 44325)*, MB Leung *(Exxon Prod Res, Houston TX 77252)*. Eng Fracture Mech 44(6) 843-855 (Apr 1993).

Fracture and fatigue failure of bonded rubber cylinders are discussed. Under large compressive forces, two modes of fracture are possible: splitting open of the free surface and tearing at or near the bonded edges; tearing energy T for the latter case is estimated. Under cyclic compression, the probably fracture mode of rubber is by crack propagation, leading to the bulged volume breaking away. The corresponding tearing energy is calculated. To predict the fatigue life, the rate of crack growth dc/dn is assumed to be proportional to T^2. A life prediction equation is thus obtained, of the form: load cycle $N = (K/g)^5$, where K is a constant, about 10 for a typical soft natural rubber compound, and g is the maximum shear strain set up at the edges of the bonded surfaces.

10A557. Modeling the long-life fatigue behavior of a cast aluminum alloy. - Jason C Ting *(Walsin Lihwa, 3F-1 No 286-8 Shih-Ya Rd Chein-Chen District, Kaohsiung, Taiwan, ROC)* and FV Lawrence Jr *(Dept of Civil Eng and Mat Sci and Eng, Univ of Illinois, 205 N Mathews, Urbana IL 61801)*. Fatigue Fracture Eng Mat Struct 16(6) 631-647 (Jun 1993).

As-cast specimens and smooth specimens of a AA 319 cast aluminium alloy containing casting porosity were fatigue tested with special attention given to the long-life region ($N \leq 1.25 \times 10^8$ cycles). Fatigue cracks were observed to initiate from the near-surface casting pores or from discontinuities resulting from the as-cast surface texture. The observed fatigue lives were strongly dependent on the size ($\sqrt{\text{area}}$) of these casting defects. The effect of casting defects on the fatigue life was modeled assuming the fatigue life to be the sum of the crack nucleation and the crack propagation life (including both the growth of short and long cracks). The crack growth behavior of (mechanically) short cracks was considered in detail by a developed crack-closure-at-a-notch (CCN) model. The CCN model predicted the fatigue lives for both as-cast and machined-notched specimens. Extension of the CCN model to reliability-based design was attempted using the measured size distribution of the fatigue-initiating casting pores.

10A558. Study of the effect of defects on the fatigue behavior and the fracture toughness for low carbon steel (API 5L grade B) gas transmission pipelines. - HAEA Atwa *(Egypt Gas, Egypt)*, NM Mawsouf, MYA Younan *(Dept of Mech Design and Prod, Fac of Eng, Cairo Univ,* *Giza, Egypt)*. Eng Fracture Mech 44(6) 921-935 (Apr 1993).

The use of low carbon steel pipes in gas transmission pipelines and network gas pipes has increased. API 5L grade B (American Petroleum Inst) pipes are welded and inspected according to the BGC/PS code (British Gas Standard). Since root undercut and lack of penetration are common defects, the acceptance and nonacceptance of these defects based on the BGC/PS/P2 code of butt welded pipes are evaluated. Pipes are welded with different degrees of root undercut and lack of penetration defects and are X-rayed. The defects are categorized based on both X-ray films and final crack area. Specimens are cut and fatigue precracked at different periods depending on the initial defect size. An equivalent crack length is calculated based on Paris' law for each defect size in the fatigue crack propagation. The crack opening displacement technique, J-integral method based on Begley and Landes and the residual strength method have been used to determine the fracture toughness. The results have been compared to the parent material and the initial defect size to evaluate the restrictions of the BGC/PS/P2 code. The equivalent crack length results showed that the depth of lack of penetration welding defect should be taken into consideration for both API and BGC codes since this depth has a significant effect on the equivalent crack length. The application of the Begley and Landes approach is shown to be suitable since it permits the use of specimens of different initial crack lengths. The technique is applied here for cracks of different shapes. The results are close and can be used as comparative results between different categories and the parent material since the conditions of specimen dimensions are not valid as restricted by Begley and Landes. Critical crack opening displacement is calculated which gives reliable results for different categories. Crack opening displacement technique based on the British Standard requires different specimens with the same initial crack length, which is not satisfied. The residual strength method based on ASTM gives reliable results for the different categories of defects. The depth of lack of penetration welding defect should be taken into consideration for both API and BGC codes. The BGC code should specify an allowable depth for the root undercut welding defects.

274F. STRESS OR STRAIN LIFE ANALYSIS OF FATIGUE

10A559. Cyclic notch tip strains in very high strain amplitude fatigue. - L'ubomir Gajdos *(Inst of Theor and Appl Mech, Acad of Sci, Vysehradska 49, 128 49 Prague 2, Czech Republic)*. Acta Tech CSAV 38(2) 167-174 (1993).

Measurements of cyclic notch tip strains variations in low alloy reactor steel 15 Kh2MFA have been carried out, to compare the experimental results with theoretical predictions via i) Neuber's method, ii) Hardrath-Ohman's method, and iii) equivalent energy method. The comparison shows considerable differences between experiment and prediction in all three methods. A modification of the Neuber method is suggested, to improve the reliability of prediction.

10A560. Damage tolerance assessment of the fighter aircraft 37 Viggen main wing attachment. - B Palmberg, M-O Olsson, P-O Boman, AF Blom *(Fatigue and Fracture, Struct Dept, FFA Aeronaut Res Inst of Sweden, PO Box 110 21, S-161 11 Bromma, Sweden)*. J Aircraft 30(3) 377-381 (May-Jun 1993).

This article deals with the reassessment of the newest wing attachment frame for the fighter version of the aircraft. The purpose of this article is to briefly show the extent and complexity of the assessment. Because of the original safe life design, resulting in rather high stresses, very extensive FE analyses were necessary in order to obtain accurate stress distributions and 3D stress intensity factors in critical sections. Also, high demands have been place on the accuracy of the crack growth predictions. Hence, extensive validation of the crack growth prediction technique was required. Structural testing, including artificial flaws, was carried out with the aim of obtaining crack growth data for correlation to the prediction technique. It is concluded that the state-of-the-art methodology used was successfully verified. Furthermore, damage tolerance of the considered parts were analytically proven and experimentally verified. Finally, extension of the original design life may be possible following further considerations.

10A561. Influence of load misalignment during uniaxial low-cycle fatigue testing I. Modelling. - FA Kandil and BF Dyson *(Div of Mat Metrology, Natl Phys Lab, Teddington, Middlesex TW11 0LW, UK)*. Fatigue Fracture Eng Mat Struct 16(5) 509-527 (May 1993).

A quantitative model has been proposed which predicts the extent of lifetime scatter in low-cycle fatigue due to the influence of bending caused by load misalignment. The main components of the model are the mechanism of bending, the type of extensometer used to control strain and the fatigue characteristics of the material being assessed. Three mechanisms of bending have been studied and it is argued that the most damaging one is a consequence of a lateral offset in the centre-lines of the load-train with respect to either a machine's frame or ram. Scatter in lifetime is a maximum when strain is controlled by a single extensometer (which is generally the case) and when fatigue behavior is dictated by crack initiation at the largest surface defect. Two types of scatter have been examined, (i) repeatability scatter due to testing practice within a single laboratory, and (ii) reproducibility scatter between laboratories. An example of the magnitude of reproducibility scatter due to bending has been given by using an equation based on the universal slopes method due to Manson.

10A562. Influence of load misalignment during uniaxial low-cycle fatigue testing II. Applications. - FA Kandil and BF Dyson *(Div Mat Metrology, Natl Phys Lab, Teddington, Middlesex TW11 0LW, UK)*. Fatigue Fracture Eng Mat Struct 16(5) 529-537 (May 1993).

Models for predicting scatter bands due to bending have been applied to four alloys, namely AISI 316L, Nimonic 101, 9 Cr-1 Mo, and IN 718. The alloys were tested extensively by 26 laboratories in an international round robin exercise sponsored by the Community Bureau of Reference (BCR) of the EC. After initially selecting data for analysis on the basis of their confirmed conformance to the ASTM bending criterion, it has been shown that in all four materials a major fraction of the data scatter could be attributed to bending. Furthermore, at the lowest strain range the predicted bending component represents the highest proportion of the experimental interlaboratory scatter. Many laboratories did not report any measure of bending and so could not be used in the inital analysis. However, a further interesting deduction from the models is that the entire BCR data-set can be encompassed within a scatter band based upon a bending criterion that is twice the allowable ASTM limit. Differences in the extent of scatter between materials at a given total strain range can be attributed to the gradient of the logarithmic plot of total strain range as a function of lifetime.

10A563. Numerical and experimental verification of a new model for fatigue life. - T Svensson and M Holmgren *(Dept of Mat and Mech, Swedish Natl Testing and Res Inst, PO Box 857, 501 15 Boras, Sweden)*. Fatigue Fracture Eng Mat Struct 16(5) 481-493 (May 1993).

A new model for fatigue life prediction has been presented. The model is based on Palmgren-Miner's rule in combination with a level crossing analysis. Here an effort is made to verify the model, numerically and experimentally. Data from the literature and experimental data generated by us have been compared with fatigue life predictions made with the new model. The data have also been compared with traditional fatigue life estimations based on the rain flow count method. The fatigue lives predicted by the new model often agree better with actual lives than predictions made with the RFC-method. This is especially pronounced when the loading sequence is very irregular, ie, when the sequence contains many small cycles superimposed on large cycles. The new method is both fast and simple to use.

10A564. Possibility of estimating stress and strain at the fatigue limit of steels from the results of low cycle fatigue tests. - J Kucera *(Vysoka skola banska, fakulta strojni, trida 17, listopadu 708 33, Ostrava, Czech Republic)*. Acta Tech CSAV 38(2) 175-195 (1993).

The calculation of the fatigue limit, together with relevant threshold plastic strain, based on an extrapolation of low-cycle fatigue results is described. In the study cyclic stress-strain curve parameters, K' and n', of 222 melts and/or heat-treated modifications of 104 unalloyed and low alloyed steel grades were utilized. Results of extrapolation-fatigue limit and threshold plastic strain-were correlated with the ultimate tensile strength of these steels and are in good agreement with experimental and theoretical results published in the literature.

274G. OTHER ASPECTS OF FATIGUE

10A565. Fatigue strength evaluation from surface yielding data. - J He, H Wang, J Nan *(Xi'an Jiaotong, Xi'an, China)*. Fatigue Fracture Eng Mat Struct 16(6) 591-596 (Jun 1993).

Surface yielding was detected by X-ray diffraction. The surface yield strength σ_{sy} was significantly less than the bulk yield strength, and depends on the physical state and roughness of the surface. However σ_{sy} does not change with changes in surface residual stress. Determination of surface yielding, measured under static loading, indicates that a remarkable number of grains have been plastically deformed at the σ_{sy} stress level, which will result in damage accumulation under cyclic loading. Crack initiation predominates at the level of the fatigue endurance life for smooth parts and experiments indicate that σ_{sy} equals the smooth specimen fatigue limit, particularly that associated with a high survival probability.

10A566. Geometry factors in corrosion fatigue crack propagation. - M Jakubowski *(Ship Res Inst, Tech Univ of Gdansk, Poland)*. Fatigue Fracture Eng Mat Struct 16(5) 495-507 (May 1993).

Fatigue crack growth rates for a steel in saltwater at different but constant stress intensity factor ranges have been evaluated as a function of the crack length (as measured from the notch root) for cracks longer than so-called "short" cracks. Equations describing the crack growth rate as a function of both the crack length and the stress intensity factor range have been obtained, and the effect of simulated infinite thickness of the specimens is discussed. The equations satisfactorily describe the numerous literature data for different steels, different specimens and different test conditions.

274H. CORROSION AND EMBRITTLEMENT

10A567. Influence of microstructure and non-metallic inclusions on sulphide stress corrosion cracking in low-alloy steels. - VI

Astafjev *(Samara State Univ, 1 Pavlov St, Samara 443011, Russia)*, SV Artamoshkin, TV Tetjueva *(Res Inst Vniitneft, 110 Aurora St, Samara 443086, Russia)*. Int J Pressure Vessels Piping 55(2) 243-250 (1993).

The resistance of some low-alloy tubular steels to sulphide stress corrosion cracking (SSCC) was assessed. The influence of microstructure and non-metallic inclusions on SSCC susceptibility was investigated. Three groups of differently heat-treated low-allow steels with various microstructure and shape of non-metallic inclusions were used. Threshold values σ_{th} and K_{ISSC} were determined. To analyze specific microstructural mechanisms of damage accumulation in SSCC processes the fractographic and metallographic methods were used.

10A568. Problems related to safety and reliability of materials in environments polluted by hydrogen sulphide. - G Casarini *(Instituto Ricerche Breda, 20126 Milan, Italy)*. Int J Pressure Vessels Piping 55(2) 313-322 (1993).

The results of hydrogen-induced cracking, hydrogen stress corrosion cracking (HSCC) and HSCC tests under cathodic protection obtained on the normalized medium-high strength steels for marine applications, ASA 56, ASA F56 and ASA F60, are reported. Fatigue precracked WOL specimens were loaded at room temperature and simultaneously exposed to synthetic seawater, saturated or not by hydrogen sulphide (H_2S) and at two initial pH values (pH = 1; pH = 3). Here indications are given on the types of mechanisms controlling the damaging, the comparison of the values of the crack propagation threshold stress intensity factor in air and in corrosive media, the influence of the presence of H_2S, the role of inclusions and of their plane's orientation, the relationship between the damaging phenomena, the effect of the cathodic protection.

10A569. Summary report of an ESIS working party on fracture control guidelines for environmentally assisted cracking of low alloy steels. - G Gabetta *(CISE, Tec Innovative, CP 12081, I-20134 Milano, Italy)* and I Cole *(CSIRO, Div of Build and Construct Eng, PO Box 56, Highett Vic 3190, Australia)*. Fatigue Fracture Eng Mat Struct 16(6) 603-618 (Jun 1993).

This paper provides guidelines for obtaining and using Environmentally Assisted Cracking (EAC) test data for low alloy steels, which are used in a wide range of industrial applications. Both fracture mechanics and non-fracture mechanics tests are considered, but the emphasis is on using fracture mechanics as a part of an overall strategy - a fracture control plan - to prevent or control EAC in service. Prevention is the usual strategy, but the control of crack growth is possible for thick-walled components. Fracture control planning can, for low and medium strength steel structures, be directed to both preventing and controlling EAC in service.

274I. FRETTING, WEAR, AND EROSION

10A570. Erosion resistance of diamond coatings. - MV Kral, JL Davidson, JJ Wert *(Dept of Mat Sci and Eng, Vanderbilt Univ, Nashville TN 37235)*. Wear 166(1) 7-16 (15 Jun 1993).

Preliminary solid particle erosion testing of 10 μm thick diamond films on silicon substrates showed excellent erosion resistance. The application of diamond coatings to materials that are commonly used in erosive environments should result in significant improvement over other erosion-resistant coatings. Diamond films were applied to silicon, tungsten Ti-6Al-4V using a high-pressure microwave-assisted plasma deposition system and were determined to have a high degree of sp^3 bonding using Raman spectroscopy. Erosion tests were performed on diamond-coated silicon, tungsten and Ti-6Al-4V, as well as on uncoated substrates and alternative coatings. The erosion resistances of the target materials were compared using volume loss *versus* erodent mass plots and steady-state erosion-rate data. Diamond-coated silicon showed the highest erosion resistance. Diamond-coated Ti-6Al-4V also showed high erosion resistance when compared with uncoated materials. Erosion mechanisms were identified by examination of eroded surfaces using scanning electron microscopy. Diamond coatings on Ti-6Al-4V substrates failed by delamination of the coating from the substrate. This is believed to be a result of high residual stresses and stress concentrations at the coating-substrate interface. Diamond coatings on silicon and tungsten substrates are gradually removed by a brittle erosion process.

10A571. Hydro-abrasive erosion characteristics of 30vol%SiC_p/6061-T6 Al composite at shallow impact angles. - M Ramulu, SP Raju *(Dept of Mech Eng, Univ of Washington, FU-10, Seattle WA 98195)*, H Inoue *(Dept of Mech Eng, Univ of Osaka Prefecture, Osaka 591, Japan)*, J Zeng *(Dept of Mech Eng, Univ of Rhode Island, Kingston RI 02881)*. Wear 166(1) 55-63 (15 Jun 1993).

Hydro-abrasive erosion characteristics were investigated for 30vol%SiC_p/6061-T6 Al composite material and 6061-T6 aluminium alloy at steady-state conditions using abrasive waterjets. The erosion rates were measured for shallow impact angles (<20°) and the influence of the abrasive size, flow rate and the impact angle on the erosion process was studied. Scanning electron microscopy were used to characterize the eroded surface and the results showed that erosion in the composite occurred due to microcutting of the aluminium matrix material, with the SiC particulates being removed subsequently by the shovelling action of the oncoming jet. The experiments also revealed that the erosive wear rates for the 30vol%SiC_p6061-T6 Al composite were less than the erosive wear rates of the 6061-T6 aluminium alloy by a factor of two.

274J. CREEP

10A572. Analysis of damage in a ceramic matrix composite. - BF Sorensen *(Mat Dept, Riso Natl Lab, DK-4000 Roskilde, Denmark)* and R Talreja *(Sch of Aerospace Eng, Georgia Tech)*. Int J Damage Mech 2(3) 246-271 (Jul 1993).

Mechanisms of damage and the associated mechanical response are studied for a unidirectionally fiber-reinforced ceramic matrix composite subjected to uniaxial tensile loading parallel to fibers. A multi-stage development of damage is identified, and for each stage the governing mechanisms are discussed. For distributed matrix microcracking a continuum damage model is used as the basis for describing the associated stress-strain behavior. A simplified analysis of frictional sliding at the fiber-matrix interface is made to elucidate its effect on the stress-strain response.

10A573. Comparisons of fracture parameter evaluations for power law hardening creep. - TK Hellen *(Oakfield House, Lower Morton, Thornbury, Bristol BS12 1LD, UK)* and J Joch *(Nuclear Res Inst, 25068 Rez u Prahy, Czech Republic)*. Eng Fracture Mech 44(6) 831-841 (Apr 1993).

Convergence properties of various FE based methods for the evaluation of the crack-tip field amplitude in creep C are examined on ome representative examples. In particular, the case of non-steady-state creep, when C is contour-dependent with significant interior convergence properties, is studied. It is demonstrated that the virtual crack extension (VCE) implementation exhibits significantly better convergence properties than the conventional domain and contour integral method. The VCE method also exhibits very good convergence for J evaluation, which does not have any direct physical interpretation for dominating creep but can be useful for C estimates. The background for these estimates is summarised.

10A574. Creep damage and creep crack growth in low-alloyed heat-resisting steels. - D Regener *(Technische Univ Otto von Guericke Magdeburg, Inst fur Werkstofftech und Werkstoffprufung, O-3010 Magdeburg, PSF 4120, Germany)*. Int J Pressure Vessels Piping 55(2) 323-332 (1993).

Development of damage in components exposed to, and loaded at, high temperatures is mainly the result of creep processes as a function of time. The damage accompanying the creep crack was studied and quantified in conjunction with crack growth investigations conducted on low-alloyed heat resisting steels. The relationship between failure behavior, load, and structure is discussed.

10A575. Creep-fatigue crack growth and fractography of metallic materials in air and vacuum at elevated temperatures. - R Koterazawa *(Inst of Eng Mech, Univ of Tsukuba, Tsukuba, Japan)*. Fatigue Fracture Eng Mat Struct 16(6) 619-630 (Jun 1993).

Creep-fatigue crack growth behavior of a Type 304 stainless steel, a quenched 2-1/4Cr-1Mo steel, Hastelloy X, a Ti-6242 alloy, and a low carbon steel under different reversed loading patterns (P-P, C-P, and C-C) were investigated in air and a vacuum environment. The results are discussed in the light of fracture mechanics and fractography. Crack growth rates for all of the materials tested were successfully correlated in terms of the cyclic J integral range (ΔJ) irrespective of the loading patterns. In the low growth rate region, where fatigue fracture was predominant, crack growth rates of all the materials were about the same for the same value of ΔJ. On the other hand, growth rates were somewhat different, depending on the creep ductility of the material in the region of high growth rate, where creep fracture was predominant. Materials with lower ductility exhibited higher growth rates for the same ΔJ values. Differences were insignificant between the crack growth rates in air and vacuum and were consistent with the small differences observed in the fracture surface morphology in the two environments.

10A576. Effect of cyclic overload on the crack growth behavior during hold period at elevated temperature. - Kee Bong Yoon, A Saxena, DL McDowell *(Mech Properties Res Lab, Georgia Tech)*. Int J Fracture 59(3) 199-211 (1 Feb 1993).

Effect of tensile overload on elevated temperature crack growth behavior during the subsequent load hold period has been studied by numerical and experimental methods. FE analysis of compact specimens shows that when the tensile overload precedes the load hold period, C_t during the hold period is significantly smaller (ie, retarded) compared to the case without the overload. This is due to crack tip stress relaxation associated with large crack tip plasticity generated by the overload. A modified C_t estimation scheme is proposed by introducing a new equation for t_{pl}. Using this scheme, the retardation behavior of C_t due to the overload is successfully modeled. Creep-fatigue crack growth data for an ex-service 1.25Cr-0.5Mo steel at 538°C (1000°F) were generated in air. The hold times are 10 seconds, 98 seconds and 10 minutes. Time-dependent crack growth rate during the load hold period $(da/dt)_{avg}$ is correlated with $(C_t)_{avg}$ estimated by the new estimation scheme. $(da/dt)_{avg}$ data from all the tests with overload are higher than those from the tests without overload. The peak stress associated with the overload seems to have enhanced void nucleation and to increase the time-dependent crack growth rate due to creep. This argument is supported by microscopic observations.

10A577. Methodology for modeling tertiary creep behavior of engineering alloys under oxidizing conditions. - S Osgerby and BF Dyson *(Div of Mat Metrology, Natl Phys Lab, Teddington, Middlesex TW11 0LW, UK)*. Int J Pressure Vessels Piping 55(2) 333-341 (1993).

Several mechanisms of creep-oxidation interaction have been discussed and placed within the framework of a creep-corrosion interaction diagram by modeling the individual mechanisms, using continuum creep damage mechanics. Although validation of the models is difficult because experimental data are rare, some agreement with model predictions has been achieved where appropriate data are available.

10A578. Power law creep of a composite material containing discontinuous rigid aligned fibers. - RM McMeeking *(Dept of Mat and Dept of Mech Eng, UC, Santa Barbara CA 93106)*. Int J Solids Struct 30(13) 1807-1823 (1993).

An asymptotic analysis is presented for the power law creep of a matrix containing discontinuous rigid aligned fibers. The fibers analyzed have a high aspect ratio. As a result, the fiber length is much greater than both the fiber diameter and the spacing between neighboring fibers. For this situation, flow around the fiber ends can be neglected when the creep strength is being calculated. When the matrix is not slipping on the fiber surface or is nearly stuck, shearing flow dominates the behavior. The radial gradient of shear stress is balanced by the axial gradient of hydrostatic stress. Longitudinal, radial and circumferential deviatoric stresses are negligible. The resulting power law creep rate of the composite material is inversely proportional to the fiber aspect ratio raised to the power $1 + 1/n$ where n is the creep index. The fiber volume fraction also influences the creep rate. When the matrix slips freely on the fiber surface, or nearly so, stretching dominates the matrix flow. In this situation, the composite creep strength is not much better than the unreinforced matrix.

274K. ABLATION, SPALLATION, DELAMINATION

10A579. Analysis of inelasticity effect due to damage on stress distributions in composite laminates. - CL Chow *(Dept of Mech Eng, Univ of Michigan, Dearborn MI 48128-1491)*, F Yang, A Asundi *(Dept of Mech Eng, Univ of Hong Kong, Hong Kong)*. J Reinforced Plastics Composites 12(8) 888-915 (Aug 1993).

A damage mechanics model characterizing damage behavior of composite materials proposed earlier by the authors is employed to analyze the damage effects on stress field near the free edge in symmetrically laminated graphite-epoxy composites of finite dimensions under uniaxial tension. A quasi 3D FE analysis is developed for the present investigation. The results from the damaged and undamaged stress distributions of $[0/90°]_s$, $[90/0°]_s$ and $[\pm 45°]_s$ laminates are compared and examined. The processes of initiation and development of damage zone in these composite laminates are also discussed.

10A580. Energy balance and the speed of crack growth in a compressed plate with delamination. - W-L Yin *(Sch of Civil Eng, Georgia Tech)*. Int J Solids Struct 30(15) 2041-2055 (1993).

The evolution of the crack growth speed in a buckled 1D delamination model is studied and two approximate solutions are presented. In the quasi-dynamic analysis one assumes that the time-dependent deflection of the delaminated layer may be approximated by the static post-buckling solution for the current delamination length. In a refined analysis one introduces an indeterminate amplitude function. The local growth condition at the crack tip is not enforced but a global energy-balance condition is used. The crack growth speeds are found to be comparable to the speeds of flexural waves. For slow and moderate rates of crack growth, the present results are in close agreement with the finite-difference solutions of the dynamic problem.

274M. MICROMECHANISMS

10A581. Influence of microstructure on micromechanisms of failure in HSLA steels. - L Parilak and J Dojcak *(Inst of Mat Res, Slovak Acad of Sci, Watsonova 47, 043 53 Kosice, Slovak Republic)*. Int J Pressure Vessels Piping 55(2) 353-360 (1993).

In the present work the strength properties and fracture resistance of weldable high-strength steels are described. After the fracture toughness testing in the temperature range from -196°C to +20°C the basic stretch and process zone parameters were determined with the aid of microfractographic methods. The microstructural and temperature factors of forming of stretch and process zone were described in the above mentioned steels. Original transition temperatures T_{xo} and T{xoD} were defined.

10A582. Micromechanics approach for constucting locally averaged damage dependent constitutive equations in inelastic composites. - JG Boyd, F Costanzo, DH Allen *(Center for Mech of Composites, Texas A&M Univ, College Station TX 77843-3141)*. Int J Damage Mech 2(3) 209-228 (Jul 1993).

Homogenization techniques are utilized herein to construct locally averaged mechanical constitutive equations for composites. Techniques are first reviewed for elastic composites, followed by a review of elastic composites with cracks and inelastic composites without cracks. These reviews are followed by a development of homogenized equations for inelastic composites with cracks. All equations are constructed for the case wherein a representative volume element is subjected to spatially uniform boundary strains. Several examples are presented for a representative SiC/Ti continuous fiber composite subjected to tensile deformations transverse to the fiber direction. It is demonstrated that as the damage and matrix material model are increased in complexity, the computational requirements needed to obtain homogenized properties increase to the point where homogenization techniques may not be computationally tenable when applied recursively in macroscale structural analysis.

10A583. Numerical simulation with experimental verification of the fracture behavior in granite under confining pressures based on the tension-softening model. - T Hashida, H Oghikubo, H Takahashi, T Shoji *(Res Inst for Fracture Tech, Fac of Eng, Tohoku Univ, Sendai 980, Japan)*. Int J Fracture 59(3) 227-244 (1 Feb 1993).

The use of the tension-softening model for analyzing fracture processes of rock is examined with special reference to the effect of confining pressure on the fracture extension. Tension-softening curves are measured by means of the J-based technique from unconfined tests performed on compact tension (CT) specimens of granite. On the basis of the determined tension-softening relation, numerical analyses are executed using a BEM to simulate fracture of the granite under confining pressures. Numerical results are compared to the experimental results of two series of tests for which CT specimens and thick-walled cylindrical specimens were loaded to failure under confining pressures ranging from 0 to 26.5 MPa. It is shown that the BEM analyses can predict the observed fracture behavior. Based on the results, it is demonstrated that the tension-softening relation provides a suitable model to analyze the fracture process in the rock. The source mechanism for the pressure sensitive fracture is discussed by examining the growth of the fracture process zone.

10A584. Thermal and mechanical load induced damage behavior of a low allow steel: Mechanisms and modeling. - Tie-Jun Wang *(Dept of Eng Mech, Xi'an Jiaotong Univ, Xi'an 710049, Shaanxi, Peoples Rep of China)*. Eng Fracture Mech 44(6) 971-980 (Apr 1993).

A series of experiments, including macroscopic damage measurement and *in situ* microscopic observation at room temperature and tensile tests at eight different temperatures ranging from 20 to 900°C, is carried out. Mechanical load induced ductile damage evolution law and micromechanisms are presented, where damage evolution law is measured through a new ac potential system and the micromechanisms of damage and fracture are observed through an *in situ* technique in conjunction with a scanning electron microscope (SEM) equipped with a tensile platform. A continuum damage mechanics (CDM) model for ductile fracture proposed by Wang is employed to model and to analyse the evolution law of damage in the steel. Comparison of experimental and modelling results is presented and good agreement is found. The effect of stress triaxiality on damage evolution is also discussed in the framework of CDM. The effect of temperature rise on tensile properties including Young's modulus, yield and ultimate tensile strength and ductility (elongation and reduction in area), is also reported.

274X. STOCHASTIC ASPECTS

10A585. Probabilistic fracture mechanics analysis based on 3D J-integral database. - G-W Ye, G Yagawa, S Yoshimura *(Dept of Nucl Eng, Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Japan)*. Eng Fracture Mech 44(6) 887-893 (Apr 1993).

The development is described of a novel Probabilistic Fracture Mechanics (PFM) code based on the 3D J-integral database, giving so-called fully plastic solutions. An efficient technique for the evaluation of leak and break probabilities is also utilized, based on the Stratified sampling Monte Carlo simulation (SMC). The outline of the present PFM code is described, and the J-integral database and the numerical technique are presented. Nonlinear effects of materials on failure probabilities are discussed through the analysis of a surface cracked structure subjected to cyclic tension.

10A586. Determination of stress intensity factors and J-integrals using the method of caustics. - Ouk Sub Lee and Seong Kyeong Hong *(Dept of Mech Eng, Inha Univ, 253 Yong-Hyun Dong, Nam-Ku, Inchon 402-751, Korea).* Eng Fracture Mech 44(6) 981-989 (Apr 1993).

Applications of the optical shadow method of reflective caustics to the measurement of the stress intensity factor and J-integral in various specimens are investigated. The necessary experimental requirements to help in determining an accurate stress intensity factor and J-integral are described. The ratios of r_0 (radius of initial curve)/r_p (plastic zone size) and r_0/t (thickness of specimen) are found to be very important experimental parameters with which to obtain meaningful stress and/or strain intensities surrounding crack tips. The appropriate ranges to determine accurate values of stress intensity factor and J-integral for polycarbonate (compact tension) and aluminum (c-shaped tension) specimens are presented.

10A587. Load separation and η_{pl} development in precracked specimen test records. - MH Sharobeam *(Stockton State Col, Pomona NJ 08240-9988)* and JD Landes *(Univ of Tennessee, Knoxville TN 37996-2030).* Int J Fracture 59(3) 213-226 (1 Feb 1993).

Load separation is the theoretical basis for the single specimen J form and the incremental calculation of J-R and J_M-R curves. It is based on the assumption that the load can be represented as a multiplication of two separate functions; a crack geometry function and a material deformation function. Until recently, the main experimental basis for such an assumption was the approximate agreement between the experimental results of the single specimen J form and the energy rate interpretation of J in blunt notched bending geometries. The load separation assumption has been also implied in the growing crack records in order to develop the R-curve analysis. Both the crack geometry and material deformation functions were assumed to maintain their forms as the crack grows. Recently, an experimental study investigated the load separation in the test records of stationary crack specimens of different geometry, material, and constraint. The study showed that the load can be represented by a separable form for the entire plastic region except for a limited region at the early region of plastic behavior. Also, it was found that the load separation is not limited to a certain geometry, material, or constraint, but it is a dominant property in the ductile fracture behavior of stationary crack specimens. The study also showed that the crack geometry function is a power law function. Hence η_{pl} is a constant equal to the power law exponent of the geometry function. The objective of this study is to investigate the extension of load separation to growing crack records. Sets of test records from three different materials are used in this study. For each material three or four precracked specimen test records and one blunt notched record are analyzed for the compact specimen geometry. The study will discuss the main condition to have a separable behavior in a growing crack test record. It will also construct the geometry and deformation functions for the materials studied, these functions are compared with those obtained from stationary crack records.

276A. GENERAL THEORY

10A588. Locating a crack of arbitrary but known shape by the method of path-independent integrals. - NI Ioakimidis *(Div of Appl Math and Mech, Sch of Eng, Univ of Patras, PO Box 1120, GR-261 10 Patras, Greece).* Int J Solids Struct 30(14) 1939-1956 (1993).

The solution of a crack problem of an arbitrary, but known, shape inside an infinite plane isotropic elastic medium can be achieved in general by the method of complex singular integral equations and their numerical solution by using the Gauss- or the Lobatto-Chebyshev methods. In a few special cases, like straight or circular-arc-shaped cracks, this solution is available in closed form. In this paper we will not contribute to the above methods of solution of crack problems, but we will propose a method for the determination of the exact position of such a crack inside a closed contour in the elastic medium by gathering and using information along this contour only (by experimental techniques) and applying the method of complex path-independent integrals for the location of the crack. This paper constitutes a nontrivial generalization of relevant previous results by the author and it is of quite general applicability in fracture mechanics for nondestructive testing. Numerical results for the particular case of a straight crack are displayed for the illustration of the efficiency of the method. The generalization of the present results to the determination of additional geometric and loading parameters of the crack is also suggested very briefly and related numerical results, concerning the length of the crack and the pressure distribution on it, in the aforementioned numerical application are also presented.

10A589. $r^{-1/2}$ (ln r) singularities at interface cracks in monoclinic and isotropic bimaterials due to heat flow. - G Yan and TCT Ting *(Dept of Civil Eng Mech and Metall, Univ of Illinois, Chicago IL 60680).* J Appl Mech 60(2) 432-437 (Jun 1993).

It is known that the stress singularities at an interface crack tip of bimaterials with the effects of heat flow may have the form $r^{-1/2}$(ln r). The existence conditions of the higher order singularity $r^{-1/2}$(ln r) are studied for monoclinic bimaterials whose plane of symmetry is at $x_3 = 0$. It is shown that the higher order singularity does not exist if the bimaterial is mismatched. If the bimaterial is non-mismatched, the higher order singularity does not exist when a certain condition is satisfied. This condition is given explicitly for monoclinic bimaterials with the plane of symmetry of $x_3 = 0$ and in a simple form for isotropic bimaterials.

10A590. Universal physically consistent definition of material damage. - CW Woo and DL Li *(Dept of Mech Eng, Univ of Hong Kong, Pokfulam Rd, Hong Kong).* Int J Solids Struct 30(15) 2097-2108 (1993).

This paper proposes a physically consistent definition of material damage. The definition is based on the physical concepts of inter-atomic energy and the breaking and re-establishing of the atomic bonds. The states of material damage are physically determined in a broad sense by the configuration of the atomic bonds. The meso characteristics, such as vacancies, dislocations, pores, slips, microcavities, microcracks and so on, could be quantified through the use of subsystems each corresponding to a special configuration. The constitutive equations, referring to the material damage represented by the definition, could be developed by following both nonlocal and local theories.

10A591. Analogies between crack tip and rigid line tip stresses and displacements. - D Radaj and S Zhang *(Diamler-Benz AG, D-7000 Stuttgart 80, Germany).* Eng Fracture Mech 44(6) 913-919 (Apr 1993).

The analogies between crack tip and rigid line tip stresses and displacements are stated in respect of loading modes with singular stresses, loading modes with non-singular stresses, distribution of singular stresses, ligament related limit value formulae for stress intensity factors, notch stress related limit value formulae for stress intensity factors and elementary explicit formulae for stress intensity factors.

10A592. Axisymmetric crack problem in a nonhomogeneous medium. - M Ozturk and F Erdogan *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015).* J Appl Mech 60(2) 406-413 (Jun 1993).

In this paper, the axisymmetric crack problem for a nonhomogeneous medium is considered. It is assumed that the shear modulus is a function of z approximated by $\mu = \mu_0 e^{\alpha z}$. This is a simple simulation of materials and interfacial zones with intentionally or naturally graded properties. The problem is a mixed-mode problem and is formulated in terms of a pair of singular integral equations. With fracture mechanics applications in mind, the main results given are the stress intensity factors as a function of the nonhomogeneity parameter α for various loading conditions. Also given are some sample results showing the crack opening displacements.

10A593. Interaction of penny-shaped cracks with a half-plane crack. - X Huang *(Sch of Civil and Mining Eng, Univ of Sydney, NSW 2006, Australia)* and BL Karihaloo *(Inst of Mech, Aalborg Univ, Pontoppidanstraede 101, DK 9220 Aalborg E, Denmark).* Int J Solids Struct 30(15) 2117-2139 (1993).

Three-dimensional interactions between a half-plane crack and penny-shaped cracks which are not necessarily located in the same plane are analyzed using the "weight function" method of 3D crack analysis. Analytical expressions are given for the interaction kernels in the integral equations with the opening displacements of penny-shaped cracks as unknown functions. By using the Rayleigh-Ritz method the singularities of the kernels are weakened to make them suitable for FE calculations. The weak form equations are solved by a simple method after approximating the opening displacement over each crack by a constant times a square root function of the distance from its edge. This simple method of solution is shown to give results which are in excellent agreement with those of Laures and Kachanov (1991).

10A594. Interfacial fracture mechanics for anisotropic bimaterials. - J Qu *(Sch of Mech Eng, Georgia Tech)* and JL Bassani *(Dept of Mech Eng and Appl Mech, Univ of Pennsylvania, Philadelphia PA 19104-6315).* J Appl Mech 60(2) 422-431 (Jun 1993).

This paper focuses on aspects of fracture mechanics of interface cracks in anisotropic bimaterials. In this case there is a coupling of all three crack-tip fracture modes in the natural interface-crack coordinate system, whereas in the isotropic case, mode 3 is decoupled from modes 1 and 2.

This paper intends to shed light on how to interpret the crack-tip fields which are given explicitly along the interface in terms of two (real 3 × 3) bimaterial matrices W and D. A matric function Y is defined in terms of W and D which determines the coupling and oscillations in the crack-tip fields. Explicit expressions for the crack-tip fields and the associated stress intensity factors are given as well as for the energy release rate. The finite (Griffith) interface crack is considered in detail.

10A595. Perturbation eigensolutions of elastic structures with cracks. - IY Shen *(Dept of Eng Mech, Univ of Nebraska, Lincoln NE 68588-0347)*. J Appl Mech 60(2) 438-442 (Jun 1993).

The purpose of this paper is to determine approximate eigensolutions of a class of cracked mechanical systems governed by the 2D Helmholtz equation through a perturbation approach. Shen (1993) shows that exact eigenvalues λ^2_m and their corresponding crack-opening shapes $\Delta\Psi_m$ of such mechanical systems satisfy a Fredholm integral equation $A(\lambda^2_m)\Delta\Psi_m = 0$. Following the integral equation approach, the approximation in this paper consists of formulating the Rayleigh quotient of the Fredholm operator A (λ^2) and estimating eigenvalues $\mu(\lambda^2)$ of the operator A (λ^2) through perturbation and stationarity of the Rayleigh quotient. The zeros of $\mu(\lambda^2)$ then approximate eigenvalues λ^2_m of the cracked systems. Finally, approximate λ^2_m are calculated for 2D elastic solids under antiplane-strain vibration with an oblique internal crack and a boundary crack.

10A596. Relation between the magnitudes of J_D and J_M for test specimen geometrical configurations. - E Smith *(UMIST Mat Sci Centre, Manchester Univ, Grosvenor St, Manchester M1 7HS, UK)*. Int J Eng Sci 31(9) 1259-1268 (Sep 1993).

The paper investigates the difference between the magnitudes of the modified J and integral J_M and the deformation J integral J_D, with consideration being focused on those test configurations where the remaining ligament width is small. The results provide underpinning for the view that with a bend configuration, the J_M resistance curve lies above the J_D resistance curve, whereas the reverse is true with a tensile loading configuration. With a material having a high crack growth resistance, and provided yield is contained, the J_D and J_M resistance behaviors are essentially the same, for both bend and tensile loading. However, when the deformation is extensive, there can be a significant difference between the J_D and J_M resistance behaviors, this difference being greater with the bend configuration than with the tensile configuration.

10A597. Shape of surface cracks in fatigue. - JC Radon *(Dept of Mech Eng, Imperial Col, Exhibition Rd, London SW7 2BX, UK)*. Int J Pressure Vessels Piping 55(2) 275-285 (1993).

The shape development of surface cracks under pure bending fatigue is basically independent of the load type. Crack shape variations are initially influenced by the geometry of the starter notch, but specimen dimensions predominate in later stages of fatigue life. Also, residual stresses may significantly affect the initial crack geometry variations; however, their influence diminishes as the crack growth progresses. This paper describes the shape changes observed under constant amplitude fatigue in bending. Slight differences noted in the random loading fatigue will not be considered here and are the subject of a separate study.

10A598. Solids with periodically distributed cracks. - S Nemat-Nasser *(Center for Excellence for Adv Mat, Dept of Appl Mech and Eng Sci 0411, UCSD)*, N Yu *(Dept of Eng Sci and Mech, Univ of Tennessee, Knoxville TN 37996)*, M Hori *(Dept of Civil Eng, Univ of Tokyo, Bunkyo-ku, Tokyo 113, Japan)*. Int J Solids Struct 30(15) 2071-2095 (1993).

A systematic method is presented for estimating the overall properties of solids with periodically distributed cracks. In view of the periodicity, the displacement, strain, and stress fields of the cracked solid can be expressed in Fourier series. Elastic solids with periodically distributed flat voids are considered first. The results for cracks are then obtained by letting the thickness aspect ratio of the void approach zero. This limiting process is performed with care. The only approximation involved is the distribution of the homogenization eigenstrains, which is assumed to be piecewise constant. The estimate of overall elastic moduli, crack opening displacements and stress intensity factors eventually reduces to the calculation of several infinite series. The formulation is valid for elliptic as well as 2D line (slit-like) cracks, and cracks with arbitrary shapes. It fully includes the interaction effects.

10A600. Part-circular surface cracks in round bars under tension, bending and twisting. - A Levan and J Royer *(Lab Mec Struct, Ecole Centrale Nantes, 1 rue de la Noe, Nantes 44072 Cedex 03, France)*. Int J Fracture 61(1) 71-99 (1 May 1993).

Circular-formed cracks in round bars subject to tension, bending and twisting are considered. Numerical expressions are given allowing the calculation of stress intensity factors K_I, K_{II}, K_{III} at every point on the crack front for a wide range of crack geometries. Comparisons are made with analytical, experimental and numerical results available in the literature. Crack shapes satisfying the iso-K_I criterion are also determined, making it possible to investigate the problem of crack growth behavior under tensile or bending fatigue loads.

276E. VISCOELASTIC PROBLEMS

10A601. Self-similar and transient void growth in viscoelastic media at low concentration. - YM Wang and GJ Weng *(Dept of Mech and Aerospace Eng, Rutgers Univ, New Brunswick NJ 08903)*. Int J Fracture 61(1) 1-16 (1 May 1993).

An incremental scheme governing the self-similar and the transient void growth of aligned spheroidal voids is developed for a class of linear viscoelastic materials at low concentration and moderate strain. The theory is based upon Eshelby-Mori-Tanaka's concept in elasticity, but extended to the viscoelastic media by the Laplace transform and developed in a way suitable for the calculation of void growth. The condition of self-similar void growth is established, and it is found that the result of Budiansky, Hutchinson and Slutsky originally derived for the growth of a single void in an incompressible Maxwell solid with no elastic response continues to hold here. This incremental scheme further allows one to calculate the evolution of semi-axes of the voids, and of the void shape and concentration. It also permits one to predict the asymptotic shape of the voids towards which the voids will evolve under a given combination of axisymmetric loadings. Specific results are displayed for the transient void growth of initially spherical voids, and for the self-similar void growth of several selected oblate and prolate shapes at an initial concentration of $c_1 = 5\%$.

276F. CRACK TIP PLASTICITY PROBLEMS

10A602. Cohesive zone modeling of damage at the tip of cracks in slender beam structures. - S Ostlund and F Nilsson *(Dept of Solid Mech, RIT, 100 44 Stockholm, Sweden)*. Fatigue Fracture Eng Mat Struct 16(6) 663-676 (Jun 1993).

The use of simple beam theory for cohesive zone modelling of the damage response at the crack tip in linear elastic isotropic double cantilever beam (DCB) specimens has been investigated. Damage resistance curves (DR-curves) relating the applied stress intensity factor to the growth of the cohesive zones for beam theory modelling has been compared with 2D elasticity calculations for different material parameters and specimen dimensions. A substantial difference is observed between DR-curves for the two types of models. As expected this difference vanishes for decreasing beam heights. For large beam heights the DR-curves calculated by 2D elasticity are approaching small-scale yielding DR-curves, ie, DR-curves for an edge crack in an infinite plate. The beam height for which beam theory is applicable could be up to 10^{-3} times the height for which small scale bridging DR-curves are applicable.

10A603. Comparison of the J_D and J_M crack growth resistance curves for small-scale yielding conditions and the relevance to the integrity assessment of a cracked engineering structure. - E Smith *(UMIST Mat Sci Centre, Manchester Univ, Grosvenor St, Manchester M1 7HS, UK)*. Int J Eng Sci 31(9) 1269-1278 (Sep 1993).

A theoretical analysis, for small-scale yielding conditions, suggests that for ductile materials used in engineering structures, the deformation J integral (J_D) material crack growth resistance curve for a cracked engineering structure is essentially the same as the modified J integral (J_M) resistance curve. This means that provided small-scale yielding conditions are operative and provided J_M is preferred to J_D as a crack growth characterizing parameter, then assessment of the integrity of a cracked engineering structure can be performed by matching the J_D crack driving force curve for the structure with the material's J_M crack growth resistance curve, as obtained from a small specimen where the crack tip region is subjected to high constraint, eg, a compact tension specimen. This gives more realistic predictions than if the corresponding small specimen J_D material resistance curve is used.

10A604. Domain integrals for axisymmetric interface crack problems. - R Nahta and B Moran *(Dept of Civil Eng, NWU)*. Int J Solids Struct 30(15) 2027-2040 (1993).

New domain integrals for axisymmetric interface crack problems are derived. Special attention is given to the specification and subsequent treatment of auxiliary fields for the extraction of mixed-mode stress intensity factors using interaction energy integrals. The effect of crack front curvature is shown to play an important role in the derivation of the integrals. Numerical examples include an interphase penny-shaped crack and a longitudinal interface crack (fiber pull-out problem), and yield very accurate and consistent results, when compared with analytical solutions from the literature. The method is particularly suited for the analysis of fiber pull-out experiments and the accurate determination of fracture-parameters such as energy release rate G, mixed-mode stress-intensity factors K_I and K_{II} and phase angle ψ.

10A605. FE solutions of crack growth in incompressible elastic-plastic solids with various yielding extents and loadings: Detailed comparisons with analytical solutions. - N Liu and WJ Drugan *(Dept of Eng Mech, Univ of Wisconsin, Madison WI 53706)*. Int J Fracture 59(3) 265-289 (1 Feb 1993).

We have conducted numerical FE studies of plane strain quasistatic crack growth in elastic-plastic material for a wide range of applied loading conditions and yielding extents, especially general yielding. To facilitate precise comparisons with previous *analytical* results, we have employed a fully incompressible, nonhardening material model. A reduced-selected integration procedure is successfully used to enforce material incompressibility. For crack growth under bending-dominant conditions, we employ an experimentally-measured applied load versus crack length history for a compact tension specimen that experiences crack growth from small-scale yielding through general yielding conditions. A constant crack tip opening angle crack growth criterion is employed to investigate crack growth under tension-dormant loadings in the same geometry. We have also conducted a small-scale yielding crack growth simulation employing a highly refined mesh, and several additional general yielding stationary crack solutions to further explore the effects of different far-field loading combinations. Detailed comparisons of the FE results with Drugan and Chen's 'm-family' of asumptotic analytical solutions are made in an effort to assess the latter's accuracy and range of applicability, and to identify their asumptotically indeterminate parameters m and R as functions of crack growth history. Among several interesting results, we find that Drugan and Chen's near-tip characterizing parameter has a nearly constant value of m ≈ 1.23 for the entire crack growth process from small-scale yielding through general yielding conditions under *bending-dominant* loading when specimens have traction-free sides. However, we find m to vary significantly from that value as general yielding conditions are approached in *tension-dominant* loading situations, and whenever specimen sides are subjected to uniform applied loading. The numerical solutions confirm that Chen and Drugan's global approximate analytical solutions for general yielding crack growth are remarkably accurate to substantial distances from the crack tip under a wide variety of loading conditions. The fully incompressible material model employed also facilitates great physical insight into the global stress and deformation fields accompanying general yielding crack growth: numerous figures display the slip lines (which are characteristics for both the stress and velocity fields) throughout the plastically deforming regions.

10A606. Fractal characteristics of J-R resistance curves of Ti-6Al-4V alloys. - Bo Gong and Zu Han Lai *(State Key Lab for Fatigue and Fracture of Mats, Inst Metal Res, Acad Sinica PRC, Dept of Phys, Northeast Univ of Tech, Shenyang 110006, Peoples Rep of China)*. Eng Fracture Mech 44(6) 991-995 (Apr 1993).

J-R resistance curves of slow crack growth in Ti-6Al-4V alloys can be expressed in terms of fractal dimensions. The lineal fractal dimension D_f of crack growth profile obtained by the J-R technique correlates well with SEM observation of the crack surface.

10A607. J-R curve dependence on specimen geometry and microstructure in two austenitic: Ferritic stainless steels. - R Roberti, W Nicodemi *(Dept of Mec, Politec di Milano, 20123 Milano, Italy)*, GM La Vecchia *(Dept of Mec, Univ di Brescia, 25060 Brescia, Italy)*, S Basha *(Lab i Studimit te Materialeve, ISP6, Tirana, Albania)*. Int J Pressure Vessels Piping 55(2) 343-352 (1993).

The geometry dependence of J-R curves is a still-debated matter as it is of relevance for their transferability from laboratory test pieces to structural components. In the present research work J-R curves have been obtained for SENT and SENB specimens machined in the longitudinal and transverse direction from two duplex stainless-steel plates. The role of crack tip constraint, contained or uncontained yield, and microstructural directionality, has been considered to explain the observed geometry dependence of the J-R curves.

10A608. Quasi-static extension of cohesive crack described by the energy partition technique. - B Amini and MP Wnuk *(Univ of Wisconsin, PO Box 784, Milwaukee WI 53201)*. Int J Fracture 59(3) 245-264 (1 Feb 1993).

Nonlinear differential equation governing mode I fracture under small scale yielding condition has been derived on the basis of the energy partition concept. This technique is associated with a cohesive crack model. The nonlinear zone which precedes a propagating crack has been assumed to have a structured nature. In addition to this microstructural assumption, it has been postulated that the energy dissipated within the process zone (Δ), embedded in a larger nonlinear zone (R), remains invariant to the extent of crack growth. Upper and lower bounds of the tearing modulus have been related to the material ductility via closed form expressions. It has been demonstrated that the energy screening, measured by the ratio of the true fracture energy (W) to the total work expended in the cohesive zone during the process of irreversible deformation, is a monotonic function of the crack growth increment, resembling a reciprocal of the apparent material resistance to cracking described by an R-curve.

10A609. Stress structure and deformation behavior of mode I 3D crack in elastic-plastic state. - XM Chen and HG Hahn *(Lehrstuhl for Tech Mech, Univ Kaiserslautern, Postfach 3049, Geb 44, 6750 Kaiserslautern, Germany)*. Eng Fracture Mech 44(6) 895-912 (Apr 1993).

The effects of load and geometry on the stress structure of a Mode I 3D crack are investigated by means of FEM. The functions of plastic deformation and stress triaxiality constraint, during the failure process, are then analyzed. It is found that three regions, namely the plane strain similar zone ZI, the plane stress similar zone ZIII and the transition layer between them ZII, exist in front of the crack tip; 3D deformation behavior is different from that in 2D states even in the ZI and ZIII zones. It is also revealed that the failure form and position of a Mode I 3D crack will be determined by both plastic strain and stress triaxiality.

10A610. A 3D analysis of symmetric composite laminates with damage. - CL Chow *(Dept of Mech Eng, Univ of Michigan, Dearborn MI 48128-1491)*, F Yang, A Asundi *(Dept of Mech Eng, Univ of Hong Kong, Hong Kong)*. Int J Damage Mech 2(3) 229-245 (Jul 1993).

Damage behavior of a symmetric composite laminate without an initial imperfection or macro-crack is analyzed based on a 3D lamination theory under multi-axial loading. The global response of the laminate during the damaging process is determined from the individual response of its constituent plies and their mutual relations. Some specific results are presented to illustrate the damage characteristics of several typical composite laminates when they are subjected to proportional loading. The application of the method to characterize damage initiation and growth in more complex structures is also discussed.

10A611. Analysis of composite shear walls with interface separation, friction and slip using BEM. - JT Katsikadelis and FT Kokkinos *(Dept of Civil Eng, Natl Tech Univ, Inst of Struct Anal Zografou Campus, GR 157 73 Athens, Greece)*. Int J Solids Struct 30(13) 1825-1848 (1993).

In the present investigation a simple, efficient, versatile, and easily adaptable, iterative BE technique is presented for solving frictional contact problems with tensionless bonding arising in the analysis of composite shear walls and infilled frames. The method is developed using the total deformation formulation and is based on logical steps to establish the contact geometry and regions of slip, interface separation and adhesion. Numerical results are presented to illustrate the method and demonstrate its effectiveness.

10A612. Annular crack surrounding an elastic fibre in transversely isotropic elasticity. - HS Saxena and RS Dhaliwal *(Dept of Math and Stat, Univ of Calgary, Calgary AB, T2N 1N4, Canada)*. Eng Fracture Mech 44(6) 963-969 (Apr 1993).

The axisymmetric problem of an infinitely long transversely isotropic elastic fibre perfectly bonded to a dissimilar transversely isotropic elastic matrix containing an annular crack is considered. The annular crack, surrounding the fibre, is subjected to prescribed longitudinal tension. A potential function approach is used to find the solution of the basic equations. The mixed boundary value problem is reduced to the solution of a singular integral equation, which is further reduced, by using Chebyshev polynomials, to a system of algebraic equations.

10A613. Bulging of cracked panel in extension due to unbalanced patching. - RC Chu *(Aviation and Space Indust Dev Admin, 333 Keelung Rd, Section 1, Taipei, Taiwan, ROC)* and YS Lin *(Inst of Appl Math, Natl Chung-Hsing Univ, Taichung, Taiwan, ROC)*. Theor Appl Fracture Mech 19(1) 13-27 (Jun 1993).

When a cracked panel is patched only on one side, there is a tendency for the reinforced panel to bulge even if the load is applied in the plane. The Mindlin plate theory is applied to examine such an effect. Considered are variations of transverse shear across the adhesive and transverse normal stresses through the sheet and patch. The formulation makes use of the variational principle for determining the constitutive relations. FE is employed to discretize the system of equations and to solve for the displacements of cracked panels with unbalanced patching. Stress intensity factor solutions and stresses are obtained and compared well with available numerical results and experimental data.

10A614. Damage evolution and thermoelastic properties of composite laminates. - Weilin Zang *(Swedish Inst of Composites, Box 271, S-941 26 Pitea, Sweden)* and P Gudmundson *(Dept of Solid Mech, RIT, S-100 44 Stockholm, Sweden)*. Int J Damage Mech 2(3) 290-308 (Jul 1993).

An analytic model for the prediction of the thermoelastic properties of micro cracked composite laminates is presented. The expression for the calculations of energy release rates due to growth of micro cracks is also provided. Numerical results are presented that show that the present method, to a very good accuracy, can predict thermoelastic properties of micro cracked laminates at varying crack densities and layup configurations. In addition, a resistance curve behavior of the energy release rate is observed for both carbon-epoxy and glass-epoxy composite laminates. The reasons for this R-curve behavior are discussed. Criterion that govern the initiation and growth or micro cracks in composite laminates are discussed and compared to experimental data.

10A615. Effect of molding parameters on the interfacial strength in PEEK-carbon composites. - T Vu-Khanh and J Denault *(Indust Mat Inst, NRC, 75 De Mortagne Boucherville, PQ, J4B 6Y4, Canada).* J Reinforced Plastics Composites 12(8) 916-931 (Aug 1993).

The objective of this work was to investigate the effects of molding conditions (molding temperature, residence time at melt temperature and cooling rate) on the interfacial performance in PEEK-carbon composites made from both prepreg and commingled forms. The results show that a minimum molding temperature and residence time are essential requirements to produce efficient fiber-matrix adhesion in the commingled fabric system. Moreover, a transition between cohesive and adhesive fractures is observed when the cooling rate increases from 30°C/min to 63°C/min for the composite made from the commingled fabric. While good fabric-matrix bonding is always present in the PEEK-carbon prepreg form, the interfacial strength of the APC-2 laminates is also significantly affected by the cooling rate.

10A616. Matrix cracking in fiber reinforced ceramics. - Yih-Cheng Chiang *(Center for Composite Mats, Dept of Mech Eng, Univ of Delaware, Newark DE 19716)*, ASD Wang *(Dept of Mech Eng, Drexel Univ, Philadelphia PA 19104)*, Tsu-Wei Chou *(Center for Composite Mats, Dept of Mech Eng, Univ of Delaware, Newark DE 19716).* J Mech Phys Solids 41(7) 1137-1154 (Jul 1993).

This paper addresses critical stress at the propagation of a fiber-bridged matrix crack of arbitrary length in fiber-reinforced brittle matrix composites. The formulation of the problem follows the approach adopted earlier by Marshall, Cox and Evans, but a new shear-lag model that accounts for the matrix shear deformation above the slipping region is used here to derive the relationship between the crack opening displacement and the crack surface closure traction. The inclusion of the matrix shear deformation above the slipping region significantly affects the calculated crack tip stress intensity factor and the prediction of the critical stress at the propagation of the crack. Illustrative examples are cited using three available composite systems of SiC-borosilicate, C-borosilicate, and Nicalon-lithium-aluminosilicate (LAS).

10A617. Study of the opening displacement of transverse cracks in cross-ply laminates. - J Varna, LA Berglund *(Dept of Mat and Prod Eng, Lulea Univ of Tech, 95187 Lulea, Sweden)*, R Talerja *(Sch of Aerospace Eng, Georgia Tech)*, A Jakovics *(Dept of Phys and Math, Latvia Univ, LV 1098 Riga, Latvia).* Int J Damage Mech 2(3) 272-289 (Jul 1993).

Transverse cracks in cross-ply laminates are investigated experimentally to reveal the essential characteristics of their opening displacement under tensile loads. The average crack growth displacement is studied as a function of the longitudinal overall strain and effects of matrix toughness and transverse ply thickness on this parameter are examined. The interactive effects between closely spaced transverse cracks are also examined and found to be significant. Implications of the experimentally observed features on the micromechanics and continuum damage type models are discussed.

10A618. Experimental and numerical analysis of fracture processes in concrete. - E Schlangen *(Fac of Civil Eng, Delft Univ of Tech, Delft, Netherlands).* Heron 38(2) 1-117 (1993).

A combined experimental and numerical approach is adopted to investigate fracture processes in concrete. The experimental programme focuses on the failure of concrete subjected to mixed model I and II laoding. The influence of shear load on the nucleation and propagation of cracks in concrete is studied by means of four-point-shear tests on single and double edge notched beams. A numerical model for simulating fracture is developed in which the heterogeneous microstructure of concrete is implemented. The model is used to carry out simulations of different fracture experiments. The main conclusion derived from the experimental part of this investigation is that fracture in concrete is a mode I mechanism, even if the external loading on a specimen is a combination of tensile and shear. The numerical model developed has proved able to predict fracture in concrete quite accurately. Simulations with the model increase insight into the fracture mechanism.

10A619. R-curve model of certain ceramic composites. - M Olsson and AE Giannakopoulos *(Dept of Solid Mech, RIT, S-100 44 Stockholm, Sweden).* Fatigue Fracture Eng Mat Struct 16(5) 539-554 (May 1993).

The influence of crack-bridging on the R-curve for certain types of ceramic composites is modeled. Small scale bridging conditions are assumed. A recurrence procedure is used to solve the governing coupled integral equations, resulting in R-curves (stress intensity factor versus crack growth) that depend on well defined microstructural parameters. In addition, the bridging stresses and the crack opening diplacements were computed for all stages of the R-curve development. The numerical scheme is quite general and can be used for a variety of bridging laws. The convergence of the solution method is uniform, and the accuracy is a priori controlled. The results are normalized so that they can be applied for a large variety of composites with different micromechanical parameters. R-curves were computed for different bridging laws, and were found to be sensitive to the specific bridging law used each time. Some strength-toughness relations are also discussed. The results are particularly suitable for slow crack growth analysis.

10A620. Regularization in 3D for anisotropic elastodynamic crack and obstacle problems. - E Becache, J-C Nedelec *(CMAP, Ecole Polytech, 91128 Palaiseau Cedex, France)*, Naoshi Nishimura *(Dept of Civil Eng, Kyoto Univ, Kyoto 606, Japan).* J Elast 31(1) 25-46 (Apr 1993).

We propose, in this paper, a unified method of generating a regularized integral equation in the double layer potential approach for 3D anisotropic elastodynamics. Our regularization preserves the causality in the time-domain. The method is based on a special decomposition of the hypersingular kernel which appears in the integral represenation of the stress tensor.

10A621. Analysis of dynamic mixed mode stress fields in bimaterials by the method of caustics. - KP Herrmann and A Noe *(Lab Tech Mech, Paderborn Univ, Pohlweg 47-49, W-4790 Paderborn, Germany).* Theor Appl Fracture Mech 19(1) 49-59 (Jun 1993).

The equations of caustics for dynamically extending curvilinear interface cracks are derived where optical isotropy and anisotropy of the material have been considered, respectively. The equations have been obtained by applying the methods of generalized complex potentials. Moreover, an algorithm for the determination of stress intensity factors from experimentally obtained caustics is presented for the case of dynamic crack extension.

10A622. Assessment of dynamic fracture characteristics of weld metal. - Q Liu *(Tech Versuchs- und Forschungsanstalt, Univ of Tech, Vienna, Austria)* and T Varga *(Tech Versuchs- und Forschungsanstalt, Inst of Mat Sci and Mat Testing, Univ of Tech, Vienna, Austria).* Int J Pressure Vessels Piping 55(2) 223-232 (1993).

The dynamic fracture toughness of weld metals was tested by using the dynamic specific energy, Y_{pj}, as a measure. The results show that this approach can be used to estimate the dynamic fracture toughness of different microstructural areas of weld metal. Depending on the microstructure, different values of Y_{pj} were observed. The dynamic fracture toughness J_{Id} measured and calculated by using Y_{pj} within ±15%.

10A623. Crack propagation in cylindrical shells. - M Farshad and P Flueler *(Swiss Fed Lab for Mats Testing and Res (EMPA), Uberlandstr 129, CH-8600 Dubendorf, Switzerland).* Eng Fracture Mech 44(6) 937-947 (Apr 1993).

Results of a theoretical study of dynamic steady crack propagation in a circular cylindrical shell are presented. Equations of thin circular cylindrical shells are utilized for theoretical investigation. The semi-analytic crack tip stress solutions to shell equations are obtained by the perturbation method as well as an iterative method. Plots of internal stresses in the shell with a stationary as well as a steadily running crack are presented. These results are compared with those related to flat plates. It is concluded that the shell curvature has a pronounced effect on increasing the values of crack tip stresses. It would also qualitatively affect the variation of stress field around the crack tip. In some cases, the curvature action is shown to be even more pronounced than the inertia effects.

10A624. Application of the strain energy density concept to the determination of a crack propagation direction initiated at a sharp notch tip. - Z Knesl *(Inst of Phys Metall, Acad of Sci, Zizkova 22, 616 62 Brno, Czech Republic).* Acta Tech CSAV 38(2) 221-234 (1993).

The strain energy density distribution in the vicinity of a V-notch and the generalized strain energy density factor are used as the criteria determining directions of propagation of cracks initiated at the V-notch. It is shown that the direction of propagation depends on the ratio of notch stress intensity factors corresponding to the shear and normal modes of loading. The method for estimation of the ratio, based on FE calculation, is suggested.

10A625. Applications of ADINA to evaluate analysis methodologies for predicting cleavage arrest and reinitiation of a deep crack in an RPV. - J Keeney-Walker and BR Bass *(Marin Marietta Energy Syst, ORNL)*. Comput Struct 47(4-5) 553-564 (3 Jun 1993).

Several calculational procedures are compared for predicting cleavage arrest of a deep crack in the wall of a prototypical reactor pressure vessel (RPV) subjected to pressurized-thermal-shock (PTS) types of loading conditions. The three procedures examined in this study used the following models: (1) a static FE model (full bending); (2) a radially constrained static model; and (3) a thermoelastic dynamic FE model. A PTS transient loading condition was selected that produced a deep arrest of an axially oriented, initially shallow crack according to calculational results obtained from the static (full-bending) model. Results from the two static models were compared with those generated from the detailed thermoelastic dynamic FE analysis using ADINA. The dynamic analyses modeled cleavage-crack propagation using a node-release technique and application-mode methodologies. Comparisons presented here indicate that the degree to which dynamic solutions can be approximated by static models is highly dependent on several factors, including the material dynamic fracture curves and the propensity for cleavage reinitiation of the arrested crack under PTS loading conditions. Additional work is required to develop and validate a satisfactory dynamic fracture toughness model applicable to postcleavage arrest conditions in an RPV.

10A626. Numerical analysis of cyclic deformations and crack growth of pre-cracked steel components using the ADINA program system. - D Azodi and P Bachmann *(Gesellschaft fur Anlagen- und Reaktorsicherheit, GRS mbH, Schwertnergasse 1, 5000 Kolhn 1, Germany)*. Comput Struct 47(4-5) 565-589 (3 Jun 1993).

Our aim was to achieve a basic understanding of the vessel investigations under cyclic deformations and to validate ductile fracture mechanics concepts concerned with the cyclic J-integral. Several 3D FE analyses have been performed for components subjected to cyclic plastic deformations. Based on the slightly modified virtual crack extension method, cyclic J-integral values were computed and have been discussed. As long as the material plasticity around the crack tip is confined, the J-integral method is applicable and appears to be a suitable parameter for handling low-cycle fatigue problems.

10A627. Numerical evaluation of interface fracture parameters using ADINA. - KM Lee, O Buyukozturk, CKY Leung *(Dept of Civil and Env Eng, MIT)*. Comput Struct 47(4-5) 547-552 (3 Jun 1993).

The problem of cracking at interfaces is pertinent not only to composite materials but also to structures with adhesive joints, thin films and coatings. Criteria are needed for the study of the crack growth scenarios in the interfacial region where relative magnitudes of the fracture energy for the constitutent materials and that of the interface play an important role in cracking behavior. Interface fracture occurs when the interfacial energy release rate G is equal to the interfacial fracture energy Γ_i, that is characterized as a function of the loading phase ψ. Therefore, for the analysis of interfacial fracture both the energy release rate (G) and the loading phase angle (ψ) must be evaluated. In this paper, a numerical method is presented to obtain the values of these two parameters at the tip of an existing interface crack. Numerical analyzes of three models containing interface cracks are performed using the ADINA FE program. In general, good agreement between the results from the numerical calculation and the analytical solutions is obtained.

10A628. Closer look at estimation of fracture toughness from Charpy v-notch tests. - HJ Schindler and U Morf *(Swiss Fed Lab of Mat Testing and Res, Ueberlandstr 129, CH-8600 Dubendorf, Switzerland)*. Int J Pressure Vessels Piping 55(2) 203-212 (1993).

Although it is well known that the adequate parameters to characterise the toughness of materials are those according to the theory of fracture mechanics, the classical Charpy fracture energy is still often used in testing practice. Many efforts have been made to correlate these two types of toughness parameters with each other. In many cases these correlations give no satisfying results. In this paper it is investigated under what circumstances such correlation can exist and what type they are of. It is shown – from a theoretical point of view – that correlations are restricted to certain families of materials, ie, that there are no general applicable correlation formulas. For those purposes the standard Charpy tests have to be replaced by instrumented tests on sharp notched or pre-cracked specimens.

10A629. Evaluation method of dynamic fracture toughness by the computer-aided instrumented Charpy Impact Testing System. - I Yamamoto and T Kobayashi *(Toyhashi Univ of Tech, Tempaku-cho, Toyohashi 441, Japan)*. Int J Pressure Vessels Piping 55(2) 295-312 (1993).

The instrumented Charpy impact test has been widely used as a simple method semi-empirically evaluating the material impact toughness. The authors have developed a new dynamic fracture toughness evaluation system using a instrumented Charpy impact testing machine aided with a personal computer, which has been called "CAI (Computer-Aided instrumented Charpy Impact testing)" system. Using the CAI system, dynamic fracture toughness such as K_d, J_d, T_{mat} and various energies can be obtained from the load-deflection curve of a single pre-cracked specimen. In this paper, in addition to the detail of the CAI system, the elastic deformation behavior of the Charpy testing machine and its correspondence in the CAI system are described.

10A630. Evaluation of J_{1c} for weldment constituents by multispecimen test method. - I Glavardanov *(Fac of Tech Sci, 21 000 Novi Sad, V Perica Valtera 2, Yugoslavia)* and S Sedmak *(Fac of Tech and Metall, 11 000 Belgrade, Karnegijeva 4, Yugoslavia)*. Int J Pressure Vessels Piping 55(2) 213-221 (1993).

Crack-resistance properties of weldment constituents are required in a safety analysis of highly stressed penstock produced from 700 MPa nominal yield strength high-strength low alloy steel. Small size specimens (10 x 10 x 55 mm) with fatigue pre-crack in base metal (BM), weld metal (WM) and heat-affected zone (HAZ) were used in multi-specimens test method for J_1c evaluation. Tests were performed at room and low temperatures down to -98°C. A low-temperature cabinet for these tests has been designed based on flow of nitrogen gas, developed by heating liquid nitrogen. Fracture toughness of BM is found to be high at room temperatures (800 kN-m), but "pop-in" effect reduced it at temperatures below -40°C (650 kN-m at -40°C, 300 kN-m at -80°). Similar behavior was found for WM and HAZ, but with lower fracture toughness values compared to BM and significant scatter of results.

10A631. Measurement of dynamic elastic-plastic fracture toughness parameters using various methods. - H-W Viehrig *(Res Centre Rossendorf Inc, D-O-8051 Dresden, PF 19, Germany)*, K Popp *(Radioecology Group, Eng Ltd IAF, D-O-8054 Dresden, Karpatenstr 20, Germany)*, R Rintamaa *(Metals Lab, Tech Res Centre of Finland, SF-02151 Espoo 15, Kemistintie 3, Finland)*. Int J Pressure Vessels Piping 55(2) 233-241 (1993).

Two improved impact testing facilities are used for the dynamic fracture toughness evaluation of precracked Charpy v-notch specimens. The methods of single specimen acoustic emission and crack mouth opening displacement testing are assumed to indicate the initiation points of stable crack growth. Thus, the dynamic ductile initiation J integral J_{Id} can be derived. It was shown that the toughness J_{Id} of the heat-resistant steel 10CrMo9.10 cannot be approximated by the J value at the maximum of the load deflection curve.

10A632. Practical use of virtual reflection caustics. - RA Kitchin and EA Patterson *(Dept of Mech and Process Eng, Univ of Sheffield, Mappin St, Sheffield S1 3JD, UK)*. Fatigue Fracture Eng Mat Struct 16(6) 597-602 (Jun 1993).

The method of reflected caustics has in recent years become a widely used technique for the study of stress and strain distributions at singularities. Despite the increasing use of this technique, simple and practical descriptions of the production of caustics are limited. A particular area of ambiguity is the production and recording of the virtual caustic. The term "virtual" classically implies that the image may only be seen through a lens and cannot be focused on a screen, however a virtual caustic may be viewed on a screen, which contravenes this classical definition. Despite this contradiction much of the published literature assumes that the reader has knowledge of how the virtual caustic is produced, thus making the technique less accessible to would-be practitioners. This paper aims to clarify the definition, formation and use of the virtual caustic.

10A633. Reproducibility of measuring the crack propagation with a clip gauge. - G Nagy and J Lukacs *(Univ of Miskolc, Miskolc-Egyetemvaros H-3515, Hungary)*. Int J Pressure Vessels Piping 55(2) 269-274 (1993).

This paper describes that during measuring the fatigue crack propagation the optical and compliance methods result in approximately the same crack length. The difference is so small, that the resulted difference among the exponents of Paris-Erdogen law cannot be statistically quantified.

10A634. Acoustic emission monitoring of pressure vessels. - P Pellionisz *(Central Res Inst for Phys, KFKI, PO Box 49, Budapest 1525, Hungary)* and P Szucs *(Central Testing Lab of Power Plants, EROKAR, PO Box 67, Budapest 1602, Hungary)*. Int J Pressure Vessels Piping 55(2) 287-294 (1993).

This paper summarizes the main features of the acoustic emission testing method. A short overview is given of how common failures can be detected at pressure vessel testing and how measurement results are evaluated. Acoustic emission monitoring of pressure vessels for the power plant industry has been introduced also in Hungary: an overview is given and some of the measurement results are presented.

10A635. Ultrasonic backscattering using digitized full-waveform scanning technique. - J Schuster *(Dipl Ing, Inst fur Verbundwerkstoffe, Univ Kaiserslautern, 6750 Kaiserslautern, Germany)* and KV Steiner *(Center for Composite Mat, Univ of Delaware, Newark DE 19716-3144)*. J Composite Tech Res 15(2) 143-148 (Sum 1993).

This paper presents the results of backscattering tests based on full-waveform scans performed on composite specimens. Five samples were manufactured with varying fiber directions and different numbers of laminae per direction. Ultrasonic backscattering tests of these samples were performed using digitized full-waveform scans. An algorithm was developed to determine the fiber direction with a tolerance of 2 to 3° and the number of laminae within a range of ±0.5 lamina for sections close to the front surface.

10A636. Through-transmission equations for remote-field eddy current inspection of small-bore ferromagnetic tubes. - DD Mackintosh, DL Atherton, PA Puhach *(Dept of Phys, Queen's Univ, Kingston, ON, K7L 3N6, Canada)*. Mat Eval 51(6) 744-748 (June 1993).

The remote-field eddy current (RFEC) method is widely used for nondestructive testing of ferromagnetic tubes such as those found in heat exchangers. An exciter coil generates an electromagnetic field that diffuses through the pipe wall, axially along the outside of the pipe, and back through the pipe wall to a detector coil. Phase and amplitude readings can be interpreted to characterize pipe defects. Skin depth theory is commonly used to calculate through-transmission effects and to predict the effects of corrosion in RFEC signals. Experimentally measured deviations from skin depth theory are described. A theoretical investigation is made of through-transmission for a cylindrical wave impinging on a conducting tube. The cylindrical through-transmission equations agree well with RFEC data. The application of the new equations to RFEC defect signal analysis is discussed. A case study of an RFEC scan of a metal loss defect is described. The through-transmission equations were found to hold at the defect. However, the RFEC scan data deviated slightly from the value predicted by the through-transmission equations. The deviation was attributed to a perturbation of the field on the outside of the pipe caused by the defect, an effect not considered in a through-transmission analysis.

10A637. Radar inspection of structures. - JH Bungey and SG Millard *(Dept of Civil Eng, Univ of Liverpool, UK)*. Struct Build 99(2) 173-186 (May 1993).

During the past few years, surface scanning impulse radar systems have begun to achieve popularity in the UK for a wide range of civil engineering applications. Investigation of the structural details and of the integrity of both concrete and masonry structures has proved to be a particularly fruitful field of application. The fundamental background is outlined briefly and a wide range of reported usage on a worldwide basis is reviewed. Features of currently available equipment are described, with particular emphasis on the factors that influence reproducibility and interpretation of results, including the use of color displays and computerized signal enhancement procedures. Advantages and limitations of the technique are examined critically, and areas for future study and development are identified.

10A638. Limit states design of semi-rigid frames using advanced analysis Part 1. Connection modeling and classification. - JYR Liew *(Dept of Civil Eng, Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*, DW White, WF Chen *(Sch of Civil Eng, Purdue)*. J Construct Steel Res 26(1) 1-27 (1993).

This paper presents a method for modeling connection moment-rotation curves which are essential for proportioning 2D semi-rigid steel frame structures analyzed based on a second-order inelastic analysis. Procedures for calculating the key parameters used to describe the moment-rotation curves of various types of angle connections are presented. Design aids are generated in which salient size parameters that affect the moment-rotation behavior of the connection can be identified. Two schemes by which connections can be classified in terms of strength, stiffness and rotation capacity are presented, and their design implications are discussed. Analysis and design methodologies are provided in Part 2, a companion paper in which the ultimate strength and serviceability limit state behavior of a semi-rigid frame example are studied using an advanced analysis. The aim of these two-part papers is to advance the use of second-order plastic hinge based analysis for proportioning 2D semi-rigid frames without the need of separate specification equation checks.

10A639. Limit states design of semi-rigid frames using advanced analysis Part 2. Analysis and design. - JYR Liew *(Dept of Civil Eng, Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*, DW White *(Sch of Civil Eng, Purdue)*, WF Chen *(Dept of Civil Eng, Purdue)*. J Construct Steel Res 26(1) 29-57 (1993).

This paper presents an integrated advanced inelastic analysis method for proportioning semi-rigid steel frame structures in which the beam-to-column connections are composed of angles. The modeling of connection moment-rotation curves and their classifications have been presented and discussed in a companion paper. An approach called the second-order refined plastic hinge analysis is introduced. The method is validated by comparing the results with those obtained based on a more exact plastic zone analysis. It is shown that the refined plastic hinge analysis provides a good representation of inelastic behavior, and that it enables the full assessment of system and member inelastic behavior up to the limit state of strength. This analysis method is used to assess the adequacy of a 2D semi-rigid frame, and its members and connections in resisting the factored load effects. The design is evaluated with respect to the system's strength and serviceability limit states, including conformance with the code requirements for strength and stability of individual members, and rotation capacity of connections. The inclusions of connection nonlinear effects in advanced inelastic analysis provide a straightforward task for proportioning of frame members and connections, thus avoiding the complexity of having to perform specification member capacity checks for individual frame members.

282C. STRUCTURAL OPTIMIZATION

10A640. New approach to 2D eigenvalue shape design. - YA Melnikov *(Dept of Math and Stat, Middle Tennessee State Univ, PO Box 34, Murfreesboro TN 37132)* and SA Titarenko *(Baltic Mechanical Plant, St Petersburg, Russia)*. Int J Numer Methods Eng 36(12) 2017-2030 (30 Jun 1993).

A new approach to solve problems in the optimal shape design of eigenvalues is presented. The idea behind the approach is based on a combination of the known material derivative method and a specially adapted Green's functions formulation. In the current study, numerical testing has been limited to 2D shape optimization. The two test cases involve the first eigenvalues of boundary value problems which model (i) free vibrations of a fixed membrane and (ii) natural frequencies of clamped thin plates. The basic algorithm can easily be adapted to serve other types of boundary value problems dealing with the highest eigenvalues that occur in applied mechanics. Computational aspects of the proposed approach, such as accuracy of the obtained sensitivities, cost of computation and so on are discussed.

10A641. Optimal design of a composite structure. - DL Graesser *(Dept of Mech Eng, Univ of Washington, Seattle WA 98195)*, ZB Zabinsky *(Indust Eng Program, Univ of Washington, Seattle WA 98195)*, ME Tuttle, GI Kim *(Dept of Mech Eng, Univ of Washington, Seattle WA 98195)*. Composite Struct 24(4) 273-281 (1993).

This paper presents a design methodology for a laminated composite stiffened panel, subjected to multiple in-plane loads and bending moments. Design variables include the skin and stiffener ply orientation angles and stiffener geometry variables. Optimum designs are sought which minimize structural weight and satisfy mechanical performance requirements. Two types of mechanical performance requirements are placed on the panel, maximum strain and minimum strength. Minimum weight designs are presented which document that the choice of mechanical performance requirements cause changes in the optimum design. The effects of lay-up constraints which limit the ply angles to user specified values, such as symmetric or quasi-isotropic laminates, are also investigated.

10A642. Optimization of elastoplastic systems under random loading. - A Cyras and A Norkus *(Dept of Struct Mech, Vilnius Tech Univ, Sauletekio aleja 11, 2054 Vilnius, Lithuania)*. Mech Res Commun 20(4) 293-299 (Jul-Aug 1993).

One of the first investigations of the optimization problem of elastoplastic systems under random loading was that of (1) on the reference list. The shakedown theorem (2) to derive the mathematical model of the problem and the random process crossing theory for determination of extreme elastic stresses were used in the investigation. The Turkstra rule in determining the extreme elastic stresses was applied in this paper.

282D. ACTIVE CONTROL, SMART STRUCTURES

10A643. Active buckling control of smart composite plates: FE analysis. - K Chandrashekhara *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)* and K Bhatia *(Hartwick Prof, Troy MI)*. Smart Mat Struct 2(1) 31-39 (Mar 1993).

A FE model is developed for the active buckling control of laminated composite plates using piezoelectric materials. The FE model is based on the first order shear deformation plate theory in conjunction with linear piezoelectric theory. The piezoelectric sensors and actuators can be surface bonded or embedded and can be either continuous or segmented. The model does not introduce voltage as an additional dof and takes into account the mass and stiffness of the piezoelectric patches. The dynamic buckling behavior of the laminated plate subjected to a linearly increasing uniaxial compressive load is investigated. The sensor output is used to determine the input to the actuator using a proportional control algorithm. The forces induced by the piezoelectric actuators under the applied voltage fields enhance the critical buckling load. FE solutions are presented for composite plates with clamped and simply supported boundary conditions and the effectiveness of piezoelectric materials in enhancing the buckling loads is demonstrated.

10A644. Bending bilayer strips built from polyaniline for artificial electrochemical muscles. - Qibing Pei, O Inganas, I Lundstrom *(Lab of Appl Phys, Dept of Phys, IFM Linkoping Univ, S-581 83 Linkoping, Sweden)*. Smart Mat Struct 2(1) 1-6 (Mar 1993).

Electrically conducting conjugated polymers such as polyaniline (PANi) usually show gel properties with volume changes in the range 1-100% in response to some external stimuli. The bending beam method provides an effective and sensitive way to detect and make use of these volume changes. Bipolymer laminate strips (2.5 × 0.2 cm^2), made of PANi layer (10 μm thick) and a substrate polyimide layer (45 μm thick) bound together, were prepared. These strips bend, corresponding to volume changes in the PANi layer, during electrochemical redox of the PANi in aqueous solutions. The extension (≤ 1.0 cm) and velocity (≤ 48 cm min^{-1}) of the movement of the strips can be controlled by applying appropriate potentials and currents. We are able to obtain significant and reversible movement back and forth in seconds. The bending force of the strip is estimated to be more than 20 times the total self-weight of the strip, with an energy efficiency of around 1%. The volume change of PANi associated with the redox is ≤1%.

10A645. Neural network for feedforward controlled smart structures. - SD Synder and Nobuo Tanaka *(Vib Eng Div, Mech Eng Lab, Ministry of Int Trade and Indust, 1-2 Namiki Tsukuba Sci City, Ibaraki 305, Japan)*. J Intelligent Mat Syst Struct 4(3) 373-378 (Jul 1993).

A neural network and adaptive algorithm suitable for driving nonlinear feedforward control systems used with "smart" structures to actively control sound and vibration is presented. The neural network-algorithm combination can be viewed as an extension to the commonly used transversal filter-filtered-x LMS algorithm combination, in that the neural network is essentially a transversal filler with a nonlinear hidden layer placed between the input delay chain and output accumulator. The algorithm accommodates the transfer function and time delay between the control signal output and error signal input. The arrangement is shown in simulation to be capable of suppressing a primary disturbance, which is a nonlinear function of the reference signal fed to the control filter, and of suppressing harmonics introduced into a system by a control actuator exhibiting nonlinear performance characteristics. The results are compared to those similarly obtained using a linear adaptive control arrangement, which is incapable of providing attenuation in either case.

10A646. Systematic formulation of model uncertainties for smart structures. - R Kashani and O Fluder *(Mech Eng-Eng Mech Dept, Michigan Tech Univ MI 49931-1295)*. Smart Mat Struct 2(1) 47-54 (Mar 1993).

In this work a systematic approach is presented to formulate the structured uncertainties due to variations in the values of natural frequencies and the modal damping ratios, ie, the parameters of the A matrix of the structure's state-space model, as well as the unstructured uncertainty resulting from the fact that only a limited number of modes are included in the model of the smart structure. A computer program has been developed that takes the percentage of the variation on the parameters, as well as the desired number of modes to be included in the model and provides the user with the appropriate formulation of the uncertainty.

10A647. Effect of reliability of crack propagation measurement on the assessment of lifetimes for structural elements having flaws. - J Lukacs *(Univ of Miskolc, H-3515 Miskolc-Egyetemvaros, Hungary)*. Int J Pressure Vessels Piping 55(2) 261-268 (1993).

The assessment of the life-time for structural elements having crack-like defects as well the judgement of the effects of material features on it are becoming more and more important. An effective solution for these problems is inconceivable without computer-aided systems. This paper outlines the structure of such a computer-aided system and an example illustrates some of its possible applications.

282H. CONCRETE (REINFORCED)

10A648. Behavior of concrete beams with exposed reinforcement. - J Cairns and Z Zhao *(Dept of Civil and Offshore Eng, Heriot-Watt Univ, Edinburgh)*. Struct Build 99(2) 141-154 (May 1993).

Reinforcement corrosion is the principal cause of deterioration of reinforced concrete. It has been estimated that around £500 million is spent annually in the UK on concrete repairs. Of the alternative techniques available to extend the useful life of concrete structures, removal of concrete around affected reinforcement and subsequent reinstatement with a concrete or mortar remains the most commonly used. A detailed description of the changes in structural behavior that arise when reinforcement is exposed is provided, based on principles of equilibrium of forces and compatibility of deformations. The numerical model is shown to predict strain behavior and failure loads with good accuracy. The model is applied to specific examples to estimate loss of strength on exposure of reinforcement and to evaluate the length of bar which may be exposed without loss of ultimate strength.

10A649. Carbon fiber reinforced concrete for smart structures capable of nondestructive flaw detection. - Pu-Woei Chen and DDL Chung *(Dept of Mech and Aerospace Eng, SUNY, Box 604400, Buffalo NY 14260-4400)*. Smart Mat Struct 2(1) 22-30 (Mar 1993).

Electrically conducting concrete, as provided by the addition of short carbon fibers (0.2-0.4 vol. %) to concrete, can function as a smart structure material that allows nondestructive electrical probing for the monitoring of flaws. The electrical signal is related to an increase in the concrete's volume resistivity during crack generation or propagation and a decrease in the resistivity during crack closure. The linearity between the volume resistivity change and the compressive stress was good for mortar containing carbon fibers together with either methylcellulose or latex as dispersants. However, the linearity was poor for mortar containing carbon fibers together with both methylcellulose and silica fume, as this mortar required a minimum compressive stress for crack closure, whereas the other two mortars did not. When the compressive stress was increased in the first cycle up to the fracture stress, the volume resistivity increased by 1040% for the mortar containing carbon fibers and methylcellulose, but only 385% for that containing fibers and latex. In contrast, mortars without carbon fibers showed no variation of the resistivity upon compression up to fracture.

10A650. Effect of vertical contraction joints in concrete arch dams. - JR Mays *(Dept of Civil Eng, Univ of Colorado, Denver CO)* and LH Roehm *(US Bureau of Reclamation, PO Box 25007, Denver CO 80225)*. Comput Struct 47(4-5) 615-627 (3 Jun 1993).

The vertical joints between the blocks of concrete in arch dams allow for contraction as the concrete cools during construction. Linear analyses, which ignore the presence of these joints, indicate large horizontal tensile stresses near the joints particularly when seismic loading is included. The US Bureau of Reclamation is studying the nonlinear behavior of these vertical joints by making comparisons between parallel linear and nonlinear analyses of East Canyon Dam. This paper reports on the use of ADINA's gap element to model the contraction joints. The nonlinear analysis shows decreased values of the horizontal tensile stress at the expense of larger compressive stresses and increasing values of vertical tensile stress.

10A651. Interface effects on box-type reinforced concrete structures I. Theory. - Y Chen *(Dept of Civil Eng, Penn State Univ, Middletown PA 17057-4898)*. Comput Struct 47(3) 383-390 (3 May 1993).

A simplified interface model for studying the overall behavior of a soil-concrete interface, and the effects of the interface model on system responses are discussed. Theoretical aspects for this subject are presented in part I, and then followed by implementation and applications in part II. The paper concludes with a number of realistic examples with comparisons of the results with the others.

10A652. Interface effects on box-type reinforced concrete structures II. Implementation. - Y Chen *(Dept of Civil Eng, Penn State, Middletown PA 17057-4898)*. Comput Struct 47(3) 391-398 (3 May 1993).

Implementation, modeling, and verification of the interface model described in part I of this paper are discussed in this part. A number of realistic examples are studied by using a combined finite difference-FE approach with substructuring. The behavior of interface and the effects of interface on box-type reinforced concrete structures are also discussed. The results obtained from the study are compared with the others and those adopted by the current design code.

10A653. Nonlinear FE analysis of concrete structures. - Yuan-Gao Zhang, Ming-Wan Lu, Keh-Chih Hwang *(Dept of Eng Mech, Tsinghua Univ, Beijing 100084, Peoples Rep of China)*. Z Angew Math Phys 44(3) 537-555 (May 1993).

This paper deals with 3D nonlinear FE analysis of concrete structures. A new three-parameter failure criterion, formulated in terms of three stress invariants, is suggested for plain concrete. The criterion can accurately describe available experimental data throughout the stress range from tensile stresses to high compressive stresses. The constitutive matrix of a cracked concrete element is deduced by coupling the normal and tangential effects of crack bands. The modeling of reinforcement and its interaction with concrete are also discussed. Numerical examples of plain and reinforced concrete are presented. The computational results compare satisfactorily with experimental data.

10A654. Optimal design of reinforced concrete frames based on inelastic analysis. - KS Dinno and BB Mekha *(Dept of Civil Eng, Col of Eng, Univ of Baghdad, Iraq)*. Comput Struct 47(2) 245-252 (Apr 1993).

A new algorithm is presented for use in conjunction with the imposed rotation method as reformulated by Kaneko as a (n × 2n) linear complementarity problem. The inelastic trilinear moment rotation law, which is modelled to reflect behavior at critical sections, is adjusted during the incremental analysis in order to adhere the nonholonomic behavior of reinforced concrete (RC) when stress unloading occurs. The algorithm is utilized in performing inelastic analysis for the optimal design of RC frames. Optimum concrete dimensions and reinforcement are evaluated for minimum cost. Optimization, following the multilevel approach, is carried out on typical frames using SUMT and Rosenbrock minimization methods.

10A655. Static and dynamic refined analysis of reinforced concrete bridges. - Y Chen *(Dept of Civil Eng, Penn State Univ, Middletown PA 17057-4898)*. Comput Struct 47(4-5) 601-613 (3 Jun 1993).

A refined method for analyzing a bridge structure and system is discussed. An effective and efficient combined numerical integration scheme is proposed for dynamic analyses. Modeling techniques, distribution of vehicle live loads, seismic analysis methods, and ground motion and soil-structure interaction effects on structural responses are discussed in detail. The results obtained from the present study are compared with those from the current bridge design code. The paper concludes with a number of real examples.

10A656. Steel deck institute method for designing composite slabs. - RB Heagler *(Nicholas J Bouras and United Steel Deck, Summit NJ 07902-0662)*. Thin-Walled Struct 16(1-4) 319-326 (1993).

The Steel Deck Institute (SDI) of the US has synthesized the research and testing done on composite slabs and is ready to present a design rationale based on customary reinforced concrete methods. Two design procedures are shown: one for when there are no shear studs on the beams and the other for when there are studs. A partial composite factor is introduced for cases when shear studs may be sparsely applied.

10A657. Alternative crack width computation for prestressed members. - H Scholz *(Dept of Civil Engineering, Univ of Witwatersrand, Johannesburg)*. Struct Build 99(2) 135-140 (May 1993).

This paper describes a new method to compute the crack width attributable to the loading of prestressed flexural members. Use is made of the similarities that exist between the deflection theory and the crack theory of prestressed sections and elements. A comparison with test measurements has confirmed that the suggested alternative method is acceptable for engineering purposes. The benefits of the approach are enumerated and a numerical example is presented to illustrate the method. It is argued that for the first time a consistent interrelated method is proposed that covers cracking and deflection of prestressed members.

10A658. User-supplied concrete material model for ADINA. - M Ala Saadeghvaziri *(Dept of Civil Eng, NJIT, Newark NJ 07102)*. Comput Struct 47(4-5) 591-600 (3 Jun 1993).

ADINA's capability in providing the user with the option to construct his or her own material model is employed to add a simple concrete material model. The simplicity of the model arises from the assumption of a uniaxial state of stress and it can be used for nonlinear analysis of members under primarily flexural and/or axial load. The effectiveness of the model under monotonic, as well as cyclic loading, is shown through analyses of three test problems.

10A659. Behavior of concrete box girder bridges of deformable cross-section. - B Kermani *(Acer Consult, Bristol)* and P Waldron *(Dept of Civil and Struct Eng, Univ of Sheffield)*. Struct Build 99(2) 109-122 (May 1993).

Distortion of the cross-section, which commonly occurs in thin-walled box girder bridges that contain few intermediate diaphragms, may modify the distribution of stress throughout the structure to a significant degree. A method of analysis is presented which allows for the effects of cross-sectional distortion in addition to those of torsional warping. The approach is a rational extension of thin-walled beam theory and may be applied to continuous or simply-supported box girders of either straight or curved configuration in plan. As few test data of continuous girders were available against which the accuracy of the method could be verified, two scaled models - one straight, the other curved in plan - were fabricated for this purpose. The construction and testing of these models under a variety of concentrated and distributed torsional loads are briefly described. Results from these tests show excellent general agreement with those from the proposed analytical method.

10A660. Nonlinear modelling of cable-stayed bridges. - W Kanok-Nukulchai and Guan Hong *(Div of Struct Eng and Construct, Asian IT, GPO Box 2754, Bangkok 10501, Thailand)*. J Construct Steel Res 26(2-3) 249-266 (1993).

This paper presents an application of a powerful thin-walled element and a special cable element for 3D modelling of steel cable-stayed bridges. Both linear and nonlinear effects are considered, as geometric nonlinearity may arise from the finite displacement of the bridge deck as well as the cables. As cable-stayed bridge decks are normally built-up thin-walled cross-sections, the effects of flexural-torsion coupling as well as warping restraint are included. Finally, several examples of cable-stayed bridges serve to demonstrate the effectiveness of this most comprehensive model.

10A661. Strength and stiffness of discrete U-frames in composite plate girders. - RP Johnson *(Dept of Civil Eng, Univ of Warwick)* and Shiming Chen *(Inst of Urban Construct, Peoples Rep of China)*. Struct Build 99(2) 199-209 (May 1993).

Tests are reported elsewhere on a structure of inverted U-section consisting of twin double-cantilever composite plate girders, restrained laterally by discrete U-frames, each with the reinforced concrete slab acting as the horizontal member. Results are given here of the tests of the connections between this member and the steelwork. These and earlier tests provide the basis for tentative design rules, relating to stiffness, diagonal tension cracking of the slab, and local yielding of the steel top flange.

10A662. Accurate and efficient method for large deflection inelastic analysis of frames with semi-rigid connections. - Goman Wai-Ming Ho *(Ove Arup and Partners)* and Siu-Lai Chan *(Dept of Civil and Struct Eng, Hong Kong Polytech, Hong Kong)*. J Construct Steel Res 26(2-3) 171-191 (1993).

In the conventional analysis and design of steel frames, a pinned or rigid jointed assumption is normally made. However, all practical joints are neither frictionless pinned nor fully rigid. This characteristic has an important influence on the behavior of the structure. The bending moment determined according to these extreme joint conditions is also erroneous. In this paper, a displacement-based FE technique using the incremental secant stiffness approach and considering the effects of joint flexibility for the nonlinear analysis of 2 and 3D frames is presented. The suggested method has the advantage over the currently available methods in its accuracy in handling large deflection analysis in 3D space and fast rate of convergence.

10A663. Analysis of frame-cable structures. - W Shan, C Yamamoto, K Oda *(Centre for Space Struct Res, Taiyo Kogyo, 3-20 Syodai-Tajika Hirakata-shi, Osaka 573, Japan)*. Comput Struct 47(4-5) 673-682 (3 Jun 1993).

An approach for the analysis of frame-cable structures which are prestressed cable nets incorporating space frames is presented. The interaction between the frame members and the cables is considered and the application of ADINA in shape finding and loading analysis is discussed. A technique is described for integrated loading analysis of frame-cable structures containing beam elements. The numerical examples demonstrate the practical importance of accounting for the effects of the frame deformations.

10A664. Cold-formed steel design and research in Germany. - R Baehre *(Versuchsanstalt fur Stahl, Holz und Steine, Univ Karlsruhe, Kaiserstr 12, 7500 Karlsruhe, Germany)*. Thin-Walled Struct 16(1-4) 293-305 (1993).

The availability of authorized design rules confirms a general approval of scientific-based knowledge and provides confidence for the designer. In the field of light-gauge structures, rules for the design of sheeting and members are approved in Germany since the second part of the 1980s. They have been worked out parallel to the appropriate ECCS recommendations and to Eurocode 3, Annex A, and are considerably harmonized documents. An overall view about the contents of the German design rules is given as well as some examples for special design models. Ongoing research activities in Germany demonstrate the unbroken expansion of light-weight building techniques.

10A665. Cold-formed steel members: Design aproaches in the US. - RL Brockenbrough *(RL Brockenbrough & Assoc, Pittsburgh PA)*. Thin-Walled Struct 16(1-4) 307-317 (1993).

In the US, design specifications for cold-formed steel structural members have been developed and refined over a period of 50 years or so by a consensus group managed by the American Iron and Steel Institute (AISI). Recently the scope of these specifications has broadened significantly. The traditional allowable stress design (ASD) specification for carbon and high-strength steel sheets was extensively revised in 1986 to reflect an allowable member moment or load approach. Referred to as the unified approach, the revised specification treats all types of compression elements with a consistent effective width approach and treats all types of compression members in a consistent manner. The specification was further modified by a 1989 addendum to reflect the results of continuing research. In 1991, the ASD specification was supplemented by a separate load and resistance factor design specification (LRFD), intended to provide a more consistent index of structural reliability. The ASD and LRFD specifications of the AISI have been organized on a parallel basis to facilitate consolidation at an appropriate date. Also, as discussed in a separate paper, a new specification for the design of cold-formed stainless steel members has been recently developed by a consensus group under the auspices of the American Society of Civil Engineers (ASCE). This ASCE document, which replaces an AISI ASD specification that had not been updated for many years, is an LRFD specification that includes an appendix with the ASD approach. Thus, specification development for the design of cold-formed members in the USA has been very active. This made possible not only by the efforts of the supporting groups, but by the extensive volunteer efforts of the many engineers who participate.

10A666. Computer-aided interactive plastic design of frames. - WAM Alwis *(Dept of Civil Eng, Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*. J Construct Steel Res 26(2-3) 141-151 (1993).

A computer method for analysis and design of plane frames is presented. The method is meant primarily for plastic collapse analysis. Optimal design and elastic-plastic deformation analysis capabilities are provided as options on the same computational platform such that all activities share common internal data structures. A specific feature is the interfacing of user input with analysis calculations, resulting in an interactive design system. Four sequential levels of input data are considered: frame topology, geometry, member sections and loading. Separate calculation modules are activated at each level of input, permitting interactive data modifications, computational work that needs to be repeated to obtain the new solution is that of the modification level and the following levels if any.

10A667. Design approaches for cold-formed steel structures in the People's Republic of China. - Zhong-Quan Zhang *(Zhongnan Build Design Inst, Wuhan, Hubei 430071, Peoples Rep of China)*. Thin-Walled Struct 16(1-4) 327-341 (1993).

This paper briefly describes the limit state design method for cold-formed steel structures in China. Some basic factors affecting the structural safety, such as the reliability index, partial coefficients for loads and resistances etc. and design general expression are systemically discussed and presented. Besides, the design method for various cold-formed steel structural members and connections adopted by current Chinese Specification (GBJ 18-87) are also given in the text.

10A668. European design methods for cold-formed steel. - A Toma *(TNO Build and Construct Res, Delft, Netherlands)*. Thin-Walled Struct 16(1-4) 275-291 (1993).

A survey has been given of the framework of the Eurocodes. These codes should be regarded as the structural design codes for Europe starting in the 1990s. The safety concept of the codes is in the form of load and resistance factor design (LRFD). As far as it concerns the material steel (hot-rolled and cold-formed) the codes are largely based on ECCS documents. The hot-rolled steel has been treated in Eurocode 3, Part 1.1 and the Annexes to Part 1.1 and the cold-formed steel in the Eurocode 3, Part 1.3. In this paper the design rules for cold-formed steel and their eventual difference with the rules for hot-rolled steel are envisaged. Also the background document for the rules of cold-formed steel is reported.

10A669. Local stresses at the intersection of cross-beam flange with box girder web. - Ichiro Okura and Yuhshi Fukumoto *(Dept of Civil Eng, Osaka Univ, 2-1 Yamadaoka, Suita, Osaka 565, Japan)*. Thin-Walled Struct 17(2) 113-131 (1993).

Local stresses at the intersection of a top flange of a cross beam with a box-girder web are investigated analytically and experimentally. FE analyses of a T-shaped welded joint and a loading test of a cantilever beam of acrylic material reveal that a local stress which is different from the one caused by the stress concentration at a weld toe is developed at the intersection. FE analyses of an I-section beam show that the restraint of the vertical deformation of the cross beam at the box-girder web induces the local stress. It is pointed out that the local stress must be considered in fatigue design. A method of determining the local stress is proposed.

10A670. Use of external T-stiffeners in box-column to I-beam connections. - SL Lee, LC Ting, NE Shanmugam *(Dept of Civil Eng, Natl Univ, Kent Ridge, Singapore 0511)*. J Construct Steel Res 26(2-3) 77-98 (1993).

The effects of various types of stiffeners on the connection behavior between box-column to I-beams has been studied both experimentally and analytically using the FEM. The external T-stiffener has been found to provide the most suitable form of stiffening in terms of stiffness, strength, ductility and ease in fabrication which are the basic criteria for a good moment connection. A simple design method to determine the dimensions of the external T-stiffener for both the two-way and four-way connections has been proposed. A method for predicting the moment-rotation characteristic of the connection using a least-square curve-fitting procedure is also described. Finally, two four-way full-scale specimens designed in accordance with the design guidelines were tested to failure. The experimental results as well as results from FE analysis show the validity of both the design guidelines and the proposed moment-rotation functions.

10A671. Load testing of beam and block concrete floors. - RM Moss *(Struct Performance Div, Build Res Est)*. Struct Build 99(2) 211-223 (May 1993).

A study is made of the structural behavior of beam and block concrete floors under static and thermal loads. Particular issues addressed include the need to estimate the transverse load distribution in a floor during a load test, and the ability to compensate measured deflections for the effects of environmental temperatute changes. The research described focuses on these aspects and leads to specific recommendations for the load testing of beam and block floors. The work is limited to a study of a particular arrangement of beam and block floor which was tested at different stages of construction so that the behavior of the separate components (an ungrouted floor, a grouted floor and a floor with different screed types) could be established. Apart from a final test to failure on the floor with a bonded screed, the load levels were restricted so that repeatability could be achieved at each stage and the degree of structural interaction determined. It is noted that the additional stiffness provided by different screed types, particularly bonded screeds, could be substantial, and that a sand-cement grout simply brushed over the surface of the floor, and only partially filling the joints between components, still provides an increase in stiffness. Approximate methods using linear theory and heat conduction analysis, leading to assessment of load distribution, thermal deflections and load corrections, are developed for use in the load testing of structures. The results of these analyses compare satisfactorily with results of tests on the floor assemblies.

10A672. Simplified method for ultimate load prediction of all-steel sandwich panels. - KH Tan, TS Lok, SP Chiew *(Sch of Civil and Struct Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*. Thin-Walled Struct 17(1) 27-44 (1993).

This paper is concerned with the ultimate load prediction of a sandwich panel manufactured from a steel plate assembly. The panel essentially consists of two facing plates, spot welded onto a corrugated steel core. All the plates of a panel have identical thicknesses. Three groups of panels with varying plate thicknesses were examined. The typical panel considered in this study had plan dimensions of 2.1 m × 1.0 m with a core consisting of top-hat stiffeners of depth 60 mm, placed side by side. The panel was simply supported across its y-direction boundaries and subjected to uniform lateral loading over its entire surface. The plastic hinge theory is used to evaluate the ultimate collapse load of the panel. In this respect, two approaches are compared: one based on full-section properties and the other based on the effective width concept. It is shown that the effective section gives more reliable collapse-load predictions than the full section. Theoretical collapse-load predictions agree very well with the experimental collapse load for a series of 13 panels. To accentuate the salient features of the technique, a numerical example is presented.

10A673. Hot spot stresses of K tubular joints subjected to combined loadings. - Ai-Kah Soh and Chee-Kiong Soh *(Nanyang Tech Univ, Nanyang Ave, Singapore 2263, Republic of Singapore)*. J Construct Steel Res 26(2-3) 125-140 (1993).

An approach has been proposed to verify, and modify if necessary, the conventional method for determining the peak hot spot stresses of various configurations of tubular joints subjected to combined loadings. A typical K tubular joint, which was subjected to various loading conditions, was employed to illustrate the proposed approach. It is found that the accuracy of the peak hot spot stresses estimated by the conventional method for combined loadings are closely related to the types of loading condition involved. This is due to the possible change in peak stress locations and directions when various basic load types are combined. The peak hot spot stresses of some combined loadings are significantly over estimated by the conventional method and, thus, can be reduced in order to provide accurate data for fatigue analysis.

There are two basic approaches to passive radar cross-sectional reduction, shaping to minimize backscatter, and coating for energy absorption and cancellation. Both of these approaches have to be used coherently to achieve required levels over the appropriate frequency range. Design details are extremely important.

10A676. Fracture mechanical analysis of a reactor pressure vessel under thermal shock loading. - P Reimers *(IwiS GmbH, Pariser Str 3, D-1000 Berlin 15, Germany)*. Comput Struct **47**(4-5) 815-827 (3 Jun 1993).

Improved knowledge of cooling conditions in nuclear power plants in the case of potential emergencies and increasing irradiation embrittlement of reactor pressure vessel materials are two reasons for the fact that the safety of plant components is under permanent observation. In a loss-of-coolant accident it is possible that the injected cooling water runs in stripes down the vessel wall. This causes high thermal stresses and high stress gradients in the wall combined with a decrease of fracture toughness of the ferritic material. Assuming a circumferential crack in this region the temperature and loadtime-dependent stress intensity factors along the crack front are to be determined and compared with the temperature and life-time-dependent material toughness for the evaluation of pressure vessel safety against unstable crack propagation. Considering a reactor pressure vessel in operation the necessary ADINA FE analysis of (i) transient heat transfer through the wall of the vessel and (ii) the stress and strain fields for thermoelastic-plastic material behaviors are presented. The virtual crack extension method was used for the calculation of J-integral values along the crackfront, which were converted into the stress intensity factors being compared with the material toughness.

10A677. Stress analysis method of U-shaped bellows and its experimental verification. - H Takatsu, M Yamamoto, M Shimizu, M Ohta *(Japan Atomic Energy Res Inst, Naka-machi, Naga-gun, Ibaraki-ken, Japan)*. Fusion Eng Des **22**(3) 239-250 (Apr 1993).

A new FEM modeling technique was developed for the stress analysis of the U-shaped bellows, which is more convenient for the stress analysis of such a complicated structure as the JT-60 vacuum vessel. In the present modeling method, the bellows are replaced by an orthotropic plate having the same rigidity as the bellows. The real stress of the bellows is obtained by transformation equations, which express a physical correspondence between the membrane stresses and bending moments of the orthotropic plate and those of the bellows. The applicability of the present modeling technique was verified using four kinds of test models. The experimental results agreed well with the computed ones, and the present stress analysis method of the U-shaped bellows was found to be sufficiently applicable to the stress analysis of the JT-60 vacuum vessel.

10A678. Axisymmetric residual stresses in tubes with longitudinally nonuniform stress distribution. - T Nishimura *(Dept of Mech Eng, Tokyo Metropolitan Col, Higashiohi 1-10-40 Shinagawa-ku, Tokyo 140, Japan)*. J Appl Mech **60**(2) 300-309 (Jun 1993).

New equations for calculating residual stress distribution are derived from the theory of elasticity for tubes. The initial distribution of the stresses including the shearing stress is computed from longitudinal distributions of residual stresses measured by the X-ray methods at the surface after removal of successive concentric layers of material. For example, the residual stresses of a steel tube quenched in water were measured by the X-ray diffraction method. The new method was also applied to a short tube with hypothetical residual stress distribution. An alternative FE analysis was made for a verification. The residual stresses computed by FE modeling agreed well with the hypothetical residual stresses measured. This shows that good results can be expected from the new method. The equations can also be used for bars by simple modification.

10A679. Stress analyses of wrinkle bends in pipelines. - NW Murray *(Dept of Struct Eng, Monash Univ, Clayton, Vic 3168, Australia)*. Thin-Walled Struct 17(1) 65-80 (1993).

Wrinkle bends are made by developing local outwards-directed folds at the intrados. The stresses can arise from any combination of internal pressure and change of angle, the latter often arising from thermal effects. Although wrinkle bends are not commonly used in large pipelines nowadays, there are many in existing pipelines built years ago. The paper shows that the stresses are mainly due to local bending of the pipe wall and have peak values which can be quite large especially on the inside surface of the highest point of the wrinkle. Graphs which enable these stresses to be evaluated separately for internal pressure and for longitudinal displacement (or thermal loading) are provided.

10A680. Dynamic analysis of a reinforced retaining wall using finite and infinite elements coupled method. - Chongbin Zhoa and S Valliappan *(Sch of Civil Eng, Univ of New S Wales, PO Box 1, Kensington, NSW 2033, Australia)*. Comput Struct **47**(2) 239-244 (Apr 1993).

A simplified method for the dynamic analysis of reinforced retaining walls during earthquakes is presented, based on the plane strain assumption and the concept of the equivalent material behind the wall. The dynamic soil-retaining wall interaction is included in this method and the system is divided into several subregions. The greatest merit of this simplified method lies in that it includes all the important factors which may affect the response of the reinforced retaining wall. Since this simplified method is based on the finite and infinite elements coupled method, not only can the natural soil and the reinforced retaining wall be simulated rigorously but also the wave propagation mechanism in the system can be modelled more realistically. Some numerical results from the analysis of a reinforced retaining wall under SV- and P-wave incidences demonstrate that the backfill soil behind the retaining wall has considerable effects on the dynamic response of the wall during higher frequency wave incidences and thus the change of material properties of the backfill should be considered in the seismic design of retaining projects.

292. Friction and wear

292B. FRICTION

10A681. Analysis of the friction behavior of bolted joints. - MB Karamis *(Eng Fac, Dept of Mech Eng, Erciyes Univ, 38090 Kayseri, Turkey)* and B Sulcuk *(Eng Fac, Dept of Mech Eng, Cumhuriyet Univ, Sivas, Turkey)*. Wear **166**(1) 73-83 (15 Jun 1993).

In this study, the effect of surface roughness of bolted joint members on the friction behavior of the joint was investigated by considering theoretical studies carried out previously. For this purpose, AISI 366 structural steel sheet was used as the sample material. After the contact areas of the samples were defined and polished to different surface qualities, the surface asperities were recorded and the samples were bolted under different compressional moments and then subjected to a torsional moment on a torsion machine. The effects of surface roughness, compressional moment and torsional angle on the torsional moment were determined. It was observed that the surface roughness plays a major role in the joint reliability. High R_a values of the interfaces lead to easy loosening of the joint. Therefore, improvement of the surface quality of mechanical joints is very useful for tightening the joints.

10A682. Mechanics of friction in self-lubricating composite materials I. Mechanics of second-phase deformation and motion. - N Alexeyev *(Inst for Problems in Mech, Moscow, Russia)* and S Jahanmir *(NIST)*. Wear **166**(1) 41-48 (15 Jun 1993).

This paper is devoted to the analysis of plastic deformation of self-lubricating composite materials that contain soft second-phase particles and are subjected to sliding friction. Slip-line field analysis of plastic deformation is used to analyze the processes of deformation and flow of the soft phase toward the sliding surface. As a result of this analysis, a general relationship for the deformation and flow of the soft phase is obtained. It is shown that the properties of both the hard matrix and the soft second-phase particles, as well as the shape and size of the particles, control the processes of deformation and flow of the soft phase. The results may be used to optimize the microstructure of self-lubricating composites to obtain the best tribological performance.

10A683. Mechanics of friction in self-lubricating composite materials II. Deformation of the interfacial film. - N Alexeyev *(Inst for Problems in Mech, Moscow, Russia)* and S Jahanmir *(NIST)*. Wear **166**(1) 49-54 (15 Jun 1993).

The process of film formation in self-lubricating composites and deformation of the film are analyzed by the slip-line field method. The results show that the size of the second-phase particles in the composite, the relative shear yield limit of the matrix and the soft phase, and the thickness of the film control the tribological performance of these composites. In a given contact condition, it is possible to modify the composite's microstructure to achieve an optimum performance, ie, the lowest possible coefficient of friction.

292D. WEAR (UNINTENTIONAL)

10A684. Unlubricated sliding wear of steels: The role of the hardness of the friction pair. - Singhai Bian, Sophie Maj, DW Borland *(Mat Group, Dept of Mech and Manuf Eng, Univ of Melbourne, Parkville, Vic 3052, Australia)*. Wear **166**(1) 1-5 (15 Jun 1993).

The influence of the hardness of the sliding elements on the unlubricated wear of steels has been investigated using a pin-on-ring configuration. Pins of quenched-and-tempered steel with varying hardness have been tested against countersurfaces that are also in the quenched and tempered condition and with a similar range of hardness. A change in the predominating wear process of the pin, from oxidative to metallic wear, occurs as the hardness of the countersurface decreases, for constant hardness of the pin.

10A685. Wear behavior of acetal gear pairs. - AR Breeds, SN Kukureka *(Sch of Metall and Mat, Univ of Birmingham, Edgbaston, Birmingham, B15 2TT, UK)*, K Mao, D Walton, CJ Hooke *(Sch of Manuf and Mech Eng, Univ of Birmingham, Edgbaston, Birmingham, B15 2TT, UK)*. Wear **166**(1) 85-91 (15 Jun 1993).

The wear behavior of polymer gear pairs has been little studied. Most wear studies have used pin-on-disc or polymer against steel tests. The non-conformal contact and high transient temperatures in polymer gear pairs make it essential to study wear under actual running conditions. This paper describes the design and operation of a novel test rig for measuring the wear behavior of polymer gears continuously. Preliminary results are presented and comparisons made between failures in acetal and nylon. Wear of acetal gears is studied in more detail. It is shown that wear of acetal gears is a complex process. Optical and scanning electron microscopy show the driving and driven gears to have different features on the worn flanks, with a ridge forming at the pitch line on the driven gear and a valley on the driving gear. The wear surfaces over the addendum and dedendum are also strikingly different. This is related to the direction of rolling and friction forces on each gear face. The limits to the use of acetal as a gear material are considered. At low torques, life is limited by wear and at high loads the maximum permissible surface temperature is a limiting factor.

292E. CONTACT FATIGUE

10A686. Effect of ferrite contents on the contact fatigue property of medium carbon alloy steels. - JL Huang, YM Zhu, EY Shao *(Dept of Mat Eng, Luoyang IT, 471039 Henan, China)*. Wear **166**(1) 101-105 (15 Jun 1993).

The subcritical quenching technique was used in large size gear steels 45CrMnMo and 42CrMo to obtain ferrite and martensite compound structures with different ferrite contents. The effects of ferrite content on the contact fatigue properties of the two gear steels were investigated in systematic contact fatigue tests. The results show an obvious influence of ferrite content on the pitting lives of the tested steels. The pitting lives increase continuously with increasing ferrite content in the structures until they reach peak values with corresponding ferrite contents of 12% and 10% for 45CrMnMo steel and 42CrMo steel respectively.

10A687. Determination of probabilistic characteristics of the microgeometry of composite surfaces. - VS Luk'yanov, VR Soloveichik, AM Bykov *(Moscow, Russia)*. J Machinery Manuf Reliab **6** 46-51 (1992).

The probabilistic characteristics (the distribution and correlation functions) of a surface formed by superposition of roughnesses of different technologies origin are characterized by specific functional behavior, are obtained. The surfaces under study include those obtained by plateau honing and mechanical working of porous and sintered materials.

10A688. Development of plasma sprayed lubricant free slide plates with ceramic coat for railway use. - H Ono, T Teramoto *(R&D Dept, Nippon Sharyo, Nagoya, Atsuta, Japan)*, T Shinoda *(Dept of Mat Processing, Nagoya Univ, Furo-cho, Chikusa-ku, Nagoya, Japan)*. Mat Manuf Processes **8**(4-5) 451-463 (Jul-Sep 1993).

Ceramic coated slide plates were developed in order to ensure smooth sliding of the tongue rail and tight contact with stock rail. The 0.5 mm thickness thin metallic bonded layer was synthesized by spraying ceramic powders using conventional plasma spraying technique. Coated materials were mostly Al_2O_3 ceramic including metallic materials. It is concluded field tests that coated plates satisfied endurance specifications, corrosion, wear and load specifications without any maintenance of ceramic coated plates. Since field tests have been successfully performed, more than 10 000 slide plates are being used in Japan by Shin-kansen Rail Way and private railway companies.

10A689. Effect of atmospheric humidity on the dynamic fracture strength of SiC abrasives. - J Larsen-Basse *(NSF, 1800 G St NW 1108, Washington DC 20550)*. Wear **166**(1) 93-100 (15 Jun 1993).

Silicon carbide abrasive grits were fractured dynamically in a roller crusher at ambient temperature and under controlled levels of atmospheric humidity, covering the full range from 10 to 100% relative humidity. The fracture stress depends strongly both on the grit size below a certain value and on the partial pressure of the water vapor. The size effect causes an increase in fracture stress as the grit diameter is decreased below a certain size. This is thought to be due to scaling of the size of pre-existing surface defects with grit diameter. The moisture effect causes a drop in fracture stress at any moisture level above 0% relative humidity (rh) for sufficiently small specimens, while the number of fragments created in the crushing process increases. This effect is thought to be due to moisture-assisted sharpening of the tips of surface defects, which serve as crack initiation sites, during the early stages of loading. The tip sharpening facilitates initiation of brittle fracture. It lowers the measured fracture stress and enables smaller defects to initiate secondary fractures when the stored elastic energy suddenly is released during the primary fracture; therefore, more fragments form. The results explain the previously observed moisture-assisted self-sharpening of abrasives which may result in increased abrasive wear rates for metals as the levels of atmospheric moisture increase. The results may also have implications for the interpretation of certain types of ceramic wear.

10A690. Friction and wear behavior of a number of ceramic-coated steels matched as sliding pairs to various surface-treated steels. - YL Su and JS Lin *(Dept of Mech Eng, Natl Cheng Kung Univ, Tainan 70101, Taiwan, ROC)*. Wear **166**(1) 27-35 (15 Jun 1993).

Ceramic-coated steels (WC + 12%Co and Cr_3C_2 + 25%NiCr applied by continuous detonation spraying, and Cr_2O_3 applied by plasma spraying) were mated as sliding pairs to surface-treated steels (case hardened, tufftrided) under both dry wear and lubricated conditions in order to assess their tribological potential. Under dry wear conditions, WC-Co demonstrates the lowest coefficient of friction but surface-treated steels paired with Cr_3C_2-NiCr possess the best wear resistance under both dry wear and lubricated conditions. Five different types of generalized friction behavior were identified among the pairs studied. Under dry wear conditions, the worn surface of Cr_3C_2-NiCr is covered with continuous and "island"-transferred layers, while that of Cr_2O_3 exhibits numerous cracks. The worn surface of WC-Co can be divided into four distinct regions, each possessing a major wear characteristic in addition to that of surface polishing. Wear mechanisms for TF1 surface-treated steels include surface polishing, strain fatigue and fracture of the work-hardened layer, while those for carburized steel include surface polishing, plastic deformation, material transfer and pile-up of back-transferred material. Under lubricated conditions, the amount of material transferred is reduced.

10A691. Role of oxidation in the wear of plasma nitrided and PVD TiN coated steel. - Y Sun and T Bell *(Sch of Metall and Mat, Univ of Birmingham, Birmingham B15 2TT, UK)*. Wear **166**(1) 119-125 (15 Jun 1993).

The wear behavior of plasma nitrided En40B steel has been investigated under dry rolling contact with applied sliding traction. Particular attention has been paid to the examination of the tribochemical reaction, ie, oxidation, of the nitrided surface during the wear process. X-ray diffraction, optical and scanning electron microscopes have been employed to study the wear debris, worn surfaces and subsurfaces. Experiments revealed that, as a result of the hardening effect induced by plasma nitriding, wear of nitrided steel occurred in a mild mode via oxidation of the contact surfaces and the subsequent removal of the oxide products, and the overall wear rate was dominated by the rate of oxidation of the contact surfaces. However, the unnitrided steel was worn via surface and subsurface shear deformation, leading to severe wear. In order to further improve the wear resistance of the steel, a thin, hard titanium nitride (TiN) coating was deposited on top of the nitrided steel by ion plating. Such duplex treated steel possessed superior resistance to both subsurface shear deformation and tribo-oxidation, thus ensuring minimization of the wear rate.

10A692. Use of brittle strain-sensitive coatings in strength tests of full-scale aircraft structures. - AN Salin, BN Ushakov, AI Kosenko, NA Stepanov *(Moscow, Russia)*. J Machinery Manuf Reliab 6 91-96 (1992).

Some results of using the method of brittle strain-sensitive coatings for analyzing strain and stress fields in elements of aircraft structures, are presented. The research has been carried out jointly by the Institute of Machines Science at the Russian Acad of Sciences, Tupolev Special Design Bureau, and some other organizations.

292I. WEAR MONITORING

10A694. Antiwear mechanism of zinc dialkyl dithiophosphates added to a paraffinic oil in the boundary lubrication condition. - H So, YC Lin *(Dept of Mech Eng, Natl Taiwan Univ, Taipei 10617, Taiwan, ROC)*, Gibbs GS Huang, Terny ST Chang *(Refining and Manuf Res Centre, Chinese Pet, Chia-Yi 60036, Taiwan, ROC)*. Wear 166(1) 17-26 (15 Jun 1993).

The antiwear mechanism and performance of various zinc dialkyl dithiophosphates (ZDDPs) used in paraffin oil under the boundary lubrication condition are studied extensively. The condition of boundary lubrication is achieved with a flat-on-flat reciprocating sliding contact which can simulate the contacting condition near the top and bottom dead ends of a piston ring with the cylinder wall in an automotive engine. Three types of ZDDP, namely primary, secondary and commercial ZDDPs, are used as the antiwear additive. the antiwear performance of each ZDDP is evaluated with the contact (electrical) resistance and the worn scars on the contact surfaces. Then it is confirmed by electron spectroscopy for chemical analysis or energy-dispersive X-ray analyses on the worn surfaces. The results confirm that the antiwear mechanism depends upon the ratio of the rate of film formation to the rate of scraping the existing film. The compositions of the film formed on the contact zone affect this ratio but depend on the oil temperature and the condition of surface finish of the specimens. In general, the primary ZDDPs yield poor antiwear performance in a wide range of testing temperatures. The mixture of two secondary ZDDPs or the commercial ZDDPs provide much better antiwear performance. The formation of paste-like materials on the contact area at temperatures over 120°C also yields antiwear performance, but the paste formed with the lubricant added with ZDDPs provides a better antiwear performance.

10A695. New sensor for real-time milling tool condition monitoring. - C James Li *(Dept of Mech Eng, Columbia Univ, New York NY 10027-6699)* and SY Li *(Dept of Precision Machinery and Instruments, Changsha IT, Peoples Rep of China)*. J Dyn Syst Meas Control 115(2A) 285-290 (Jun 1993).

A new sensor has been developed to automatically detect face-milling insert fracture chipping, and wear. With a befitting PVDF (polyvinylidene fluoride) sensor, and an optical transmitter based on frequency modulation technique, a miniature sensor, with little influence on the cutting process, was positioned very close to the cutting site. Due to this closeness, the state of the insert can be reliably recognized with extremely simple and fast algorithms. A tool wear index which is sensitive to wear but insensitive to cutting conditions, a tool fracture index, and a chipping recognition scheme based on a linear pattern classifier have been developed and proven to be effective by experimental data.

10A696. Wear resistance of Ni-hard 4 and high-chromium cast iron re-evaluated. - Jinzhu Liu, Shizhuo Li, Yongfa Man *(Inst of Metal Res, Acad Sinica, Shenyang 110015, China)*. Wear 166(1) 37-40 (15 Jun 1993).

A comparison of the wear resistances of Ni-hard 4 and high-chromium (15-3) cast irons has been made under different testing conditions. Several kinds of wear tester were employed (reciprocating grooving tester, dry sand rubber wheel tester, single-pass pendulum impact grooving tester, and blasting erosion tester). The results show that whereas Ni-hard 4 seems to be more suitable to resist blasting erosion, high-chromium cast iron is better at resisting grooving wear, the ranking of materials changing with testing conditions. The measured wear resistance of the irons has been explained in terms of microstructure and hardness. Material removal occurred as a result of different mechanisms. For grooving wear, a harder metal surface is preferable, under blasting erosion conditions, material removal is mainly determined by the matrix.

10A697. Necessary and sufficient conditions for homokinetic transmission in chains of Cardan joints. - DA Johnson and PY Willems *(Dept of Mech Eng, Univ Catholique, Louvain-la-Neuve, Belgium)*. J Mech Des 115(2) 255-261 (Jun 1993).

The classical double universal joint for constant velocity ratio transmission is subject to strict geometrical requirements as regards configuration, and it is generally accepted that similar constraints also prevail for longer chains of joints. This paper examines the constant velocity conditions from a necessary point of view and establishes new configuration possibilities for chains of 3 or more joints, which allow to envisage more flexible design in some applications.

10A698. Redundant-drive backlash-free robotic mechanisms. - Sun-Lai Chang and Lung-Wen Tsai *(Mech Eng Dept and Syst Res Center, Univ of Maryland, College Park MD 20742)*. J Mech Des 115(2) 247-254 (Jun 1993).

In this paper, we introduce a new and innovative concept for the control of backlash in gear-coupled robotic mechanisms. Based on this concept, a methodology for the enumeration of admissible redundant-drive backlash-free robotic mechanisms has been established. Some typical 2 and 3 dof mechanisms have been sketched. Furthermore, actuator torques have been derived as functions of either joint torques or end-effector dynamic performance requirements.

10A699. Refined concept of the contact strength of gearings and the prospects for increasing their reliability. - RM Ignatishchev *(Mogilev, Russia)*. J Machinery Manuf Reliab 6 59-61 (1992).

In the process of normal operation of a gearing the teeth radii of curvature may suffer substantial changes. The recognition of this fact opens new vistas on the way to improving design calculations, allows developing an unprecedented industrial method for predicting the onset of pitting and increasing longevity of gears whose module exceeds 5 mm, by a factor of 2 to 5.

10A700. Load characteristics of radial cylindrical aerostatic supports with discrete sources. - VS Balasan'yan *(Moscow, Russia)*. J Machinery Manuf Reliab 6 52-58 (1992).

A method for calculating load characteristics and optimal parameters of radial cylindrical aerostatic supports with discrete sources is discussed. The method is based on introduction of discreteness, nonlinearity, and double-throttling coefficients into formulae obtained by solving analytically the gas-lubrication problem for small eccentricities and taking into account circumferential flow.

10A701. Routes to chaos in ball bearings. - B Mevel *(SNR Roulements, 1 rue des usines BP 17, F74010 Annecy, France)* and JL Guyader *(Lab Vibrations Acoustique Bt303, INSA de Lyon, 20 ave A Einstein, F69621 Villeurbanne Cedex, France)*. J Sound Vib 162(3) 471-487 (22 Apr 1993).

The dynamic motion of a lightly loaded ball bearing is studied in order to show and to gain understanding of the different mechanisms involved in transitions to chaotic behaviors. By varying a control parameter, different routes to chaos are described. The most widely known is the subharmoic route, which is characterized by an increasing number of subharmonics of the driving frequency. Alternance of period doubling and tripling has been noticed, as the ball pass frequency is around the first resonance of the bearing. The second route is a quasi periodic route. It is characterized by competition between the second resonance of the bearing and the ball pass frequency. It results in an increasing number of combinations of two incommensurate frequencies. During the quasi periodic sequence, mode locking occurs each time the two frequencies are locally commensurate. The last type of chaos that is observed is involved by the quasi periodic breakdown of an attractor. It looks like intermittency and, in the present case, it is obtained by introduction of some over sized balls. Finally, the occurrence of loss of contact between balls and raceways is studied and related to the existence of chaos.

10T702. Present and future technology for seals. - Shoji Shiomi *(R&D No 2 Dept, Eagle Indust, 1500 Katayanagi Sakado-shi, Saitama 350-02, Japan)*, Hiroo Tanoue *(Product Planning Dept, Eagle Indust, 1500 Katayanagi Sakado-shi, Saitama 350-02, Japan)*, Hidekazu Takahashi *(Seal Equip No 1 Dept, Eagle Indust, 1500 Katayanagi Sakado-shi, Saitama 350-02, Japan)*. Japan J Trib 37(9) 1139-1147 (1992).

10A703. Dimensional synthesis of closed-loop linkages to match force and position specifications. - C Huang and B Roth *(Dept of Mech Eng, Stanford)*. J Mech Des 115(2) 194-198 (Jun 1993).

By combining classical kinematic synthesis and static synthesis, we consider force conditions as well as motions in the dimensional synthesis of linkages. We are concerned with determining the dimensions of linkages that guide a rigid body through several positions and support a specified external load at each position. Three types of planar linkages are studied in detail: four-bar, slider-crank, and double-slider linkages. Incompletely specified problems and spring element synthesis are also discussed.

296C. BALANCING

10A704. Balancing of multithrow double-shaft separating mechanisms. - AB Roitman, SL Ryagin, AD Shamrovskii *(Zaporozh'e)*. J Machinery Manuf Reliab 6 21-26 (1992).

Balance of forces and moments of inertia acting on multithrow double-shaft separating mechanisms is analyzed by considering a five-section strawwalker of a harvester. Balanced shaft configurations differing only in the relative positions of cranks, are obtained. By varying cranks radii and section masses, balanced configurations with minimum stresses in the critical cross-sections, are found.

296E. OPTIMIZED DESIGN

10A705. Determination of optimal dimensions of the units of a rotor flow-modulation apparatus. - AM Balabyshko and AI Zimin *(Tula)*. J Machinery Manuf Reliab **6** 62-67 (1992).

The rotor flow-modulation apparatus considered in this paper, has been designed for generating fine stable emulsions and is the best of its kind. It was awarded the Golden Medal of the USSR Exhibition of the Achievements of People's Economy and surpasses the best domestic and foreign analogues in many technological and economic indicators.

296F. KINEMATICS OF MECHANISMS

10A706. Analytical method for the identification of redundant constraints in multiple-loop spatial mechanisms. - R Srivatsan, DA Hoeltzel, A Das *(Lab for Intelligent Des, Dept of Mech Eng, Columbia Univ, New York NY 10027)*. J Mech Des **115**(2) 324-331 (Jun 1993).

An analytical method for the explicit identification of redundant constraints in multiple-loop spatial mechanisms is presented. The kinematic constraint equations for each independent loop of multiple-loop mechanisms are developed. The independence of these equations is established and used to detect the presence of redundant constraints. The nature of the redundant constraints present is indicated by the type of redundant kinematic constraint equations present. Interaction of the constraints of adjacent loops in a multiple-loop mechanism also has to be taken into account. An example which illustrates the identification of redundant constraints in a cardan joint has been included to demonstrate the utility of this approach for real-world mechanism design problems. General guidelines for the elimination of redundant constraints, following their identification, are also provided.

10A707. Circuit analysis of Watt chain six-bar mechanisms. - JA Mirth *(Dept of Eng, Univ of Denver, Denver CO 80208)* and TR Chase *(Productivity Center, Mech Eng Dept, Univ of Minnesota, Minneapolis MN 55455)*. J Mech Des **115**(2) 214-222 (Jun 1993).

The number of circuits and the extent of each circuit are shown to be determinable from the circuit attributes of the two component four-bars and by the limits of motion that these two four-bars place on each other. The circuit composition of all pin jointed Watt mechanisms is summarized in chart form. The chart enables detecting a change of circuit between any two trial positions of the same mechanism. The chart is suitable for both automated and manual analysis. Examples of circuit analysis of both Watt I and Watt II mechanisms are provided.

10A708. Circuits and branches of single-dof planar linkages. - TR Chase *(Mech Eng Dept, Productivity Center, Univ of Minnesota, Minneapolis MN 55455)* and JA Mirth *(Dept of Eng, Univ of Denver, Denver CO 80208)*. J Mech Des **115**(2) 223-230 (Jun 1993).

Improved definitions for circuits and branches of mechanisms are proposed and discussed in application to planar linkages. The difficulty of circuit and branch identification of multi-loop planar linkages is introduced. The nomenclature used by various authors is correlated with the definitions proposed here. The danger of confusing circuits with branches is illustrated by demonstrating that mechanisms satisfying published "branch" criteria may actually require disassembly to reach all desired positions, rendering them useless in practice. Furthermore, a change of branch within a circuit is shown to be irrelevant to some applications.

10A709. Five position triad synthesis with applications to four and six-bar mechanisms. - T Subbian and DR Flugrad Jr *(Mech Eng Dept, Iowa State Univ, Ames IA 50011)*. J Mech Des **115**(2) 262-268 (Jun 1993).

The displacement equations for triads with motion generation and prescribed timing capabilities are developed and cast in polynomial forms. These equations are solved for five precision points using a continuation method. A detailed description of the method used to generate the solution curves is provided in the paper. Two infinities of solutions can be obtained for the problem under consideration as we are solving four equations in six unknowns. The solution procedure discussed is applied to synthesize a four-bar function generating mechanisms and a six-bar mechanism.

10A710. Opposite pole quadrilateral as a compatibility linkage for parameterizing the center point curve. - JM McCarthy *(Dept of Mech Eng, UC, Irvine CA 92717)*. J Mech Des **115**(2) 332-336 (Jun 1993).

In planar four-position kinematics, the centers of circles containing four positions of a point in a moving rigid body form the center point curve. This curve can be parameterized by analyzing a "compatibility linkage" obtained from a complex number formulation of the four-position problem. In this paper, we present another derivation of the center point curve using a special form of dual quaternions and the fact that it is identical to the pole curve. The defining properties of the pole curve lead to a parameterization by kinematic analysis of the opposite pole quadrilateral as a four-bar linkage. Thus the opposite pole quadrilateral becomes the compatibility linkage. This derivation generalizes to provide parameterizations for the center point cone of spherical kinematics and the central axis congruence of spatial kinematic theory.

10A711. Optimum tolerancing of planar mechanisms based on an error sensitivity analysis. - WL Cleghorn, RG Fenton, Jing-fan Fu *(Dept of Mech Eng, Univ of Toronto, Toronto, ON M5S 1A4, Canada)*. J Mech Des **115**(2) 306-313 (Jun 1993).

This paper presents an analytical procedure to determine the optimum set of tolerance bands of the dimensions of a planar mechanism. The analysis technique presented permits identification of the most sensitive link dimension, the most sensitive combination of input errors, and the most sensitive period within the entire cycle, which make the largest contribution to the output error. The optimum tolerancing procedure is then presented. Examples applied to single and multiple loop mechanisms are included.

10A712. Stewart platform of general geometry has 40 configurations. - M Raghavan *(Power Syst Res Dept, General Motors Res Labs, 30500 Mound Rd, Warren MI 48090-9055)*. J Mech Des **115**(2) 277-282 (Jun 1993).

The forward kinematics problem for the Stewart platform may be stated as follows: given the values of the six prismatic joint displacement inputs to the linkage, compute the position and orientation of the coupler link. This problem may be set up as a system of nonlinear multivariate polynomial equations. We solve this problem using a numerical technique known as polynomial continuation. We show that for Stewart platforms of general geometry (ie, platforms in which the linkage parameters are arbitrary complex numbers) this problem has 40 distinct solutions.

10A713. Design of multi-dof mechanisms for optimal dynamic performance. - Z Shiller and S Sundar *(Mech Aerospace and Nucl Eng Dept, UCLA)*. J Mech Des **115**(2) 199-206 (Jun 1993).

Design methods for selecting the actuator sizes and the link lengths of multi-dof mechanisms for minimum time motions along specified paths and between given end points are presented. The design problem is first formulated as a parameter optimization, using the actuator sizes and the link lengths as the design variables, and motion time along the path as the cost function. A more efficient method for obtaining near-optimal designs is then presented, based on the acceleration lines which have been shown to approximate the geometric shapes of time optimal paths. Near-optimal designs are simply obtained by curve fitting the acceleration lines to the desired path, or to the end points. Examples of the design of two and five-bar mechanisms demonstrate significant reductions in motion times for the optimal and the near-optimal designs, and significant savings in computation time for the approximate method.

10A714. Modal analysis solution technique to the equations of motion for elastic mechanism systems including the rigid-body and elastic motion coupling terms. - AG Jablokow *(Dept of Mech Eng, Penn State)*, S Nagarajan *(IBM Corp, Rochester MN 55901)*, DA Turcic *(Dept of Mech Eng, Univ of Wisconsin, Madison WI 53706)*. J Mech Des **115**(2) 314-323 (Jun 1993).

This paper presents a modal analysis solution technique for the matrix equations of motion of elastic mechanism systems including the rigid-body elastic motion coupling terms and general damping. The results obtained using the techniques developed within show this is true for some, but not all mechanisms. The solution technique adds the rigid-body elastic motion coupling terms to the system mass, damping, and stiffness matrices thus allowing them to affect the system response appropriately. The resulting nonsymmetric matrices are then rewritten in first order form allowing general damping to be included in the analysis. Modal analysis techniques are utilized to solve for the steady-state response of the elastic mechanism system. A number of examples are presented that establish the validity of this approach to the solution of the matrix equations of motion for elastic mechanism systems. The results show that the rigid-body elastic motion coupling terms can become significant at higher operating speeds.

10A715. Asymptotic estimates of the probability of failure-free performance, obtained using "load-resistance" models. - VV Bolotin and VP Chirkov *(Moscow, Russia)*. J Machinery Manuf Reliab **6** 1-7 (1992).

Estimates of the probability of failure-free performance, obtained using "load-resistance" models, are proposed. The estimates are based on asymptotic distributions of extreme values of random quantities and approximation of integrands by asymptotic expansions and are the more accurate the smaller the failure probability. The estimates may be used for numerical prediction of safety indicators of technological objects with the help of structural integrity criteria.

298B. MECHANICAL JOINTS

10A716. Connections in cold-formed steel. - A Toma *(TNO Build and Construct Res, Delft, Netherlands)*, G Sedlacek, K Weynand *(Inst of Steel Construct, RWTH Aachen, Germany)*. Thin-Walled Struct **16**(1-4) 219-237 (1993).

A survey has been given of the fastening possibilities in cold-formed steel, being mechanical fasteners, welding and adhesive bonding. The selection of a fastening type should not be based only on structural requirements but also on non-structural requirements. For the mechanical properties of the connections has been referred to Eurocode 3 part 1.3. Furthermore, background studies has been presented for the rules for the mechanical fasteners. These studies are based on statistical evaluations and have led to improved versions of existing design rules and a uniform partial safety factor for resistance.

10A717. Design of bolted joints in cold-formed steel sections. - ER Bryan *(Univ of Salford, Manchester, UK)*. Thin-Walled Struct **16**(1-4) 239-262 (1993).

This paper gives background information on the behavior of bolted joints and the parameters that affect strength and flexibility. Design expressions for the bearing strength of bolted joints and for the joint movement under load are also given. Moment connections are considered and design expressions for moment capacity and moment-rotation relationships for various bolt groups under practical conditions are given. Computer analysis of cold-formed steel assemblies is outlined and two worked examples of manual analysis, incorporating the above design expressions, are given. It is shown how economical design may be achieved by selecting the correct semi-rigid joint in such assemblies.

10A718. Effect of slit nuts on durability of threaded connections manufactured of heat-resistant steels and subjected to cyclic loading. - RV Kagan and VA Kagan *(Vilnius)*. J Machinery Manuf Reliab 6 37-42 (1992).

A technique for estimating the coil-by-coil stressed state in threaded connections with longitudinally slit nuts, is discussed. Recommendations on disassembly and optimal design, substantiated by the results of service-life tests, are given. Cyclic durability was increased by a factor of 1.5 to 2.0.

10A719. Effects of eyebar shape and pin-hole tolerance on its ultimate strength. - YS Choo, KC Choi, KH Lee *(Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*. J Construct Steel Res **26**(2-3) 153-169 (1993).

The present paper addresses the problem of the nonlinear elasto-plastic behavior of an eyebar or pin-connection under increasing quasi-static load with reference to the effects of shape and pin-hole tolerance on the ultimate strength. The study uses ABAQUS to model the geometric and material nonlinearities of the eyebar and the boundary nonlinearity due to the increasing contact between the pin and plate-around the hole. The results are compared with those of other investigators and are found to be accurate. The effect of shape on ultimate strength is found to be limited. For an eyebar with given hole and plate dimensions, there appears to be an approximately linear reduction in strength due to an increase in pin-hole tolerance within the range of parameters investigated.

10A720. Analysis of welding-induced residual stresses with the ADINA system. - WW Wilkening and JL Snow *(Knolls Atomic Power Lab, General Electric, Schenectady NY 12301)*. Comput Struct **47**(4-5) 767-786 (3 Jun 1993).

The welding-induced residual stresses analysis procedure (WIRSAP), based on the ADINA system of nonlinear FE software, is described and the results of several WIRSAP analyses are discussed. Several 2D axisymmetric WIRSAP analyses have been performed for pipe girth welds and for several multi-pass girth-like welds attaching small nozzles to large, thick-walled pressure vessels. The analytical methodology follows closely the basic techniques outlined by Rybicki *et al*, enhanced by the use of several specialized modeling techniques available in the ADINA system. For example, the element birth option is used to simulate the addition of weld metal, and the mixed pressure-displacement element formulation is used, in conjunction with the temperature-dependent bilinear plasticity material model. Some of the welds analyzed involve backing rings, which were subsequently "machined off" via use of the element death option. The auto-time-stepping algorithm and the matrix update iteration scheme are used in the structural solutions. WIRSAP involves, in general, a pass-by-pass analysis of the uncoupled thermal and structural problems, but some analyses have been performed with an "enveloping" technique for grouping several weld passes together to study the feasibility of modeling multi-pass welds on a layer-by-layer basis.

10A721. Closed-loop control of a weld penetration using front-face vision sensing. - YM Zhang, R Kovacevic *(Center for Robotics and Manuf Syst and Dept of Mech Eng, Univ of Kentucky, Lexington KY)*, L Wu *(Natl Lab for Welding, Harbin IT, Harbin, China)*. J Syst Control Eng **207**(I1) 27-34 (1993).

Feedback control of weld penetration based on a front-face sensor is a challenging problem in the field of welding. A novel vision-based approach is proposed in this paper for full penetration control of the gas tungsten arc welding (GTAW). Owing to the relationship between the front-face weld geometry and the back-face weld width (representation of the full penetration state), which has been reported earlier by the present authors, it is possible to use the front-face geometry as feedback of full penetration. Based on the dynamic modeling and the analysis of accepted adaptive control algorithms, an adaptive predictive decoupling controller is developed. Simulations and experiments under a variety of welding conditions have been conducted to verify the effectiveness of the proposed approach and controller.

10A722. Computer-aided design of explosive welding systems. - PV Vaidyanathan and AR Ramanathan *(Fac of Eng and Tech, Annamalai Univ, Annamalainagar 608 002, India)*. J Mat Processing Tech **38**(3) 501-516 (May 1993).

Whilst explosive welding has reached the stage of commercial application in some parts of the globe, it remains at laboratory and research level in other parts. The techniques, the development of the right explosives, parameter optimization and know-how are kept secret. Despite a thorough understanding of the process through theoretical and experimental studies, optimization attempts had been, by and large, through trial-and-error means. The authors propose a procedure for the optimum fool-proof design of explosive welding systems. The procedure is based on the basic requirements of explosive bonding and conditions favorable for producing acceptable strong welds. A computer program has been developed for determining the optimum values of parameters of practical importance. The program is useable for clad plates of different metal combinations and thicknesses. The results obtained through the CAD not only suggest the correct explosive, its optimum loading and best suited geometry for acceptable strong welds, but also predicts the nature of the resulting interface. The authors believe that the CAD procedure proposed will be useful for both researchers and industry, as a means of avoiding trial-and-error.

10A723. Estimation of weld pool sizes in GMA welding process using neural networks. - TG Lim and HS Cho *(Dept of Autom and Des Tech Eng, Korea Adv Inst of Sci and Tech, Seoul, Korea)*. J Syst Control Eng **207**(I1) 15-26 (1993).

In gas metal arc (GMA) welding processes, the geometrical shape and size of the weld pool are utilized to assess the integrity of the weld quality. Monitoring of these geometrical parameters for on-line process control as well as for on-line quality evaluation, however, is an extremely difficult problem. The paper describes the design of a neural network estimator to estimate weld pool sizes for on-line use in quality monitoring and control. The neural network estimator is designed to estimate the weld pool sizes from surface temperatures measured at various points on the top surface of the weldment. The main task of the neural network is to realize the mapping characteristics from the point temperatures to the weld pool sizes through training. The chosen design parameters of the neural network estimator, such as the number of hidden layers and the number of nodes in a layer, are based on an estimation error analysis. A series of bead-on-plate welding experiments were performed to assess the performance of the neural network estimator. The experimental results shows that the proposed neural network estimator can estimate the weld pool sizes with satisfactory accuracy.

10A724. Behavior of bolted joints tightened in plastic region: Analysis based on rigid-plastic model. - Hirokazu Tsuji and Kazuo Maruyama. J Japan Soc Precision Eng **59**(4) 589-594 (Apr 1993).

The axial tension of the bolt in the plastic region tightening method depends on the yield point load of the threaded portion under the combined loads of the axial tension and the thread torque induced by the tightening. A new estimation method for the yield point load of the threaded portion is proposed taking account of the general yield criterion based on the rigid-plastic solution for combined loads. Considering the coefficient of friction at the flank of the thread and the residual thread torque after tightening, simple formulas are derived for the yield clamping force and the maximum additional axial tension under externally loading. It is confirmed from the experimental results obtained by a combined loading test that the proposed estimation method is superior to the conventional one taking into account only the local yield criterion. Upon applying the local or general yield criterion, the range of the initial clamping force is bounded between the elastic region tightening, the yield point tightening and the plastic region tightening.

10A725. Dependence of contact durability on the hardened layer thickness. - ON Chermenskii *(Moscow, Russia)*. J Machinery Manuf Reliab **6** 43-45 (1992).

It is shown that the thickness of a hardened surface layer of a rolling part operating for a long time under load, should be no less than $b/2$. Experimental data on contact durability of specimens with a carburized surface layer of variable thickness, are presented. For thicknesses less than $b/2$ durability is shown to decrease drastically.

V. MECHANICS OF FLUIDS

350. Rheology

10A726. Applicability of simplified expressions for design with electro-rheological fluids. - D Brooks *(Adv Fluid Syst, 10-14 Pensbury Indust Estate, Pensbury St, London SW8 4TJ, UK)*. J Intelligent Mat Syst Struct **4**(3) 409-414 (Jul 1993).

There are three key factors that enable electrorheological (ER) fluids to be related to engineering hardware: *off-state*, which is characterized by the suspension viscosity; *on-state*, which is characterized by the excess shear stress; and *power requirement*, which is characterized by the current density. This article discusses the potential benefits of using ER fluids and outlines some of the basic design problems. Some simplified expressions are derived that permit parametric design of ER fluid-based systems.

10A727. Axial laminar channel flow of a Williamson liquid: Convergence of approximate solutions. - M Fortova *(Inst of Hydrodyn, Acad of Sci, Podbabska 13, 166 12 Prague 6, Czech Republic)*. Acta Tech CSAV **38**(2) 153-166 (1993).

To solve the equations of flow for a Bingham liquid, it is usually necessary to use a numerical method, even when the model is parametrized or replaced by a similar model. Proof is given in the paper for the existence and the uniqueness of the close solution for the Williamson model and for the convergence of approximate solutions. The problem is nonlinear and it is, therefore, convenient to solve it by minimization of the functional, whose characteristics were also studied.

10A728. Electrorheological material under oscillatory shear. - JH Spurk *(Tech Hochshule, Petersenstr 30, 6200 Darmstadt, Germany)* and Zhen Huang *(August Bilstein, Postfach 1151, 5828 Ennepetal, Germany)*. J Intelligent Mat Syst Struct **4**(3) 403-408 (Jul 1993).

Two typical electrorheological materials, which are anhydrous dispersions of silica particles in silicone oil with surface active additives are sheared in oscillatory motion in a gap, formed by an outer fixed cylinder and an inner, axially movable cylinder. The rheometer is operated at tuneable resonance frequencies, such that only the reaction of the material is measured. Long time oscillatory shear measurements show that the electroviscous stress deteriorates under dc electric field, while electroviscous stress is stable when ac fields are used. Electroviscous stress is found to depend on field frequency through the dependence of the dielectric constant of the disperse phase on field frequency. A dim[illegible]ss quantity, which relates the electr[illegible]tress to the electric field strength[illegible] all the experimental data for [illegible]li-tudes and shear frequencies for each fluid. The phenomenological theory of Huang and Spurk predicts this efficiency with satisfactory accuracy.

10A729. Energy considerations in the flow enhancement of viscoelastic liquids. - A Siginer and A Valenzuela-Rendon *(Dept of Mech Eng, Auburn Univ, Auburn AL 36849)*. J Appl Mech **60**(2) 344-351 (Jun 1993).

Flow enhancement effects due to different waveforms in the tube flow of rheologically complex fluids driven by a pulsating pressure gradient are investigated. It is found that the squarer the waveform the larger the enhancement. In each case the enhancement is strongly dependent on the viscosity function, but the elastic properties also play an important role. We determine that considerable energy savings may be obtained in the transport of viscoelastic liquids if an oscillatory gradient is superposed on a mean gradient. The closer the oscillation to the square wave the larger the energy savings.

10A730. Die swell in semi-rigid polymer solutions. - C Allain, M Cloitre *(Lab Fluides, Automatique et Syst thermiques, Bat 502, Campus Univ, 91405 Orsay, Cedex, France)*, P Perrot, D Quemada *(Lab de Biorheologie et d'Hydrodyn physicochimique, Tour 33-34, 2 place Jussieu, 75230, Paris, Cedex 05, France)*. Eur J Mech B **12**(2) 175-186 (1993).

This paper reports on an experimental study of jets of xanthan solutions. Die swell of this semi-rigid polymer is similar to that which is observed with flexible polymer solutions or fiber suspensions. At low shear rates, we relate the variation of the swell ratio to the shear thinning properties of the solutions. At high shear, stable delayed die swell is observed above a critical shear rate. Using the jet shape and the dependence on the shear rate of the distance from the nozzle to the station where the swelling is maximum, we show that delayed die swell can be either smooth or discontinuous depending on the polymer concentration.

352. Hydraulics

10A731. Solvability of water distribution networks with unknown pipe characteristics. - PF Boulos *(Dept of Comput Aided Eng, Montgomery Watson, 301 N Lake Ave, Suite 900, Pasadena CA 91101)*, T Altman *(Dept of Comput Sci and Eng, Univ of Colorado, Denver CO)*, JCP Liou *(Dept of Civil Eng, Univ of Idaho, Moscow ID)*. Appl Math Model **17**(7) 380-387 (Jul 1993).

Necessary and sufficient conditions for the solvability of water distribution networks with unknown pipe characteristics are developed. They are predicted on the interdependence between the unknown pipe characteristics and the network hydraulic performance. These characteristics are determined to exactly satisfy defined values of nonlinear boundary equality constraints. The constraint set consists of the stated supply pressure or energy grade requirements to be maintained at critical locations throughout the distribution network. The determination of such conditions is important for a comprehensive and effective modeling and optimization of water networks.

10A732. Vortex particle methods for periodic channel flow. - JJ Monaghan and RJ Humble *(Dept of Math, Monash Univ, Clayton, Vic 3168, Australia)*. J Comput Phys **107**(1) 152-159 (Jul 1993).

The boundary conditions for vortex particles in 2D channel flow with periodic boundary conditions require infinitely many image vortices. By using the Poisson summation formula with Ewald's trick the effect of image vortices can be calculated efficiently. When combined with a tree code and appropriate smoothing, a fast robust algorithm can be designed. Applications to Kirchhoff and Kida vortices are described.

354C. ROTATIONAL (NONVISCOUS) FLOW, VORTICES

10A733. Hairpin removal in vortex interactions II. - AJ Chorin *(Dept of Math, UCB)*. J Comput Phys **107**(1) 1-9 (Jul 1993).

A vortex method in 3D is simplified through the removal of small folds ("hairpins"). The procedure is justified as a real-space renormalization, within a framework provided by recent results on the statistical equilibria of vortex filaments. An application to a vortex ring is carried out. Applications to other numerical methods as well as open questions are discussed.

10A734. Note on leapfrogging vortex rings. - N Riley and DP Stevens *(Sch of Math, Univ of E Anglia, Norwich NR4 7TJ, UK)*. Fluid Dyn Res **11**(5) 235-244 (May 1993).

In this paper we provide examples, by numerical simulation using the Navier-Stokes equations for axisymmetric laminar flow, of the "leapfrogging" motion of two, initially identical, vortex rings which share a common axis of symmetry. We show that the number of clear passes that each ring makes through the other increases with Reynolds number, and that as long as the configuration remains stable the two rings ultimately merge to form a single vortex ring.

10A735. Stratified Sadovskii flow in a channel. - S Chernyshenko *(Inst of Mech, Moscow Univ, 117192 Moscow, Russia)*. J Fluid Mech **250** 423-431 (May 1993).

Stably stratified and non-stratified flows past a touching pair of vortices with continuous velocity are considered. An asymptotic solution for the very long eddies is determined. Numerical results cover the whole range of subcritical stratification and eddy length.

354D. VISCOUS FLOW

10A736. Stokes flow past a sphere with mixed slip: Stick boundary conditions. - BS Padmavathi, T Amaranath, SD Nigam *(Sch of Math and Comput-Info Sci, Univ of Hyderabad, PO Central University, Hyderabad 500 134, India)*. Fluid Dyn Res **11**(5) 229-234 (May 1993).

We give a general solution of Stokes equations for an incompressible, viscous flow past a sphere with mixed slip-stick boundary conditions. The Faxen's law for drag and torque on the sphere is also given and illustrated with an example.

10A737. Arbitrary Stokes flow past a porous sphere. - D Palaniappan *(Dept of Math, Indian*

Int of Sci, Bangalore 560 012, India). Mech Res Commun 20(4) 309-317 (Jul-Aug 1993).

The motion of a fluid through porous particles is of great practical interest and has been extensively studied. A comprehensive review on this subject is given in Jones. The empirical boundary condition proposed by Beavers and Joseph proved to be an efficient one in dealing with Stokes flow problems involving permeable (ie, porous region where Darcy law holds) plane boundaries. Theoretical results of Beavers and Joseph were confirmed experimentally by Beavers et al, whereas Saffman provided a theoretical justification of the empirical condition using statistical approach. Jones subsequently generalized the Beavers-Joseph condition for cuved permeable surfaces. Using the generalized Beavers-Joseph condition together with continuity of normal velocity and pressure across the permeable surface, Jones solved the problem of uniform flow past a spherical shell. Nir exploited the same conditions as Jones and presented solutions for an isolated porous sphere either rotating in quiescent fluid or at rest in a linear shear-flow. He also gave an expression for effective viscosity of dilute suspension of porous spherical particles. However, these analyses of the flow field around a porous sphere in an unbounded fluid have been limited to the case when a particular velocity field is postulated at a large distance from the porous sphere. In this note, the flow fields interior to a porous sphere (where Darcy law holds) and exterior to it (Stokes flow region) are solved for the case when the velocity profile at a large distance is quite arbitrary. This has been made possible using the velocity representation of Stokes equations which is due to Palaniappan et al together with the boundary conditions of Jones. The expressions for velocity fields (both interior and exterior) are given explicitly. The Faxen's laws for a porous sphere are derived and the limiting cases of rigid and shear-free (bubble) spheres are then deduced. Some illustrative examples are given.

10A738. Flow past a spinning sphere in a slowly rotating fluid at small Reynolds numbers: A numerical study. - CV Raghava Rao and TVS Sekhar *(Dept of Math, Indian IT, Madras-600 036, India).* Int J Eng Sci 31(9) 1219-1231 (Sep 1993).

The axisymmetric flow due to a uniform stream at infinity past a slowly rotating sphere in a viscous, incompressible, rotating fluid is studied by numerical method and the results are presented mostly in the form of graphs of the streamlines and vorticity lines. The governing equations are the nonlinear Navier-Stokes equations. They are written as three coupled, nonlinear, elliptic partial differential equations for the stream function Ψ, vorticity ζ, rotational velocity component Ω. Finite difference method is used for solving the governing equations. Second order derivatives are approximated by central differences of order h^2 or k^2 and nonlinear terms are approximated by upwind differences of order h or k. A region of reversed flow and vortex formation is found to occur near the front or rear stagnation point or both under certain conditions depending upon the speed of the uniform stream at infinity, the radius of the sphere and the angular velocity of the sphere and fluid. The fluid may rotate in the same or opposite directions of the sphere rotation.

10A739. Oscillatory line singularities of Stokes' flows. - A Avudainayagam and J Geetha *(Dept of Math, Indian IT, Madras-600 036, India).* Int J Eng Sci 31(9) 1295-1299 (Sep 1993).

The fundamental singular velocity and pressure fields generated by the presence of an isolated force and a couple acting at a point in a 2D unbounded viscous incompressible medium executing oscillatory motions are obtained. These line singularities, the stokeslet and the rotlet, are used to construct new solutions for certain oscillatory plane viscous flow problems in the region exterior to a circular cylinder.

10A740. Propagation of intrusion fronts of high density ratios. - HP Grobelbauer, TK Fannelop *(Inst of Fluid Dyn, Swiss Fed IT, Zurich, Switzerland),* RE Britter *(Dept of Eng, Univ of Cambridge, Cambridge CB2 1P2, UK).* J Fluid Mech 250 669-687 (May 1993).

The propagation of gravity fronts of high density ratios has been studied experimentally (exchange flow) and by computer simulation. Non-Boussinesq fronts are known to occur in certain safety problems (chemical spills and fires), and we have investigated seven gas combinations giving density ratios from near unity to well over 20. The results are presented in terms of a density parameter ρx which remains finite both in the weak (ρx = 0) and the strong (ρx = 1) limit. The front velocities, measured by means of hot wires, are found to fall on two distinct curves, one for the slower light-gas fronts and one for the faster heavy-gas fronts. Two fractional depths, $\Phi = 1/2$ (lock exchange) and $\Phi = 1/6$, have been investigated in detail and results for the interesting case $\Phi \to 0$ have been obtained by extrapolation. To aid in the extrapolation and for comparison, all experimental (and some intermediate) cases have been simulated by means of a general purpose CFD-code (PHOENICS). Good agreement is found for cases without convergence problems, ie, for heavy-gas fronts of density ratio less than 5. Further information on frontal shape etc. has been obtained from visualization. The extrapolations to infinite depth indicate a limiting speed for both the heavy- and light-gas fronts close to the values predicted from shallow-layer theory for the analogous dam-break problem.

354K. ROTATING FLOW OR SURFACES

10A741. Barotropic flow over finite isolated topography: Steady solutions on the beta-plane and the initial value problem. - L Thompson *(Sch of Oceanog WB-10, Univ of Washington, Seattle WA 98195)* and GR Flierl *(54-1426, MIT).* J Fluid Mech 250 553-586 (May 1993).

Solutions for inviscid rotating flow over a right circular cylinder of finite height are studied, and comparisons are made to quasi-geostrophic solutions. To study the combined effects of finite topography and the variation of the Coriolis parameter with latitude a steady inviscid model is used. The analytical solution consists of one part which is similar to the quasi-geostrophic solution that is driven by the potential vorticity anomaly over the topography, and another, similar to the solution of potential flow around a cylinder, that is driven by the matching conditions on the edge of the topography. When the characteristic Rossby wave speed is much larger than the background flow velocity, the transport over the topography is enhanced as the streamlines follow lines of constant background potential vorticity. For eastward flow, the Rossby wave drag can be very much larger than that predicted by quasi-geostrophic theory. The combined effects of finite height topography and time-dependence are studied in the inviscid initial value problem on the f-plane using the method of contour dynamics. The method is modified to handle finite topography. When the topography takes up most of the layer depth, a stable oscillation exists with all of the fluid which originates over the topography rotating around the topography. When the Rossby number is order one, a steady trapped vortex solution similar to the one described by Johnson (1978) may be reached.

10A742. Slow axisymmetric rotation of a sphere in a transversely-isotropic fluid. - G Iosilevskii *(Fac of Aerospace Eng, Technion-Israel IT, Technion City, Haifa 32000, Israel),* AE Mendoza-Blanco *(Dept of Phys, Univ Natl Autonoma de Mexico, Ciudad Univ, 04510 Mexico DF),* H Brenner *(Dept of Chem Eng, MIT).* Quart J Mech Appl Math 46(1) 153-161 (Feb 1993).

The creeping flow engendered by the steady axisymmetric rotation of a sphere in a transversely-isotropic Newtonian fluid is investigated in the limiting case when the material properties of the fluid are unaffected by the fluid motion. By introducing an appropriate coordinate transformation, the problem is reduced to that of a spheroid rotating about its axis of symmetry in an isotropic fluid. Closed-form results are obtained for both the velocity field and the couple required to maintain the rotation.

10A743. Numerical simulation of flows past periodic arrays of cylinders. - AA Johnson, TE Tezduyar *(Dept of Aerospace Eng and Mech, Army High Performance Comput Res Center,, Minnesota Supercomput Inst, Univ of Minnesota, 1200 Washington Ave S, Minneapolis MN 55415),* J Liou *(Tulsa Res Center, Amoco Prod, Tulsa OK 74102).* Comput Mech 11(5-6) 371-383 (1993).

We present a detailed numerical investigation of three unsteady incompressible flow problems involving periodic arrays of staggered cylinders. The first problem is an uniperiodic flow with two cylinders in each cell of periodicity. The second problem is a biperiodic flow with two cylinders in each cell, and the last problem is a uniperiodic flow with ten cylinders. Both uniperiodic flows are periodic in the direction perpendicular to the main flow direction. In all three cases, the Reynolds number based on the cylinder diameter is 100, and initially the flow field has local symmetries with respect to the axes of the cylinders parallel to the main flow direction. Later on, these symmetries break, vortex shedding is initiated, and gradually the scale of the shedding increases until a temporally periodic flow field is reached. We furnish extensive data, including the vorticity and stream function fields at various instants during the temporal evolution of the flow field, time histories of the drag and lift coefficients, Strouhal number, initial and mean drag coefficients, amplitude of the drag and lift coefficient oscillations, and the phase relationships between the drag and lift oscillations associated with each cylinder. Our data confirms that, at this Reynolds number, there are no stable steady-state solutions with local cylinders parallel to the main flow direction and taking half of the computational domain needed normally. In such cases, the "steady-state" flow fields obtained would be identical to the flow fields observed at the initial stages of our computations. However, we show that such flow fields do not represent the temporally periodic flow fields even in a time-averaged sense, because, in all three cases, the initial drag coefficients are different from the mean drag coefficients. Therefore, we conclude that stability studies involving periodic arrays of cylinders should be carried out, as it is done in this work, with the true implementation of the spatial periodicity.

10A744. Numerical solution of steady viscous flow past a streamlined cylinder in von Mises coordinates. - I Husain and OP Chandna *(Dept of Math and Stat and Fluid Dyn Res Inst, Univ of Windsor, Windsor, ON, N9B 3P4, Canada)*. Mech Res Commun **20**(4) 343-352 (Jul-Aug 1993).

The numerical solution of steady viscous incompressible flow past a cylinder of streamlined cross-section have been obtained using the von Mises coordinates, (x, ψ), where ψ is the streamfunction of the flow. The governing equations are reduced to a system of two equations in two unknowns $y(x,\psi)$ and $\omega(x,\psi)$. This system is solved subject to the appropriate boundary conditions in the von Mises computational domain at Reynolds numbers up to 40 for two specific cross-sections.

10A745. Application of the small-parameter method to the problem of the spatial flow of a viscous gas past bodies. - GA Tirskii, SV Utyuzhnikov, NK Yamaleyev *(Moscow, Russia)*. J Appl Math Mech **56**(6) 929-938 (1992).

The solution of the problem of the spatial hypersonic flow of a viscous gas past spherically blunted bodies is considered using the system of equations of a complete viscous shock layer (CVSL). The use of the small-parameter method (SPM) in conjunction with the method of global iterations enables one to reduce the computer time required by a factor of approximately 100 compared with the time needed to calculate similar problems in a strictly spatial formulation by establishment methods. The flow past blunt cones and bicones of long length at low angles of attack is considered as well as the flow past a body, which differs slightly from an axisymmetric one, at zero angle of attack. The applicability of the SPM is confirmed by comparison with experimental and computed data.

10A746. Behavior of a three-torus in truncated Navier-Stokes equations. - C Giberti and R Zansai *(Dipartimento Matematica Pura Appl, Univ Modena, via Campi 213 B, 41100 Modena, Italy)*. Physica D **65**(3) 300-312 (30 May 1993).

The presence of a three-torus in a seven-mode truncation of the 3D Navier-Stokes equations is investigated numerically by means of cross-section and power spectra. Furthermore, by taking advantage of particular features of the model, rotation vectors, circle maps and torus maps can be computed with high accuracy and used to study the dynamics. In particular, some interesting phenomena of partial phase-locking are described in deep detail. The three-torus, which arises via a Hopf bifurcation and persists in a wide parameter range, is found to break and originate a strange attractors. The onset of chaos and the associated bifurcation point can be defined quite precisely.

10A747. Biorthogonal series method for Oseen type flows. - HC Kuhlmann *(Center of Appl Sci Tech and Microgravity, Univ of Bremen, Hochschulring-Am Fallturm, 2800 Bremen 33, Germany)* and RR Adabala *(Dept of Math, Indian Inst of Sci, Bangalore-560 012, India)*. Int J Eng Sci **31**(9) 1243-1258 (Sep 1993).

A biorthogonal series method is developed to solve Oseen type flow problems. The theory leads to a new set of eigenfunctions for a specific class of linear non-self-adjoint operators containing the biharmonic one. These eigenfunctions differ from those given earlier in the literature for the biharmonic operator. The method is applied to the problem of thermocapillary flow in a cylindrical liquid bridge of the finite length with axial through flow. Flow and temperature distributions are obtained at leading order of an expansion for small surface tension Reynolds number and Prandtl number. Another related problem considered is that of cylindrical cavity flow. Solutions for both cases are presented in terms of biorthogonal series. The effect of axial through flow on velocity and temperature fields is discussed by numerical evaluation of the truncated analytical series. The presence of axial through flow not only convectively shifts the vortices induced by surface forces in the direction of the through flow, but also moves their centers toward the outer cylindrical boundary. This process can lead to significantly asymmetric flow structures.

10A748. Comparison of GMRES and CGSTAB accelerations for incompressible Navier-Stokes problems. - P Chin *(Dept of Elect and Comput Eng, Univ Waterloo ON, Canada)* and PA Forsyth *(Dept of Comput Sci, Fac of Math, Univ of Waterloo ON, Canada)*. J Comput Appl Math **46**(3) 415-426 (Jun 1993).

Recently, incomplete LU preconditioned conjugate-gradient-type matrix solvers have been used in conjunction with Newton or Newton-like methods to solve the fully-coupled incompressible Navier-Stokes equations. A number of acceleration methods can be used for the large sparse nonsymmetric linear systems that arise from such situations. In this work, we compare GMRES and CGSTAB, a "stabilized" variant of CGS. By observing the effect of various factors (eg, grid size, preconditioning), we attempt to determine the classes of problems to which each acceleration method is best suited. Numerical results obtained with several 2D geometries are provided.

10A749. Convergence analyses of Galerkin least-squares methods for symmetric advective-diffusive forms of the Stokes and incompressible Navier-Stokes equations. - LP Franca *(Lab Nacional Computacao Cientifica, LNCC-CNPq, Rua Lauro Muller 455, 22290 Rio de Janeiro RJ, Brazil)* and TJR Hughes *(Div of Appl Mech, Durand Bldg, Stanford)*. Comput Methods Appl Mech Eng **105**(2) 285-298 (Jun 1993).

Symmetric advective-diffusive forms of the Stokes and incompressible Navier-Stokes equations are presented. The Galerkin least-squares method for advective-diffusive equations is used for both systems and is related to other stabilized methods previously studied. The presentation reveals that the convergence analysis for advective-diffusive equations, as applied before to a linearized form of the compressible Navier-Stokes equations, carries over in a straightforward manner to the Stokes problem and to a linearized form of the compressible Navier-Stokes equations.

10A750. Convergence of Fourier methods for the Navier-Stokes equations. - E Weinan *(Sch of Math, Inst for Adv Study, Princeton NJ 08540)*. SIAM J Numer Anal **30**(3) 650-674 (Jun 1993).

Optimal orders of convergence for the Fourier-Galerkin method for 2D Navier-Stokes equations in various energy norms and in LP-norms of the velocity field are proved. Optimal orders of convergence for the Fourier-collocation method are also proved. Extensions of these results to 3D Navier-Stokes equations in the original form and the rotational form are presented. Semigroup formulations and the variation of constants formula are the essential tools in the analysis.

10A751. Efficient 3D calculation procedure for incompressible flows in complex geometries. - SK Choi, HY Nam, YB Lee, M Cho *(Fast Breeder Reactor Coolant Dept, Korea Atomic Energy Res Inst, PO Box 7 Daeduk-Danji, Daejon 305-606, Korea)*. Numer Heat Transfer B **23**(4) 387-400 (Jun 1993).

A 3D finite-volume calculation procedure for incompressible flows in complex geometries is presented. The scheme is based on the modified Rhie and Chow momentum interpolation method, in which the original scheme has been modified to employ the curvilinear covariant velocity components as cell face velocities to provide always a simple and diagonal dominant pressure or pressure correction equation. The coupling between the continuity equation and the momentum equations is effected using the SIMPLE algorithm. The present scheme is applied to test problems, and the results are compared with available experimental data and other numerical results.

10A752. FE analysis of viscous incompressible flows using primitive variables. - JN Reddy *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843-3123)*. Comput Struct **47**(4-5) 857-869 (3 Jun 1993).

This paper contains an overview of the primitive variable FE models of viscous, incompressible fluids in 3D enclosures, with emphasis on penalty FE models. The mixed and penalty FE models are described and their computational aspects are discussed. Methods for the solution of large systems of equations associated with the FE analysis of 3D problems are also discussed. Numerical results are included to illustrate the applicability of the penalty FE model and solution methods described here.

10A753. FE solution of the 3D compressible Navier-Stokes equations by a velocity-vorticity method. - G Guevremont, PL Kotiuga, WG Habashi *(Concordia Univ, Montreal, PQ, H3G 1M8, Canada)*, MM Hafez *(UC, Davis CA 95616)*. J Comput Phys **107**(1) 176-187 (Jul 1993).

This paper presents an alternative formulation to the primitive variable form of the Navier-Stokes equations. The approach is based on the use of the velocity and vorticity variables as a logical extension of the stream function-vorticity method which is quite effective for 2D flows. Second-order equations are obtained for the variables and discretization is through a weak-Galerkin FEM, followed by a Newton linearization. The velocity and vorticity components are solved simultaneously by a direct solver. The scheme is demonstrated for 2D and 3D incompressible and subsonic internal enclosed flow problems.

10A754. Iterative method of integral relations scheme for wake flows. - R-J Yang *(Dept of Eng Sci, Natl Cheng-Kung Univ, Taiwan, ROC)* and W-S Yeung *(Dept of Mech Eng, Univ of Lowell, Lowell MA)*. Commun Numer Methods Eng **9**(6) 525-531 (Jun 1993).

The orthonormal method of integral relations is extended to calculate wake flow problems. Two previous difficulties are overcome: (1) the non-constant integral domain is eliminated by introducing a linear transformation in the formulation; (2) the difficulty associated with determining unique orthonormal weighting functions is overcome by an iterative scheme. The new formulation is applied to calculate a wake flow. A high-order solution for N up to 4 is obtained with relative ease.

10A755. Progress on adaptive hp-FEMs for the incompressible Navier-Stokes equations. - JT Oden *(Tex Inst for Computational Mech, Univ of Texas, Austin TX)*, SR Kennon, WW Tworzydlo, JM Bass, C Berry *(Computational Mech, Austin TX)*. Comput Mech **11**(5-6) 421-432 (1993).

This paper outlines recent results obtained in the development and application of hp-adaptive

FEMs to 3D problems in incompressible viscous flow simulation.

10A756. Second-order convergence of a projection scheme for the incompressible Navier-Stokes equations with boundaries. - TY Hou *(Courant Inst of Math Sci, 251 Mercer St, New York NY 10012)* and BTR Wetton *(Dept of Math, Univ of British Columbia, Vancouver, BC, V6T 1Y4, Canada)*. SIAM J Numer Anal 30(3) 609-629 (Jun 1993).

A rigorous convergence result is given for a projection scheme for the Navier-Stokes equations in the presence of boundaries. The numerical scheme is based on a finite-difference approximation, and the pressure is chosen so that the computed velocity satisfies a discrete divergence-free condtion. This choice for the pressure and the particular way that the discrete divergence is calculated near the boundary permit the error in the pressure to be controlled and the second-order convergence in the velocity and the pressure to the exact solution to be shown. Some simplifications in the calculation of the pressure in the case without boundaries are also discussed.

10A757. SUPG FE computation of viscous compressible flows based on the conservation and entropy variables formulations. - SK Aliabadi, SE Ray, TE Tezduyar *(Dept Aerospace Eng and Mech, Army High Performance Comput Res Center, Minnesota Supercomput Inst, Univ of Minnesota, 1200 Washington Ave S, Minneapolis MN 55415)*. Comput Mech 11(5-6) 300-312 (1993).

In this article, we present our investigation and comparison of the SUPG-stabilized FE formulations for computation of viscous compressible flows based on the conservation and entropy variables. This article is a sequel to the one on inviscid compressible flows by Le Beau et al (1992). For the conservation variables formulation, we use the SUPG stabilization technique introduced in Aliabadi and Tezduyar (1992), which is a modified version of the one described in Le Beau et al (1992). The formulation based on the entropy variables is same as the one introduced in Hughes et al (1986). The two formulations are tested on three different problems: adiabatic flat plate at Mach 2.5, Reynolds number 20 000; Mach 3 compressions corner at Reynolds number 16 800; and Mach 6 NACA 0012 airfoil at Reynolds number 10 000. In all cases, we show that the results obtained with the two formulations are very close. This observation is the same as the one we had in Le Beau et al (1992) for inviscid flows.

10A758. Three-step FEM for unsteady incompressible flows. - Chun Bo Jiang and Mutsuto Kawahara *(Dept of Civil Eng, Chuo Univ, Kasuga 1-13-27, Bunkyo-ku Tokyo 112, Japan)*. Comput Mech 11(5-6) 355-370 (1993).

This paper describes a three-step FEM and its application to unsteady incompressible fluid flows. The stability analysis of the 1D purely convection equation shows that this method has third-order accuracy and an extended numerical stability domain in comparison with the Lax-Wendroff FEM. The method is cost effective for incompressible flows, because it permits less frequent updates of the pressure field with good accuracy. In contrast with the Tayler-Galerkin method, the present three-step FEM does not contain any new higher-order derivatives, and is suitable for solving non-linear multi-dimensional problems and flows with complicated outlet boundary conditions. The three-step FEM has been used to simulate unsteady incompressible flows, such as the vortex pairing in mixing layer. The properties of the flow fields are displayed by the marker and cell technique. The obtained numerical results are in good agreement with the literature.

10A759. Aerodynamic computations for a transonic projectile at angle of attack by total variation diminishing schemes. - Herng Lin and Ching-Chang Chieng *(Natl Tsing Hua Univ, Hsinchu, Taiwan, ROC)*. J Spacecraft Rockets 30(3) 304-315 (May-Jun 1993).

Several total variation diminishing (TVD) schemes and the Beam-Warming solution algorithm have been incorporated in a computer code for solving 3D time-dependent, Reynold's averaged Navier-Stokes equations in generalized coordinates. A finite-volume fully implicit, approximately factored scheme is employed with a time-step convergence acceleration. Transonic turbulent flows past a scant ogive cylinder boat tail projectile at Mach numbers 0.94 and 0.97 including base flow region were studied. Conditions at 0- and 2-deg angle of attack were computed. Results of zero angle of attack showed that third-order TVD schemes gave little improvements over the second-order TVD schemes. Van Leer's third-order MUSCL-type TVD scheme yields somewhat better results and faster convergence than Chakravarthy's upwind-biased TVD scheme. The convergence rate of the Beam-Warming scheme is similar to that of the second-order TVD schemes. The Beam-Warming scheme gives comparative results over most of the projectile except regions of coarse grids because the scheme is very sensitive to grid resolution. For angle-of-attack computations, Van Leer's third-order MUSCL-type TVD scheme still gives better agreement with measurement.

10A760. On boundary-layer transition in transonic flow. - RI Bowles and FT Smith *(Dept of Math, Univ Col, Gower St, London WC1E 6BT, UK)*. J Eng Math 27(3) 309-342 (Aug 1993).

Boundary-layer transition in transonic external flow is addressed theoretically. The transonic area is rich in different flow structures, and transition paths, and the work has wide potential application in transonic aerodynamics, including special reference to the example of flow transition over an engine nacelle. The investigation is intended partly to aid, compare with, and detect any limitations of, a quasi-parallel empirical methodology for design use in the area, especially with respect to the transonic range, and partly to develop an understanding and possible control of the nonlinear natural or by-pass properties of the compressible transition present. The mechanisms behind three major factors, (a) substantial external-flow deceleration, (b) rapid boundary-layer thickening, (c) 3D nonlinear interactions, are identified; these three are involved in the specific application above and in more general configurations, depending on the disturbance background present. It is found also that some similarities exist with the phenomenon of buffeting on transonic airfoils, and the relevant physics and governing equations throughout are identified. Sensitive nonlinear effects are important in all the factors (a)-(c), especially a resonance linkage between shock buffeting and boundary-layer thickening, and nonlinearly enhanced 3D growth triggered by slight 3D warping for instance, peculiar to the transonic range. The latter enhanced growth is perhaps the most significant finding. The implications, in the general setting as well as for the nacelle-flow context in particular, are also presented.

356D. SUPERSONIC FLOW

10A761. Lifting line theory for supersonic flow applications. - I Jadic *(Dept of Numer Simul in Fluid Mech, Inst of Appl Math, Bd Pacii 220 Section 6, Bucharest, Romania)* and VN Constantinescu *(Aeronaut Eng Fac, Polytech Inst, Bucharest, Romania)*. AIAA J 31(6) 987-994 (Jun 1993).

The paper is devoted to the study of a supersonic lifting line theory intended to provide both a means of aerodynamic calculation and a benchmark for the validation of the control point position for the related constant pressure panel methods. The model is based on the small perturbations assumption. A constant distribution of bound vortices is assumed along the chord whereas the spanwise load distribution is calculated by means of trigonometrical series, formally similar to the subsonic methods. The calculated aerodynamic coefficients are in good agreement with the reference data, the precision being compatible with the small perturbations assumption. The control point position obtained is shown to vary as a function of aspect ratio from 100 to 88% of the local chord.

356E. HYPERSONIC FLOW

10A762. Comparison of gas-dynamic models for hypersonic flow past bodies. - SV Zhluktov, SV Utyuzhnikov, VS Shchelin, VG Shcherbak *(Moscow, Russia)*. J Appl Math Mech 56(6) 939-944 (1992).

Various gas-dynamic models for describing chemically non-equilibrium flows are compared using the example of the steady flow past the blunt nose of the "Buran" and "Space Shuttle" vehicles during their descent from orbit. Models of locally self-similar approximations of the Navier-Stokes equations, of a chemically equilibrium and non-equilibrium complete viscous shock layer (CVSL) and a model of a thin viscous shock layer (TVSL) are considered. In all the models the occurrence of physicochemical processes was taken into account in the same way using fixed values of the constants for the gas-phase chemical reactions. Good agreement between the results of calculations of the heat flux at the critical point is found. Chemically non-equilibrium flows have been considered earlier using the approximate Navier-Stokes equations, within the framework of a TVSL and a CVSL. The TVSL and CVSL models were compared in the case of flows of a uniform gas.

10A763. Extension of unsteady embedded Newtonian theory. - LE Ericsson *(Lockheed Missiles & Space, Sunnyvale CA 94086)* and HHC King *(ETAK, Menlo Park CA)*. J Spacecraft Rockets 30(3) 316-322 (May-Jun 1993).

A previously developed unsteady embedded Newtonian theory has been extended to be able to predict the hypersonic unsteady aerodynamics of axisymmetric bodies of general shape with the accuracy needed for preliminary design. The static aerodynamics determined by a 3D finite difference method are used together with unsteady embedded Newtonian flow concepts to provide the vehicle dynamics without significantly adding computational time to the static computer program.

10A764. Numerical solution of the kinetic model equations for hypersonic flows. - Nobuyuki Satofuka, Koji Morinishi, Tsutomu Oishi *(Kyoto IT, Matsugasaki, Sakyo-ku, Kyoto*

606, Japan). Comput Mech 11(5-6) 452-464 (1993).

A numerical method for solving the model kinetic equations for hypersonic flows has been developed. The model equations for the distribution function are discretized in phase space using a second order upwind finite difference scheme for the spatial derivatives. The resulting system of ordinary differential equations in time is integrated by using a rational Runge-Kutta scheme. Calculations were carried out for hypersonic flow around a double ellipse under various free stream conditions. Calculated results are compared with the Navier-Stokes solutions and the Direct Simulation Monte Carlo (DSMC) method for the corresponding case. The agreement is quite excellent in general.

10A765. Stabilization of the Burnett equations and application to hypersonic flows. - X Zhong, RW MacCormack, DR Chapman *(Dept of Aeronaut and Astronaut, Stanford)*. AIAA J 31(6) 1036-1043 (Jun 1993).

Numerical solutions of the Burnett equations for hypersonic flow at high altitudes in the continuum transitional regime were not possible except for some 1D flows. It is shown from both analytical investigation and numerical computations that the Burnett equations are unstable to disturbances of small wavelengths. This fundamental instability arises in numerical computations when the grid spacing is less than the order of a mean free path and precludes Burnett flowfield computations above a certain maximum altitude for any given aerospace vehicle. A new set of equations termed the "augmented Burnett equations" has been developed and shown to be stable both by a linearized stability analysis and by direct numerical computations for 1D and plane 2D flows. The latter represents the first known Burnett solutions for 2D hypersonic flow over blunt leading edges. The comparison of these solutions with the conventional Navier-Stokes solutions reveals that the difference is small in low-altitude low-speed flows but significant in high-altitude hypersonic flows.

10A766. Hydrodynamics, gravitational sensitivity, and transport phenomena in continuous flow electrophoresis. - MS Bello *(Inst of Macromol Compounds, Russian Acad of Sci, 199004 Bolshoi pr 31, St Petersburg, Russia)* and VI Polezhaev *(Inst for Prob in Mech, Russian Acad of Sci, 117527 pr Vernadskogo 101, Moscow, Russia)*. AIAA J 31(6) 997-998 (Jun 1993).

A multizone mathematical model for hydrodynamics, heat and mass transfer in continuous flow electrophoresis (CFE) is reported. The model divides the electrophoretic cell into three zones: the entrance region, the zone of the mixture injection, and the zone of the parallel fluid flow. Three-dimensional transport equations, including Navier-Stokes equations, and equations of heat and mass balance are significantly simplified in each zone. The length of the cell entrance region and recirculation flows in the CFE cell are found to be affected by thermal convection caused by internal heating of the fluid. The influences of convective diffusion and electro-osmosis on concentration profiles of separated fractions are studied numerically for a wide range of the Peclet number.

356M. ROTATING FLUIDS OR SURFACES

10A767. Geometrical and numerical considerations in computing advanced propellar noise. - VL Wells *(Dept Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287)* and A Han *(Dept Mech and Aerospace Eng, VPI)*. J Aircraft 30(3) 365-371 (May-Jun 1993).

A previously developed technique for numerically solving the acoustic analogy equation for rotating surfaces with supersonic regions results in smooth pressure time waveforms. The method appears to provide results superior to those of other schemes because it eliminates erratic noise in the computed waveforms and deals only with nonsingular integrals. This article discusses the application of the method to propellar type rotor blades. Several different sweep geometries are considered, and presented results show the effect of blade shape on the noise produced and on the numerical procedure for computing that noise. Computed waveforms exhibit expected behavior, deduced from analysis of the retarded blade shapes and the critical points along the blade edges where the Mach number in the direction of the observer equals one.

10A768. Swirling free surface flow in cylindrical containers. - A Siginer and R Knight *(Dept of Mech Eng, Auburn Univ, Auburn AL 36849)*. J Eng Math 27(3) 245-264 (Aug 1993).

Free surface flow in a cylindrical container with steadily rotating bottom cap is investigated. A regular domain perturbation in terms of the angular velocity of the bottom is used. The flow field is made up of the superposition of azimuthal and meridional fields. The meridional field is solved both by biorthogonal series and a numerical algorithm. The free surface on the liquid is determined at the lowest significant order. The aspect ratio of the cylinder may generate a multiple cell structure in the meridional plane which in turn shapes the free surface.

10A769. Unsteady blade pressure on a propfan at takeoff: Euler analysis and flight data. - M Nallasamy *(Aeromech Dept, NASA Lewis Res Center Group, Sverdrup Tech, Brook Park OH 44142)*. J Aircraft 30(3) 372-376 (May-Jun 1993).

The unsteady blade pressures due to the operation of the propfan at an angle to the direction of the mean flow are obtained by solving the unsteady 3D Euler equations. The configuration considered is the eight-bladed SR7L propfan operating at takeoff conditions, and the inflow angles considered are 6.3, 8.3, and 11.3 deg. The predicted blade pressure waveforms are compared with in flight measurements. At the inboard radial station ($r/R = 0.68$) the phase of the predicted waveforms show reasonable agreement with measurements, whereas, the amplitudes are overpredicted in the leading edge region of the blade. At the outboard radial station ($r/R = 0.95$), the predicted amplitudes of the waveforms on the pressure surface are in good agreement with flight data for all inflow angles. The measured waveforms show a relative phase lag compared to the computed waveforms. The phase lag depends on the axial location of the transducer and the surface of the blade. On the suction surface, in addition to the relative phase lag, the measurements show distortion of the waveforms. The extent of the distortion increases with increase in the inflow angle. This distortion seems to be due to viscous separation effects which depends on the azimuthal location of the blade and the location of the transducer.

356Y. COMPUTATIONAL TECHNIQUES

10A770. Comparison of two Navier-Stokes codes for simulating high-incidence vortical flow. - NM Chaderjian *(Appl Computation Fluids Branch, NASA Ames Res Center, Moffett Field CA 94035)*. J Aircraft 30(3) 357-364 (May-Jun 1993).

Computations from two Navier-Stokes, NSS and F3D, are presented for a tangent-ogive cylinder body at high angle of attack. Features of this steady flow include a pair of primary vortices on the leeward side of the body, as well as secondary vortices. The topological and physical plausibility of this vortical structure is discussed. The accuracy of these codes are assessed by comparison of the numerical solutions with experimental data. The effects of turbulence model, numerical dissipation, and grid refinement are presented. The overall efficiency of these codes are also assessed by examining their convergence rates, computational time per time step, and maximum allowable time step for time accurate computations. Overall, the numerical results from both codes compared equally well with experimental data, however, the NSS code was found to be significantly more efficient than the F3D code.

10A771. Energy-bounded flow approximation on a Cartesian-product grid over rough terrain. - DK Purnell and MJ Revell *(Atmos Div, Natl Inst of Water & Atmos Res, Wellington, New Zealand)*. J Comput Phys 107(1) 51-65 (Jul 1993).

We construct a method for modeling the 3D, time dependent, compressible fluid flow in a gravitational field on a rotating Cartesian-product grid with a spatially rough metric that bounds solutions by the total initial physical energy. Specifically: (1) the total physical energy is an l_2 norm on the model state and (2) this total energy cannot increase provided the timestep does not exceed CFL limits. In particular, the first property means that our measure of the energy is always positive unless the mass, momentum, and internal energy are all everywhere zero. These conditions guarantee that no error can grow unchecked. This is thought to be a desirable property, although only in the case of linear systems is it sufficient for convergence of a consistent approximation to the true solution.

10A772. Global coefficient adjustment method for Neumann condition in explicit Chebyshev collocation method and its application to compressible Navier-Stokes equations. - Jian-ping Wang, Yoshiaki Nakamura *(Dept of Aeronaut Eng, Nagoya Univ, Nagoya 464-01, Japan)*, Michiru Yasuhara *(Aichi IT, Toyoda 470-03, Japan)*. J Comput Phys 107(1) 160-175 (Jul 1993).

The present paper consists of two parts. In part 1, a new technique of treating Neumann boundary conditions with an explicit Chebyshev collocation method is developed. Any Neumann boundary condition can be satisfied by adjusting all the Chebyshev coefficients of a solution, which results in a small influence on the solution and its derivatives except at the boundary. Comparisons between the new technique and several traditional ones are made for a 1D advection-diffusion problem, which confirms the superiority of the new technique. The spectral accuracy of the new technique is also demonstrated. In part 2, a Chebyshev collocation code for the compressible Navier-Stokes equations is developed to solve the high-speed flows around a sphere. Good resolutions are obtained in the boundary layer by using the new technique, and comparison between the calculation and the experiment shows good agreement.

10A773. New flux splitting scheme. - Meng-Sing Liou and CJ Steffen Jr *(Internal Fluid Mech Div, NASA Lewis Res Center, Cleveland OH 44135)*. J Comput Phys **107**(1) 23-39 (Jul 1993).

A new flux splitting scheme is proposed. The scheme is remarkably simple and yet its accuracy rivals, and in some cases surpasses, that of Roe's solver in the Euler and Navier-Stokes solutions carried out in this study. The scheme is robust and converges as fast as the Roe splitting. We propose an appropriately defined cell-face advection Mach number using values from the two straddling cells via associated characteristic speeds. This interface Mach number is then used to determine the upwind extrapolation for the convective quantities. Accordingly, the name of the scheme is coined as the advection upstream splitting method (AUSM). We also introduce a new pressure splitting which is shown to behave successfully, yielding much smoother results than other existing pressure splittings. Of particular interest is the supersonic blunt body problem in which the Roe scheme gives anomalous solutions. The AUSM produces correct solutions without difficulty for a wide range of flow conditions as well as grids.

10A774. Non-oscillatory spectral element Chebyshev method for shock wave calculations. - D Sidilkover and GE Karniadakis *(Dept of Mech and Aerospace Eng, Program in Appl and Comput Math, Princeton)*. J Comput Phys **107**(1) 10-22 (Jul 1993).

A new algorithm based on spectral element discretization and non-oscillatory ideas is developed for the solution of hyperbolic partial differential equations. A conservative formulation is proposed based on cell averaging and reconstruction procedures, that employs a staggered grid of Gauss-Chebyshev and Gauss-Lobatto-Chebyshev discretizations. The non-oscillatory reconstruction procedure is based on ideals similar to those proposed by Cai *et al* but employs a modified technique which is more robust and simpler in terms of determining the location and strength of a discontinuity. It is demonstrated through model problems of linear advection, inviscid Burgers equation, and 1D Euler system that the proposed algorithm leads to stable, non-oscillatory accurate results. Exponential accuracy away from the discontinuity is realized for the inviscid Burgers equation example.

10A775. Numerical aspects of a block structured compressible flow solver. - BJ Geurts and H Kuerten *(Dept of Appl Math, Univ of Twente, PO Box 217, 7500 AE Enschede, Netherlands)*. J Eng Math **27**(3) 293-307 (Aug 1993).

A block structured compressible flow solver based on a finite volume approach with central spatial differencing is described and its performance in 2D on flow around an airfoil is studied. Variations in the number and dimensions of the blocks do not influence the convergence behavior nor the solution, irrespective of the relative positions of a possible shock and the block-interfaces. Mixed calculations, in which the governing equations, either Euler or Reynolds averaged Navier-Stokes, differ per block, give accurate results provided that Euler blocks are defined outside the boundary layer and or in the far field wake regions. Likewise, extensive grid distortions near block interfaces can be allowed for outside the boundary layer. Finally, an unbalanced advancement in time, in which each block is advanced independently over several time steps gives no serious decrease in convergence rate.

10A776. Posteriori error bounds for numerical solutions of regularized compressible flow problems. - Koichi Niijima *(Dept of Civil Eng and Sci, Kyushu IT, Iizuka 820, Japan)*. Commun Numer Methods Eng **9**(6) 511-523 (Jun 1993).

We give *a posteriori* error bounds for numerical solutions of regularized compressible flow problems. To verify the efficiency of our method, numerical experiments are performed.

10A777. Theoretical estimates of vibrational relaxation in nitrogen up to 40,000 K. - CF Hansen *(Chem Phys Inst, Univ of Oregon, Eugene OR 97403)*. AIAA J **31**(6) 1044-1050 (Jun 1993).

Vibrational relaxation of N_2 molecules is considered at temperatures up to 40,000 K in gas mixtures that contain electrons as well as heavy collision partners. The theory of vibrational excitation due to N_2-N_2 collisions is fit to experimental data to 10,000 K by choice of the shape of the intermolecular potential and size of the collision cross section. These values are then used to extrapolate the theory to 40,000 K. Electron collisions promote vibrational transitions much more readily than the heavy particle collisions; and equilibration of vibrational temperature with the electron temperature occurs almost instantaneously for many practical purposes. Subsequently, vibrational relaxation depends on heavy particle collisions; the electrons merely drain off some of the vibrational energy changes and delay the approach to full equilibrium. As temperature increases beyond 10,000 K, multiple quantum jumps become increasingly important and small perturbation assumptions become invalid. However, these effects compensate such that small perturbation results provide a fair approximation at somewhat higher temperatures than might be expected. Anharmonic effects do not appear to be highly important to the total relaxation rate at temperatures up to 40,000 K, though they distort the transition rates in the uppermost levels.

10A778. Character of two-phase gas-particulate flow equations. - AD Fitt *(Fac of Math, Univ of Southampton, Southampton SO9 5NH, UK)*. Appl Math Model **17**(7) 338-354 (Jul 1993).

Complex characteristics arise as a result of multiphase flow averaging, and the consequent omission of important physical terms. With care, however, these effects may be reintroduced into the equations. Using such as approach, the specific case of gas-particular two-phase flow is considered. The aim is not to propose a definitive, demonstrably "correct" system of equations for unsteady two-phase gas-particulate flow; the assumptions made are too general and specific cases must be treated on their individual merit. Rather a methodology of analysis is illustrated and qualitative results concerning the nature of added terms in the equations are obtained. The effect of each term and also of combinations of terms is studied, and general conclusions are drawn concerning the hyperbolicity of the equations.

10A779. Experimental studies of the deformation of a synthetic capsule in extensional flow. - KS Chang and WL Olbricht *(Sch of Chem Eng, Cornell)*. J Fluid Mech **250** 587-608 (May 1993).

Experiments are described to study the motion and deformation of a synthetic, liquid-filled capsule that is freely suspended in hyperbolic extensional flow. The capsule is a composite particle consisting of a viscous liquid drop surrounded by a thin polymeric membrane. The method used to fabricate capsules suitable for macroscopic flow experiments is described. The deformation of the capsule is measured as a function of strain rate for an extensional flow generated in a four-roll mill. The data agree well with results from small-deformation theory developed by Barthes-Biesel and co-workers, provided the deformation of the capsule is not too large. Using the theory to correlate the experimental data produces an estimate for the elastic modulus of the membrane that agrees reasonably well with the elastic modulus obtained by an independent technique. However, for sufficiently large strain rates, the membrane exhibits strain hardening and a permanent change in its structure, both of which are reflected in the shape of the capsule.

10A780. Experimental studies of the deformation and breakup of a synthetic capsule in steady and unsteady simple shear flow. - KS Chang *(Kimberly-Clark, 2100 Winchester Rd, Neenah WI 54957-0999)* and WL Olbricht *(Sch of Chem Eng, Cornell)*. J Fluid Mech **250** 609-633 (May 1993).

An experimental study is reported of the motion, deformation, and breakup of a synthetic capsule that is freely suspended in Couette flow. The capsule is a liquid drop surrounded by a thin polymeric membrane. The shape and orientation of the capusle are measured in steady flow and following the start-up of Couette flow. Results are compared with predictions of the small-deformation theory of Barthes-Biesel and co-workers. The data suggest that the capsule membrane is viscoelastic, and comparisons with theory yield values of the membrane elastic modulus and the membrane viscosity. The values of the elastic modulus of the capsule membrane deduced from the flow data are compared with independent measurements for the same capsule. When the flow-induced deformation becomes sufficiently large, the capsules break. Breakup begins at points on the membrane surface near the principal strain axis of the undisturbed flow. By examining the local deformation within the membrane, it is shown that breakup is correlated with local thinning of the membrane and is initiated at points where the thickness is a minimum.

10A781. Microstructure suspended in 3D flows. - AJ Szeri *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717-3975)* and LG Leal *(Dept of Chem and Nucl Eng, UC, Santa Barbara CA 93106)*. J Fluid Mech **250** 143-167 (May 1993).

The dynamical behavior of stretchable, orientable microstructure suspended in a general 3D fluid flow is investigated. Model equations given by Olbricht, Rallison & Leal (1982) are examined in the case of microstructure traveling through arbitrarily complicated flows of the carrier fluid. As in the 2D analysis of Szeri, Wiggins & Leal (1991), one must first treat the orientation dynamics problem; only then can the equation for stretch of the microstructure be analyzed rationally. In 3D flows that are steady in the Lagrangian frame, attractors for the orientation dynamics are shown to be equilibria or limit cycles; this asymptotic behavior was first deduced by Bretherton (1962). In 3D flows that are time periodic in the Lagrangian frame (eg, recirculating flows), the orientation dynamics may be characterized by periodic or quasi-periodic attractors. Thus, robust (generic) behavior in these cases is always characterized by a single global attractor; there is no asymptotic dependence of orientation dynamics on the initial orientation. The type of asymptotic orientation dynamics – steady, periodic, or quasi-periodic – is signified by a simple criterion. Details of the relevant bifurcations, as well as history-dependent strong flow criteria are developed. Examples which illustrate the various types of behavior are given.

10A782. Particle-driven gravity currents. - RT Bonnecaze *(Dept of Chem Eng, Univ of Texas, Austin TX 78712-1062)*, HE Huppert, JR Lister *(Inst of Theor Geophys, Dept of Appl Math and Theor Phys, Univ of Cambridge, Silver St, Cambridge CB3 9EW, UK)*. J Fluid Mech **250** 339-369 (May 1993).

Gravity currents created by the release of a fixed volume of a suspension into a lighter ambient fluid are studied theoretically and experimentally. The greater density of the current and the buoyancy force driving its motion arise primarily from dense particles suspended in the interstitial fluid of the current. The dynamics of the current are assumed to be dominated by a balance between inertial and buoyancy forces; viscous forces are assumed negligible. The currents considered are 2D and flow over a rigid horizontal surface. The flow is modeled by either the single- or the two-layer shallow-water equations, the two-layer equations being necessary to include the effects of the overlying fluid, which are important when the depth of the current is comparable to the depth of the overlying fluid. Because the local density of the gravity current depends on the concentration of particles, the buoyancy contribution to the momentum balance depends on the variation of the particle concentration. A transport equation for the particle concentration is derived by assuming that the particles are vertically well-mixed by the turbulence in the current, are advected by the mean flow and settle out through the viscous sublayer at the bottom of the current. The boundary condition at the moving front of the current relates the velocity and the pressure head at that point. The resulting equations are solved numerically, which reveals that two types of shock can occur in the current.

360C. LIQUID-GAS MIXTURE

10A783. Optical measurement of slope, thickness, and velocity in liquid film flow. - CF Than, KC Tee, KS Low *(Univ of Malaya, 59100 Kuala Lumpur, Malaysia)*, CP Tso *(Nanyang Tech Univ, Singapore 2263, Singapore)*. Smart Mat Struct **2**(1) 13-21 (Mar 1993).

A new optical system for measuring the slope, thickness and wave velocity of a liquid film flow is presented. The theory of the system is discussed and the equations derived are employed in simulations involving film flow with low- and high-amplitude waves. The results, which show that it is possible to determine the three parameters for a low-amplitude wave, while only the wave velocity may be found for a high-amplitude wave, may have potential applications in multiphase flow systems.

360E. LIQUID DROP FORMATION

10A784. Breakup of latex doublets by impaction. - W John *(Air and Indust Hygiene Lab, CA Dept of Health Services, 2151 Berkeley Way, Berkeley CA 94704)* and V Sethi *(Dept of Civil and Env Eng, Univ of Cincinnati, Cincinnati OH 45221)*. Aerosol Sci Tech **19**(1) 57-68 (Jul 1993).

The breakup by impaction of a simple agglomerate consisting of two identical spherical particles has been studied. The agglomerates were doublets produced by nebulizing suspensions of latex particles. The doublet concentrations before and after impaction were determined from the particle size spectra obtained with an optical particle counter. Preliminary experiments showed that the latex doublets did not break up in the acceleration nozzle of the impactor. The doublet fraction (DF) is defined as the doublet-singlet concentration ratio after impaction to that before impaction. The DF of 299-μm Dow latex measured at $\sqrt{Stk} = 1.62$ decreased by a factor of 2 as the relative humidity (RH) was varied from 8% to 85%. The remaining experiments were made at low RH with seven different surfactant-free suspensions of polystyrene latex stabilized by the addition of charged surface functional groups. All the data, for particle sizes ranging from 1.62 to 4.07 μm and impact velocities from 10 to 80 m-s, could be fitted by the expressions, $DF = 18.2\ v^{0.58}D^{-1.60}$, where the impact velocity v is in m-s and the particle diameter D is in μm. The van der Waals adhesion energy is calculated to be less than 1/3000 of the kinetic energy needed to break up half of the doublets. The repulsive electrostatic energy of the surface functional groups is estimated to be about 1.25 times larger than the van der Waals adhesion energy. It is concluded that the doublets are probably bound by bridges of residue left after droplet evaporation.

10A785. Threshold for resuspension by particle impaction. - W John *(Air and Indust Hygeine Lab, CA Dept of Health Services, 2151 Berkeley Way, Berkeley CA 94704)* and V Sethi *(Dept of Civil and Env Eng, Univ of Cincinnati, Cincinnati OH 45221)*. Aerosol Sci Tech **19**(1) 69-79 (Jul 1993).

The threshold velocity for the resuspension of 8.6-μm, diameter ammonium fluorescein particles from a Tedlar surface by impaction of 3-μm ammonium fluorescein particles has been measured to be 9.3 ± 4.3 m-s. The resuspension rate, observed with an optical particle counter, has a wide variability. Image analysis of the particle patterns on the surface suggests that particle resuspension takes place at a radius somewhat smaller then that of the nozzle of the impactor used in the experiments. Exposure of some test surfaces to laboratory air for several days prior to the measurements did not change the results significantly. A theoretical model has been shown to predict a threshold velocity within a factor of 2 of the experiment. The major uncertainty involves the value of the surface energy parameter, a difficulty encountered previously in a study of particle bounce. The model is based on the transfer of vertical momentum to the struck particle which is subsequently compressed against the surface. Elastic rebound then supplies the lift-off force to overcome the surface adhesion force. An alternative calculation based on inceptive rotational motion induced by off-center impacts predicts a threshold almost two orders of magnitude lower than observed.

360F. BUBBLE DYNAMICS

10A786. Deformation and location of an acoustically levitated liquid drop. - Yuren Tian, RG Holt, RE Apfel *(Dept of Mech Eng, Yale Univ, New Haven CT 06520)*. J Acoust Soc Am **93**(6) 3096-3104 (Jun 1993).

A theoretical method to determine the location and static deformation of an acoustically levitated liquid drop in air is presented. The interacation between drop and sound field, involving nonspherical acoustic scattering and drop volume variation, is the crux of this analysis, which is valid for drops with aspect ratio as large as 2. Numerical calculations are presented of drop shape and location as functions of sound pressure, surface tension, and drop volume in both gravity (1g) and gravity-free (0g) environments. The numerical results agree well with our experimental measurements and those of other researchers.

10A787. Dynamic simulations of flows of bubbly liquids at large Reynolds numbers. - AS Sangani *(Dept of Chem Eng and Mat Sci, Syracuse Univ, Syracuse NY 13244)* and AK Didwania *(Dept of Appl Mech and Eng Sci, UCSD)*. J Fluid Mech **250** 307-337 (May 1993).

Results of dynamic simulations of bubbles rising through a liquid are presented. The Reynolds number of the flow based on the radius and the terminal speed of bubbles is large compared to unity, and the Weber number, which is the ratio of inertial to surface tension forces, is small. It is assumed that the bubbles do not coalesce when they approach each other but rather bounce instantaneously, conserving the momentum and the kinetic energy of the system. The flow of the liquid is assumed to be irrotational and is determined by solving the many-bubble interaction problem exactly. The viscous force on the bubbles is estimated from the rate of viscous energy dissipation. It is known that the random state of bubbly liquids under these conditions is unstable and that the bubbles form aggregates in planes transverse to gravity. These aggregates form even when the size distribution of the bubbles is nonuniform. While the instability results primarily from the nature of inertial interaction among pairs of bubbles, which causes them to be attracted toward each other when they are aligned in the plane perpendicular to gravity, it is shown that the presence of viscous forces facilitates the process.

360Y. COMPUTATIONAL TECHNIQUES

10A788. Aerosol bolus transport through a hollow airway cast by steady flow in different gases. - JK Briant *(Pacific NW Lab, 902 Battelle Blvd, Richland WA 99352)* and M Lippmann *(Nelson Inst of Env Med, NYU Med Center, 350 First Ave, New York NY 10016)*. Aerosol Sci Tech **19**(1) 27-39 (Jul 1993).

Transport of aerosol through the airways of a hollow cast of a canine tracheobronchial tree was measured for steady flow in different gas mixtures. A small bolus of 0.5-μm aerosol particles was inserted as a tracer of convective motion in the flow at the entrance of the trachea, and particles were collected and counted as they arrived at a flow-balanced sampling bag at a peripheral segment of the cast. Transport was fastest in the gas of highest kinematic viscosity (helium), and slowest in the gas of lowest kinematic viscosity (sulfur hexafluoride). This is consistent with the lubrication theory that describes an axial core in the divergent flow field of the bronchial tree. The finer core in helium transports the particles at a greater velocity to distal airways. Transport of gases through the in vivo respiratory tract should also be influenced by these fluid mechanics of convection resembling Poiseuille flow that is substantially modified according to lubrication theory. As predicted by some other investigators, gas and aerosol particles penetrate much deeper into the lungs than the volumetric depth of inhalation.

360Z. EXPERIMENTAL TECHNIQUES

10A789. Determination of particle vapor pressures using the tandem differential mobility analyzer. - Shou-Hua Zhang, JH Seinfeld, RC Flagan *(Dept of Chem Eng, California IT, Pasadena CA 91125)*. Aerosol Sci Tech **19**(1) 3-14 (Jul 1993).

The application of the tandem differential mobility analyzer (TDMA) as a means of measuring vapor pressures of aerosol species is extended to include vapor saturation effects in the particle evaporator. To verify the analysis experiments were conducted with the controlled evaporation of dioctyl phthalate (DOP) particles with initial sizes ranging from 60 to 95 nm in diameter in a laminar flow evaporator. Vapor pressures of DOP determined with the TDMA were found to agree within 14% of those available in the literature. The results presented enable the use of the TDMA as a means to determine particle vapor pressure for substantially higher particle number concentrations than previously reported.

10A790. Respirator leak detection by ultrafine aerosols: A predictive model and experimental study. - Benjamin YH Liu *(Particle Tech Lab, Mech Eng Lab, Univ of Minnesota, Minneapolis MN 55455)*, Jae-Keun Lee *(Dept of Mech and Precision Eng, Pusan Natl Univ, Pusan 609-735, Korea)*, H Mullins, SG Danisch *(Occupational Health & Env Saftey Products Div, 3M, St Paul MN 55144)*. Aerosol Sci Tech 19(1) 15-26 (Jul 1993).

The leak performance of half-mask, maintenance-free respirators was studied theoretically and experimentally. A predictive model for the theoretical protection factor and leakage flow has been developed that uses the equation of particle conservation inside and outside the respirator. An experimental study was conducted using NaCl particles of 10 nm in diameter and a condensation nucleus counter as the particle detector. A respirator fitted with controlled leak holes of 20-3000 μm in diameter was tested at steady flow rates of 10, 32, and 100 L-min. Results showed that the aerosol penetration into a respirator was strongly influenced by the filter efficiency, leak hole size, and flow rate through the respirator. The results are in good agreement with theory, but some discrepancy has been noted at lower flow rates and smaller leak hole sizes. For the dust-mist respirators, the experimental protection factor for ultrafine 0.01-μm NaCl particles ranged from 3145 to as low as 3. For the high efficiency dust-mist-fume-radionuclide respirator, a protection factor as high as 4.1×10^9 was measured on the ultrafine aerosol. For all respirators, the protection factors decreased rapidly with increasing leak hole size and increased as flow rate decreased.

362. Wall layers (inci boundary layers)

10A791. Buoyancy effects in stably stratified horizontal boundary-layer flow. - PG Daniels and RJ Gargaro *(Dept of Math, City Univ, Northampton Square, London, EC1V 0HB, UK)*. J Fluid Mech 250 233-251 (May 1993).

This paper describes numerical and asymptotic solutions of the steady 2D boundary-layer equations governing buoyant flow on a horizontal, thermally insulated surface. The class of flows considered is one for which there is a uniform external stream at constant temperature but for which conditions upstream lead to a statically stable temperature field within the boundary layer. This has the effect of generating an adverse pressure gradient which, if sufficiently strong, causes the boundary-layer solution to terminate in a singularity. Results are obtained for a range of Prandtl numbers.

10A792. Temperature dissipation in a turbulent round jet. - RA Antonia and J Mi *(Dept of Mech, Univ of Newcastle, NSW, 2308, Australia)*. J Fluid Mech 250 531-551 (May 1993).

Parallel cold wires used to measure the temperature derivative, in each of the three spatial directions, in the self-preserving region of a turbulent round jet. The temperature derivative variances were inferred from the correlation method and from the temperature derivative spectra after correcting these for the effect of wire separation. Both methods yielded fully consistent results for the components of the average temperature dissipation: the radial and azimuthal values are nearly equal and only slightly larger than the axial component. The resulting departure from isotropy of the temperature dissipation is small, especially when compared with results in other free shear flows. The high-wavenumber behavior of the corrected temperature derivative spectra conforms closely with isotropy on the jet axis but small departures occur away from the axis. Conditional averages, based on spatially coherent temperature jumps, indicate that, while the organized motion makes a significant contribution to the temperature variance, its contribution to the temperature-derivative variances is small.

10A793. Mechanism for bypass transition from localized disturbances in wall-bounded shear flows. - DS Henningson *(Dept of Math, MIT)*, A Lundbladh, AV Johansson *(Dept of Mech, RIT, S-10044 Stockholm, Sweden)*. J Fluid Mech 250 169-207 (May 1993).

The linear, nonlinear and breakdown stages in the transition of localized disturbances in plane Poiseuille flow is studied by direct numerical simulations and analysis of the linearized Navier-Stokes equations. Three dimensionality plays a key role and allows for algebraic growth of the normal vorticity through the linear *lift-up* mechanism. This growth primarily generates elongated structures in the streamwise direction since it is largest at low streamwise wavenumbers. For finite-amplitude disturbances such structures will be generated essentially independent of the details of the initial disturbance, since the preferred nonlinear interactions transfer energy to low streamwise wavenumbers. The nonlinear interactions also give a decrease in the span-wise scales. For the stronger initial disturbances the streamwise vorticity associated with the slightly inclined streaks was found to roll up into distinct streamwise vortices in the vicinity of which breakdown occurred. The breakdown starts with a local rapid growth of the normal velocity bringing low-speed fluid out from the wall. This phenomenon is similar to the low-velocity spikes previously observed in transition experiments. Soon thereafter a small turbulent spot is formed. This scenario represents a *bypass* of the regular Tollmien-Schlichting, secondary instability process. The simulations have been carried out with a sufficient spatial resolution to ensure an accurate description of all stages of the breakdown and spot formation processes. The generality of the observed processes is substantiated by use of different types of initial disturbances and by Blasius boundary-layer simulations. The present results point in the direction of universality of the observed transition mechanisms for localized disturbances in wall-bounded shear flows.

10A794. Subharmonic transition spectra generation and transition prediction in boundary layers. - MB Zelman and II Maslennikova *(Inst of Theor and Appl Mech, Russian Acad of Sci, Novosibirsk, Russia)*. Eur J Mech B 12(2) 161-174 (1993).

The nonlinear resonant interaction of Tollmien-Schlichting waves is investigated within the first-order weakly nonlinear approximation to explain and model the broadening of the frequency and wave-number spectra of disturbances in subharmonic (S –) type laminar-turbulent transition in boundary layers. The transition process is concluded to be initiated by a cascade of energy towards 3D low frequency waves, whose "explosive" growth can be restricted only by transition. The results we obtain are applied to explain experimental measurements and to design a new approach to the determination of transition Reynolds number Re_{tr} in the case of low initial disturbance amplitudes. A physically based interpretation of the semiempirical e^N-method used to compute Re_{tr} is suggested.

10A795. Rational extension of the Clauser Eddy viscosity model to compressible boundary-layer flow. - T Kiss and JA Schetz *(Aerospace and Ocean Eng Dept, VPI)*. AIAA J 31(6) 1007-1013 (Jun 1993).

An extension of the Clauser eddy viscosity model for the outer part of a compressible, turbulent boundary layer is proposed. This extension, unlike all of the previous ones, is based on a derivation, and not on ad hoc assumptions. The logic of the derivation of the original model is followed, except that the Crocco integral and the Howarth-Dorodnitsyn transformation are used for the purpose of the comparison with the velocity defect law. Predictions with the new model and two earlier ad hoc extensions of the Clauser model are compared to the measured data. Improved predictions are obtained with the new model for both the outer part of the layer and the skin friction coefficient.

10A796. Investigation of a contoured wall injector for hypervelocity mixing augmentation. - IA Waitz *(Dept of Aeronaut and Astronaut, MIT)*, FE Marble, EE Zukoski *(Dept of Mech Eng, California IT, Pasadena CA 91125)*. AIAA J 31(6) 1014-1021 (Jun 1993).

An experimental and computational investigation of a contoured wall fuel injector is presented. The injector was aimed at establishing shock-enhanced mixing for the supersonic combustion ramjet engines currently envisioned for applications on hypersonic vehicles. Three-dimensional flowfield surveys and temporally resolved, planar Rayleigh scattering measurements are presented for Mach 1.7 helium injection into Mach 6 air. These experimental data are compared directly with a 3D Navier-Stokes simulation to provide a detailed characterization of the flow about the injector array. Time-mean mixing rate data and preliminary conclusions concerning various sources for axial velocity are presented.

10A797. Corrective technique for numerical prediction of liquid flow rate in annular flow study. - CP Tso *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263)* and S Sugawara *(O-arai Eng Center, Power Reactor and Nucl Fuel Dev, Japan)*. Commun Numer Methods Eng 9(6) 533-542 (Jun 1993).

The computer code FIDAS-3DT, developed by Power Reactor & Nuclear Fuel Development Corporation of Japan, has been used to solve by the finite-difference method an air-water horizontal annular flow problem based on two-phase, three-fluid and two-component velocity modeling. In an attempt to improve the water flow rate results, as compared with those of a reported experiment, several corrections applied to the code are investigated, and the recommended technique is presented.

10A798. Shear layer flow in a channel: Estimate on the dimension of the attractor. - A Miranville *(Lab d'Anal Numer, Univ Paris-Sud, Batiment 425, 91405 Orsay, France)*. Physica D 65(1-2) 135-153 (May 1993).

Our aim in this article is to derive an upper bound on the dimension of the attractor for the shear-layer channel flow in space dimension two. In that case we improve the result obtained in R. Temam, Infinite Dimensional Dynamical Systems in Mechanics and Physics for a fluid driven by its boundary passing from a bound which is exponential with respect to the Reynolds number to a physically more realistic bound of the form cRe^3.

10A801. Eddy structure in Stokes flow in a cavity. - PN Shankar *(Comput and Theor Fluid Dyn Div, Natl Aeronaut Lab, Bangalore 560 017, India)*. J Fluid Mech 250 371-383 (May 1993).

Stokes flow in a 2D cavity of rectangular section, induced by the motion of one of the walls, is considered. A direct, efficient calculational procedure, based on an eigenfunction expansion, is used to study the eddy structure in the cavity. It is shown that some of the results of earlier studies are quantitatively in error. More importantly, two interesting questions, namely the extent of the symmetry of the corner eddies and their relationship to the large-eddy structure are settled. By carefully examining the rather sudden change in the main eddy structure for cavities of depth around 1.629, it is shown that the main eddies are formed by the merger of the primary corner eddies; the secondary corner eddies then become the primary corner eddies and so on. Thus, in the evolution of the large-eddy structure the corner eddies, in some sense, play the role of progenitors. This explicit prediction should be experimentally verifiable.

10A802. Zones of influence in the compressible shear layer. - Dimitri Papamoschou *(Dept Mech and Aerospace Eng, UC, Irvine CA 92717)*. Fluid Dyn Res 11(5) 217-228 (May 1993).

The effect of Mach number on communication between regions of a shear layer is analyzed in the limit of geometric acoustics. Communication is quantified in terms of the acoustic intensity emitted by a point source and received by an observer moving with the flow. The generalized Snell's law is used to trace the sound rays which are shown to be highly distorted because of the Mach-number gradient. Sound-intensity calculations reveal that the influence of the source on the surrounding medium becomes confined to a smaller and smaller area as the Mach number increases. The zones of influence on the Lagrangian observer are funnel-shaped and become narrower with increasing Mach number. Communication is inhibited primarily in the axial direction, both upstream and downstream, and to a lesser extent in the transverse direction. Hindrance of communication may be the fundamental reason for enhanced stability of high Mach numbers.

368D. TURBULENT INCOMPRESSIBLE

10A803. Control of circular cylinder flow by end plates. - S Szepessy *(Dept SKSS, Alfa Laval Separation AB, S-147 80 Tumba, Stockholm, Sweden)*. Eur J Mech B 12(2) 217-244 (1993).

The present work involves an experimental study of the effect of end plate boundaries on the flow around a circular cylinder for Reynolds numbers 4×10^3-4.8×10^4 and cylinder aspect ratios $0.25 < L/d < 27.6$. The deviation from uniformly distributed flow along the body span is measured and discussed. End plate design is found to have a strong influence on the spanwise variation of the base pressure. A sufficiently long trailing edge distance is of vital importance in obtaining as uniform a pressure distribution along the span as possible, but the leading edge distance is also found to influence the flow. Within the measured Reynolds number range it is possible to define an optimized end plate design that, as far as possible, reduces spanwise flow nonuniformities. The end plate performance is markedly better at $Re = 4 \times 10^4$ than at 1×10^4. The influence of the end plate horse shoe vortex layer is found to be weak. Details of its formation are analyzed and discussed. Varying the cylinder aspect ratio showed a strong Reynolds number dependence and extreme flow patterns were found at an aspect ratio around 1. Keeping the aspect ratio about 1, in combination with the use of a short leading edge distance, was found to inhibit the onset of vortex shedding, resulting in a steady wake for Re $< 1 \times 10^4$. At $Re = 4 \times 10^4$, in contrast, a peak in base suction indicating the strongest vortex shedding was observed with $L/d=1$.

10A804. Buoyancy induced heat and mass transfer from a concentrated point source. - R Ganapathy *(Dept of Math, Natl Col, Tiruchirapalli 620 001, India)*. Fluid Dyn Res 11(5) 187-196 (May 1993).

This paper reports an analytical study of an unsteady heat and mass transfer flow induced by an instantaneous concentrated point source in an unbounded fluid. Assuming the thermal Rayleigh number to be small, analytical solutions are obtained for the flow field, temperature, and species concentration in the form of series expansions of the dependent variables in terms of the Rayleigh number. The impact of species diffusion on the buoyancy induced heat and fluid flow has been highlighted. Streamlines are drawn to demonstrate the evolution of the flow field at different times. Even though heat was specified to be one of the two diffusion mechanisms, the results apply as well to the case where the source generates simultaneously two different chemical components.

10A805. Mixing by a turbulent plume in a confined stratified region. - SSS Cardoso and AW Woods *(Inst of Theor Geophys, Dept of Appl Math and Theor Phys, Univ of Cambridge, Silver St, Cambridge CB3 9EW, UK)*. J Fluid Mech 250 277-305 (May 1993).

An experimental and theoretical study of the mixing produced by a plume rising in a confined stratified environment is presented. As a result of the pre-existing stable stratification, the plume penetrates only part way into the region; at an intermediate level it intrudes laterally forming a horizontal layer. As time evolves, this layer of mixed fluid is observed to increase in thickness. The bottom front advects downward in a way analogous to the first front in the filling box of Baines & Turner (1969), while the lateral spreading of the plume occurs at an ever-increasing level and an ascending top front results. We develop a model of this *stratified filling box*; the model predicts the rate at which the two fronts advance into the environment.

368I. JET-SOLID SURFACE INTERACTION

10A806. Flapping motion of a planar jet impinging on a V-shaped plate. - Cheng-Kuang Lin *(Aeronaut Res Lab, Chung Shan Inst of Sci and Tech, Taichung Taiwan, ROC)*, Fei-Bin Hsiao, Shyh-Shiun Sheu *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan, ROC)*. J Aircraft 30(3) 320-325 (May-Jun 1993).

The behavior of a planar jet impinging on a V-shaped plate is studied experimentally by means of pressure and velocity measurements and flow visualization. The plate with a symmetrically variable opening angle is located downstream at distance L from the jet exit. Data indicate that, for the presence of the plate, not only the large-scaled coherent structures in the shear layers exist in the jet, but also the whole jet column exhibits a prominent periodic flapping motion with a preferred frequency f_F in the flowfield. Results also show an unstable regime occurring for the flapping motion, in which criteria to determine the boundary of the regime are governed by the location and the opening angle of the plate. Moreover, the nondimensional Strouhal number $f_F L/U_j$ is found to maintain a constant value of 0.11, and this value is nearly insensitive to the opening angle of the plate in the operating Reynolds number range.

10A807. Onset of stochastic pulsations at the early nonlinear stage of the development of perturbations in the jet of an incompressible fluid propagating along a wall. - AA Burov and OS Ryzhov *(Moscow, Russia)*. J Appl Math Mech 56(6) 921-927 (1992).

The Korteweg-De Vries equation, which describes the nonlinear propagation of perturbations in a jet of incompressible fluid emanating from a slit in a planar screen and propagating along a wall is considered. When account is taken of the natural vibrations of the wall, the equation becomes inhomogeneous. If an external action is specified in the form of a running wave, the particular solution of the inhomogeneous equation may be sought in an analogous form. As a result, the simplest problem in the theory of dynamical systems in the Hamiltonian formulation arises. As usual, the existence of a homoclinic structure in the neighborhood of the separatrices is deduced from an analysis of a Poincare transformation. Among the trajectories belonging to the homoclinic structure in the secant plane, there are some with properties which are formulated in terms of determinate chaos. A fundamentally important conclusion concerning the dual role of solitons at the nonlinear stage of the wave motion of the fluid follows: on the one hand, they serve as the nuclei of large-scale coherent structures and, on the other hand, they are responsible for the onset of stochastic pulsations.

368J. JET-FLOW INTERACTION

10A808. Flip-flop jet nozzle extended to supersonic flows. - G Raman *(NASA Lewis Res Center Group, Sverdrup Tech, Brook Park OH 44142)*, M Hailye *(Univ of Michigan, Ann Arbor MI 48103)*, EJ Rice *(NASA Lewis Res Center, Cleveland OH 44135)*. AIAA J 31(6) 1028-1035 (Jun 1993).

An experiment studying a fluidically oscillated rectangular jet flow was conducted. The Mach number was varied over a range from low subsonic to supersonic. Unsteady velocity and pressure measurements were made using hot wires, piezoresistive pressure transducers, and pitot probes. In addition, smoke flow visualization using high-speed photography was used to document the oscillation of the jet. For the subsonic flip-flop jet, it was found that the apparent time-mean widening of the jet was not accompanied by an increase in the mass flux. Fluidically oscillated jets up to a Mach number of about 0.5 have been reported before, but to our knowledge there is no information on fluidically oscillated supersonic jets. It was found that it is possible to extend the operation of these devices to supersonic flows. The streamwise velocity perturbation levels produced by this device were much higher than the perturbation levels that could be produced using conventional excitation sources such as acoustic drivers. In view of this ability to produce high amplitudes, the potential for using a small-scale fluidically oscillated jet as an unsteady excitation source for the control of shear flows in full-scale practical applications seems promising.

10A809. Measurement of the nonsteady flow field in the opening of a resonating cavity excited by grazing flow. - HR Graf *(Lab for Vib and Acoust, Sulzer Brothers, CH-8401 Winterthur, Switzerland)* and WW Durgin *(Dept of Mech Eng, Worchester Polytech Univ, Worcester MA 01609)*. J Fluids Struct 7(4) 387-400 (May 1993).

Flow past the opening of a cavity can excite acoustic resonsance. The periodic velocity field in the region of the cavity opening has been measured for various flow conditions and the vorticity distribution has been computed from the measured data using numerical differentiation. The results indicate that the shear layer rolls up into discrete vortices, which travel across the cavity opening. Two resonances were found. The first is characterized by a single vortex being present and results in the greatest amplitude. The second is characterized by the presence of two vortices which excite a distinct but lesser amplitude resonance. As the flow velocity changes, the position of these vortices shifts relative to the phase of the acoustic cycle. The timing of the interaction between the moving vortices and the acoustic particle velocity determines, to a large extent, the intensity of the excitation, and therefore also the oscillation amplitude. The measurements also indicate that the boundary layer upstream of the leading edge pulsates considerably.

10A810. Numerical simulation of nonswirling and swirling annular liquid jets. - SG Chuech *(Taiwan Aerospace, Taipei, Taiwan, ROC)*. AIAA J 31(6) 1022-1027 (Jun 1993).

A numerical simulation method is described for analyzing the fluid dynamics of nonswirling and swirling annular liquid jets. In the present theoretical study, a general mathematics model for simulating these two types of annular film jets has been established using a curvilinear coordinate system conforming to the film boundaries. The study involves the derivation of governing equations, numerical solutions for annular film flow structure of both nonswirling and swirling cases, and model validation with available measurements. The solutions of flow structure consist of jet velocity, film thickness, and jet trajectory. The present model can predict the "transition" phenomenon of jet-shape formation from nonswirling "bell" to swirling "hollow cone". In verification studies, first the model is validated against other measurements and analyses of non-swirling bell-like jets. The second case includes a validation study on spray angle of swirling conical sprays and a comparison of fuel spray configuration of a pressure atomizer. The assessment results are encouraging and indicate a good capability of the current model.

10A811. Spatial stability of the Daniels and Eagles profiles. - ME Muwezwa *(Math Dept, Univ of Botswana, Gaborone, Botswana, Africa)*. J Eng Math 27(3) 233-244 (Aug 1993).

Daniels and Eagles obtained velocity profiles for exponential slender tubes. The spatial stability of these profiles is examined using a quasi-parallel approach. Contrary to expectation the profiles turn out to be stable.

10A812. Dynamics of liquid jets revisited. - RMSM Schulkes *(Dept of Appl Math and Theor Phys, Univ of Cambridge, Silver St, Cambridge CB3 9EW, UK)*. J Fluid Mech 250 635-650 (May 1993).

In this paper we investigate the long-wavelength approximations of the equations governing the motion of an inviscid liquid jet. Using a formal perturbation expansion it will be shown that the 1D equations presented by Lee (1974) are inconsistent. The inconsistency arises from the fact that terms which have been retained in the boundary conditions should have been rejected in view of the approximations made in the momentum equations. With the correct equations a number of anomalies between Lee's model and other models are eliminated. An explicit periodic solution to the nonlinear evolution equations we have derived is presented. However, it turns out that the wavenumbers for which this solution is valid lie outside the range in which the long-wavelength approximations are applicable. In addition we present numerical solutions to the nonlinear equations we have derived. In the unstable regime we find that, as disturbances grow, the characteristic axial lengthscales of the major features are typically of the order of the radius of the jet. This casts some doubt on the validity of the long-wavelength approximations in the study of nonlinear liquid jet dynamics.

10T813. Monotonicity and boundedness in the Boussinesq-equations. - BJ Schmitt and W von Wahl *(Lehrstuhl fur Angewandte Math, Univ Bayreuth, PO Box 101251, W-8580 Bayreuth, Germany)*. Eur J Mech B 12(2) 245-270 (1993).

10A814. Numerical investigations from compressible to isobaric Rayleigh-Benard convection in 2D. - J Frohlich *(Fachbereich Math, Univ Kaiserslautern, 6750 Kaiserslautern, Germany)* and S Gauthier *(Centre d'Etudes de Limeil-Valenton, 94195 Villeneuve-St-Georges, Cedex, France)*. Eur J Mech B 12(2) 141-159 (1993).

In studies of non-constant density flows several different sets of continuum equations are used in the literature, depending on the physical situation that is being considered. The present paper is concerned with the so-called Low Mach Number equations that allow, in contrast of the classical Boussinesq equations, large variations in the density. In particular the transition between regimes covered by these equations and those requiring the complete Navier-Stokes equations is studied. The discussion of the different regimes shows some essential features of the modeling of convection. Numerical results obtained by spectral methods for the 2D Rayleigh-Benard problem quantify the effect of compressibility on the flow field and furnish some indication on when to use one or the other set of equations.

10A815. Oscillatory instabilities produced by heat from a temperature-controlled hot wire below an interface. - C Roze, G Gouesbet, R Darrigo *(Lab d'Energetique des Syst et Procedes, URA CNRS no 230, INSA de Rouen, BP 08-76131, Mont St Aignan Cedex, France)*. J Fluid Mech 250 253-276 (May 1993).

New experimental results are reported for the motion of a liquid surface caused by the heat released from a hot wire below the surface. Starting from a base state with steady convection and steady deformation of the free surface caused by variations in surface tension and heat transport to the surface, the system loses its stability through a supercritical Hopf bifurcation occurring on a curve $f(\delta T_x, d) = 0$ in which d is the distance between hot wire and surface and δT_x a critical temperature difference. These experiments are a model for more complex laser heating experiments in which chaotic motions may occur. Some emphasis is placed on the characterization of propagating waves produced on the surface after the occurrence of the bifurcation.

10A816. Convection in a rotating spherical fluid shell with an inhomogeneous temperature boundary condition at infinite Prandtl number. - K Zhang and D Gubbins *(Dept of Earth Sci, Univ of Leeds, Leeds, LS2 9JT, UK)*. J Fluid Mech 250 209-232 (May 1993).

We examine thermal convection in a rotating spherical shell with a spatially nonuniformly heated outer surface, concentrating on three distinct heating modes: first, with wavelength and symmetry corresponding to the most unstable mode of the uniformly heated problem; secondly, with the critical wavelength but opposite equatorial symmetry; and thirdly, with wavelength much larger than that of the most unstable mode. Analysis is focused on boundary-locked convection, the associated spatial resonance phenomena, the stability properties of the resonance solution, and time-dependent secondary convection. A number of new forms of instability and convection are found: the most interesting is perhaps the saddle-node bifurcation, which is the first to be found for realistic fluid systems governed by partial differential equations. An analogous Landau amplitude equation is also analyzed, providing an important mathematical framework for understanding the complicated numerical solutions.

10A817. Measurements of the primary instabilities of film flows. - Jun Liu, JD Paul, JP Gollub *(Dept of Phys, Haverford Col, Haverford PA 19041)*. J Fluid Mech 250 69-101 (May 1993).

We present novel measurements of the primary instabilities of thin liquid films flowing down an incline. A fluorescence imaging method allows accurate measurements of film thickness h(x,y,t) in real time with a sensitivity of several microns, and laser beam deflection yields local measurements with a sensitivity of less than one micron. We locate the instability with good accuracy despite the fact that it occurs (asymptotically) at zero wavenumber, and determine the critical Reynolds number R_c for the onset of waves as a function of angle β. The measurements of $R_c(\beta)$ are found to be in good agreement with calculations, as are the growth rates and wave velocities. We show experimentally that the initial instability is convective and that the waves are noise-sustained. This means that the waveform and its amplitude are strongly affected by external noise at the source. We investigate the role of noise by varying the level of periodic external forcing. The nonlinear evolution of the waves depends strongly on the initial wavenumber (or frequency f). A new phase boundary $f^x_s(R)$ is measured, which separates the regimes of saturated finite amplitude waves (at high f) from multipeaked solitary waves (at low f). This boundary probably corresponds approximately to the sign reversal of the third Landau coefficient in weakly nonlinear theory. Finally, we show that periodic waves are unstable over a wide frequency band with respect to a convective subharmonic instability. This instability leads to disordered 2D waves.

10A818. Nonlinear evolution of waves on a vertically falling film. - H-C Chang *(Dept of Chem Eng, Univ of Notre Dame, Notre Dame IN 46556)*, EA Demekhin, DI Kopelevich *(Dept of Appl Math, Krasnodar Polytech Inst, Krasnodar 350072, Russia)*. J Fluid Mech 250 433-480 (May 1993).

Wave formation on a falling film is an intriguing hydrodynamic phenomenon involving transitions among a rich variety of spatial and temporal structures. Immediately beyond an inception region, short, near-sinusoidal capillary waves are observed. Further downstream, long, near-solitary waves with large-tear-drop humps preceded by short, front-running capillary waves appear. Both kinds of waves evolve slowly downstream such that over about ten wavelengths, they resemble stationary waves which propagate at constant speeds and shapes. We exploit this quasi-steady property here to study wave evolution and selection on a vertically falling film. All finite-amplitude stationary waves with the same average thickness as the Nusselt flat film are constructed numerically from a boundary-layer approximation of the equations of motion.

372. Turbulence

10A819. Momentum and heat transport in the turbulent intermediate wake of a circular cylinder. - M Matsumura *(Dept of Appl Mech Eng, Kitami IT, Kitami, Hokkaido, 090, Japan)* and RA Antonia *(Dept of Mech Eng, Univ of Newcastle, NSW, 2308, Australia)*. J Fluid Mech 250 651-668 (May 1993).

Hot-wire anemometry has been used in the intermediate wake (x/d = 10 to 40) of a slightly heated circular cylinder in order to quantify the contribution from the coherent motion to various conventionally averaged quantities, in particular the average momentum and heat fluxes. The overall contribution to the lateral heat flux is always greater than that to the Reynolds shear stress, indicating that the turbulent Karman vortex street transports heat more effectively than momentum. The difference in these contributions is reflected in the topologies of the velocity and temperature fields. There is significant streamwise evolution of these topologies througout the intermediate wake. At x/d = 10, the net heat transport associated with the vortical motion occurs in the downstream region of each vortex. At other downstream stations, the net heat transport is equally distributed between the upstream and downstream regions of individual vortices.

10A820. Direct numerical simulation of laminar and turbulent flow over riblet-mounted surfaces. - DC Chu and GE Karniadakis *(Dept of Mech and Aerospace Eng, Program in Appl and Comput Math, Princeton)*. J Fluid Mech 250 1-42 (May 1993).

The flow in a channel with its lower wall mounted with streamwise riblets is simulated using a highly efficient spectral element-Fourier method. The range of Reynolds numbers investigated is 500 to 3500, which corresponds to laminar, transitional, and turbulent flow states. A complete study is presented for V-groove riblets; the effect of rounded riblets is also investigated. Our results suggest that in the laminar regime there is no drag reduction, while in the transitional and turbulent regimes drag reduction exists (approximately 6% at Reynolds number 3500) for the riblet-mounted wall in comparison with the smooth wall of the channel. For the first time, we present detailed turbulent statistics (turbulence intensities, Reynolds shear stresses, skewness and flatness) as well as a temporal analysis using a numerical analog of the VITA technique. The flow structure over the riblet-mounted wall is also analyzed in some detail and compared with the corresponding flow over the smooth wall in an attempt to identify the physical mechanisms that cause drag reduction. The accuracy of the computation is established by comparing flow quantities corresponding to the smooth wall with previous direct numerical simulation results as well as with experimental results; on the riblet-mounted wall comparison is made with available experimental results. The agreement is very good for both cases. The current computation is the first direct numerical simulation of turbulence in a complex geometry domain.

10A821. Structure of a 3D turbulent boundary layer. - AT Degani *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*, FT Smith *(Math Dept, Univ Col London, London WC1E 6BT, UK)*, JDA Walker *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*. J Fluid Mech 250 43-68 (May 1993).

The 3D turbulent boundary layer is shown to have a self-consistent two-layer asymptotic structure in the limit of large Reynolds number. In a streamline coordinate system, the streamwise velocity distribution is similar to that in 2D flows, having a defect-function form in the outer layer which is adjusted to zero at the wall through an inner wall layer. An asymptotic expansion accurate to two orders is required for the cross-stream velocity which is shown to exhibit a logarithmic form in the overlap region. The inner wall-layer flow is collateral to leading order but the influence of the pressure gradient, at large but finite Reynolds numbers, is not negligible and can cause substantial skewing of the velocity profile near the wall. Conditions under which the boundary layer achieves self-similarity and the governing set of ordinary differential equations for the outer layer are derived. The calculated solution of these equations is matched asymptotically to an inner wall-layer solution and the composite profiles so formed describe the flow throughout the entire boundary layer. The effects of Reynolds number and cross-stream pressure gradient on the cross-stream velocity profile are discussed and it is shown that the location of the maximum cross-stream velocity is within the overlap region.

10A822. Systematic comparison of mathematically simple turbulence models for 3D boundary layers. - MSG Bettelini and TK Fannelop *(Dept of Fluid Dyn, Swiss Fed IT, Zurich 8092, Switzerland)*. AIAA J 31(6) 999-1006 (Jun 1993).

The paper presents a systematic comparison of some widely used turbulence models with one another and with experiments. The mathematically simplest models applicable to 3D steady, incompressible boundary layers are of primary interest. Besides the more widely used algebraic formulations, models using simplified transport equations for turbulence quantities, such as the Johnson-King model, are considered. These models are applied to a variety of well-established 2D and 3D test cases, for which accurate and reliable experimental data are available. To avoid differences associated with different numerical integration procedures, all models have been used with the same finite difference method especially developed for this purpose. This method solves the first-order boundary-layer equations written in terms of streamline coordinates. One broad conclusion of this study is that all models considered give reasonable predictions for the gross boundary-layer parameters, but important differences become apparent for certain local values. Specific recommendations for the choice of turbulence model in practical applications are included.

10A823. Numerical computation of convective dispersion in turbulent buoyant jets. - JCF Pereira and JMP Rocha *(Dept of Mech Eng, Inst Superior Tecnico-Tech Univ of Lisbon, l'Av Rovisco Pais, 1096 Lisboa Codex, Portugal)*. Numer Heat Transfer A 23(4) 399-414 (Jun 1993).

Numerical predictions of mean and turbulent characteristics of the axisymmetric vertical jet and plume are reported. An algebraic stress and flux model is used to close the time-averaged Navier-Stokes and energy equations. Special attention was given to the numerical model, which is based on a finite-volume discretization of the elliptic form of flow equations. A special procedure is used to treat free boundaries and to compute the flow up to the similarity regime. The model was applied to the prediction of the flow for the momentum-dominated (jet) and buoyancy-dominated (plume) regime. The results show that the essential characteristics of the flows, especially for the plume, are correctly reproduced. However, some discrepancies arise from the comparison of predicted and experimental levels.

10A824. Intermittency in a cascade model for turbulence. - R Benzi, L Biferale, G Parisi *(Dipartimento di Fisica, Univ "Tor Vergata", Via della Ricerca Scientifica, I-00133 Rome, Italy)*. Physica D 65(1-2) 163-171 (May 1993).

In this note we study the possibility of performing analytic computations of the exponents characterizing the multifractal behavior of turbulence. A simple analytic computation is presented in the framework of the cascade model (or shell model).

10A825. Implementation of a one-equation turbulence model within a stabilized FE formulation of a symmetric advective-diffusive system. - K Jansen, Z Johan, TJR Hughes *(Div of Appl Mech, Durand Bldg, Stanford)*. Comput Methods Appl Mech Eng 105(3) 405-433 (June 1993).

The success of stabilized FEMs for symmetric advective-diffusive formulations of the laminar Navier-Stokes equations has motivated extension of these concepts to turbulent flows. A one-equation model which preserves the symmetry of the system's advective and diffusive matrices has been developed. This model is based on the work of Norris and Reynolds and utilizes a transport equation for the turbulent velocity scale q and an algebraic relation for the turbulent length scale l. From these two quantities, an eddy viscosity can be calculated. This model has been implemented by way of a Galerkin-least-squares FEM. Solutions are presented which verify the good behavior of the formulation.

10A826. Low Reynolds number κ-ε modeling with the aid of direct simulation data. - W Rodi *(Inst fur Hydromech, Univ Karlsruhe, Kaiserstr 12, Karlsruhe, Germany)* and NN Mansour *(NASA Ames Res Center, Moffett Field CA 94035)*. J Fluid Mech 250 509-529 (May 1993).

The constant $C\mu$ and the near-wall damping function $f\mu$ in the eddy-viscosity relation of the κ-ϵ model are evaluated from direct numerical simulation (DNS) data for developed channel and boundary-layer flow, each at two Reynolds numbers. Various existing f_μ model functions are compared with the DNS data, and a new function is fitted to the high-Reynolds-number channel flow data. The ε-budget is computed for the fully developed channel flow. The relative magnitude of the terms in the ε-equation is analyzed with the aid of scaling arguments, and the parameter governing this magnitude is established. Models for the sum of all source and sink terms in the ε-equation are tested against the DNS data, and an improved model is proposed.

A computer code has been developed to simulate collisional effects in plasmas for the regime where plasma instabilities are dominant but are modified by weak collisions. The numerical method developed for the code is composed of a Galerkin method embedded within a locally 1D approach. This algorithm is used to solve, over the (x,v) phase plane, a simplified Fokker-Planck equation with a 1D Fokker-Planck operator, including a velocity dependent collision frequency. A stability analysis for the numerical scheme is given. The effects of small angle collisions on the Landau damping of plasma waves and the two-stream instability are examined. Results confirm and extend earlier numerical observations.

10A830. Explicit symplectic integration scheme for plasma simulations. - JR Cary and I Doxas *(Astrophys Planet and Atmos Sci Dept, Univ of Colorado, Boulder CO 80309-0391)*. J Comput Phys 107(1) 98-104 (Jul 1993).

An explicit symplectic integration scheme which describes the self-consistent wave particle interaction is developed. The integrator does not split the Hamiltonian trivially into a kinetic and potential part. The integrator yields accurate growth rates for the gentle-bump instability even when the timestep is of the order of the inverse plasma frequency. This represents up to a tenfold reduction in computation compared to conventional schemes. The integrator is generalizable to arbitrary order without increase in storage requirements, but tests show that when the accuracy requirements are of the order of a few percent, the second-order method is the most efficient.

10A831. Particle loading for a plasma shear layer in a magnetic field. - D Cai *(Inst of Info Sci and Electron, Univ of Tsukuba, Ibaraki 305, Japan)*, LRO Storey, T Neubert *(STAR Lab, Stanford)*. J Comput Phys 107(1) 84-97 (Jul 1993).

Some new particle loading methods have been developed for use in simulating a plasma shear layer with nonuniform density and temperature in the presence of a magnetic field, especially with a large effective ion gyroradius. The numerical approach to the shear instability with strong velocity shear consists of starting a simulation from a state of equilibrium, perturbing this equilibrium in some way, then observing the linear growth of the perturbation and its ultimate saturation. With the usual particle loading method, it is difficult to reproduce the equilbrium state if the ion gyroradius is not small on the scale of the shear. The reason is that, with nonuniform velocity shear, ie, with the nonuniform E-field, a particle may have more than one guiding-center, the particle distribution cannot be obtained analytically, and it may need to be evaluated numerically. If an equilibrium state is not achieved in the particle loading, the shear may relax by means of an "artificial instability" in the course of the simulation, obscuring the physics' of interest. With the particle loading method here presented, we simulate a shear layer in a state close to equilibrium without having to solve the Vlasov-Boltzmann equation.

10A832. Simulation of low-frequency electromagnetic phenomena in kinetic plasmas of 3D. - Motohiko Tanaka *(Natl Inst for Fusion Sci, Nagoya 464-01, Japan)*. J Comput Phys 107(1) 124-145 (Jul 1993).

An advanced kinetic simulation method has been developed and implemented in the HIDENEK code to study large space-scale, low-frequency electromagnetic phenomena occurring in inhomogeneous plasmas. The present method is specially designed for high magnetic field ($\omega_{ce} \geq \omega_{pe}$), inhomogeneous plasma simulations. The guiding-center approximation with magnetic drifts is adopted to the perpendicular motion of the electrons, whereas the inertia effect is retained in their parallel motion. Also, a slightly backward time-decentered scheme is introduced to the equations of motion and the Maxwell equations. These equations are combined to yield the full-implicit coupled, field-particle equations which allow us to determine the future electromagnetic field in a large time step compared to the electron time scales with the diamagnetic drift and magnetization currents being included.

378B. WINGS AND AIRFOILS

10A833. Aerodynamics of maneuvering slender wings with leading-edge separation. - TS Tavares *(Aeromech Div, Comput Fluid Dyn Branch, US Air Force Wright Lab, WPAFB)* and JE McCune *(Dept of Aeronaut and Astronaut, MIT)*. AIAA J 31(6) 977-986 (Jun 1993).

A nonlinear theoretical technique is presented for treating the unsteady aerodynamics of low-aspect-ratio wings with leading-edge separation in incompressible flow. Cases are treated for wings in steady flight and for those undergoing severe unsteady maneuver. The treatment extends classical slender wing theory to allow for large-scale motion along with possibly asymmetric wake development. Calcualted results are presented for a variety of cases and are compared with related analyses and experiments. Examples studied include wings of delta and clipped-delta planform. Flight conditions and maneuvers treated include sideslip, sudden plunge, and rapid constant-rate roll at zero angle of attack. New results are interpreted in the light of wake history effects, a framework which provides a simplified means of interpreting the aerodynamic response in the severe maneuver case. The ability of the calculations to reproduce observed phenomena under a wide variety of conditions supports the practical usefulness of the extended slender wing treatment as a tool for gaining increased insight into the unsteady interaction between low-aspect-ratio wings and their wakes.

10A834. Contruction and calculation of optimal nonlifting critical airfoils. - DW Schwendeman, MCA Kropinski, JD Cole *(Dept of Math Sci, RPI)*. Z Angew Math Phys 44(3) 556-571 (May 1993).

Numerical calculations are carried out in the hodograph plane to construct optimal critical airfoil shapes and the flow about them. These optimal airfoil shapes give the highest free-stream Mach number M_∞ for a given thickness ratio δ and tail angle θ_T (nonlifting) for which the flow is nowhere supersonic. A relationship between M_∞ and δ for various θ_T is given. Analytical and numerical solutions to the same problem are found on the basis of transonic small-disturbance theory. These results provide a limiting case as $M_\infty \to 1$, $\delta \to 0$ and agree well with the calculations of the full problem. Using a numerical method to calculate the flow about general (subsonic) airfoils, a comparison is made between the critical free-stream Mach numbers for some standard airfoil shapes and the optimal free stream Mach number of the corresponding δ and θ_T. A significant increase in the critical free-stream Mach number is found for the optimal airfoils.

10A835. Effects of blowing on delta wing vortices during dynamic pitching. - LS Miller *(Dept Aerospace Eng, Wichita State Univ, Wichita KS 67208)* and BE Gile *(Appl Aerodyn Div, Subsonic Aerodyn Branch, NASA Langley Res Center MS 286, Hampton VA 23665)*. J Aircraft 30(3) 334-339 (May-Jun 1993).

An experimental investigation was conducted in a water tunnel to identify the effects of apex blowing on two delta wing models undergoing constant pitch-rate motion. One wing was of 60° sweep and the other was of 76° sweep. Flow visualization methods were utilized to determine vortex burst locations for a range of pitch up and pitch down rates, apex jet strengths, and blowing directions. Results indicate, individually, that blowing direction on the 60° wing and blowing rate on the 76° wing have the greatest effect on vortex behavior under both static and dynamic pitch-up conditions. Vortex improvements, for any blowing direction or rate examined, are most dramatic during dynamic pitch-down conditions. In this case, the use of blowing resulted in the reformation of unburst vortices with significant length.

10A836. Indicial lift approximations for 2D subsonic flow as obtained from oscillatory measurements. - JG Leishman *(Dept Aerospace Eng, Univ of Maryland, College Park MD 20742)*. J Aircraft 30(3) 340-351 (May-Jun 1993).

An approach is described to obtain generalized approximations to the indicial lift response due to angle of attack and pitch rate in 2D subsonic flow. Starting from an assumed representation, the approximations are accomplished by means of a nongradient optimization algorithm in which the coefficients of the approximation are free parameters. The optimization is subject to prescribed constraints in terms of the known initial and asymptotic behavior of the indicial response, and by requiring the response duplicate the known exact solutions at earlier values of time. The approach is applied to extract the intermediate forms of the indicial lift response, generalized in terms of Mach number and pitch axis location, from experimental measurements of the unsteady lift in the frequency domain.

10A837. Nonequilibrium turbulence modeling study on light dynamic stall of a NACA0012 airfoil. - M Dindar, U Kaynak *(TUSAS Aerospace Insdust, PO Box 18, Ankara, Turkey)*, K Fujii *(Inst of Space and Aeronaut Sci, Kanagawa, Japan)*. J Aircraft 30(3) 304-308 (May-Jun 1993).

A computational study on the nonequilibrium turbulence modeling effects for the prediction of the light stall phenomenon has been done for the NACA0012 airfoil. For this, an unsteady thin-layer Navier-Stokes solver was developed that is capable of solving the flowfield around an airfoil undergoing unsteady harmonic motion. In the program, the Baldwin-Lomax and Cebeci-Smith turbulence models were used as baseline models, and the Johnson-King turbulence model was used to study the nonequilibrium effects. It was found that the nonequilibrium effects are important for the prediction of the light stall, and only the Johnson-King model yields light stall hysteresis loop that is similar to the experiment. It was also found that the wind tunnel wall effects are important, and a mean angle of attack increase in the computation was necessary to yield a better agreement with the experiment.

10A838. Slender wing rock revisited. - LE Ericsson *(Lockheed Missiles and Space, Sunnyvale CA 94088)*. J Aircraft 30(3) 352-356 (May-Jun 1993).

Analysis of experimental results for slender delta wings reveals that asymmetric liftoff of the leading-edge vortices on slender delta wings does not start the wing rock, although it is responsible for the large limit cycle amplitude observed in experiments. As a consequence, the interaction of slender wing rock does not depend upon the interaction between the two leading-edge vortices, but can be generated by one wing half by itself, making slender wing rock more likely to occur on high agility aircraft than previously thought.

10A839. Velocity and vorticity distributions over an oscillating airfoil under compressible dynamic stall. - MS Chandrasekhara *(Dept of Aeronaut and Astronaut, NASA Ames Res Center, MS 260-1, Moffett Field CA 94035-1000)* and S Ahmed *(MCAT Inst, San Jose CA 95127)*. AIAA J 31(6) 995-996 (Jun 1993).

The velocity and vorticity fields around an oscillating airfoil in compressible dynamic stall are reported. Phase averaged, two component laser velocimetry data were obtained at a freestream Mach number of 0.3 and a reduced frequency of 0.05. This is the first set of velocity data available at a high Reynolds number (540,000) under compressible flow conditions and it serves as a good database for development and validation of computer codes. Of particular interest is the formation of a separation bubble, which bursts coincidentally with the formation of the dynamic stall vortex, adding an extra degree of physical complexity to the problem.

10A840. Vortex generators used to control laminar separation bubbles. - M Kerho *(Aerospace Eng, Univ Illinois, Urbana IL)*, S Hutcherson, RF Blackwelder, RH Liebeck *(Aerospace Eng, USC, Los Angeles CA 90089)*. J Aircraft 30(3) 315-319 (May-Jun 1993).

This study examines the effect of various forms of vortex generators on the laminar separation bubble of a 2D low Reynolds number Liebeck LA2573A airfoil. The objective of this research was to determine the effects that different generator sizes and spacings have upon the separation bubble and the drag. Windtunnel measurements were made on several generator configurations at Reynolds numbers ranging from 200 000 to 600 000 at angles of attack less than the stall angle where the separation bubble can provide a significant contribution to the airfoil drag. The vortex generators used were constructed small enough to be contained completely within the laminar boundary layer. Wind tunnel data included airfoil drag and mean and fluctuating velocity measurements in the laminar and turbulent boundary layers. Results have shown that the use of vortex generators provides a measurable decrease in airfoil drag at the lower range of Reynolds number tested. At the airfoil's design condition and Reynolds number of 235 000, the submerged vortex generators were shown to decrease the airfoil drag by a maximum of 38% at $C_l = 0.572$.

10A841. FE multigrid solution of Euler flows past installed aero-engines. - J Peraire, J Peiro *(Dept of Aeronaut, Imperial Col, London SW7 2BY, UK)*, K Morgan *(Dept of Civil Eng, Univ Col, Swansea SA2 8PP, UK)*. Comput Mech 11(5-6) 433-451 (1993).

A FE based procedure for the solution of the compressible Euler equations on unstructured tetrahedral grids is described. The spatial discretization is accomplished by means of an approximate variational formulation, with the explicit addition of a matrix form of artificial viscosity. The solution is advanced in time by means of an explicit multi-stage time stepping procedure. The method is implemented in terms of an edge based representation for the tetrahedral grid. The solution procedure is accelerated by use of a fully unstructured multigrid algorithm. The approach is applied to the simulation of the flow past an installed aero-engine nacelle, at three different free stream conditions. Comparison is made between the numerical predictions and experimental pressure observations.

10A842. Refinements in determining satellite drag coefficients: Method for resolving density discrepancies. - MM Moe *(Dept of Physics, Sch of Phys Sci, UC, Irvine CA 92717)*, SD Wallace *(Dept of Elec and Comput Eng, Sch of Eng, UC, Irvine CA 92717)*, K Moe *(Acquisition Meteorol Office, Space and Missile Syst Center, Los Angeles AFB CA 90009)*. J Guidance Control Dyn 16(3) 441-445 (May-Jun 1993).

The discrepancies in atmospheric densities deduced from satellites of compact and long cylindrical shapes can be used to improve our knowledge of drag coefficients. Constraints on the accommodation coefficient imposed by experiments in space and in the laboratory make it possible to resolve the discrepancies and gain information on the angular distribution of molecules reemitted from satellite surfaces. We present a sample calculation based on some limited published data. If the published nominal length-to-diameter ratio of the cylindrical satellites is the actual ratio, then we can conclude that the assumption of a diffuse angular distribution of reemitted molecules is adequate (at least near 200-km altitude), even for the long cylindrical sides where most of the molecules strike at grazing incidence. The method can be used with detailed orbital data and precise satellite shapes to infer reflection characteristics and drag coefficients for a range of altitudes and perigee velocities.

Computational investigation of a pneumatic forebody flow control concept. - K Gee *(MCAT Inst, MS 258-1, Moffett Field CA 94035)*, D Tavella *(CSC Corp, Ames Res Center, Moffett Field CA 94035)*, LB Schiff *(High Alpha Tech, Fluid Dyn Div, NASA Ames Res Center, MS 258-1, Moffett Field CA 94035)*. J Aircraft 30(3) 326-333 (May-Jun 1993).

The effectiveness of a tangential slot blowing concept for generating lateral control forces on an aircraft forebody is analyzed using computational fluid dynamics (CFD). The flow about a fighter forebody is computed using a multiple-zone, thin-layer Navier-Stokes code. Tangential slot blowing is modeled by the use of an actuator plane. The effects of slot location and slot length on the efficiency of the system are analyzed. Results of the study indicate that placement of the slot near the nose of the aircraft greatly enhances the efficiency of the system, whereas, the length and circumferential location of the slot are of secondary importance. Efficiency is defined by the amount of side force or yawing moment obtained per unit blowing coefficient. The effect of sideslip on the system is also analyzed. The system is able to generate incremental changes in forces and moments in flow with a sideslip angle of 10 deg comparable to those obtained at zero sideslip. These results are used to determine a baseline configuration for an experimental study of the tangential slot blowing concept.

10A847. Unsteady transonic 2D Euler solutions using FE. - GA Davis and OO Bendiksen

(Mech Aerospace and Nucl Eng Dept, UCLA). AIAA J 31(6) 1051-1059 (Jun 1993).

A FE solution of the unsteady Euler equations is presented, and demonstrated for 2D airfoil configurations oscillating in transonic flows. Computations are performed by spatially discretizing the conservation equations using the Galerkin weighted residual method and then employing a multistage Runge-Kutta scheme to march forward in time. Triangular FEs are employed in an unstructured O-mesh computational grid surrounding the airfoil. Grid points are fixed in space at the far-field boundary and are constrained to move with the airfoil surface to form the near-field boundary. A mesh deformation scheme has been developed to efficiently move interior points in a smooth fashion as the airfoil undergoes rigid-body pitch and plunge motion. Both steady and unsteady results are presented, and a comparison is made with solutions obtained using finite volume techniques. The effects of using either a lumped or consistent mass matrix were studied and are presented. Results show that the FEM provides an accurate solution for unsteady transonic flows about isolated airfoils.

10A848. Millisecond aerodynamic force measurement with side-jet model in the ISL shock tunnel. - KW Naumann, H Ende, G Mathieu, A George *(Dept of Gas Dyn, French-German Res Inst, 68301 St Louis, France)*. AIAA J 31(6) 1068-1074 (Jun 1993).

This paper presents a description of a novel millisecond aerodynamic force meausurement technique and the first experiments in hypervelocity flow with a model, which is equipped with laterally blowing jets and a set of accelerometers. A fast-acting mounting support releases the model and grips it again after a free flight duration of some milliseconds. Using measured acceleration and Pitot pressure histories allows direct straightforward time-dependent evaluation of the aerodynamic coefficients. This procedure is insensitive against nonlinearities or disturbances in the starting phase of the flow and compensates flow variations, if the flow is quasistationary and maintains a roughly uniform Mach number. The results quantify the time necessary to establish quasistationary flow for the actual test conditions. Quantitaitve results are also obtained for the force, which is produced by interaction of side jets and ambient flow and acts on the surface of the model. At the troposheric hypervelociy conditions of our test, the interaction force on a flat plate substantially increases jet thrust.

10A849. Implicit finite volume methods and application to a delta wing problem. - CP Li. Comput Mech 11(5-6) 408-420 (1993).

Numerical performance of three schemes has been assessed by focusing on the formulations of convective flux for inviscid and viscous supersonic flows. The central scheme stabilized by flux limiters and Lax-Friedrichs' viscosity has significantly improved the solution obtained by the conventional scheme blended with artificial damping. Themodified scheme produces nearly as nonoscillatory results for solution discontinuities as the upwind-biased TVD schemes and as accurate viscous layer as the centered scheme for supersonic flow past a delta wing. Its attractive attributes include generality, simplicity and independence of tuning parameters.

10A850. Multiblock Navier-Stokes solutions about the F/A-18 wing-LEX-fuselage configuration. - F Ghaffari, JM Luckring *(Transonic Aerodyn Branch, Appl Aerodyn Div, NASA Langley Res Center, Hampton VA 23665)*, JL Thomas *(Comput Aerodyn Branch, Fluid Mech Div, NASA Langley Res Center, Hampton VA 23665)*, RT Biedron *(Anal Services and Mat, Hampton VA 23666)*. J Aircraft 30(3) 293-303 (May-Jun 1993).

3D thin layer Navier Stokes computations are presented for the F/A 18 configuration. The modeled configuration includes an accurate surface representation of the fuselage, leading-edge extension (LEX), and wing, both with and without leading-edge flap deflection. A multiblock structured grid strategy is employed to decompose the computational flowfield domain around the subject configuration. Steady-state solutions are obtained from an algorithm that solves the compressible Navier-Stokes equations with an upwind biased, flux difference splitting approach. The results presented are based on a fully turbulent flow assumption, simulating the high Reynolds number flow conditions that correspond to a recent F/A-18 flight experiment. Good agreements between the computations and the flight test results are obtained for both surface flow patterns as well as surface pressure distributions. Furthermore, a correlation between the computed LEX vortex-core and the flight test results, observed by the way of smoke visualization, is also presented.

10A851. Experimental and theoretical study for nonlinear aeroelastic behavior of a flexible rotor blade. - DM Tang *(Dept of Mech Eng and Mat Sci, Duke Univ, Durham NC 27706)* and EH Dowell *(Sch of Eng, Duke Univ, Durham NC 27706)*. AIAA J 31(6) 1133-1142 (Jun 1993).

The purpose of this paper is to study the flutter instability and forced response of a nonrotating flexible rotor blade model with a geometrical structural nonlinearity and a freeplay structural nonlinearity. The ONERA stall aerodynamic model is used. External excitations are provided by base harmonic excitations in the pitch angle and the chordwise direction, respectively. Two cases are considered in this paper. Case A is for a nonlinear blade structure with an unstalled unsteady aerodynamic model. Case B is for the nonlinear blade structure with a large effective mean angle of attack. The effects of the structural and aerodynamic nonlinearities and initial disturbance on instability and forced response behavior are discussed. A wind-tunnel test has also been carried out in the Duke University low-speed wind-tunnel. The wind-tunnel tests show generally good agreement between theory and experiment for both static and dynamic behavior. Although the mathematical and experimental model of the nonrotating blade is different from the operational rotating hingeless rotor blade, the results from the experimental-theoretical correlation study provide fundamental understanding of the nonlinear aeroelastic behavior for a flexural-flexural-torsional hingeless rotor blade.

382. Lubrication

10A852. Fast method for the analysis of thermal-elastohydrodynamic lubrication of rolling-sliding line contacts. - Rong-Tsong Lee and Chao-Ho Hsu *(Dept of Mech Eng, Natl Sun Yat-Sen Univ, 80424 Kaohsiung, Taiwan)*. Wear 166(1) 107-117 (15 Jun 1993).

A fast method for the analysis of thermal-elastohydrodynamic lubrication between two deformable cylinders was developed at high loads and high slip ratios with low computing time in a personal computer. The coupled Reynolds, elasticity, rheology, and energy equations are solved simultaneously by combining the advanced multilevel method and the Newton-Raphson method based on a mean viscosity across the film. Standard second-order central differences are used to approximate the Reynolds and energy equations to reduce the error in the mass flow-continuity. The new approach is in very good agreement with exact solutions and predicts closer values than Cheng's to the traction measurement. Results show that the maximum mean temperature rise, the minimum film thickness, the coefficient of friction, and the pressure spike are significantly influenced by the slide-roll ratio. The thermal effect must be included in the EHL analysis to predict the reliable lubrication performance. The algorithm can also be extended to treat the complete problem of the thermal-elastohydrodynamic lubrication of point contacts with high computational and storage efficiency.

10A853. Present and future technology for lubricants. - Yuji Ikemoto *(Nippon Oil, 8 Chidori-cho Naka-ku Yokohama-shi, Kanagawa 231, Japan)*. Japan J Trib 37(9) 1057-1066 (1992).

In this report, lubricating oil which is presently used for the mechanical elements of general industrial machines, aircraft, and automobiles under severe environmental and operating conditions is described. Also, the future perspective for lubricating oil is stated.

10T854. Present and future technology for gas-lubricated bearings. - Hiroshi Yabe *(Dept of Precision Mech, Fac of Eng, Kyoto Univ, Yoshida-honmachi Sayko-ku Kyoto-shi, Kyoto 606, Japan)*. Japan J Trib 37(9) 1129-1138 (1992).

10A857. Effective use of transonic stabilization law in calibration of pressure probes. - S Santhakumar *(Dept of Aerospace Eng, Indian IT, Madras-600 036, India).* Mech Res Commun 20(4) 329-333 (Jul-Aug 1993).

Experimental studies play an important role in the study of fluid flows and of turbo-machinery cascade flows in particular. In experimental studies, the most important task is in the calibration of measuring instruments since the accuracy of the obtained results depends on it. It should also be worthwhile to establish the accuracy of the calibration charts if such a facility can be made available. This paper deals with the calibration of five-hole pressure probe used in turbomachinery cascade flow measurements. The calibration had to be carried out for a wide velocity range which included transonic speeds. It is well known that getting accurate experimental results in the transonic regime is very difficult owing to blockage and wall interference. In order to check the accuracy of the results obtained experimentally, the transonic stabilization law was made use of. Stabilization law is traditionally applied to pressure data in the form of a pressure coefficient as a function of free stream Mach number. It can be seen from this paper that this form is cumbersome to use. Two other non-dimensional presentations of pressure data are found to be more convenient from the view point of ease of application of the law.

10A858. Effects of blowing and suction on free convection boundary layers on vertical surfaces with prescribed heat flux. - MA Chaudhary and JH Merkin *(Dept of Appl Math, Univ of Leeds, Leeds LS2 9JT, UK).* J Eng Math 27(3) 265-292 (Aug 1993).

The effects that blowing and suction have on the free convection boundary layer on a vertical surface with a given surface heat flux are considered. Similarity equations are derived first, their solutions being dependent on the wall flux exponent n and a dimensionless transpiration parameter γ, (as well as on the Prandtl number). The range of existence of solutions is considered, with it being shown that solutions exist only for $n > -1$ for blowing, whereas they exist for all $n > n_0$ for suction, where $n_0 < -1$ depends on γ. The solutions for strong suction and blowing are derived. In the latter case the asymptotic structure is found to be different for n in the three ranges $-1 < n < -1/4$, $-1/4 < n < 7/2$, $n > 7/2$. Results are then obtained for the non-similarity problem of constant heat flux with a constant transpiration velocity. Solutions valid for large distances from the leading edge for both suction and blowing are derived.

10A859. Laminar mixed convection heat transfer in 3D horizontal channel with a heated bottom. - Heiu-Jou Shaw *(Dept of Naval Architec and Marine Eng, Natl Cheng Kung Univ, Tainan, Taiwan 70101, ROC).* Numer Heat Transfer A 23(4) 445-461 (Jun 1993).

Mixed convection heat transfer phenomena are studied in a 3D channel with a cavity heated from below. A general purpose computer program is developed to analyze the flow field and temperature distribution in the channel. Numerical computation is performed by using the alternating direction implicit method based on the SIMPLER algorithm. The influences of Reynolds number and Grashof number on the Nusselt number of the cavity are discussed. As a convenience to the reader, 3D streaklines and 3D isothermal surfaces are presented.

10A860. Mixed convection from a localized heat source in a cavity with conducting walls: A numerical study. - E Papanicolaou *(Adv Thermal Eng Lab, IBM, Endicott NY 13760)* and Y Jaluria *(Dept of Mech and Aerospace Eng, Rutgers Univ, New Brunswick NJ 08903).* Numer Heat Transfer A 23(4) 463-484 (Jun 1993).

Mixed convection is studied numerically in the case of an isolated, constant source of heat input within a rectangular enclosure. An external flow enters the enclosure through an opening in the left vertical wall and exits from another opening in the right vertical wall. This configuration leads to a conjugate heat transfer problem and simulates the air cooling of electronic components. Various parameters arise in this problem, particularly the Reynolds number, the buoyancy parameter Gr-Re^2, the ratio of thermal conductivity of the wall material to that of the fluid taken as air, and several geometric parameters. The time-dependent continuity and Navier-Stokes equations are transformed into a system of equations with the stream function and the vorticity as the dependent variables. The energy equation is solved over the entire domain, using the corresponding properties for the solid and fluid regions. The control volume approach is employed in order to discretize the governing equations for their numerical solution. A time marching procedure is followed, until steady state is reached. Results are presented for different values of the buoyancy parameter in the laminar regime, and the critical value of Gr-Re^2, ie, the highest value that leads to a convergent steady solution, is determined. Oscillatory results characterized by a single frequency were observed as this value was exceeded, up to a point where the oscillations showed irregular patterns, indicating that the flow was approaching the turbulent regime. Of particular interest here is the heat transfer, from the heat source to the fluid and from all the inner walls (solid-fluid interfaces) to the fluid, expressed in terms of the corresponding Nusselt numbers.

10A861. Study of the transport process of buoyancy-induced and thermocapillary flow of molten alloy. - Wei Shyy and Ming-Hsiung Chen *(Dept of Aerospace Eng Mech and Eng Sci, Univ of Florida, 231 Aerospace Bldg, Gainesville FL 32611).* Comput Methods Appl Mech Eng 105(3) 333-358 (June 1993).

Two-dimensional numerical computations have been conducted to investigate the steady-state convection and scalar transport characteristics of buoyancy-induced and thermocapillary flow of molten alloys. The cases considered are for temperature-induced convection counteracting either solute-induced convection or surface tension-induced convection. A finite volume approach utilizing the non-orthogonal curvilinear coordinates is employed. Various combinations of the dimensionless parameters, including the Marangoni number, thermal and solutal Grashof numbers, Prandtl number, Schmidt number, and aspect ratio have been studied. A wide variety of transport characteristics evolve in a qualitatively orderly manner with respect to changes in these parameters, resulting in different numbers, sizes, and directions of the convection eddies. The strong effects of the fluid properties on the transport processes are particularly noticeable. For flow domain with non-unity aspect ratio, issues of multiple steady-state solutions have also been explored.

402P. TRANSPORT MECHANISMS

10A862. Numerical model for dendritic solidification of binary alloys. - SD Felicelli, JC Heinrich *(Dept of Aerospace and Mech Eng, Univ of Arizona, Tucson AZ 85721),* DR Poirier *(Dept of Mat Sci and Eng, Univ of Arizona, Tucson AZ 85721).* Numer Heat Transfer B 23(4) 461-481 (Jun 1993).

A FE model capable of simulating solidification of binary alloys and the formation of freckles is presented. It uses a single system of equations to deal with the all-liquid region, the dendritic region, and the all-solid region. The dendritic region is treated as an anisotropic porous medium. The algorithm uses the bilinear isoparametric element, with a penalty function approximation and a Petrov-Galerkin formulation. Numerical simulations are shown in which an NH_4Cl-H_2O mixture and a Pb-Sn alloy melt are cooled. The solidification process is followed in time. Instabilities in the process can be clearly observed and the final compositions obtained.

10A863. Surface motion induced by the interaction of pulsed laser radiation with highly absorbing dielectric fluids. - KA Naugol'nykh, OV Puchenkov, VV Zosimov, AE Pashin *(NN Andreev Acoust Inst, 117036 Moscow, Russia).* J Fluid Mech 250 385-421 (May 1993).

The disturbances on the free surface of dielectric fluids resulting from intense laser heating of their boundary layer are studied theoretically and experimentally. The heating is accompanied by pronounced evaporation from the surface and thereby leads to a recoil pressure momentum applied to the surface. For small values of total momentum transferred to the fluid, the low-amplitude initially hollow-like displacement of the surface in the impact zone decays to produce linear gravity-capillary waves (GCW) spreading out on the surface. This regime is treated analytically and the results obtained are compared with experiments involving weakly viscous (water, ehtanol) and highly viscous (glycerol) liquids. An experimental arrangement for remote generation and subsequent detection of probe GCW-packets is given. The evolution of broadband GCW-disturbances on clean and surfactant-contaminated water surfaces are described. Results of GCW-attenuation spectrum measurements on clean water surfaces and on film-covered surfaces are presented.

10A864. Non-Darcy free convection from vertical surfaces in thermally stratified porous media. - P Singh and K Tewari *(Dept of Math, Indian IT, Kanpur, India)*. Int J Eng Sci 31(9) 1233-1242 (Sep 1993).

In this paper, non-Darcy free convection boundary layer flow along an isothermal vertical plate embedded in a thermally stratified fluid saturated porous medium has been described. The main aim in the analysis is to study the effect of stratification on non-Darcian free convection flow and heat transfer. The solutions are obtained by perturbation technique and the resulting ordinary differential equations are solved numerically. It is found that the heat transfer is significantly affected by the modified Grashof number and the stratification parameter.

402Y. COMPUTATIONAL TECHNIQUES

10A865. Hybrid relaxation: A technique to enhance the rate of convergence of iterative algorithms. - R Marek and J Straub *(Inst A for Thermodyn, Tech Univ, Arcisstr 21, W-8000 Munich 2, Germany)*. Numer Heat Transfer B 23(4) 483-497 (Jun 1993).

In solving multidimensional transient fluid flow and heat transfer problems, the strongly coupled conservation laws of mass, momentum, and energy require segregated iterative procedures. Derived from the SIMPLE algorithm, the fully explicit iteration scheme MAPLE (Modified Algorithm for Pressure-Linked Equations) for the pressure-velocity coupling is introduced here. A substantial speedup is gained in the iteration by utilizing hybrid relaxation, a combination of under- and overrelaxation, instead of the usual underrelaxation. Moreover, hybrid relaxation is not restricted to pressure-velocity algorithms only, but can be applied in more general iterations.

10A866. Multidimensional single-step vector upwind schemes for highly convective transport problems. - G de Felice, FM Denaro, C Meola *(Dept Energetica Termofluidodinamica e Condizionamenti Ambientali, Univ delgi Stude di Napoli Federico II, 80125 Napoli, Italy)*. Numer Heat Transfer B 23(4) 425-460 (Jun 1993).

After a synthesis of existing numerical approaches, a family of single-step time-marching upwind schemes is proposed for the convective-diffusive balance of a scalar in multidimensional incompressible laminar flows. A functional description of the new approach is given too. The schemes are adequate to the simulation of purely or highly convective transport phenomena. The proposed schemes were applied to a scalar test problem (rotating hill) and the results evaluated after an analysis of the intrinsic limitations of test itself. A third-order, fully upwind-biased scheme of the family is applied to the lid-driven and thermally driven square cavity problems. In the lid-driven case a steady-state solution is not achieved at Re = 10^4.

10A867. Solution of nonlinear elliptic convection-diffusion problems through the integral transform method. - AJK Leiroz and RM Cotta *(Mech Eng Dept EE-COPPE-UFRJ, Univ Fed Rio de Janeiro, Cidade Univ, Cx PO Box 68503, Rio de Janeiro-RJ 21945, Brazil)*. Numer Heat Transfer B 23(4) 401-411 (Jun 1993).

The hybrid numerical-analytical solution of nonlinear elliptic convection-diffusion problems is investigated through extension of the ideas in the generalized integral transform technique. An application is selected to illustrate the convergence characteristics of the proposed eigenfunction expansion approach, for different values of the parameters that govern the relative importance of convection and diffusion effects.

10A868. Hysteresis phenomena in subcooled flow boiling of well-wetting fluids. - GP Celata, M Cumo, T Setaro *(ENEA Casaccia, ENE-IMPRE-IPROT, Via Anguillarese, 301 00060 Rome, Italy)*. Exp Heat Transfer 5(4) 253-275 (Oct-Dec 1992).

Detailed knowledge of the physical phenomena involved in subcooled boiling is of great interest for the design of liquid-cooled heat-generating systems with high heat fluxes. An electrically heated stainless steel tube, 2.3 m long, with a 7.57-mm inner diameter, was used to study the incipience of flow boiling in subcooled, well-wetting fluids (R-12 and R-114) over a wide range of pressure, mass flux, and heat flux. Hysteresis in boiling observed by increasing and decreasing heat flux seems to be ascribed to the small contact angle of refrigerants on surfaces such as stainless steel, allowing the larger cavities in the wall to be flooded. A higher temperature excess may be reached in the wall before boiling sets in than the temperature achieved when boiling has been developed. Some existing correlations were tested, revealing the general inadequacy in predicting the higher superheating required in well-wetting fluids for the onset of nuclear boiling. Classic theory on bubble growth, heat transfer relationships, and the force balance equation at the bubble-liquid interface, coupled with an empirical correlation for the determination of the boiling incipience conditions, accomplish a very successful prediction of the experimental data.

10A869. Behavior of bubbles and heat transfer in transition boiling. - Kinichi Torikai, Kohichi Suzuki, Masatoku Yamaguchi, Syuichi Kobayashi *(Dept of Mech Eng, Sci Univ of Tokyo, 2641 Yamazaki, Noda-shi, Japan)*. Exp Heat Transfer 5(4) 277-292 (Oct-Dec 1992).

The behavior of boiling bubbles on a heating surface made of transparent quartz glass is observed directly from its back side. The surface is heated by a fused salt that is transparent at high temperature. Freon R-11 and R-113 are used as the boiling liquids. In transition boiling, dry parts of bubbles contacting the heating surface develop into larger vapor films with increasing superheat of the surface. Vapor film patches appear repeatedly in a short period. The behavior of bubbles and vapor films is different from that in nucleate boiling and in film boiling.

10A870. Evaporation of a circular meniscus of NH_3 flowing parallel to a gaseous NH_3-H_2 stream. - DA Kouremenos, KA Antonopoulos, A Stegou-Sagia *(Dept of Mech Eng, Thermal Section, Natl Tech Univ, 42 Patission St, Athens 106 82, Greece)*. Numer Heat Transfer A 23(4) 415-431 (Jun 1993).

A solution is presented for the 3D heat and mass transfer during evaporation of a circular meniscus of liquid NH_3, flowing parallel to a gaseous NH_3-H_2 stream, as encountered in the evaporator of small neutral gas absorption refrigerators. The procedure developed is based on a finite difference solution of a set of differential equations expressing the 3D transport of momentum, heat, and mass. Expressions are also provided for the thermodynamic and transport properties of the real NH_3-H_2 mixture. The results of the numerical solution include the fields of velocity, temperature, NH_3 mass fraction, enthalpy, and entropy.

10A871. Liquid film thickness and topography determination using fresnel diffraction and holography. - J Yang, LC Chow, MR Pais *(Dept of Mech Eng, Univ of Kentucky, Lexington KY 40506)*, A Ito *(Dept of Prod Syst Eng, Oita Univ, Oita 870-11, Japan)*. Exp Heat Transfer 5(4) 239-252 (Oct-Dec 1992).

A noninvasive experimental method to measure time-averaged maximum film thickness and surface topography is developed. The film thickness is measured by the change in the line of sight using a laser beam. The surface topography is measured using a holographic technique. In the holographic method, interference patterns created by the substrate and the superajacent film surface are used to determine the topography. Measurements of liquid film thickness and topography under conditions of droplet impingement on a surface were taken, and the results are presented. Applicability and limitations of the techniques are discussed.

406. Conduction

10A872. Heat conduction across a semi-infinite interface in a layered plate. - FD Zaman *(Dept of Math Sci, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)*. Utilitas Math 43 89-96 (May 1993).

We consider the problem of heat flow across a semi-infinite plane contact in a two-layered plate in which the contact between the layers takes place in one part of the interface while the other part is perfectly insulated. The Wiener-Hopf technique has been employed to obtain the solution in a closed form.

10A873. Measurements of thermal conductivity and optical properties of porous partially stabilized zirconia. - Pei-feng Hsu and JR Howell *(Dept of Mech Eng, Univ of Texas, Austin TX 78712)*. Exp Heat Transfer 5(4) 293-313 (Oct-Dec 1992).

Experimental measurements of the high-temperature ($300 < T < 800$ K) thermal conductivity of highly porous (porosity greater than 80%), partially stabilized zirconia (PSZ) were performed. A method of simultaneously inverting conductivity and extinction coefficient from the experimental data is presented. The effect of natural convection within the porous plates with heating from below was found to be negligible. The thermal conductivity integral method was incorporated into the version of conductivity and radiative properties from the diffusion approximation of the combined radiation and conduction heat flux measurement. The measured conductivity decreased slightly as the pore size of the PSZ increased. The extinction coefficient decreased with increased pore size, and for pore size greater than 0.6 mm the trend had good agreement with the geometric optics limit prediction.

10A874. Analysis of transient heat transfer in straight fins of various shapes with its base subjected to a decayed exponential function of time in heat flux. - Jung-Kuei Tseng *(Dept of Mech Eng, Chinese Military Acad, Feng-Shang, PO Box 90602-6 Kao-Hsiung, Taiwan, ROC)*, Chia-Lin Shih *(Tahan Junior Col of Eng and Business, Hua-Lien, Taiwan, ROC)*, Wen-Jyi Wu *(Dept of Mech Eng, Chinese Military Acad, Feng-Shang, PO Box 90602-6, Kao-Hsiung, Taiwan, ROC)*. Comput Struct 47(2) 289-297 (Apr 1993).

The theoretical study of heat flow within finned heat exchangers is of considerable practical importance because of the extensive utilization of finned surfaces for heat transfer enhancement in applications varying from air-cooled heat exchangers in the process industries to heat rejection equipment in space vehicles. This paper investigates the transient heat transfer in 2D straight fins of various shapes with its base subjected to a decayed exponential function of time in a heat flux. In order to obtain the solutions of the governing equation, which is a partial differential equation, the following procedures of analysis should be performed: 1) normalize the governing partial differential equation subjected to the appropriate initial and boundary conditions, 2) take a Laplacian transform with respect to time, 3) utilize the integral method to solve the transformed system and 4) achieve and inverse Laplace transform by the Fourier series technique.

10A875. Semianalytic approach to general transient problems and its applications to heat transfer. - JY Zhang *(Col of Machine and Elec, Tianjin Univ, Tianjin 300380, China)*, RW Lewis *(Dept of Civil Eng, Univ of Wales, Swansea SA2 8PP, UK)*, JS Peng *(Dept of Phys, Normal Univ of Sichuan, Nanchong 637002, China)*. Numer Heat Transfer B 23(4) 413-424 (Jun 1993).

In this article a new method of solving the transient problems is developed that is based on convolution-type variational principles, where FE discretization in the space domain and series representation in the time domain are considered. This approach can overcome the shortcomings of existing methods and combine the advantages of those methods for solving transient problems. The examples show that the new method is a most effective method of obtaining solutions for transient problems.

10A876. Formulation of model equations for heating by microwave radiation. - JM Hill *(Dept of Math, Univ of Wollongong, NSW 2522, Australia)* and MJ Jennings *(Dept of Appl Math and Theor Phys, Univ of Cambridge, Silver St, Cambridge CB3 9EW, UK)*. Appl Math Model 17(7) 369-379 (Jul 1993).

In general, heating by microwave radiation involves simultaneously solving Maxwell's equations of electromagnetism coupled with the heat equation and for which all electrical, magnetic, and thermal parameters are nonlinearly dependent upon the temperature T. The solution of this coupled nonlinear system, either analytically or numerically, is formidable even if sufficient data existed to properly specify the various electrical and magnetic parameters. Accordingly, the proposition of reducing the problem to studying the heat equation alone with a certain nonlinear body heating Q(T) is an extremely attractive one. In order to identify the body heating term Q(T) as accurately as possible, an exhaustive examination is made of existing experimental results of von Hippel, which have been available for almost 40 years. We show that for the higher frequencies the experimental data are very accurately approximated by both parabolic and linear fits for the body heating Q(T). At the lower frequencies one of two types of exponential curves provides an adequate fit of the experimental data. At intermediate frequencies in the experimental data exhibit both parabolic and exponential behavior, and we propose a body heating term Q(T), consisting of a linear combination of the previously used exponential curves, which very accurately fits the data over the full range for which it is available. Finally, we demonstrate the changes in variation of Q(T) with changing frequency but for which insufficient data exist to properly quantify. The principal objective of this investigation is to obtain simple analytical forms for Q(T) rather than an application of elaborate curve-fitting procedures, and the mathematical consequences of the specific forms established here will be the subject of future work.

10A877. Numerical model for combined conductive and radiative heat transfer in annular packed beds. - K Kamiuto, S Saito, K Ito *(Dept of Prod Syst Eng, Oita Univ, Dannoharu 700, Oita 870-11, Japan)*. Numer Heat Transfer A 23(4) 433-443 (Jun 1993).

A numerical model is developed for quantitatively analyzing combined conductive and radiative heat transfer in concentric annular packed beds. A packed bed is considered to be a continuous medium for heat transfer, but the porosity distribution within a packed bed is taken into account. To examine the validity of the proposed model, combined conductive and radiative heat transfer through annular packed beds of cordierite or porcelain beads is analyzed numerically using finite differences under conditions corresponding to heat transfer experiments of these packed beds. The resultant temperature profiles and heat transfer characteristics are compared with the experimental results.

10A878. State space approach to thermoelasticity with two relaxation times. - HH Sherief *(Dept of Math, Fac of Sci, Univ of Alexandria, Alexandria, Egypt)*. Int J Eng Sci 31(8) 1177-1189 (Aug 1993).

In this work the state space formulation of thermoelasticity with two relaxation times is introduced. The formulation is valid for problems with or without heat sources. The resulting formulation together with the Laplace transform technique are applied to a variety of problems. The solution to a thermal shock problem and to a problem of a layer media both without heat sources are obtained. Also a problem with a distribution of heat sources is considered. A numerical method is employed for the inversion of the Laplace transforms. Numerical results are given and illustrated graphically for the problems considered. Comparisons are made with the results predicted by the coupled theory and with the theory of generalized thermoelasticity with one relaxation time.

10A879. Temperature changes due to elastic deformations, and Poisson's equation in thermodynamics of metals. - V Pekarek *(Inst of Elec Eng, Acad of Sci, Dolejskova 5, 182 02 Prague 8, Czech Republic)*. Acta Tech CSAV 38(2) 145-152 (1993).

The internal pressure in the interior of a metal, is modified through external mechanical load acting upon the system (adiabatic process). Elastic changes in volume, aroused in this way, are interrelated with the changes in internal pressure through the same equation as that derived by Poisson for adiabatic processes in gases. The validity of the equation in thermodynamics of metals is investigated in the present paper and proved in terms of the theory of elasticity. Poisson's equation along with the First Law allow temperature changes due to elastic deformations in metals to be evaluated.

10A880. Buckling and post-buckling of composite plates and shells subjected to elevated temperature. - V Birman *(Eng Educ Center, Univ of Missouri, St Louis MO 63121)* and CW Bert *(Sch of Aerospace and Mech Eng, Univ of Oklahoma, Norman OK 73019)*. J Appl Mech 60(2) 514-519 (Jun 1993).

Effects of temperature on buckling and post-buckling behavior of reinforced and unstiffened composite plates or cylindrical shells are considered. First, equilibrium equations are formulated for a shell subjected to the simultaneous action of a thermal field and an axial loading. These equations are used to predict a general form of the algebraic equations describing the post-buckling response of a shell. Conditions for the snap-through of a shell subjected to thermomechanical loading are formulated. As an example, the theory is applied to prediction of post-buckling response of flat large-aspect-ratio panels reinforced in the direction of their short edges.

10A881. Post-buckling of geometrically imperfect shear-deformable flat panels under combined thermal and compressive edge loadings. - L Librescu *(Dept of Eng Sci and Mech, VPI)* and MA Souza *(Dept of Civil Eng, Pontificia Univ Catholica, Rio de Janeiro, Brazil)*. J Appl Mech 60(2) 526-533 (Jun 1993).

The static post-buckling of simply-supported flat panels exposed to a stationary nonuniform temperature field and subjected to a system of subcritical in-plane compressive edge loads is investigated. The study is performed within a refined theory of composite laminated plates incorporating the effect of transverse shear and the geometric nonlinearities. The influence played by a number of effects, among them transverse shear deformation, initial geometric imperfections, the character of the in-plane boundary conditions and thickness ratio are studied and a series of conclusions are outlined. The influence played by the complete temperature field (ie, the uniform through thickness and thickness-wise gradient) as compared to the one induced by only the uniform one, is discussed and the peculiarities of the resulting post-buckling behaviors are enlightened.

10A882. Separation of strain components in composite materials from thermoelastic temperature measurements. - SA Dunn *(Dept of Mech and Manuf Eng, Univ of Melbourne, Parkville, Vic, Australia)*. J Appl Mech 60(2) 443-448 (Jun 1993).

In this paper experimental data is used to demonstrate how point-to-point strain components can be determined from thermoelastic temperature data. This is done by making use of the very obvious effects of thermal conduction on the cyclic surface temperature changes which can occur as a composite material undergoes an oscillating stress. By observing the cyclic surface temperature changes for different loading frequencies, the adiabatic heat generated in the different plies may be determined. With this knowledge, the strain components experienced by a composite laminate may be found.

10A883. Thermo-stress analysis of a plated-through-hole in a composite printed wiring board. - JM Whitney *(Graduate Mat Eng, Univ of Dayton, Dayton OH 45469-0240)*, IU Haq, SR Soni *(AdTech Syst Res, Dayton OH 45432)*. J Thermoplastic Composite Mat 6 29-37 (Jan 1993).

A stress analysis model for determining the thermal stresses in the vicinity of a plated-through-hole in a printed wiring board is presented. The model is based on an axisymmetric deformation and the superposition of an exact elasticity solution for far field stresses (away from the outer free surfaces) and an approximate near field solution (near the outer free surfaces). The approximate solution exactly satisfies point-by-point equilibrium, but violates compatibility.

10A884. Thermal effects in Mindlin-type plates. - P Schiavone *(Dept of Elec Eng and Appl Math Inst, Univ of Alberta, Edmonton AB, T6G 2G1, Canada)* and RJ Tait *(Dept of Math, Univ of Alberta, Edmonton AB, T6G 2G1, Canada)*. Quart J Mech Appl Math **46**(1) 27-39 (Feb 1993).

We derive a linear thermoelastic plate model based on a Mindlin-type assumption on the displacements. Initial-boundary-value problems of the Dirichlet, Neumann, and mixed type are formulated and appropriate uniqueness results are obtained. The exterior problems are solved in special classes of finite-energy functions having a specific 'far-field pattern' which allow some divergence at infinity. These are larger than the class of admissible functions used in classical elasticity. We also indicate how results on existence and uniqueness are obtained in problems of static equilibrium and steady thermoelastic oscillations. The latter are governed by systems of elliptic equations and can be solved numerically using a generalized Fourier-series technique developed earlier for thin micropolar plates. Finally, we mention the generalization to a theory of thermoelastic micropolar plates.

10A885. Thermoelastic frictional contact problems: Modeling, FE approximation and numerical realization. - L Johansson and A Klarbring *(Dept of Mech Eng, Div of Solid Mech and Strength of Mat, Linkoping Univ and IT, Linkoping, Sweden)*. Comput Methods Appl Mech Eng **105**(2) 181-210 (Jun 1993).

In this paper frictional contact including frictional heat generation and heat transfer across the contact interface is studied. A model for the behavior of the contact interface is proposed and combined with the conventional equations of linear thermoelasticity for the bulk material of the contacting bodies. A FE discretization in space and a finite difference discretization in time are introduced, and an iterative algorithm is proposed to deal with the coupled thermal-mechanical nature of the problem. Finally, several numerical examples are given.

10A886. Application of the BE technique to periodic heat transfer in a fin assembly. - JM Houghton, DB Ingham *(Dept of Appl Math Stud, Univ of Leeds, Leeds LS2 9JT, UK)*, PJ Heggs *(Dept of Chem Eng, Univ of Bradford, Bradford BD7 1DP, UK)*. Numer Heat Transfer A **23**(4) 379-398 (Jun 1993).

Time dependent heat transfer has been investigated in a fin assembly comprising an array of fins attached to a supporting wall. Convective heat exchange from the supporting wall and thermal interactions between the wall and fins are considered. A new implementation of the BEM solution technique has been devised to investigate oscillatory heat transfer in a fin assembly and is extended to investigate fin assembly heat transfer that is of a general periodic nature.

10A887. Thermosolutal convection heat and mass transfer in a vertical annular enclosure. - LW Wang and CY Wei *(Dept of Mech Eng, Yuan-Ze IT, Taoyuan, Taiwan, ROC)*. Exp Heat Transfer **5**(4) 315-328 (Oct-Dec 1992).

The purpose of the present study is to investigate flows resulting from buoyancy forces due to a combination of temperature and species concentration effects in a vertical annular enclosure. An electrochemical system is described that enables opposing temperature and concentration gradients to be imposed. Complex flow patterns are observed as the parameters are varied.

10A888. Autowave propagation for general reaction diffusion systems. - IA Molotkov and SA Vakulenko *(Inst of the Terrestrial Magnetism Ionosphere and Radio Wave Propagation, ISMIR AN, Troitsk, Moscow 142092, Russia)*. Wave Motion **17**(3) 255-266 (May 1993).

We discuss autowave propagation for general reaction-diffusion systems. It is shown that when the front curvature is small, the wave behavior depends on two constants and does not depend on a nonlinearity form in detail. The formulae for the normal velocity of the front is found to contain the mean curvature and the two constants. We give an energetic interpretation for the equations describing wave propagation even when the original system has no clear energetic interpretation. New effects are found for multistable systems.

10A889. BEM for convective heat transfer. - Y Shi and PK Banerjee *(Dept of Civil Eng, SUNY, Buffalo NY 14260)*. Comput Methods Appl Mech Eng **105**(2) 261-284 (Jun 1993).

A BEM is developed for the linearized convective heat transfer problem using a newly derived integral formulation based on a convective fundamental solution. Details of the numerical implementation are provided for this linearized problem, which can be solved with only surface discretization. Significant attention is given to the algorithm so that the method could be applied to problems involving heat transfer at high Peclet numbers. Several numerical examples of steady state flows in 2D are included to demonstrate the accuracy of the present methodology, and to highlight its practical utility and limitations.

10A890. Eulerian-Lagrangian localized adjoint method: The theoretical framework. - I Herrera *(Inst Geofisica, UNAM, Apdo Postal 22-582, 14000 Mexico)*, RE Ewing *(Col of Sci, Texas A&M Univ, College Station TX 77843-3257)*, MA Celia *(Water Resources Program, Dept of Civil Eng and Operations Res, Princeton)*, TF Russell *(Dept of Math, Univ of Colorado, Denver CO 80204-5300)*. Numer Methods PDE **9**(4) 431-457 (Jul 1993).

This is the second of a sequence of papers devoted to applying the localized adjoint method, in space-time, to problems of advective-diffusive transport. We refer to the resulting methodology as the Eulerian-Lagrangian localized adjoint method (ELLAM). The ELLAM approach yields a general formulation that subsumes may specific methods based on combined Lagrangian and Eulerian approaches, so-called characteristic methods. In the first paper of this series the emphasis was placed in the numerical implementation and a careful treatment of implementation of boundary conditions was presented for 1D problems. The final ELLAM approximation was shown to possess the conservation of mass property, unlike typical characteristic methods. The emphasis of the present paper is on the theoretical aspects of the method. The theory, based on Herrera's algebraic theory of boundary value problems, is presented for advection-diffusion equations in both 1D and multidimensional systems. This provides a generalized ELLAM formulation. The generality of the method is also demonstrated by a treatment of systems of equations as well as a derivation of mixed methods.

10A891. Multi-grid methods for steady state diffusion in random media. - D Braess, M Biebighauser *(Inst for Math, Ruhr-Univ, D-4630 Bochum, Germany)*, P Grassberger, R Leuverink *(Dept of Phys, Univ of Wuppertal, D-5600 Wuppertal 1, Germany)*. J Comput Phys **107**(1) 118-123 (Jul 1993).

We apply multi-grid methods to study steady state densities for hopping diffusion in 2D random media. We show that these methods are very efficient. For our fastest algorithm, which also uses overrelaxation, CPU times increase as $L^{2.2}$ in order to reach equilibrium on square lattices of size $L \times L$ with a prescribed accuracy. Compared to standard Gauss-Seidel methods, this is at least an improvement by a factor $\propto L$. For $L = 128$, the improvement is about a factor of 10 and even more than 80 if overrelaxation is added.

416C. IGNITION (THERMAL AND HETEROGENEOUS)

10A892. Self-ignition of small-ring hydrocarbons behind reflected shock waves. - VG Slutsky, OD Kazakov, ES Severin, EV Bespalov, SA Tsyganov *(Semenov Inst of Chem Phys and Russian Acad of Sci, Moscow 117977, Russia)*. Combust Flame **94**(1-2) 108-112 (Jul 1993).

Self-ignition of stoichiometric airlike argon mixtures of monocyclic and bicycle small-ring hydrocarbons was investigated behind reflected shock waves at 1200-1600 K and 0.6 ± 0.1 MPa. The reactivity of small-ring hydrocarbons has been found to be determined by the properties of their thermal decomposition products. New high-temperature decomposition channels for spiropentane, methylenecylobutane, and methylencyclopropane have been discovered.

416D. LAMINAR FLAME PROPAGATION

10A893. Experimental investigation of stretched premixed flames burning mixtures of methane and methyl chloride in air and comparison with numerical simulations. - MH Yang and IK Puri *(Dept of Mech Eng (M/C 251), Univ of Illinois, Chicago IL 60680-4348)*. Combust Flame **94**(1-2) 25-34 (Jul 1993).

Experimental measurements of the laminar burning velocities of flames burning methane-methyl chloride mixtures, and methyl chloride in air, are made in a counterflow burner. The flame speeds are observed to decrease with increasing chlorine loading, from 40 cm s^{-1} for a stoichiometric methane-air flame to 4.9 cm s^{-1} for a stoichiometric methyl chloride-air flame. Good agreement is found between flame speeds deduced from experiments and those predicted by numerical simulations at the periphery of the domain, ie, for methane-air and methyl chloride-air flames. The agreement between experiments and calculations at intermediate regions, that is, for varying methane-methyl chloride-air mixtures is at best reasonable. Sources for the discrepancies in the kinetic mechanism are identified. The critical extinction stretch rate for flames burning methyl chloride in air is measured, as is the stretched flame speed close to extinction.

10A894. Local response and surface properties of premixed flames during interactions with Karman vortex streets. - T-W Lee, JG Lee, DA Nye, DA Santavicca *(Turbulent Combust Lab, Dept of Mech Eng, Penn State)*. Combust Flame **94**(1-2) 146-160 (Jul 1993).

Premixed flames interacting with Karman vortex streets have been experimentally investigated, in which local flame responses consistent with the results of stretched laminar flame theories are observed in that the OH LIF intensity increases when the local flame curvature becomes positive (negative) for thermodiffusively unstable (stable) flames. Departure of the peak OH LIF intensity for hydrogen flames ranges from 20% to 150% of the value at zero flame curvature for flame curvature ranging from -1.5 to 0.7 mm^{-1}, while for propane-air flames the variation is within ±20% of the value at zero curvature. Variation in the averaged peak OH LIF intensity is nearly linear with respect to the variation in flame curvature from -1.2 to 0.8 mm^{-1}. The flame area during interactions with Karman vortex streets increases as a relatively weak function of the vortex velocity, while the vortex size affects the flame area increase in the smaller vortices are found to be less effective in generating flame area. The effect of Lewis number on the flame front is to enhance (suppress) the amplitude of the wrinkles generated by vortices for thermodiffusively unstable (stable) flames, thus resulting in larger (smaller) flame area. The flame curvature pdfs for flames interacting with Karman vortex streets exhibit a bias toward positive flame curvature due to the large area of positively-curved flame elements that develop downstream along the V-flame. A decrease in vortex size tends to increase the flame curvature and thus broadens the pdfs, while the vortex velocity, and Lewis number have relatively small effects on the flame curvature pdfs. The flame orientation distribution is peaked near the normal direction of flame propagation for small vortex velocity, while an increase in vortex velocity results in broadening of the flame orientation distribution and a shift toward large flame angle due to the increased distortions in the flame front and increases in the effective flame propagation speed, respectively.

416E. TURBULENT FLAME PROPAGATION, FLAMMABILITY

10A895. Direct simulations of premixed turbulent flames with nonunity Lewis numbers. - CJ Rutland *(Dept of Mech Eng, Univ of Wisconsin, 1513 University Ave, Madison WI 53760)* and A Trouve *(Center for Turbulence Res, Stanford)*. Combust Flame 94(1-2) 41-57 (Jul 1993).

A principal effect of turbulence on premixed flames in the flamelet regime is to wrinkle the flame fronts. For nonunity Lewis numbers, Le ≠ 1, the local flame structure is altered in curved regions. This effect is examined using direct numerical simulations of 3D isotropic turbulence with constant density, single-step Arrhenius kinetics chemistry. Simulations of Lewis numbers 0.8, 1.0, and 1.2 are compared. At the local level, curvature effects dominated changes to the flame structure while strain effects were insignificant. A strong Lewis-number-dependent correlation was found between surface curvature and the local flame speed. The correlation was positive for Le < 1 and negative for Le > 1. At the global level, strain-related effects were more significant than curvature effects. The turbulent flame speed changed significantly with Lewis number, increasing as Le decreased. This was found to be due to strain effects that have a nonzero mean over the flame surface, rather than to curvature effects that have a nearly zero mean. The mean product temperature was also found to vary with Lewis number, being higher for Le > 1 and lower for Le < 1.

10A896. Images of the quenching of a flame by a vortex: To quantify regimes of turbulent combustion. - WL Roberts, JF Driscoll *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109)*, MC Drake *(General Motors Res Lab, Warren MI 48090)*, LP Gross *(Syst Res Lab, Dayton OH 45440)*. Combust Flame 94(1-2) 58-69 (Jul 1993).

A laminar toroidal vortex i[illegible]ted with a laminar premixed flame in [illegible] and to visualize some of the fur[illegible] of turbulent combustion. Lo[illegible] f the flame was observed [illegible]uced fluorescence imagin[illegible] OH molecules in the counterflow flamefront region near the vortex leading edge. A quenching limit curve was measured as a function of vortex size and strength. In the second part of the study, the measurements are combined with concepts proposed by Poinsot, Veynante, and Candel in order to infer the thin flame limit, namely, the onset of distributed reactions, on a classical premixed turbulent combustion regime diagram. The measured thin flame limit indicates when laminar flamelet theories become invalid, since quenching allows hot products and reactants to coexist. Results are compared with Klimov-Williams criterion. Vortex core diameters were as small as the flame thickness in some cases. The main conclusion is that small vortices are less effective at quenching a flame than was previously believed; therefore the inferred regime within which thin flame theories are valid extends to a turbulence intensity that is more than an order of magnitude larger than that which was previously predicted. Results also indicate that micromixing models, which assume that the smallest eddies exert the largest strain on a flame are not realistic. Measured trends are in agreement with the direct numerical simulations of Poinsot, et al, but absolute values differ.

416I. KINETICS AND MECHANISMS

10A897. Reduced kinetic mechanism for premixed CH_3Cl/CH_4/air flames. - KY Lee and IK Puri *(Dept of Mech Eng, Univ of Illinois, M/C 251, Chicago IL 60680-4348)*. Combust Flame 94(1-2) 191-204 (Jul 1993).

A reduced kinetic consisting of nine-global steps is derived to describe freely propagating flames burning mixtures of methyl chloride and methane in air. The fuel blend contains two fuels with distinct (methyl chloride and methane) thermochemical properties, whose contribution to the radical pool in the flame is different. Our objective is to (1) obtain predictions of flame speeds, particularly for rich flames, and (2) describe the gross chemistry by predicting the concentration profiles of the (a) fuels, (b) oxidizer, (c) products, in particular the C_2-containing species (since halogenated flames are generally sooting), and (d) the significant atomic-radical species in the flame. Chlorine atoms available from methyl chloride inhibit the flames, resulting in lower flame speeds. The mechanism is able to predict flame speeds for flames burning rich mixtures of equal molar amounts of methyl chloride and methane in air, and for stoichiometric flames burning methyl chloride and air in the range of 30%-67% methyl chloride in the methane-methyl chloride mixture. These predictions are in good agreement with simulations and measurements made in our laboratory though large discrepancies exist in the measured flame speeds when data due to other investigators is included. The species concentration profiles obtained by using the reduced mechanism are in agreement with those predicted by the detailed mechanism from which it is derived.

416L. HETEROGENEOUS AND MULTIPHASE COMBUSTION

10A898. Spray structure in counterflowing streams with and without a flame. - SC Li, PA Libby, FA Williams *(Dept of Appl Mech and Eng Sci, UCSD)*. Combust Flame 94(1-2) 161-177 (Jul 1993).

An experimental and theoretical study is performed on two-phase counterflowing streams with and without flames in which methanol sprays, transported in nitrogen from a lower circular duct, flow upward to meet a pure oxygen stream that flows downward from the upper circular duct. The spray structure and entire flowfield are measured by a two-component phase doppler particle analyzer. The relative motion of droplets as a function of droplet diameter and the effect of the flame on the counterflow field are determined. The influences of the flowfield and the flame sheet on spray structure are measured. A theoretical analysis of droplet behavior in counterflowing streams is also performed on the basis of the spray equation applied away from the stagnation plane. Comparisons between measured and predicted number density as a function of axial position are made. These experimental and theoretical results help in understanding the fundamental mechanisms of spray combustion.

10A899. Upper explosive limit of dusts: Experimental evidence for its existence under certain circumstances. - KJ Mintz *(Mining Res Lab, CANMET Energy Mines and Resources, Ottawa, ON, K1A 0G1, Canada)*. Combust Flame 94(1-2) 125-130 (Jul 1993).

An experimental study of the explosibility of cornstarch using the 20-L vessel shows that, for a narrow size fraction near its limiting particle size for explosibility, an upper explosion limit exists. Upper explosive limits were also observed with both cornstarch and Pittsburgh Standard coal dust at low oxygen concentrations. These upper limits occur at accessible dust concentrations. A simple mechanism, "the oxygen depletion" phenomenological concept, is described. The optimum dust concentration, calculated using this mechanism, gives reasonable agreement with the experimental values, as well as explaining the variation of optimum concentration with particle size and oxygen concentration.

416P. SOLID FUELS

10A900. Continuum limits of interacting particle systems. - JM Greenberg and R Peszek *(Dept of Math and Stat, UMBC, Baltimore MD 21228)*. Physica D 65(1-2) 172-190 (May 1993).

We study the continuum limits of discrete particle systems with short range repulsive forces. We establish the existence of a class of short range interparticle force laws with the property that the asymptotic trajectories of two sufficiently energetic particles of equal mass entering and leaving the region of a binary interaction are the same as the asymptotic trajectories of particles which undergo a simple point-mass elastic collision. Using such force laws, we consider the evolution of an N particle gas, each particle having mass 1-N, for initial data which are guaranteed to generate only binary collisions. We show that such problems are exactly solvable and we characterize the continuum limit ($N \to \infty$) of such solutions. These limit flows are independent of the details of the repulsive forces and are the same as obtained if one replaces the interparticle force law by the elastic collision rule which simply interchanges particle velocities during a collision.

416Q. LIQUID FUELS

10A901. Analytical and numerical modeling of flame-balls in hydrogen-air mixtures. - J Buckmaster *(Dept of Aeronaut and Astronaut Eng, Univ of Illinois, Urbana IL)*, M Smooke *(Dept of Mech Eng, Yale Univ, New Haven CT)*, V Giovangigli *(Centre Math Appl and CNRS, Ecole Polytech, Palaiseau, France)*. Combust Flame 94(1-2) 113-124 (Jul 1993).

Flame-balls are stationary spherical premixed flames observed in certain near-limit mixtures. It is believed that radiative heat losses are an important stabilizing influence. Numerical solutions of flame balls are constructed for hydrogen-air mixtures using an accurate description of the chemical kinetics, diffusive transport, and radiation losses. A lean limit equivalence ratio of 0.0866 is predicted and a rich limit of 2.828. For any equivalence ratio between the two limits there are two solutions. One is characterized by a small flame, incomplete reactant consumption, and negligible radiation losses. The other by a large flame, complete consumption of one of the reactants, and significant radiation losses. The maximum temperature varies between 1200 and 900 K as the two solution branches are traversed. Much of our discussion is a reprise and modification of previously published analytical results, for these provide physical insight into the nature of the solutions, and suggest that a portion of the large flame branch near the lean limit is stable and so corresponds to observable flames.

10A902. **Asymptotic analysis of monopropellant droplet burning for the reaction nA → B.** - AV Orlov *(Tashkentskaya St 10-2 39, Moscow 109444, Russia)*. Combust Flame 94(1-2) 35-40 (Jul 1993).

The transport phenomena of convection, diffusion, and thermal conduction are analyzed for large-activation-energy burning of a spherical monopropellant droplet. The reaction is assumed to be nA → B with arbitrary n. The reciprocal value of the activation energy is the small parameter. The two lowest-order terms of the mass flow rate, the flame position and the flame structure are obtained.

416Y. COMPUTATIONAL TECHNIQUES

10A903. **Numerical model for temperature gradient and particle effects on Rijke bruner oscillations.** - RL Raun *(Hercules Inc, Bacchus Works, Magna UT 84044)* and MW Beckstead *(Dept of Civil Eng, Brigham Young Univ, Provo UT 84602)*. Combust Flame 94(1-2) 1-24 (Jul 1993).

Equations that describe acoustic oscillations in a Rijke burner have been developed. Eigenvalues giving frequencies and growth rates of acoustic modes can be calculated from these equations. In their most general form, these acoustic equations include the effects of nonuniform gas temperature and entrained, burning particles. In general, analytical solution of the equations is not possible. A computer program has been developed that uses numerical methods to calculate eigenvalues from the general equations. For some limiting cases, analytical solution of the equations is possible. Analytical solutions are presented for three such cases. Eigenvalues predicted by the numerical model compare well to the analytical solutions. The Bailey and McIntosh flame-acoustic interaction models were tested with the computer program. Predicted frequencies and growth rates agreed well with experimental data when heat loss was taken into account. The program matched one experimental frequency and growth rate exactly when a time lag was added to the Bailey model. The McIntosh model did nearly as well as without any adjustments. A particle combustion-acoustic interaction model for burning aluminium particles has been developed. This model was also tested in the Rijke burner model. The predictions show qualitative but not quantitative agreement with experimental measurements of particle combustion effects. A mechanism is suggested that may explain the discrepancy.

416Z. EXPERIMENTAL TECHNIQUES

10A904. **Coherent anti-Stokes Raman spectroscopy (CARS) and laser-induced fluorescence (LIF) measurements in a rocket engine plume.** - DR Williams, D McKeown, FM Porter *(Combust Dept, Harwell Lab, Oxfordshire OX11 0RA, UK)*, CA Baker *(Epsilon Res, Buckinghamshire HP10 9BZ, UK)*, AG Astill *(Combust Dept, Harwell Lab, Oxfordshire OX11 0RA, UK)*, KM Rawley *(Defence Res Agency, Ft Halstead, Kent, UK)*. Combust Flame 94(1-2) 77-90 (Jul 1993).

Coherent anti-Stokes Raman spectroscopy (CARS) and laser-induced fluorescence (LIF) measurements in the plume of a liquid-fueled rocket engine are compared with the results predicted by a mathematical model of the plume. Single-shot CARS nitrogen thermometry extensively mapped the temperature profile of the plume. At most positions, high signal success rates were obtained. Success rates were lower during initial runs, while the system was optimized for operation in the rocket environment, and on axis close to the nozzle where the probing laser beams were severely deflected by the plume. For each position studied, the spectra taken were fitted for temperature and a mean temperature and standard deviation calculated from the results. The mean temperatures were compared with predicted temperature values obtained from a marching procedure parabolic computer program. CARS spectra from water vapor in the plume were also recorded and fitted for temperature and concentration. Excellent agreement between theory and experiment was obtained. Results showed a strong positive correlation between water vapor concentration and temperature at each measurement position - some contributions to this may arise from similarities of the effects of temperature and concentration on spectral shape. However, shear layer mixing and entrainment of cold gas into the plume may significantly affect the composition and temperature of the plume gases. LIF was used to visualize the plume structure. Imaging of the flow field was performed by detecting sodium fluorescence, after the oxidant was seeded with sodium. Images were obtained without excessively high background levels and large fluctuations in the plume structure were observed. This is consistent with the observations from the CARS experiments.

10A905. **Dynamic burning rate measurements of metalized composite propellants using the laser-recoil technique.** - MQ Brewster, MH Hites, SF Son *(Dept of Mech and Indust Eng, Univ of Illinois, Urbana IL 61801)*. Combust Flame 94(1-2) 178-190 (Jul 1993).

The combustion mechanism of metalized AP-HTPB-Al composite propellants have been investigated using a newly developed pulsed laser-recoil technique to measure dynamic propellant burning rate. The results demonstrate that aluminum has a stronger influence on the combustion of AP-HTPB propellants than is indicated by the small changes observed in macroscopically steady burning rate or the mean burning rate during macroscopically unsteady burning. The addition of 18% Al in AP-HTPB propellant causes only a 10% increase in the mean burning rate at 1 atm pressure but a 300% increase in the amplitude of the laser-perturbed fluctuating component of the burning rate at 40Hz. The prominent resonance observed at 40 Hz does not correspond to the classical thermal conduction-relaxation mechanism but appears to be related to the processes of unsteady accumulation, agglomeration, ignition, and departure of aluminum at the burning surface of the propellant. It was also found that a small quantity (1%) of chopped Kevlar fibers effectively damped the 40 Hz resonance and increased the steady burning rate at pressures below 5.4 MPa (800 psia). These observations are attributed to a flame-holding effect of the Kevlar fibers which protrude through the surface of the propellant and anchor the partially premixed, leading edge flame near the propellant surface.

10A906. **Radial-piston gas engine for transformation of low-potential thermal energy.** - VI Ivlev and GV Kreinin *(Moscow, Russia)*. J Machinery Manuf Reliab 6 8-12 (1992).

The problem of transformation of low-potential thermal energy into mechanical work with the help of a radial-piston gas engine working on $LaNi_5$-H_2 heated and cooled by warm and cold water flows respectively, is considered. Experimental data on the dynamic characteristics of a thermosorption source are used for deriving relationships describing the pressure and temperature variations within the engine's working chambers. The mechanical and power characteristics and exergetic efficiency of the engine are estimated and compared with those of a nitinol thermal engine designed for analogous purposes.

10A907. **Advanced pogo stability analysis for liquid rockets.** - BW Oppenheim and S Rubin *(Vehicle and Control Syst Div, Aerospace Corp, El Segundo CA 90245)*. J Spacecraft Rockets 30(3) 360-373 (May-Jun 1993).

An advanced modeling method for determining engine-coupled Pogo oscillation modes, with general applicability to any liquid rocket vehicle, is presented. The modes result from interaction of structural vibrations with pressure and flow oscillations in the liquid propulsion system. A time-invariant linearized mathematical model of the system is developed for a selected flight time. Perturbations of the propulsion system are modeled using FE representations for its physical elements (such as flow duct, pump, accumulator, and thrust chamber), each of which undergoes structural motion described in terms of the vibration modes of the overall vehicle. The structural modes, developed in a separate analysis, are determined with the fluids frozen in place in the feedlines and engines and involve motions of the propulsion elements. The system equations are written in a homogeneous second-order matrix form in the Laplace domain, yielding coefficient matrices that are all complex, unsymmetric, and singular. The major advances are 1) rigorous treatment of arbitrary translational motions of the vessels through which the fluids flow, including all forces (pressure area, inertial, and momentum) that react on the structural system, and 2) a powerful numerical eigensolver that yields eigenvalues and eigenvectors directly, without requiring elimination of dependent fluid state variables (pressure and flows).

10A909. **Flow over a highly porous inclined bed under surface traction: Boundary layer in the porous region.** - HS Guha *(Dept of Math, Taki Government Col, India)* and TK Chaudhury *(Dept of Math, Univ of Burdwan, Burdwan 713 104, India)*. Int J Eng Sci 31(8) 1191-1196 (Aug 1993).

The flow of viscous incompressible fluid over an inclined highly porous bed due to a uniform surface traction acting for a finite interval of time is investigated where the flow within the porous bed is taken to be governed by the Brinkman's equation. The growth of boundary layer thickness within the porous region due to surface traction is studied for different permeabilities. Equivalence of Darcy's law with slip-flow hypothesis (B-J condition) and Brinkman's equation with rigorous (physically realistic) boundary condition for the flow in the free-fluid region is established and the justification for using Darcy's law for flow in the porous region with small permeability is found from the boundary layer growth curves.

10A910. Mechanical model of lung parenchyma as a two-phase porous medium. - P Kowalczyk *(Inst of Fund Tech Res, Polish Acad of Sci, ul Swietokrzyska 21, 00-049 Warsaw, Poland)*. Transport Porous Media 11(3) 281-295 (Jun 1993).

The anatomy and geometry of the lung at the micro- and macroscopic level have been described briefly. A notion of lung parenchyma - a macroscopically continuous medium whose mechanical properties result from those of microstructural components - has been adapted. Simplifying assumptions propounded in the constitutive model have been discussed. Two phases have been distinguished in the medium: the solid phase - a highly deformable, nonlinearly elastic skeleton in the form of a thin-walled tissue structure on the micro-scale - and the fluid phase - perfect gas (air) filtrating through the structure. General constitutive relations for both phases and their mechanical interactions have been formulated. Further, the fundamental set of differential equations of the quasi-static coupled problem has been developed. Large deformations, material nonlinearities, and dependence of permeability on skeleton deformation have been included. Matrix formulation of the problem has been presented from the point of view of the FEM. An implicit time integration scheme has been proposed. The algorithm has been illustrated with results of simple numerical tests.

10A911. Use of conventional cocurrent and countercurrent effective permeabilities to estimate the four generalized permeability coefficients which arise in coupled, two-phase flow. - RG Bentsen *(Dept of Mining, Metall and Pet Eng, Univ of Alberta, Edmonton, AB, T6G 2G6, Canada)* and AA Manai *(Apex Energy Consult, Calgary, AB, T2P 3P2, Canada)*. Transport Porous Media 11(3) 243-262 (Jun 1993).

In the case of coupled, two-phase flow of fluids in porous media, the governing equations show that there are four independent generalized permeability coefficients which have to be measured separately. In order to specify these four coefficients at a specific saturation, it is necessary to conduct two types of flow experiments. The two types of flow experiments used in this study are cocurrent and countercurrent, steady-state permeability experiments. It is shown that, by taking this approach, it is possible to define the four generalized permeability coefficients in terms of the conventional cocurrent and countercurrent effective permeabilities for each phase. It is demonstrated that a given generalized phase permeability falls about midway between the conventional, cocurrent effective permeability for that phase, and that for the countercurrent flow of the same phase. Moreover, it is suggested that the conventional effective permeability for a given phase can be interpreted as arising out of the effects of two types of viscous drag: that due to the flow of a given phase over the solid surfaces in the porous medium and that due to momentum transfer across the phase 1-phase 2 interfaces in the porous medium. The magnitude of the viscous coupling is significant, contributing at least 15% to the total conventional cocurrent effective -ability for both phases. Finally, it is the nontraditional generalized which arise out of viscous couplin equal one another, even when t' is unity and the surface tension

10A912. Viscous coupling in two-phase flow in porous media and its effect on relative permeabilities. - R Ehrlich *(Chevron Oil Field Res, PO Box 446, La Habra CA 90633)*. Transport Porous Media 11(3) 201-218 (Jun 1993).

An idealized model of a porous rock consisting of a bundle of capillary tubes whose cross-sections are regular polygons is used to assess the importance of viscous coupling or lubrication during simultaneous oil-water flow. Fluids are nonuniformly distributed over tubes of different characteristic dimension because of the requirements of capillary equilibrium and the effect of interfacial viscosity at oil-water interfaces is considered. With these assumptions, we find that the importance of viscous coupling depends on the rheology of the oil-water interface. Where the interfacial shear viscosity is zero, viscous coupling leading to a dependence of oil relative permeability on oil-water viscosity ratio for viscosity ratios greater than one is important for a range of pore cross-section shapes and pore size distributions. For nonzero interfacial shear viscosity, viscous coupling is reduced. Using values reported in the literature for crude oil-brine systems, we find no viscous coupling.

10A913. Bifurcation of plane voidage waves in fluidized beds. - MF Goz *(Kernforschungszentrum Karlsruhe, Inst for Neutronenphys and Reaktortech, Pf 3640, W-7500 Karlsruhe 1, Germany)*. Physica D 65(4) 319-351 (15 Jun 1993).

A 2D fluidized bed model is investigated from a bifurcation point of view. It is shown that bifurcation to periodic travelling waves occurs when the basic state of uniform fluidization becomes unstable. The nature of these waves may be 1- or 2D. Here the main focus is on the bifurcation of oblique travelling waves, ie, plane voidage waves propagating into various directions in space. These waves can be described by a 2D dynamical system, which can be analysed extensively using phase plane methods. Several stationary and periodic solutions as well as homoclinic and heteroclinic orbits are shown to exist in the model studied.

10A914. Penetration of jets into fluidized beds. - PE Roach *(Inst of Fluid Dyn and Heat Transfer, Tech Univ, A-1040 Vienna, Austria)*. Fluid Dyn Res 11(5) 197-216 (May 1993).

The present paper is concerned with the penetration of jets into fluidized beds. Simple models are developed and compared with data from the author's experiments and those from the literature. Differentiation is made between three jet flow regimes: jetting, bubbling, and the transition between these two. Jet penetration length is found to increase as the orifice gas velocity increases, and the rate of increase is a function of the particular flow regime. This appears to be one of the main reasons for the large disagreement between the various correlations available in the literature. It is also found that the bed gas velocity has a first-order effect on the jet penetration length, something which is overlooked by most correlations in the literature. A simple analysis has been used successfully to define the extent of the transition zone.

10A915. Results on the nonlinear theory of dipolar porous elastic solids. - M Ciarletta *(Dept dell'Ingegneria dell'Informazione e Matematica Applicata, Univ Salerno, 84100 Salerno, Italy)* and A Scalia *(Dept Matematica, Univ Catania, Viale A Doria n-6-I, 95125 Catania, Italy)*. Int J Eng Sci 31(8) 1165-1172 (Aug 1993).

In this paper we establish some uniqueness and existence results in the framework of the nonlinear theory of porous elastic solids with microstructure.

10A916. Pressure transient response of stochastically heterogeneous fractured reservoirs. C Braester *(Dept of Civil Eng, Technion, Haifa 2000, Israel)* and DG Zeitoun *(Dept of Mech and Civil Eng, Univ of Vermont)*. Transport Porous Media 11(3) 263-280 (Jun 1993).

A stochastic model for flow through inhomogeneous fractured reservoirs of double porosity, based on Barenbiatt *et al's* continuum approach, is presented. The fractured formation is conceptualized as an interconnected fracture network surrounding porous blocks, and amenable to the continuum approach. The block permeability is negligible in comparison to that of the fractures, and therefore the reservoir permeability is represented by the permeability of the fracture network. The fractured reservoir inhomogeneity is attributed to the fracture network, while the blocks are considered homogeneous. The mathematical model is represented by a coupled system of partial differential random equations, and a general solution for the average and for the correlation moments of the fracture pressure are obtained by the Neumann expansion (or Adomian decomposition). The solution for pressure is represented by an infinite series and an approximate solution for radial flow, is obtained by retaining the first two terms of the series. The purpose of this investigation is to get an insight on the pressure behavior in inhomogeneous fractured reservoirs and not to obtain type curves for determination of reservoir properties, which owing to the nonuniqueness of the solution, is impossible. For the present analysis it is assumed an ideal reservoir with cylindrical symmetric inhomogeneity around the well. Fractured rock reservoirs being practically inhomogeneous, it is of interest to compare the pressure behavior of such reservoirs, with Warren and Roots's solution for (ideal) homogeneous reservoirs, used as a routine for determining the fractured reservoir characteristic parameters λ and ω, using the results of well tests. The comparison of the results show that inhomogeneous and homogeneous reservoirs exhibit a similar pressure behavior.

10A917. Darcy-Forchheimer natural, forced and mixed convection heat transfer in non-Newtonian power-law fluid-saturated porous media. - AV Shenoy *(Dept of Energy and Mech Eng, Shizuoka Univ, 3-5-1 Johoku, Hamamatsu 432, Japan)*. Transport Porous Media 11(3) 219-241 (Jun 1993).

The governing equation for Darcy-Forchheimer flow of non-Newtonian inelastic power-law fluid through porous media has been derived from first principles. Using this equation, the problem of Darcy-Forchheimer natural, forced, and mixed convection within the porous media saturated with a power-law fluid has been solved using the approximate integral method. It is observed that a similarity solution exists specifically for only the case of an isothermal vertical flat plate embedded in the porous media. The results based on the approximate method, when compared with existing exact solutions show an agreement of within a maximum error bound of 2.5%.

454D. SEISMOLOGY

10A918. "Pull up and "push down" effects is seismic reflection:. A useful constraint. - J Dyment *(Inst Physique du Globe CNRS URA 323, Univ Louis Pasteur, 5 rue R Descartes, 67084 Strasbourg Cedex, France)* and M Bano *(Ndermarrja Gjeofizike, Qendra e Perpuimit Sizmik, Fier, Albania)*. Geophys Trans 37(4) 279-295 (Mar 1993).

"Pull up" and "push down" effects are commonly observed in seismic sections. These fictitious deformations of seismic reflections under local velocity anomalies can, if they are not identified, lead to misinterpretation of seismic sections. However, in some cases and using simplifying assumptions, these effects can provide a useful constraint in the estimation of the seismic velocities and therefore help interpretation in complex areas. Two examples are presented: the first displays a distinct "pull up" effect related to the high seismic velocities associated with a salt diapir, the second shows a significant "push down" effect related to the low velocity of sedimentary basins.

10A919. Effects of transverse isotropy on P-wave AVO for gas sands. - Ki Young Kim *(Marine Tectonics Lab, Korea Ocean R&D Inst, Ansan PO Box 29, Seoul 425-600, Korea)*, KH Wrolstad, F Aminzadeh *(Seismic Res and Appl Div, Unocal, 376 S Valencia Ave, Brea CA 92621)*. Geophys 58(6) 883-888 (Jun 1993).

Velocity anisotropy should be taken into account when analyzing the amplitude variation with offset (AVO) response of gas sands encased in shales. The anisotropic effect on the AVO of gas sands in transversely isotropic (TI) media are reviewed. Reflection coefficients in TI media are computed using a plane-wave formula based on ray theory. We present results of modeling special cases of exploration interest having positive reflectivity, near-zero reflectivity, and negative reflectivity.

10A920. Elastic waves through a simulated fractured medium. - Chaur-Jian Hsu *(Schlumberger-Doll Res, Old Quarry Rd, Ridgefield CT 06877-4108)* and M Schoenberg *(Schlumberger Cambridge Res, Madingley Rd, Cambridge CB3 0EL, UK)*. Geophys 58(7) 964-977 (Jul 1993).

Ultrasonic velocities were measured on a block composed of lucite plates with roughened surfaces pressed together with a static normal stress to simulate a fractured medium. The measurements, normal, parallel, and oblique to the fractures, show that for wavelengths much larger than the thickness of an individual plate, the block can be modeled as a particular type of transversely isotropic (TI) medium that depends on four parameters. This TI medium behavior is the same as that of an isotropic solid in which are embedded a set of parallel linear slip interfaces, specified by (1) the excess compliance tangential to the interfaces and (2) the excess compliance normal to the interfaces. At all static stress levels, we inverted the data for the background isotropic medium parameters and the excess compliances. The background parameters obtained were basically independent of stress level and agreed well with the bulk properties of the lucite. The excess compliances decreased with increasing static closing stress, implying that increasing static stress forces asperities on either side of a fracture into greater contact, gradually eliminating the excess compliance that gives rise to the anisotropy. A medium with such planes of excess compliance has been shown, theoretically, to describe the behavior of a medium with long parallel joints, as well as a medium with embedded parallel microcracks.

10A921. Propagation of a nonlinear seismic pulse in an anelastic homogeneous medium. - DW Kosik *(Butler Univ, 4600 Sunset Ave, Indianapolis IN 46208)*. Geophys 58(7) 949-963 (Jul 1993).

Seismic surveys are often conducted using dynamite charges buried near the surface in unconsolidated material. In such material a large zone near the source should exist wherein nonlinear anelastic wave propagation, can be expected to take place, and have a significant impact on the way in which a seismic pulse forms and how its energy gets distributed into the surrounding medium. To obtain a solution for a propagating pulse in this zone, the equations of motion for nonlinear anelastic wave propagation, good to second order in the displacements, are solved numerically for the problem of a Gaussian pressure pulse acting on the interior cavity of a cylindrically symmetric hole in the medium. An implicit finite-difference algorithm is used for the solution to the equations of motion for this problem. The anelastic medium is characterized by multivalued stress-strain relations that exhibit hysteresis, and therefore a loss of energy per cycle, corresponding to a medium with a constant Q factor. Several numerical examples are calculated contrasting the nonlinear anelastic, linear anelastic, and linear elastic propagating pulses to one another. The nonlinear anelastic propagating pulse is found to have an amplitude that is several times larger than would be expected for a pulse in a linear medium and has a peak propagation velocity that is slightly less than that for a linear pulse. Dispersive effects are also evident for the nonlinear pulse.

10A922. Vertical open fractures and shear-wave velocities derived from VSPs, full waveform acoustic logs, and televiewer data. - F Lefeuvre *(TOTAL, 24 Cours Michelet Cedex 47 La Defense 10, 92069 Paris La Defense, France)*, R Turpening, C Caravana, A Born *(Earth Res Lab, MIT)*, L Nicoletis *(Inst Francais du Petrole, BP 311, 92506 Rueil-Malmaison Cedex, France)*. Geophys 58(6) 818-834 (Jun 1993).

Fracture or stress-related shear-wave birefringence (or azimuthal anisotropy) from vertical seismic profiles (VSPs) is commonly observed today, but no attempt is made to fit the observations with observed in-situ fractures and velocities. With data from a hard rock (limestones, dolomites, and anhydrites) region of Michigan, fast and slow shear-wave velocities have been derived from a nine-component zero offset VSP and compared to shear-wave velocities from two full waveform acoustic logs. To represent the shear-wave birefringence that affects the shear wave's vertical propagation, a propagator matrix technique is used allowing a local measurement independent of the over-burden layers. The picked times obtained by using a correlation technique have been corrected in the birefringent regions before we compute the fast and slow velocities. Although there are some differences between the three velocity sets, there is a good fit between the velocities from the shear-wave VSP and those from the two logs. We suspect the formations showing birefringence to be vertically fractured. To support this, we examine the behavior of the Stoneley wave on the full waveform acoustic logs in the formation. In addition, we analyze the borehole televiewer data from a nearby well. There is a good fit between the fractures seen from the VSP data and those seen from the borehole.

454Y. COMPUTATIONAL TECHNIQUES

10A923. Mixed-phase wavelet estimation using fourth-order cumulants. - GD Lazear *(Conoco, 4494 RW PO Box 1267, Ponca City OK 74602-1267)*. Geophys 58(7) 1042-1051 (Jul 1993).

In recent years methods have been developed in the field of high-order statistics that can reliably estimate a mixed-phase wavelet from the noisy output of a convolutional process. These methods use high-order covariance functions of the data called cumulants, which retain phase information and allow recovery of the wavelets. The assumption is that the reflection coefficient series is a non-Gaussian, stationary, and statistically independent random process. The method described in this paper uses the fourth-order cumulant of the data, and a moving-average, noncasual parametric model for the wavelet. The fourth-order moment function of this wavelet matches the fourth-order cumulant of data in the minimum mean-squared error sense. Numerical simulations demonstrate that the method can accurately estimate mixed-phase wavelets, even when the reflectivity has a distribution close to Gaussian. Three seismic data examples demonstrate possible uses of the method. In the first two, an average source wavelet is estimated from marine shot records acquired with air gun and water gun sources, respectively. These wavelets compare favorably with recorded far-field signatures modified for receiver ghosting. In the third example, a wavelet estimate from marine stacked data is used to correct the phase of the stacked section, resulting in zero-phase water bottom and salt top reflections.

10A924. Reasonable choices for material constants in seismic modeling. - JH Rosenbaum *(Bellaire Res Center, Shell Dev, PO Box 481, Houston TX 77001)*. Geophys 58(7) 978-986 (Jul 1993).

In exploration geophysics, the seismic response is often modeled with the assumption that the earth consists of homogeneous formulations that may exhibit transverse isotropy and moderate, "constant Q" attenuation. The geophysicist usually has only incomplete knowledge of the formation characteristics and must make educated guesses at the unknown elastic and absorption parameters. An extension of the long-wavelength-equivalent-medium theory to the anelastic case has been used to derive default options and stability criteria, which require minimal information from the geophysicist, appear reasonable for many earth materials and reduce to a proper description in the case of isotropy. A very simple earth model is used to demonstrate that parasitic modes are excited and the computations can become unstable when the assumed anelastic model parameters violate some stability condition or are inconsistent.

10A925. Sensitivity of prestack depth migration to the velocity model. - R Jan Versteeg *(Dept of Comput and Appl Math, Rice Univ, PO Box 1892, Houston TX 77251-1892)*. Geophys 58(6) 873-882 (Jun 1993).

To get a correct earth image from seismic data acquired over complex structures it is essential to use prestack depth migration. A necessary condition for obtaining a correct image is that the prestack depth migration is done with an accurate velocity model. In cases where we need to use prestack depth migration determination of such a model using conventional methods does not give satisfactory results. Thus, new iterative methods for velocity model determination have been developed. The convergence of these methods can be accelerated by defining constraints on the model in such a way that the method only looks for those components of the true earth velocity field that influence the migrated image. In order to determine these components, the sensitivity of the prestack depth migration result to the velocity model is examined using a complex synthetic data set (the Marmousi data set) for which the exact model is known. The images obtained with increasingly smoothed versions of the true model are compared, and it is shown that the minimal spatial wavelength that needs to be in the model to obtain an accurate depth image from the data set is of the order of 200 m. The model space that has to be examined to find an accurate velocity model from complex seismic data can thus be constrained. This will increase the speed and probability of convergence of iterative velocity model determination methods.

10A926. Shortest path ray tracing with sparse graphs. - R Fischer and JM Lees *(Dept of Geol and Geophys, Yale Univ, Kline Geol Lab, 210 Whitney Ave, New Haven CT 06511-8130)*. Geophys 58(7) 987-996 (Jul 1993).

A technique for improving the efficiency of shortest path ray tracing (SPR) is presented. We analyze situations where SPR fails and provides quantitative measures to assess the performance of SPR ray tracing with varying numbers of nodes. Our improvements include perturbing the ray at interfaces according to Snell's Law, and a method to find correct rays efficiently in regions of low velocity contrast. This approach allows the investigator to use fewer nodes in the calculation, thereby increasing the computational efficiency. In 2D cross-borehole experiments we find that with our improvements, we need only use 2/3 as many nodes, saving up to 60% in time. Savings should be even greater in 3D. These improvements make SPR more attractive for tomographic applications in 3D.

10A927. Three dimensional time-variant dip moveout by the f-k method. - HA Meinardus and KL Schleicher *(Halliburton Geophys Services, PO Box 5019, Sugar Land TX 77487-5019)*. Geophys 58(7) 1030-1041 (Jul 1993).

The standard seismic imaging sequence consists of normal moveout (NMO), dip moveout (DMO), stack, and zero-offset migration. Conventional NMO and DMO processes remove much of the effect of offset from prestack data, but the constant velocity assumption in most DMO algorithms can compromise the ultimate results. Time-variant DMO avoids the constant velocity assumption to create better stacks, especially for steeply dipping events. Time-variant DMO can be implemented as a 3D f-k domain process using the dip decomposition method. Prestack data are moved out with a set of NMO velocities corresponding to discrete values of inline and crossline dips. The dip-dependent NMO velocity is computed to remove the trace offset and azimuth dependence of event times for an arbitrary velocity function of depth. After stacking the moved out CMP gathers, a 3D dip filter is applied to select the particular in-line and crossline dip. The final zero-offset image is obtained by summing all the dip-filtered sections. This process generates a saddle-shaped 3D impulse response for a constant velocity gradient. The impulse response is more complicated for a general depth-variable velocity function, where the response exhibits secondary branches, or triplications, at steeper dips. These complicated impulse responses, including amplitude and phase effects, are implicitly produced by the f-k process. The dip-decomposition method of 3D time-variant DMO is an efficient and accurate process to correct for the effect of offset in the presence of an arbitrary velocity variation with depth. The impulse response of this process implicitly contains complex features like a 3D saddle shape, triplications, amplitude, and phase. Field data from the Gulf of Mexico shows significant improvement on a steep salt flank event.

10A928. Two dimensional velocity inversion-imaging of large offset seismic data via the tau-p domain. - EC Reiter *(Aware, One Memorial Dr, Cambridge MA 02142-1301)*, GM Purdy *(Dept of Geol and Geophys, Woods Hole Oceanog Inst, Woods Hole MA 02543)*, MN Toksoz *(Earth Res Lab, Dept of Earth Atmos and Planet Sci, MIT)*. Geophys 58(7) 1002-1016 (Jul 1993).

We describe a method for determining a 2D velocity field from refraction data that has been decomposed into some function of slowness. The most common decomposition, intercept time-slowness or τ - p, is used as an intermediate step in an iterative wavefield continuation procedure previously applied to 1D velocity inversions. We extend the 1D approach to 2D by performing the downward continuation along numerically computed raypaths. This allows a correction to be made for the change in ray parameter induced by 2D velocity fields. A best fitting velocity model is chosen as a surface defined by critically reflected and refracted energy that has been downward continued in a 3D space of velocity, offset, and depth. Synthetic data are used to demonstrate how this approach can compensate for the effects of known lateral inhomogeneities while determining an underlying 1D velocity field. We also use synthetic data to show how multiple refraction lines may be used to determine a general 2D velocity model. Large offset field data collected with an Ocean Bottom Hydrophone are used to illustrate this technique in an area of significant lateral heterogeneity caused by a sloping seafloor.

10A929. Two-layer stacking procedure to enhance converted waves. - BLN Kennett *(Res Sch of Earth Sci, Austral Natl Univ, Canberra, ACT 0200, Australia)*. Geophys 58(7) 997-1001 (Jul 1993).

For marine seismic sources quite efficient conversion of P-waves to S-waves can occur at hard seafloors, eg, carbonate horizons in tropical waters. The S-waves are reflected back from structures at depth and are reconverted to P-waves in the water before detection by the receiver array. Such PSSP reflections can carry useful information on the structure beneath the sea bed but are most significant at large offsets and so are not easily stacked with a conventional normal moveout (NMO) procedure based on hyperbolic time trajectory. A two-layer stacking procedure that separates the water layer from the region below the seafloor provides a very effective means of extracting the PSSP arrivals, but also works well for P-waves. There is no direct analytic form for the stacking trajectories but they can be calculated quite efficiently numerically. A further advantage is that the stacking velocity for S-waves in the lower layer can be interpreted directly in terms of S-wave propagation, so that S-wave interval velocities can be found. Stacking procedures based on such simple physical models are likely to be useful in other cases where attention needs to be focused on a particular aspect of the wavefield.

10A930. Wave processes in vertically-inhomogeneous media. A new strategy for a velocity inversion. - AS Alekseev, AV Avdeev, AG Fatianov, VA Cheverda *(Comput Center, Siberian Div, Russian Acad of Sci, Novosibirsk 630090, Russia)*. Inverse Prob 9(3) 367-390 (Jun 1993).

This paper describes a closed cycle of mathematical modelling of wave propagation processes. The half-space $z > 0$ is assumed to be filled with a vertically-inhomogeneous medium with the wave propagation velocity $c(z)$. A source located on the free surface $z = 0$ causes the wave process $U(x,y,z,t)$, described by the initial boundary value problem for the wave equation. We consider two main problems: (1) assuming $c(z)$ is known for all z, we wish to calculate the wave field $U(x,y,z,t)$; (2) if $c(z)$ is unknown, we find it using the additional information $U(x,y,t) = U(x,y,0,t)$. In order to solve problem (2) the optimization approach is proposed and verified. Uniqueness and stability of the minimum point of the data misfit functional are proved and convergence if iterative methods for its search is investigated. The search for the minimum point in the domain of space-time frequencies can essentially increase the efficiency of the whole process of finding the velocity $c(z)$.

454Z. EXPLORATIONS AND MEASUREMENTS

10A931. Estimation of near-surface elastic parameters using multicomponent seismic data. - EZ Ata *(INTEVEP, SA Res and Dev Center, Apdo 76343, Caracas 1070A, Venezuela)*, D Corrigan *(ARCO Exploration and Prod Tech, 2300 W Plano Pkwy, Plano TX 75075)*, GA McMechan *(Center for Lithospheric Stud, Univ of Texas at Dallas, PO Box 830688, Richardson TX 75083-0688)*, JE Gaiser *(W Geophys, 7229 S Alton Way, Englewood CO 80112)*. Geophys 58(7) 1017-1029 (Jul 1993).

In multicomponent seismic reflection surveys, surface and near-surface effects can severely deteriorate the quality of reflection data. Such effects are more pronounced on shear-wave than on compressional-wave profiles. Amplitude anomalies, statics, and strong coherent source-generated noise (ie, surface waves) are often associated with inhomogeneous, poorly compacted near-surface sediments of the weathering layer. The magnitude of such effects increases when sources and receivers are deployed or near the surface in proximity to such inhomogeneities. Near-surface effects can be investigated with respect to their depth of occurrence by burying seismic sources and/or receivers at various depths below the inhomogeneous weathering layer. In this context, an experiment was conducted to collect multicomponent seismic field data on a borehole-controlled test site in E Texas. Data were recorded on three-component surface and buried receivers using a full-vector wave-field surface source. Although the geology appears simple, results of modeling one or two components of the field data with synthetics yields nonunique estimates of elastic parameters. Effects of anisotropy and heterogeneities are better identified and estimated with full-wavefield surface and buried receiver observations. Single fold data from buried receivers yield reflection events with higher signal-to-noise ratio than 30-fold CDP surface data previously acquired in the same area.

456. Earthquake mechanics

10A932. Note on attenuation of earthquake intensity in Macedonia. - LS Timiovska *(IZIIS, 9100 Skopje, Macedonia)*. Soil Dyn Earthquake Eng 11(8) 457-463 (1992).

The attenuation of strong shaking is related to the dissipation of earthquake energy. It varies with distance from the epicenter, and depends on the local geological conditions. The 1437 data points have been collected from the Atlas of Isoseismal Maps (Catalogue of Earthquakes) in the UNDP-UNESCO *Survey of the Seismicity of the Balkan Region* (1974) and from unpublished data on seismic intensities in the Balkan region up to 1989. A regression analysis has been performed to describe the attenuation of earthquake intensity in Macedonia in terms of epicentral intensity, I_0, epicentral distance, R, and local geological conditions at the recording site, s (s = 0, 1, or 2 for soft, medium and hard geological site conditions).

10A933. Nonlinear seismic response of antenna-supporting structures. - E Guevara and G McClure *(Dept of Civil Eng and Appl Mech, McGill Univ, Montreal, PQ, Canada)*. Comput Struct 47(4-5) 711-724 (3 Jun 1993).

In the event of a severe seismic excitation, preservation of essential infrastructures, such as telecommunication facilities, is of high priority. The objective of this paper is to investigate the geometrically nonlinear response of anetnna-supporting guyed towers under earthquake loading. Two guyed towers are analyzed: a 350 ft (107 m) tower with six stay levels and an 80 ft (24 m) mast with only two stay levels. Two horizontal accelerograms are used, El Centro and Parkfield, with each record being scaled to match the elastic design spectra of the 1990 National Building Code of Canada. Elements of response analyzed are: guy tensions, horizontal shears, and displacements and rotations at the tip of the mast. Results indicate that although the absolute values of the dynamic amplifications are well below the limit strength and serviceability criteria for such towers, dynamic interactions between the guy-wires and the mast are important, especially in the vertical direction. Multiple support excitation of the tallest tower also causes additional dynamic effects that are not present when only synchronous ground motion is studied.

10A934. One and 2D maximum softening damage indicators for reinforced concrete structures under seismic excitation. - SRK Nielsen *(Dept of Build Tech and Struct Eng, Univ of Aalborg, DK-9000 Aalborg, Denmark)*, HU Koyluoglu, AS Cakmak *(Dept of Civil Eng and Operations Res, Princeton)*. Soil Dyn Earthquake Eng 11(8) 435-443 (1992).

The maximum softening concept is based on the variation of the vibrational periods of a structure during a seismic event. Maximum softening damage indicators, which measure the maximum relative stiffness reduction caused by stiffness and strength deterioration of the actual structure, are calculated for an equivalent linear structure with slowly varying stiffness characteristics. In the paper, a 1D scalar-valued and a 2D vector-valued maximum softening damage indicator are defined. The 1D damage indicator, defined considering the variation in the first period of the structure, analogous to a SDOF system, is a genuine global damage index representing the average damage throughout the whole structure. The 2D damage indicator is defined considering the variations in the first and second periods, and thus is analogous to an equivalent linear two-dof system. The components of the damage vector can be interpreted as damage indicators for the lower half and the upper half of the structure, hence representing a simple local description of the damage state of the structure. Since statements on the post earthquake reliability should be obtained solely from knowledge of the latest recorded values of the damage indicators above defined, these are required to possess a Markov property. This problem has been investigated based on numerical Monte-Carlo simulations, and it is observed that the Markov assumption of the 1D damage indicator is justified for the mean value of the transition probability function, whereas some deviations are observed for the variance and higher order statistical moments.

10A935. Probabilistic seismic analysis of a steel frame structure. - Hitoshi Seya *(Tech Res Lab, Takenaka, Tokyo, Japan)*, ME Talbott *(Dept of Civil and Operations Res, Princeton)*, HHM Hwang *(Center for Earthquake Res and Info, Memphis State Univ, Memphis TN 38152)*. Probab Eng Mech 8(2) 127-136 (1993).

In this study we present a probabilistic seismic analysis of a steel frame structure to generate fragility curves and to investigate the correlation between the response modification factor and the system ductility factor. As an example, we use a five-story hypothetical steel frame structure located in New York City and designed according to the provisions specified in the ANSI standard A58.1-1982 and the AISC ASD specification. We quantify uncertainties in seismic and structure parameters that define the earthquake-structure system by choosing several representative values for each parameter. Then, by using the Latin hypercube sampling technique, we combine these representative values to establish 18 samples of the earthquake-structure system for probabilistic seismic response analysis. The nonlinear seismic analysis is performed by using the DRAIN-2D computer program.

10A936. Review of reference models for assessing inelastic seismic torsional effects in buildings. - JC Correnza, GL Hutchinson *(Dept of Civil and Env Eng, Univ of Melbourne, Parkville, Vic 3052, Australia)*, AM Chandler *(Dept of Civil and Env Eng, Univ Col, Gower St, London WC1E 6BT, UK)*. Soil Dyn Earthquake Eng 11(8) 465-484 (1992).

This paper reviews the various forms of reference model adopted for studies that evaluate inelastic seismic torsional effects and assess their implications for building design. Both qualitative and quantitative comparisons are presented. The importance of selecting an appropriate reference model in accordance with the above aims is emphasized. It is found that variations in the reference models adopted in analyses of inelastic seismic torsional effects may lead to significant differences in the results obtained and, hence, to the conclusions drawn from such studies. It is demonstrated that accidental torsional effects, as incorporated in code design provisions, result in significant changes to the distribution of element strengths and the inelastic response behavior of symmetric and generalized torsionally balanced reference models. Such changes should be considered when employing such models to evaluate the inelastic response of torsionally unbalanced building systems.

10A937. Seismic energy demands on reinforced concrete moment-resisting frames. - WK Tso *(Dept of Civil Eng and Eng Mech, McMaster Univ, 1280 Main St W, Hamilton, ON, Canada)*, TJ Zhu *(Buckland and Taylor, N Vancouver, BC, Canada)*, AC Heidebrecht *(Dept of Civil Eng and Eng Mech, McMaster Univ, 1280 Main St W, Hamilton, ON, Canada)*. Earthquake Eng Struct Dyn 22(6) 533-545 (Jun 1993).

This paper examines the seismic energy demands on reinforced concrete ductile moment-resisting frames. Three frames having 4, 10 and 18 storeys, representing low, medium and tall frames, were designed to the current Canadian seismic provisions and structural design requirements. Three groups of earthquake records having different frequency contents were selected as input ground motions. The input, hysteretic and damping energies were evaluated for these three frames and correlation was established with other response parameters. The use of equivalent single dof systems to estimate the energy demands on these frames was examined in order to simplify the computational effort. It is shown that the energy demand concept together with the equivalent single dof system is a viable design approach for low-rise frames. Additional research to allow for the higher modal effect is required before the same concept can be extended to medium and tall frames.

Linear water waves superimposed on an opposing current varying linearly down to a depth h are investigated. Fluxes of mass, momentum, and energy are calculated. Of main interest is the expression for the energy flux and its possible decomposition into terms in such as way that the contribution from wave energy is clearly shown. Such a decomposition would link the kinematic group-velocity concept to the dynamic concept of velocity of propagation of wave energy. We write the energy flux in a form that generalizes the simple expression found by Brink-Kjaer for the case of a linear current extending down to the bottom. In this expression the term corresponding to the group velocity appears quite naturally, as the energy flux of 'pure wave energy.'

10A941. Generation of a Stoneley-Scholte-Lamb atmospheric surface wave by an acoustic source located in an ocean waveguide. - LA Gasilova, IY Gordeeva, YV Petukhov *(Inst of Appl Phys, Russian Acad of Sci)*. Acoust Phys 39(1) 19-23 (Jan-Feb 1993).

The dispersion properties of a modified Stoneley-Scholte-Lamb surface wave propagating along the interface between an isothermal atmosphere and an ocean wave guide are investigated. The interface is modeled by a homogeneous compressible fluid layer on top of a homogeneous elastic half-space. The frequency dependence of the excitation coefficients of the wave is determined for perturbations of the pressure and particle velocity of the medium in the atmosphere for an underwater point mass source. It is shown that this wave exists only at frequencies below a certain critical frequency, which decreases with increasing depth of the water layer, and that it propagates with supersonic (for air) velocity above another critical frequency and with subsonic velocity below this frequency, which also decreases with increasing depth of the water layer.

10A942. Material testing and evaluation from the point of view of the nuclear power plant safety. - P Trampus *(Paks Nucl Power Plant, PO Box 71, Paks H-7031, Hungary)*. Int J Pressure Vessels Piping 55(2) 187-202 (1993).

This paper describes the material testing and evaluation of the nuclear power plant's main components by aging of structural material during normal operation and accidents which affect the material structure. Specific feature of the Hungarian regulation are reported. Some examples of the in-service inspection and reactor pressure vessel surveillance activity at Paks NPP and the documentation system are also reported.

10A943. Role of microstructure in the propagation of ultrasound in bainitic low-alloy steels. - F Bergner, B Kohler, K Popp *(Central Inst for Nucl Res Rossendorf, Dresden O-8051, Germany)*. Int J Pressure Vessels Piping 55(2) 251-260 (1993).

The propagation characteristics of ultrasound in two types of bainitic Cr-Mo-V steels including the Soviet type reactor pressure vessel steel 15Kh2MFA have been examined. In order to find out the factors affecting the sound velocity the steels have been exposed to different heat treatments and to neutron irradiation. It turned out that the sound velocity is considerably changed by tempering but only slightly by neutron irradiation. The effect of tempering can be explained on the basis of the decomposition of retained austenite and carbide precipitation. The main mechanisms of ultrasonic attenuation are Rayleigh scattering at prior austenite grains and thermoelastic absorption in the vicinity of packet boundaries. Both effects have been shown to depend on the orientation relationship between bainitic ferrite and parent austenite.

10A944. CAD of transmission lines. - AH Peyrot *(Univ of Wisconsin, Madison WI 53706)*, EM Peyrot *(Power Line Syst, Madison WI 53705)*, T Carton *(Electricite de France, Paris, France)*. Eng Struct 15(4) 229-237 (Jul 1993).

This paper gives an overview of structural and geometric design concepts for electrical power lines. It presents a new integrated computerized environment for generating new designs or evaluating existing ones. In that environment, productivity can be radically improved and the risk of errors is reduced. New design concepts that achieve greater economy can be implemented. The manner in which such diverse utility groups as surveyors, planners, engineers and CAD technicans interact with each other can be improved. Electrical parameters or power lines are only discussed insofar as they affect the line geometry.

10A945. Guyed structures for transmission lines. - HB White *(PO Box 939 Hudson, PQ, Canada)*. Eng Struct 15(4) 289-302 (Jul 1993).

Guyed structures have become the dominant type for use on transmission lines remote from urban areas or where land use restrictions are prohibitive. All other attributes, including cost of materials, erections and performance are positive and the continuing pace of innovations of types and techniques is adding to their attractions. This review of old and new types and practices illustrates adaptability and some of the many new ideas produced in response to frequently changing demands and conditions.

10A946. Nonlinear FE analysis of latticed transmission towers. - FGA Al-Bermani and S Kitipornchai *(Center for Transmission Line Struct, Dept of Civil Eng, Univ of Queensland, St Lucia, Queensland 4072, Australia)*. Eng Struct 15(4) 259-269 (Jul 1993).

Current design practices for transmission tower structures are based on 3D linear elastic truss analyses and on full-scale testing experience. This paper reviews current practices and presents a nonlinear analytical technique for accurate simulation and prediction of the ultimate strength and behavior of transmission towers under static load conditions. Both geometric and material nonlinearities are accounted for in the analysis. A formex formulation is used for the automatic generation of data that is necessary for the analysis. The behavior of four different full-scale towers is described and the predicted results are compared with tests.

10A947. Optimization methods for transmission line design. - AH Peyrot *(Univ of Wisconsin, Madison WI 53706)*, EM Peyrot *(Power Line Syst, Madison WI 53705)*, A Senouci *(Univ of Wisconsin, Madison WI 53705)*. Eng Struct 15(4) 239-246 (Jul 1993).

The companion paper to this one "CAD of transmission lines" discussed the general parameters considered in the overall design of a line, and presented an integrated and interactive computerized environment for complete engineering of a line. This paper discusses the roles that standardization and optimization can play in the selection of some of the design parameters. It also presents new developments in the two areas where optimization has been used successfully: firstly, a primary optimization of the combination of conductor type, conductor tension, and structure family; and secondly, a secondary optimization for structure spotting.

10A948. Review of dynamic aspects of transmission line design. - BW Smith *(Flint & Neill Partnership, 14 Hobart Pl, London SW1W 0HH, UK)*. Eng Struct 15(4) 271-275 (Jul 1993).

A review of current practice in the UK is pro- ' regarding the dynamic problems associated with conductors, including galloping, wake induced vibrations and vortex excitation. The response of transmission line towers is discussed and the parameters which are of most importance highlighted. The background to the treatment adopted in the UK Code of Practice is described, including the development of the parameter to assess the dynamic sensitivity of towers. This parameter is used to judge whether simplified static procedures may be safely used in design.

10A949. Structural optimization of transmission line conductors. - HB White *(PO Box 939 Hudson, PQ, Canada)*. Eng Struct 15(4) 247-249 (Jul 1993).

Structural optimization of a transmission line requires careful attention to the structural properties of the conductor. In turn, the selection of the most efficient conductor will be governed by the controls or limits of use that are specified. The % rated tensile strength concepts that have guided the industry for the past many decades are slowly being replaced by limits on H/w or the catenary constant, which is itself a good measure of the stress in the outer aluminum wires as well as being an important parameter.

10A950. System reliability analysis of transmission lines. - HJ Dagher and Q Lu *(Dept of Civil Eng, Univ of Maine, Orono ME 04469)*. Eng Struct 15(4) 251-258 (Jul 1993).

Structural system reliability analysis of transmission lines is a useful tool in designing new lines and in evaluating or uprating existing lines. This paper describes a practical approach to estimate the system reliability of existing lines. The problem is divided into two components: firstly, obtaining the reliability of typical supporting structures; and secondly obtaining the reliability of the complete line. The first step may be carried out using standard structural system reliability analysis methods. A number of computer programs are currently available for structural system reliability analysis; those programs which are specifically designed for the reliability analysis of transmission structures are briefly described. It is shown that the reliability of every supporting structure in the line need not be obtained. Only the reliabilities of typical structures are needed. Once this is accomplished, the second step is to estimate the reliability of the entire line. This can be carried out using a simple approximate relationship between the reliability of a fully-utilized supporting structure and the reliability of the complete line. Two numerical examples are used to illustrate how the reliability of a complete line may be estimated.

10A951. Transmission tower development in the UK. - C Lomas *(Natl Grid, Woodbridge Rd, Guildford, Surrey GU1 1EJ, UK)*. Eng Struct 15(4) 277-288 (Jul 1993).

This paper looks back on the development of the lattice steel tower and the use of lattice towers on overhead transmission lines in the UK over the past sixty years. It reviews the current regulations and the National Grid Company's approach to alternative tower types.

514. Environmental mechanics

10A952. Fracture mechanics in modeling of icebreaking capability of ships. - RV Goldstein and NM Osipenko *(Lab on Mech of Strength and Fracture, Mat and Struct, Inst for Prob in Mech, Russian Acad of Sci, Prospect Vernadskogo 101, Moscow 117526, Russia)*. J Cold Regions Eng 7(2) 33-43 (Jun 1993).

The basis of the present paper is the approach suggested previously by the writers. By matching inner and outer solutions, a separate modeling of the deformation and fracture processes in stressed ice covers, taking into account the difference in relevant characteristic geometric and force parameters, is accomplished. In the outer problem, the scale is determined by the channel length; in the inner, by the size of the active fracture zone near the channel tip. A similarity criterion is introduced having the form of a characteristic length that incorporates the fracture toughness. Using this parameter, it is possible to formulate relations for critical loads or dimensions of fracture pieces that are formed in the process of icebreaker-ice-cover interaction. These relations may be derived separately for the inner problem, taking into account matching conditions with the outer problem. The characteristic form of the relation is shown for the case of fracture near an icebreaker hull due to cylindrical bending, taking into account the velocity effect of icebreaker motion. This paper presents a system for choosing modeling parameters for ice fracture using fracture toughness and strength dependencies, salinity, and temperature data for model ice. The data were collected from the ice basin of the Russian Artic and Antarctic Scientific Research Institute.

10A953. Role of liquid crystals in the lubrication of living joints. - BI Kupchinov, SF Ermakov, VG Rodnenkov, SN Bobrysheva, ED Beloenko, VN Kestelman *(Metal-Polymer Res Inst, Belarus Acad of Sci, Gomel 246652, Belarus)*. Smart Mat Struct 2(1) 7-12 (Mar 1993).

This investigation was devoted to the study of a natural phenomenon, low friction in living joints, and development of synthetic lubricants. The experiments conducted allowed us to establish that the known property of synovia to ensure the high antifrictional ability of joint cartilages is provided by the realization of a liquid-crystalline state of the lubricant in the friction zone that was unknown before. An idea was advanced that molecules of liquid-crystalline cholesterol compounds found in synovia are arranged with their longer axis aligned with prevailing microgroove locomotions on cartilage surfaces to make a liquid-crystalline nematic phase, thus reducing energy dissipation during relative motion of contacting cartilages and leading to the medicative effect revealed by experimentation.

10T954. Numerical analysis of steady generalized Newtonian blood flow in a 2D model of the carotid artery bifurcation. - JPW Baaijens, AA Van Steenhoven, JD Janssen *(Dept of Mech Eng, Univ of Tech, Eindhoven, Netherlands)*. Biorheol 30(1) 63-74 (Jan-Feb 1993).

10A955. Planar model for mucociliary transport: Effect of mucus viscoelasticity. - M King, M Agarwal, JB Shukla *(Pulmonary Defense Group, Univ of Alberta, 519 Newton Res Bldg, Edmonton, AB, T6G 2C2, Canada)*. Biorheol 30(1) 49-61 (Jan-Feb 1993).

A planar two-layer fluid model is proposed to study the transport of mucus in the respiratory tracts due to cilia beating and air motion by considering mucus as a viscoelastic fluid. The effect of air motion due to forced expiration and other processes is considered by prescribing shear stress at the mucus-air interface. It is shown that the transport of mucus increases as the pressure drop, shear stress due to air motion and the velocity generated by cilia tips and the serous sublayer increase. Mucus transport also increases as the shear modulus of elasticity decreases. This property is effective only in the presence of pressure drop or air motion. It is noted that the effect of gravity is similar to pressure drop. It is observed that mucus transport decreases as the viscosity of serous layer fluid increases, but any increase at high values of mucus viscosity does not seem to affect the mucus transport. It is also found that for a given total depth of serous and mucus layers, there exists a serous fluid layer thickness for which the mucus transport is maximum. The functional dependence of mucus transport predicted by the model is discussed in relation to experimental observations.

10A956. Study of numerical fluid analysis around a prosthetic heart valve using the finite difference method under steady flow conditions. - Yukiaki Kikuta, Toshio Yuhta, Satoru Igarashi *(Fac of Eng, Hokkaido Univ, N-13 W8 Kita-ku, Sapporo 060)*, Yoshinori Mitamura *(Fac of Eng, Hokkaido Tokai Univ, 5-1 Minaminosawa, Minami-ku Sapporo 005)*, Bu gil Kim *(Med Sch and Hospital, Chonbuk Natl Univ, 2-20 Keum-am Dong, Chonju 560-180, Korea)*. Int J Japan Soc Precision Eng 27(1) 54-60 (Mar 1993).

A simulation would be a very effective method for analysis associated with a prosthetic heart valve. In this paper we developed a simulation program with the finite difference method for fluid analysis under steady flow condition. The numerical fluid analysis that obtained by this analysis program was consistent with the results of flow visualization experiment. By combining the Euler method and the Lagrange method simulated flow visualization of imaged particles is possible. This is effective for an understanding of flow dynamics around prosthetic heart valves.

10A957. Dynamics of bipedal gait Part I. Objective functions and the contact event of a planar five-link biped. - Y Hurmuzlu *(Dept of Mech Eng, S Methodist Univ, Dallas TX 75275)*. J Appl Mech 60(2) 331-336 (Jun 1993).

Previous approaches to the problem of prescribing the motion of bipedal machines do not completely characterize the desired walking patterns in terms of coherent parameters. A well-structured parametric formulation that ties the objective functions to the resulting gait patterns has never been established. This article presents an approach that can be followed to formulate objective functions which can be used to prescribe the gait of a planer, five-element, bipedal automaton during single support phase. The motion of the biped is completely characterized in terms of progression speed, step length, maximum step height, and stance knee bias. Kinematic relations have been derived and the inverse problem has been solved to perform a parametric study that correlates the regions of the 4D parameter space with the respective gait patterns. Major limitations include the assumptions of rigid elements and point contact between the lower limbs and the walking surface. Most importantly, the motion of the biped is assumed to perfectly conform with the objective functions at the instant of contact. The control and stability issues are presented in Part II of this paper.

10A958. Dynamics of bipedal gait Part II. Stability analysis of a planar five-link biped. - Y Hurmuzlu *(Dept of Mech Eng, S Methodist Univ, Dallas TX 75275)*. J Appl Mech 60(2) 337-343 (Jun 1993).

A general approach based on discrete mapping techniques is presented to study stability of bipedal locomotion. The approach overcomes difficulties encountered by others on the treatment of discontinuities and nonlinearities associated with bipedal gait. A five-element bipedal locomotion model with proper parametric formulation is considered to demonstrate the utility of the proposed approach. Changes in the stability of the biped as a result of bifurcations in the 4D parameter space are investigated. The structural stability analysis uncovered stable gait patterns that conform to the prescribed motion. Stable nonsymmetric locomotion with multiple periodicity was also observed, a phenomenon that has never been considered before. Graphical representation of the bifurcations are presented for direct correlation of the parameter space with the resulting walking patterns. The bipedal model includes some idealizations such as neglecting the dynamics of the feet and assuming rigid bodies. Some additional simplifications were performed in the development of the controller that regulates the biped.

552. Human factors, rehabilitation, sports

10A959. Design guide of master arms considering operator dynamics. - Y Yokokohji and T Yoshikawa *(Dept of Mech Eng, Fac of Eng, Kyoto Univ, Kyoto 606, Japan)*. J Dyn Syst Meas Control 115(2A) 253-260 (Jun 1993).

In this paper, a design guide of master arms for teleoperation is discussed. The quality of the master arm design has a considerable influence on the maneuverability of master-slave systems. A quantitative measure of the manipulative ability of master arms is proposed, and is obtained by extending the concept of the dynamic manipulability. It is pointed out that the directional property of the manipulability ellipsoid in the work space is an important factor. A second quantitative measure is proposed which evaluates the similarity of the manipulability ellipsoids produced by two situations – when the operator maneuvers the master arm and when he has no payload. Numerical examples and several guidelines for master arm design are shown.

10A960. Human centered control in robotics and consumer product design. - H Asada *(Center for Info-Driven Mech Syst, Dept of Mech Eng, MIT)*, CC Federspiel *(Johnson Controls, Milwaukee WI)*, Sheng Liu *(Center for Info-Driven Mech Syst, Dept of Mech Eng, MIT)*. J Dyn Syst Meas Control 115(2B) 271-280 (Jun 1993).

Human factors in the control and programming of robots and electric appliances are addressed in this paper. Systems and control techniques for the enhancement of human-machine communication as well as learning and adaptation to human needs are described with exemplary case studies. First, fundamental issues and methodologies, as well as historical perspective of relevant fields, are summarized, and two case studies are then discussed. One is user-adaptable control of air conditioners, a new type of adaptive control that allows an air conditioner to learn the thermal preference of the user. The other is a user-friendly programming method for advanced robot control. A task-level adaptive control system is developed by acquiring control skills by direct communication with human experts. The importance of human-machine communication and its impact on product development are addressed from the systems and control point of view.

10A961. Human extenders. - H Kazerooni *(Mech Eng Dept, UCB)* and J Guo *(Inst of Naval Architec and Ocean Eng, Natl Taiwan Univ, Taipei, Taiwan, ROC)*. J Dyn Syst Meas Control 115(2B) 281-290 (Jun 1993).

A human's ability to perform physical tasks is limited by physical strength, not by intelligence. We coined the word "extenders" as a class of robot manipulators worn by humans to augment human mechanical strength, while the wearer's intellect remains the central control system for manipulating the extender. Our research objective is to determine the ground rules for the control of robotic systems worn by humans through the design, construction, and control of several prototype experimental direct-drive and non-direct-drive multi-dof hydraulic-electric extenders. The design of extenders is different from the design of conventional robots because the extender interfaces with the human on a physical level. The work discussed in this article involves the dynamics and control of a prototype hydraulic 6-dof extender. This extender's architecture is a direct drive system with all revolute joints. Its linkage consists of two identical subsystems, the arm and the hand, each having 3-dof. Two sets of force sensors measure the forces imposed on the extender by the human and by the environment (ie, the load). The extender's compliances in response to such contact forces were designed by selecting appropriate force compensators. The stability of the system of human, extender, and object being manipulated was analyzed. A mathematical expression for the extender performance was determined to quantify the force augmentation. Experimental studies on the control and performance of the experimental extender were conducted to verify the theoretical predictions.

Author Index for October 1993

The codes after each name give the sequence numbers of the items in the Book Reviews section (R = Review, N = Note) or the Journal Literature section (A = Abstract, T = Title). Books listed by title only or as "under review" are not included in this index.

applied mechanics reviews

AIMS

The primary aim of *AMR* is to serve engineering scientists worldwide by assessing, reviewing, and reporting on advances in a broad range of mechanical engineering sciences. To this end *AMR* publishes (i) state-of-the-art review articles, bibliographic surveys, reviews with a special focus on emerging technology, tutorials, historical perspectives, periodic summaries of trends and advances; (ii) critical reviews of books, software, and databases; (iii) indexed compilations of carefully selected abstracts from high quality research journals; (iv) book-length monographs and symposium proceedings as special issues or supplements; and (v) editorials, announcements, and letters-to-the-editor.

A secondary aim of *AMR* is to serve technical and reference librarians, information specialists, professional engineers, and college professors through reliable, comprehensive, and timely information about all types of books within its subject scope. The annual cumulative index issue of *AMR* together with its monthly classified listings of abstracts is in effect a comprehensive bibliography of the mechanical engineering sciences, including essentially every article in some 50-60 core journals; this core includes all ASME Transaction journals.

SCOPE

The scope of *AMR* encompasses all the engineering sciences represented in the journals and symposia sponsored by the American Society of Mechanical Engineers and is outlined by *AMR*'s Subject Classification Scheme, which is reprinted on the back cover. It includes basic discipline-oriented areas such as dynamics, continuum mechanics, solid and fluid mechanics, structures, heat transfer, tribology, geomechanics, and biomechanics, as well as cross-disciplinary subjects and emerging critical technological areas such as new numerical and computational techniques, systems control technology, engineering design tools, manufacturing technology, materials and energy technology, and environmental engineering.

The American Society of Mechanical Engineers

INFORMATION FOR AUTHORS OF REVIEW ARTICLES

(1) Prospective authors are strongly urged to communicate with one of the Associate Editors or the Editor-in-Chief, Professor Arthur W Leissa, Department of Engineering Mechanics, Ohio State University, 155 W Woodruff Ave, Columbus, Ohio 43210 (TEL 614-457-4337 or 614-292-2680) before submitting an article, and to furnish a one-page outline of the proposed article and information as to its type, audience, and probable length. A form, *Prospectus for a Review Article*, is available for this purpose. Refer to the editorials in the January 1985 and March 1991 issues of *AMR* and the box at left for further discussion of *AMR*'s editorial criteria.

(2) *Submit four clean copies* of the manuscript to one of the Associate Editors or to the Editor-in-Chief. (Hold all separate original artwork until the article has been accepted.) All articles will be reviewed critically by at least two independent and anonymous referees chosen by the editor involved. This procedure will be followed even if the article is the result of solicitation or encouragement by the editors, or if the author is also an *AMR* editor. The final decision on publication is made by the Editor-in-Chief upon recommendation of an Associate Editor. If appropriate, the article will carry a footnote saying "Transmitted by Associate Editor . . ."

(3) Submission of a manuscript is a representation that it has not been published previously nor is currently being submitted for publication elsewhere. The authors will be asked to sign a statement *transferring copyright to ASME*. It is the author's responsibility to obtain permission to copy material from other sources, if needed.

(4) There are *no page charges* in *AMR* and no numerical length limitations. The length of the article should be appropriate to the subject and the audience. It is certainly one factor that will be evaluated by the editors and their referees, who may recommend changes (30-120 manuscript pages is typical). Each author of a review article will receive *a year's free subscription to AMR*. After publication the author will receive *100 free reprints* (to be shared if there are more than one author). In addition, ASME will distribute reprints singly and in bulk.

(5) Along with the final *manuscript* send the *compuscript on diskette*, if available, (with format identified) incorporating all corrections and additions, and with the tables and figure captions *in place within the text*. If the figures are computer graphics, place them also within the compuscript where they belong. Also, send a head-and-shoulders *photograph and short biographical sketch* (100-200 words) of each author, including grades of ASME membership, if any; include the bio at the end of the compuscript.

(6) *Order of parts:* Title of article, authors' names, authors' institutional affiliations, abstract (200-300 words suitable for abstracting services), table of contents (only if the article is so long that it needs one), list of symbols and abbreviations (if necessary), main text incorporating tables (each starting with a caption) and figure captions (in place where you want them in the text), list of references, biographical sketch, and original figures (if computer graphics, place in text above captions).

(7) *Format (for details, request Author Kit):* (a) Paper size: A4 or 8.5×11 inch (220×280 mm). (b) Word processor settings: One column of width 3.4 in (87 mm) leaving rest of page for referee and editorial comments; Type size 10 point (72 point = 6 pica = 1 inch = 25.4 mm) Times Roman or similar proportionally spaced style; Line spacing 12 points. These as-printed *AMR* specifications will help to insure that equations, tables, and figures are properly designed for the available space. (c) Use metric SI units; with other units in parentheses, if appropriate. (d) Cite references by last name and year; reference list at end alphabetical by author (in 7-point type). (e) Number figures with arabic numerals; design figures for column width (83 mm or 3.1 in), if possible; they should be professionally drawn or computer generated with lettering of consistent size (not smaller than the printed text after reduction); use your wordprocessor to place an empty box of the correct dimensions (or the figure itself, if a computer graphic) in the text above each figure caption. (f) Number tables with roman numerals. (g) Latin letters used as math symbols should be in italics both in text and in displayed equations. Subscripts and superscripts should be 7 point type. Fractional powers are preferred to root signs, exp(..) to $e^{\cdot\cdot}$, and a solidus (/) for fractions, if that will save vertical space.

(8) *Camera-ready copy:* Typeset (or near-typeset) quality pages or galleys generated by the author (after review and acceptance) are preferred, and could result in faster publication. Reproduce the format of published *AMR* review articles (basically, two of the columns defined above per page). Camera-ready pages along with a diskette (for DOS) is requested. Microsoft Word is suggested. Questions on this should be directed to the Production Editor at 201-882-1170, ext 232.

SPECIAL ISSUES: From time to time Guest Editors are invited to produce Special Issues consisting of three or more articles grouped around a common theme. SUPPLEMENTS are booklength monographs or symposium proceedings published as part 2 of a regular issue. Proposals for Special Issues or Supplements are very welcome. Guest Editorials, Letters-to-the-Editor, Announcements: Contact the Editor-in-Chief.

BOOK REVIEWS AND NOTES

REVIEW OF THE JOURNAL LITERATURE

EDITORIAL

This is Part I of a two-part issue of *Applied Mechanics Reviews* for November, 1993. Part II is the Annual Supplement which is sent to libraries and other non-member subscribers throughout the world. It is entitled *Mechanics Pan America 1993.*

This year the Annual Supplement consists of 37 technical papers chosen from nearly 200 that were presented at the third Pan American Congress of Applied Mechanics (PACAM III) which took place in São Paulo, Brazil in early January of this year. They were selected by a committee as being among the best of those presented. Authors were invited to extend their short (4 page minimum) papers into full-length ones.

PACAM is an international congress devoted to the full range of areas in mechanics, open to participants from throughout the world. It takes place in the Western Hemisphere every odd-numbered year, in early January, sponsored by the American Academy of Mechanics. PACAM I was held in Rio de Janeiro, Brazil in 1989, and PACAM II in Viña del Mar, Chile in 1991. Annual Supplements of selected and extended papers from those congresses were also published by *Applied Mechanics Reviews.* PACAM IV will take place in Buenos Aires, Argentina, during January 3-6, 1995.

Arthur W Leissa
Editor-in-Chief

TECHNICAL EDITORS WANTED

Applied Mechanics Reviews is seeking qualified applicants for the position of Technical Editor. It is expected to fill one or more new positions during the next six months.

Technical Editors scan journals in their fields of expertise in mechanics and the mechanical engineering sciences and perform two essential functions:

1. Determine which articles are suitable to have their abstracts included in the *Review of the Journal Literature*, which is the primary section in *AMR* each month.

2. Classify each selected abstract in the *AMR* subject classification scheme (main headings are shown on the back cover of each issue; complete classification scheme is listed annually in the December issue).

The work is part-time, typically requiring 3 to 5 hours per week, with pay on an hourly basis. This is an excellent way for a researcher, who can spare the time, to keep up with most of the technical literature in his or her field. It is also an opportunity to be a member of the team which produces *AMR* each month --- Technical Editors, Associate Editors, and Production Staff.

Technical Editors should have at least 10 years of significant research experience beyond the PhD degree. Interested applicants should send a copy of their complete professional résumé and a statement elaborating upon their particular qualifications to:

Professor Arthur W Leissa
Editor-in-Chief
Department of Engineering Mechanics
Ohio State University
155 W Woodruff Ave
Columbus, Ohio 43210

APPLIED MECHANICS REVIEWS BOARD OF ASSOCIATE EDITORS

BOOK REVIEWS

Items with a reviewer byline (coded R) are by AMR's corps of dedicated outside volunteer reviewers. AMR will attempt to get critical reviews of all relevant textbooks, professional books, reference works, and handbooks. Items without a reviewer byline (coded N) are prepared by AMR in-house staff and are largely based on material such as a book's table of contents and editor's preface or foreword. In the interest of timeliness most conference proceedings and multi-author contributed volumes will receive descriptive notes in this fashion. Books deemed to be somewhat peripheral to AMR's basic scope may simply be listed by title (no code; not included in annual index). Also listed by title when first received are books under review.

I. FOUNDATIONS & BASIC METHODS

11N1. **Theoretical and Applied Mechanics 1992.** Proceedings of the 18th International Congress, Haifa, Israel, Aug 22-28, 1992. - Edited by SR Bodner, J Singer, A Solan, Z Hashin. Elsevier, UK. 1993. 492 pp. ISBN 0-444-88889-6. $185.75.

Contained in this volume are the full texts of the invited general and sectional lectures presented at this conference concerning mechanics and its development. The entire field of mechanics is covered, including analytical, solid and fluid mechanics and their applications. A survey of work in the fields of fluid and solid mechanics is also given. The papers are written by leading experts, which is reflected in the quality and diversity of the lectures and posters presented. They will provide a valuable key to the latest and most important developments in the various subfields of mechanics.

Contents include: Preface; Sponsoring organizations and companies; Congress committees; List of participants; Report on the Congress. Opening and Closing Lectures: Instability and turbulence in shear flows by A Roshko; Micromechanics of fracture by GI Barenblatt. Introductory lectures of minisymposia. Instabilities in solid and structural mechanics: Material instabilities and phase transitions in thermoelasticity by R Abeyaratne; Propagating instabilities in structures by S Kyriakides; Computational approaches to plastic instability in solid mechancis by Y Tomita. Sea surface mechanics and air-sea interaction: The role of wave breaking in air-sea interaction by WK Melville; Extreme waves and breaking wavelets by OM Phillips; Effect of wind and water shear on wave instabilities by PG Saffman. Biomechanics: Nature's structural engineering of bone on a daily basis by SC Cowin; Liquid layer dynamics in pulmonary airways by RD Kamm; Energy-saving mechanisms in animal movement by R McN Alexander. Advanced Formulations in Boundary Element Methods. - Edited by MH Aliabadi and CA Brebbia. Comput Mech, Billerica MA. 1992. 300 pp. ISBN 1-56252-111-X. ASME Book No 08. $144.00. (Under review)

II. DYNAMICS & VIBRATION

11R2. **Turbomachinery Rotordynamics--Phenomena, Modeling & Analysis.** - Dara Childs *(Mech Eng, Texas A&M Univ, College Station TX)*. Wiley, New York. 1993. 476 pp. ISBN 0-471-53840-X. $89.95.

Reviewed by Joseph Motherway (555 Park Shore Dr #213, Naples FL 33940).

This is a professional book which presents analytical techniques and results useful in computer modeling and dynamic design of rotating machines. The author is well known for his extensive research in the dynamic behavior of fluid film bearings, liquid and gas seals, and fluid-structure interaction of rotors.

Curiously, the author divides the book rather unevenly into three parts. The first and third contain only one chapter each; page length is 85 and 26, respectively. The second part consists of six chapters. However, most of its materials, 262 out of 345 pages, is contained in chapters 3-6, covering the author's specialty. This emphasis also makes for uneven coverage of the field described by the title.

Part 1 deals with fundamental rotordynamic phenomena. These are illustrated by examining analytical results for some simple idealized models. This is the sort of material for which the designer must have a qualitative understanding before beginning a development of a simple rotating machine, eg, a single stage horizontal centrifugal pump for commercial application. It would also be useful to an engineer who is beginning to become involved in rotating machine failure analysis.

The second part constitutes the major portion of the book. Chapter 2 is a 45-page review of matrix structural analysis methods, and chapter 7 devotes an additional 36 pages to more advanced aspects of this topic. Together they compromise a rudimentary introduction to the mathematics associated with the most common eigenanalysis methods. However, no detail is given on the numerical and computer methods used to implement these analyses.

The middle four chapters of this part are devoted to developing the dynamic coefficients for stiffness and damping used in the modeling of bearings, seals, and rotors. Clearly, this is the meat of the book, containing 60% of its pages and listing 230 references. Chapter 3 is a very extensive treatment of hydrodynamic bearings and squeeze film dampers. Although full journal bearings are principally treated, there is also some discussion of multilobe, step, and tilting-pad bearings. Squeeze-film dampers are also included. The fourth chapter considers liquid annular seals. Equations and solutions for flow and pressure are presented. Force coefficients are developed, and moment coefficients resulting from rotor tilt are considered. Chapter 5 is devoted to annular gas seals. In these two seal chapters, there are several comparisons of theoretical and experimental results. Also, they both end with an interesting section which poses some practical questions and supplies their answers. Chapter 6 is a somewhat brief (40 pages) treatment of the modeling of forces induced by the interaction of turbines and pump impellers with their structural surroundings. Space limitations have restricted coverage of fluid dynamical computational methods in these four chapters, but the material presented is of considerable use to rotor dynamic analysts.

The eighth chapter is a somewhat brief description of the rotordynamic analysis of a high pressure fuel turbopump used in the Space Shuttle's main engine. It applies some of the material discussed earlier in the book. Although interesting, a more detailed treatment would have improved the utility of the book for engineers who are not expert in the field.

Unfortunately, several very important rotordynamics topics are not addressed. These include balancing, torsional and coupled lateral-torsional vibrations, and active control of bearings and dampers. Given the emphasis on bearings and dampers, active control is a particularly significant omission.

This author contends that this book could serve as a text for a rotordynamics course, or as a supplementary reference for machine design courses, as well as a source for practicing engineers involved in design, analysis and operation of turbomachines. This is much too broad a statement. Coverage of rotordyanmics is not sufficiently broad in scope or (except for chapters 3-6) detailed in presentation to warrant use as a text. The large majority of users of *Turbomachinery Rotordynamics: Phenomena, Modeling and Analysis* will be researchers in the field of dynamic behavior of bearings and seals.

11N3. Multibody Computer Codes in Vehicle System Dynamics. Supplement to Vehicle System Dynamics, vol 22. - Edited by W Kortum *(Deutsche Forschungsanstalt fur Luft and Raumfahrt, Germany)* and RS Sharp *(Cranfield IT, England)*. Swets N America, Berwyn. 1993. 265 pp. ISBN 90-265-1365-8.

Vehicle Dynamics is one of the prime areas for the application of multibody methods. Systems of great commercial interest typically require representation as many interconnected rigid or flexible bodies, making them difficult or prohibitive to analyze by hand. Several computer codes have been written to automate model building and solving, some of them having special affinity to vehicle dynamics problems.

In this volume, such computer codes are reviewed against a background of explanation of the technologies built into them and surrounding them. Much information supplied by the code developers has been organized and presented. Representative problems, two from rail vehicle dynamics and two from road vehicle dynamics, have been specified and they have then been solved by a number of contributors. Precise problem statements are made and "good" solutions to the problems established through agreement of independent solvers. The benchmarking problems are used to further characterize the codes reviewed and they are expected to provide a useful resource for code evaluations in the future.

Contents include: Introductions: Review of multibody computer codes for vehicle system dynamics by W Kortum; Testing and demonstrating the capabilities of multibody software systems in a vehicle dynamics context by RS Sharp. Section 2: Description of Programs: The A'GEM multibody dynamics package by RJ Anderson; Autodyn and Robotran by P Fisette, P Maes, J-C Samin and PY Willems; Autosim by MW Sayers; Bond graph based modeling using macros, an introduction to the progam Bamms by CH Verheul and HB Pacejka; CMSP-Multibody systems analysis and optimization program package by Dao Trong Lien; A brief description of COMPAMM; FASIM-a modular program for simulation of nonlinear vehicle dynamics by M Hiller, K-P Schnelle and A van Zanten; Program LMS by J Auzinsh and P Sliede; MADYMO (MAthematical DYnamical MOdel); Description of the general 3D computer program 3D-MCADA by C Orlandea and NV Orleanda; MECANO: A FE software for flexible multibody analysis by M Geradin, DB Doan and I Klapka; The multibody program MEDYNA by W Schwartz; The software NEWEUL by G Leister, E Kreuzer and W Schiehlen; NUBEMM: a special multibody system as a part of a modern simulation concept in the automotive industry by E Pankiewicz.

Also: Multibody program NUSTAR; OKAM2-General kinematic analysis and ODAM-General dynamic analysis by V Stejskal and M Valasek; An integrated MBS modeling environment for vehicle motion control studies by AS Cherry, AN Costa and RP Jones; Dynamic vehicle simulation "SIDIVE Program" by JG Gimemez, LM Martin and H Sobejano; SIMPACK-An [illegible]sis and design tool for mechanical syst[illegible]ka and A Eichberger; Multibody [illegible]are-VAMPIRE by GA Scott; [illegible]am-ics analysis software b[illegible]way dynamic codes-VOCO [illegible] for computation of multibody systems dynamics by J Cervinka and F Hofmann; ADAMS-Mechanical systems simulation software by RR Ryan; The program system alaska; An introduction to DADS in vehicle system dynamics by RR Kading and J Yen; MESA VERDE-Generation and application of complete simulation models for multibody systems by A Schmidt; NUCARS-New and untried car analytic regime simulation. Section 3: Description of Benchmarks: Benchmark to test wheel/rail contact forces; Railway benchmark model #2: Bogie vehicle; Simulation of the IAVSD railway vehicle benchmark #2 with MEDYNA, SIDIVE and VOCO; Simulation of the IAVSD road vehicle benchmark bombardier Iltis with FASIM, MEDYNA, NEWEUL and SIMPACK; Road vehicle benchmark 2- 5 link suspension; names and addresses of developers and distributors.

III. AUTOMATIC CONTROL

11R4. Measurement Errors: Theory and Practice. - Semyon Rabinovich. AIP. 1993. 270 pp. ISBN 0-88318-866-X. $100.00.

Reviewed by Eugene E Covert (Aeronaut and Astronaut Dept, MIT, Rm 33-215, Cambridge MA 02139-4307).

Encyclopedic in its discussion of the material described by the title, the book is made up of 10 chapters: General information about measurements; Measuring instruments and their properties; Prerequisites for the analysis of the inaccuracy of measurements and for synthesis of their components; Statistical methods for analysis of multiple measurements in the absence of systematic errors; Direct measurements; Indirect measurements; Simultaneous and combined measurements; Combining results of measurements; Calculation of the errors of measuring instruments and problems in the theory of calibration. Chapters 1 and 2 are largely definitional. Chapter 3 deals primarily with the difficulties and false leads that can arise in defining standards and procedures. Chapters 4, 5, 6, and 7 are standard material not usually located in a single source. The material in chapters 8, 9, and 10 are well described by their title.

This book is completely different from Kurt Lion's book, *Instrumentation in Scientific Research, Electrical Input Transducers* and HKP Neubert's book, *Instrument Transducers, An Introduction to their Performance and Design*. The former is a compendium of transducers. The latter is less complete in that regard, but very complete in its discussion of the role of instrument dynamics in treating unsteady data. RW Hamming's book, *Digital Filters* treats problems associated by sampling and is appropriate to the digital age. *A Practical Guide to Data Analysis for Physical Science Students* by Louis Lyons, treats elementary statistics as an adjunct to experimentation. (There are many other books that I could have listed and apologize to those authors in advance, but to keep this review short I had to make choices.) Rabinovich's book, *Physical Measurements and Analysis*, complements all those listed above. He discusses most of the topics in the books cited, but not in great depth.

Except for Lion's and Neubert's discussion of transducers, the book under review synthesizes the most material contained in the books cited above, as well as treating topics not usually discussed. To quote from the back cover of the book, "Building from the fundamentals of the theory of measurement, the author offers a wealth of practical recommendations and procedure." This is true.

I suggest that every technical library should own a copy of *Measurement Errors: Theory and Practice*. Serious experimentalists whose interests are broad will surely want to examine the book with the intent of buying it.

As for the more general audience, they ought to be sure their referencing system will remind them of this book when it is needed. At $100 per copy, it is not for everyone.

IV. MECHANICS OF SOLIDS

11R5. Mechanics of Composite Structures. - Valery V Vasiliev *(Comp Struct, Moscow Aviation Tech Inst, Moscow, Russia)*. Taylor & Francis, Washington DC. 1993. 506 pp. ISBN 1-56032-034-6.

Reviewed by Charles Parr (Eng and Mat Sci Div, Southwest Res Inst, PO Box 28510, San Antonio TX 78284).

This is a book for engineers written in the Timoshenko tradition. The equations are written out in full; tensor notation is not used. Of the 48 references, half are to works published in the USSR (or Russia?). About one quarter are to Vasiliev's work. Most of the rest are English, which makes an interesting contrast with the number of Soviet works one would find referenced in an English language book.

The book is divided into seven chapters; the first two chapters cover constituent properties and the equations of elasticity of composite materials. The second chapter discusses simplification of the elasticity equations for thin-walled structures, hygrothermal effects, and several types of nonlinearity. Included are elastic-plastic behavior, nonlinear elasticity, structural nonlinearity, nonlinearity due to resin crazing, viscoelasticity, geometric nonlinearity, buckling, and dynamic response. This chapter takes 120 of the book's 500 pages.

The remaining chapters are devoted to standard structural forms: Composite beams, columns, and rings; Thin walled beams; Composite panels and plates; Circular cylindrical shells; and Axisymmetric deformation of shells of revolution. In these chapters, the equations are developed to the point that an engineer can easily apply them to a particular structure. Only brief mention is made of FEMs of solution.

This is the first English edition of the first Russian edition. It is edited by Robert Jones of VPI & SU who wrote one of the first books on mechanics of composites, the well known *Mechanics of Composite Materials* almost 20 years ago. The text is lucid, a tribute to Jones and the translator, Lucia Man of the Institute of Crystallography, Academy of Sciences, Moscow.

Mechanics of Composite Structures would be a very readable and useable text with only a first course in elasticity. No problems are given, however. It is also recommended for the practicing engineer who designs composite structures, but has a minimum amount of training in advanced mechanics.

11R6. The Science and Practice of Welding, 10th Edition, Vols 1 and 2. Vol 1: Welding science and technology; Vol 2: The practice of welding. - A C Davies *(Welding Inst, UK)*. Cambridge UP, New York. 1993. 500 pp. ISBN 0-521-43404-1. Paper ISBN 43566-8. $75.00. Paper $27.95.

Reviewed by Carl E Cross (Metallurgy, Colorado Sch of Mines, Hill Hall, Golden CO 80401).

This two volume text on welding science, technology, and practice serves as a general introduction to a very broad and encompassing subject. It is presented at a level that technicians can easily comprehend, requiring little more than a high school background. As such, no topic is treated in great depth, making this text of limited value to engineers or veteran welding technicians.

References are made to British Standards where appropriate and sample questions are presented from examinations of the City and Guilds of London Institute. Craftsmen working to such standards would find this information most useful, which undoubtedly accounts for its popularity. (There have been nine previous editions and ten reprintings since the book was first published in 1941.)

A serious effort is made to incorporate both English and metric (SI) units as well as British and American welding symbols and alloy designations. This duality permits the text to be used across continents and may be particularly useful to those having to work with both systems. On the other hand, this duality may also serve to confuse the beginning student.

The first volume, *Welding Science and Technology*, deals with some of the basic fundamentals of welding metallurgy, electrical power, inspection, testing, and design drawings. It suffers from poor organization of topics and inclusion of superfluous information. For example, details are given of atomic structure and extractive metallurgy processes that some might consider impertinent information for shop welders. Regarding structure (in the chapter on metallurgy), the discussion of alloys is found to oscillate between wrought cast, ferrous and non-ferrous topics in a disorganized, confusing manner. The chapter following the discussion of metallurgical principles is devoted to phase diagrams, inserted as if by accident or afterthought.

The breadth of subjects covered is comprehensive, including a discussion of modern-day issues such as duplex stainless steel and inverter-type power supplies. Also, a brief discussion is given to the crack-opening-displacement test, although the basic fundamentals of fracture mechanics are never addressed. Missing is an explanation of the important relationship between welding input, cooling rate, and microstructure using time-temperature transformation curves. Also missing is a good review of the many types of welding defects, although bits of information are scattered throughout the text. Also missing (in both volumes) is the use of references and a bibliography; suggestions for further reading are not given.

The second volume, *The Practice of Welding* consists of a comprehensive survey of welding methods, tools, equipment, and techniques. A wide spectrum of methods are addressed, but no one method is treated in depth. Concerns unique to certain alloys are identified, as are safety issues. A special chapter on the welding of plastics is included. Missing is information regarding the use of variable polarity welding, a relatively new innovation for welding aluminum.

In summary, Davies' two volume, comprehensive text on welding is designed primarily for the entry level technologist with guild (or union) certification in mind. It is particularly well suited for those who work to British Standards. Almost every pertinent welding subject is covered to a small extent, at a level that is easily comprehended. However, its organizational structure leaves much more to be desired. From the standpoint of nomenclature, other comparable texts may prove to be more suitable for use in North America, (eg, *Modern Welding Technology*, Prentice Hall Pub, 1989).

***Correction:** The second paragraph of review 6R23 on page B88 of AMR Vol 46, no 6, June 1993, appeared incorrectly. Our apologies to Professor Popescu. The corrected paragraph follows:*

This reviewer, who in 1987 was in charge of reviewing the first edition of the above mentioned successful book for *Engineering Geology* (Elsevier) is most pleased to review this new edition.

11N7. Advanced Materials and Coatings for Combustion Turbines. Proceedings from Materials Week '93. - Edited by V Swaminathan. ASM Int, Materials Park OH. 1993. 265 pp. ISBN 0-87170-487-0. $83.00.

This collection of papers provides critical information about developments and applications of advanced gas turbine materials, with emphasis on hot gas path components. These include superalloys used in transition ducts, nozzles, and blades. Application and service experience of newly developed alloys and coatings, as well as conventional alloys and coatings to both land-based gas turbine and aircraft engine components, are covered. Metallurgical and mechanical property degradation of alloys and coatings during service is also included.

Other areas covered include applications of aero-engine technology to land-based gas turbines; materials and coating in electric utility applications; chemistry and microstructural modifications on mechanical properties, corrosion, and oxidation resistance; effects of service exposure on properties and degradation of components; and directionally solidified and single crystal blade technology.

11N8. Computational Methods in Contact Mechanics. - Edited by MH Aliabadi and CA Brebbia. Comput Mech, Billerica MA. 1993. 360 pp. ISBN 1562521136. $160.00.

Modern engineering design leads to the realization of the importance of contact problems in many technological fields. Contact problems are complex and inherently nonlinear due to their moving boundaries and the existence of friction along contact surfaces. Until a few years ago, researchers were engaged only in the fundamental concepts of contact problems. Today, due to the great improvement in computer technolgy and computational methods, it is possible to solve many complex practical contact problems accurately and efficiently.

This book presents a comprehensive review of the current state of theory of contact mechanics with particular emphasis on computational methods. Much attention is devoted to the physical interpretation of the contact properties as well as to the numerical methodologies necessary to solve complex engineering problems. As such, the book covers formulations based on load incremental and mathematical programming approaches using both FE and BEMs. The mathematical modeling techniques described include the constraint method, the flexibility approach, the penalty method and the Lagrange multiplier technique. In chapter one, the applications of BEM to frictional contact problems are presented using a fully load incremental technique together with a constraint approach. Its application to fracture mechanics is also described. Chapter two deals with the BE flexibility formulation for the analysis of frictionless and frictional contact problems. The formulation is described in detail and several examples are presented to demonstrate the accuracy of the method.

In chapter three, the Lagrange multiplier formulation for the FEM is presented. General algorithms are described for the detection of overlapping meshes and the evaluation of contact forces. An example problem of contact stress analysis in an orthopedic knee is presented.

Chapters four and five concentrate on the application of the penalty method in contact problems using the FE and BEMs respectively. Particular attention is paid to the numerical implementation of the method, and several examples are presented to demonstrate the accuracy of the methods.

In chapter six, the application of the BEM to 3D contact problems is described. The authors present a detailed formulation of the problem before proceeding to solve some classical problems.

The remaining three chapters of the book deal with mathematical programming approaches. Chapter seven presents a formulation to deal with both small and large displacement contact problems. In chapter eight, a general solution method for 3D quasistatic frictional contact problems is presented. The formulation is based on the BEM and mathematical programming approaches. Finally, in chapter nine, the application of the FEM to elastic-plastic contact problems is presented employing a parametric quadratic programming approach.

11N9. Contact Mechanics. - Edited by MH Aliabadi and CA Brebbia *(Wessex Inst of Tech, UK)*. Comput Mech, Billerica MA. 1993. 536 pp. ISBN 1562521632. $157.00.

Modern engineering design leads to the realization of the importance of contact problems in many technological fields. Today, due to the great improvement in computer technology and computational methods, it is possible to solve many complex practical contact problems accurately and efficiently.

This book consists of the edited version of the papers presented at the First International Conference on Contact Mechanics, which took place July 13-15, 1993 in Southampton, UK. The conference attracted papers on mechanical models such as rolling, impact and shock, unilateral contact etc; numerical models such as FEM, BEM, mathematical programming etc; mathematical models such as penalty method, Lagrange multiplier, constraint methods, etc; and engineering applications such as fracture mechanics, composite materials, forming process, etc.

Contents: Analysis of 2D and axisymmetric contact and friction problems using BE software; Transitional contact and wrinkling in sheet metal forming; Computer modeling of layered conformal contact; FE modeling with contact and friction for plane strain sheet forming process; A nonlinear mathematical model for finite periodic rail corrugations; Influence of local slip in hertzian contacts on the subsurface elastic material stresses of rolling element components; A revisitation of the infinite element method for water wave diffraction problems; Numerical evaluation of Bessel functions with complex arguments, with application to plates resting on elastic foundations; Fast solver for 3D normal and tangential contact mechanics in the half-space; Numerical methods for 3D dynamical frictional contact problems; FE modeling of pavement joints for dynamic analysis; Unilateral contact and friction in fractal interfaces; Numerical applications; Numerical resolution of the contact vibrations under harmonic loads; Mechanical analysis of a flat, deformable layer underlain by a rigid foundation and indented by a paraboloidal punch; Thermomechanical contact elements for healing in polymers; Numerical modeling of contact for low velocity impact in compact laminates; FE analysis of indentation experiments; Perturbation method used for static and dynamic contacts in nonlinear materials; Contact analysis in clamping roller free wheel clutches; Complete 3D elasticity solutions in the half-space for constant and linearly varying pressure loads; Stress analysis model for contact problems involving rolling and sliding; Differential quadrature solution of uniformly loaded circular plate resting on an elastic half-space; Numerical study on interface between sand and steel; Contact and loading conditions in soil-structure interaction; and Frictional contact analysis using BEM.

11N10. The Effect of Temperature and Other Factors on Plastic. - ASM Int, Materials Park OH. 1993. ISBN #6336F. $285.00. 2-vol set.

This book is the first data-bank compiled with extensive and specific plastics design information which allows you to evaluate plastics properties as they are exposed to environments other than room temperature and standard humidity conditions. More than 600 uniform and easy to read graphs are provided for more than 45 generic types of plastics. Mechanical, electrical and physical properties are graphed as functions of temperature, humidity level, filler content and/or specimen thickness. Electrical properties are also provided vs frequency. Stress vs strain curves are provided at different temperatures, strain rates and humidity levels. Data for multiple grades of material within each generic family is provided, and specific grades and unique test methods are always shown.

11N11. Friction, Lubrication and Wear Technology for Advanced Composite Materials. - Edited by P Rohatgi. ASM Int, Materials Park OH. 1993. 200 pp. ISBN 0-87170-490-0. $88.00.

This volume, consisting of more than 20 contributed papers, covers many facets of the tribology of composite materials. Among the areas covered are wear behavior of aluminum alloy-based ceramic particulate composites, tribological properties of nonferrous and polymer based composites, plus papers on mechanics of friction in self-lubricating composite materials, tribological behavior of undirectional fiber-reinforced graphite-epoxy composites, ceramic composites for bearings, wear behavior of silicon nitride, and tribological characteristics of aluminum-matrix composites.

11N12. Joining and Adhesion of Advanced Inorganic Materials. Proceedings from the 1993 Spring MRS Symposium Proceedings held in San Francisco, California.. - Edited by AH Carim *(Penn St Univ)*, DS Schwartz *(McDonnell Douglas)*, RS Silberglitt *(FM Tech)*. Mat Res Soc, Pittsburgh PA. 1993. 249 pp. Available in microfiche. ISBN 1-55899-212-X. $63.00.

This book covers many aspects of materials joining and adhesion, from fundamental theoretical aspects of adhesion, to joining techniques being applied in the commercial world. Adhesion of thin films and coatings is discussed at the atomic-electronic level, as well as on the practical level of coatings for wear resistance. Joining of a broad range of materials is covered, including ceramics and ceramic matrix composites, metals and metal matrix composites, and semiconductors. Also discussed are a variety of novel joining techniques.

In 29 papers, the book covers the topics of: fundamentals and overviews of adhesion and bonding; interfacial thermodynamics, microstructure, and mechanical properties; microwave, laser, and infrared joining; advanced and novel joining techniques: capacitor discharge welding and SHS, other approaches; and joining and adhesion in electronic materials.

11N13. Machining Technology for Composite Materials. Proceedings from ASM's Materials Week '93. - Edited by TS Srivatsan, DM Bowden, CT Lane. ASM Int, Materials Park OH. 1993. 240 pp. ISBN 0-87170-489-7. $88.00.

A follow-up to the 1992 publication *Machining of Composite Materials*, this book offers the latest advances in the technology developed for machining all types of composite materials, from polymers and ceramics to metal-matrix composites, plus updates on machine tools, waterjet cutting systems, laser cutting, welding and processing, and drilling.

11N14. Materials Properties Handbook: Titanium Alloys. - Edited by R Boyer, EW Collings, G Welsch. ASM Int, Materials Park OH. 1993. 800 pp. ISBN 0-87170-481-1. $245.00.

This book provides a data base for information on titanium and its alloys, and the selection of specific alloys for specific applications. The most comprehensive titanium data package ever assembled provides extensive information on applications, physical properties, corrosion, mechanical properties (including design allowables where available), fatigue, fracture properties, and elevated temperature properties. The appropriate specifications for each alloy are included. This international effort has provided a broad information base that has been compiled and reviewed by leading experts within the titanium industry, from several countries, encompassing numerous technology areas. Inputs have been obtained from the titanium industry, fabricators, users, government and academia. This up-to-date package covers information from almost the inception of the titanium industry, in the 1950s, to mid-1992. The information, organized by alloy, makes this exhaustive collection an easy-to-use data base.

The 60-plus data sheets supply not only extensive graphical and tabular information on properties, but the datasheets also describe or illustrate important factors which would aid in the selection of the proper alloy or heat treatment. The datasheets are further supplemented with background information on the metallurgy and fabrication characteristics of titanium alloys. An especially extensive coverage of properties, processing and metallurgy is provided in the datasheet for the workhorse of the titanium industry, Ti-6A1-4V.

This compendium includes the newest alloys made public, even those still under development. In many cases, key references are included for further information on a given subject.

Comprehensive datasheets provide extensive information on: applications, specifications, corrosion, mechanical design properties, fatigue and fracture properties, fabrication characteristics, and effects of processing on properties.

11N15. Mechanisms and Mechanics of Composite Fracture. - Edited by R Bhagat, R Arsenault, S Fishman. ASM Int, Materials Park OH. 1993. 490 pp. ISBN 0-87170-488-9. $90.00.

From a veritable who's who in metal-and ceramic-matrix composites research, this volume delivers the state of the art on this constantly advancing topic.

Areas covered in this volume include deformation and damage in particulate composites; crack initiation and propagation; micromechanical modeling; interface debond analysis and creep; fracture and fatigue; and microstructural tailoring. The majority of papers deal with metal-matrix and ceramic-matrix composites, with submissions from government, industry and university research facilities. Contributed papers hail from all over the world: Canada, China, India, Japan, the

Netherlands, the Ukraine, as well as the United States.

11N16. Micromechanics of Concrete and Cementitious Composites. Proceedings of the International Conference JMX 13, EPFL, Lausanne, March 9-10, 1993.. - Edited by Christian Huet. Presses Polytech Romandes, Lausanne. 1993. $56.00.

Micromechanics of concrete and cementitious composites has stimulated immense worldwide activity during the past 20 years in close relationship to the distinctive microstructural characteristics of this material. In fact, cement-based materials are deformable and breakable heterogeneous media whose behavior also involves complex, interrelated chemical, thermal, and hygral phenomena. The problems which this posed at the outset have since opened up whole new areas in the development of science and mechanics of materials.

This book is devoted to the proceedings of the international conference held in Lausanne on this subject March 9 and 10, 1993, which gathered some 100 participants from Europe and other continents.

It comprises the full texts and discussions of the lectures given by 15 invited speakers. It provides a valuable overview of the work being carried out in this field around the world, as well as an outline of the Swiss contribution to this activity.

Contents include: Basic methods and current trends; The materials science approach for advanced studies in cement-based materials; Damage process and fracture mechanism of uniaxially loaded concrete; Optimization of high-performance concrete; Experimental and numerical study of effective properties of composite materials; Characterization and quantification of microcracking by electron microscopy; Ultrasound propagation in nonlinear microcracked medium; An integrated approach of concrete micromechanics; 3D simulation of microstructural development of cement paste during hydration; Analysis of fracture mechanisms in particle composites; Multilevel numerical microscopy and tri-dimensional reconstruction of concrete microstructure; Numerical and experimental study of size and boundary conditions effects on the apparent properties of specimens not having the representative volume; Interface fracture and crack propagation in concrete composites; Numerical simulation of thermo-mechanical behavior of concrete through a 3D granular cohesive model; A numerical model for studying the influences of pre-existing microcracks and granular character on the fracture of concrete materials and structures.

V. MECHANICS OF FLUIDS

11R17. The Avoidance of Cavitation Damage. - Wolfgang Tillner, Horst Fritsch, Rudolf Kruft, Wilfried Lehmann, Hartmut Louis, Gunther Masendorf. ASME, New York. 1993. 268 pp. ISBN 0-85298-807-9. $134.00.

Reviewed by Clayton Purdy (30 Meadowbrook Rd, Syosset NY 11791).

This is a reference book for design and installation engineers specializing in centrifugal and axial pumps, positive displacement pumps, hydraulic turbines, and pump turbines. They also describe how cavitation occurs, how to avoid damage from cavitation, and also how to limit damage whenever it occurs. The authors describe how to detect cavitation directly by viewing and inspection, and indirectly by changes in performance. The types of pumps and their installations are treated in detail. The book includes an extensive discussion of requirements for selecting materials for components exposed to cavitation. There is a good subject index, good quality figures, and many relevant references.

The authors' aim, to transmit an extensive knowledge of cavitation to other engineers, has been achieved. The book is recommended for purchase by individual engineering companies specializing in design and installation of centrifugal and axial flow pumps, hydraulic turbines, and pump turbines as well as technical libraries.

This book, translated from German is well written. The following comments are considered minor and should not detract from the overall recommendation. No attempt was made to coordinate quantities, symbols, and dimensions where different chapters were written by different authors. The words "impeller" and "runner" are used interchangeably even though the rotating element of a pump is an impeller and that of a hydraulic turbine is a runner. Double suction pumps are called twin flow. A contradictory statement includes: "pumps should be mounted low down to avoid or minimize cavitation damage," and then, "pumps so mounted can be smaller and higher speed" (which leads to more cavitation). There is an error in Figure 4.7: "low section number" should be "low suction number." The titles of German references were not translated into English.

The Avoidance of Cavitation Damage would have been enhanced if a summary of recommendations and guidelines had been included. Although centrifugal pumps, hydraulic turbines, and pump turbines are similar machines with similar cavitation damage problems, there are no references in this book to cavitation damage avoidance produced by the hydraulic turbine industry. One such book that does address this topic is the two volume set, *Cavitation Pitting Mitigation in Hydraulic Turbines*, by the Electric Power Research Institute, August 1986.

11N18. Groundwater Modeling Utilities. - William C Walton *(Consultant, Mahomet IL)*. Lewis Publishers, Chelsea MI. 1993. ISBN CAT NO L679. $114.00.

This book is a handy reference guide designed to help groundwater industry professionals learn to use a variety of microcomputer software applications for groundwater modeling and numerical modeling in flow and contaminent migration studies.

The book provides the following: handy operation and logic reference supplements to selected groundwater model, pre-processor, post-processor, geostatics, graphics, CAD, and word processing software supporting documentation; selected model operation practice exercises with extensive step by step input-option prompt and response documentation; and six convenient model database manipulation utility programs stored on two 5-1/4" diskettes included with this book. The disks can be used with all IBM and IBM-compatible computers. The utility programs allow you to convert values from one system of units to another; interpolate between control data points on a curve or surface; calculate heads and partial penetration effects in production wells; create, edit, and covert grid, triplet, listed, and unformatted model data files; and view tabular and category displays of model data files.

This book covers some of the most popular and thoroughly tested public domain finite-difference numerical microcomputer model software; commercial model software; public domain geostatistics software; and commerical graphics, CAD, and word processing software. Using actual groundwater modeling-specific examples, learn to work with software such as MODFLOW, MOD PATH, MOC, INTERTRANS, INTERSAT, GEOPACK, GRAPHER, SURFER, CADD 5.0, and WordPerfect 5.1.

VI. HEAT TRANSFER

11R19. Applied Combustion. - Eugene L Keating *(Env Branch, US Navy, Naval Surface Warfare Center, Annapolis MD)*.

Marcel Dekker, New York. 1993. 568 pp. ISBN 0-8247-8127-9. $150.00.

Reviewed by Tanvir Ahmad (Thermosci Dept - 254 REB, General Motors Res Labs, 30500 Mound Rd, Warren MI 48090-9055).

The author's stated intention is for this book to serve as a textbook as well as a technical reference. The objective seems to be to provide a broad engineering treatment of combustion theory and practical applications of the theory.

The book consists of 12 chapters. The first chapter sets the theme of the book by providing a perspective on the relationship between combustion-fuels and engines. Also discussed in this chapter is a general conceptual model of various stages in technology development. This chapter is expected to put the reader in a practical as opposed to a theoretical frame of mind. This theme recurs throughout the book in that after providing a minimal and often insufficient theoretical treatment of a concept, the focus is switched to example problems on practical applications. The compromise in covering theoretical details can be viewed as a necessary tradeoff in a book of this size (501 pages, excluding tables, etc)

Chapters 2 and 3 cover applications of the first and second laws of thermodynamics to reactive systems. A few useful example problems are presented to demonstrate calculations of flame temperature and specific heat, etc. Unfortunately, the energy-entropy charts, Figures 3.4 and 3.5, are reduced versions of the usual fold-in type illustrations and are illegible.

Chapters 4, 5, and 6 deal with solid, liquid, and gaseous fuels and their combustion, respectively. In the solid-fuels chapter, several practical combustion systems, including coal-combustion systems, solid-waste incinerators, and fluidized-bed systems, are described. However, no related theory is presented. In the liquid-fuels chapter, the physical and chemical properties of various fuel families are briefly discussed and simple stoichiometric-combustion calculations are presented. Similarly, in the gaseous-fuels chapter, the emphasis is on fuel properties and their stoichiometric equilibrium combustion. It is unusual for a combustion book to devote almost half of its pages to a largely descriptive discussion of fuel properties without discussing their combustion and aero-thermochemical behavior. For instance, in chapter 4, a treatment of surface-combustion processes, as encountered in coal-burning and fires, would have been highly desirable. Similarly, chapter 5 seems incomplete without even a mention of spray combustion and a wide variety of related practical problems. In this reviewer's opinion, most of the material on fuel properties and preparation is available in fuels handbooks and should have been left out. In its place, a thorough treatment of coal combustion, sprays, and gas-jet combustion would have been more consistent with the scope of the book.

Chapter 7, Fuel Mechanics, provides the student with only a bare minimum background in classical fluid mechanics of combustion. The chapter does contain a brief treatment of the conservation equations for compressible flows. However, important phenomena like turbulent combustion, which are of great significance to almost all practical combustion systems, are not covered at all. It appears that for even an undergraduate-level combustion course, this material would have to be supplemented by consulting another book providing a more detailed treatment of these areas. Chapter 8, on chemical kinetics, provides some background in this facet of combustion. Again, the basic flame theory and the subject of premixed and diffusion combustion are covered in a nonmathematical manner over a few pages.

Chapter 9, on combustion-engine testing, covers the nomenclature related to internal-combustion engines and discusses methods and examples of performance and emissions testing. In the next chapter, on spark-ignition engine combustion, simple thermodynamic calculations for fixed and variable specific heats are presented. The chapter lacks a discussion on flame propagation and the effect of engine-design parameters on flame speed and combustion efficiency. Also lacking is a treatment of mechancisms of NO_x and HC formation, which is an area of intense activity worldwide. Chapter 11 covers similar material on compression-ignition engines and has similar limitations except that diesel emissions are briefly discussed. The material covered in the last chapter, Gas Turbine Engine Combustion, closely resembles that in chapters 10 and 11 in terms of its deficiencies: details of combustion and emissions aspects of the turbine engine are not discussed.

In this reviewer's opinion, the book falls short of its stated objective of serving as a textbook. Its lack of detailed treatment of several important combustion, topics such as spray combustion, flame propagation, turbulent combustion, emissions, and fires, limits its ability to serve as a comprehensive textbook even for an undergraduate combustion course. The book provides a great deal of descriptive material on fuel properties that would better benefit a fuels handbook. On the positive side, the selection of the example problems does cover a broad spectrum of practical combustion systems. Each example problem is followed by useful tutorial comments about the significance of the problem. Additionally, the problems employ both the English and SI units and provide useful linkage between various prevalent dimensioning practices used by the practicing engineer.

Overall, *Applied Combustion* would have to be supplemented by at least another book on classical combustion theory in order to serve as a useful textbook.

11N20. Phase Transformations in Thin Films--Thermodynamics and Kinetics. Volume 311 in the MRS Symposium Proceedings Series. - Edited by M Atzmon *(Univ of Michigan, USA)*, AL Greer *(Cambridge Univ, USA)*, JME Harper *(IBM TJ Watson Res Center, USA)*, MR Libera *(Stevens IT, USA)*. Mat Res Soc, Pittsburgh PA. 1993. 399 pp. Microfiche. ISBN 1-55899-207-3. $72.00.

This book contains 61 papers and covers both basic and applied aspects of phase formation and atomic transport, including experimental, numerical, and theoretical studies. Based on a symposium held at the 1993 MRS Spring meeting in San Francisco, California, the book discusses interfacial reactions; solid-state amorphization, crystallization; stress effects on phase transformations; radiation effects on phase transformations; silicides; and film growth and fundamentals, microstructure.

Convective Heat Transfer, Second Edition. - Louis Burmeister *(Univ of Kansas)*. Wiley, New York. 1993. 576 pp. ISBN 0-471-57709-X. $79.95. (Under review)

Numerical Methods for Problems with Moving Fronts. - Bruce A Finlayson *(chem eng, Univ of Washington WA)*. RP, Seattle. 1993. 605 pp. Mackintosh diskette incl. ISBN 0-9631765-0-1. $60.00. (Under review)

VII. EARTH SCIENCES

11R21. Geotextiles in Filtration and Drainage. - Edited by Stephen Corbet *(G Maunsell and Partners, UK)* and John King *(Geotextiles, Don and Low Ltd, UK)*. Telford, London. 1993. 142 pp. ISBN 0-7277-1924-6. £35 UK and Europe.

Reviewed by Thomas Edgar (Dept of Civil and Architec Eng, Univ of Wyoming, PO Box 3295, Laramie WY 82071).

The use of geotextiles in construction has increased dramatically in the past twenty years. Typical applications of geotextiles include providing tensile strength in sands and gravels, support and separation of different soil types and (the subject of this volume) filtration and drainage of fluids in soil. This book contains the proceedings from the Geofad '92 Conference on Geotextiles in Filtration and Drainage, organized by the United Kingdom chapter of the International Geotextile Society and held in September, 1992. The book has 142 pages divided into eleven chapters.

The direction of fluid flow in filtration is typically perpendicular to the fabric. Drainage usually implies that flow is in the plane of the fabric or, in the case of geocomposites, is parallel to the fabric in open void spaces provided by a deformed core material. This volume deals with both the selection and specification of appropriate fabrics and applicable design methods for a variety of situations. Fabric selection and design procedures in filtration and drainage applications are made more complex because fluid flow can also cause the soil being filtered to enter the fabric structure and clog the pore spaces.

Topics of the papers include geotexties use in road construction and drainage, filtration of hazardous wastes and landfills, shoreline and dike protection, consolidation of soil augmented by wick drains, and testing procedures to determine long terms stability of the fabric. The papers are practice oriented, having results of field testing in almost every paper. Where appropriate, current research and design procedures in England, Europe, and the United states are discussed and compared. Several of the papers have printed discussions that provide a balanced view between the researchers, industry, and practice. The last four chapters are concerned with future uses of and required research in geotextiles from the viewpoint of consultants, manufacturers, clients and cooperative efforts in the European Economic community.

Unlike many conference proceedings, these papers are tightly integrated to present a clear picture of the state of knowledge in this area of geotextile use. People with little previous knowledge of geotextiles can easily read this book. I believe *Geotextiles in Filtration and Drainage* would be a valuable addition to the library of an engineer who works with specific geotextiles.

Developments in Dynamic Soil-Structure Interaction. Proceedings of the NATO Advanced Study Inst, Kemer, Antalya, Turkey, July 8-16, 1992. - Edited by Polat Gulkan *(Civ Eng and Earthquake Eng Res Center, Middle East Tech Univ, Ankara, Turkey)* and Ray W Clough *(Civil Eng, UCB, Ankara, Turkey)*. IX. BIOENGINEERING

11R22. Biomechanics. A Practical Approach. - Edited by Julian F V Vincent *(Center for Biomimetics, The University, Reading)*. Oxford UP, New York. 1992. 247 pp. Paperback. ISBN 0-19-963222-7. Cloth ISBN 0-19-963222-5. $50.00. Cloth $70.00.

Reviewed by V A Pollak (Dept of Elec Eng, Division of Biomed Eng, Univ of Saskatchewan, Saskatoon, SK S7N OWO, Canada).

Examination of a living organism or of its parts has two principal aspects: one is concerned with the material substrates of which the organism is composed, and one is the functionality of its systems. Of course the border between the two is fluent. Functionality dictates more often than not the necessary properties of the material which implements it and, reversely, these properties impose limits upon functional performance. That dichotomy applies equally to technological systems and to products of nature.

In technology the interdependence between material, form, and function has been recognized and has been the subject of extensive studies. In the life sciences emphasis has, for a long time, been on function. The properties of the material an organism uses to implement these functions have only recently become the focus of attention. In many respects these "biomaterials" differ dramatically from those used in technology. The techniques used for the examination of their properties are also, in many respects, significantly different from those used in standard engineering practice. Discussion of practical approaches to these tasks is the principal subject of this book. The study of biomaterials is a typical example of modern interdisciplinary work. To be successful in that field one has to have adequate expertise not only in the physical and engineering facets of the problem, but also in those which belong to the realm of biology and of the life sciences in general. There are not too many people around who have adequate knowledge in both of these two heterogeneous disciplines.

Presently, most of the work in this area is carried out by life science specialists with only limited expertise in the complementary discipline. It is mainly to members of this circle that the book addresses itself. As the title implies, little theory is offered. Emphasis is placed on practical and down-to-earth rules and advices to follow when examining and measuring the mechanical parameters of biomaterials, and how to avoid the most common mistakes. The effort to reduce theory to a minimum may have in some places been taken too far, which makes the underlying rationale to some recommendations for the non-specialist difficult to comprehend.

The discussion centers in general on established techniques for the measurement of the principal mechanical parameters of biomaterials and on the pitfalls likely to be encountered. The range of topics covered is very wide. The humorously styled introduction summarizes the intent of the book. This is accompanied by a list of mistakes, where lack of understanding of the complementary discipline has made laboriously obtained results practically worthless. The first chapter of the main text presents a lucid discussion of the mechanical properties of some biological liquids. It is followed by a sequence of six well-written chapters on different kinds of solid biomaterials of animal origin and their mechanical characteristics. The presentation is rounded off by an analogous, but less detailed, chapter on plant material. The book is terminated by an informative discussion on bio-adhesives, preceded by a treatise on fractures and on the mechanisms involved in the fracture failing of biomaterials.

Overall, the text is well organized and is accompanied by a multitude of largely schematic but nonetheless clear and informative illustrations. Attached to most chapters is a list of some pertinent publications and of reference material for further reading. A useful appendix contains the names and addresses of specialized material and equipment suppliers, which may prove helpful in some of the unconventional approaches.

The book should be of value to graduate students involved in the material aspects of biomechanics, and to practitioners in that vast field, especially to those with a life science background. But it might also be a helpful guide for those with an engineering or physics background when dealing with the hands-on design of specific tests and experiments on biological specimens. The index is well worked out and sufficiently detailed so that any specific topic treated in the book can be easily located.

In summary, the book is a useful addition to the existing rich literature on biomechanics and biomaterials. Its main value is in its practical orientation, which is quite underrepresented in present publications.

A future edition might profit from the inclusion of some reference to modern hybrid measurement methods, eg, of the mechano-optical or mechano-electrical type. Their discussion, if only brief, might be helpful for special applications of the science of biomaterials in human and veterinary medicine, and biology. They may also be of value for tests on materials of biological origin intended for technological applications.

11N23. Biomechanics. Clinical Aspects of Biomedicine Vol 2. - Edited by J Valenta *(Tech Univ of Prague, Czech)*. Elsevier, UK. 1993. 616 pp. ISBN 0-444-98764-9. $282.75.

Biomechanics is one of the branches of science contributing significantly not only to increasing our knowledge of the development of living systems but also to our understanding of the relevant laws of mechanics and their mechanical functions. Important anatomical and biomechanical data as related to the individual functions of the organism and their biomechanical significance are focussed on in this publication. The locomotor and circulatory apparatus and the identification of the mechanical properties of living tissue and materials used in osteosynthesis and alloarthroplasty are among the fields covered. The phenomena observed in the cardiovascular system are described using the basic equation of motion of viscous fluids. Suitable hydraulic models are proposed for investigation and testing of vascular grafts, artificial cardiac valves and artificial heart. Important research data are presented about biomechanical structures of the locomotoric apparatus, and joint rheology. A section is included presenting the fundamentals of biomechanical analysis in criminology and in bioballistics.

Contents include: Some phenomenological models of the mechanical response of biomaterials: Introduction by J Valenta; Identification of mechanical properties of living tissues; Application of the theory of catastrophes to the evolution of biosystems by J Valenta; On some aspects of the structure of bone tissue and its re-modelling; Biomechanical heterogeneity by V Kafka; Piezoelectric response of bone tissue to mechanical loading by J Valenta; Cyclic deformation and its constitutive model by M Satra; Basic mechanical properties of tissues of the locomotion system by P Komarek; Mechanical properties of tissues of the cardio-vascular system; Mechanical properties of some other tissues of the human body.

Materials used in osteosynthesis and alloartboplasty: Introduction; A list of metallic materials used in the manufacture of implants; Nonmetallic materials, and Plastics by K Lobl and S Beznoska.

Rheology of biological fluids and biomechanics of the cardio-vascular system: Introduction; Rheological properties of human blood; Rheometry of visco-elastic fluids; Mathematical modeling of flow curves; The effect of the physical and biological properties of blood on its viscosity; The limits of validity of continuum models of blood; Rheological properties of synovial fluids; Some aspects of the current state of knowledge and new trends in research into the hydrodynamics of the cardio-vascular system by F Klimes; The basic equations of motion and viscous fluids; Physical-mathematical models of the pulsating flow of blood in blood vessels; Fundamental theoretical analysis of oscillating and pulsatile flows of fluids in tubes; Harmonic analysis of some hydrodynamical variables of blood circulation in the vascular system; Hydrodynamic aspects of the formation of arteriosclerosis; Experimental research and testing of artificial heart valves and complete heart replacements; Hydrodynamics of the artificial heart; Some basic problems of microcirculation.

The locomotive apparatus of man by V Karas and S Otahal: Composition of the locomotive apparatus; Elements and bonds of the locomotive apparatus; System of skeletal muscles; Skeleton: the basic of the segmentary structure of the body; General problems of occupational and sports biomechanics.

Criminalistic biomechanics by V Porada: Introduction; Biomechanical analysis of tracks of human locomotion; Distribution of forces in human locomotion and their measurement; Some theoretical aspects of the identification of a criminal by his tracks in a dispersive environment; Method of measuring the geometric features with biomechanical content for the analysis of tracks of bare feet; Biobalistics; Subject index.

11N24. Biomolecular Materials. - Edited by C Viney *(Univ of Washington)*, ST Case *(Univ of Mississippi Medical Center)*, JH Waite *(Univ of Delaware)*. Mat Res Soc, Pittsburgh PA. 1993. 287 pp. Microfiche available. ISBN 1-55899-187-5. $69.00.

Biomolecular materials are partial, complete, or modified replicas of biological materials whose synthesis and utilization may be unrelated to their original biological source. This new book explores the goal of attaining biomolecular materials that have industrial, medical, or agricultural applications--whether the objective is to replicate the properties of a biological material, or to produce derivatives with novel properties.

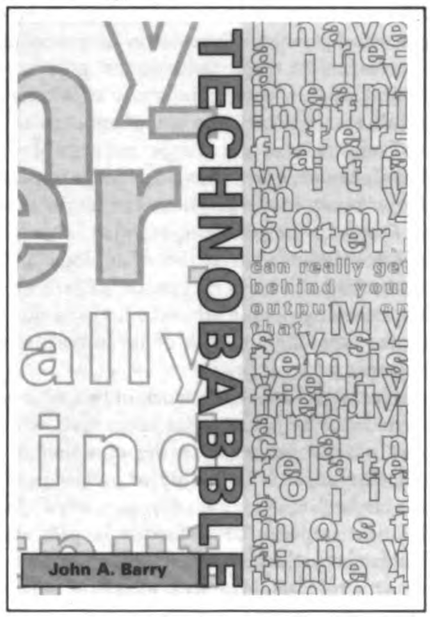
Documenting proceedings from a symposium held at the 1992 MRS Fall meeting in Boston, this volume covers lessons from nature, cellular synthesis, non-cellular synthesis, structural and mechanical properties, and applications.

X. GENERAL & MISCELLANEOUS

11R25. Technobabble. - John A Barry. MIT Press, Cambridge MA. 1993. 268 pp. ISBN 0-262-52182-2. $12.50.

Reviewed by Everett E McEwen (Civ and Env Eng, Univ of Rhode Island, Bliss Hall, Kingston RI 02281).

Technobabble is an extremely well-written, easily read book. The author is a computer expert and linguist, and he probably has linguists in mind as his intended audience. The intent of the book is to present the history of computer and computer science development in terms of the words and phrases coined to describe this new technology. The author describes how the language of the computer user has found its way into more general language usage where, in many instances, it has no relation to technology.



The author is obviously well versed in computerese and knowledgable in computer history. This is reflected in his ability to trace the development of hundreds of computer related words and expressions.

It appears that the chapters are almost independent of each other. It is possible to read the introduction to a chapter, and then to skip over that chapter without significant loss of continuity.

The subject index is very complete. The bibliography is not extensive, but the footnotes are very detailed, providing both informative and interesting reading. The glossary is excellent but somewhat limited in that it includes only terms generally not described elsewhere in the text. The format, appearance, and particularly the front section add to the readability of the text. The nature of the book precludes the use of figures.

Barry's book can perhaps best be classified as both general interest and reference. Although it is somewhat difficult to anticipate its potential audience, it could be of interest to: 1) computer scientists and engineers who are knowledgeable in computerese and who are interested in the linguistic development of the terminology; and 2) Linguists who perhaps have little knowledge or interest in computers but for whom the tracing of the history of hundreds of computer terms is of professional interest.

For anyone who has been a long time user of computers and who has never found the time to give much thought to the language that he has come to use on a daily basis, *Technobabble* is most enjoyable reading.

11N26. Complex Variables: An Introduction. Pure and Applied Mathematics: A Series of Monographs and Textbooks/176. - Watson Fulks *(Univ of Colorado, Boulder)*. Marcel Dekker, New York. 1993. 416 pp. ISBN 0-8247-9079-0. $49.75.

Contents include: Complex numbers and complex functions; Analyticity; Cauchy's theorem; Mappings; Residues; Potential theory; Bibliography; and Solutions and hints for selected problems.

11N27. Concise Encyclopedia of Building & Construction Materials. - Edited by Fred Moavenzadeh *(MIT)*. Pergamon, Tarrytown, NY. 1990. 698 pp. ISBN 0-08-034728-2. $200.00.

This book presents, in a single volume, the work of numerous specialists in the field. There are articles covering general building materials, their mechanical properties and economic and historical aspects, as well as those dealing specifically with the use of materials such as clays, ceramics, cement, sand, gravels, glass, metals, wood, polymers, plastics and composites. Intended primarily for all those interested in having a useful reference source in building and construction materials at hand, this work would also be a course reference for students in architecture, civil and structural engineering and related disciplines.

A selection of articles: Acoustic properties of wood; Architectural design and materials; Binders; clay minerals; Building materials: an introduction; Carbon-fiber-reinforced plastics; Ceramics as construction materials; Composites: an overview; Construction materials: industrial minerals; Corrosion of iron and steel; Design with polymers; Design with wood; Economics of materials, energy and growth; Electrogalvanized steel; Epoxy resins; Failure analysis; Fatigue: engineering aspects; Fracture and fatigue of glass; Glazing; Glued joints in wood; Glued laminated timber; International trade in materials; Iron production; Materials availability; Offshore structure materials; Paints, varnishes and lacquers; Particulate composites; Portland cements, blended cements and mortars; Recycling of demolition wastes; Roofing materials; Sand and gravel; Structural clay products; Structure of materials; Welding: an overview; Welding of bridges; Wood as a building material; Index.

11N28. Concise Encyclopedia of Composite Materials. - Edited by Anthony Kelly FRS *(Univ of Surrey, UK)*. Pergamon, Tarrytown, NY. 1989. 317 pp. ISBN 0-08-034718-5. $160.00.

The 55 articles in this encyclopedia provide a full and up-to-date account of all aspects of composite materials, including fiber composites, particulate composites, and naturally-occurring composite materials and their properties. Current coverage is also given to metal matrix composites and thermoplastic resins reinforced with fibers. This book will be of interest to materials scientists, mechanical and materials engineers and all other interested and informed parties seeking the most comprehensive and up-to-date account of composite materials available in a single volume.

A selection of articles: An introduction to composites; Aircraft and aerospace applications of composites; Artificial bone; Asbestos fibers; Automobile tires; Boron fibers; Carbon fibers; Carbon-carbon composites; Creep of composites;

Dental composites; Fiber-reinforced cements; Fiber-reinforced ceramics; Fibrous composites: Thermomechanical properties; Glass-reinforced plastics: thermoplastic resins; Laminates: elastic properties; Metal-matrix composites; Natural composites; Natural-fiber-based composites; Oxide inorganic fibers; Paper and paperboard; Plywood; Polymer-polymer composites; Silicon carbide fibers; Strength of composites; Toughness of fibrous composites; Whiskers; Wood-polymer composites; Woven fabric composites: properties; Index.

11N29. Concise Encyclopedia of Magnetic & Superconducting Materials. - Edited by J Evetts *(Univ of Cambridge, UK)*. Pergamon, Tarrytown, NY. 1992. 726 pp. ISBN 0-08-034722-3. $250.00.

This encyclopedia draws together, for the first time in a single volume, the remarkable advances seen in recent years in the discovery of new materials and improvements of existing materials, in the elucidation of a new and deeper understanding of their phenomenology, and in the expansion and diversification of their application in technology. Magnetic and superconducting materials have much in common: they both have experienced, over the past decade, a revolution that has revitalized and galvanized their respective fields. In each case, the impetus has come from the discovery of new materials; this, in turn, has stimulated a reevaluation of a wide range of basic mechanisms and phenomena. Details of all important materials systems and their properties are included, and key areas such as thin films are covered. The volume contains 110 articles, alphabetically organized and written by more than 120 acknowledged experts within the field of magnetic and superconducting materials.

Selected articles: AC applications of superconducting materials; AC losses in superconducting materials; Amorphous superconductors; Anisotropy in magnetic materials; Anisotropy in superconducting materials; Biomagnetic measurements; Chevrel phases; Coercivity and domain wall pinning; Coherence length, proximity effect and fluctuations; Design with magnetic materials; Design with magnetic materials: computer simulation; Domains and domain walls; Ferrites, hard; Fluids, magnetic; Flux creep phenomena; Flux pinning and the summation of pinning forces; Granular superconductors; High-frequency impedance of superconducting materials; High-frequency properties of magnetic materials.

Also: Josephson effects in weak links; Magnetic energy storage; Magnetic properties of superconductors; Magnetic separation; Magnetic storage media; Magnetic units and material specification; Magnetization imaging; Magnetocaloric effect; Magnetoelastic phenomena; Magnetooptic materials; Magnetooptic storage media; Millimeter-wave detection; Multifilamentary superconducting composites; Nanocrystalline soft magnetic materials; Niobium-titanium alloys; Nonequilibrium superconductivity; Nuclear magnetic resonance imaging; Optical properties of superconductors; Organic and molecular ferromagnets; Oxide glasses as magnetic materials; Oxide superconductors: ceramic processing; Oxide superconductors: physical properties; Oxide superconductors: thin-film deposition; Power loss in magnetic materials; Radiation effects on magnetic materials; Radiation effects on superconducting materials; Superconducting magnets; Superconducting materials: BCS and phenomenological theories; Thin films and multilayers, magnetic.

11N30. Concise Encyclopedia of Medical & Dental Materials. - Edited by David Williams *(Univ of Liverpool, UK)*. Pergamon, Tarrytown, NY. 1990. 432 pp. ISBN 0-08-036194-3. $180.00.

Containing more than 60 articles, this book presents the work of nearly 70 world experts on the current techniques and applications of materials which have been specially developed to staisfy the increasing needs of medical and dental science. Alphabetically arranged, articles cover the basic materials used including prostheses, implants, sutures and wound dressings. The biocompatibility, wear, corrosion, and surface properties of the materials are also covered, as well as the mechancis of their implantation, adhesion and repair. Widely illustrated and complemented by a comprehensive three-level subject index, this is an up-to-date survey of dental and medical materials available in a single volume.

Selected articles: Acoustic measurements of bone and bone-implant systems; Acrylic dental polymers; Acrylics for implantation; Adhesives in medicine; Aluminum oxide; Arteries, synthetic; Biocompatibility of dental materials; Biocompatibility: an overview; Biodegradation of medical polymers; Biomaterial-blood interactions; Carbons; Chemical adhesion in dental restoratives; Cobalt-based alloys; Collagen; Corrosion of dental materials; Dental amalgams; Dental implants; Dental materials: clinical evaluation; Dental plaster and stone; Dental porcelain; Denture base resins; Drugs: attachment to polymers; Endodontic materials; Elastomers for dental use; Fracture toughness; Glasses: agricultural and veterninary applications; Glasses: medical applications; Gold alloys for dental use; Heart-valve replacement materials, Hemodialysis membranes; Heparinized materials; Hydrogels; Invasive sensors; Iron-based alloys; Maxillofacial prostheses; Metals for medical electrodes; Ormosils: organically modified silicates; Polyesters and polyamides; Polymers for controlled drug delivery; Polysiloxanes; Polyurethanes; Porcelain-metal bonding in dentistry; Porous biomaterials; Silver in medical applications; Soluble polymers in drug delivery systems; Sterilization using ethylene oxide; Surface structure and properties; Suture materials; Tantalum and niobium; Titanium and titanium alloys; Wrought dental wires; Zirconia-toughened ceramics.

11N31. Differential Equations. Proceedings of the 1987 EQUADIFF Conference. - Edited by CM Dafermos *(Brown Univ, Providence RI)*, G Ladas *(Univ of Rhode Island, Kingston)*, G Papanicolaou *(NYU)*. Marcel Dekker, New York. 1993. 808 pp. ISBN 0-8247-8077-9. $160.00.

Partial contents include: The Jabotinsky equations by J Aczel and D Gronau; Global decoupling of coupled symmetric oscillators by JC Alexander and B Fiedler; Void formation in solidification by V Alexiades; Forced oscillations for Hamiltonian systems by O Arino and A Cherif; Eigenvalues, bifurcation, and center manifolds in the presence of noise by L Arnold and P Boxler; An unusual wave equation arising in water-wave theory by GA Athanassoulis; Controllability and approximate controllability for linear integral Volterra-Stieltjes equations by L Barbanti; Determinants for formally hyperbolic differential equations by P Berglez; Two new applications of Gurtin's coordinate transformation by M Bertsch and D Hilhorst; The thermal stability of a chemically reacting gas in a porous sphere by AR Bestman; Higher regularity of solutions of semilinear evolution equations and applications by MA Boudourides and AC Nikoudes; Maximal attractor of the scalar reaction diffusion equation by P Brunovsky.

Also: Stability of bifurcating solutions of reaction-diffusion equations in cylindrical domains by A Calsina; Numerical evaluation of the solutions to the equations of elastostatics for a stratified sphere by L Carlomusto and A Pianese; Existence of positive exponentially decreasing solutions for nonlinear differential equations in IR with an unbounded coefficient by A Chaljub-Simon; Shadowing lemma for maps in infinite dimensions by Shui-Nee Chow, Xiao-Biao Lin; and KJ Palmer; Asymptotic method for invariant solutions of IR_m maps by RL Clerc and C Hartmann; Orthogonal polynomials in symmetrical domains of R_m by J Cnops; Hyperbolic conservation laws with memory by CM Dafermos; Fully nonlinear equations in banach spaces by G Da Prato; The number of solutions of some semilinear boundary value problems by M d'Aujourd'Hui; Some nonlinear Sturmian theory for (Iu'IP-2) + c(t)IuIP-2u = 0 by M Del Pino and R Manasevich; Short survey of non standard analysis contribution to the theory of ordinary differential equations by F Diener and M Diener; New approach to inverse problems in linear kinetic theory by K Dressler; Bounded entire solutions of higher order semilinear equations by AL Edelson and R Vakilan.

Minors of the Wronskian of the differential equation $L_n y + p(x)y = 0$ and their applications by U Elias; Explicit solutions of the Fokker-Planck equation by MJ Englefield; Full and half-range eigenfunction expansions for an elliptic boundary value problem involving an indefinite weight by M Faierman and GF Roach; The general similarity solution of Laplace's equation with applications to boundary-value problems by Chao-Kang Feng; Uniform asymptotic stability in functional differential equations by T Furumochi; Removability of blowup points for semilinear heat equations by Y Giga and RV Kohn; and Behavior of the nonoscillatory solutions of first order neutral delay differential equations by JR Graef, MK Grammatikopoulos and PW Spikes.

11N32. Differential Equations in Banach Spaces. Lecture Notes in Pure and Applied Mathematics Series/148. - Edited by Giovanni Dore, Angelo Favini, Enrico Obrecht, Alberto Venni *(Univ of Bologna, Italy)*. Marcel Dekker, New York. 1993. 288 pp. ISBN 0-8247-9067-7. $115.00.

Contents include: Abstract linear non-autonomous parabolic equations: A survey, by P Acquistapace; On some classes of singular variational inequalities by ML Bernardi and F Luterotti; Non-uniqueness in L∞: An example by JE Bouillet; Some results on abstract evolution equations of hyperbolic type by P Cannarsa and G Da Prato; Interpolation and extrapolation spaces and parabolic equations by G Di Blasio; On the diagonalization of certain operator matrices related to volterra equations by KJ Engel; Second order abstract equations with nonlinear boundary conditions-applications to von Karman system with boundary damping by A Favini and I Lasiecka; Linear parabolic differential equations of higher order in time by A Favini and H Tanabe; Analytic and gevry class semigroups generated by -A +iB, and applications by A Favini and R Triggiani; The Kompaneets equation by JA Goldstein; and Multiplicative perturbation of resolvent positive operators by A Holderrieth.

Also: Uniform decay rates for semilinear wave equations with nonlinear and nonmonotone boundary feedback-without geometric conditions by I Lasiecka and D Tataru; Sharp trace estimates of solutions to Kirchhoff and Euler-Bernoulli equations by I Lasiecka and R Triggiani; Boundary values of holomorphic semigroups, H∞ functional calculi and the inhomogeneous abstract Cauchy problem by R deLaubenfels; Stability of linear evolutionary systems with applications to viscoelasticity by J Pruss; Generation of analytic semigroups by variational operators with L∞ coefficients by V Vespri; Asynchronous exponential growth in differential equations with homogeneous nonlinearities by GF Webb; The inversion of the vector-valued Laplace transform in Lp(X)-spaces by L Weis; Some quasilinear parabolic problems in applied mathematics by A Yagi.

11N33. Encyclopedia of Materials Science and Engineering, 11 vol set. - Edited by MB Bever *(MIT)*. Pergamon, Tarrytown, NY. 1986. 6200 pp. ISBN 0-08-042298-5. $3900.00.

A major eight-volume reference work providing the first complete coverage of the materials science and engineering field. Over 1550 authoratative articles, averaging 3000 words in length and complete with detailed bibliographies, make the encyclopedia indispensible for researchers, instructors and students in materials science and engineering who wish to gain access to specialist knowledge and modern interpretations across the entire field. The encyclopedia is extensively cross-referenced, carefully indexed and illustrated, and, in addition to its uniquely comprehensive scientific and technological coverage, contains many articles on the policy and social aspects of materials.

Selected articles include: Production, processing and properties of all the basic classes of materials such as metals, ceramics, and polymers; materials for specific applications including electronic, nuclear, biomedical and building materials; materials-related phenomena and methods such as investigative and analytical techniques, nondestructive evaluation, materials degradation, failure analysis, and surfaces and interfaces. Overview articles provide guidance in more than 40 specific areas of materials science and engineering. General subjects include materials science, materials engineering, materials resources, materials policy and economics.

11N34. Encyclopedia of Materials Science and Engineering, Supplementary volume 2. - Edited by Robert W Cahn *(Univ of Cambridge, UK)*. Pergamon, Tarrytown, NY. 1990. 831 pp. ISBN 0-08-036196-X. $380.00.

The continuing rapid development of materials science and engineering is graphically reflected in the 130 articles in this second supplementary volume to the highly acclaimed *Encyclopedia of Materials Science and Engineering*. More than 160 authorities worldwide provide new articles in the expanding areas of composite materials, advanced and traditional ceramics, electronic and superconducting materials, elastomers and polymer applications, wood and paper, industrial minerals, materials characterization, surfaces and interfaces, fundamental physical metallurgy and metals processing, production and fabrication. All articles are extensively cross-referenced, subject-indexed and provided with select bibliographies for further reading.

Selected articles include: Adhesive for wood: an update; Aluminum-based glassy alloys; Aluminum nitride; Armor, ceramic; Armor, composite; Automotive composite components: fabrication; Biomaterials: surface structure and properties; Ceramic powders: chemical preparation; Ceramics: construction applications; Coal: world resources; Colloidal crystals; Composite materials: aerospace applications; Composite materials: fatigue; Composite materials: structure-performance maps; Dental elastomers: an overview; Diamondlike and diamond thin films; Diffusion in silicon; Fiber-reinforced ceramics; Fumigation of wood; Gas sensors, solid state; Health hazards in wood processing; High-level radioactive waste disposal: safety; High-resolution electron microscopy; Lignin-based polymers; Lime; Microengineering of materials: laser fusion targets; Natural fiber based composites; Nitrogen in steels; Polyethylene processing to produce ultimate properties; Portland cement raw materials; Quasicrystals; Scanning tunnelling microscopy and spectroscopy; Silicon: preparation for semiconductors; Superconductors, ceramic; Superconductors, magnetic structure; Thin films: x-ray characterization; Titanium aluminides; Welding of thermoplastics; Wood: surface chemistry.

11N35. Encyclopedia of Materials Science and Engineering, Supplementary Vol 3. - Edited by Robert W Cahn FRS *(Univ of Cambridge, UK)*. Pergamon, Tarrytown, NY. 1993. 704 pp. ISBN 0-08-040590-8. $500.00.

The third and last supplementary volume to the *Encyclopedia of Materials Science and Engineering* continues the process of updating the 8-volume set by including further important developments made in the field since its publication in 1986.

Particular attention is paid to extractive metallurgy, polymer science and the characterization of materials; coverage is included in the areas of superconductivity and electronic materials where major advances have been made in recent years.

As with all the volumes of this exhaustive major work, Supplementary volume 3 provides detailed cross-references and bibliographies for all the articles, plus a cumulative analytical contents list and subject index for all the supplementary volumes, allowing efficient use in conjunction with the other volumes of the encyclopedia.

Selected articles include: A15 compound superconductors; Anodization spectroscopy; Arsenic production; Biocompatibility of biomedical materials; Biosynthetic and biomimetic materials; Bonding of elastomers and metals: processes; Brazing, reactive; Ceramics: cathodoluminescence analysis; Ceramics: mechanical performance and lifetime prediction; Crystal surfaces:melting and roughening; Diamond films: tribological properties; Diamond properties as a function of composition; Economics of the semiconductor industry; Elastomer processing hazards; Embedded atom method and related techniques; Fibers, superabsorbent; Grain boundary motion, diffusion-induced; Injection metallurgy; Lamp envelopes; Laser coating of surfaces; Magnetic alloys: rare earth intermetallics; Metal ores: bacterial leaching; Microtextural analysis; Microwave processing; Nonlinear optical effect: new crystals; Optical microscopy, confocal; Organic superconductors: anisotropic molecular metals; Organic superconductors: doped C_60 (Fullerene); Oxide superconductors: solid-state chemistry; Pitting corrosion; Polymer blends: phase separation; Polymer electrolytes; Prices of metals: history and current problems; Quantum wells; Radiation-induced segregation and diffusion; Recording head technology; Self-propagating high-temperature synthesis; Semiconductors: grain boundaries; Semiconductors: liquid phase epitaxy; Silicon nitride fibers; Silver: medical applications; SQUIDs: design, fabrication and application; Superconductors: magnetic properties; System design of materials; Thermal wave imaging; Thin films and multilayers, magnetic; Titanium alloys: surface treatment; Turbine materials for motor vehicles; Vulcanization, continuous; Welding in space; X-ray diffraction, time-resolved; X-ray emission, particle-induced.

REVIEW OF THE JOURNAL LITERATURE

for core list of journals scanned see Index Issue, published as Part 2 of the Dec issue of last year

I. FOUNDATIONS & BASIC METHODS

100. Continuum mechanics

11A1. **Geometric structure of the stress and strain tensors, dual variables and objective rates in continuum mechanics.** - C Sansour *(Inst Mechanik (Bauwesen), Univ Stuttgart, Stuttgart, Germany)*. Arch Mech 44(5-6) 527-556 (1992).

The geometric structure of the stress and strain tensors arising in continuum mechanics is investigated. All tensors are classified into two families, each consists of two subgroups regarded as physically equivalent since they are isometric. Special attention is focused on the Cauchy stress tensor and it is proved that, corresponding to it, no dual strain measure exists. Some new stress tensors are formulated and the physical meaning of the stress tensor dual to the Almansi strain tensor is made apparent by employing a new decomposition of the Cauchy stress tensor with respect to a Lagrangian basis. It is shown that push-forward and pull-back under the deformation gradient applied to the work conjugate stress and strain tensors do not result in further dual tensors.

11A2. **Axiomatic basis of space-time theory Part II. Construction of a C^0-manifold.** - J Schroter and U Schelb *(Dept of Phys, Univ of Paderborn, D-4790 Paderborn, Germany)*. Reports Math Phys 31(1) 5-27 (Feb 1992).

In this paper the investigations are continued. A physical theory ϕ_4 was formulated in the sense of Ludwig. In this paper ϕ_4 is extended by adding four axioms thus arriving at a theory ϕ_{T4}. These axioms are nonstructural ones so that the basic domain and the correspondence rules of ϕ_4 are the same. Within ϕ_{T4} a C^0-space-time-manifold is constructed which is also a full casual space.

11A3. **Relativistic Kepler problem in the Lobachevsky space.** - NA Chernikov *(Joint Inst for Nucl Res, Lab of Theor Phys, 141980 Dubna, Russia)*. Acta Phys Polonica B B24(5) 927-950 (May 1993).

Equations of gravitation in the Lobachevsky space are formulated. The problem of the gravitational field of point mass in the Lobachevsky space is solved. In the Newtonian (nonrelativistic) case, this problem was posed and solved by Lobachevsky himself. In the relativistic case, one should first find adequate equations for the metric describing the gravitational field and then find their solutions. These equations are found by the author on the basis of the theory, developed by him, with two affine connections; one called Christoffel and the other, background. The latter is given by the equations of motion of free material particle in the Lobachevsky space. It is independent of the light velocity c. The static spherically symmetric metric found here depends on the ratio of the gravitational radius γMc^{-2} of mass M to the Lobachevsky constant k for the visible world. In the limit $k \to \infty$ it turns into the well known Schwarzschild metric. The world line of a planet is geodesic with respect to this metric. The relativistic Kepler problem in the Lobachevsky space is reduced to a nonlinear differential equation.

11A4. **Stochastic motion of a particle in a model fluctuating medium.** - M Moreau *(Lab Phys Thorique Liquides, Univ P et M Curie CNRS-URA 765, Boite 121, 75252 Paris, France)*, B Gaveau *(UFR Math, Univ P et M Curie, Paris, France)*, M Frankowicz *(Fac of Chem, Jagellonian Univ, Ingardena 3, 30-060 Krakow, Poland)*, A Perera *(Lab Phys Thoriques Liquides, Univ P et M Curie CNRS-URA 765, Boite 121, 75252 Paris, France)*. Acta Phys Polonica B B24(4) 891-908 (Apr 1993).

We present several models of time fluctuating media with finite memory, consisting in 1 and 2D lattices, the nodes of which fluctuate between two internal states according to a Poisson process. A particle moves on the lattice, the diffusion by the nodes depending on their internal state. Such models can be used for the microscopic theory of reaction constants in a dense phase, or for the study of diffusion or reactivity in a complex medium. In a number of cases, the transmission probability of the medium is computed exactly; it is shown that stochastic resonances can occur, an optimal transmission being obtained for a convenient choice of parameters. In more general situations, approximate solutions are given in the case of short and moderate memory of the obstacles. The diffusion in an infinite 2D lattice is studied, and the memory is shown to affect the distribution of the particles rather than the diffusion law.

11A5. **The string model of dislocation damping revisited.** - F Marchesoni and D Segoloni *(Inst Nazionale Fisica Nucleare, Univ di Perugia, I-06100 Perugia, Italy)*. Acta Phys Polonica B B24(4) 865-890 (Apr 1993).

The classic Granato-Lucke model for dislocation damping is revisited by accounting for possible refinements to the basic vibration string mechanism. We argue that the perturbation approach, which consists in separating the (linear) dislocation dynamics from the equilibrium lattice environment, is not suitable, no matter how accurate the description of the coupling, to explain the finite decrement function observed experimentally in a variety of samples at vanishingly small frequencies. A few ideas for a more general theory are discussed in some detail.

11A6. **Tidal forces in vertical spaces of Finslerian space-time.** - PC Stavrinos *(Dept of Math, Univ of Athens, 15571, Greece)*. Reports Math Phys 31(1) 1-4 (Feb 1992).

The classical equation of geodesic deviation is extended in the case of vertical geodesics associated with a Finslerian space-time. It is shown that the deviations can appear only if the vertical component of the energy-momentum tensor differs from zero.

102. Finite element methods

102A. GENERAL THEORY

11A7. **Automation of the FEM: A personal historical view.** - EL Wilson *(Dept of Eng, Emeritus, UCB)*. Finite Elements Anal Des 13(2-3) 91-104 (Jun 1993).

A summary of the evolution of computational and numerical methods for the static and dynamic analysis of FE systems will be presented. The majority of the material discussed will reflect the personal experience of the author during the past 35 years. It is the opinion of the author, that at the present time, the FEM is far from being completely automated for complex structures.

11T8. **FE structural analysis and complementary energy.** - RH Gallagher *(Clarkson Univ, Potsdam NY 13676)*. Finite Elements Anal Des 13(2-3) 115-126 (Jun 1993).

11A9. **Field theory: A 2D case for not using FEs or BEs.** - WD Pilkey and Yongquan Liu *(Dept of Mech and Aerospace Eng, Univ of Virginia, Charlottesville VA 22903)*. Finite Elements Anal Des 13(2-3) 127-136 (Jun 1993).

A numerical solution methodology for 2D field theory problems is addressed. It is the contention of this paper that if the governing differential equation, eg, a Poisson's equation, of a 2D field theory problem can be transformed into an integral equation, the FEM may not be needed to solve the problem. Instead, such boundary solution methods as the BEM and the method of direct integration of the integral equation can be utilized, leading to better solutions than the FEM. The direct integration appears to give the most accurate and efficient solutions.

11T10. **Identifying the characteristics of FE analysis convergence curves.** - RJ Melosh *(Dept of Civil and Env Eng, Duke Univ, Durham NC 27706)*. Finite Elements Anal Des 13(2-3) 105-113 (Jun 1993).

102C. STRUCTURAL APPLICATIONS

11A11. **Applications of a super element model for nonlinear analysis of stiffened box structures.** - J Jiang and MD Olson *(Dept of Civil Eng, Univ of British Columbia, Vancouver, BC, V6T 1Z4, Canada)*. Int J Numer Methods Eng 36(13) 2219-2243 (15 Jul 1993).

Numerical investigations are carried out to verify the new super element model developed for nonlinear analysis of stiffened box girders. The results presented here are obtained from a variety of examples which are chosen to illustrate the accuracy and convergence of the model in various applications. Good agreement is obtained for most of the problems considered and the present formulation is found to be accurate and economical for preliminary engineering design.

11A12. **FE analysis of composite plates using a weak form of the Kirchhoff constraints.** - RS Rao and HK Stolarski *(Civil and Mineral Eng Dept, Univ of Minnesota, Minneapolis MN 55455)*. Finite Elements Anal Des 13(2-3) 191-208 (Jun 1993).

A six-node triangular C° plate element is developed using the assumed strain method. A weak form of the Kirchhoff constraints is used to define the assumed shear strain field. The element so developed is free of shear locking and performs well even when the element boundaries are curved. It is demonstrated that the element provides satisfactory results in the analysis of various composite plates.

11A13. **FE Analysis of flange connections.** - E Zahavi *(Pearlstone Center for Aeronaut Eng Stud, Mech Eng Dept, Ben-Gurion Univ of the*

Negev, Beersheva, Israel). J Pressure Vessel Tech 115(3) 327-329 (Aug 1993).

The present work pertains to nonlinear analysis of forces and deformation in pressurized flange connections, taking into consideration changes of geometry and friction. This allows greater accuracy in computing bolt forces and in predicting the leakage point.

11A14. FE Modeling of tillage tool design. - RL Kushwaha *(Dept of Agri and Bioresource Eng, Univ of Saskatchewan, Saskatoon, SK, S7N 0W0, Canada)*. Trans Can Soc Mech Eng 17(2) 257-269 (1993).

A nonlinear FE model was developed for 3D soil cutting by tillage tools. A hyperbolic constitutive relation for soil was used in the model. Analysis was carried out to simulate soil cutting with rectangular flat and triangular tillage blades at different rake angles and with curved blades. Interface elements were used to model the adhesion and the friction between soil and blade surface. Soil forces obtained from the FE model for the straight blades were verified with the results from laboratory tillage tests in the soil bin. The FE model predicted draft force accurately for both tillage tools. Results indicated that the draft was a function of rake angle, tool shape, and the curvature.

11A15. Super element model for nonlinear analysis of stiffened box structures. - J Jiang and MD Olson *(Dept of Civil Eng, Univ of British Columbia, Vancouver, BC, V6T 1Z4, Canada)*. Int J Numer Methods Eng 36(13) 2203-2217 (15 Jul 1993).

A numerical model for nonlinear static and dynamic analysis of stiffened box structures is presented. The model is based on a new super element formulation which provides complete C^1 continuity for both plate and beam elements. Geometric and material nonlinearities are included and the temporal equations are solved by the implicit Newmark-β method with Newton-Raphson subiteration. The new formulation has been applied to the static, vibration and transient analysis of various structures such as flat plates, folded plates and rectangular boxes. Both isotropic and beam stiffened structures are considered and the results obtained are compared with other available solutions. It is observed that the new super element formulation can provide reasonable solutions in both linear and nonlinear problem of stiffened box structures. The mathematical formulation of the model is presented in this paper, while the numerical verifications are given in the companion paper.

102E. OTHER SOLID MECHANICS APPLICATIONS

11A16. FE analysis of progressive failure for laminated FRP plates with inplane loading. - Li-Ren Tsau *(Dept of Mech Eng, Chung Cheng IT, Ta-Shi, Taiwan 33509 ROC)* and R Plunkett *(Dept of Aerospace Eng and Mech, Univ of Minnesota, Minneapolis MN 55455)*. Eng Fracture Mech 45(4) 529-546 (Jul 1993).

Composite materials can sustain a much higher load in inplane tension after the onset of local damage. The ultimate strength of composite laminates can be accurately predicted with FE analysis if the proper increment is used in each step. An analysis of the appropriate nodal spacing both in the plane of the specimen and in the thickness direction has been made with particular attention to the problem of stress concentration at the free edges. The load for final catastrophic failure and the failure pattern in progressive failure both agree well with experimental results.

11A17. FE simulation of elastic wave propagation in orthotropic composite materials. - KMA Jaleel *(Dept of Mech Eng, Univ of Toronto, ON, Canada)*, NN Kishore, V Sundararahan *(Dept of Mech Eng, Indian IT, Kanpur 208016, India)*. Mat Eval 51(7) 830-838 (Jul 1993).

Defects such as cracks and inclusions act as sources of wave scattering when illuminated by an incident ultrasonic pulse through reflection, diffraction, and mode conversion. Interaction of elastic waves with cracks provides all the necessary information regarding the inverse characterization of the defects which has not yet been thoroughly solved. In the present work, a plane strain FE model has been developed to study the elastic wave propagation and scattering in general anisotropic media. The interaction of pulsed compression waves and Rayleigh waves with cracks in isotropic material has been studied. The wave interaction with an interface crack in a layered graphite-epoxy composite structure has been investigated. It predicts the mode-conversion and diffraction of waves by cracks. It is found that for quasi-longitudinal waves the displacement along the fiber is prominent whereas for quasi-transverse, that displacement perdendicular to the fiber is prominent.

11A18. Improved preconditioned conjugate gradient method and its application in FEA for engineering. - Hong Zheng and Xiu-run Ge *(Inst of Rock and Soil Mech, Acad Sinica, Wuhan, China)*. Appl Math Mech 14(4) 371-380 (Apr 1993).

In this paper two theorems with theoretical and practical significance are given in respect to the preconditioned conjugate gradient method (PCCG). The theorems discuss respectively the qualitative property of the iterative solution and the construction principle of the iterative matrix. The authors put forward a new incompletely LU factorizing technique for the non-M-matrix and the method of constructing the iterative matrix. This improved PCCG is used to calculate the ill-conditioned problems and large-scale 3D FE problems, and simultaneously contrasted with other methods. The abnormal phenomenon is analyzed when PCCG is used to solve the system of ill-conditioned equations. It is shown that the method proposed in this paper is quite effective in solving the system of large-scale FE equations and the system of ill-conditioned equations.

11A19. Numerical analysis of IPIRG cracked pipe experiments subjected to dynamic and cyclic loading. - B Brickstad *(Swedish Plant Inspection, PO Box 49306, S-100 29 Stockholm, Sweden)*. Int J Pressure Vessels Piping 55(3) 395-422 (1993).

This report contains results of a FE study aiming to identify the influence of loading history and geometry for cracked pipes subjected to complex loading. The experiments have been performed within the International Piping Integrity Research Group Program. The majority of the numerically analyzed experiments were conducted on straight pipes with an outside diameter of 168 mm and containing a large circumferential through-wall crack. The considered pipes were loaded in four-point bending under displacement control and at a temperature of 288°C. The types of loading were combinations of either quasi-static or dynamic and also monotonic or cyclic loading with different loading ratios R. Some analyses were also performed on surface-cracked pipes subjected to slow, monotonic loading. In the FE study, 20-node solid elements were used for the through-wall cracked pipes and a combination of shell and nonlinear line spring elements for the surface-cracked pipes. Stable crack growth was simulated by gradual node relaxation and crack closure is accounted for by using simple contact elements. The J-integral for a remote contour is calculated and used as a characterizing fracture parameter although the cyclic loading violates the theoretical basis for this procedure. The near-tip J can not be used for growing cracks because of the weak energy singularity. The results of the numerical study confirm the trends from the experiments in that a high loading rate has a negative influence on the fracture properties of the studied carbon steel and that large cyclic loading, especially at R = -1, lowers the apparent J^R-curve for both carbon and stainless steels. To some extent geometry effects appear to be present when comparing the results from pipes containing surface cracks and through-wall cracks with results from CT specimens. These effects are more pronounced for large amounts of stable crack growth than at initiation.

102G. FLUID MECHANICS APPLICATIONS

11A20. Behavior of several stress-velocity-pressure mixed FEs for Newtonian flows. - GC Buscaglia *(Div Mec Comput, DIA Centro Atomico Bariloche, CNEA, 8400-SC de Bariloche, Argentina)*. Int J Numer Methods Fluids 17(2) 99-113 (30 Jul 1993).

The Q_2/P_1, $P^+{}_2/P_1$, P_2/P_0 and Q_1/P_0 velocity-pressure mixed elements are extended to the stress-velocity-pressure formulation, using the same interpolants for stress and velocity, and tested in the 4-to-1 contraction problem for Stokes flow. The comparison shows significant differences among them, which are not present when the velocity-pressure formulation is used. To provide a better understanding of the phenomenon, several variants, of the previous elements are introduced, obtained by either changing the pressure space or by enriching the stress space with bubble functions. The formulation exhibits a strong sensitivity to the first alternative, while the second produces only a minor effect. These observations are confirmed by a convergence test effected on a regular problem with the explicit analytical solution. Also, as a result of the whole comparison, the $P^+{}_2/P^+{}_2/P_1$ element looks promising for three-field calculations.

11A21. Perturbation technique that works even when the nonlinearity is not small. - M Senator *(Davidson Lab, Stevens IT, Hoboken NJ 07030)* and CN Bapat *(Dept of Mech Eng, CCNY)*. J Sound Vib 164(1) 1-27 (8 Jun 1993).

We extend the Lindstedt-Poincare small nonlinearity based perturbation scheme to strongly nonlinear systems. The extended technique starts from a physically non-existent neighboring linear system. This system is created by adding an optimal linear spring term to the system side of each linear differential equation, starting at the zeroth level, and balancing that term by adding an equal one to the forcing side one level down. Unlike the Ritz method, which also works for strongly nonlinear systems, results can be obtained beyond the first level without resorting to numerical techniques. Thus, the extended method keeps the intuition-guiding straightforwardness to the perturbation method, while giving accurate, beyond first level, hand-derivable numerical results. Examples are presented for free vibrations with cubic and antisymmetric quadratic nonlinearities and for harmonic solutions of the undamped Duffing equation. The forms of the solution allow the regions of validity of the expansion to be estimated. An internal method of estimating accuracy of the perturbation solutions is developed and checked with the free vibration examples, the exact solution of which are available. The internal method is then used to estimate the accuracy of the new solutions to the Duffing equation. These new Duffing equation solutions give accurate results in all regions where stable harmonic solutions are known to exist. In particular, they give accurate results at and near the vertical tangent to the resonance curve, a region where Hayashi's amplitude expansion based perturbation solution necessarily breaks down.

11A22. Streamline upwind control volume FEM for modeling fluid flow and heat transfer problems. - CR Swaminathan *(Dept of Mech Eng, Univ of Minnesota, Minneapolis MN 55455)*, VR Voller *(Dept of Civil and Mineral Eng, Univ of Minnesota, Minneapolis MN 55455)*, SV Patankar *(Dept of Mech Eng, Univ of Minnesota, Minneapolis MN 55455)*. Finite Elements Anal Des 13(2-3) 169-184 (Jun 1993).

Galerkin and control volume FE approximations are compared and contrasted. Streamline upwinding and pressure stabilizing Petrov-Galerkin formulations for the numerical modeling of fluid flow problems are discussed. These formulations are then adapted to a control volume FE discretization. The resulting control volume FE scheme permits an equal order interpolation for velocity and pressure, is readily implemented and retains the property of local conservation, normally associated with control volume schemes.

102J. OTHER APPLICATIONS

11A23. FE analysis of the 3D transient temperature field in steam turbine casings. - P Dhananjaya Rao, A Sarkar, VMK Sastri *(Dept of Mech Eng, Indian IT, Madras 600 036, India)*. Int J Mech Sci 35(7) 587-595 (Jul 1993).

One of the important considerations going into the process of optimization of start-up schedules for steam turbines is the estimation of thermal stresses during the transients. This in turn requires prediction of the transient temperature fields. In the case of the turbine casing, the procedures are complex in view of the irregular geometrical shape. FE analysis offers better scope in this regard and has been employed in the present work to compute the 3D transient temperature distribution in the casing metal. The metal results obtained by a code developed for a specific type of turbine casing have been compared with the values measured by experiment and have been found to validate the code. Time-temperature histories for two typical locations inside the casing metals are presented. Isotherm surfaces across the metal at a given instant are shown.

11A24. Closed-form error estimators for the linear strain and quadratic strain tetrahedron FEs. - PS Shiakolas, KL Lawrence, RV Nambiar *(Dept of Mech Eng, Univ of Texas, Arlington TX)*. Comput Struct 47(6) 907-915 (17 Jun 1993).

Closed-form representations of the Zienkiewicz-Zhu error estimators for straight edge linear and quadratic strain tetrahedral elements are presented. The closed-form representation of the element error estimators was developed using symbolic algebra. Dramatic computational time savings result in the element error estimator evaluation phase of the FEM process when the closed-form representation is used as compared with the use of Gaussian cubature.

11A25. Mesh stability study of FEM explicit algorithms for structural large-scale deformation impact responses. - Ming-Cheng Zhu *(Dept of Civil Eng, Tsinghua Univ, Beijing 100084, Peoples Rep of China)*, Lie-Quan Liu *(Dept of Mech, Huazhong Univ of Sci and Tech, Wuhan 430074, Peoples Rep of China)*, Sou-Yi Zheng *(Mech Teaching Group, Changsha Eng Inst, Changsha 410072, Peoples Rep of China)*. Acta Mech Solida Sinica 6(3) 302-308 (Jul 1993).

To FEM explicit algorithms for structural large-scale deformation impact responses, algorithm stability is discussed in the present paper. Algorithm stability is thought to include two aspects: one is called difference pattern stability and the other is called mesh stability. A self-adaptive adjusting method is proposed to ensure mesh stability with little amount of computation increased.

11A26. Optismoothing: An optimization-driven approach to mesh smoothing. - SA Canann, MB Stephenson *(Brigham Young Univ, Provo UT)*, T Blacker *(Sandia)*. Finite Elements Anal Des 13(2-3) 185-190 (Jun 1993).

This paper presents a mesh smoothing technique that uses optimization principles to minimize a distortion metric throughout a mesh. A comparison is made with Laplacian and isoparametric smoothing techniques.

11A27. Power method for the generalized eigenvalue problem. - W Kozlowski *(Warszawa, Poland)*. Matematyka Stosowana 35 5-19 (1992).

In this paper the Power Method for the generalized eigenvalue problem for matrix pencil ($A - \lambda B$) $x = 0$ is considered. At any step of this iterative process the system of linear algebraic $By = Ax$ has to be approximately solved with respect to y. We try to answer the question: how accurately we have to solve this system on each step of iteration, in order to guarantee resolution of the eigenproblem with given precision.

102N. ELEMENT DEVELOPMENT

11A28. Construction of an optimal weakly divergence-free macroelement. - Xiu Ye *(Dept of Math and Stat, Univ of Arkansas, Little Rock AR 72204)* and CA Hall *(Dept of Math and Stat, Univ of Pittsburgh, Pittsburgh PA 15260)*. Int J Numer Methods Eng 36(13) 2245-2262 (15 Jul 1993).

The divergence-free FEM (DFFEM) is a method to find an approximate solution of the Navier-Stokes equations in a divergence-free space. That is, the continuity equation is satisfied *a priori*. DFFEM eliminates the pressure from the calculations and reduces significantly the dimension of the system to be solved at each time step. For the standard 8-node velocity and 4-node pressure DFFEM an optimal basis for the weakly divergence-free subspace is constructed such that each basis function has non-zero support on at most nine contiguous elements. Given this basis, weakly divergence-free macroelements are constructed.

11A29. Explicit FE formulation for very large deformations based on updated material reference frame. - Young M Yun *(Sch of Civil Eng, Purdue)*. Finite Elements Anal Des 13(2-3) 209-224 (Jun 1993).

An explicit FE formulation which has the capability of handling very large geometrical changes is developed. The formulation is based on an updated material reference frame and hence a true stress-strain test can be directly applied to properly characterize properties of materials which are subjected to very large deformations. For the large deformations, a consistent formulation based on the continuum mechanics approach is derived. The kinematics is referred to an updated material frame. Body equilibrium is also established based on the updated geometry. The second Piola-Kirchhoff stress tensor and the updated Lagrangian strain tensor are used in the formulation. Numerical examples of frame structures are solved to validate the presented formulation and to demonstrate the importance of imposing material properties properly.

11A30. Six-noded element for analyzing power-type singularities under thermal loads. - BK Dutta *(Reactor Eng Div, Bhabha Atomic Res Centre, Trombay, Bombay-400085, India)*. Int J Numer Methods Eng 36(13) 2287-2303 (15 Jul 1993).

The shape functions of a 6-noded triangular element have been derived to model power-type singularities under thermal loads. A number of case studies have been presented, which involve variable-order singularities under mechanical and thermal loads. The results show the usefulness of the element.

11A31. Symmetric Galerkin boundary formulations employing curved elements. - JH Kane and C Balakrishna *(Mech and Aeronaut Eng Dept, Clarkson Univ, Potsdam NY 13699)*. Int J Numer Methods Eng 36(13) 2157-2187 (15 Jul 1993).

Accounts of the symmetric Galerkin approach in BE analysis have recently been published. This paper attempts to add to the understanding of this method by addressing a series of fundamental issues associated with its potential computational efficiency. A new symmetric Galerkin theoretical formulation for both the (harmonic) heat conduction and the (biharmonic) elasticity problem that employs regularized singular and hypersingular boundary integral equations (BIEs) is presented. The novel use of regularized BIEs in the Galerkin context is shown to allow straightforward incorporation of curved, isoparametric elements. A symmetric reusable intrinsic sample point (RISP) numerical integration algorithm is shown to produce a Galerkin (ie, double) integration strategy that is competitive with its counterpart (ie, singular) integration procedure in the collocation BEA approach when the time saved in the symmetric equation solution phase is also taken into account. This new formulation is shown to be capable of employing hypersingular BIEs while obviating the requirement of C^1 continuity, a fact that allows the employment of the popular continuous element technology. The behavior of the symmetric Galerkin BEA method with regard to both direct and iterative equation solution operations is also addressed. A series of example problems are presented to quantify the performance of this symmetric approach, relative to the more conventional unsymmetric BEA, in terms of both accuracy and efficiency. It is concluded that appropriate implementations of the symmetric Galerkin approach to BEA indeed have the potential to be competititve with, if not superior to, collocation-based BEA, for large-scale problems.

104. Finite difference methods

11A32. Improved approximation technique to obtain numerical solution of a class of two-point boundary value similarity problems in fluid mechanics. - NG Kafoussias *(Dept of Math, Univ of Patras, 261 10 Patras, Greece)* and EW Williams *(Dept of Appl Math and Theor Phys, University, Liverpool L69 3BX, UK)*. Int J Numer Methods Fluids 17(2) 145-162 (30 Jul 1993).

A simple and efficient approximate numerical technique is presented to obtain solutions to a wide class of two-point boundary value similarity problems in fluid mechanics. This technique is based on the common finite difference method with central differencing, a tridiagonal matrix manipulation and an iterative procedure. The technique described in this paper has been successfully applied to three different representative similarity problems of fluid mechanics. Each one of these problems is described by a coupled, nonlinear system of three ordinary differential equations and has already been solved elsewhere using a different numerical method. So, the obtained numerical results, by our efficient numerical technique, permit a comparative study and show the accuracy and the effectiveness of this technique.

11A33. Finite difference method at arbitrary meshes for the bending of plates with variable thickness. - Guang-yao Li *(Dept of Comput Sci, Guizhou Univ, Guiyang, China)* and Han-bin Zhou *(Dept of Eng Mech, Tongji Univ, Shanghai, China)*. Appl Math Mech 14(3) 299-304 (Mar 1993).

A finite difference method at arbitrary meshes for the bending of plates with variable thickness is presented in this paper. The method is completely general with respect to various boundary conditions, load cases and shapes of plates. This difference scheme is simple and the numerical results agree well with those obtained by other methods.

11A34. Local uniform grid refinement and systems of coupled partial differential equations. - R Trompert *(CWI, PO Box 4079, 1009 AB Amsterdam, Netherlands)*. Appl Numer Math 12(4) 331-335 (Jun 1993).

In this paper we consider an adaptive grid method based on local uniform grid refinement to applied systems of coupled time-dependent PDEs. Local uniform grid refinement means that the PDEs are solved on a series of nested, uniform, increasingly finer subgrids which cover only a part of the domain. These subgrids are created up to a level of refinement where sufficient spatial accuracy is obtained and their location and shape is adjusted after each time step in order to follow the moving steep fronts. When a system of coupled PDEs is solved, the behavior of the local and global error associated with each separate PDE can be very different from one PDE to another. A refinement strategy based on a global error analysis has been developed which takes these differences into account. This refinement strategy aims at the domination of the global space error by the space discretization error at the finest subgrid.

11A35. The numerical solution of functional differential equations. A survey. - Z Jackiewicz *(State Univ, Tempe AZ)* and M Kwapisz *(Gdansk, Poland)*. Matematyka Stosowana 33 57-78 (1992).

Significant progress has been made in the last few years in the numerical solution of functional differential equations. It is the purpose of this paper to review the results in this area. Special attention is given to implementation on one-step methods and predictor corrector methods for functional differential equations including equations of neutral type and to the stability theory of numerical methods of these equations.

11A36. Surface grid generation with a linkage to geometric generation. - M Suzuki *(Inst of Comput Fluid Dyn, 1-16-5 Haramachi, Meguro-ku, Tokyo 152, Japan)*. Int J Numer Methods Fluids 17(2) 163-176 (30 Jul 1993).

This paper describes a new method to generate surface grids over complex configurations defined by a geometric generation system. The scheme is designed for direct utilization of the surface definition provided by a geometric modeller based on a boundary representation (the so-called B-rep modeller). Thus, the conversion of the geometric representation for the surface grid generator is not required. Consequently, this technique eliminates not only laborious tedium in the conversion of data, but also errors in the representation of the surface induced in the process of the conversion. The proposed method is accomplished over several stages. First, the triangulation is performed on the surface of the geometry, on which the area to be grided is laid. Then linear partial differential equations are mapped and solved on these triangular elements. Finally, the surface grid is constructed by searching for the contours inside the solution domain. After the co-ordinate values of the grid points are obtained by a linear interpolation within each triangular element, these values are mapped onto the surface of the geometry through surface parametric functions provided by the B-rep modeller. An example of generating surface grid over a car configuration is given to illustrate the capability of the method.

11A37. Adaptive BE for multiple subregions. - N Kamiya and M Koide *(Dept of Mech-Info and Syst, Nagoya Univ, Nagoya 464-01, Japan)*. Comput Mech 12(1-2) 69-80 (Jun 1993).

The sample point error analysis and related adaptive BE refinement, proposed by one of the present authors, is extended to the problem with subregion partition which is often required for maintaining higher accuracy and for treatment of composite dissimilar materials. The present study is devoted to regularization of the requirement that the interface between neighboring subregions should be discretized by the unified criterion for the both, while, in general, the error influences on the point on the interface from one region differs from that from the other. Two examples concerning the 2D Laplace equation are tested to verify the availability of the proposed method.

11A38. Compatible BEM for plane elasticity and fracture mechanics. - Lei Gu *(Dept of Civil Eng, Robert R McCormick Sch of Eng and Appl Sci, Tech Inst, NWU)*. Appl Math Model 17(8) 394-405 (Aug 1993).

A new compatible BE technique for solving biharmonic boundary value problems, based on Muskhelishvili's theory, is presented. The general solution of this kind of problem involves two independent analytic functions. These functions are represented by Vekua's integral formula where the path of the integral is taken around the external boundary of the solid. In this way, we derive a new type of boundary integral equation for plane elasticity problems as well as thin plate problems. In particular, the edge crack and central crack problems of plane elasticity have been investigated. The real density functions appearing in the boundary integral equations are determined by the BEM. The numerical results obtained show good agreement with the theoretical results.

11A39. Elastoplastic analysis of 2D problems with hole by BEM using complex variables. - S Tang *(Dept of Eng Mech, Tongji Univ, Shanghai 200092, Peoples Rep of China)* and R Kitching *(Dept of Mech Eng, Appl Mech Div, UMIST, Manchester, UK)*. Int J Mech Sci 35(7) 577-586 (Jul 1993).

A direct formulation of the BEM using complex variable functions for 2D elastoplastic analysis has been developed. Based on the initial stress approach and complex potential fundamental solutions, the method simplified the computer program and reduced the input data and the order of the equation system greatly; the function of the computer program has been improved and the singular solution behavior in the yield region near the boundary is eliminated. Two numerical examples have shown that the method can be used in practical applications of elastoplastic analysis in engineering.

This paper deals with the pseudospectral solution of differential equations with coordinate singularities such as those which describe situations in spherical or cylindrical geometries. We use the differential equation, together with a smoothness assumption on the solution, to construct "pole conditions." The pole conditions, which are straightforward and easily implemented, serve as numerical boundary conditions at the coordinate singularity. Standard pseudospectral methods, including fast transformation techniques, can then be applied to the singular problem. The method is illustrated using the eigenvalue probelm of Bessel's equation and a Poisson equation on the unit disk. Numerical results show that spectral convergence is achieved.

11A41. **Langevin equations with multiplicative noise. Application to domain growth.** - JM Sancho, A Hernandez-Machado *(Dept Estructura Constituents Materia, Univ Barcelona, Av Diagonal 647, E-08028 Barcelona, Spain)*, L Ramirez-Piscina, AM Lacasta *(Dept Fisica Aplicada, Univ Politec Catalunya, Jordi Girona Salgado 31, E-08034 Barcelona, Spain)*. Acta Phys Polonica B B24(4) 733-750 (Apr 1993).

Langevin Equations of Ginzburg-Landau form, with multiplicative noise, are proposed to study the effects of fluctuations in domain growth. These equations are derived from a coarse-grained methodology. The Cahn-Hilliard-Cook linear stability analysis predicts some effects in the transitory regime. We also derive numerical algorithms for the computer simulation of these equations. The numerical results corroborate the analytical predictions of the linear analysis. We also present simulation results for spinodal decomposition at large times.

11A42. **On randomly interrupted diffusion.** - J Luczka *(Dept of Theor Phys, Silesian Univ, Bankowa 14, 40-007 Katowice, Poland)*. Acta Phys Polonica B B24(4) 717-724 (Apr 1993).

Processes driven by randomly interrupted Gaussian white noise are considered. An evolution equation for single-event probability distributions are presented. Stationary states are considered as a solution of a second-order differential equation with two imposed conditions. A linear model is analyzed and its stationary distributions are explicitly given.

An irregular perturbation problem around a quasi-static solution for a motion of a thick-walled spherical container made from viscoplastic material and subjected to a time-dependent internal pressure is dealt with. Only the first perturbations are taken into account. A practically important case of a power excess stress function above the static yield stress is considered.

106I. ALGORITHMS AND SOFTWARE DEVELOPMENT

11A44. **Frontal approach for internal node generation in Delaunay triangulations.** - J-D Muller, PL Roe *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109-2140)*, H Deconinck *(Von Karman Inst for Fluid Dyn, 72, Chaussee de Waterloo, B-1640 Rhode-Saint-Genese, Belgium)*. Int J Numer Methods Fluids 17(3) 241-255 (Aug 1993).

The past decade has known an increasing interest in the solution of the Euler equations on unstructured grids due to the simplicity with which an unstructured grid can be tailored around very complex geometries and be adapted to the solution. It is desirable that the mesh can be generated with minimum input from the user, ideally, just specifying the boundary geometry and, perhaps, a function to prescribe some desired mesh size. The internal nodes should then be found automatically by the grid generation code. The approach we propose here combines the Delaunay triangulation with ideas from the advancing front method of Peraire *et al* and Lohner *et al* Both methods are briefly reviewed in Section 1. Our method uses a background grid to interpolate local mesh size parameters that is taken from the triangulation of the given boundary nodes. Geometric criteria are used to find a set of nodes in a frontal manner. This set is subsequently introduced into the existing mesh, thus providing an updated Delaunay triangulation. The procedure is repeated until no more improvement of the grid can be achieved by inserting new nodes.

11A45. **Global approach to error estimation and physical diagnostics in multi-dimensional computational fluid dynamics.** - DC Haworth, SH El Tahry, MS Huebler *(Thermosci Dept, General Motors Res, 30500 Mound Rd, Warren MI 48090-9055)*. Int J Numer Methods Fluids 17(1) 75-97 (Jul 1993).

An approach for simultaneously assessing numerical accuracy and extracting physical information from multidimensional calculations of complex (engineering) flows is proposed and demonstrated. The method is based on global balance equations, ie, volume-integrated partial differential equations for primary or derived physical quantities of interest. Balances can be applied to the full computational domain or to any subdomain down to the single-cell level. Applications to in-cylinder flows in reciprocating engines are used for illustration. It is demonstrated that comparison of the relative magnitude of the terms in the balances provides insight into the physics of the flow being computed. Moreover, for quantities that are not conserved at the cell or control volume level in the construction of the numerical scheme, the imbalance allows a direct assessment of numerical accuracy in a single run using a single mesh. The mean kinetic energy imbalance is shown to be a particularly sensitive indicator of numerical accuracy. This simple and powerful diagnostic approach can be implemented for finite-difference, finite-volume or FEMs.

106K. COMPUTER ARCHITECTURES, SYSTEMS, HARDWARE

11A46. **Use of recursive stochastic algorithm for neural networks synthesis.** - AS Poznyak *(Inst of Control Sci, USSR Acad of Sci, Profsoyuznaya 65, Moscow, Russia)*, K Najim *(Dept of Chem Eng, Univ of Laval, PQ, G1K 7P4, Canada)*, M Chtourou *(CNRS URA 192, GRECO SARTA, ENSIGC, Chemin de la Loge 31078 Toulouse, Cedex, France)*. Appl Math Model 17(8) 444-448 (Aug 1993).

A new method based on a recursive stochastic algorithm is presented for neural networks synthesis. The cost function of the difference between the output of the net and the output of the process to be modeled by the net has nonunique stationary points. The common optimization techniques lead to local optima. It is shown that the solution of this optimization problem is connected with the construction of a convex envelope, characterized by local extrema of the intial problem. Then a recursive stochastic random search algorithm is derived for finding the optimum using realizations of a random variable associated with the function to be minimized. The application of this method is illustrated by an experimental example concerning neural networks synthesis for an industrial calcinator.

11A200. Active systems in the vibration control of vehicles

150D. DYNAMICS OF RIGID BODIES AND PARTICLES

11A49. **Dynamical systems with impulses: Stroboscopic maps approach.** - A Kleczkowski *(Inst of Phys, Jagellonian Univ, Reymonta 4, PL-30-059 Krakow, Poland)*. Acta Phys Polonica B B24(6) 1061-1071 (Jun 1993).

A stroboscopic maps approach for continuous dynamic systems has been elaborated and generalized. For an impulse perturbation, the map equivalent to a given equation can be found analytically for a large class of systems, in the limit of the impulse width going to 0. This technique can be used for analyzing dynamical systems in which the perturbation has an impulse form, or can be joined with the Generalized Modulated Kicks Approximation to model a system with continuous or noisy perturbation. The validity of a "naive" method of finding the map is discussed.

150F. MULTIBODY AND VARIABLE MASS SYSTEMS

11A50. **Routh's equations for general non-holonomic mechanical systems of variable mass.** - Yao-huang Luo *(Yunnan Univ, Kunming, China)* and Yong-da Zhao *(Yunnan Inst of Educ,* *Kunming, China)*. Appl Math Mech 14(3) 285-298 (Mar 1993).

In this paper, Routh's equations for the mechanical systems of the variable mass with nonlinear nonholonomic constraints of arbitrary orders in a noninertial reference system have been deduced not from any variational principles, but from the dynamical equations of Newtonian mechanics. And then again the other forms of equations for nonholonomic systems of variable mass are obtained from Routh's equations.

150G. DEFORMABLE BODY DYNAMICS

11A51. Nonlinear dynamics of a flexible beam in a central gravitational field I. Equations of motion. - MRM Crespo da Silva and CL Zaretzky *(Dept of Mech Eng, Aeronaut Eng and Mech, RPI)*. Int J Solids Struct 30(17) 2287-2299 (1993).

The complete nonlinear differential equations governing the nonlinear motions of a beam able to undergo bending and pitching in space, are formulated in this paper. The formulation is based on a variational principle and accounts for all the nonlinearities due to deformation and gravity gradient effects. The nonlinearities due to deformation arise due to geometric effects, which consist of nonlinear curvature and nonlinear inertia terms. Expanded equations governing the nonlinear perturbed motion about an equilibrium are also developed for the case when the beam is in circular orbit. Such equations are suited for a perturbation analysis of the motion, and nonlinearities up to cubic order in a bookkeeping parameter are retained in them. Nonlinear motions involving interactions between bending and pitching of the beam are investigated in Part II of this work using the equations developed here.

11A52. Nonlinear dynamics of a flexible beam in a central gravitational field II. Nonlinear motions in circular orbit. - MRM Crespo da Silva and CL Zaretzky *(Dept of Mech Eng, Aeronaut Eng and Mech, RPI)*. Int J Solids Struct 30(17) 2301-2316 (1993).

The coupled nonlinear pitch-bending response of a free-free beam in a circular orbit, when the beam is subjected to a periodic external excitation, is analyzed. The nonlinearities present in the differential equations of motion are due to deformation of the beam (ie, curvature and inertia nonlinearities) and to the gravity-gradient moments. Perturbation methods are used to analyze the motion. Several resonant motions exhibited by the system are analyzed in detail, namely, harmonic resonances when the frequency of the external excitation, Ω, is either near the natural frequency of the flexural or the pitch motion, and a superharmonic resonance when Ω is near one half of the natural frequency for the pitch motion. The latter two resonances are associated with very low excitation frequencies.

11A53. Bifurcations and chaos in voice signals. - H Herzel *(Inst of Theor Phys, Humboldt Univ, Invalidenstr 42, 0-1040 Berlin, Germany)*. Appl Mech Rev 46(7) 399-413 (Jul 1993).

The basic physical mechanisms of speech production is described. A rich variety of bifurcations and episodes of irregular behavior are observed. Poincare sections and the analysis of the underlying attractor suggest that these noise-like episodes are low-dimensional determ[illegible] chaos. Possible implications for the [illegible] diagnosis of brain disorder are discuss[illegible]

11A54. Chaos and noise in dynamical systems. - T Kapitaniak *(Div of Control and Dyn, Tech Univ of Lodz, Poland)* and J Brindley *(Sch of Math, Univ of Leeds, Leeds LS2 9JT, UK)*. Appl Mech Rev 46(7) 359-444 (Jul 1993).

This collection of papers is concerned with chaos and noise in a range of dynamical systems, mostly within a context of mechanics.

11A55. Controlling chaos in mechanical systems. - B Blazejczyk, T Kapitaniak, J Wojewoda *(Div of Control and Dyn, Tech Univ, Stefanowskiego 1-15, 90-924 Lodz, Poland)*, J Brindley *(Dept of Appl Math Stud and Centre for Nonlinear Stud, Univ of Leeds, Leeds LS2 9JT, UK)*. Appl Mech Rev 46(7) 385-391 (Jul 1993).

The problem of controlling chaos, that is to convert the chaotic behavior to a periodic time dependence is discussed. We described a number of effective controlling methods in the context of mechanical systems.

11A56. Destruction of quasiperiodic oscillations in weakly nonlinear systems. - AB Belogortsev *(Dept of Phys and Astron, Univ of Maine, Orono ME 04469)*, DM Vavriv *(Radio Astron Inst, Acad of Sci of Ukraine, Kharkov 310002, Ukraine)*, OA Tretyakov *(Dept of Radio Phys, Kharkov State Univ, Kharkov 310077, Ukraine)*. Appl Mech Rev 46(7) 372-384 (Jul 1993).

We consider the main regularities of the arising of the dynamical chaos in weakly nonlinear oscillatory systems. We show that the chaotic oscillations in such systems can occur due to the destruction of quasiperiodic oscillations. Various analytical approaches are applied to study the properties of the quasiperiodically forced passive and active single-mode oscillators as well as the conditions for the appearance of chaos. The results of numerical and experimental investigations are also discussed.

11A57. Dynamics of a rolling wheelset. - Hans True *(Tech Univ of Denmark and ES-Consult, DK-2800 Lyngby, Denmark)*. Appl Mech Rev 46(7) 438-444 (Jul 1993).

We discuss the kinematics and dynamics of a wheelset rolling on a railway track. The mathematical model of a suspended wheelset rolling with constant speed on a straight track is set up and its dynamics is investigated numerically. The results are presented mainly on bifurcation diagrams. Several kinds of dynamical behavior is identified within the investigated speed range. We find a stationary equilibrium point at low speeds and at higher speeds symmetric and asymmetric oscillations are found and ranges with chaotic motion are identified. The bifurcations are described.

11A58. Homoclinics in the reconstruction of dynamic systems from experimental data. - VS Anishchenko and MA Safonova *(Phys Dept, Saratov State Univ, Astrachanskaja B3, Saratov 410071, Russia)*. Appl Mech Rev 46(7) 361-371 (Jul 1993).

The role of homoclinic effects in solution of a reconstruction problem of system attractors and model equations from experimental observable in the presence of external noise is investigated numerically. It is shown that the possibility of reconstruction essentially depends on character of origin system homoclinic trajectories and noise intensity. If the homoclinic structure belongs to the attractor, then the reconstruction results in restoration origin system attractors. A small noise influence causes in this case a small perturbation of attractors probability measure and practically disappears due to filtering properties of the reconstruction algorithm. The homoclinic structure does not belong to the attractor, then in the absence of noise the probability measure concentrates at the attractor, the structure of which is not [illegible]ined by the homoclinics. The noise perturba[illegible] induces new regimes. Then the attractor [illegible]ure essentially depends on the homoclinics [illegible]ure and noise level. In this case the model system attractor of which reproduces "invisible" homoclinic structure, is obtained as a result of reconstruction.

11A59. Hopf bifurcation in gas journal bearings. - K Czolczynski *(Div of Control and Dyn, Tech Univ, Stefanowskiego 1-15, 90-924 Lodz, Poland)*. Appl Mech Rev 46(7) 392-398 (Jul 1993).

This paper reviews a numerical investigation of the problem of small self-excited vibrations in gas journal bearings. The method of analysis is based on the Hopf bifurcation theory, in which the approximate periodic solutions of nonlinear equations of motion are computed using the Fredholm alternative. This theory enables us to construct the bifurcating periodic solutions and to determine their stability. The equations of motion of the investigated gas journal bearing have been formulated after estimating the damping and stiffness coefficients of a gas film. For this purpose, a new method of identification has been proposed.

11A60. Sectional curvature and chaos in dynamical problems: Toward the invariant measure of chaos in Hamiltonian systems. - M Szydlowski *(Astron Observatory, Jagiellonian Univ, Orla 171, 30-244 Krakow, Poland)* and A Krawiec *(Dept of Economics, Jagiellonian Univ, Wislna 2, 31-007 Krakow, Poland)*. Appl Mech Rev 46(7) 427-437 (Jul 1993).

Chaotic phenomena in general relativity are investigated. In relativistic astrophysical problems no space-time coordinate system is privileged in any way as far as the physical description of phenomena is concerned. Effects which depend on the choice of the particular coordinate system should be treated as an artifact of the incorrect methods. To avoid such difficulties the gauge invariant theory of chaos is proposed.

11A61. Spatio-temporal versus temporal chaos in a spatially extended magnetic dynamical system. - JJ Zebrowski and A Sukiennicki *(Inst of Phys, Warsaw Univ of Tech, Koszykowa 75, 00-662 Warszawa, Poland)*. Acta Phys Polonica B B24(4) 785-800 (Apr 1993).

Nonlinear dynamical states of a spatially extended micromagnetic system - the Bloch wall - were analyzed by means of spatio-temporal diagrams and power spectral analysis in the spatial frequency domain. The system studied exhibits dynamics with propagating coherent spatial structures - Bloch lines - which have soliton properties. Although it is spatially extended only temporal chaos occurs. The symptoms of this type of chaos (spatially complex patterns changing violently with the time) in such a spatially extended system should not be confused with chaos in the space and time simultaneously. The system is not spatially chaotic due to the existence in it of coherent spatial structures with a fixed length scale (kink solitons).

11A62. Synchronization and chaotization of oscillations in coupled self-oscillating systems. - PS Landa *(Dept of Phys, Lomonosov Moscow State Univ, 119899 Moscow, Russia)* and MG Rosenblum *(Mech Eng Res Inst, Russian Acad of Sci, 101830 Moscow, Russia)*. Appl Mech Rev 46(7) 414-426 (Jul 1993).

The effects of synchronization of chaotic and periodic self-oscillation systems are discussed. Two mechanisms of synchronization of periodic systems which manifest themselves at synchronization of chaotic systems are determined. Examples of synchronization of chaotic systems by harmonic external force, mutual synchronization of periodic and chaotic systems, as well as of mutual synchronization of two and more chaotic systems are discussed.

11A63. Accelerated iterative method for the dynamics of constrained multibody systems. - Kisu Lee *(Dept of Mech Eng, Chon Buk Natl Univ, Chon Ju, Chon Buk 560-756, Korea).* Comput Mech 12(1-2) 27-38 (Jun 1993).

An accelerated iterative method is suggested for the dynamic analysis of multibody systems consisting of interconnected rigid bodies. The Lagrange multipliers associated with the kinematic constraints are iteratively computed by the monotone reduction of the constraint error vector, and the resulting equations of motion are easily time-integrated by a well established ODE technique. The velocity and acceleration constraints as well as the position constraints are made to be satisfied at the joints at each time step. Exact solution is obtained without the time demanding procedures such as selection of the independent coordinates, decomposition of the constraint Jacobian matrix, and Newton Raphson iterations. An acceleration technique is employed for the faster convergence of the iterative scheme and the convergence analysis of the proposed iterative method is presented. Numerical solutions for the verification problems are presented to demonstrate the efficiency and accuracy of the suggested technique.

11A64. Sufficient conditions for penalty formulation methods in analytical dynamics. - AJ Kurdila *(Dept of Aerospace Eng, Texas A&M Univ, College Station TX 77843-3141)* and FJ Narcowich *(Dept of Math, Texas A&M Univ, College Station TX 77843-3368).* Comput Mech 12(1-2) 81-96 (Jun 1993).

This paper derives sufficient conditions for the convergence of a class of penalty methods by extending the Rubin-Ungar theorem. One advantage of the approach taken in this paper is that considerable simplification of the original Rubin-Ungar derivation is achieved for the convergence of transverse constraint velocities. This paper also emphasizes the importance of maintaining a rank condition on the Jacobian of the constraint matrix. This is of particular importance in that one claimed benefit of certain penalty methods is that they are effective in cases in which the constraint Jacobian loses rank. For the class of penalty methods considered in this paper, if the Jacobian does not meet the specified rank conditions, a diverse collection of spurious, pathological responses can be obtained using this method. In one sense, this type of pathological response is worse then encountering a "configuration-singular" generalized mass matrix and having a simulation diverge; indeed, the *regularized* solution procedure can proceed along some incorrect trajectory with little to no indication that something is amiss.

11A65. Geometric methods in determining rigid-body dynamics. - GS Nusholtz *(Chrysler, 800 Chrysler Dr E, CIMS 483-05-10, Auburn Hills MI 48326-2757).* Exp Mech 33(2) 153-158 (Jun 1993).

This research develops a measurement system using linear accelerometers to determine the 3D, 6-dof, impact response of an anthropomorphic test device (dummy). A procedure using spherical geometric analysis (SGA) was developed. It uses three triaxial accelerometer clusters for determining angular velocity, angular acceleration, and linear acceleration. SGA differs in its calculation of angular velocity from other procedures which determine rigid-body motion. Unlike procedures which use linear accelerometers to determine angular velocity by integration of angular acceleration, SGA uses the topology of the sphere to obtain both angular acceleration and angular velocity through algebraic manipulation of the output from the linear accelerations. The validation of SGA is accomplished by the use of hypothetical as well as experimental data.

152A. GENERAL THEORY

11A66. Forced harmonic response analysis of nonlinear structures using describing functions. - O Tanrikulu *(Tubitak-Sage, PK 119 Bahcelievler, Ankara, Turkey),* B Kuran, HN Ozguven *(Dept of Mech Eng, Middle E Tech Univ, Ankara 06531, Turkey),* M Imregun *(Dept of Mech Eng, Imperial Col of Sci Tech and Med, London SW7 2BX, UK).* AIAA J 31(7) 1313-1320 (Jul 1993).

The dynamic response of multiple-dof nonlinear structures is usually determined by numerical integration of the equations of motion, an approach which is computationally very expensive for steady-state response analysis of large structures. In this paper, an alternative semianalytical quasilinear method based on the describing function formulation is proposed for the harmonic response analysis of structures with symmetrical nonlinearities. The equations of motion are converted to a set of nonlinear algebraic equations and the solution is obtained iteratively. The linear and nonlinear parts of the structure are dealt with separately, the former being represented by the constant linear receptance matrix [α], and the latter by the generalized quasilinear matrix [Δ] which is updated at each iteration. A special technique that reduces the computation time significantly when the nonlinearities are localized is used with success to analyze large structures. The proposed method is fully compatible with standard modal analysis procedures. Several examples dealing with cubic stiffness, piecewise linear stiffness, and coulomb friction type of nonlinearities are presented in the case of a ten-dof structure.

11A67. Normal modes for nonlinear vibratory systems. - SW Shaw and C Pierre *(Dept of Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109).* J Sound Vib 164(1) 85-124 (8 Jun 1993).

A methodology is presented which extends to nonlinear systems the concept of normal modes of motion which is well developed for linear systems. The method is constructive for weakly nonlinear systems and provides the physical nature of the normal modes along with the nonlinear differential equations which govern their dynamics. It also provides the nonlinear co-ordinate transformation which relates the original system co-ordinates to the modal co-ordinates. Using this transformation, we demonstrate how an approximate nonlinear version of the superposition can be employed to reconstruct the overall motion from the individual nonlinear modal dynamics. The results presented herein for nonlinear systems reduce to modal analysis for the linearized system when nonlinearities are neglected, even though the approach is entirely different from the traditional one. The tools employed are from the theory of invariant manifolds for dynamical systems and were inspired by the center manifold reduction technique. In this paper the basic ideas are outlined, a few examples are presented and some natural extensions and applications of the method are briefly described in the conclusions.

11A68. Note on modal summations and averaging methods as applied to statistical energy analysis. - AJ Keane *(Dept of Eng Sci, Univ of Oxford, Parks Rd, Oxford OX1 3PJ, UK).* J Sound Vib 164(1) 143-156 (8 Jun 1993).

In this note the power transmission between two, point spring coupled, axially vibrating rods under various conditions is examined. The effects of using a modal description for the rods, are examined, with particular attention being paid to the number of modes used when assessing energy flows. Also considered are the various methods commonly used to calculate the average energy flows for this system. These studies have been carried out as part of a larger study on variability in SEA predictions for more complex models. The differences between the averaging methods used are shown to be significant and demonstrate the inherent dangers of assuming that frequency and ensemble averages are equivalent, a common assumption of traditional SEA. The adoption of a modal description for the system being studied is seen to be sustainable provided that the correct number of modes is used within the calculations. This number rises with coupling strength and also if the point of coupling shows model coherence (such as occurs at the ends of the free-free rod). These results lend credence to the adoption of modal methods when studying SEA but indicate that frequency averaging should be handled with care.

152D. STOCHASTIC EFFECTS, INCL RANDOM EXCITATION

11A69. Chaotic behavior of a nonlinear oscillator. - Qin-Yuan Pei *(Changsha Railway Univ, Changsha, China)* and Li Li *(Peking Polytech Univ, Beijing, China).* Appl Math Mech 14(5) 395-405 (May 1993).

Behavior of bifurcation and chaos in a forces oscillator $x1 + \delta x1 + \omega^2{}_0 x1 - \beta x^2{}_0 = f\cos\omega\tau$ containing a square nonlinear term is investigated by using Mel'nikov method and digital computer simulations.

11A70. Non-conservatively loaded stochastic columns. - R Ganesan, TS Sankar *(Concordia Univ, Montreal, H3G 1M8, Canada),* SA Ramu *(Indian Inst of Sci, Bangalore, India).* Int J Solids Struct 30(17) 2407-2424 (1993).

A new FEM is developed to analyze non-conservative structures with more than one parameter behaving in a stochastic manner. As a generalization, this paper treats the subsequent non-self-adjoint random eigenvalue problem that arises when the material property values of the non-conservative structural system have stochastic fluctuations resulting from manufacturing and measurement errors. The free vibration problems of stochastic Beck's column and stochastic Leipholz column whose Young's modulus and mass density are distributed stochastically are considered. The stochastic FEM that is developed, is implemented to arrive at a random non-self-adjoint algebraic eigenvalue problem. The stochastic characteristics of eigensolutions are derived in terms of the stochastic material property variations. Numerical examples are given. It is demonstrated that, through this formulation, the FE discretization need not be dependent on the characteristics of stochastic processes of the fluctuations in material property value.

11A71. Spectral response of a bilinear oscillator. - RN Miles *(Dept of Mech and Indust Eng, SUNY, Binghamton NY 13902-6000).* J Sound Vib 163(2) 319-326 (May 1993).

An approximate analytical procedure is presented to estimate the response power spectral density of a randomly excited spring-mass-damper system having a bilinear spring. The approximate expression for the response spectrum is developed by representing the nonlinear oscillator as a linear system having a natural frequency that depends on the envelope of the random response. This approximate representation of the system leads to estimates of the response spectrum that agree extremely well with those obtained by direct numerical simulation of the governing equation.

11A72. Beam-like damper for attenuating transient vibrations of light structures. - LA Chen and SE Semercigil *(Dept of Mech Eng, McMaster Univ, Hamilton, ON, L8S 4L7, Canada)*. J Sound Vib **164**(1) 53-65 (8 Jun 1993).

When a flexible robot arm, a cantilevered beam type of structure, moves with a fast speed between workstations and is suddenly stopped after a new positioning is completed, excessive transient vibrations are produced as a result of the flexibility. An impact damping technique may be used to control these excessive transient vibrations. Effect of the orientation of the robot arm relative to the gravitational acceleration is investigated for the conventional impact damper. A new impactor, in the form of another cantilevered beam, is suggested here as an impact damper the performance of which is independent of the orientation of the arm. Design charts, produced from numerical simulations, are presented to demonstrate the vibration attenuation capability of the conventional and the proposed impact damper. Experiments are described briefly to confirm the validity of the numerical model.

11A73. Community response to aircraft noise around six Spanish airports. - A Garcia, LJ Faus *(Lab of Acoust, Appl Phys Dept, Univ of Valencia, Spain)*, AM Garcia *(Preventive Med and Public Health Dept, Univ of Valencia, Spain)*. J Sound Vib **164**(1) 45-52 (8 Jun 1993).

The community response to aircraft noise has been studied through a social survey. A total of 1800 persons living in the vicinity of six major Spanish airports have been interviewed at their homes concerning the environmental quality of the area, dissatisfaction with road traffic noise and aircraft noise, activities interfered with by noise, most disturbing aircraft types, and subjective evaluation of airport impact. All the responses obtained in this survey have been compared with aircraft noise levels corresponding to the residence locations of the people interviewed (values of NEF levels were calculated with the INM model). The results obtained in this work allow one to evaluate the impact of aircraft noise under a wide range of different situations.

11A74. Computing eigenvector derivatives in structural dynamics. - Zhong-Sheng Liu, Su-Huan Chen, You-Qun Zhao, Chun-Sheng Shao *(Center for Comput Mech, Jilin Univ of Tech, Changchun 130022, Peoples Rep of China)*. Acta Mech Solida Sinica **6**(3) 291-299 (Jul 1993).

This paper presents an improved modal superposition method for computing eigenvector derivatives in which the contribution due to the unavailable higher modes to the eigenvector derivatives is considered. The proposed approach not only improves the accuracy previously published method, but also provides error estimates for the computed results.

11A75. FEM for computation of structural intensity by the normal mode approach. - L Gavric and G Pavic *(Dept Acoustique, CETIM, BP 67, 60304 Senlis, France)*. J Sound Vib **164**(1) 29-43 (8 Jun 1993).

A method for numerical computation of structural intensity in thin-walled structures is presented. The method is based on structural FEs (beam, plate and shell type) enabling computation of real eigenvalues and eigenvectors of undamped structure which then serve in evaluation of complex response. The distributed structural damping is taken into account by using the modal damping concept, while any localized damping is treated as an external loading, determined by use of impedance matching conditions and eigenproperties of the structure. Emphasis is given to aspects of accuracy of the results and efficiency of the numerical procedures used. High requirements on accuracy of the structural response (displacements and stresses) needed in intensity applications are satisfied by employing the "swept static solution", which effectively takes into account the influence of higher modes otherwise inaccessible to numerical computation. A comparison is made between the results obtained by using analytical methods and the proposed numerical procedure to demonstrate the validity of the method presented.

11A76. Rayleigh quotient method for computing eigenvalue bounds of vibrational systems with interval parameters. - Zi-Ping Qiu, Su-Huan Chen, Jing-Xin Na *(Center for Comput Mech, Jilin Univ of Tech, Changchun 130022, Peoples Rep of China)*. Acta Mech Solida Sinica **6**(3) 309-318 (Jul 1993).

In this paper, an effective method, the Rayleigh quotient iteration, for computing the bounds of structures with interval parameters is presented. When the uncertainty of the structural parameters is described by using the interval, ie, an unknown-but-bounded version, the structural vibration eigenvalues will become the interval. It is desirable to give these interval eigenvalues. An application of this method is illustrated by a numerical example. The results show that the Rayleigh quotient iteration method is very effective for constructing the upper and lower bounds on the eigenvalues of structures with interval parameters.

11A77. Application of the harmonic balance principle to the nonlinear free vibration of beams. - MI Qaisi *(Dept of Mech Eng, Jordan Univ, Amman, Jordan)*. Appl Acoust **40**(2) 141-151 (1993).

This paper presents an analytical method for determining the vibration modes of geometrically nonlinear beams under various edge conditions. The method assumes a continuum periodic solution which allows the harmonic balance principle to be employed to derive modal components that satisfy the equation of motion exactly. Nonlinear normal modes are constructed from four such components and used to compute the natural frequencies for beams with restrained ends and for cantilevered beams. Numerical results for beams with restrained ends show good agreement with those available from other techniques.

11A78. Small vibrations of flexible bars by using the FEM with equivalent uniform stiffness and mass methodology. - DG Fertis and AO Afonta *(Dept of Civil Eng, Univ of Akron, Akron OH 44325-3905)*. J Sound Vib **163**(2) 343-358 (May 1993).

The object of this research is to calculate natural frequencies and mode shapes of a small oscillation vibration, superimposed on large static displacement, by using the FEM in conjunction with the equivalent uniform stiffness and mass method. The equivalent uniform stiffness and mass matrices are determined from the differential equation by using Galerkin's method. The analysis herein is three-fold. First, the large static equilibrium configuration of the deformed flexible beam is established. This is achieved by using the Euler-Bernoulli equation in conjunction with equivalent pseudo-linear and/or equivalent nonlinear systems of constant stiffness. This concept and methodology were used quite extensively by the authors to study large deformation characteristics of various flexible beam problems of uniform and variable stiffness and of arbitrary loading conditions (see, for example, the work of Fertis and Afonta, and Fertis and Lee). Secondly, the differential equation of motion for small amplitude vibrations from the large static equilibrium configuration is derived. Galerkin's technique is used to approximate the differential equation of motion. Finally, the natural frequencies of vibration and the associated mode shapes are determined by solving the resulting eigenvalue problem. A canned eigensolver from the University of Akron IMSL is used to extract the eigenvalues and eigenvectors. The concept of equivalent pseudo-linear systems of constant stiffness is used extensively in this research, in order to simplify the solution of these complex nonlinear problems.

11A79. Accurate free vibration analysis of clamped Mindlin plates using the method of superposition. - SD Yu and WL Cleghorn *(Dept of Mech Eng, Univ of Toronto, Toronto, ON, M5S 1A4, Canada)*. Trans Can Soc Mech Eng **17**(2) 243-255 (1993).

The method of superposition is further developed to analyze free flexural vibration of clamped rectangular Mindlin plates. Comparison of results given by Mindlin's theory of plates with those previously obtained by Reissner's theory has shown that the rotatory inertia does not significantly affect plate flexural vibration. Accurate eigenvalues are presented for a number of values of plate aspect ratio along with two representative values of thickness ratio.

11A80. Finite strip-elements for the dynamic analysis of orthotropic plate structures. - BW Golley and J Petrolito *(Dept of Civil Eng, Univ Col, Austral Defence Force Acad, Campbell ACT 2600, Australia)*. J Sound Vib **163**(3) 479-491 (22 May 1993).

A finite strip-element method is presented for the dynamic analysis of orthotropic plate structures. In the strip-element a hierarchical interpolation is used that is a combination of FE shape functions and trigonometric shape functions. A transformation of variables is used to calculate the strip-element stiffness and mass matrices. This enables continuous plates and plates with point and line supports to be analyzed. Convergence is rapid, with few hierarchical terms being required for engineering accuracy.

11A81. Generic free vibration of orthotropic rectangular plates with clamped and simply supported edges. - SD Yu and WL Cleghorn *(Dept of Mech Eng, Univ of Toronto, ON, M5S*

1A4, Canada). J Sound Vib 163(3) 439-450 (22 May 1993).

The generic free vibration of specially orthotropic rectangular plates with combinations of clamped and simply supported edges is investigated by the superposition technique. The introduction of affine transformation reduces the two rigidity parameters required for the free vibration analysis to one, making complete tabulation of computed eigenvalues much easier. Numerical calculations are performed on clamped plates, plates with one edge simply supported, and plates with two adjacent edges simply supported, along with a number of representative values of the generalized rigidity parameter and the affine aspect ratio.

11A82. Modeling the vibration restraints of wedge lock card guides. - DB Barker and YS Chen *(CALCE Electron Packaging Res Center, Univ of Maryland, College Park MD 20742).* J Electron Packaging 115(2) 189-194 (Jun 1993).

One of the most dominate parameters that influence the calculation of PWB's natural frequency is the boundary conditions along the edges of the board. A series of experiments was conducted with Calmark three and five-part wedge locks to determine the boundary condition restraint offered by these commonly used card guides. The wedge locks are modeled as simple supports preventing transverse deflection of the plate edge and as linear elastic springs restraining the rotation of the plate edge. The rotational spring constant for the wedge lock was then calculated in a semi-inverse manner by measuring the natural frequency response of a well-characterized plate.

11A83. Roles of domain decomposition method in plate vibrations: Treatment of mixed discontinuous periphery boundaries. - KM Liew, KC Hung, MK Lim *(Div of Appl Mech, Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263).* Int J Mech Sci 35(7) 615-632 (Jul 1993).

The detailed development of a domain decomposition method (DDM) for the vibrational modelling of rectangular plates with mixed-edge boundary conditions is presented. In the DDM, the complex plate domain is decomposed into small simple subdomains and the appropriate shape function of each subdomain is represented by sets of admissible orthogonal polynomials generated using the Gram-Schmidt recurrence process. The continuity matrices that couple the eigenvectors of adjacent subdomains are derived based on the satisfaction of continuity conditions along the interconnecting boundaries. The stiffness and mass matrices of each subdomain after pre- and post-multiplication by the respective continuity matrices are assembled to form the global stiffness and mass matrices. To demonstrate the effectiveness and accuracy of the DDM, a vibration study of several partially mixed edge plates have been carried out. Convergence tests for example problems are presented in which the accuracy of the results is established. The frequency parameters and mode shapes obtained, where possible, are verified by comparison with data published in the open literature.

11A84. Studies on dynamic behavior of a cantilever square plate with varying thickness. - PK Roy and N Ganesan *(Machine Dyn Lab, Dept of Appl Mech, Indian IT, Madras-600 036, India).* Comput Struct 47(6) 995-1003 (17 Jun 1993).

The effects of different types of variations in profile and thickness on the amplitude and the dynamic bending stresses of a square cantilever plate excited by a point harmonic load resonance has been investigated. A four-noded plate bending element has been used for the analysis. The response has been determined for the first three modes of vibration. In each case the results obtained for different thickness variations are compared with those of the uniform thickness plate. It is observed that considerable reductions in amplitude and/or bending stresses can be achieved by the proper selection of thickness variation.

11A85. Theoretical basis for the experimental realization of boundary conditions in the vibration analysis of plates. - AV Bapat *(Laser and Plasma Tech Div, PRIP Shed, Bhabha Atom Res Centre, Bombay 400 085, India)* and S Suryanarayan *(Dept of Aeronaut Eng, Indian IT, Bombay 400 076, India).* J Sound Vib 163(3) 463-478 (22 May 1993).

In the experimental analysis of beams and plates the realization of classical boundary conditions is one of the crucial prerequisites which governs the accuracy and reliability of the results obtained. The support structure used in the experimental set-up invariably has a small amount of flexibility when one wants it to be zero, and a large but finite flexibility when one wants it to be infinite. Hence one needs to evolve a criterion to be met by the design of the support structure to ensure that the edge conditions are simulated correctly. This paper is a study in this direction. A typical case of a rectangular plate with two opposite edges simply supported and uniform elastic restraint on the other two has been studied extensively. The numerical results presented clearly bring out the range of values and the interdependence of the translational and rotational flexibilities of the edge support for a good realization of classical boundary conditions. The application of the numerical results to a typical design of a simply supported edge is also presented.

11A86. Use of the substructure method for vibration analysis of rectangular plates with discontinuous boundary conditions. - KM Liew, KC Hung *(Div of Appl Mech, Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263),* KY Lam *(Dept of Mech and Prod Eng, Natl Univ, Kent Ridge Crescent, Singapore 0511).* J Sound Vib 163(3) 451-462 (22 May 1993).

A substructure method is presented for analysis of the free vibration of a rectangular plate with mixed edge boundary conditions. The method involves the partitioning of the entire plate domain into appropriate elements to approximate the deflection function of each element by a set of admissible orthogonal polynomials. The continuity conditions along the interconnecting boundaries provide the coupling between the coefficients of each element. Summing the strain and kinetic energies of each element, and minimizing the resulting Rayleigh quotient with respect to the unknown coefficients, leads to the governing eigenvalue equation for the entire plate. Several plate problems are solved to demonstrate the applicability and accuracy of the present method. Where possible, the results obtained are verified by comparisons with existing published values from the literature.

11A87. Vibration analysis of continuous plate structures using boundary integrals. - O Weiss and A Moshaiov *(Dept of Solid Mech Mat and Struct, Tel Aviv Univ, Tel Aviv 69978, Israel).* Comput Struct 47(6) 971-976 (17 Jun 1993).

The natural frequencies of thin continuous plates, including the influence of in-plane forces, are calculated using boundary integrals. This study deals in particular with continuous plate structures consisting of several fields of different thickness and possibly with the inclusion of internal supports. The concepts of compatibility and equilibrium conditions along the common boundaries have been imposed in conjunction with a BE formulation for each panel. Several examples are presented and the results are compared with analytical as well as FE solutions demonstrating the effectiveness of the formulation. Some numerical issues are discussed as well.

11A88. Vibration of rectangular Mindlin plates by the spline strip method. - T Mizusawa *(Dept of Construct and Civil Eng, Daido IT, Hakusuicho-40, Minami-ku, Nagoya 457, Japan).* J Sound Vib 163(2) 193-205 (May 1993).

This paper presents an analysis of the vibrations of rectangular Mindlin plates by the spline strip method. To demonstrate the convergence and accuracy of the method, several examples are solved, and results are compared with those obtained by analytical and other numerical methods. Stable convergence and excellent accuracy are obtained by using high order spline strip models. Frequencies of rectangular thick plates with several boundary conditions have been obtained and the results are presented in tabular form.

11A89. Magnetic damping effects on vibration of conductive shells. - Y Yoshida *(Nucl Eng Res Lab, Univ of Tokyo, 2-22 Shirakata-shirane, Tokai-mura, Ibaraki-ken 319-11, Japan),* K Miya, K Demachi, M Kurokawa *(Nucl Eng Res Lab, Univ of Tokyo, Tokai-mura Naka-gun Ibaraki, Japan).* Int J Appl Electromagnetics Mat 4(1) 1-11 (Jun 1993).

In conductors moving in magnetic field eddy current is induced by the electromotive force (given by v × B) that leads to the generation of Lorentz force acting against the original motion. Such kind of interaction between a moving conductor and a magnetic field is called magnetic damping. For thin structures of fusion reactors the damping effect is significant because the components are placed in a very strong magnetic field. In this paper two benchmark problems of the TEAM workshop were analyzed for vertifying the numerical code developed here. A simplified model of an ITER (International Thermonuclear Experimental Reactor) first wall was also analyzed to see the magnetic damping effect on the coupled vibration of the first wall under the magnetic environment of the ITER-CDA design. A verification of the code was done by the comparison between calculated and experimental results. The effect of wall thickness on the vibration was clarified.

11A90. Dynamic response of a rotating blade with time-dependent rotating speed. - TH Young and GT Liou *(Dept of Mech Eng, Natl Taiwan IT, Taipei, Taiwan, ROC).* J Sound Vib 164(1) 157-171 (8 Jun 1993).

The general vibration of a rotating blade with time-dependent angular speed is investigated in this paper. A simple plate model is used to represent the blade, and its angular speed is characterized as a small periodic perturbation superimposed on a constant speed. Due to this non-constant rotational speed, terms with time-dependent coefficients appear in the equations of motion, which results in parametric instability. The method of multiple scales is used to derive approximate solutions and expressions for the boundaries of the unstable regions. All cases of possible resonant combinations up to the second order are studied, and the effects of system parameters, such as the damping coefficient, aspect ratio, rotating speed and setting angle, on the boundaries of the unstable regions are also investigated.

11A91. Point-load solution and simulation of a flexible spinning disk using various disk-to-

baseplate air-flow models. - GG Adams *(Dept of Mech Eng, Northeastern Univ, Boston MA 02115).* Trib Trans 36(3) 470-476 (Jul 1993).

In magnetic and/or optical recording on flexible media, an elastic disk rotates at a constant angular velocity in close proximity to a stationary baseplate. Such a configuration can be used to stabilize the transverse motion of the flexible disk, whose natural frequencies and critical speeds would otherwise be too low for stability of the flexible-disk-to-head interface. In this investigation, the air-flow between the disk and the baseplate is accounted for by two foundation parameters, stiffness and damping, for each Fourier mode. The effect of using this new model and three other models on the pointload solution and on the simulation of the disk-to-head interface is investigated. Steady-state solutions are obtained by using an exponential Fourier series expansion in the circumferential direction and a finite difference approximation radially. The simulation solution also accounts for the effect of disk-to-head contact in an approximate manner. It is further shown that the use of a Fejer sum for the Fourier series can accelerate the convergence of the simulation solution.

11A92. Influence of external damping on the stability and response of a horizontal rotor with anisotropic bending stiffness. - C Rajalingham, RB Bhat, GD Xistris *(Dept of Mech Eng, Concordia Univ, Montreal, PQ, Canada).* Trib Trans 36(3) 393-398 (Jul 1993).

Design features, such as keyways of blind holes, produce noncircular cross-sections which introduce anisotropies in the bending stiffness characteristics of rotor shafts. Rotors with appreciable stiffness anisotropy have been found to exhibit vibrations at one-half the synchronous frequency. In horizontal single-disk rotors with anisotropic bending stiffness characteristics, gravity induces vibrations at one-half the synchronous frequency. Previous studies have neglected the damping effect of the surrounding medium and have predicted the operation of the rotor in between the two critical speeds to be unstable. This investigation examines the influence of external damping on rotor response to imbalance of gravity excitations and shows that sufficient amount of damping can suppress the reported instability caused by anisotropic bending stiffness characteristics.

11A93. Application of the classical Rayleigh-Ritz method in dynamics of circular arches. - B Olszowski *(Krakow Univ of Tech, Krakow, Poland).* Eng Trans 41(1) 3-20 (1993).

The paper deals with Rayleigh-Timoshenko and Bernoulli-Euler models of circular arches with extensible or inextensible axes clamped with free radial sliding at both ends. The general algebraic equation defining the eigenproblem has been derived from Hamilton's principle. Spectra properties of the models were analysed by means of the classical Rayleigh-Ritz approximation method. Eigenfrequencies as functions of the subtending angle of the arch are plotted and tabulated.

11A94. Design of steel frames for specified seismic member ductility via inverse eigenmode formulation. - Tsuneyoshi Nakamura, M Tsuji, I Takewaki *(Dept of Architec, Kyoto Univ, Sakyo-ku, Kyoto 606, Japan).* Comput Struct 47(6) 1017-1030 (17 Jun 1993).

A new direct method of ductility design is presented for planar moment-resisting steel frames such that a set of member stiffnesses and the corresponding member strengths of a frame with realistic cross-sectional proportions are found for a specified distribution of member ductility factors under design major earthquakes. An inverse method of stiffness design is developed such that every predominant member-end strain in a frame under design earthquakes estimated on the basis of lowest eigenvibration would coincide with the specified value. A concept called "a set of similar cross-sections" is introduced to make it possible to obtain a set of members with realistic cross-sectional proportions. It is then shown that this inverse formulation for specified predominant member-end strains is quite useful for developing a direct stiffness design method for specified mean maximum member-end strains under design earthquakes.

11A95. Kinematic model for dynamic analysis of space frames. - R Karpurapu *(Dept of Civil Eng, Royal Military Col, Kingston, ON, K7K 5L0, Canada)* and M Yogendrakumar *(Golder Assoc, 224 W 8th Ave, Vancouver BC, V5Y 1N5, Canada).* Comput Struct 47(6) 945-955 (17 Jun 1993).

This paper presents a kinematic model for dynamic analysis of framed structures. The accuracy of the proposed method is demonstrated by analyzing the dynamic responses of two space frames of varying stiffness properties.

11A96. Dynamic response of sandwich beams with an adhesive damping layer (generalized Maxwell model for a viscoelastic adhesive layer). - T Fujii *(Dept of Mech Eng, Doshisha Univ, Kyoto 602, Japan).* Int J Adhesion Adhesives 13(3) 201-209 (Jul 1993).

A simple numerical method using a 1D approximation is presented for analyzing the dynamic response of adhesively bonded sandwich beams. The viscoelastic characteristics of the adhesive damping layer are represented by a generalized Maxwell model. Combining an incremental constitutive equation for a generalized Maxwell model solid between time t and $t + \Delta t$ with the FE discretization gives incremental equations of motion with respect to time for each element. A new method is proposed to obtain the frequency response function numerically. An impact test was carried out on a cantilever sandwich beam having an adhesive damping layer. Good agreement between the experimental and calculated results confirms the validity of the present method.

11A97. Vibration and damping analysis of multi-span sandwich beams with arbitrary boundary conditions. - S He *(Associated Spring, 10 Main St, Bristol CT 06010)* and MD Rao *(Dept of Mech Eng and Eng Mech, Michigan Tech Univ, Houghton MI 49931).* J Sound Vib 164(1) 125-142 (8 Jun 1993).

This paper presents an analytical model for the study of the coupled transverse and longitudinal vibration of multi-span sandwich beam systems with arbitrary boundary conditions. The energy method and Hamilton's principle approach is used to derive the governing equations of motion and the natural and forced boundary condition equations for each span. The shear, longitudinal and transverse strain energy of the adhesive layer are included in the analysis, together with the transverse and the longitudinal inertia of the composite beam system. A matrix equation to obtain the system natural frequencies and loss factors is developed based on the governing equations of motion for individual spans and system boundary and continuity conditions. Possible boundary conditions that can be programmed to obtain numerical solutions are discussed. Numerical results are generated for an example case of a two-span sandwich beam. The effects of the adhesive thickness, location of the intermediate support, operating temperature and the damping material properties on the system resonance frequency and modal loss factor are studied for the example case.

154N. COMPOSITE MATERIALS

11A98. Active vibration control of 1D piezoelectric laminates. - M Pietrzakowski *(Inst of Machine Des Fund, Warsaw Univ of Tech, Poland).* J Theor Appl Mech 31(3) 637-655 (1993).

In this paper a theoretical model of a simply supported three-layer 1D plate with a distributed actuator-sensor pair has been examined. A velocity feedback control is used to achieve active damping of structure. The transfer functions relating the out-of-plane deformation to the actuator voltage input for the system without control loop and for the system with velocity feedback as well as the open-loop transfer function are obtained. The numerical results show the influence of the actuator-sensor location and controller parameters on the modal system response.

11A99. FE analysis of damping the vibrations of laminated composites. - R Rikards, A Chate, E Barkanov *(Riga Tech Univ, Kalku St 1, Riga LV 1047, Latvia).* Comput Struct 47(6) 1005-1015 (17 Jun 1993).

There are several ways of decreasing the vibration energy of structures, such as diminishing the source energy, designing structures with desired eigen-frequencies and excitation frequencies, using materials that have damping properties, etc. Special damping layers made of various viscoelastic materials are widely applied in structures subjected to dynamic loading, especially those used in ship building and aerospace technology. A typical structure is that whose basic layer is covered with a damping layer and a thin constraining layer. Such classical sandwich structures have been widely investigated, especially with reference to the analysis of elastic vibrations.

11A100. Analytical and numerical study of nonlinear behavior of the electromechanical system. - J Awrejcewicz *(Univ of Tech, Lodz, Poland).* J Tech Phys 34(1) 57-68 (1993).

The nonlinear behavior of a generator with an amplifier (modeled by a simple oscillator) supplying a current to the string embedded in the electromagnetic field is analyzed. The dynamics of this system is governed by a set of ordinary and partial differential equations and integral equations with a time delay. The method of averaging proposed and the symbolic computations applied lead to the set of four averaged amplitude ordinary differential equations. The numerical analysis reveals interesting nonlinear phenomena.

11A101. Application of the harmonic acceleration method for nonlinear dynamic analysis. - I Senjanovic *(Fac of Mech Eng and Naval Architec, Univ of Zagreb, Zagreb, Croatia)* and Z

Lozina *(Fac of Elec and Mech Eng and Naval Architec, Univ of Split, Split, Croatia)*. Comput Struct 47(6) 927-937 (17 Jun 1993).

The application of the harmonic acceleration method, which shows some advantages in linear transient vibration analysis compared to the other commonly used methods, is extended to nonlinear problems employing the mode superposition technique and an iteration procedure. Stability analysis shows that the method is unconditionally stable. A higher degree of accuracy is achieved. The efficiency of the method is illustrated by some numerical examples.

11A102. Eigensolutions sensitivity for nonsymmetric matrices with repeated eigenvalues. - A Luongo *(Dept of Struct Eng, Univ of L'Aquila, Monteluco Roio, 67040 L'Aquila, Italy)*. AIAA J 31(7) 1321-1328 (Jul 1993).

A perturbation algorithm is developed for evaluating eigenvalue and eigenvector directional derivatives of nonsymmetric defective matrices. Some properties of these matrices are recalled; in particular, chains of generalized right and left eigenvectors and their orthogonal properties are defined. Small perturbations of the matrix are then considered. An asymptotic expansion of the eigensolutions of the perturbed problem is obtained in terms of noninteger powers of the perturbation parameter. Marked sensitivity of the eigensolutions is highlighted. Particular attention is devoted to the eigenvectors of the perturbed system and to the strong coupling that occurs between the chains. An example is developed to illustrate the algorithm and compare perturbative and numerical solutions.

11A103. Linear system response by DFT: Analysis of a recent modified method. - JF Hall and JL Beck *(Div of Eng and Appl Sci, 104-44 Dept of Civil Eng, California IT, Pasadena CA 91125)*. Earthquake Eng Struct Dyn 22(7) 599-615 (Jul 1993).

An analysis of a recent modified frequency-domain procedure for computing the response of linear systems using the fast Fourier transform algorithm is described. This modified procedure eliminates the appended free-vibration interval that is used in the standard approach. The duration of the period of computation still needs to be longer than that of the response interval of interest, but only slightly. Reducing the period of computation lowers the number of frequencies at which the transfer function needs to be defined. The major drawback of the method is a high sensitivity to errors in the computed values of the transfer function, which reduces the role of interpolation in the transfer function definition. The modified method is related to the discrete Laplace transform.

11A105. Hovercraft overwater heave stability. - MJ Hinchey *(Ocean Eng Group, Memorial Univ of Newfoundland, St John's, NF, A1B 3X5, Canada)* and PA Sullivan *(Inst for Aerospace Stud, Univ of Toronto, Downsview, ON, M3H 5T6, Canada)*. J Sound Vib 163(2) 261-273 (May 1993).

The dynamic heave stability of an air cushion vehicle or hovercraft hovering over deep water without forward motion is investigated here analytically. The principal feature of the analysis is the modeling of the motion of the water surface beneath the cushion caused by fluctuations in the pressure of the cushion or cavity air. This surface motion interacts with the vehicle dynamics by modulating both the volume and exit flow area of the cushion. For analytical simplicity, the geometry chosen for study is a 2D section of a rigid wall plenum chamber; this enables exploitation of classical linear wave formulas developed by Lamb for the surface motion generated by a spatially uniform surface pressure oscillating sinusoidally in time. To assess stability characteristics, the Nyquist criterion is applied to the linearized equations. Results are presented for two cases: one is representative of a small test vehicle, and the other of a large ice-breaking platform. They show that the water surface motion significantly affects stability through both of the proposed mechanisms, with cushion exit flow area modulation usually being more important. A feature of the results is that as the weight of a vehicle decreases many stability transitions occur. This suggests that simple guidelines for avoiding instability may not exist, so that stability augmentation devices may be required for vehicles designed to hover for extended periods over water.

11A106. Kevin-Helmholtz wave generation beneath hovercraft skirts. - PA Sullivan, C Walsh *(Inst for Aerospace Stud, Univ of Toronto, Downsview, ON, M3H 5T6, Canada)*, MJ Hinchey *(Ocean Eng Group, Memorial Univ of Newfoundland, St John's, NF, A1B 3X5, Canada)*. J Sound Vib 163(2) 275-282 (May 1993).

When a hovercraft is hovering over water, the air flow beneath its skirts can interact with the water surface and generate waves. These, in turn, can cause the hovercraft to undergo violent self-excited heave motions. This note shows that the wave generation is due to the classical Kelvin-Helmholtz mechanism where, beyond a certain air flow rate, small waves at the air-water interface extract energy from the air stream and grow.

156I. AIRCRAFT

11A107. Analysis of helicopter spatial motion dynamics for different models of induced velocity field. - Z Dzygadlo and G Kowaleczko *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 42(1) 3-31 (1993).

A spatial motion dynamics of a helicopter is discussed for three known from literature models of velocity field induced in the lifting rotor zone. There are the constant distribution of velocity and the Glauert and Mangler-Squire models, in which the velocity distribution depends on the azimuth and radius. A helicopter own motions were studied without and with consideration the coupling between the longitudinal and lateral motion for three mentioned above the induced velocity models.

11A108. Analysis of spatial motion dynamics of a helicopter for various models of the induced velocity field. - Z Dzygadlo and G Kowaleczko *(Military Univ of Tech, Warszawa, Poland)*. J Tech Phys 34(2) 119-143 (1993).

Problems of dynamics of spatial motion of a helicopter are considered making use of the three models of induced velocity field over the region of the main rotor, which are known from the literature. They are: the uniform velocity distribution and the Glauert and Mangle-Squire models, in which the velocity depends on the azimuth and the radius. The natural motions of the helicopter have been studied for the three models of induced velocity mentioned above, the couplings between the longitudinal and lateral motions being and not being taken into consideration.

11A109. FE analysis of natural vibrations of an aeroplane with asymmetric variable wing geometry. - J Blaszczyk *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 79-100 (1993).

A dynamic model of an aeroplane with an aerofoil which can rotate in its plane about a cylindrical joint located on the fuselage. In the general case the aeroplane under consideration is an asymmetric structure, which means the existence of a coupling between the longitudinal and lateral motions. Equations of dynamic equilibrium of deformable assemblies are established by means of the FE technique and multistage synthesis of a structure. The vibration spectrum of an aeroplane are calculated of such configuration has been calculated assuming uniform distribution of the mass and the elastic parameters of assemblies, if the rotation angle of the wing varies within a range $x_s = 0$ to 70°.

11A110. Numerical analysis of aircraft free vibrations with unsymmetrical geometry of airfoil. - J Blaszczyk and W Krason *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 42(1) 33-45 (1993).

The results are presented of numerical analysis of an aircraft with unsymmetrical alteration of the airfoil geometry, the dynamic model of which has been proposed earlier. The variation in oscillation spectrum for hypothetical aircraft of constant mass and geometrical parameters have been studied within the range of 0 - 70° for the rotation angle of airfoil. The conclusions are presented connected with accepted for the aircraft the aerodynamic constructional configuration, resulting from the studied spectrum.

11A111. Add-on suspension for controlling the vibrations of shafts accelerating to supercritical speeds. - TP Turkstra and SE Semercigil *(Dept of Mech Eng, McMaster Univ, Hamilton, ON, L8S 4L7, Canada).* J Sound Vib 163(2) 327-341 (May 1993).

An add-on switching support is proposed to limit the transient vibrations of a flexible beam by continuously varying its displacement response. A FE technique has been utilized to simulate the dynamic response of a flexible shaft operating at supercritical speeds. During acceleration, amplitude reductions of 66% are obtained with the actuation of the add-on support. Experimental verification is also described, achieving comparable amplitude reductions.

11A112. Development of an electrical controllable detuner for shaftings of combustion engines. - H Brunk *(Germanischer Lloyd, Vorsetzen 3203 65 Elbchaussee 277, 2000 Hamburg 11, Germany).* Ship Tech Res 40(2) 95-106 (May 1993).

For power packages with internal combustion engines the electrical, controllable vibration detuner in a novel, interesting alternative to traditional torsional vibration dampers. It combines simple structures with high efficiency and controllability and needs no maintenance. For laboratory tests a detuner for translational vibrations was built and tested. Experimental results were confirmed by FE-computations of the magnetic field. A rotational vibration detuner for a marine propulsion system was designed and simulated on a computer for examining its efficiency and for testing different control concepts.

11A113. Study and performance evaluation of some nonlinear diagnostic methods for large rotating machinery. - Liangsheng Qu, Ailin Xie, Xiao Li *(Res Lab of Machinery Surveillance and Diagnostics, Xian Jiaotong Univ, Xian 710049, ROC).* Mech Machine Theory 28(5) 699-713 (Sep 1993).

In this paper, some nonlinear diagnostic methods for large rotating machinery are introduced and evaluated from the practitioners' points of view, ie, their sensitivity to nonlinear phenomena, their applicability in machinery diagnostic practice, their effectiveness in computer execution and finally, their acceptability in the enterprises. The evaluated methods are pseudo-phase diagrams or limit cycle detection, singular spectrum analysis, the Wigner distribution and the Kullback index of the complexity based on information theory. Examples show the pseudo-phase diagrams are the most convenient for on-line diagnostics. It can be directly applied in the productional practice, while all the other methods can be used as supplementary diagnostic measures.

11A114. Optimum damping in linear isolation systems. - JA Inaudi and JM Kelly *(Dept of Civil Eng, UCB EERC, Richmond Field Sta, 1301 S 46th St, Richmond CA 94804).* Earthquake Eng Struct Dyn 22(7) 583-598 (Jul 1993).

Optimum isolation damping for minimum acceleration response of base-isolated structures subjected to stationary random excitation is investigated. Three linear models are considered to account for the energy dissipation mechanism of the isolation system: a Kelvin element, a linear hysteretic element and a standard solid linear element, commonly used viscoelastic models for isolation systems comprising natural rubber bearings and viscous dampers. The criterion selected for optimality is the minimization of the mean-square floor acceleration response. The effects of the frequency content of the excitation and superstructure properties on the optimum damping and on the mean-square acceleration response are addressed. The study basically shows that the attainable reduction in the floor acceleration largely depends on the energy dissipation mechanism assumed for the isolation system as well as on the frequency content of the ground acceleration process. Special care should be taken in accurately modeling the mechanical behavior of the energy dissipation devices.

11A115. Passive vibration control scheme using circular viscoelastic waveguide absorbers. - YS Shin, SJ Watson, KS Kim *(Dept of Mech Eng, Naval Postgraduate Sch, Monterey CA 60439).* J Pressure Vessel Tech 115(3) 256-261 (Aug 1993).

A waveguide absorber is a device mounted on a vibrating structure at the selected points to transfer energy from the structure to the device which dampens the energy. The waveguide absorbers reported here are made of viscoelastic material which absorbs vibration energy and dissipates it in the form of heat. The novelty of this approach to damping is the simplicity of application and the effectiveness in the braodband frequency range with relatively less material. In this study, the impedances of the circular viscoelastic waveguide absorbers were evaluated experimentally at different temperatures and the results were compared with those of prediction. The application of the waveguide absorbers in the most effective manner to maximize damping of the structure is also studied. The impedance matching techniques were studied to minimize the vibration amplitude of the structure.

156Y. COMPUTATIONAL TECHNIQUES

11A116. Identification and control of flexible civil structures with time delays. - M Abdel-Rohman *(Dept of Civil and Comp Eng, Kuwait Univ, PO Box 5969, Kuwait)*, OA Sebakhy *(Dept of Elec and Comput Eng, Kuwait Univ, PO Box 5969, Kuwait)*, M Al-Halabi *(Dept of Civil and Comp Eng, Kuwait Univ, PO Box 5969, Kuwait).* Comput Struct 47(6) 977-986 (17 Jun 1993).

The identification of flexible civil structures as discrete-time mathematical models in a ready form for computer control is shown by using a simple identification technique and neglecting the noise problem. The use of a control mechanism for the purpose of modeling and also for the control of the flexible structure justifies the noise-free consideration. The effect of time delay during a control process on the dynamics and stability of the structural systems is shown in illustrative examples. The design of a feedback control law to compensate for the detrimental effect of time delay is given with an application to control the response of a flexible frame structure using a tendon control mechanism.

11A117. Neural networks for computing in structural analysis: Methods and prospects of applications. - S Kortesis and PD Panagiotopoulos *(Dept of Comput Sci, Sch of Tech, Aristotle Univ, GR-54006 Thessaloniki, Greece).* Int J Numer Methods Eng 36(13) 2305-2318 (15 Jul 1993).

A neural network model is proposed and studied for the treatment of structural analysis problems. Both the cases of bilateral and unilateral constraints are considered and Hopfield-like neural models are proposed. Moreover, new results, generlizing the results of Hopfield and Tank, are obtained. Numerical applications illustrate the theory and show clearly the advantages of the neural network approach. Finally, the parameter identification problem is formulated and solved as a learning problem for a neural network.

11A118. Superelement method for transient dynamic analysis of structural systems. - MV Belyi *(Dept of Appl Math, Moscow Civil Eng Inst, 129337 Yaroslavskoe Shosse 26, Russia).* Int J Numer Methods Eng 36(13) 2263-2286 (15 Jul 1993).

A superelement algorithm for the transient dynamic analysis of structural systems is presented. The method represents a generalization of existing static and dynamic superelement (substructure) algorithms. Natural frequencies and modal spaces of a fixed boundary substructure are used to obtain equations of motion of a superelement. An implicit time-stepping algorithm is presented for the numerical solution of a resulting superelement system of equations of motion. Numerical examples are given to illustrate the presented approach. The method is believed to be effective for large-scale problems of structural analysis.

11A120. Discrete model of wave propagation in a nonprismatic bar with rigid unloading characteristics. - Z Szczesniak *(Military Tech Acad, Warszawa, Poland).* Eng Trans 41(1) 77-96 (1993).

A discrete model is proposed for the propagation of waves in a nonprismatic bar made from a material whose unloading characteristic is rigid. Arbitrary time-dependent applied load is considered. In such a situation the modelling of wave propagation must allow in each cross-section for multiple effects of its alternating rigid and activated behavior. These effects are nonlinear and thus it is very difficult to approach them analytically. An algorithm for numerical solutions is proposed and errors of the results are discussed. Effectiveness and applicability of the model are illustrated by means of numerical examples.

158G. NONLINEAR MOTIONS

11A121. Nonlinear thermoelastic solid with uniaxial wave propagation. - MC Singh *(Dept of Mech Eng, Univ of Calgary, Calgary, AB, T2N 1N4, Canada)* and DVD Tran *(Combustion Dyn, Medicine Hat, AB, Canada)*. Trans Can Soc Mech Eng 17(2) 229-242 (1993).

This study is devoted to an examination of wave motion in nonlinear thermoelastic solids. For this purpose, a new materially nonlinear constitutive relation for thermoelastic solids has been developed. The development makes use of the principles of continuum thermomechanics and takes into account Gibb's free energy. On the basis of the nonlinear constitutive relations so developed the fundamental equations of wave propagation for a nonlinear thermoelastic uniaxial solid have been constructed. These are further simplified for a nonconducting nonlinear uniaxial material. The initial conditions and boundary conditions are stated. The jump conditions for simple waves and shock waves in such a material are derived. Shock amplitude relation has been obtained on the basis of kinematic compatibility relations. Solution of the system of basic equations, with boundary conditions, initial conditions and jump and shock conditions at the wave front has been obtained by the method of characteristics and a combination of finite difference and FEM. Numerical results are presented in graphical form for uniaxial waves.

158H. PLASTIC, VISCOPLASTIC WAVES

11A122. Isothermal and adiabatic flow laws of metallic elastic-plastic solids at finite strains and propagation of acceleration waves. - Nguyen Huu Viem *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(5-6) 595-602 (1992).

From the earlier proposed constitutive equations for metallic elastoplastic materials at finite strains with induced anisotropy, the flow laws for isothermal and adiabatic processes are derived and examined. If certain minor coupling effects are disregarded, the difference between them consists only in the hardening functions. It is shown that deviation from plastic normality may arise from the plastic spin. On the basis of these equations, we consider the propagation of acceleration waves and give the expressions for the eigenvalues. They reduce in the case of small deformations.

11A123. Propagation pressure of long cylindrical shells under external pressure. - JY Dyau and S Kyriakides *(Eng Mech Res Lab, Dept of Aerospace Eng and Eng Mech, Univ of Texas, Austin TX 78712-1085)*. Int J Mech Sci 35(8) 675-713 (Aug 1993).

Local imperfections induced in long tubes subjected to high external pressures can lead to local collapse, from which a propagating buckle can be initiated. This can result in catastrophic collapse of large sections of the structure. The *propagation pressure* is the lowest pressures at which such a buckle will propagate. For common structural metal tubes with diameter-to-thickness ratios of less than 100, the propagation pressure is typically half an order of magnitude lower than the collapse pressure of the intact tubes. As a result, the design of several tubular structures with external pressure loading requires that the collapse and propagation pressures be accurately known. This paper deals with the experimental and analytical challenges of establishing the propagation pressure. A special purpose 3D analysis, in combination with experimental observations and results, is used to demonstrate a mechanism of initiation of propagating buckles in long tubes, to study the parametric dependence of the propagation pressure and to illustrate the effect of axial tension on the propagation pressure. Propagation pressures predicted with this analysis are used to evaluate the strengths and weaknesses of simpler models developed in the past.

158I. VISCOELASTIC WAVES

11A124. Couple-stress effect on the propagation of waves in a thermo-visco-elastic layer. - TK Das, A Mukherjee *(Indian Inst of Mech of Continua, 201 Manicktala Main Rd, Suite 42, Calcutta 70054 W Bengal, India)*, RP Sengupta *(Dept of Math, Univ of Kalyani, W Bengal, India)*. Acta Geophys Polonica 40(3-4) 235-246 (1992).

The aim of this paper is to study the effects of couple-stress on the 2D thermo-visco-elastic wave propagation in an elastic solid layer of finite thickness. Considering the linearized theory of couple-stress visco-elasticity and using the influence of thermal field of thermo-visco-elasticty, firstly the field equations of motion have been derived. The displacement equations of motion have been solved by introducing two displacement potential functions. Making use of the boundary conditions for stresses, couple-stresses, viscosity and radiative conditions for temperature the wave velocity equation for propagation of 2D waves has been derived. It is then discussed for certain interesting particular cases of wave propagation in layer and semi-space with particular emphasis on surface waves. This wave velocity equation tallies with the corresponding classical wave propagation problem when the couple-stress, thermal effect and viscosity effect are vanishing small.

11A125. Mechanical energy dissipation in small deformation elasticity and the simple analytic expression for the viscous kink-shaped solitary wave. - A Blinowski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(5-6) 615-620 (1992).

Wave propagation in the material abruptly changing its elastic moduli with the change of the deformation sign is considered. According to Cz Eimer, such a material models the behavior of a cracked linear elastic medium under 1D deformation. The solution obtained earlier for the shock propagation is compared now with the, proposed by the present author, simple analytic expression for diffuse shock propagation in Eimer's material endowed with the Voigt viscosity. It is shown that neither the propagation velocity, nor the total mechanic dissipation powers depends on the viscosity coefficient. These quantities retain, for arbitrary viscosity, the same values as in the case of discontinuity propagation in a purely elastic material. The slope of stress (strain) wave-profile changes with the viscosity change, tending to infinity if the latter tends to zero. The results obtained prove that an apparent paradox of a well-defined dissipation power, which can be calculated in the framework of purely elastic model within the small deformation approach in spite of the fact, that even the dissipation mechanism had not been defined earlier, can be explained on the basis of the limit transition for the viscoelastic solution.

158Q. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

11A126. Diffraction by a half-plane in a chiral medium (normal incidence). - S Przezdziecki *(Inst of Fand Tech Res, Polish Acad of Sci, Swietokrzyska 21, Warszawa, Poland)*. Acta Phys Polonica A 83(6) 739-750 (Jun 1993).

An exact, closed form solution is presented for a diffraction problem by a half-plane embedded in a chiral medium. The incidence direction of an electromagnetic plane wave is assumed to be normal to the edge of the half-plane. The problem has been reduced to a boundary value problem for two modal potentials satisfying distinct Helmholtz equations and coupled by the boundary conditions at the half-plane. A solution is constructed with the aid of the Wiener-Hopf technique. A basic feature of the problem is its two-mode character excited by: two families of diffracted rays, reflection coupling of the modes, excitation of lateral waves.

11A127. Diffraction of torsional elastic waves by a rigid annular disc at a bimaterial interface. - SC Mandal and ML Ghosh *(Dept of Math, N Bengal Univ, Darjeeling, India)*. Eng Trans 41(1) 97-116 (1993).

The problem of diffraction and normally incident torsional wave by an annular rigid disc lying at the interface of two bonded dissimilar semi-infinite elastic media is analysed. The three-part mixed boundary value problem is reduced to the solution of a set of integral equations which are solved by using iterative technique for low frequency, assuming that the ratio of the inner and outer radii is small. The stress distribution on the disc, the torque and far-field amplitudes of the displacement in both the media are evaluated. The variation of dynamic stress intensity factors with normalized frequency for various values of the material parameters, and also the variation in far-field amplitude with the polar angles for a fixed radial distance have been shown by means of graphs.

11A128. Extended X-ray bremsstrahlung isochromat fine structure. - E Sobczak *(Inst of Phys, Polish Acad of Sci, Al Lotnikow 32-46, 02-668 Warszawa, Poland)*. Acta Phys Polonica A 83(2) 135-156 (Feb 1993).

Main aspects concerning a new method of extended X-ray bremsstrahlung isochromat fine structures (EXBIFS) are specified and discussed. The EXBIFS effect is studied here by application of a single-scattering theory, which explains well the experimental phenomenon that EXBIFS of Cu and Pd is strikingly similar to the p partial density of states, although the s- and d-symmetry contributions are not negligible. The single-scattering model of EXBIFS has been successfully applied for explanation of temperature effects resulting in a smearing of oscillations for big k values. It is established here that interatomic distances can be evaluated from EXBIFS by means of the single-scattering theory and the Fourier analysis.

11A129. Fast algorithm to compute the wave-scattering solution of a large strip. - WC Chew and CC Lu *(Electromagnetics Lab, Dept of Elec and Comput Eng, Univ of Illinois, Urbana IL 61801)*. J Comput Phys 107(2) 378-387 (Aug 1993).

A truncated, nonuniform, finite array of strips does not have a closed form solution. Using translational symmetry, a recursive algorithm that calculates the scattering solution with $N\log^2 N$ computational complexity is described. First, the algorithm is validated with the method of moments for both the TM-to-z and TE-to-z polarizations. Then the scattering solution from a large strip is calculated for both TE and TM polarizations. The current distribution for the TE polarization shows small-length-scale oscillations not present in the TM polarization.

11A130. Scattering of compressional waves in an inhomogeneous medium. - BK Rajhans and SK Samal *(Dept of Appl Math, Indian Sch of Mines, Dhanbad 826004, India)*. Acta Geophys Polonica 40(3-4) 219-234 (1992).

Scattering of compressional waves by a rigid cylinder embedded in a inhomogeneous medium is considered. It is assumed that the velocity of compressional and shear waves are functions of the distance from the centre of the cylinder and are given by $\alpha = \alpha_0 r^q$, $\beta = \beta_0 r^q$, $q < 1$. The problem is investigated by the method of integral transformation developed by Friedlander. The resulting integrals are evaluated asymptotically to obtain the short-time estimate of the motion near the wave front in the illuminated zone. Numerical computations are done to investigate the behavior of reflected P and S waves, respectively. The results show that the expectations for a homogeneous earth are also valid in the heterogeneous case.

11A131. Transmission properties of single-mode W-type optical fibers. - J Tyl *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 15-28 (1993).

A theoretical model for analysis of the phenomenon of propagation of electromagnetic waves based on an approximation (by means of Chebyshev series) to the profile of the refracting index and the distribution of the fields in the waveguide has been presented. Numerical analysis was performed for the transmission problem of a signal through a cylindrical waveguide with inner cladding (type W). The dependence of the transmission parameters on the type of distribution of the refracting index in the core and the inner cladding has been investigated.

11A132. Analytical modeling of hammer impact for pile driving. - AJ Deeks and MF Randolph *(Dept of Civil Eng, Univ of W Australia, Nedlands 6009, W Australia)*. Int J Numer Anal Methods Geomech 17(5) 279-302 (May 1993).

Estimation of the drivability of piles requires modelling of the hammer impact in order to provide the input force wave at the pile head. Historically, this has been achieved through a numerical model of the hammer components (ram, cushion and anvil), which is then linked with that of the pile in order to effect the drivability analysis. This paper presents an analytical model of hammer impact, based on lumped ram and anvil masses separated by a cushion with internal damping, and connected to the pile which is modelled as a dashpot. Force-time responses derived from the analytical model are compared with actual field data, and also with results from commercially available numerical models of hammer impact. The analytical model is then used to explore the characteristics of hammer impact, with particular attention to combinations of parameters that lead to hammer bounce and, hence, significant loss of energy transferred to the pile.

11A133. Estimation of clearances and impact forces using vibroimpact response: Random excitation. - SQ Lin and CN Bapat *(Dept of Mech Eng, CCNY)*. J Sound Vib 163(3) 407-421 (22 May 1993).

A novel clearance estimation approach has been developed for a randomly excited vibroimpact system. The clearance estimates based on this approach were obtained using data from the mechanical analogue of an impact oscillator and simulation using a digital computer, and they reasonably agree with the actual clearances.

11A134. Extension of clearance and impact force estimation approaches to a beam-stop system. - SQ Lin and CN Bapat *(Dept of Mech Eng, CCNY)*. J Sound Vib 163(3) 423-438 (22 May 1993).

Three novel approaches to estimate clearances and impact forces, developed for a one-dof impact oscillator, have been extended to a simple undamped beam-stop system to demonstrate the applicability of the previously proposed methods. The case considered here is more practical, as the impact location is remote from the sensing location. The predictions of estimations of impact forces and clearances obtained using data from the mechanical experiments were compared with measured impact forces and actual clearances respectively, and indicated a good agreement.

11A135. High-order formulation of the water-wave problem. - M Glozman, Y Agnon, M Stiassnie *(Coastal and Marine Eng Res Inst, Fac of Civil Eng, Israel IT, Haifa 32000, Israel)*. Physica D 66(3-4) 347-367 (Jul 1993).

The water-wave problem has a Hamiltonian formulation as derived by Zakharov. This leads to coupled nonlinear evolution equations for discrete wave modes. Discrete spectra occur naturally for standing waves in a basin. For high enough order, high enough energy and a sufficient number of dof, chaos may emerge. We have derived the Hamiltonian and evolution equations to arbitrary order. The conditions for the convergence of the expansion of the Hamiltonian are discussed. We performed numerical studies of the interaction of two standing wave modes for various cases and for increasing order. Using Poincare sections, the onset of local chaos in resonance and near-resonance conditions is manifested. Chaos appears at low order models but vanishes with increasng order. The significance of the newly derived high-order formulation for water waves is clearly demonstrated.

11A136. Coastal amplification of a tsunami wave train. - B Hunt *(Dept of Civil Eng, Univ of Canterbury, Christchurch, New Zealand)*. J Hydraul Res 31(3) 415-423 (1993).

Steady-state wave solutions are obtained in closed form for two simple coastal geometries. The first model consists of two regions of constant depth separated by a step, and the second model consists of a constant-depth region joined by a step to a region in which the mean depth decreases linearly to a value of zero at the shore line. The step, which is used to model a continental shelf, can create resonance and large wave amplifications in both cases, but amplifications are found to be much greater for the second model. Furthermore, peak amplifications at resonance are found to not change with incident wave frequency for the first model but to increase with wave frequency for the second model. Finally, since wave amplifications in the second model depend very strongly on incident wave frequencies, periods are calculated for waves near the leading edge of a tsunami wave train moving through water of constant depth.

11T137. Interaction between two nonpropagating hydrodynamic solitons. - JR Yan, XH Yan, JQ You, JX Zhong *(China Center of Adv Sci and Tech (World Lab), PO Box 8730, Beijing 100080, Peoples Rep of China)*. Phys Fluids A 5(7) 1651-1656 (Jul 1993).

11A138. Singular behavior in the vicinity of intersection between the body and free surface. - Lin-sheng Zhu *(Huazhong Univ of Sci and Tech, Wuhan, China)* and Yi-shan Dai *(Shipbuild Eng Inst, Haerbin, China)*. Appl Math Mech 14(5) 459-468 (May 1993).

The singular behavior in the vicinity of intersection between the body and free surface is presented. It is shown that in the linear regime the singularity of velocity potential for transient problems is in $d^2 \ln d$. The singular behavior for harmonic problem is the same as the result for the transient problem. In particular, the singularity for the harmonic problem with infinite frequency is in $d^2 \ln d$ for velocity potential (d is the distance between field point and intersection).

11T139. Water wave refraction and diffraction over frictional topography. - Qihua Zuo, Guoquan Yao, Bingcan Ding *(Nanjing Hydraul Res Inst, Nanjing 210024)*. China Ocean Eng 7(1) 73-84 (1993).

This paper deals with permanent gravity-capillary waves on the interface with surface tension in a two-layer, inviscid, and incompressible fluid between two horizontal, rigid boundaries. It is shown that, if the Bond number τ, a nondimensional surface tension coefficient, is greater than some critical value τ_0, and the Froude number F is less than, but near some critical value F_0, there exists a solitary wave solution which decays to zero at infinity. When τ is less than τ_0, solitary waves plus a small oscillation at infinity will appear, and the existence of such type of solutions will be investigated in a subsequent paper. Discussions about several critical cases, such as τ and τ_0 or a density ratio near some critical value, are also given.

Extending the results of our previous study, we now investigate the propagation of interior shocks corresponding to the signaling problem of small-amplitude, high-frequency type. We derive a formula for the shock front and show that the previously constructed asymptotic solution is valid on both sides of this front. This solution is further distinguished to a higher order in which the effects of material inhomogeneity are accounted for. Moreover, if $\lambda = \lambda(u,x)$ represents the eigenvalue under consideration, we show that the single-wave-mode boundary disturbance can lead only to a λ-shock. We also derive an entropy condition for the shock wave. As an application for our theory, the fluid-filled hyperelastic tube problem is further examined and an example calculation made in which we show that a compressive shock wave is generated at the shock-initiation point. This demonstration is effected as a particular example of the solution to a general bifurcation problem.

11A146. Stability of shock waves. - AA Barmin and SA Egorushkin *(Res Inst of Mech, Moscow State Univ, Michurin prosp 1, 119 899 Moscow V-192, Russia)*. Adv Mech 15(1-2) 3-37 (1992).

The article presents summary of papers dealing with the stability of shock waves in the gas. The following problems are being considered: linear theory of stability, connection of stability with correct formulation of a certain mathematical problem, influence of shock wave structure on its stability, nonlinear theory of shock wave stability, stability of flow with shock waves. The article discusses some urgent problems to be solved.

11A147. Weak shock structure on the basis of modified hydrodynamical equations. - AD Khonkin and AV Orlov *(Tashkentskaya St 10-2-39, Moscow 109444, Russia)*. Phys Fluids A 5(7) 1810-1813 (Jul 1993).

The structures of a normal shock wave is calculated on the basis of the hydrodynamics of fast processes to investigate the validity of the theory for this classical problem. The analysis shows that the theory predicts the continuous shock profile to exist only for $M < 1.27$. The shock thickness and the asymmetry factors resulting from the Mott-Smith method, the Navier-Stokes and the Burnett equations, and also from the experiments and simulations are compared to the present results for a gas of Maxwell molecules.

11A148. Wave motion of a compressible viscous fluid contained in a cylindrical shell. - JH Terhune and K Karim-Panahi *(GE Nucl Energy, General Elec, San Jose CA 95125)*. J Pressure Vessel Tech 115(3) 302-312 (Aug 1993).

The free vibration of cylindrical shells filled with a compressible viscous fluid has been studied by numerous workers using the linearized Navier-Stokes equations, the fluid continuity equation, and Fiugge's equations of motion for thin shells. It happens that solutions can be obtained for which the interface conditions at the shell surface are satisfied. Formally, a characteristic equation for the system eigenvalues can be written down, and solutions are usually obtained numerically providing some insight into the physical mechanisms. In this paper, we modify the usual approach to this problem, use a more rigorous mathematical solution and limit the discussion to a single thin shell of infinite length and finite radius, totally filled with a viscous compressible fluid. It is shown that separable solutions are obtained only in a particular gage, defined by the divergence of the fluid velocity vector potential, and the solutions are unique to that gage. The complex frequency dependence for the transverse component of the fluid velocity field is shown to be a result of surface interaction between the compressional and vortex motions in the fluid and that this motion is confined to the boundary layer near the surface. Numerical results are obtained for the first few wave modes of a large shell, which illustrate the general approach to the solution. The axial wave number is complex for wave propagation, the imaginary part being the spatial attentuation coefficient. The frequency is also complex, the imaginary part of which is the temporal damping coefficient. The wave phase velocity is related to the real part of the axial wave number and turns out to be independent of frequency, with numerical value lying between the sonic velocities in the fluid and the shell. The frequency dependencies of these parameters and fluid velocity field modes shapes are computed for a typical case and displayed in nondimensional graphs.

11A149. Hydraulic forces acting on a circular cylinder with surface source of minute air bubbles and its cavitation characteristics. - A Ihara, H Watanabe, Hiroyuki Hashimoto *(Inst of Fluid Sci, Tohoku Univ, Sendai, Japan)*. J Fluids Eng 115(2) 275-282 (Jun 1993).

Experiments are performed by using two circular cylinders made of porous filter material, that is, bronze sintered compact, with a different filter size, respectively, in a water tunnel. The effects of minute air bubbles injected from the surface of the circular cylinder into its boundary layer on its hydraulic force characteristics are investigated over the Reynolds number $(1.2 \sim 4.2) \times 10^5$, changing the airflow rate of bubble injection. The pressure distributions on the porous cylinders are also measured. Their cavitation characteristics are studied, too. Compared with a smooth surface cylinder, the critical Reynolds numbers of the porous cylinders decrease owing to the increase in the surface roughness caused by the bronze particles which compose the sintered compact. The effects of the bubble injection on the hydraulic force characteristics are different according to the size of the bronze particles. Though a little difference is recognized, the hydraulic force characteristics show a similar tendency in both cases of bubble injection and cavitation occurrence.

11A150. FE analysis of lateral sloshing response in axisymmetric tanks with triangular elements. - F Ru-De *(Dept of Comput Sci and Info Math, Univ of Electro-Commun, Chofu-shi, Tokyo, Japan)*. Comput Mech 12(1-2) 51-58 (Jun 1993).

A FE analysis is presented for the sloshing motion of liquid-filled axisymmetric tanks during lateral excitation, for a circumferential mode number, m = 1, antisymmetric. The system of FE equations concerned is derived by means of variational principle. Linear basis functions associated with the regular triangulation of Friedrichs-Keller type was used. The analytical expressions of the mass and stiffness matrices for a FE were obtained. Numerical results of the free vibration for cases of annular and cylindrical tanks were obtained, and compared with existing experiments and other predicted results, showing a good agreement between the experiment and numerical results.

11A151. Effects of layer thickness on the vibration response of a plate-fluid layer system. - T Onsay *(Dept of Mech Eng, Michigan State Univ, E Lansing MI 48824-1226)*. J Sound Vib 163(2) 231-259 (May 1993).

Dynamic interaction between the bending vibrations of a plate and a fluid layer is investigated by using analytical and experimental methods. The frequency response behavior of the coupled plate-fluid layer system is studied, with emphasis on the influence of the layer thickness. The effects of compressibility, viscosity and inertia of the fluid are included in the analytical model. A critical layer thickness is introduced and utilized in the illustration of linear dynamic regimes of a fluid layer. A detailed analysis is carried out for the wave modes of the system, the free wave number of the fluid layer and for the mode shapes of the plate. The use of a powerful transfer matrix method is demonstrated in the formulation of the coupled plate-fluid layer system response. The drive-point mobility, the power flow and the resonance behavior of a physical system are analyzed at different layer thicknesses. Detailed experiments are conducted to confirm the predicted frequency response behavior of a particular plate-air layer system. The attenuation and frequency shift of the plate's resonances are demonstrated with experimental results. Air layer attenuation is found to be very effective in damping the low frequency flexural vibrations of the plate.

11A152. Method for suppressing the irregular frequencies from integral equations in water wave-structure interaction problems. - S Liapis *(Aerospace and Ocean Eng, VPI)*. Comput Mech 12(1-2) 59-68 (Jun 1993).

It is well known that at certain frequencies the boundary integral equation describing water wave-structure interactions does not have a unique solution. Large numerical errors occur in a frequency band width close to each "irregular" frequency and the fact that these frequencies are not a priori known for a given body adds to the severity of the problem. The present work describes a new method to suppress the influence of the irregular frequencies. The boundary integral equation is supplemented with a set of moment equations - the null-field equations. The resulting overdetermined system is then solved by a least squares procedure. It is shown that this procedure will produce a unique solution. Numerical results for a circular cylinder and a box barge demonstrate the effectiveness of the method.

11A153. Forced vibrations of a liquid filled shells of revolution. Bibliographical review. (Polish). - B Blocka *(Poland)*. Marine Tech Trans 3 5-24 (1992).

Two basic approaches to dynamic problems of shells of revolution filled with liquid is considered. The first one is a semi-analytical approach in which the governing equations of motion of the liquid are solved analytically and the governing equations of the shell motion are solved by means of numerical methods. The second approach is to make use of numerical methods for the liquid and the shell field. The later allows to solve wider class of interaction problems, but the former one leads, generally, to the systems of differential equations of a smaller size.

11A154. Influence of stator-rotor gap on axial-turbine unsteady forcing functions. - T Korakianitis *(Dept of Mech Eng, Washington Univ, Campus Box 1185, One Brookings Dr, St Louis MO 63130)*. AIAA J 31(7) 1256-1264 (Jul 1993).

This paper investigates the effects of stator-to-rotor axial gap on the 2D propagation of pressure disturbances due to potential-flow interaction between the blade rows and viscous-wake effects from upstream blade rows in axial-turbine-blade rotor cascades. Results are obtained by modeling the effects of the upstream stator viscous wake and potential-flowfield on the downstream rotor flowfield, and computing the unsteady flowfields in the rotor frame. The amplitudes of the two types of disturbances for typical turbines are based on a review of available experimental and computational data. The potential-flowfield is modeled as a sinusoidal pressure disturbance of amplitude 4% of the local pressure across the stator trailing edges that decays downstream. This potential-flow disturbance from upstream is affected by the potential-flowfield of the downstream cascade. The velocity wake is modeled as a Gaussian velocity defect of varying amplitude and width, depending on the stator-rotor gap between the blade rows. The wake amplitudes and widths are based on conservation of loss of incoming momentum to the rotor due to the wake. The axial gap between rotor and stator is varied to show how the two disturbances propagating in different directions reinforce or counteract each other at different stator-rotor gaps. The corresponding forces on rotor blades are computed for typical values of reduced frequency. Analyses of this type will enable turbomachinery designers to predict (and with geometric design modifications to reduce) the unsteady stresses acting on turbomachinery blades.

11A155. Dynamic FE analysis for interaction between two phase saturated soil foundation and platform. - Lingxi Qian, Wanxie Zhong, Hongwu Zhang *(Dalian Univ of Tech, Dalian 116023)*. China Ocean Eng 7(1) 21-29 (1993).

In this paper, the foundation soil of offshore structure is simulated as a two phase saturated porous medium. The dynamic equations of porous medium and FE formulation are given. For structural analysis, the technique of multilevel substructure is used, and the saturated soil analysis is set in the highest level substructure model. Based on these theories a dynamic FE analysis program DIASS for the analysis of interaction between the two phase ocean soil foundation and platform structures has been developed. A numerical example is given here to illustrate the influence of the pore water in soil on the structural response of an ocean platform.

11A156. Investigation of the solid-liquid phase transition for SnIn alloys by the positron annihilation method. - S Chabik, W Rudzinska *(Inst of Phys, Pedagogical Univ, Oleska 48, 45-052 Opole, Poland)*, M Szuszkiewicz *(Inst of Exp Phys, Univ of Wroclaw, pl Maxa Borna 9, 50-204 Wroclaw, Poland)*, C Szymanski *(Inst of Phys, Pedagogical Univ, Oleska 48, 45-052 Opole, Poland)*. Acta Phys Polonica A 83(3) 261-266 (Mar 1993).

The monovacancy formation energy in Sn-17 wt% In and Sn-32 wt% In was determined on the basis of the temperature dependence of the peak counting rate for these alloys. A sudden increase in the counting rate was observed between solidus and liquidus temperatures. This phenomena is connected with the formation of large defects acting as positron traps.

170C. EXPLOSION, DETONATION, DEFLAGRATION

11A157. Analysis of jet and slug parameters in process of jet formation by charges with lined wedge cavities Part I. The hydrodynamic steady-state theory. - E Wlodarczyk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 41(12) 13-42 (1992).

This paper considers stationary model of cumulation theory. It is presented extensive analysis of parameters of jet and slug. Direction of detonation wave-front propagation and its influence on the jet and slug are discussed. It is presented a method describing explosively formed penetrators employing stationary cumulation model.

11A158. Computer simulation of cumulation flux creation process and its influence on armour. - K Jach, R Swierczynski, E Wlodarczyk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 41(12) 43-60 (1992).

This paper presents complex, spatial 2D numerical model enabling computer simulation of shaped charge jet formation and estimation of the penetration depth, surface temperature of the crater etc. The model describing schaped charge includes elastovisco-plasticity equations describing process of deformation of conical liner and metal casing. The model is complemented by semi-empirical relations describing metal behavior under dynamic loading (EOS state equation, Steinberg-Guinan model and cracks formation model). The detonation products behavior was described by hydrodynamics equations considering the JWL state equations. Received solution enables description of time-spatial distribution of mass velocity and jet density. The hollowed crater depth was calculated with help of hydrodynamics theory. It was evaluated, that the surface layers temperature of the crater hollowed by active part of the jet, exceeds melting temperature of penetrated material and can achieve its evaporation point.

11A159. Geometric singular perturbation analysis of detonation and deflagration waves. - I Gasser and P Szmolyan *(Inst Angewandte Numer Math, Tech Univ Wien, Wiedner, Hauptstr 8-10, Austria)*. SIAM J Math Anal 24(4) 968-986 (Jul 1993).

The existence of steady plane wave solutions of the Navier-Stokes equations for a reacting gas is analyzed. Under the assumption of an ignition temperature the existence of detonation and deflagration wave close to the corresponding waves of the ZND-model is proved in the limit of small viscosity, heat conductivity, and diffusion. The method is constructive, since the classical solutions of the ZND-model serve as singular solutions in the context of geometric singular perturbation theory. The singular solutions consists of orbits on which the dynamics are slow-driven by chemical reaction and of orbits on which the dynamics are fast-driven by gasdynamic shocks. The approach is geometric and leads to a clear, complete picture of the existence, structure, and asymptotic behavior of detonation and deflagration waves.

11A160. Modification of JWL equation of state - W equation of state. - E Wlodarczyk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 41(10) 3-24 (1992).

In the paper modification of the JWL isentrope and equation of state for detonation products of condensed explosives is proposed. The modified state equation has been called briefly the W state equation. The JWL isentrope was replaced by the Poisson isentrope with so called effective exponent γw. Besides it the two-term isentrope with discrete variable exponent (γw, $\gamma k1$) was constructed, which covers the entire range of variation of the state parameters of detonation products of condensed explosives during the process of gas expansion. For a variety of detonation products of these materials the γw and $\gamma k1$ exponents enable reduction of 1D gas-dynamic equations to the Euler-Darboux equation having known general solution. It simplifies remarkable solution of the boundary problems of 1D gas dynamics with participation of detonation products of condensed explosives.

170P. OTHER TOPICS IN EXPLOSIONS AND BALLISTICS

11A161. Analysis of explosive compaction conditions of a cermet copper-aluminium oxide. - R Trebinski and E Wlodarczyk *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 3-13 (1993).

In the work the compaction process of a cermet copper-aluminium oxide in an explosion fixture with a shock adsorbing water layer has been analyzed. On the base of the mathematical modeling results of the wave processes, taking place in a multilayer cylindrical fixture loaded by a grazing detonation, pressure and temperature values have been appraised. Making use of the results of the theoretical estimations and the results of experiments, the conditions of explosion compaction have been estimated.

11A162. An analysis of the propellant gas outflow through the gap between the missile and the barrel surface. - A Paplinski and E Wlodarczyk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 41(10) 95-103 (1992).

Propellant gas pressure rise and the outflow of the gases through the interface between the missile and the gun tube face in the process of missile engraving into the barrel grooves is investigated. It was stated, that modification of missile barrel driving band characteristics enables to lower the propellant gases outflow and to restrain the erosive action of the gases upon the barrel surface.

11A163. Dynamical problems of aerial bomb motion processes family. - J Niczyporuk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 42(1) 47-62 (1993).

Description of a system of aerial bomb motion processes is proposed in the aiming consideration, in the form of performing the dependence between the regions of acceptable initial and aiming conditions, which is determined by kinetic operator L. A set of logically systematized problems explaining the fundamental concepts of the proposed theory are formulated. The method for investigation of solution set structure and the properties of evolution with respect to the initial conditions and parameters is presented. The methodology studies follows the need for the result suitability for solution of the superordinate problem of "unacceptable variance of bombarded processes".

11A164. Study of basic characteristics of aerial bomb fall processes system. - J Niczyporuk *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 42(1) 63-88 (1993).

A method is applied for modeling the dynamic properties of the bomb fall processes in a complex and aiming treatment in the form of the base variety: initial for release and aiming for fall. The problem has been solved for case of an object drop from the horizontal and diving flight in the range of small and medium angles of diving. The characteristics present the basic structures acceptable of description for bombardment process systems.

11A165. Transformations of graphite and boron nitrite in shock waves. - R Trebinski and E Wlodarczyk *(Warszawa, Poland)*. Biuletyn

Wojskowej Akademii Technicznej 41(10) 25-62 (1992).

In the present work the accessible information concerning polymorphous transformations of graphite and graphitic boron nitride is analysed. The peculiarities of dynamic compressibility curves of graphite and αBN are interpreted, basing on the data concerning the atomic mechanism of the transformation. It has been known that these peculiarities correspond to the formation of the wurtzitic modifications, ie, lonsdaleite and γBN. A survey of data concerning the mechanism of the new phase crystallization and the kinetics of the polymorphous transformation is preformed.

170Y. COMPUTATIONAL TECHNIQUES

11A166. Approximate analytical solution of the cylindrical detonation wave generated by the linear explosion. - Yi-wu Yuan *(Central S Univ of Tech, Changsha, China)*. Appl Math Mech 14(5) 437-441 (May 1993).

The solution of the cylindrical detonation wave generated by the linear explosion was obtained by numerical methods. In this paper, when the ratio of specific heat $\gamma >> 1$ by using the enlargement coordinate method, the first-order analytical solutions are obtained. The perturbation parameter is $\varepsilon = 1/\gamma_2$. The correction of these solutions is checked at the end of this paper.

172A. GENERAL THEORY

See the following:

11A53. Bifurcations and chaos in voice signals

172B. SOUND GENERATION BY MOVING SURFACES

See the following:

11A167. Low frequency aeroacoustics of buried nozzle systems

172C. SOUND GENERATION BY FLOW

11A167. Low frequency aeroacoustics of buried nozzle systems. - MV Taylor *(Int Comput, Lovelace Rd, Bracknell, Berkshire RG12 4SN, UK)*, DG Crighton *(Dept of Appl Math and Theor Phys, Univ of Cambridge, Silver St, Cambridge CB3 9EW, UK)*, AM Cargill *(Rolls-Royce, Moor La, Derby DE2 8BJ, UK)*. J Sound Vib 163(3) 493-526 (22 May 1993).

A simplified model of a "buried nozzle" aeroengine system is considered. The primary flow issues into a co-annular flow within a mixing chamber, and then the co-annular flow issues into the ambient medium from a secondary nozzle. Within the mixing chamber only fine scale mixing takes place, and shear layers within the mixing chamber and downstream of the secondary nozzle are assumed to sustain large scale instability waves. Excitation of this system is provided by low frequency plane waves, incident from upstream on the primary nozzle (and emanating from combustion processes in the hot core of an aeroengine). The response of this system, in the acoustic far field and in the mixing chamber, is obtained analytically from the asymptotic solution, at low frequency, of model sub-problems the solutions of which determine the wave reflection and transmission processes at the primary and secondary nozzles. In these sub-problems the shear layers are represented by vortex sheets and the nozzle walls by semi-infinite circular ducts, with Kutta conditions imposed on the unsteady flow at the primary and secondary nozzle lips. Analytical descriptions are given of the various wave modes (quasi-plane acoustic waves, and instability waves localized on the primary and secondary shear layers), of the acoustic field strength and directivity (essentially monopole, dipole, and quadrupole fields), and of the conditions under which near-resonant response may occur, with large amplitudes of the perturbations in the mixing chamber and in the acoustic field.

172D. SOUND WAVES IN GASES

11A168. Method for the prediction of peak sound pressure level related to opencast blasting. - M Clerico and M Patrucco *(Dept Georisorse e Territorio, Politec di Torino, Corsa Duca degli Abruzzi 24, 10129 Torino, Italy)*. Appl Acoust 40(1) 47-56 (1993).

The sudden noise caused by blasting can give rise to substantial complaints from people living in the proximity of opencast mines, quarries or construction sites. A measurement technique and simple prediction method are proposed which can be effectively applied for community exposure planning and reduction. The prediction method is based on measurements of the peak sound pressure level generated by small unconfined explosive charges; the sound propagation characteristics in the area can then be defined, as typical coefficients, and critical propagation directions can be taken into account. By means of a numerical relationship, in which also the main round parameters are considered, the peak sound pressure level in each position in the surrounding areas can be predicted.

172E. SOUND WAVES IN LIQUIDS (UNDERWATER ACOUSTICS)

11A169. Evaluation of ship radiated noise level from near-field measurements. - Takaaki Musha *(Acoust Dept, Ono Sokki, 1-16-1, Hakusan, Midori-ku, Yokohama, Japan)* and Akira Shinohara *(Fac of Textile Sci and Tech, Shinshu Univ, Ueda, Nagano-ken, Japan)*. Appl Acoust 40(1) 69-78 (1993).

Recently it has become necessary to determine far-field characteristics of marine vehicle noise from near-field measurements. It is possible to compute far-field characteristics from near-field measurements by using the Helmholtz integral equation. But this method is not practical because a great number of points are required to obtain them. This paper presents a simple equation to obtain the source levels of marine vehicles, which is used to evaluate far-field characteristics from near-field data. Good agreement with experimental results from ships is obtained.

11A170. Time-averages for plane traveling waves: The effect of attenuation I. Adiabatic approach. - SN Makarov *(Inst of Math and Mech, State Sankt-Petersburg Univ, Sankt-Petersburg-Petrodvoretz 198904, Russia)*. J Sound Vib 163(2) 311-317 (May 1993).

The analysis of the effect of attenuation on the time-averages for a plane traveling wave is presented. The barotropic equation of state is considered: ie, acoustic heating is assumed to be negligible. The problem statement consists of calculating means in a finite region bounded by a transducer surface as well as by a perfectly absorbing surface, respectively. Although the simple wave approximation cannot be used throughout the field it is still valid near the perfect absorber. The result for radiation pressure is different from the conclusions given previously by Beyer and Livett, Emery and Leeman.

172F. SOUND WAVES IN SOLIDS

See the following:

172H. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

11A171. Acoustic wave scattering from axisymmetric bodies. - HS Kim, JS Kim, HJ Kang *(Acoust Lab, Korea Res Inst of Ships and Ocean Eng, PO Box 1 Daeduk Science Town, Daejeon 305-606, Korea)*. J Sound Vib 163(3) 385-396 (22 May 1993).

Scattering from axisymmetric bodies subject to a non-axisymmetric incident wave is studied by means of the Helmholtz integral equation method. By expansion of circumferential components of the pressure and normal velocity as well as the incident wave into Fourier series, decoupled integral equations for each Fourier component are obtained. The fact that only discretization of the generator is needed offers a significant savings of computational efforts compared to that for surface discretization. The number of Fourier expansion terms needed to achieve convergence becomes larger as frequency increases, but it is still smaller than that or at least comparable to the number of nodes along the generator, which makes the present formulation attractive for acoustic wave scattering or radiation problems of axisymmetric bodies.

11A172. Analysis of 3D muffler with BEM. - Chao-Nan Wang, Chuan-Cheung Tse, Yih-Nan Chen *(Dept of Naval Architec, Natl Taiwan Univ, Taipei, Taiwan ROC)*. Appl Acoust 40(2) 91-106 (1993).

A numerical scheme for solving the 3D interior acoustic problem governed by the Helmholtz equation has been developed. The main feature of this formulation is that the singularity can be removed analytically. The boundary integral equation is solved for a specific geometry by using second-order quadrilateral surface elements and does not have the difficulty of non-uniqueness associated with the boundary integral equation formulation in an exterior problem. The transmission loss of a muffler is computed by using the derived four-pole parameters. The effects of higher-order modes due to the area discontinuity as well as the various inlet-outlet alignment on the acoustic performance of a muffler are also studied. The case of a muffler with elliptic cross-section, which is troublesome in analytical solution, can be treated easily by the present scheme. Finally, the transmission loss characteristics of a muffler with extended inlet-outlet are investigated. All the numerical results are compared with experimental measurement and agreement is good.

11A173. Axisymmetric integral equation formulation for free space non-axisymmetric radiation and scattering of a known incident wave. - P Juhl *(Acoust Lab, Tech Univ, Bldg 352, DK-2800 Lyngby, Denmark)*. J Sound Vib 163(3) 397-406 (22 May 1993).

This paper gives a brief account of the formulation of the Helmholtz integral equation specialized to the case of an axisymmetric body in free space. In this case of the surface integral of the Helmholtz integral equation may be reduced to a combination of a line integral and an integral over the angle of revolution; only the former integral needs to be discretized, and thus the dimension of the problem is reduced to one. In order to allow for non-axisymmetric boundary conditions the sound field is expanded in a cosine series over the angle of revolution. This expansion is as general as a full Fourier expansion but more efficient. The singularities in the Green function and its normal derivative are integrated analytically over the angle of revolution and expressed as sums of elliptic integrals. The formulation is tested for scattering and radiation problems.

11A174. Evaluation of methods for predicting the scattering from simple rigid panels. - TJ Cox and YM Lam *(Dept of Appl Acoust, Univ of Salford, Salford M5 4WT, UK)*. Appl Acoust 40(2) 123-140 (1993).

The accuracies and computational times of theoretical methods used to predict the scattering from rigid plane and curved reflectors have been evaluated. These methods were based on different solutions of the Helmholtz-Kirchhoff integral equation. The prediction results were compared to measurements. It was found that a boundary integral method provided accurate predictions for both panel types. For the more approximate prediction methods their limitations were defined in terms of the accuracy achieved and the range over which the methods were applicable. These methods were also used to investigate the use of cut-off frequency to describe the limit above which specular type reflections dominate the scattering. It was found to be applicable only close to the geometric scattering angle.

11A175. Theoretical and experimental analysis of the drift problem of cellouse fibres in an acoustic field. - H Czyz and J Smela *(Inst of Phys, Pedagogical Univ, Pl-00-000 Rzeszow, Rejtana 16A, Poland)*. Bull Polish Acad Sci Tech Sci 41(2) 153-156 (1993).

In the paper there was considered the problem of diffraction of a plane acoustic wave on a rigid cylinder in case of an arbitrary angle of incidence. The obtained formula was used to calculate the force and torque on a thin cylinder of a finite length. Some predictions were made concerning the acoustic radiation force on such particles and results of adequate experiments were reported.

11A176. Use of the diffraction phenomenon of a light wave on acoustic phase grating as a means of precision measurement of distance. - H Kowalski, A Klewski, M Figurski *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 29-35 (1993).

The subject matter of the present paper are the principles of a new method for measuring distances, based on the phenomenon of light diffraction on acoustic waves. An information block diagram of a range-finder system has been presented in which a distance is measured by the frequency measurement of the angle between two diffraction orders. The advantages of the method are discussed.

11A177. Wave propagation and scattering in elastic plate with periodically grooved surface. - E Danicki and D Bogucki *(Inst of Fund Tech Res, Polish Acad of Sci, Swietokrzyska 21, 00-049 Warszawa, Poland)*. Arch Acoust 18(1) 113-130 (1993).

Bragg reflection of plate waves in isotropic elastic plate with a periodically grooved surface is analyzed. Mode-coupling effect is also taken into account. The analyzed problem may be applied in the construction of piezoelectric resonators and RAC filters.

172J. NOISE CONTROL AND REDUCTION (INCL ACTIVE CONTROL)

11A178. Design verification of ground run-up noise suppressors for afterburning engines. - SA Fisher, AM Abdel-Fattah *(DSTO Aeronaut Res Lab, 506 Lorimer St, Fishermens Bend, Victoria Melbourne, Australia)*, LA Challis *(Challis and Associates Pty, PO Box 199 Kings Cross, NSW 2011 Sydney, Australia)*. J Propulsion Power 9(4) 628-635 (Jul-Aug 1993).

New facilities for ground running of engines in Royal Australian Air Force F-A-18 aircraft feature air-cooled exhaust augmentors for noise suppression. Aerothermodynamic aspects of the augmentor designs were appraised in some detail, making use of isothermal scale model tests, ejector theory, and available empirical data. Quantitative assessments were made of cooling flow pumping performance, and geometric features were identified which are important to the symmetry of the flow in the augmentor ducts. The final designs displayed satisfactory aerodynamic behavior, tolerant to both inlet asymmetries and reasonable levels of engine jet misalignment. The estimated pumping performance exceeded the design requirements.

11A179. Investigations into hygienic attenuators. - KO Ballagh *(Marshall Day, PO Box 5811 Wellesley St, Auckland, New Zealand)*. Appl Acoust 40(2) 107-122 (1993).

Investigations have been made into the feasibility of using reactive elements in hygienic or cleanable duct mounted attenuators. Worthwhile attenuations can be achieved and plane wave theory can be used to provide initial estimates of performance. Flow of up to 15 m-s has little effect on the attenuation achieved. Further development is required to optimize designs for cleanability to improve the accuracy of prediction techniques and to achieve higher and more broadband attenuation.

172Y. COMPUTATIONAL TECHNIQUES

11A180. Acoustic wave propagation in mercury in constant external magnetic field. - A Skumiel *(Inst of Acoust, Adam Mickiewicz Univ, Matejki 48-49, 60-769 Poznan, Poland)*. Acta Phys Polonica A 83(2) 173-186 (Feb 1993).

This paper gives a theoretical analysis of the effect of an external constant magnetic field on the propagation of ultrasonic waves in electrically conducting liquids as well as the results of measurements carried out in mercury. The theoretical part is based on Euler's equation, the equation of continuity, the thermodynamical equation, and Maxwell's equations. In the experimental part we propose and apply two methods for the measurement of the ultrasonic propagation velocity and its variations, as well as a pulse method perfected by the use of analog memory for the determination of the amplitude absorption coefficient. The correctness of the theoretical basis underlying the calculation of the small changes in propagation velocity induced by the magnetic field is confirmed by the experiment.

11A181. Analysis and implementation of hydroacoustic methods for estimation of high densities of fish in sea pens. - A Stepnowski *(Dept of Electron, Tech Univ, 80-952 Gdansk, Poland)*. Arch Acoust 18(1) 67-82 (1993).

The paper presents the feasibility of different acoustic methods with reference to system design, capable of estimating high density of fish, eg, in aquaculture facilities. The velocity, attenuation and backscattering measurement methods are critically examined. The new, recursive echo integration method is introduced, which accounts for attenuation loss by dense collections of fish. The proposed implementation of this estimation technique employs the modified design of a dual-beam sonar-system ECOLOG II. The system provides the real-time absolute estimates of fish density in sea pens.

11A182. Dispersion-relation-preserving finite difference schemes for computational acoustics. - CKW Tam and JC Webb *(Dept of Math, Florida State Univ, Tallahassee FL 32306-3027)*. J Comput Phys 107(2) 262-281 (Aug 1993).

Acoustics problems are governed by the linearized Euler equations. According to wave propagation theory, the number of wave modes and their wave propagation characteristics are all encoded in the dispersion relations of the governing equations. Thus one is assured that the numerical solutions of a high order finite difference scheme will have the same number of wave modes (namely, the acoustic, vorticity, and entropy waves), the same wave propagation characteristics (namely, nondispersive, nondissipative, and isotropic) and the same wave speeds as those of the solutions of the Euler equations if both systems of equations have the same dispersion relations. Finite difference schemes which have the same dispersion relations as the original partial differential equations are referred to as dispersion-relation-preserving (DRP) schemes. A way to construct time marching DRP schemes by optimizing the finite difference approximations of the space and time derivatives in the wave number and frequency space is proposed. The stability of these schemes is analyzed and a sufficient condition for numerical stability is established. A set of radiation and outflow boundary conditions compatible with the DRP schemes is constructed. These conditions are derived from the asymptotic solutions of the governing equations. The asymptotic solutions are found by the use of Fourier-Laplace transforms and the method of stationary phase. A sequence of numerical simulations has been carried out. These simulations are designed to test the effectiveness of the DRP schemes and the radiation and outflow boundary conditions. The computed solutions agree very favorably with the exact solutions. The radiation boundary conditions perform satisfactorily causing little acoustic reflections. The outflow boundary conditions are found to be quite transparent to outgoing disturbances even when the disturbances are made up of a combination of acoustic, vorticity, and entropy waves.

11A183. Dynamic stiffness-BEM for the prediction of interior noise levels. - RS Langley *(Dept of Aeronaut and Astronaut, Univ of Southampton, Highfield, Southampton S09 5NH, UK)*. J Sound Vib 163(2) 207-230 (May 1993).

A method is presented for the prediction of the noise transmission into structures which have a constant cross-sectional geometry. The structural vibrations are analyzed by using the dynamic stiffness method, while the BEM is used to calculate the interior noise levels. The analysis procedure is a direct one, which means that there is no need to calculate the modes of vibration of either the structure or the interior airspace. Furthermore, a method is presented for the suppression of numerical damping in the BEM analysis, which allows the use of much fewer BE than would otherwise be needed. Particular attention is paid to the case of airborne noise transmission into an aircraft fuselage structure, and comparisons are made with previous experimental and theoretical results for a circular cylindrical test article.

11A184. Spectrum analysis of acoustic emission signals. - I Malecki *(Asfaltowa 11 M 12, Pl-02-527 Warszawa, Poland)*. Bull Polish Acad Sci Tech Sci 41(2) 111-117 (1993).

The processing channel influences the form of the received acoustic emission (AE) signals. There are compared various methods of analysis of the amplitude distribution and spectrum of a priori assumed group of AE sources. Each source is treated as the evaluating system with own relaxation time. The spectral distribution depends on the activation energy. In the model of randomly oscillating defects there is considered the dependence of the spectrum on the correlation degree. The amplitude distribution for continuous and burst AE signals is compared. The cases of amplitude distribution of the primary AE signal are: Rayleigh, rectangular and triangular.

11A185. Ultrasonic attenuation in alloys. - SK Kor and RK Singh *(Dept of Phys, Univ of*

Allahabad, Allahabad-211 002, India). Acta Phys Polonica A 83(6) 751-758 (Jun 1993).

Ultrasonic attenuation was evaluated in metallic alloys, Ni_xCu_{1-x} (x = 1.00, 0.70, 0.60, 0.45, and 0) due to phonon-phonon (p-p) interaction and thermoelastic loss in a wide temperature region along <110> crystallographic direction for longitudinal and shear waves. Ultrasonic Gruneisen parameters, nonlinearity constants and ultrasonic attenuation due to p-p interaction and thermoelastic loss were determined from 50 K to 500 K using the Born-Mayer and electrostatic potentials. The results were compared with available results.

11A186. Wide-band dispersive lines with an acoustic surface wave. - A Kawalec and J Filipiak *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 69-78 (1993).

The subject matter of the present considerations are the results of numerical and experimental investigations into problems of dispersive delay lines with an acoustic surface wave with a 50% relative passband. The set of dispersive lines had a carrier frequency f_0 = 80 MHz, a passband B = 40 MHz and a slope μ = 4 MHz/μs and was composed of a transmitting and receiving dispersive lines. The transmitting dispersive line (TDL) had a flat amplitude characteristic in the passband while the characteristic of the receiving dispersive line (RDL) was described by the Hamming function. Width of the signal after compression was 35 ns and the sidelobe level was -32 dB. The dispersive lines were constructed with a crystal of quartz (Y,X). The insertion loss was minimum to amounting 50 dB.

172Z. EXPERIMENTAL TECHNIQUES

11A187. Acoustic emission during nonhomogeneous tensile deformation of ARMCO-iron. - A Pawelek *(Aleksander Krupowski Inst of Metal Res, Polish Acad of Sci, ul Reymonta 25, 30-059 Krakow, Poland)* and S Pilecki *(Inst of Fund Tech Res, Polish Acad of Sci, ul Swietokrzyska 21, 00-049 Warszawa, Poland)*. Arch Acoust 18(1) 163-170 (1993).

Measurements of acoustic emission count rates and RMS value in the ARMCO-iron have been carried out in tensile loading. Specimens of the ARMCO-iron have been used in two stands: annealed or pre-rolled and cut in parallel or perpendicular direction. Experimental results have been discussed in the light of possibility proliferation and annihilation as well as their accelerated and decelerated movement.

11A188. Experimental investigation of discrete sound production in deep cavity exposed to airflow. - M Meissner *(Inst of Fund Tech Res, Polish Acad of Sci, ul Swietokrzyska 21, 00-049 Warszawa, Poland)*. Arch Acoust 18(1) 131-156 (1993).

The results are presented of the experimental investigation of the discrete sound generation in the process of airflow over the deep cavity. During the increase of the airflow velocity, three discrete components, referred to as A, B and C, are excited successively, which, as indicated by an analysis of results, are the f_{13}, f_{12} and f_{11} modes, respectively. In the process of sound generation two stages have been distinguished: stage 1, characterized by strong dependence of the frequencies of the discrete components A, B and C on the velocity of the airflow and stage 2, where the frequency, of the discrete component C, as the function of the velocity, varies approximately ten times less as compared with stage 1. In stage 1, the "leading edge - trailing edge interaction" is of fundamental significance in the production of the discrete components, whereas the stage 2 is dominated by the feedback involving the effect of cavity-resonance modes on the disturbances of the shear layer.

11A189. Influence of vapors of some organic compounds and water on acoustic properties of selected polymer layers. - W Jakubik and M Urbanczyk *(Inst of Phys, Silesian Tech Univ, 44-100 Gliwice, Poland)*. Arch Acoust 18(1) 157-161 (1993).

The paper deals with an investigation of the interaction of thin polymer layers with an ambient atmosphere in view to using them to design gas sensors. The changes in physical properties of a polymer layer were recorded as a change in a differential frequency of dual acoustic delay line with a surface wave. The preliminary results demonstrate a selective sensitivity of polymer layers to gases in the ambient atmosphere.

11A190. Intensity assessment employing probe reversal. - RW Guy *(Centre for Build Stud, Concordia Univ, Montreal, PQ, H3G 1M8, Canada)*. Appl Acoust 40(1) 57-68 (1993).

Pressure-pressure (P-P) intensity measurements with probe reversal are made within highly reactive standing wave fields. A formulation is developed to correct both channel phase mismatch and finite difference error when applied to reversal measurement in discrete frequency planar fields, and greatly improved accuracy is shown in estimating the true intensity both in magnitude and direction; the prospect of extending low-frequency limits for given probe spacing in these fields is also demonstrated. In addition, a probe reversal formulation for a corrected intensity in arbitrary field conditions is formalized and a general comparison made with an alternative mean square pressure based correction.

11A191. Measurement of reverberation time using time delay spectrometry (TDS). - G Papanikolaou, V Psaroudakis, M Nistikakis *(Dept of Elec Eng, Univ of Thessaloniki, Greece)*. Arch Acoust 18(1) 33-45 (1993).

The present authors, basing on their experience collected during TDS system applications, especially to reverberation measurements, present below a practical approach, facilitating the appropriate use of TDS measuring systems in various applications.

11A192. Microstructure of sound. Formants in the dynamical spectra of violin sounds. - H Harajda *(Lab of Acoust, Pedagogical Univ, 65-069 Zielona Gora Pl, Slowianski 6, Poland)*, W Mikiel *(Speech Acoust Lab Inst of Fund Tech Res, Polish Acad of Sci, Swietokrzyska 21, 00-049 Warszawa, Poland)*, P Gabryelczyk, P Fedyniuk *(Lab of Acoust, Pedagogical Univ, 65-069 Zielona Gora Pl, Slowianski 6, Poland)*. Arch Acoust 18(1) 17-32 (1993).

The aim of the present study was to obtain the picture of the structural changes occurring in the spectra of the violin sound, with the four bowing techniques: detache, staccato, legato and martele. FFT analysis has been carried out using the system Volyzer and Split on IBM XT personal computer. Experimental material selected for this investigation consisted of the isolated sounds g (196 Hz), d^1 (293.7 Hz), a^1 (440 Hz), e^2 (659.3 Hz) and d^3 (1175 Hz) obtained with five instruments. Total number of randomly selected dynamical spectra, was 35. The tone structures have been analyzed with 0-220 ms timescales, in 20 ms segments. In this time span the spectrum continually undergoes the changes comprising the range of the spectrum, the number of the format maxima and their amplitude levels. Three types of formats exist: continuous, non-continuous, and fragmentary. The changes of the position of the format maxima on the frequency scale, the forms in which the amplitude levels of these maxima vary, the durations of the specific format creation and the stabilization of the full format set in the spectrum of sound have been analyzed.

11A193. Modeling auditorium acoustics with light. - RJ Pinnington and CB Nathanail *(Inst of Sound and Vib Res, Univ of Southampton, Highfield, Southampton SO9 5NH, UK)*. Appl Acoust 40(1) 21-46 (1993).

An optical method is presented for estimating the loudness, subjective spaciousness or clarity index within a proposed auditorium. A mirrored small scale model is constructed which contains a finite size light source. The intensity and size of the multiple reflected images are related to the magnitudes and time delays of individual echos. Various wall surfaces giving combinations of specular reflection, diffuse reflection and absorption are investigated. A photographic method for measuring the size and intensity of the image is assessed.

11A194. Structure of cyclohexane + t-butanol mixtures from positron annihilation and ultrasonic velocity measurements. - K Jerie, A Baranowski *(Inst of Exp Phys, Univ of Wroclaw, pl Maxa Borna 9, 50-204 Wroclaw, Poland)*, J Glinski *(Inst of Chem, Univ of Wroclaw, F Joliot-Curie 14, 50-383 Wroclaw, Poland)*. Acta Phys Polonica A 83(3) 321-326 (Mar 1993).

The densities of and sound velocities in t-butyl alcohol solutions in cyclohexane were determined in the temperature range 25 to 45° C. From these data adiabatic compressibility coefficients of the solutions were calculated, as well as excess densities and compressibilities. The positron annihilation spectra of the solutions were measured at room temperature. The results plotted against alcohol concentration show structural processes, which can be attributed to dimerization of the solute molecules.

11A195. Ultrasonic and thermodynamic effects of self-association of aliphatic alcohols in c-C_6H_{12} II. Preliminary and tertiary pentanols. - K Bebek, R Manikowski, S Ernst *(Inst of Chem, Silesian Univ, 40-006 Katowice ul, Szkolna 9, Poland)*. Arch Acoust 18(1) 105-111 (1993).

The ultrasound velocities in and densities of mixtures of cyclohexane with n-pentanol [x_1n-$C_5H_{11}OH$ + $(1-x_1)C_6H_{12}$] and with 2-methylbutan-2-ol [$x_1$tert-$C_5H_{11}OH$ + $(1-x_1)C_6H_{12}$] have been measured at 293.15 K. Using this measurement results in connection with the literature data, the following quantities have been determined: isothermal and adiabatic compressibility coefficients, $\beta_T = -1/V(\partial V/\partial p)_T$ and $\beta_s = -1/V(\partial V/\partial p)_s$, respectively, the adiabatic compressibility, $x_s = -(\partial V/\partial p)_s$, the free intermolecular length, L, and the excess values of the molar volume, V^E, of the adiabatic compressibility coefficient, $\beta^E{}_s$, and of the adiabatic compressibility, $x^E{}_s$. The dependence of those excess functions on the mixture composition, expressed in mole fractions, were represented by Redlich-Kister equations.

11A196. Semi-analytical static nonlinear structural sensitivity analysis. - RT Haftka *(Dept of Aerospace and Ocean Eng, VPI)*. AIAA J 31(7) 1307-1312 (Jul 1993).

The paper discusses two uses of the semi-analytical method for nonlinear sensitivity analysis. First, the application to noncritical response is analyzed. It is shown that the semi-analytical method is equivalent to a particular form of the overall finite difference approach. It is concluded that the difference between overall finite differences and the semi-analytical approach is blurred for the case of nonlinear static response. Next, the application of the semi-analytical method to calculating sensitivities of limit loads is discussed. A formulation that is easy to implement in general purpose FE programs is derived. Three examples are used to demonstrate the application of the formulation and to explore its accuracy.

11A197. Multiobjective optimization of large-scale structures. - RV Grandhi, G Bharatram *(Dept of Mech and Mat Eng, Wright State Univ, Dayton OH 45435)*, VB Venkayya *(Anal and Optim Branch, Flight Dyn Directorate, WPAFB)*. AIAA J 31(7) 1329-1337 (Jul 1993).

This paper presents a multiobjective optimization algorithm based on generalized compound scaling techniques. The algorithm handles any number of objective functions, similar to handling behavior constraints. This technique generates a partial Pareto set while solving the optimization problem. A reliability-based decision criterion is used for selecting the best compromise design. The example cases considered in this work include various disciplines in airframe structures, such as stress, displacement, and frequency with hundreds of design variables and constraints. This paper also discusses the concept of Pareto-optimal solutions in the context of a multiobjective structural optimization problem and the commonly used methods of generating Pareto-optimal solutions.

11A198. Optimal location of actuators for active damping of vibration. - J Holnicki-Szulc *(Dept of Electromech, Univ da Beira Interior, 6200 Covilhai, Portugal)*, F Lopez-Almansa *(Dept of Architec and Struct Diagonal 649, Tech Univ of Catalonia, Barcelona 08028, Spain)*, J Rodellar *(Dept of Appl Math III, Gran Capitan, Tech Univ of Catalonia, Barcelona 08028, Spain)*. AIAA J 31(7) 1274-1279 (Jul 1993).

A computationally efficient procedure for selection of placement of actuators is described in this paper. This method is formulated in modal coordinates and is based on the so-called progressive collapse analogy of an adjoint structure made of a hypothetical elastic-brittle material and having the same shape as the eigenmodes of the structure to be controlled. The computer simulation of progressive collapse for the adjoint structure provides us (as a side effect) with the location of the most sensitive spots, the best for placement of actuators. The presented methodology can be applied to damping of free vibration as well as to quasistatic shape control problems.

11A199. Optimization algorithm based on Legendre polynomial method for the linear quadratic optimal control problem with disturbances. - J Pelczewski *(Inst of Math, Univ of Lodz, Ul Stefana Banacha 22, 90-238 Lodz, Poland)*. Bull Polish Acad Sci Tech Sci 40(4) 377-386 (1992).

The shifted Legendre polynomials method is employed in order to obtain the approximate algorithm for the linear quadratic optimal control problem with given deterministic disturbances. According to the properties of these polynomials the optimization procedure was reduced to the constrained minimization of an algebraic function with respect to elements of an unknown matrix. The numerical procedure is based on the obtained results.

11A200. Active systems in the vibration control of vehicles. - S Michalowski *(Dept of Mech Eng, Cracow Univ of Tech, Poland)*. J Theor Appl Mech 31(3) 513-523 (1993).

The optimization procedure for the vibrocontrol system of a vehicle is presented. The vehicle is represented by a two dof model with discrete parameters. Input random kinematic excitation is assumed to be stationary and ergodic. The elektrohydraulic compensator is working parallely with the convectional suspension system. The structure and parameters of the active part, respectively, were obtained for the optimum criterion taken as a quadratic form. The relationships between values of the system parameters and the coefficients that describe fair comfort and fair safety are discussed.

11A201. Adaptive control of flexural waves propagating in a beam. - SJ Elliott *(Inst of Sound and Vib Res, Univ of Southampton, Southampton SO9 5NH, UK)* and L Billet *(Dept of Acoust Mec Vib, Electricite France, Clamart, France)*. J Sound Vib 163(2) 295-310 (May 1993).

Broadband active control of flexural (bending) waves propagating along a beam is investigated theoretically and experimentally. In particular, a simple practical arrangement is studied in which the output of a single detection sensor (an accelerometer) is used to drive a single secondary force via a feedforward controller. The feedforward controller is implemented as an adaptive digital filter, the coefficients of which are adjusted to minimize the mean square output from a single downstream error sensor (another accelerometer). Fundamental limits on the performance of such an active control system are found at low and high frequencies. The low frequency limit is caused by the near field of the secondary source corrupting the output of the error sensor. The increasing group velocity of bending waves in the beam with frequency imposes a high frequency limit on the performance, because of the electrical delay in the controller. The bandwidth of useful operation imposed by these low and high frequency limits is found to increase as the thickness of the beam is reduced. Experimental results on a 6 mm steel beam confirm the predicted high frequency limit, although in practice the low frequency limit of control was found to be determined by a lack of coherence between the detection and error sensor due to background noise. Attenuation in the bending wave amplitude of between 10 and 30 dB were measured in the experiments over a frequency range from 100 to 600 Hz.

11A202. Enhancing induced strain actuator authority through discrete attachment to structural elements. - Z Chaudhry and CA Rogers *(Center for Intelligent Mat Syst and Struct, VPI)*. AIAA J 31(7) 1287-1292 (Jul 1993).

In structural control, induced strain actuators are used by bonding them or embedding them in a structure. With bonded or embedded actuators used for inducing flexure, the developed in-plane force contributes indirectly through a locally generated moment. Control authority in this configuration is thus limited by actuator offset distance. In this paper, a new concept of flexural or shape control is presented, whereby induced strain actuators such as piezoelectric ceramic patches or shape memory alloys are attached to a structure at discrete points (as opposed to being bonded). This paper specifically addresses discretely attached induced strain actuators like piezoceramic and electrostrictive actuators which are available in the form of plates or patches, and includes actuator flexural stiffness considerations. This configuration is different from the bonded actuator configuration in two ways. One, because the actuator and the structure are free to deform independently, the in-plane force of the actuator can result in an additional moment on the structure and enhanced control. Second, the actuator can be offset from the structure without an increase in the flexural stiffness of the basic structure. This allows for the optimization of the offset distance to maximize control. Enhanced control is demonstrated by comparing the static response of a discretely attached actuator beam system with its bonded counterpart system. The advantage of this configuration over the bonded configuration is also verified experimentally.

11A203. Some results of the APC-1p digital autopilot flight tests. - A Tomczyk and T Dziedzic *(Tech Univ of Rzeszow, Poland)*. J Theor Appl Mech 31(3) 601-619 (1993).

This paper presents methodology and results of the digital autopilot flight tests. The structure of autopilot, methods of experiment applied in tests on four prototypes with PZL M20 Mewa are shown. Ways of data analysis and some obtained results are discussed.

11A204. Analysis of distributed thermopiezoelectric sensors and actuators in advanced intelligent structures. - SS Rao and M Sunar *(Sch of Mech Eng, Purdue)*. AIAA J 31(7) 1280-1286 (Jul 1993).

The quasistatic equations of piezoelectricity and thermopiezoelectricity are used to develop a FE formulation of distributed piezoelectric and thermopiezoelectric media. The formulation is then integrated with the distributed sensing and control of advanced intelligent structure design. The procedure is illustrated with the help of two example problems. The purpose of the first example, which consists of two piezoelectric layers used as a bimorph robotic finger, is to check the accuracy of the FE solution with the analytical one. As a second example, an aluminum beam is utilized along with two polyvinylidene fluoride layers acting as distributed actuator and sensor to study the distributed control of the beam when thermal effects are present. It is concluded that the thermal effects are important in the precision distributed control of intelligent structures.

11A205. Back-propagation learning using the trust region algorithm and application to nondestructive testing in applied electromagnetics. - Fumio Kojima *(Mech Eng Dept, Osaka IT, 5-16-1, Ohmiya, Asahi-ku, Osaka 535, Japan)*. Int J Appl Electromagnetics Mat 4(1) 27-33 (Jun 1993).

An artificial neural network is applied by nondestructive inspections in aerospace materials. The use of an artificial neural network is presented for classifying testing data as corresponding to sample materials with defect and without defect. The back-propagation learning for a multilayer feed-forward neural network is applied to this classification. The trust region method is adopted to the back-propagation learning problem. Results of numerical tests are summarized.

11A206. Intelligent control of the gear-shaving process. - JS Zhong *(Dept of Mech Eng, Wuyi Univ, Jiangmen, Guangdong, Peoples Rep of China)* and LS Qu *(Dept of Mech Eng, Xi'an Jiaotong Univ, Xi'an, Peoples Rep of China)*. Proc Inst Mech Eng B 207(B3) 159-165 (1993).

The objective of this paper is to describe how AI (artificial intelligence) and fuzzy logic techniques can be combined to implement an on-line computer control of an axial gear-shaving process in order to improve the quality of workpiece gears. The basic principle of correcting the geometric errors of workpiece gears is introduced. The final knowledge base is obtained by the iterative procedure of trying the expert controller, observing the results and then modifying the control rules accordingly. Inference is provided by a fuzzy logic engine. Experimental results showed that accuracy of the shaved gears was greatly enhanced. The total cumulative pitch error and the individual pitch error was reduced by approximately two times. In particular, the flank grooves, which commonly occur in the middle of tooth profiles, were removed.

11A207. Trajectory planning using artificial intelligence. - M Eroglu and KF Gill *(Dept of Mech Eng, Univ of Leeds, UK)*. Proc Inst Mech Eng B 207(B3) 193-198 (1993).

In this paper, the aim is to introduce artificial intelligence techniques into trajectory planning and obstacle avoidance, to achieve the minimum time trajectory. The method presented has many areas of application including NC-CNC (numerically controlled and computer numerically controlled) machining operations, precision assembly and transportation problems.

11A208. Certain methods of determining the ellipses and ellipsoids of the positioning accuracy of robot manipulators. - W Szczepinski and Z Wesolowski *(Inst of Fund Tech Res, Polish Acad of Sci, Warsaw, Poland)*. J Theor Appl Mech 31(3) 465-482 (1993).

When analyzing the problem of positioning accuracy of robot manipulators it is important to know how large many random deviations of the hand be from the desired position if the joint positioning errors possess a normal distribution. Two simple methods of determining the ellipses and ellipsoids of probability concentration are proposed. One of them consists in finding at first the polygon or polyhedron of the positioning accuracy, and then in finding the ellipse or ellipsoid of the principal axes and second order moments coinciding with those of the polygon or polyhedron, respectively. In the second of the proposed methods a computer generates random Gaussian deviations from the desired joint positions. The calculated numerous positioning errors are forming an elliptical or ellipsoidal pattern demonstrating good agreement with theoretically obtained ellipses or ellipsoids of probability concentration.

11A209. Walking machines. - DE Okhotsimsky, AK Platonov, AA Kiril'chenko, VV Lapshin, VG Tolstuosova *(Keldysh Inst of Appl Math, Russian Acad of Sci, Miusskaya sq 4, 125047 Moscow, Russia)*. Adv Mech 15(1-2) 39-70 (1992).

Problems arising in the development of walking machines with higher passability as compared with usual transport vehicles are discussed. Possible applications are described. Different control methods and motion control systems are considered along with information, mechanics power and structure problem. Statically and dynamically stable motion modes are studied. Examples of implemented designs of the legged machines are presented.

11A210. Approach for ensuring manipulator tip accuracy near singularities. - RP Podhorodeski *(Adaptive Robotic Telesyst Lab, Dept of Mech Eng, Univ of Victoria, PO Box 3055, Vic, BC, V8W 3P6, Canada)*. Mech Machine Theory 28(5) 641-649 (Sep 1993).

An approach for ensuring both manipulator tip accuracy and feasible joint rates near singularities is presented for serial-chain manipulators. The approach is based upon joint rate truncation and on-line planning of a suitable alternative end effector velocity. Screw quantities reciprocal to the nontruncated joint axes are used to define feasible alternative motions. Optimization, subject to these reciprocity-based motion feasibility constraints, is used to find an alternative velocity satisfying priority objectives of the original desired motion. In this work, alternative velocity components satisfying end tip translational accuracy at the sacrifice of minimal angular error are derived. Furthermore, a method for resolving the reciprocal screw quantities required to enforce alternative motion feasibility is presented. The method is suitable for manipulators having at least one pair of interesting revolute axes. Analytical and numerical results are presented to illustrate the alternative velocity planning approach.

11A211. Dynamic simulation and choice of generalized coordinates for a free-floating closed-chain planar manipulator. - SK Agrawal and MP Shelly *(Dept of Mech Eng, Ohio Univ, Athens OH 45701)*. Mech Machine Theory 28(5) 615-624 (Sep 1993).

Free-floating manipulators are inherently different from fixed-base planar manipulators due to conservation of linear and angular momentum. In this paper, we present simulation studies of a free-floating closed-chain planar manipulator. A fundamental question which an analyst is faced with during dynamic simulation of closed-chain mechanisms is how to choose the generalized coordinates during simulation. The independence of coordinates is dependent on the instantaneous properties of the governing constraints. For free-floating manipulators, this question becomes even more difficult due to the presence of constraints of momentum conservation. The objectives of this paper are to: (a) present a modular algorithm to build a rigid-body dynamic model of a free-floating closed-chain planar manipulator such that the instantaneous properties of the constraints can be easily studied; and (b) examine the momentum and closure constraints to build an algorithm for selection and switching of the generalized coordinates during simulation. In this algorithm, the free-floating manipulator is broken into component subsystems and the equations of constraint on these subsystems. This algorithm clearly describes the instantaneous properties of the constraints during the motion of the mechanism and helps in the selection of the generalized coordinates. The simulation results with this dynamic model and the algorithm for switching of coordinates are presented.

11A212. Feasibility study of manipulator inverse kinematics problems with applications of optimization principles. - Shinobu Sasaki *(Japan Atomic Energy Res Inst, Tokai-mura Naka-gun, Ibaraki-ken 319-11, Japan)*. Mech Machine Theory 28(5) 685-697 (Sep 1993).

This paper studies three different methods for solving inverse kinematics problems relevant to a six-link robot manipulator. In a problem formulation, governing kinematic equations are transformed into an unconstrained optimization problem with an objective function defined by a sum of squares of the errors, and then the two nonlinear models - ie, the variable metric method and the least squares method - are applied to derive stable joint solutions together with a practical linearized model. The results of computer simulation show that these numerical solutions are highly reliable over a much wider application range as compared with a traditional method.

11A213. Improvement of a robot performance due to elimination of both dynamic interactions and joint limits in the manipulator arm. - K Nazarczuk *(Inst of Aviation Eng and Appl Mech, Warsaw Univ of Tech, Poland)*. J Theor Appl Mech 31(3) 621-636 (1993).

The possibility of improvement of robot capabilities due to the elimination of both dynamic interactions and joint limits in its arm has not been fully exploited till now. Two different dynamic schemes of such an arm driven directly have been presented. A manipulator 1:5 model revealing the complete dynamic interactions elimination due to the suitable mass distribution in terms of a proper driving motors arrangement has been shown. Based on the presented dynamic analysis one can state that the designs being proposed ensures a considerable simplification of the robot control system as well as a great shortening of time taken in some motions.

11A214. Indirect discrete-time adaptive algorithm for manipulator control. - MS Mahmoud *(Dept of Elec and Comput Eng, Kuwait Univ, PO Box 5969, Safat 13060, Kuwait)* and AA Bahnasawi *(Dept of Electron and Commun Eng, Cairo Univ, Giza, Egypt)*. Appl Math Model 17(8) 423-429 (Aug 1993).

An adaptive controller design is proposed for discrete-time robotic control. The position of the robot arm is shown to converge to a desired point through two control loops. The first loop is an indirect adaptive perturbation controller based on the decoupled dynamics approach and using a perturbation model for the torque generation. The second loop generates the nominal torque component through a nonlinear controller representing the inverse manipulator dynamics. Simulation results on a typical three-link manipulator have indicated the potential and applicability of the developed design.

IV. MECHANICS OF SOLIDS

250. Elasticity

250B. LINEAR THEORY

11A216. More general displacement solutions for the plane elasticity problems. - Yi-wu Yuan *(Central S Univ of Tech, Changsha, China)*. Appl Math Mech 14(3) 247-252 (Mar 1993).

In this paper, the author obtains the more general displacement solutions for the isotropic plane elasticity problems. The general solution obtained is merely the particular case of this paper. In comparison, the general solutions of this paper contain more arbitrary constants. Thus they may satisfy more boundary conditions.

250C. NONLINEAR AND FINITE DEFORMATION PROBLEMS

11A217. An approach to approximate analysis of deformation and strain. - Hui-Er Xiong *(Hunan Univ, Changsha 410082, Peoples Rep of China)* and Quan-Shui Zheng *(Jiangxi Polytech, Nanchang 330092, Peoples Rep of China)*. Acta Mech Solida Sinica 6(3) 261-273 (Jul 1993).

An approach to approximate analysis of deformation and strain is developed from recent work on Cauchy mean rotation. The approximate expressions of Green strain usually employed in solving problems of nonlinear mechanics and their errors are discussed. The estimation of error is strictly based on the definition of small strain and medium or large rotation.

11A218. FE analysis of rubber coextrusion using a power-law model. - GC Buscaglia *(Div Mecanica Computational DIA, Centro Atomico Bariloche CNEA, 8400-SC de Bariloche, Argentina)*. Int J Numer Methods Eng 36(13) 2143-2156 (15 Jul 1993).

A FEM to simulate coupled thermal viscous coextrusion is presented, with a power-law viscosity function obtained from viscometric data on rubber composites. It combines, by successive substitution iterations, various well-known schemes, such as streamline integration for updating interfaces and Lagrange-Galerkin treatment of the energy equation. Some details of the implementation are discussed. The method is then applied to a comparison of two pre-forming plates for the dual tuber head extruder of Farrel Corp. Both the normal stress and the temperature at the interface suggest that the presence of a deflector deteriorates the adherence properties. This prediction is in agreement with operational experience.

11A219. Finite deformations of polar elastic media. - PH Dluzewski *(Inst of Fund Tech Res, Swietokrzyska 21, 00-049 Warsaw, Poland)*. Int J Solids Struct 30(16) 2277-2285 (1993).

In many papers on oriented continua some orthonormal angular coordinates were proposed. With respect to the curvature of the orientation space, it is obvious that such coordinates could not be applied in practice. Therefore, instead of these coordinates a tensor field of rotations had to be used to define the wryness tensor. In this paper the curvilinear coordinates in orientation space are considered. The Euler angles are an example of such coordinates. The inertia conservation law is replaced here by a constitutive relation. From the physical point of view this relation is more general and seems to be better justified than the mentioned law. Within the framework of the polar continuum theory a micromorphic structure is discussed. Some remarks on the principle of a material frame-indifference are also presented.

11A220. Initial problem for elastodynamic equations of compressible bodies. - A Szymaniec *(Warszawa, Poland)*. Biuletyn Wojskowej Akademii Technicznej 41(12) 89-104 (1992).

The solvability of the solutions to the Cauchy problem for incompressible strongly elliptic hyperelastic materials was proved using the method of Sobolev spaces. In particular, the existence, uniqueness and continuous dependence on given data above mentioned solution has been proved for the nonlinear equations for elastodynamics of incompressible bodies.

11A221. Static and dynamic precursors of displacive transformations near crystalline defects. - PC Clapp *(Center for Mat Simul, Inst of Mat Sci, Univ of Connecticut, Storrs CT 06269-3136)*. Physica D 66(1-2) 26-34 (Jun 1993).

An exact nucleation energy formula has been derived for the fluctuation energy necessary to initiate a coherent martensitic transformation in the strain field of a defect of arbitrary potency within the framework of a standard Ginzburg-Landau strain free energy model of the form: $f(n) = g(n) + K_1(\nabla n)^2$. The formula is limited to planar defects and planar interface propagation geometries, and precursor metastable strain profiles are calculated exactly. The defect induced strain field expands as the driving force is increased until the athermal instability limit is reached. This limit can be simply expressed in terms of the defect potency, or alternatively in terms of the strain spinodal, but the latter condition proves to be the weaker of the two in most cases tested. Once the nucleation condition is achieved, the equations of growth become identical to those previously tested by Chan.

11A462. Accurate measurement of 3D deformations in deformable and rigid bodies using computer vision

250E. STRESS CONCENTRATIONS AND SINGULARITIES

11A222. Problems of stress concentration in the neighborhood of a spherical defect. - GY Popov *(Russia)*. Adv Mech 15(1-2) 71-110 (1992).

A defect is understood as a surface, which if crossed leads to discontinuity of displacements and stresses. A review of publications in considering the problem of stress concentration in the neighborhood of a spherical defect, made in the paper, testifies that the problem in the non-axially-symmetric approach have not been previously investigated, neither have been examined the problems in the axially-symmetric approach for defects of more general nature than the cracks and thin inclusions. Here an exact solution of non-axially-symmetric problems of stress concentration in the neighborhood of a spherical defect has been obtained, it relates to such defects as a crack or a thin inclusion: the way to find the solution of the defect problem of more general nature has been pointed out, as for instance for an exfauliated rigid inclusion. The main difference between the proposed method of finding the exact solution and the earlier ones consists in that both the problem of the crack and that of the thin inclusion are reduced to three identical separately solved, 1D integral equations.

250F. ELASTIC IMPERFECTIONS (DISLOCATIONS, ETC)

11A223. Heterogeneous nucleation of dislocation loops under epitaxial strain. - Wei Yang and Hong Zhang *(Dept of Eng Mech, Tsinghua Univ, Beijing 100084, Peoples Rep of China)*. Acta Mech Solida Sinica 6(3) 243-259 (Jul 1993).

Heterogeneous nucleation of dislocation loops driven by high epitaxial strain describes a possible failure mode of multi-layer superlattice structures. The present paper furnishes a close form solution for the 2D mechanics analysis. A 3D BEM calculation facilitated by a singularity exclusion scheme is conducted for circular dislocation loops nucleated from a sperical void. The results show that the critical epitaxial strain necessary to nucleate a dislocation loop minimizes at an intermediate range of defect sizes.

11A224. Nonlinearities in the static energetics and in the kinematics of dislocations. - JP Hirth and RG Hoagland *(Mech and Mat Eng Dept, Washington State Univ, Pullman WA 99164-2920)*. Physica D 66(1-2) 71-77 (Jun 1993).

Methods for the atomistic simulation of dislocation core regions are discussed. Simulations of this type are shown to lead to a variety of core configurations and energies that are of nonlinear origin. The motion of dislocations by double kink formation is considered as an example of nonlinear dynamic effects.

250H. CONTACT PROBLEMS AND INCLUSIONS

11A225. Axial loading of a rigid circular anchor plate embedded in an elastic half-space. - APS Selvadurai *(Dept of Civil Eng and Appl Mech, McGill Univ, Montreal, PQ, H3A 2K6, Canada)*. Int J Numer Anal Methods Geomech 17(5) 343-353 (May 1993).

The present paper examines the axisymmetric problem related to the loading of a rigid circular anchor plate which is embedded in bonded contact with an isotropic elastic half-space. A Hankel transform development of the governing equations is used to reduce the associated mixed boundary value problem to a set of coupled Fredholm integral equations of the second kind. These equations are solved in a numerical fashion to generate results of engineering interest. In particular, the results indicate the influence of the depth of embedment of the axial stiffness of the rigid anchor plate.

11A226. BEM frictional contact analysis: Load incremental technique. - KW Man, MH Aliabadi *(Wessex IT, Ashurst, Southampton SO4 2AA, UK)*, DP Rooke *(Defense Res Agency, RAE Farnborough, Hants GU14 7TU, UK)*. Comput Struct 47(6) 893-905 (17 Jun 1993).

A BE formulation for solving structural problems associated with frictional contact is presented; it uses an efficient, iterative and fully load-incremental technique. Problems with any number of 2D bodies in contact can be analyzed using this technique; the bodies may be conforming or non-conforming, of similar or dissimilar materials. The interface may be frictionless or frictional and undergo slip or partial slip. Numerical solutions for both normal and tangential traction distributions can be obtained automatically for successive load increments. The technique utilizes automatic updating procedures in order to model the continuously changing boundary conditions occurring inside the contact region. Results obtained show that an accurate account of the nonlinear behavior, caused by the frictional effects, can be obtained only by following the loading history as well as the contact history.

11A227. General approach to axial deformation of bonded elastic mounts of various cross-sectional shapes. - MHBM Shariff *(Sch of Comput and Math, Univ of Teesside, Middlesbrough TS1 3BA, UK)*. Appl Math Model 17(8) 430-436 (Aug 1993).

Bonded elastic mounts of various cross-sections (3D) are widely used in engineering. Previous approximate explicit analyses have mainly been restricted to 2D analysis. None of the previous approximate analyses are based solely on the formal general equations of elasticity but involve mixed assumptions not necessarily related to each other. In this paper an approximate explicit 3D solution is obtained that is reasonable, easy to use, and compares well with experimental data. The method developed makes use of a variational principle that is equivalent to the general equations of elasticity expressed in terms of the displacement and a scalar function associated with the mean pressure. The analysis developed here unifies previous analyses and allows scope for better approximations. Upper and lower bounds on the axial nominal stress, energy, and apparent Young's modulus are given.

11A228. Simulation of the vertical split head failure in rails. - CH Kuo, LM Keer *(Dept of Civil Eng, NWU)*, RK Steele *(Tech Center, Assoc of American Railroads, 3140 S Federal St, Chicago IL 60616)*. Int J Solids Struct 30(16) 2177-2197 (1993).

A 2D analysis is presented to assess a possible mechanism to account for the axial cracking behavior in rails which is usually called a vertical split head failure. This failure is potentially damaging and may eventually lead to derailment. The vertical split head is simulated in the present analysis as a vertical crack in an eccentrically loaded infinite strip, representing the head, loaded on its upper surface and constrained on its lower surface, approximating the web constraint. The vertical crack is modeled as distributed dislocations. By using Fourier transforms, the interior stress field and stress intensity factors at the crack tip are determined from the derived coupled integral equations. The calculated stress field indicates that the initiation of a vertical defect is more likely to be caused by the influence of residual stresses upon an existing rail defect, such as an inclusion. Moreover, the growth of the crack is constrained to within the rail head by the high magnitudes of compressive stresses that occur beneath the contact loading and the head-web juncture.

11A229. On-line determination of texture-dependent materials properties. - HJ Bunge *(Dept of Phys Metall, TU Clausthal, Germany)*. J Nondestruct Eval 12(1) 3-11 (Mar 1993).

Macroscopic properties of polycrystalline materials may strongly depend on crystal orientation distribution, ie, the texture of the material. This applies to all kinds of crystallographically anisotropic volume and boundary properties. The necessary texture parameters can be determined from a low number of intensity values measured with a fixed-angle, X-ray texture analyzer which is particularly suited for on-line determination. Alternatively, the texture-property relationship can be used to calculate the texture parameters from property measurement in different sample direction. On-line measurement of the texture can also be used as an indicator for other material properties such as recrystallization or fatigue.

11A230. Evaluation of the stress tensor in 3D elastostatics by direct solving of hypersingular integrals. - O Huber, G Lang, G Kuhn *(Lehrstuhl Tech Mech, Friedrich-Alexander-Univ Erlangen-Nurnberg, Egerlandstr 5, 8520 Erlangen, Germany)*. Comput Mech 12(1-2) 39-50 (Jun 1993).

A new method of direct numerical evaluation of hypersingular boundary integrals has been applied to the differentiated form of the Somigliana-identity (hypersingular identity) in 3D elastostatics. Through this method it is possible to evaluate the stress tensor on the boundary of a complex 3D structure in a very accurate manner by employing the direct BEM. The geometry of the elements and their arrangements over the boundary of the structure are not subjected to any restrictions. Numerical examples illustrate the accuracy of the proposed method.

11A231. Hadamard-type stability of single integral constitutive equations for viscoelastic liquids. - Y Kwon and AI Leonov *(Dept of Polymer Eng, Univ of Akron, Akron OH 44325-0301)*. J Non-Newtonian Fluid Mech 47 77-91 (Jun 1993).

This paper studies the Hadamard type stability of viscoelastic constitutive equations (VECEs) of single-integral type by the analysis of local linear stability against extremely short and fast disturbances. The analysis is quite similar to that previously considered for Maxwell-like VECEs of differential type. The necessary and sufficient conditions for the global stability (ie, stability for any type of flow and any value of velocity gradient) are obtained in algebraic form for the time-strain separable single-integral VECEs with instantaneous elasticity. These conditions are then applied to the analysis of the stability for some single-integral VECEs proposed in the literature: Oldroyd-Lodge model, some specifications of the Kaye-BKZ model and two modifications of the VECEs proposed by Wagner. It is shown that apart from very particular cases, both Wagner's VECEs are unstable in the Hadamard-type sense, seemingly due to poor (or the absence of any) relations to thermodynamic description.

11A232. "Necking" in high-speed spinning revisited. - A Ziabicki *(Inst of Fund Tech Res, Polish Acad of Sci, 21 Swietokrzyska St, 00-049 Warsaw, Poland)* and Jianjun Tian *(Man-Made Fibers Res Inst, China Textile Univ, 1882 W Yan-An Rd, Shanghai 200051, China)*. J Non-Newtonian Fluid Mech 47 57-75 (Jun 1993).

The conditions required for "necking" in melt-spinning are discussed. The adopted criterion defines necking as a filament-radius profile R(x) exhibiting two inflexion points (R" = 0), one characterized by a negative, the other one by a positive, third gradient R"'. Analysis of the dynamics of spinning of a nonisothermal corotational Maxwell fluid leads to the conclusion that the conditions of necking require either long relaxation times (Deborah number > 1/2), or a large, positive tension gradient F' possibly controlled by inertia. In inertialess Newtonian filaments, the necking condition can also be satisfied by local reduction of viscosity. The above three mechanisms of necking, viscoelastic, inertial, and viscous, are analyzed and discussed.

11A233. Study of stress distribution in contraction flows of an LLDPE melt. - DG Kiriakidis, HJ Park, E Mitsoulis *(Dept of Chemical Eng, Univ of Ottawa, Ottawa, ON K1N 6N5, Canada)*, B Vergnes, J-F Agassant *(Center de Mise en Forme des Materiaux, Ecole des Mines de Paris, URA CNRS 1374 BP 207, 06904 Sophia Antipolis, France)*. J Non-Newtonian Fluid Mech 47 339-356 (Jun 1993).

Numerical simulations are carried out for a linear low-density polyethylene (LLDPE) flowing through an 8:1 planar contraction equipped with slit dies of different length (L/2H = 2 and 8) at two different temperatures (145 and 205° C). The emphasis is on determining the stress distribution and comparing it with birefringence experimental results that have previously appeared in the literature. The working constitutive equation is a realistic integral model of a K-BKZ type with a spectrum of relaxation times. The material parameters have been obtained by fitting experimental viscosity and normal stress data as measured in shear, and by using elongational viscosity data available in the literature. The numerical simulations are performed for a wide range of apparent shear rates ($10s^{-1} < \gamma_a < 140s^{-1}$) with good and fast convergence of the iterative scheme. The results show that as the apparent shear rate increases, viscoelastic effects dominate, exhibiting a delayed relaxation of stresses along the slit and stress overshoots at the die exit. This behavior is in close agreement with the experimental birefringence patterns. Elastic recovery is also captured in an enhanced extrudate swell which is always higher for the short die at the same temperature.

11A234. Modeling creep in thermoplastic composites. - Ilsup Chung, CT Sun *(Sch of Aeronaut and Astronaut, Purdue)*, IY Chang *(Composite Div, EI du Pont de Nemours, Wilmington DE 19880-0702)*. J Composite Mat 27(10) 1009-1029 (1993).

A creep model for unidirectionally reinforced fiber composites was developed on a one-parameter potential function. The same potential function was used to describe plastic flow and time-dependent creep deformation. The material constants in the model were terminated by using the uniaxial tension test of off-axis coupon specimens. In terms of effective stress and effective creep strain, the anisotropic creep behavior can be given by a stress-dependent master creep curve irrespective of loading direction relative to fiber orientation. DuPont's AS4/PEKK thermoplastic composites were used in the creep experiment. Results for both unidirectional and laminated composites were presented.

11A235. Viscoelastic analysis of bonded tubular joints under torsion. - Haiming Zhou and MD Rao *(Mech Eng, Eng Mech Dept, Michigan Tech Univ, Houghton MI 49931)*. Int J Solids Struct 30(16) 2199-2211 (1993).

In this paper, a theoretical analysis to evaluate the stress field in the adhesive layers of tubular bonded joints subjected to torsional loading is presented. The formulation is suitable to study the static behavior of the joint under general loading conditions as well as steady-state behavior under cyclic loading conditions. The adhesive material is modeled using linear viscoelasticity and numerical results for the shear stresses in the adhesives, joint compliance and joint loss factor are presented for various cases that provide some insights and guidelines in the design of the joint.

11A236. Calculation of viscoelastic flow using molecular models: The CONNFFESSIT approach. - M Laso and HC Ottinger *(Inst fur Polymere, Eidgenossische Tech Hochschule, ETH-Zentrum, CH-8092 Zurich, Switzerland)*. J Non-Newtonian Fluid Mech 47 1-20 (Jun 1993).

A new method for numerical calculation of viscoelastic flow based on simulation of molecular models of polymers is presented. The CONNFFESSIT (Calculation of Non-Newtonian Flow: FE and Stochastic Simulation Technique) approach directly combines standard FEM as currently used in the calculation of viscoelastic flow with stochastic simulations of polymer dynamics and thus obviates the need for a rheological constitutive equation to describe the fluid. The stresses are obtained from the molecular configurations rather than from constitutive equations. As an illustration of the method, the time development of plane Couette flow is studied for the upper-convected Maxwell, Oldroyd-BFENE-P and FENE fluids. For the upper-convected Maxwell, Oldroyd-B and FENE-P models comparisons with analytical and existing numerical solutions are presented. Significant deviations between the behavior of the FENE-P and FENE models for the start-up of plane Couette flow are found.

11A237. Spectral methods for the viscoelastic time-dependent flow equations with applications to Taylor-Couette flow. - M Avgousti *(Polymer Processing Inst and Dept of Chem Eng, Stevens IT, Hoboken NJ 07030)*, B Liu *(Dept of Chem Eng, UCLA)*, AN Beris *(Dept of Chem Eng, Univ of Delaware, Newark DE 19716)*. Int J Numer Methods Fluids 17(1) 49-74 (Jul 1993).

The time evolution of finite amplitude axisymmetric perturbations (Taylor cells) to the purely azimuthal, viscoelastic, cylindrical Couette flow was numerically simulated. Two time integration numerical methods were developed, both based on a pseudospectral spatial approximation of the variables, efficiently implemented using fast Poisson solvers and optimal filtering routines. The first method, applicable for finite Re numbers, is based on a time-splitting integration with the divergence-free condition enforced through an influence matrix technique. The second one, is based on a semi-implicit time integration of the constitutive equation with both the continuity and the momentum equations enforced as constraints. Stability results for an upper convected Maxwell fluid were obtained for the supercritical bifurcations, either steady or time-periodic, developed after the onset of instabilities in the primary flow. At small elasticity values, ε = De/Re, the time integration of finite amplitude disturbances confirms the stability of the single branch of steady Taylor cells. At intermediate ε values the rotating wave family of time-periodic solutions developed at the onset of instability is stable, whereas the standing wave is found to be unstable. At high ε values, and in particular for the limit of creeping flow ($\varepsilon = \infty$), the present study shows that the rotating wave family is unstable and the standing (radial) wave is stable, in agreement with previous FE investigations. It is thus shown that spectral techniques provide a robust and computationally efficient method for the simulation of complex, nonlinear, time-dependent viscoelastic flows.

254A. GENERAL THEORY

11A238. Application of the twelve-angled polygonal yield criterion to pressure vessel problems. - Xiaoying Zeng, Jinxiang Li, Jinwei Li, Gangling Li *(S China Univ of Tech, Bldg 26 Apt 101, S Living Quarters No 1, Guangzhou 510641, Peoples Rep of China)*, Zhichao Yang *(Petrochem Works, Guangzhou 510726, Peoples Rep of China)*, Jinyu Li *(Bai-Yun-Shan Med Works, Guangzhou 510515, Peoples Rep of China)*. Int J Pressure Vessels Piping 55(3) 385-393 (1993).

This paper deduces and expounds the general equations of a twelve-angled polygonal yield criterion, and it application to pressure vessels. We consider an open-ended cylinder made of ideal plastic material and deduce two practical integral formulas using the MN yield line and the MN plus MH yield lines. Thus far the calculation of an open-ended cylinder autofrettage is solved overall.

11A239. Deformation behavior of alloys comprising two ductile phases I. Deformation theory. - Z Fan and AP Miodownik *(Dept of Mat Sci and Eng, Univ of Surrey, Guildford, Surrey GU2 5XH, UK)*. Acta Metall Mat 41(8) 2403-2413 (Aug 1993).

A topological transformation has been proposed, which allows a two-phase microstructure with any combination of grain-size, grain-shape, and phase distribution, to be translated into a body consisting of three well-defined microstructural elements aligned along a particular direction of interest. The resultant three-element body is shown to be mechanically equivalent to the original body along this direction. The concept of contiguity and allied topological parameters have been combined with Eshelby's continuum transformation theory to determine the internal stresses and strains, the true stress strain curve, and the *in situ* stress and the *in situ* plastic strain distribution in the three microstructural elements and thus derive the mechanical properties of the aggregate. This approach incorporates the interaction between particles of the same phase and the effect of phase distribution as well as the effect of volume fraction. Applications of the theory are given in a companion paper.

11A240. Deformation behavior of alloys comprising two ductile phases II. Applications of the theory. - Z Fan and AP Miodownik *(Dept of Mat Sci and Eng, Univ of Surrey, Guilford, Surrey, GU2 5XH, UK)*. Acta Metall Mat 41(8) 2415-2423 (Aug 1993).

True stress-true strain curves, the mean internal stresses and the *in situ* stress and plastic strain distribution have been calculated for α-β titanium alloys, ferrite-martensite dual-phase steels and α-γ stainless steels, using the theory developed in Part I. It is shown that the theoretical predictions are in very good agreement with the experimental results drawn from the literature. The effects of microstructural parameters and the effect of differences in the mechanical properties of the constituent phases on the deformation behavior of these two-ductile-phase alloys are discussed in detail. In contrast to existing deformation theories, the present approach predicts that there are four deformation stages in the total deformation process of two-ductile-phase alloys, and that there should always be a drop in the flow stress after the onset of the plastic deformation in microstructural element III. This phenomenon has been explained in terms of internal stress changes and the balance of the elastic strain energy associated with prior plastic deformation in the three microstructural elements used to describe the overall deformation process.

11A241. Extremal properties of endochronic plasticity Part I. Extremal path of the constitutive equation without a yield surface. - Xianghe Peng *(Chongqing Univ, China)* and ARS Ponter *(Univ of Leicester, University Rd, Leicester LE 17 RH, UK)*. Int J Plasticity 9(5) 551-566 (1993).

Based on the general extremal properties of time-independent inelastic materials proposed by Ponter and Martin, some extremal properties of endochronic theory of plasticity are investigated. The extremal path of an endochronic constitutive equation without using a yield surface is found, which makes plastic work act as a potential such that the deviatoric stress can be derived from its derivative with respect to plastic strain. These properties are important because they provide the possibility for the irreversible thermodynamically based constitutive equations, which is strongly history-dependent, to be applied to simplified analysis in engineering problems. Using the derived extremal properties, the principal of minimum potential energy is extended to endochronic theory of plasticity. As an example, the stress and strain fields of a hinge-joint three-bar truss are analyzed.

11A242. Extremal properties of endochronic plasticity Part II. Extremal path of the constitutive equation with a yield surface and application. - Xianghe Peng *(Chongqing Univ, China)* and ARS Ponter *(Univ of Leicester, University Rd, Leicester LE 17RH, UK)*. Int J Plasticity 9(5) 567-581 (1993).

Extremal paths for endochronic constitutive equations without using a yield surface and the corresponding principle of minimum potential work were obtained in Part I of this article. In this paper, the extremal properties of endochronic constitutive equation with a yield surface and the corresponding method for deformation bound analysis are proposed. An example is presented that demonstrates that the application of endochronic constitutive models to simplified analysis is not significantly different from classical models due to the derived extremal properties. The adopted constitutive model involves both linear isotropic and kinematic hardening, which may provide more accurate results in simplified and bounding analysis.

254C. NONLINEAR AND FINITE DEFORMATION PROBLEMS

11A243. Dynamic large deformation response of rigid plastic arches under impact. - De-Min Wei and Gui-Tong Yang *(Taiyuan Univ of Tech, Taiyuan, Shanxi 030024, Peoples Rep of China)*. Acta Mech Solida Sinica 6(3) 275-289 (Jul 1993).

This paper presents a theoretical analysis of the dynamic large deformation response of highly circular arches under impact. By the Instantaneous Configuration Method, the solutions of the entire large deformation response process of the problem are obtained. The influences of the mass ratio, the energy ratio and the supported condition on the final deformation, the response time and the occurrence of plastic deformation are discussed in detail. The necessary conditon for occurrence of the "local reverse bending" phenomenon has been found. An approximate method is provided to describe the phenomenon. The numerical results are in good agreement with experimental data.

11A244. Effect of annealing, size and cut-outs on axial collapse behavior of circular tubes. - NK Gupta *(Dept of Appl Mech, Indian IT, Hauz Khas, New Delhi 110016, India)* and SK Gupta *(Centre for Mat Sci and Tech, Indian IT, Hauz Khas, New Delhi 110016, India)*. Int J Mech Sci 35(7) 597-613 (Jul 1993).

Axial compression tests were performed on round tubes of different sizes and made of aluminium and mild steel, both in as-received and annealed conditions. Length to diameter and diameter to thickness ratios of these tubes were varied in different tests, and cut outs in the form of circular holes, varying in diameter, number and position, were laterally drilled in them. Typical histories of their deformation and load-compression curves are presented and the influence thereon of the annealing process, the tube size, or the cut-outs is discussed. Relations are presented to describe these influences and to express the first peak and mean collapse loads in terms of the Vickers hardness number. It is seen that the presence of holes in the tubes alters their mode of collapse and, as a consequence, affords the possibility of avoiding Euler buckling even when relatively much longer tubes are employed.

11A245. Modeling of large plastic deformations based on the mechanism of micro-shear banding. Physical foundations and theoretical description in plane strain. - RB Pecherski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(5-6) 563-584 (1992).

Shear banding is related to large plastic deformations produced by mechanisms of crystallographic slip and/or twinning and micro-shear. Physical foundations and motivations to formulate simplified phenomenological model are considered. Plane deformations of elastoplastic material accounting for micro-shear bands are studied. The derived relations show that the micro-shear bands produce the non-coaxiality between the principal directions of stress and rate of plastic deformations. It transpires that, depending on the contribution of the mechanisms involved in plastic flow, a fully active range, separated from the elastic range by a truly nonlinear zone called the partially active range, may exist. In case of continued plastic flow with the deviations from proportional loading contained within the fully active range the incremental plastic response is linear, whereas the constitutive relations derived for the partially active range appear thoroughly nonlinear. Relations to known nonlinear flow laws in rates of deformation and stress are discussed.

11A246. Theoretical and computational aspects in the shakedown analysis of finite elastoplasticity. - H Stumpf *(Lehrstuhl fur Allgemeine Mech, Ruhr-Univ Bochum, Postfach 10 21 48, W-4630 Bochum, Germany)*. Int J Plasticity 9(5) 583-602 (1993).

A fully nonlinear shakedown analysis is considered for structures undergoing large elastic-plastic strain. The underlying kinematics of finite elastoplasticity are based on the multiplicative decomposition of the deformation gradient into elastic and plastic parts. It is shown that the notion of a fictitious, self-equilibrated residual stress field of Melan's linear shakedown theorem has be replaced by the notion of real, self-equilibrated residual state. Path-dependent and path-independent shakedown theorems are presented that can be realized in an incremental step-by-step procedure using FE codes. The numerical implementation is considered for highly nonlinear truss structures undergoing large cyclic deformations with ideal-plastic, isotropic and kinematic hardening material behavior. Path-dependency of the residual states in the case of non-adaptation and path-independency in the case of shakedown are shown, and the shakedown domain is determined taking into account also the stability boundaries of the structure.

254F. MATERIAL CHARACTERIZATION

11A351. Plain strain rigid plastic FE formulation for sheet metal forming process

254G. WORK HARDENING

11A247. Elastic-plastic response of thin-walled tubes under combined axial and torsional loads Part I. Monotonic loading. - W Jiang *(Mech Eng Dept, Florida Int Univ, Miami FL 33199)*. J Pressure Vessel Tech 115(3) 283-290 (Aug 1993).

This paper investigates the elastic-plastic response of thin-walled tubes subjected to combined axial and torsional loads. The kinematic hardening model is used and exact closed-form solutions are obtained for linear loading paths. The characteristics of the stress-strain relationships are discussed and the corresponding movements of the yield center are illustrated. The response of the material under nonproportional loading is proved to be path-dependent, and the hardening behavior is shown to be different from that under proportional loading. The investigation then shows that such a difference will finally disappear when the stresses tend to infinity.

11A248. Elastic-plastic response of thin-walled tubes under combined axial and torsional loads Part II. Variable loading. - W Jiang *(Mech Eng Dept, Florida Int Univ, Miami FL 33199)*. J Pressure Vessel Tech 115(3) 291-296 (Aug 1993).

This paper continues the investigation of the elastic-plastic response of thin-walled tubes subjected to combined axial and torsional loads. The stress-strain loop under arbitrary variable loading is first discussed. It is then shown that due to the kinematic hardening, a steady state, either one of the reversed plasticity or one of the elastic shakedown, can always be reached under cyclic loadings, with a hysteresis loop in the form of a parallelogram or a straight line. As a result, the difference in response between nonproportional and proportional loading will finally disappear. The investigation indicates that the simple kinematic hardening rule is able to describe, at least qualitatively, certain basic characteristics of the maerial behavior observed in nonproportional tests.

254H. CYCLIC AND VARIABLE LOADING

11A249. Extension of the static shakedown theorem to a certain class of inelastic materials with damage. - A Hachemi and D Weichert *(Ecole des Mines Douai and Lab Mec, Univ de Lille, Villeneuve, D'Ascq, France)*. Arch Mech 44(5-6) 491-498 (1992).

In this paper, an extension of the static shakedown theorem (Melan's Theorem) to elastic-plastic damaging material behavior is presented. Damage is taken into account by using the Ju-model, and the generalized standard material model with plastic hardening.

11A250. Macroscopic observations and related microscopic phenomena of the mechanical behavior of metallic materials. - B Wack and A Tourabi *(Lab des Sols Solides, Struct, Grenoble, France)*. Arch Mech 44(5-6) 621-662 (1992).

On the basis of some experimental macroscopic results a qualitative correspondence may be established between the macroscopic hysteresis behavior and the microstructural phenomena which are responsible for the deformation.

See also the following:

11A248. Elastic-plastic response of thin-walled tubes under combined axial and torsional loads Part II. Variable loading

254I. VISCO- AND ELASTO-PLASTIC MEDIA

11A251. Antiplane shearing motions of a visco-plastic solid. - JM Greenberg *(Dept of Math and Stat, Univ of Maryland, Baltimore County, Baltimore MD 21228)* and Anne Nouri *(Univ de Nice, Parc Valrose, 06034 Nice Cedex, France)*. SIAM J Math Anal 24(4) 943-967 (Jul 1993).

The authors consider antiplane shearing motions of an incompressible isotropic visco-plastic solid. The flow rule employed is a properly invariant generalization of Coulomb sliding friction and assumes a constant yield stress or threshold above which plastic flow occurs. In this model stresses above yield are possible; but when this condition obtains, the plastic flow rule forces the plastic strain to change so as to lower the stress levels in the material and dissipate energy. On the yield surface, the flow rule looks like the classical one for a rate independent elastic-perfectly plastic material when the velocity gradients are small enough but differs from the classical model for large gradients.

11A252. Elasto-plastic response of orthotropic pipes under bending, pressure, and axial force. - CJ Tay, KH Lee, ED David *(Dept of Mech and Prod Eng, Natl Univ, Singapore 0511)*. Thin-Walled Struct 17(3) 203-221 (1993).

An elasto-plastic analysis of circular thin-walled pipes in the non-buckled configuration subjected to bending moment, pressure, and axial loads is presented. Plastic stress-strain relationships based on Drucker's postulates, Hill's yield criterion,and the deformation theory are utilized. The analysis includes orthotropic behavior with the assumption of a linear strain-hardening material. Results are presented for both isotropic and orthotropic materials.

11A253. Fundamental requirements and formulation of elastoplastic constitutive equations with tangential plasticity. - K Hashiguchi *(Dept of Agri Eng, Kyushu Univ, Fukuoka 812, Japan)*. Int J Plasticity 9(5) 525-549 (1993).

In order to extend an elastoplastic constitutive equation to describe the dependency of a plastic stretching on a stress rate component tangential to the yield surface, two fundamental requirements are first formulated, which have to be fulfilled in elastoplastic constitutive equations. One of them is the *work rate* or *stiffness relaxation*. The other is the *continuity condition* of stress rate. The elastoplastic constitutive equation with a "single, smooth" yield surface is formulated to fulfill these requirements, in which a plastic stretching (its magnitude and direction) depends on a stress rate component tangential to the yield surface; thus it is called a *tangential plasticity*. Based on this, a concrete constitutive equation of metals with isotropic-kinematic hardening and tangential plasticity is formulated, which, among existing concrete constitutive equations with a tangential plasticity, is capable of describing the general loading behavior including nonproportional, reverse loading, and reloading. Its mechanical response is shown in comparison with the traditional J_2 flow theory with the associated flow rule.

11A254. Nonlocal versus local elastoplastic behavior of heterogeneous materials. - M Berveiller, D Muller *(Lab de Phys et Mec des Mat URA CNRS 1215, Univ of Metz, ISGMP Ile du Saulcy, 57045 Metz, France)*, J Kratochvil *(Czechoslovak Acad of Sci, Na Slovance 2, 18040 Prague 8, Czechoslovakia)*. Int J Plasticity 9(5) 633-652 (1993).

The scale transition methods have been developed for many years in order to obtain the overall behavior of polycrystalline materials from their microscopic behavior and their microstructure. Nevertheless, some basic aspects are absent from such formalisms. The most significant one seems to be the heterogenization by plastic straining which involves nonlocality of hardening. In this article, a nonlocal theory based upon crystalline plasticity is developed from which a nonlocal constitutive equation at the grain level is derived. With regard to the polycrystal, in order to deduce the behavior of a local equivalent homogeneous medium, an integral equation is proposed and solved for nonlocal inhomogeneous materials by the self-consistent approximation. This scheme is developed in case of a two-phase nonlocal material representing the dislocation cell structure induced during plastic straining. Numerical simulations based on a simplified model show significant effects on the intragranular heterogeneization.

11A255. Variational theory for finite-step elasto-plastic problems. - G Romano, L Rosati, F Marotti de Sciarra *(Dipartimento di Sci delle Construzioni, Fac Ing, Uinv Napoli Federico II, 80125 Piazzale Tecchio, 80-Napoli, Italy)*. Int J Solids Struct 30(17) 2317-2334 (1993).

An extended version of *generalized standard* elasto-plastic material is considered in the framework of an internal variable theory of associated plasticity. According to a backward difference scheme for time integration of the flow rule, a finite-step structural problem is formulated in a geometrically linear range. Convex analysis and a brand new potential theory for monotone multi-valued operators are shown to provide the natural mathematical setting for the derivation of the related variational formulation. A general stationarity principle is obtained and then specialized to obtain a minimum principle in terms of displacements, plastic strains and internal variables. A critical comparison with an analogous minimum principle recently proposed in literature is performed, showing the inadequacy of classical procedures in deriving non-smooth variational formulations.

254K. ANISOTROPIC AND NONHOMOGENEOUS MEDIA

11A256. Constitutive equations for finite deformations of elastic-plastic metallic solids with induced anisotropy. - Nguyen Huu Viem *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland).* Arch Mech **44**(5-6) 585-594 (1992).

The object of this paper is to formulate the constitutive relations for elastic-plastic metallic solids at finite strain, making some plausible physical assumptions and employing Mandel's formalism. Thermodynamic terms are included. The equations are further simplified which should make them more useful for solving problems.

11A257. Crystallography-based prediction of plastic anisotropy of polycrystalline materials. - KJ Kozaczek, CO Ruud *(Penn State)*, J Hirsch *(VAW Aluminum, Bonn, Germany)*, JC Conway Jr *(Penn State)*, CJ Yu *(Concurrent Technologies, Johnstown PA 15909).* J Nondestruct Eval **12**(1) 97-107 (Mar 1993).

Several models of plasticity of a polycrystalline material were reviewed, and their applicability to the prediction of plastic anisotropy of face-centered cubic (FCC) metals were evaluated. A tailored set of cold-rolled copper alloy samples was designed and manufactured, representing the wide spectrum of textures and cold work levels typical for the sheet metal industry. The texture was quantitatively described in the form of the orientation distribution functions derived by the inversion of four incomplete pole figures. The Taylor-Bishop-Hill model was applied in order to calculate the planar variation of the plastic strain ratio. The continuum mechanics of textured polycrystals approach was also used for the prediction of the plastic strain-rate ratio for the same set of deformed materials. The theoretical predictions were compared with the plastic strain ratios measured in tensile tests using strain gauges. The applicability of the models for prediction of the plastic anisotropy of FCC metals was discussed in view of the operating deformation mechanism and other factors such as strain hardening sensitivity and grain size-shape effects.

11A258. Deformation-induced plastic anisotropy of sheet metals. - W Szczepinski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland).* Arch Mech **44**(5-6) 663-698 (1992).

Problems connected with the theoretical description of plastic flow of polycrystalline sheet metals are discussed and commented. Sheet metals display distinct anisotropic properties in the plastic range of deformation. It is observed that these properties may be different depending on the plastic deformation histories in the course of the manufacturing process. Much attention has been devoted to the experimental tests of plastic anisotropy of sheet metals and to the comparison of test results with various descriptions.

254L. RESIDUAL STRESS

See the following:

11A444. Effect of residual stresses on hardness measurements

254Y. COMPUTATIONAL TECHNIQUES

11A259. Computational limit analysis of rigid-plastic bodies in plane strain. - Yuan-Gao Zhang, Pi-Xin Zhang, Ming-Wan Lu *(Dept of Eng Mech, Tsinghua Univ, Beijing 100084, Peoples Rep of China).* Acta Mech Solida Sinica **6**(3) 341-348 (Jul 1993).

This paper deals with the computational methods for limit analysis of plane strain problems. The FE mathematical programming formula (FE-MPF) for determining the upper bound load multiplier established by the authors earlier is adopted and modified for plane strain problems. The penalty method is used to impose the incompressibility constraint. The FE-MPF is solved by a direct iteration procedure without the need of a searching process. This algorithm is not sensitive to the volumetric locking effect. And it can be easily extended to the limit analysis of 3D problems. The results of numerical examples are satisfactory and show the stable convergency of the present algorithm.

11A260. Symmetric formulation of tangential stiffnesses for non-associated visco-plasticity with an implicit time integration scheme. - Wen-lin Xiong *(Wuhan Univ of Hydraul and Elec Eng, Wuhan, China).* Appl Math Mech **14**(3) 269-276 (Mar 1993).

A numerical scheme is presented which enables the use of symmetric equation solvers in tangential stiffness programs for non-associated viscoplastic materials.

11A261. Elastic-plastic strain analysis by photoelastic coating method. - J Kapkowski and B Kozlowska *(Fac of Fine Mech, Warsaw Univ of Tech, Poland).* J Theor Appl Mech **31**(3) 483-512 (1993).

In the paper the method of determining the strain and stress distribution in plastified zones of the construction by using isochromatic patterns obtained in testing by the method of photoelastic coating is presented. Calculation of the strain components (strain separation) requires introduction of both the schematization of the material characteristics and the physical relations valid in regions, where the yield point was exceeded. The introduced relations were applied to the strain separation along the axis of symmetry. The process of calculations was illustrated by an example.

11A262. Prediction of electrical properties of plain-weave fabric composites for printed wiring board design. - RK Agarwal and A Dasgupta *(CALCE Electron Packaging Res Center, Univ of Maryland, College Park MD 20742).* J Electron Packaging **115**(2) 219-224 (Jun 1993).

A mechanistic model is presented for predicting the effective dielectric constant and loss tangent of woven-fabric reinforced composites with low-loss constituents. A two-scale asymptotic homogenization scheme is used to predict the orthotropic effective properties. A 3D unit-cell enclosing the characteristic periodic repeat patterns in the fabric weave is isolated and modeled mathematically. Electrostatic boundary value problems are formulated in the unit-cell and are solved analytically to predict effective dielectric constant of the composite, using 3D series-parallel reactance nets. Results are also verified numerically, using FEMs. The effective dielectric constant and the effective loss tangent are then obtained, analogous to mechanical viscoelastic problems for low-loss materials. The predicted dielectric constant and loss tangent are compared with experimental results for E-glass and epoxy laminates. Frequency dependence of the effective dielectric constant and loss tangent is obtained from the corresponding behavior of the constituent materials. Trade-off studies are conducted to investigate the effect of the constituent material properties on orthotropic effective dielectric permittivity.

11A263. Computer simulation of anisotropic grain growth in ceramics. - U Kunaver and D Kolar *(Inst Jozef Stefan, Univ of Ljubljana, Ljubljana, Slovenia).* Acta Metall Mat **41**(8) 2255-2263 (Aug 1993).

Anisotropic grain growth in ceramics has been simulated by a Monte Carlo computer model. Microstructures, similar to experimental ones, were obtained and the influence of the energy anisotropy and the number of anisotropical grains on microstructure development were studied. It was shown that a single grain with higher energy in one direction, embedded in a matrix of grains with the isotropic boundary energy, grows anisotropically with a nearly constant rate. The growth rate is linearly proportional to the energy anisotropy of the grain. The aspect ratio increases with the cube root of time. Faceted grain boundaries were simulated. Microstructures with less than 50% of anisotropic grains develop, after a short time, a bimodal grain size distribution. At this point, the mean aspect ratio of anisotropic grains reaches a maximum. The heights of the maxima are proportional to the energy anisotropy and inversely proportional to the fraction of anisotropic grains. Weighted aspect ratio distributions and their mean values agree well with experimental data.

11A264. Deformational resistance of fresh concrete through bent and tapered pipes. - Anura SM Nanayakkara *(Dept of Civil Eng, Univ of Moratuwa, Sri Lanka, Japan)*, K Ozawa *(Dept* *of Civil Eng, Univ of Tokyo, 7-3-1 Hongo Bunkyo-ku, Tokyo 113, Japan)*, K Maekawa *(Eng Res Inst, Univ of Tokyo, 7-3-1 Hongo Bunkyo-ku, Tokyo 113, Japan)*. Proc JSCE 466(V-19) 97-107 (May 1993).

This is to report on the resistance of deformation of fresh concrete when the rearrangement of constituent particles of fresh concrete, ie, gravel, sand, and cement, is introduced. For realizing the simple deformation field in shear, bent, and tapered pipe units were adopted in test and stable flow of fresh concrete through them was produced. Herein, the pressure at the inlet of deformed pipes was measured as an indicator of deformability of fresh concrete, which is regarded as the particulate assembly with different sizes. The effect of volume fraction of gravel, sand, and cementitious powder on the resistance to deformation was mainly focused in the series of test based upon the multiphase concept of hydrodynamics. The sensitivity of volume fractions to the total deformation resistance of concrete was of experimental interest to the authors.

11A265. **Interdependence of microstructure and strength of structural lightweight aggregate concrete.** - SL Sarkar *(Fac des Sci Appl, Univ de Sherbrooke, Sherbrooke, PQ, J1K 2R1, Canada)*, S Chandra, L Berntsson *(Div of Build Mat, Chalmers Univ of Tech, S-412 96 Gothenburg, Sweden)*. Cement & Concrete Composites 14(4) 239-248 (1992).

The demand for lightweight concrete is steadily increasing because of economic and practical considerations. Hence, the inherent internal and external features of lightweight aggregates have been a subject of intense research in recent years. This study provides new insight into the microstructural and chemical factors which influence the strength properties of structural lightweight aggregate concrete. These are described with respect to four expanded clay lightweight aggregates used in nine concrete compositions containing various types and proportions of dispersing dispersing agents such as water-reducing admixtures and superplasticizers, with silica fume and ground granulated blast-furnace slag as optional mineral admixtures. The microstructural characteristics of the paste-aggregrate interface and the paste porosity of these concretes are discussed. The methods used include scanning electron microscopy-energy-dispersive X-ray analysis, X-ray diffraction analysis, optical microscopy and compressive strength testing.

11A266. **Anisotropic permeability of fiber preforms: Constant flow rate measurement.** - AW Chan, DE Larive, RJ Morgan *(Michigan Molecular Inst, 1910 W St Andrews Blvd, Midland MI 48640)*. J Composite Mat 27(10) 996-1008 (1993).

Fiber preform permeability has a strong influence on the resin impregnation behavior during polymer composites fabrication. A straightforward procedure has been developed for determining the general anisotropic in-plane permeability character of fiber preforms from constant flow rate mold filling experiments. The procedure is based on the application of Darcy's law to a 2D in-plane flow situation. From experimental data changes in flow front position and inlet pressure with model filling time, the components of the in-plane permeability tensor can be calculated directly using parameters obtained from two linear plots. Experimental data for a commercial fabric confirms the applicability of the procedure. The required equipment setup and the analytical procedure are both uncomplicated in nature. The proposed method provides a simple solution to the measurement of permeability and comparison of different preforms for polymer composites application.

11A267. **FE simulations of fiber pull-out.** - GL Povirk and A Needleman *(Div of Eng, Brown Univ, Providence RI 02912)*. J Eng Mat Tech 115(3) 286-291 (Jul 1993).

Fiber pull-out is simulated through a quasi-static analysis of a circular elastic cylinder with a rigid cylindrical fiber embedded in its center. The interface between the fiber and the matrix is characterized in terms of a rate dependent internal variable friction constitutive relation. The analysis is carried out in two steps; one simulating the residual stresses that develop while cooling the cylinder from its processing temperature and the other simulating the mechanical response during fiber pull-out. Depending on parameter values, fiber pull-out can occur smoothly or a stick-slip instability can occur. Numerical simulations of fiber pull-out are presented that explore the effects of loading device stiffness, loading rate, and friction law parameters on the predicted behavior. For example, the amplitude of the load fluctuations during stick-slip was found to decrease as the rate of pull-out increased.

11A268. **Influence of cool-down temperature histories on the residual stresses in fibrous metal-matrix composites.** - Nan-Ming Yeh *(Marketing Dept Manager, Fu Chun Shin Machinery Manuf, Bay-Tow Village Kwang-Meow Hsiang, Tainan County, Taiwan, ROC)* and E Krempl *(Mech of Mat Lab, RPI)*. J Composite Mat 27(10) 973-995 (1993).

The vanishing fiber diameter model together with the thermoviscoplasticity theory based on overstress including a recovery of state formulation is introduced. They are employed to analyze the effects of temperature rate and of annealing at constant temperature on the residual stresses at room temperature when unidirectional fibrous metal-matrix composites are cooled down from 1000°C during the manufacturing process. For the present analysis the fibers are assumed to be transversely isotropic thermoelastic and the matrix constitutive equation is isotropic thermoviscoplastic including recovery of state. All material functions and constants can depend on current temperature. Yield surfaces and loading-unloading conditions are not used in the theory in which the inelastic strain rate is solely a function of the overstress, the difference between stress and the equilibrium stress, a state variable of the theory. Assumed but realistic material elastic and viscoplastic properties as a function of temperature which are close to W/9Cr-1Mo steel composite permit the computation of residual stresses. Due to the viscoplasticity of the matrix time-dependent effects such as creep and change of residual stresses with time are found. It is found that the residual stress, upon reaching room temperature, is highest for the fastest cooling rate, but after 30 days rest the influence of cooling rate is hardly noticeable since relaxation takes place. Annealing periods can reduce the residual stresses compared to continuous cooling.

11A269. **Modeling the densification of metal matrix composite monotape.** - DM Elzey and HNG Wadley *(Dept of Mat Sci and Eng, Univ of Virginia, Charlottesville VA 22903)*. Acta Metall Mat 41(8) 2297-2316 (Aug 1993).

The consolidation of monotapes consisting of a layer of continuous aligned ceramic fibers embedded in a plasma sprayed metal or intermetallic matrix is becoming a preferred approach for the processing of high performance composite systems. We present a first model that enables prediction of the density (and its time evolution) of a monotape lay-up subjected to a hot isostatic or vacuum hot pressing consolidation cycle. Our approach has been to break down the complicated (and probabilistic) consolidation problem into simple, analyzable parts and to combine them in a way that correctly represents the statistical aspects of the problem, the change in the problems interior geometry and the evolving contributions of the different deformation mechanisms. The model gives two types of output. One is in the form of maps showing the relative density dependence upon pressure, temperature, and time for step function temperature and pressure cycles. They are useful for quickly determining the best place to begin developing an optimized process. The second gives the evolution of density over time for any (arbitrary) applied temperature and pressure cycle. This has promise for refining process cycles and possibly for process control. Examples of the models application are given for Ti_3Al+Nb,γ TiAl, Ti6Al4V and pure aluminum.

11A270. **Silica particle-glass fiber-reinforced polyester resin.** - Y Zhang and J Cameron *(Mat and Metall Eng Dept, Queen's Univ, Nicol Hall, Kingston, ON, K7L 3N6, Canada)*. J Composite Mat 27(11) 1114-1127 (1993).

In this work, a method of producing silica particle-modified glass fibre-reinforced polyester composite is introduced. Silica particles, which are of low density, high hardness and good chemical compatibility with the polymer matrix, are coated on the glass fibre by a thin film of polyester resin which is also subsequently incorporated into the composite as the matrix phase. After initial coating of the fibre by the silica particles, the fibre plus polyester plus silica is passed through carefully spaced pressure rollers to produce a uniform coating on the continuous fibre. The effect of the particles on the viscosity of the bulk-phase polyester matrix and the shear strength of the composites made from the modified fibre were investigated. Also, the mechanism of reinforcement of the modified fibre is discussed. The modified fibres have higher shear strength, a larger surface area and show better bonding with the polyester matrix than conventional fibres.

11A271. **Treatments of polyproplylene fibres to optimize their reinforcing efficiency in cement composites.** - A Peled, H Guttman *(Sch of Appl Sci and Tech, Hebrew Univ, Israel Fibre Inst, Jersualem, Israel)*, A Bentur *(Natl Build Res Inst, Fac of Civil Eng, Technion IT, Haifa, Israel)*. Cement & Concrete Composites 14(4) 277-285 (1992).

The effect of the geometry of polypropylene fibres and their surface treatment by chemical and physical means was studied to obtain cementitious composites with optimal flexural properties. Monofilaments of polypropylene were more efficient than split film or bundled multifilament strands. Acid, detergent and rubbing treatments of monofilaments were found to be particularly effective in enhancing the first crack stress and post-cracking behavior of the composite. The influence of the various treatments was discussed in terms of the bonding nature as deduced by scanning electron microscope observations of the fibre-matrix interface.

11A272. Experimental investigation on impact response of laminated composite beams. - NC Pal and AK Ghosh *(Dept of Civil Eng, IIT Kharagpur, Kharagpur 721302, India)*. Exp Mech 33(2) 159-164 (Jun 1993).

Experiments based on a new technique were carried out to study the response of glass-epoxy laminated composite beams subjected to impact loading. A number of glass-epoxy composite beams with different fiber orientations, spans, thicknesses, and support conditions were impacted with an instrumented impact hammer and the responses were picked up using an accelerometer in conjunction with a spectrum analyzer. Free vibration test for some sample beams were also carried out to determine their fundamental frequencies.

11A273. Laminates and microstructures. - P Pedregal *(Dept Matematica Aplicada, Univ Complutense, 28040 Madrid, Spain)*. European J Appl Math 4(2) 121-149 (Jun 1993).

This paper deals with the mathematical characterization of microstructure in elastic solids. We formulate our ideas in terms of rank-one convexity and identify the set of probability measures for which Jensen's inequality for this type of function holds. This is the set of laminates. We also introduce generalized convex hulls of sets of matrices and investigate their structure.

11A274. Study on the application of work factor approach to composite laminates. - KY Rhee *(Dept of Mech and Aerospace Eng, Rutgers Univ, Piscataway NJ 08855-0909)* and HA Ernst *(Sch of Mech Eng, Georgia Tech)*. J Composite Mat 27(10) 962-972 (1993).

Static fracture tests using the cracked lap shear (CLS) specimens made of thermoplastic composite APC-2 were conducted to verify if the elastic work factor developed previously is a valid parameter to calculate energy release rate from a single specimen. Also, the elastic work factor was derived theoretically based on a beam analysis. The experimentally determined elastic work factor, $(\eta_{el})_{exp}$ was compared with those calculated from a beam analysis and a FE analysis. The results showed that the elastic work factors determined from these three ways are comparable to each other. In addition, the elastic work factor was applied to determine a critical energy release rate, and it was found that the elastic work factor approach can be used to determine energy release rate from a single specimen.

256J. MICROMECHANICS

11A275. Modeling of non-uniform composite microstructures. - RK Everett and JH Chu *(Composites and Ceramics Branch, Code 6371, Naval Res Lab, Washington DC 20375-5343)*. J Composite Mat 27(11) 1128-1144 (1993).

The microstructural effects of non-uniform composite microstructures are modeled. Relationships are observed between the degree of nonuniformity and fiber spatial information which may be measured via image analysis or derived from Dirichlet cell tessellations. For artificial patterns containing chain-like clustering which simulate composite microstructures: (a) the nearest-neighbor distances of random and clustered patterns are smaller than those normally estimated by a square or hexagonal arrays, (b) increased clustering may be associated with increased mean cell volume fraction, cell volume fraction distribution standard deviation, number of cell sides, distribution standard deviation, nearest-neighbor distance distribution skewness, and decreased nearest-neighbor distances and (c) accounting for non-uniform fiber diameters is generally unnecessary, except possibly at low fiber volume fraction or with patterns exhibiting a high degree of chaining. For Nicalon SiC-zirconia titanate composite samples with microstructures which exhibit clustering, the maximum value of skewness, determined from sub-regions of the sample, correlates with the flexure strength of that sample.

11A276. Models of moisture transport and moisture-induced stresses in epoxy composites. - Myung Cheon Lee *(Dept of Chem Eng, Dongguk Univ, Chung-gu Pildong, Seoul, Korea)* and NA Peppas *(Sch of Chem Eng, Purdue)*. J Composite Mat 27(12) 1146-1171 (1993).

Mathematical models are presented to describe moisture transport in epoxy composites using concentration and stress dependent diffusion coefficients. These models take into consideration the stresses induced due to moisture and their influence on the transport mechanism. All governing differential equations are solved with appropriate boundary conditions to obtain concentration and stress profiles. It is concluded that non-Fickian and anomalous transport of moisture in epoxy composites can occur under certain conditions, leading to stress accumulation close to the fibers of the composite.

256L. MACROSCOPIC CHARACTERIZATION

11A277. Indentability of conventional and negative Poisson's ratio foams. - RS Lakes *(Dept of Theor and Appl Mech, Cornell)* and K Elms *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*. J Composite Mat 27(12) 1193-1202 (1993).

The indentation resistance of foams, both of conventional structure and of a novel re-entrant giving rise to negative Poisson's ratio, was studied using holographic interferometry. In holographic indentation tests, re-entrant foams had higher yield strengths σ_y and lower stiffness E than conventional foams of the same original relative density. Damage in both kinds of foam occurred primarily directly under the indenter. Calculated energy absorption for dynamic impact is considerably higher for re-entrant foam than conventional foam.

256N. DYNAMIC BEHAVIOR

11A278. Dynamic deformation behavior of Al-Zn-Mg-Cu alloy matrix composites reinforced with 20 vol % SiC. - SI Hong, GT Gray III *(Mat Sci and Tech Div, LANL)*, JJ Lewandowski *(Dept of Mat Sci and Eng, Case W Reserve Univ, Cleveland OH 44106)*. Acta Metall Mat 41(8) 2337-2351 (Aug 1993).

The dynamic mechanical response and substructure evolution of underaged and overaged Al-Zn-Mg-Cu alloys with and without 20 vol% SiC particles were investigated and compared to those following quasi-static compression. The hardening rates of the overaged composites and control alloys were found to be smaller than those of their underaged counterparts. Overaged composites and the control alloys showed more strain rate sensitive behavior than the underaged composites and alloys. The flow stress of the composites was found to decrease at total strains larger than 0.15 in the high-rate Hopkinson pressure bar tests. A more rapid decrease in stress in the underaged composites suggests that microstructural damage in the underaged condition is greater than that in the overaged condition tested at high strain rates. Cracks near the SiC-matrix interfaces were observed more frequently in the underaged Hopkinson pressure bar samples. The more frequent interface cracks in the underaged composites are thought to result from much slower relaxation of the stresses and strains built up at the interface due to much more difficult thermally activated deformation.

11A279. Can the curvature of an optical glass fiber be different from the curvature of its coating?. - E Suhir *(AT&T Bell Lab, 600 Mountain Ave, Rm 7D-326, Murray Hill NJ 07974)*. Int J Solids Struct 30(17) 2425-2435 (1993).

The study is aimed at the elevation of the relationship between the measured (or imposed) constant curvature of the coating of an optical glass fiber and the elastic curve of the fiber itself. It is shown that the buffering effect of the coating is different for different points along the curved area and depends on the length of this area, and the compliance of the coating. In the case of a very short curved area and/or a very compliant coating, the curvature of the glass fiber is smaller than the curvature of the coating and increases with an increase in the length of the curved area and the coating stiffness. In the case of a long curved area and/or a stiff coating, both curvatures are practically the same for almost the entire curved area. Only when approaching the ends of this area, the ratio of the curvature of the glass fiber to the coating curvature somewhat increases (by a factor of 1.043) and then rapidly drops to unity at the ends. There are, however, some "intermediate" unfavorable combinations of the lengths of the curved area and coating compliances that result in curvature ratios exceeding (by up to a factor of 1.086) the coating curvature in the midportion of the curved area. It is shown that such a paradoxical situation is due to the redistribution of the interfacial radial load at certain combinations of the lengths of the curved areas and spring constant of the coating. For a current AT&T dual-coated fiber design with 30 μm thick silicone primary coating, the curvature ratio is greater than unity when the lengths of the curved area fall within the range between 1.84 and 4.27 mm, and reaches the 1.086 value when the length of curved area is about 2.44 mm.

11A280. Physical discretization approach to evaluation of elastic moduli of highly filled granular composites. - VV Moshev and OC Garishin *(Ural Dept, Russian Acad of Sci, Inst of Continuous Media Mech, Academic Korolev St 1, Perm 614061, Russia).* Int J Solids Struct 30(17) 2347-2355 (1993).

A structural model for highly filled granular composites is suggested. Composites investigated represent rather dense random assemblies of hard spherical particles embedded in softer elastic matrices. The concept forming the foundation of the model approach is the so-called physical discretization principle which comes from the fact that the really complicated field interactions in the system considered here can be substituted by simpler linear elastic ones. The indispensable stages of model development are the generation of random composite architecture and the solution of some special boundary problems. The model reveals clearly the infuence of structural parameters of macroscale behavior. The predicted properties proved to be in reasonable agreement with experimental observations. Of particular concern is the insight into the internal pattern of structural forces that makes it possible to obtain new information about the peculiarities of composite internal elastic resistance.

11A283. Optimal orientation of flakes in oriented strand board (OSB). - V Sharma *(Dept of Mech Eng, Rm E53-384, MIT)* and A Sharon *(Lab for Manuf and Productivity Room 35-237, MIT).* Exp Mech 33(2) 91-98 (Jun 1993).

Panelized housing can reduce both the cost and construction time of residential housing. The panels, generally comprised of rib-reinforced OSB sheets, are assembled into floor, wall, and roof structures. Irrespective of application, commerically available OSB sheets incorporate flakes oriented generally in the longitudinal direction along the faces and in the cross direction in the core. This often results in directional material properties that are not ideally suited for the specific application, requiring excessive sheet thickness and flake density in order to provide the necessary strength. It is proposed that through proper orientation of flakes, material properties of OSB can be tailored to a specific application, resulting in appreciable improvement in load-bearing capacity over commercially available OSB of equal density. In this paper we present a method for determining the near-optimal orientation of flakes in OSB sheets under specific loading. Using three-point bending and rupture tests, we experimentally verify that OSB with optimally oriented flakes is significantly superior to commerically available OSB of equal density.

11A284. Static and dynamic analysis of sandwich plates with unidirectional variation of thickness. - B Mrozek and I Nowotarski *(Military Univ of Tech, Warszawa, Poland).* J Tech Phys 34(2) 199-213 (1993).

General relationships for the static and dynamic calculations of sandwich plates with variable thickness of their cores are determined with the use of the FEM. The honey-comb-type core is treated as inextensible in the direction of its thickness and transmitting shearing stress only. In the thin faces a membrane stress state is assumed: its influence on the transverse shear action is taken into account. The computational results are compared with the results of authors tests.

A refined engineering theory for beams is presented. It contains higher order effects not present in such refined theories as the one by Timoshenko. A comparison with the latter theory is carried out.

11A287. Calculations of the constraints in a thin film deposited on the substrate. - G Bertholon *(ENISE, 58 rue Jean Parot St-Etienne, 42023 Cedex, France),* C Dupuy *(Univ Claude Bernard-Lyon 1, Villeurbanne, 69622 Cedex, France),* C Surry *(ENISE, 58 Rue Jean Parot St-Etienne, 42023 Cedex, France),* R Redon *(Univ Claude Bernard-Lyon 1, Villeurbanne, 69622 Cedex, France),* H Zahouani *(ENISE, 58 rue Jean Parot St-Etienne, 42023 Cedex, France).* Acta Phys Polonica A 83(5) 581-586 (May 1993).

The aim of the present paper is to give simple calculations of the constraints in a thin film deposited on the substrate. The thin film can be obtained by recrystallization of the surface. It is considered in relation to its substrate, where the force is linearly proportional to the surface area of the film. On the other hand, it is considered to be under the action of a force related to the thermic and compressional constraints. The initial and final boundary conditions in the linearized model play an essential role in the model adopted.

11A288. Free vibrations of Timoshenko beams on rigid blocks. - NM Auciello *(Dept of Struct Eng and Soil Mech, Univ of Basilicata, Potenza, Italy).* Eng Trans 41(2) 177-186 (1993).

The aim of the paper is to analyze the vibration of Timoshenko beam resting on the most arbitrary elastically flexible supports. The boundary conditions are defined by means of a 2×2 flexibility matrix, and the structure is discretized according to the so-called cell procedure. The Lagrangian coordinates are selected to be the vertical displacement of the end points of the rigid bars, plus the four possible displacements of the external constraints. A numerical example is worked out in which the obtained results are compared with some known results.

11A289. Thin-walled beams with open and closed cross-sections. - A Prokic *(Koce Kapetana, 11000 Belgrade, Serbia, Yugoslavia).* Comput Struct 47(6) 1065-1070 (17 Jun 1993).

A new warping function for 3D thin-walled beams is proposed that enables the analysis of structures made up of members with arbitrary open and closed cross-sections. An updated Lagrangian formulation is used to give the stiffness matrix. The method is illustrated by examples.

11A290. Variationally correct assumed strain field for the simple curved beam element. - G Prathap and BR Shashirekha *(Struct Div, Natl Aeronaut Lab, Bangalore-560 017, India).* Comput Struct 47(6) 1071-1073 (17 Jun 1993).

The classical curved beam element (the cubic-linear element) has been discredited for a long time because of poor performance. In a previous paper, the first author showed that the poor performance could be attributed to the inconsistency in the membrane strain field interpolations and that this could be improved by designing a new membrane strain field which met the consistency requirements. This paper shows that this formulation can be improved by re-constituting the "assumed" strain field in a variationally correct manner.

260A. GENERAL THEORY

11A291. Recent developments in the homogenization theory of elastic plates and their application to optimal design Part I. - T Lewinski *(Inst of Struct Mech, Civil Eng Fac, Warsaw Univ of Tech, Armii Ludowej 16, PL-00-637 Warsaw, Poland).* Struct Optim 6(1) 59-64 (Jun 1993).

The paper presents an upt-to-date review of results concerning the evaluation of the stiffnesses of elastic plates with periodic structure. The homogenization formulae of Kohn and Vogelius (1984) (model a = 1) are viewed as the formulae of reference. The paper discusses the range of applicability of the homogenization formulae for the 2D plate models of Kirchhoff and Reissner-Hencky. Transversely symmetric as well as asymmetric plates are considered. Particular attention is paid to plates stiffened asymmetrically with ribs in one direction. For this case, the closed formulae for effective membrane, reciprocal and bending stiffnesses are derived. The homogenization results overviewed are a prerequisite for the discussion of the methods of regularization of optimum design plate problems presented in Part II of the paper.

260B. NONLINEAR AND FINITE DEFORMATION THEORY

11A292. Problems of u-shaped bellows with nonlinear deformation of large axisymmetrical deflection I. Counting nonlinear deformations of ring shells and compressed angle of bellows. - Liang Hu *(Shanghai Inst of Appl Math and Mech, Shanghai Univ of Tech, Shanghai, China).* Appl Math Mech 14(3) 253-267 (Mar 1993).

This paper follows the work of [1,2]. There are some progress in dealing with moderately small rotations (the squares of rotation angles are the order of magnitude of strains) of middle surface normals of inside and outside ring shells and compressed angle of bellows. Calculation results agree with experiments well. To bellow design, the method given in this paper is of practical value and the discussion of the influence of compressed angle on characteristic relation is helpful.

11A293. Unified approach for the linear and nonlinear analysis of plates and shallow shells. - Jianqiao Ye *(Dept of Theor Mech, Univ of Nottingham, Nottingham NG7 2RD, UK).* Thin-Walled Struct 17(3) 223-236 (1993).

The geometric nonlinear behavior of thin plates and shells is studied in this paper by using a boundary integral equation approach. Two types of plates and shells are considered. One of them is rectangular with moveable edges and the other is axisymmetric with various boundary conditions. A plate analog procedure is suggested to simplify the solution. With such simplification, only a knowledge of the boundary integral equation of plates is required in the present study. A number of numerical examples are given in the paper to show the effectiveness of the proposed method.

260C. PLATES (FLEXURE AND TORSION)

11A294. Approximate solution with high accuracy of transverse bending of thin rectangular plates under arbitrarily distributed loads. - Ding Zhou *(E China IT, Nanjing, China).* Appl Math Mech 14(3) 241-246 (Mar 1993).

Ritz method is an effective way widely used to analyze the transverse bending of thin rectangular plates. Its accuracy depends completely on the basis functions selected. This paper selects the superposition of sine series with polynomials as the basis functions of thin rectangular plates. The calculating formulae are not only simple and easily programmed, but also have high accuracy. Finally, two numerical results are given and compared with those obtained by the classical method.

11A295. FE large displacement analysis of stiffened plates. - D Venugopal Rao, AH Sheikh, M Mukhopadhyay *(Dept of Naval Architec, Indian IT, Kharagpur-721 302, India).* Comput Struct 47(6) 987-993 (17 Jun 1993).

A FE analysis of the large deflection behavior of stiffened plates using the isoparametric quadratic stiffened plate bending element is presented. The evaluation of fundamental equations of the stiffened plates is based on Mindlin's hypothesis. The large deflection equations are based on von Karman's theory. The solution algorithm for the assembled nonlinear equilibrium equations is based on the Newton-Raphson iteration technique. Numerical solutions are presented for rectangular plates and skew stiffened plates.

11A296. Study of elastic behavior of plates containing cracks by FE analysis. - JM Minguez *(Dept Fisica Aplicade II, Fac Ciencias, Univ del Pais Vasco, Aptdo 644, 48080 Bilbao, Spain).* Comput Struct 47(6) 917-925 (17 Jun 1993).

This work applies FE analysis very simply to cracked plates. An infinite plate and a finite plate, both with a central crack, are considered to study their elastic behavior and some fracture mechanics concepts, such as the geometry factor and the fracture toughness. These magnitudes are calculated by means of FEMs and the results are in very good agreement with the established theory, which proves that the FE approach is very appropriate. The fracture toughness fraction is defined and calculated for a finite plate to predict its failure.

260E. SHELLS (BENDING THEORY)

11A297. Bending analysis of orthotropic conical shells. - Liyong Tong *(Co-operative Res Center for Aerospace Struct, Unit 3 276-278 Abercrombie St, Chippendale, NSW 2008, Australia),* B Tabarrok *(Dept of Mech Eng, Univ of Victoria, Victoria, BC, V8W 3P6, Canada),* Tsun Kuei Wang *(Dept of Appl Mech, Beijing Univ of Aeronaut and Astronaut, Beijing, China).* Trans Can Soc Mech Eng 17(2) 215-227 (1993).

Using Donnell type shell theory a simple and exact procedure is presented for bending analysis of orthotropic conical shells under various loads. The solution is in the form of a power series in terms of a particularly convenient coordinate system, and its convergence radius is obtained.

11A298. Numerical stress analysis of intersecting cylindrical shells. - VN Skopinsky *(Mat Strength Chair Head, Motor-Car Construct Inst, Moscow 109280, Russia).* J Pressure Vessel Tech 115(3) 275-282 (Aug 1993).

This paper presents the numerical approach for the stress analysis of the intersecting shells. For a systematic study of this problem, the classification of the model joints is introduced. Stress analysis has been made with the application of the FEM based on the modified mixed formulation. The developed special-purpose computer program SAIS is used for elastic stress analysis of the model joints of the intersecting shells. Comparison of the calculated and experimental results for ORNL-1 model are presented for internal pressure and moment loadings. The parametric study of the model joints of the intersecting cylindrical shells under internal pressure loading was performed. The presented results show the effects of changing various geometric and angular parameters on the maximum effective stresses in the shells.

11A299. Thickness changes in pressurized shells. - LA Godoy and FG Flores *(Dept de Estructuras, FCEFyN, Univ Nacional de Cordoba, Casilla de Correo 916, Cordoba 5000, Argentina).* Int J Pressure Vessels Piping 55(3) 451-459 (1993).

A pressurized thin spherical shell with reductions in thickness is analyzed using a geometrically linear and a nonlinear version of a FE formulation. The change in thickness is assumed to have a circular shape and is symmetric about the middle surface of the shell. The influence of two parameters is considered on the nonlinear behavior: the change in thickness and the extent of the zone affected. The results show that the most critical stresses arise from the hoop membrane action at the edges of the zone affected. It is also shown that a linear analysis can be highly conservative in terms of bending action.

260G. STIFFENED AND SANDWICH PLATES AND SHELLS

11A300. Efficient higher order composite plate theory for general lamination configurations. - Maenghyo Cho and RR Parmerter *(Dept of Aeronaut and Astronaut FS-10, Univ of Washington, Seattle WA 98195).* AIAA J 31(7) 1299-1306 (Jul 1993).

An efficient higher order plate theory for laminated composites is developed. A composite plate theory for general lamination configurations is obtained by superimposing a cubic varying displacement field on a zig-zag linearly varying displacement. The theory has the same number of dependent unknowns as first-order shear deformation theory, and the number of unknowns is independent of the number of layers. The displacement satisfies transverse shear stress continuity conditions at the interface between layers as well as shear free surface conditions. Thus, an artificial shear correction factor is not needed. To demonstrate and compare with other theories, the analytical solution for cylindrical bending is obtained. The present theory gives deflections and stresses that compare well with other known theories.

11A301. Large deflections of rectangular Hoff sandwich plates. - Zhen-Qiang Cheng, Xiu-xi Wang, Mao-guang Huang *(Dept of Modern Mech, Univ of Sci and Tech, Hefei, Anhui 230026, Peoples Rep of China).* Int J Solids Struct 30(17) 2335-2346 (1993).

The nonlinear theory of Hoff type sandwich plates underlying geometrically nonlinear dynamic response is derived from Hamilton's principle. It is shown how the fundamental equations and boundary conditions of dimensionless form can be simplified to the Reissner-Mindlin type theory of moderately thick plates, the Reissner's theory of sandwich plates, and the Kirchhoff theory of thin plates. Nonlinear bending of rectangular sandwich plates is investigated under lateral pressure with some symmetric boundary conditions. Exact solutions of series form are obtained by developing a new technique of mixed Fourier series in nonlinear analysis. The nonlinear partial differential equations are reduced to an infinite set of simultaneous nonlinear algebraic equations, which are truncated and solved by iteration in numerical computations. The present solutions are satisfactory in comparison with other available results.

11A302. Nonlinear bending of simply supported rectangular sandwich plates. - Ren-huai Liu *(Shanghai Univ of Tech, Shanghai Inst of*

Appl Math and Mech, Shanghai, China) and Zhen-qiang Cheng *(Dept of Modern Mech, Univ of Sci and Tech, Hefei, China)*. Appl Math Mech 14(3) 217-234 (Mar 1993).

In this paper, fundamental equations and boundary conditions of the nonlinear bending theory for a rectangular sandwich plate with a soft core are derived by means of the method of calculus of variations. Then the nonlinear bending for a simply supported rectangular sandwich plate under the uniform lateral load is investigated by use of the perturbation method and a quite accurate solution is obtained.

260H. PLATES AND SHELLS ON FOUNDATIONS

11A303. Design of a circular plate on an elastic halfspace for minimum differential settlement. - M Zmerli and RH Plaut *(Charles E Via Jr, Dept of Civil Eng, VPI)*. Struct Optim 6(1) 52-58 (Jun 1993).

A circular plate resting on an elastic halfspace is considered. The plate is deflected downward by a uniform load and sometimes additional edge loads and moments. Translational and rotational supports at the edge are included in some cases. The interface between the plate and the halfspace is assumed to be frictionless. The plate has piecewise-constant thickness, and the segment thicknesses and radii are allowed to vary. For given total volume of the plate, the difference between the maximum deflection (which occurs at the centre) and minimum deflection (which occurs at the edge) is minimized. Optimal solutions depend on the relative stiffness between the plate and the halfspace. The results can be applied to the bottom plate of a ground-supported liquid storage tank.

11A304. Nonlinear static behavior of shallow spherical shell on a Kerr foundation. - DN Paliwal *(Inst-Indust Interaction Cell, Motilal Nehru Regional Eng Col, Allahabad 211004, India)* and R Srivastava *(Dept of Appl Mech, Motilal Nehru Regional Eng Col, Allahabad 211004, India)*. Int J Pressure Vessels Piping 55(3) 481-494 (1993).

A large deflection analysis of a shallow spherical shell on a Kerr foundation is carried out for a uniformly distributed load and for different edge conditions, using the Sinharay and Banerjee approach. Detailed parametric studies involving variations in geometric, material and foundation properties are made; load-deflection curves for shells on a Kerr foundation are compared with those for shells on an equivalent Pasternak foundation. This study shows that the deflection reduces if the curvature, the Poisson's ratio or the foundation parameters of the shear and lower spring layer are increased. Shells with immovable edges are found to be more prone and vulnerable to changes in various parameters than those with movable edges.

260I. THICK PLATES AND SHELLS

11A305. Analytical solutions for thick closed laminated cylindrical shells. - Jiarang Fan *(Dept of Appl Math and Mech, Hefei Univ of Tech, Hefei, Anhui, Peoples Rep of China)* and Kewei Ding *(Dept of Civil Eng, Anhui Architec Indust Col, Hefei, Peoples Rep of China)*. Int J Mech Sci 35(8) 657-668 (Aug 1993).

Discarding any assumption about displacement models and stress distributions, the state equation for orthotropy is established in full in a cylindrical coordinate system. The analytical solutions are presented for the statics, dynamics, and buckling of thick closed laminated cylindrical shells by means of dividing any layer into several thin plates. No matter how many layers are considered, the calculation always leads to the solution of a set of linear algebraic equations in three unknowns. Every equation of elasticity can be satisfied and all the elastic constants can be taken into account. Arbitrary precision of a desired order can be obtained.

11A306. Solution of cosine pressures on a hollow cylinder and the limit when k → 0. - Zhu-hai Liu *(NE Heavy Machinery Inst, Qiqihaer, China)* and Zuo-yu Qi *(Shanghai Heavy Machinery Plant, Shanghai, China)*. Appl Math Mech 14(5) 443-448 (May 1993).

A new stress function is found in this paper and then the problems of cosine pressures on a hollow cylinder are solved with the new stress function, which provides the basis for the solution of the problems of space symmetrical deformation of a hollow cylinder. When the pressures do not vary in the axial direction, that is, when k→0, the lame formulae can be deduced.

262. Structural stability (buckling, postbuckling)

262C. POSTBUCKLING THEORY

11A308. Postbuckling analysis of plates under combined loads by a mixed FEM and BEM. - Jianqiao Ye *(Dept of Theor Mech, Univ of Nottingham, University Park, Nottingham NG7 2RD, UK)*. J Pressure Vessel Tech 115(3) 262-267 (Aug 1993).

The postbuckling behavior of thin plates under combined loads is studied in this paper by using a mixed BEM and FEM. The transverse and the in-plane deformation of the plates are analyzed by the BEM and the FEM, respectively. Spline functions were used as the interpolation functions and shape functions in the solution of both methods. A quadratic rectangular spline element is adopted in the FE procedure. Numerical results are given for typical problems to show the effectiveness of the proposed approach. The possibilities to extend the method developed in this paper to more complicated postbuckling problems are discussed in the concluding section.

262E. COLUMNS AND BEAMS

11A309. Stabilization of beam parametric vibrations. - A Tylikowski *(Inst of Machine Des Fund, Warsaw Univ of Tech, Poland)*. J Theor Appl Mech 31(3) 657-670 (1993).

A theoretical investigation of dynamic stability for linear elastic beams due to time dependent harmonic axial forces is presented. The concept of intelligent structure is used to insure the active damping. In the present paper the applicability of active vibration control is extended to linear continuous system with parametric harmonic excitations. The study is based on the application of distributed sensors, actuators, and an appropriate feedback and is adopted for stability problems of system consisting of beam with control part governed by uniform partial differential equations with time dependent coefficients. To estimate deviations of solutions from the equilibrium state (the distance between a solution with nontrivial initial conditions and the trivial solution) a scalar measure of distance equal to the square root of the functional is introduced. The Lyapunov method is used to derive a velocity feedback implying nonincreasing of the functional along an arbitrary beam motion and in consequence to balance the supplied energy by the parametric excitation and the dissipated energy by the inner and control damping. In order to calculate the energetic norm of disturbed solution as a function of time the partial differential equation is solved numerically. The numerical tests performed for the simply supported beam with surface bounded actuators and sensors show the influence of the feedback constant on the vibration decrease.

262F. RINGS AND ARCHES

11A310. New phenomena in the buckling of arches described by refined theories. - SS Antman and RS Marlow *(Dept of Math and Inst for Phys Sci and Tech, Univ of Maryland, College Park MD 20742)*. Int J Solids Struct 30(16) 2213-2241 (1993).

In this paper we study the local and global behavior of buckled states of nonlinearly elastic circular arches under the action of hydrostatic pressure, concentrating on new effects exhibited by the solution branches. We employ very general (geometrically exact) models for arches that can suffer flexure, extension and shear. The constitutive equations used are intimately related to those of the 3D theory of nonlinear elasticity. These new effects are caused by the interaction of the nonlinearity of material response, the nature of boundary conditions, the cross-sectional geometry, the thickness and the location of the material curve on which the pressure is applied.

262G. FRAMED STRUCTURES

11A311. Worst shapes of imperfections for space trusses with multiple global and local

buckling modes. - Ralf Peek *(Dept of Civil Eng, Univ of Michigan, 2340 GG Brown Lab, Ann Arbor MI 48109).* Int J Solids Struct 30(16) 2243-2260 (1993).

The initial postbuckling behavior and imperfection sensitivity of truss-type structures in which the joints do not transmit moments is determined by means of the Lyapunov-Schmidt-Koiter approach. Such structures possess local buckling modes involving the buckling of individual members, and global modes involving axial deformations of all members but no member buckling. Of particular interest is the case in which thorough optimization (or otherwise) a number of local and global modes are coincident. The worst shape of imperfection for this case is determined from the bifurcated equilibrium branch on which the load drops most rapidly. It is shown that this critical bifurcated branch initially involves the buckling of one member only. The general theory is illustrated by a number of examples involving 2D and 3D lattice columns. The leading order asymptotic results for these examples are compared to exact results obtained by tracking the appropriate equilibrium branch numerically.

A structurally orthotropic shell of revolution is loaded by tensile forces applied to the ends of the shell. Stability of the structure is analyzed by means of the asymptotic method and the Galerkin procedure.

262K. STIFFENED AND ANISOTROPIC STRUCTURES

11A315. Effects of multiple delaminations on compressive buckling behaviors of composite panels. - Hiroshi Suemasu *(Inst for Composite Mat, Univ of Kaiserslautern, Erwin-Schrodinger Str 6750, Kaiserslautern, Germany).* J Composite Mat 27(12) 1172-1192 (1993).

Compressive buckling stability of composite panels with through-width equally spaced multiple delaminations are investigated analytically and experimentally. An analytical method is formulated on the basis of Rayleigh-Ritz approximation technique. Timoshenko type shear effects are included. An experiment and a FE analysis are also conducted on the present model. The analytical results agree very well with the experimental and FE results. The buckling load, which is the compressive strength of the panel in the case of the present model, reduces significantly due to the existence of multiple delaminations. The mechanism causing the significant loss of the compressive buckling load due to the delaminations is well explained.

11A316. Postbuckling behaviors of composite panels with multiple delaminations. - Hiroshi Suemasu *(Inst for Composite Mat, Univ of Kaiserlautern, Erwin-Schrodinger Str, 6750 Kaiserlautern, Germany).* J Composite Mat 27(11) 1077-1096 (1993).

Compressive behaviors of composite panels with through-width, equal-size, equally-spaced multiple delaminations are investigated analytically. An analytical method is formulated on the basis of the Rayleigh-Ritz approximation technique. Contact problem on the delaminated surfaces is considered by the introduction of a constraint, which restricts a relative out-of-plane displacement and a relative slope between the upper and lower portions at a contact point. The postbuckling paths of delaminated panels are solved numerically and the results are compared with the experimental results. If appropriate initial imperfections are assumed, the analytical results can explain well the behaviors of the delaminated panels which are observed in the compressive experiment. The results of the postbuckling analysis indicate that the simplified buckling analysis, where the opening of the delamination is not considered, is sufficient to estimate the buckling load. A method to estimate a total energy release rate is also proposed.

11A317. Postbuckling failure of composite plates with holes. - HH Lee *(Agency for Defense Dev, Yuseong, Taejon, 305-600, S Korea)* and MW Hyer *(Dept of Eng Sci and Mech, VPI).* AIAA J 31(7) 1293-1298 (Jul 1993).

This paper summarizes a study focused on understanding the failure mechanisms present in a plate with a centrally located circular hole loaded in-plane into the postbuckling range of deflections. The study was numerical and experimental in nature and had as a goal the a priori prediction of failure using existing failure data and a stress analysis. The maximum stress failure criterion was used to predict failure and both intralaminar and interlaminar stresses were considered. Four laminates were studied. The phenomenon of modal interaction, or the jumping from one deformed configuration, is discussed. The study concludes that the failure of the $(\pm 45/0/90)_{2S}$ and $(\pm 45/0_2)_{2S}$ laminates is due to fiber compression failure and is predictable. The failure load is, for the most part, independent of response configuration. The $(\pm 45/0_6)_S$ laminate fails due to interlaminar shear along the simple support, while the response and failure of the $(\pm 45)_{4S}$ laminate is governed to a large degree by material nonlinearities and progressive failure.

11A318. Static and dynamic buckling of a fiber embedded in a matrix with interface debonding. - YW Kwon and M Serttunc *(Dept of Mech Eng, Naval Postgraduate Sch, Monterey CA 93943).* J Pressure Vessel Tech 115(3) 297-301 (Aug 1993).

Analyses were performed for static and dynamic buckling of a continuous fiber embedded in a matrix in order to determine effects of interfacial debonding on the critical buckling load and the domain of instability. A beam on elastic foundation model was used for the study. The study showed that a local interfacial debonding between a fiber and a surrounding matrix resulted in an increase of the wavelength of the buckling mode. An increase of the wavelength yielded a decrease of the static buckling load and lowered the dynamic instability domain. In general, the effect of a partial or complete interfacial debonding on the domain of dynamic instability was more significant than its effect on the static buckling load. For dynamic buckling of a fiber, a local debonding of size 10 to 20 percent of the fiber length had the most important influence on the domains of dynamic instability regardless of the location of debonding and the boundary conditions of the fiber. For static buckling, the location of a local debonding was critical to a free, simply supported fiber, but not to a fiber with both ends simply supported.

262L. DYNAMIC STABILITY

11A319. Dynamic stability of a spinning beam carrying an axial dead load. - MB Rosales *(Dept of Eng, Univ Nacional del Sur, 8000 Bahia Blanca, Argentina)* and CP Filipich *(Mech Syst Anal Group, Univ Tecnologica Nacional FRBB, 8000 Bahia Blanca, Argentina).* J Sound Vib 163(2) 283-294 (May 1993).

The linear dynamic behavior of a uniform beam with its cross-section having at least two symmetry axes (the shear centre is coincident with the centroid), rotating with constant velocity about its longitudinal axis and carrying an axial dead load is analyzed. Internal damping is also considered by means of the viscoelastic behavior of the beam material described by the Voigt-Kelvin model. The stability of the solution is investigated by characterizing the eigenvalues under the action of the two external control parameters (spin velocity and axial load). In this way instability and stability regions are distinguished in a map as the control parameters vary. Both (linear) divergence and flutter instabilities arise for certain ranges of compressive axial load. The inclusion of internal damping results in qualitative changes in the stability of the motion if compared with the undamped case. The particular case of a beam with $J_x = J_y$ is also included.

11A320. Nonlinear dynamic buckling and stability of autonomous structural systems. - AN Kounadis *(Dept of Struct Anal and Steel Bridges, Natl Tech Univ, 42 Patission St, Athens 106 82, Greece).* Int J Mech Sci 35(8) 643-656 (Aug 1993).

A general approach for the nonlinear dynamic buckling and stability of dissipative or nondissipative structural systems governed by the autonomous ordinary differential equations is presented. Geometrically imperfect systems with or without symmetric imperfections, as well as statically stable systems, which, in addition to a monotonically rising (stable) equilibrium path exhibit an unstable complementary path, are considered. The role of the dynamic buckling mechanism of the basin of attraction of a stable equilibrium point (on the prebuckling path), as well as the inset (stable) and outset (unstable) manifolds of a saddle (on a physical or complementary unstable path), are comprehensively explained. A static energy criterion for determining dynamic buckling loads for vanishing (but nonzero) damping and lower bound estimates of exact dynamic buckling loads are presented. Metastability, loading discontinuity and chaos-like phenomena are also revealed. The analysis is supplemented by two illustrative models of practical engineering importance.

262M. VISCOELASTIC AND CREEP BUCKLING

11A321. Bifurcation buckling of circular cylindrical shells subjected to axial compression during creep deformation. - N Miyazaki *(Dept of Chem Eng, Kyushu Univ, Higashi-ku, Fukuoka 812, Japan)* and S Hagihara *(Dept of Mech Syst Eng, Kyushu IT, Iizuka-shi, Fukuoka-ken 820, Japan).* J Pressure Vessel Tech 115(3) 268-274 (Aug 1993).

In the present work, analytical and experimental investigations were performed on creep buckling. Special attention was focussed on bifurcation behavior during creep deformation. The FEM was used to analyze creep buckling of circular cylindrical shells without initial imperfection. The number of circumferential waves obtained from the analyses agrees well with those of the experiments. The present experimental investigation shows that the circumferential waves are suddenly caused near a bulge. It is also found that there is no correlation between the wavelength of the circumferential waves observed at creep buckling and that of the circumferential initial imperfection. Deformation patterns at the bifurcation creep buckling obtained from the analyses are analogous to those of the experiments. It is concluded from the analyses and the experiments that the circumferential waves observed in creep buckling experiments are due to bifurcation buckling during creep deformation.

11A322. Creep buckling of cross-ply symmetric laminated cylindrical panels. - Ying-jian Wang *(Dept of Mech, Peking Univ, Beijing, China)* and Zhen-ming Wang *(Inst of Mech, Acad Sinica, Beijing, China)*. Appl Math Mech 14(4) 313-318 (Apr 1993).

A creep buckling analysis of cross-ply symmetric laminated cylindrical panels is given in this paper. By means of theoretical analysis, a method to determine the critical load of creep buckling of the panels with simply supported boundary conditions is obtained.

262N. PLASTIC AND ELASTOPLASTIC BUCKLING

11A323. Dynamic buckling and plastic collapse of rectangular strips under axial slamming impact. - Shi-Qi Ji and Ji-Jia Zheng *(Dept of Naval Architec and Ocean Eng, Huazhong Univ of Sci and Tech, 430074 Wuhan, Peoples Rep of China)*. Acta Mech Solida Sinica 6(3) 349-356 (Jul 1993).

The dynamic buckling and plastic collapse of elastic-plastic rectangular strips under axial slamming impact are investigated experimentally. The dynamic response of the specimens is measured by several back-to-back paris of strain gages located at different positions. According to the experimental records, the compressive and bending motions of the rectangular strips are analyzed. The strips exhibit three different critical dynamic conditions: buckling, plastic incipience, and plastic collapse. Based on the response characters, three criteria are proposed which completely define the elastic-plastic dynamic behavior of rectangular strips under axial slamming impact with loading durations ranging from 14 to 18 milliseconds. These conditions are estimated by introducing three critical axial compressive strains. Moreover, the effect of geometric imperfection on the dynamic behavior of the strips is discussed.

Influence of annealing time at 395-400°C on the ΔE effect, magnetostriction and magnetic anisotropy in $Fe_{78}Si_8B_{14}$ metallic glasses. - Luciano Lanotte *(Dept of Phys Sci, GNSM-CIFM Group, Univ of Naples, Piazzale V Tecchio 80, 80 125 Naples, Italy)*, Zbigniew Kaczkowski *(Polish Acad of Sci, Inst of Phys, Al Lotnikow 32-46, PL-02-668 Warsaw, Poland)*, Carlo Luponio *(Dept of Phys Sci, GNSM-CIFM Group, Univ of Naples, Piazzale V Tecchio 80, 80 125 Naples, Italy)*. Int J Appl Electromagnetics Mat 4(1) 59-64 (Jun 1993).

The Young's modulus (E), magnetostriction (λ) and magnetic anistropy (K_u) in rapid quenching $Fe_{78}Si_8B_{14}$ alloy were investigated. Effects of subsequent annealing at 395-400°C are reported. Connections between ΔE effect and magnetic anisotropy confirm the role of structural relaxations. A relation between E and minimum and maximum changes of magnetostriction is theoretically and experimentally pointed out.

11A325. Magnetic forces in high T_c superconductors. - CS Chou and JL Liang *(Inst of Appl Mech, Natl Taiwan Univ, Taipei, Taiwan, ROC)*. Int J Appl Electromagnetics Mat 4(1) 43-48 (Jun 1993).

Magnetic forces between a permanent magnet and bulk YBCO high T_c, superconducting specimens prepared in different processes are investigated in this paper. The magnetic forces in specimens prepared by melting growth are larger than those of the sintered specimens. Repulsion forces between magnet and specimens were measured when the superconducting specimens raised toward the magnet. The repulsion force decreased and became an attraction force in some specimens when the specimen was lowered away from the magnet. This attraction force is closely related to the pinning of the specimen. The levitation of a magnet on specimens having attraction force was stable in a continuous range of positions and orientations. The magnetic forces are closely related to the microstructures of the specimens which are discussed in this paper.

11A326. New numerical analysis method of dynamic behavior of a thin plate under magnetic field considering magnetic viscous damping effect. - T Takagi and J Tani *(Inst of Fluid Sci, Tohoku Univ, Katahira 2-1-1, Aoba-ku, Sendai 980, Japan)*. Int J Appl Electromagnetics Mat 4(1) 35-42 (Jun 1993).

A new numerical method, the so-called MMD method, for electromagnetomechanical coupling analysis was proposed and applied to a thin plate dynamic behavior analysis for its verification test. It becomes important to evaluate the dynamic behavior of electrically conducting structure under strong magnetic field. The coupling effect between eddy current and deformation of structure plays an important role in the dynamic behavior in the field. The method developed here considering the coupling effect is based on a modal analysis method and FEM. Magnetic viscous damping coefficient for each natural vibrational mode can be obtained. Using this coefficient eddy current and plate bending can be calculated separately but considering the coupling effect. Numerical results of the verification test show good agreement between the proposed method and the conventional one.

11A327. Numerical modeling of 2D magnetic properties for the FEM. - M Enokizono and K Yuki *(Dept of Elec Eng Fac of Eng, Oita Univ, 700 Dannoharu, Oita 870-11, Japan)*. Int J Appl Electromagnetics Mat 4(1) 49-58 (Jun 1993).

In the past, the magnetic properties of a material were estimated by measured scalar quantities in a measurement direction under the condition of an alternating magnetic field excitation. Also, in the conventional magnetic field analysis which is applied to such things as rotating machines, the magnetic properties of the arbitrary direction has been modeled by using the magnetic properties of the easy axis and its perpendicular direction. Such kind of numerical modeling cannot exactly show the phase difference between the magnetic flux density B and the magnetic field strength H in the case of a rotating magnetic field excitation. In this paper, we measure the B and H values as vector quantities in the case of the rotating magnetic field excitation. The magnetic properties of the material are expressed by the magnetic reluctivity tensor. This new expression can be applied to the rotting magnetic field analysis. As a result, it is shown that our new method is applicable to the problem in the case of the rotating magnetic field excitation.

11A328. Surface magnetostriction. - H Szymczak and R Zuberek *(Inst of Phys, Polish Acad of Sci, Al Lotnikow 32-46, 02-668 Warszawa, Poland)*. Acta Phys Polonica A 83(5) 651-660 (May 1993).

Experimental and theoretical research on magnetostriction of nanoscale magnetic multilayers is reviewed. The importance of interfaces and the occurrence of the surface magnetostriction is emphasized. It is shown that the dependence of magnetostriction on the magnetic layer thickness is due to the magnetostriction strain localized at the interface.

11A329. Beltrami fields, within continuous source regions, volume integral equations, scattering algorithms and the extended Maxwell-Garnett model. - A Lakhtakia and B Shanker *(Dept of Eng Sci and Mech, Penn State)*. Int J Appl Electromagnetics Mat 4(1) 65-82 (Jun 1993).

Singularities of 3D and quasi-2D frequency-domain Green's dyadics are used to derive expressions for a Beltrami field in its source region. The mathematical developments are utilized to set up 3D volume integral equations and scattering algorithms for scattering by inhomogeneous bianisotropic scatterers embedded in a homogeneous biisotropic ambient medium. Application is also made towards the effective medium properties of a particulate composite formed by randomly dispersing bianisotropic particles in a biisotropic host medium.

11A330. Fourier series with Legendre polynomials as solving functions of mixed multi-periodic boundary value problems. - D Gafka *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. J Tech Phys 34(2) 173-183 (1993).

A complementary pair of functions filling the multi-periodic conditions have been constructed. The Fourier series expansions of these functions have also been given. The coefficients of series are related to Legendre polynomials. The pair of functions presented can be used to obtain a numerical solution of any boundary value problem with mixed multi-periodic boundary conditions. It was used in electro-elasticity especially in surface acoustic wave propagation problems.

264G. MECHANICS OF SUPERCONDUCTING MATERIALS

11A331. **Experimental and numerical analysis of 3D high-T_c superconducting levitation systems.** - M Uesaka, Y Yoshida, N Takeda, K Miya *(Nucl Eng Res Lab, Fac of Tokyo, Ibaraki-prefecture 319-11, Japan)*. Int J Appl Electromagnetics Mat 4(1) 13-25 (Jun 1993).

Magnetic levitation properties of MPMC-YBaCuO in 3D geometries of practical interests were investigated experimentally. Especially, it was confirmed that the vertical and horizontal magnetic forces are strongly dependent on grain structure, cracks and applied magnetic field configuration. Furthermore, a 3D computer code based on the current vector potential (T) method was upgraded. The dependence of critical current density (J_c) on applied magnetic field can be taken into account. Magnetic force behavior in several configurations was numerically analyzed by using this code and the results were compared with the experimental ones. It is concluded that the discrepancy between the experimental and numerical results is mainly due to material imperfections such as grain boundary, cracks and deterioration of J_c of large MPMG-YBaCuO samples.

11A332. **Influence of nanometer-scale copper filaments in niobium on mechanical and superconducting properties.** - R Zhou, S Hong *(Superconducting Tech, Oxford Instruments, 600 Milik St, Carteret NJ 07008)*, BH Kear *(Dept of Mech and Mat Sci, Rutgers Univ, New Brunswick NJ 08903)*, PJ Lee *(Appl Superconductivity Center, Univ of Wisconsin, Madison WI 53706-1687)*. Nanostruct Mat 2(1) 73-80 (Jan-Feb 1993).

Nanometer-scale copper filaments are introduced into niobium as artificial flux pinning centers (APC's) by multiple extrusion. A ribbon-like structure is observed in both niobium and copper at the final wire size. The composite experiences extensive work hardening during mechanical reduction. The pinning force of niobium with APC's is significantly enhanced relative to that of cold worked bulk niobium.

11A333. **Exact solution for static analysis of an intelligent structure under cylindrical bending.** - MC Ray, KM Rao, B Samanta *(Dept of Mech Eng, Indian IT, Kharagpur-721 302, India)*. Comput Struct 47(6) 1031-1042 (17 Jun 1993).

An exact static analysis of a simply supported intelligent structure under cylindrical bending is presented. The performance of the actuator layer of the intelligent structure to cause induced axial and transverse stresses in the substrate layer is investigated. The capability of the sensor layer to sense the deformations of the structure is shown in terms of induced electric potential on its surface. The distribution of electric potential across the thickness of the piezoelectric sensor and actuator implies that the linear variation can be adopted for choosing the electric potential function to model the laminated intelligent structure for complicated geometry and boundary conditions with refined approximate tehcnique. The results presented here will be helpful to obtain correlation between theoretical and experimental results and to numerical analysis to verify their results.

264Z. EXPERIMENTAL TECHNIQUES

11A334. **Acoustoelectrical relaxation in GaAs by the formation and the recovery of metastable EL2x.** - J Ertel, HG Brion, P Haasen *(Inst Metallphys, Univ Gottingen, Hospitalstr 3-7, W-3400 Gottingen, Germany)*. Acta Phys Polonica A 83(1) 11-24 (Jan 1993).

The transformations between the normal and metastable state of EL2 in GaAs are investigated. We apply the internal friction technique as a probe for very small conductivities and discuss the changes in conductivity by the formation and recovery of EL2x. At 40 K both shallow acceptors and EL2 are photoquenched into neutral metastable states. The acceptors are likely to be associated with EL2x forming an electrically inactive state. We identify two damping peaks at 60 and 95 K with the regeneration of the acceptors and EL2 respectively. The latter indicates a regeneration via the charged deflect $(EL2)^+$.

11A335. **Dielectric properties of isatomalononitrile.** - SM Khalil *(Dept of Physics, Alexandria Univ, Egypt)* and AMA Hassaan *(Dept of Chem, El-Minia Univ, Egypt)*. Acta Phys Polonica A 83(4) 477-480 (Apr 1993).

The paper reports dielectric measurements carried out for isatomalononitrile at different temperatures (346 to 383 K) and various frequencies (50 to 5×10^5 Hz). Kramers-Kronig relations are used to ascertain the magnitude of the dc conductivity and to enhance the reliability of dielectric measurements. The analysis of the results shows that there exists certain very slow dielectric phenomena in isatomalononitrile. The frequency dependent conductivity of isatomalononitrile increases approximately linear with frequency. The frequency exponent has the value of 0.5, independent of temperature.

11A336. **Investigation of the dependence of dielectric properties of D-serine admixtured TGS crystals of the distance from the seed of the crystal growth.** - J Stankowska, A Czarnecka, B Dongo Gemi *(Inst of Phys, A Mickiewicz Univ, Grunwaldzka 6, 60-780 Poznan, Poland)*. Acta Phys Polonica A 83(4) 485-494 (Apr 1993).

Dielectric properties of a D-serine admixtured triglycine sulphate (TGS) crystal were studied on samples cut from different sites in the crystal. The value of spontaneous polarization P_S measured on b-cuts was found to be independent of the site. Whereas the coercive field E_c values were higher for the samples cut closer to the seed than for those cut at the ends of the crystals along b axis. After rejuvenation of the values of the bias field E_b increased in contrary to the effect observed in the pure TGS crystals. An exponentially decreasing dependence on the maximum permittivity ε_{max} on the site of samples (b-plates) cut along b axis from - b to + b positions, was obtained.

11A337. **Derivation of material variability from settlement measurements.** - DG Zeitoun *(Hydrological Service, POB 6381, 91063 Jersualem, Israel)* and J Uzan *(Dept of Civil Eng, Israel IT, 32000 Technion City, Israel)*. Int J Numer Anal Methods Geomech 17(5) 303-322 (May 1993).

In pavement evaluation using non-destructive testing (NDT), a large amount of deflection bowls are analysed in terms of the elastic moduli of the layers. The results are used to evaluate the material variability which could serve in an overlay design procedure based on the concept of reliability. The model currently used for interpreting deflection bowls is based on the random variable theory which neglects the spatial distributions of the elastic modulus of the material. Since the subgrade and pavement materials have a spatial distribution, the analysis of NDT could lead to an underestimate of the material variability. The random field theory, which is more adequate than the random variable theory, is presented and used to correct the NDT analysis. The pavement is modelled as a multilayer random elastic medium with, for each layer, a constant Poisson's ratio and a random shear modulus characterized by three statistical moments: average value, standard deviation and autocorrelation function. The stochastic integral formulation presented in the previous publication is generalized here for a multilayer system. The multilayer system is analysed with the random field theory and the covariance matrix of the deflection bowl is obtained and used to generate deflection bowls corresponding to the properties of the random field. These bowls are then interpreted with the current procedure and elastic modulus variabilities are computed. It is found that the current procedure for interpreting deflection bowls underestimates the variability of the subgrade, by a factor of 0.4-1.0.

11T338. **Settlement analysis. The deformation method.** - J Pieczyrak *(Silesian Tech Univ, Gliwice, Poland)*. Inzynieria Budownictwo 50(2) 70-73 (1993).

11A339. **Influence of surface active additives on the properties of asphalt and mineral-asphalt mixtures.** - B Stefanczyk *(Inst of Civil Eng, Szczecin Univ of Tech, Poland)*. Arch Civil Eng 38(4) 353-374 (1992).

The use of inferior quality aggregates such as gravel, sand-gravel mix and quartzite in the laying of bituminous pavements requires a modernization of the production process. In particular, inadequate bond of asphalt to those materials must be enhanced. The best results in this respect have been obtained by using certain surface active agents (SAA) that, depending on their chemical structure, can be aniono-active or cationo-active. In the described investigations two additives were used: aniono-active Pakwat Fe and cationo-active Kaminoaks D. Their effect on the asphalts of various Compositions (D70, D50, Dex70) were examined in a broad range of temperatures. Penetration and viscosity were tested above freezing point and higher temperatures, whereas their mechanical properties were measured below freezing point. The behavior of asphalts with and without the additives was investigated by means of thin films of binder on the surfaces of two different mineral materials (limestone, granite). In each particular test two different characteristics of the binder were examined: adhesion and cohesion. Effectiveness of the surface active additives were also tested in a medium-grained mineral-asphalt mixture on the basis of both Polish and American Codes. The investigation have led to the conclusion that the effectiveness of surface active additives depends on the chemical and mineralogical type or rock, chemical-group composition of asphalt as well as a type and amount of additives in the asphalt and in the mineral-asphalt mixture.

272B. APPLICATIONS OF PLASTICITY THEORY

11A340. Limit strain predictions for out-of-plane stretching of sheet metals. - A Zeghloul and G Ferron *(Lab de Phys et Mec des Mat URA CNRS 1215 ISGMP, Univ of Metz, Ile du Saulcy, 57045 Metz Cedex 1, France).* Int J Plasticity 9(5) 603-618 (1993).

An investigation is performed to predict the limits of sheet metals stretchability in different out-of-plane experiments. Based on the time-independent flow theory, the analysis includes the effects of strain hardening and normal anisotropy and utilizes different yield functions with the assumption of isotropic hardening. The limit strains, determined either from the condition of bifurcation at maximum pressure for hydrostatic bulging, or from the analysis of flow localization in hemispherical punch stretching, depend on the type of the test. For a given test, however, the plot of the limit strains in the usual ε_1-ε_2 diagram does not exhibit a marked sensitivity to the yield function utilized. This behavior contrasts with the predictions of instability models assuming in-plane stretching.

272D. EXTRUSION

11A341. Development and application of aluminum extrusion for automotive parts, mainly bumper reinforcement. - Mitsuyuki Isogai and Satoshi Murakami *(Aisin Keikinzoku, Nagonoe 12-3, Shinminato-shi, Toyama, Japan).* J Mat Processing Tech 38(4) 635-654 (Jul 1993).

Whilst there is an advancing tendency toward lighter vehicles, the application of aluminum extrusion to the production of automotive parts has been quite rare due to cost, strength and corrosion problems. In this report, it is explained how new materials, product design, and processing have been developed to match the automotive parts to which is aimed the adoption of the aluminum extrusion technique. Also activity to solve the problems in applying this technique, and the endeavor to widen the application of aluminum extrusion are reported.

11A342. Hyperbolicity and change of type in steady co-extrusion flow of upper-convected Maxwell fluids. - KangPing Chen *(Dept of Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287-6106).* J Non-Newtonian Fluid Mech 47 157-167 (Jun 1993).

The linearized equations governing the steady axisymmetric co-extrusion flow of two upper convected Maxwell fluids through a circular die are studied and conditions are found under which the vorticity equation can change its type from elliptic to hyperbolic in the core and the annulus regions.

11A343. Numerical prediction of extrudate swell of a high-density polyethylene: Further results. - A Goublomme *(Polyflow sa, 16 Place de L'Universitat, 1348 Louvain-la-Neuve, Belgium)* and MJ Crochet *(Unite de Mec Appl, Univ Catholique de Louvain, 2 Place du Levant, 1348 Louvain-la-Neuve, Belgium).* J Non-Newtonian Fluid Mech 47 281-287 (Jun 1993).

We investigate the effect of temperature and of the second normal stress difference on the extrudate swell of a high-density polyethylene at high shear rates with the use of a Wagner model. We find that the flow is indeed non-isothermal but that temperature has little effect upon the swelling ratio. However, the second normal stress difference produces major effects on the swelling ratio. We conclude that any realistic prediction of extrudate swelling requires an accurate measurement of the second normal stress difference.

11A344. Peripheral-recrystallized structures formed in Al-Zn-Mg-Cu-Zr alloy materials during extrusion and their quenching sensitivity. - S Kikuchi, H Yamazaki, T Otsuka *(Showa Aluminum, 480 Inuzuka, Oyama, Tochigi, Japan).* J Mat Processing Tech 38(4) 689-701 (Jul 1993).

A study was done on the peripheral-recrystallized structures formed in Al-Zn-Mg-Cu-Zr alloy materials during extrusion and on their quenching sensitivity. It was found that the peripheral-recrystallized structures were thicker at the head and tail sections of the extrusion than at the other sections. The further downwards towards the tail, the greater the thickness of the structures became. The peripheral-recrystallized structures had a remarkable quenching sensitivity and under some heat treatment conditions, attained only half of the hardness of the fiber structure. Even with the same fiber structure, the extrusion (material) tail had a higher quenching sensitivity than that of the head portion. It is thought that the drop in strength that is encountered frequently in the proximity of the tail portion of the extrusion during actual production of this type of alloy may occur under the same mechanism as controls the above-described phenomenon, and that the phenomenon of the sharpening of sensitivity to quenching is caused by the change of Al_3Zr from a precipitate coherent with the matrix to a precipitate incoherent with the matrix, resulting from the strain during extrusion. The incoherent Al_3Zr precipitate is thought to become an η-phase precipitation site. This zone of sharp quenching sensitivity responds to the surface or to the tail, which latter undergoes a large plastic strain during extrusion. In the section undergoing plastic strain, the quenching sensitivity is especially acute, and if an adequate quench rate cannot be achieved during solution treatment, such a high quenching sensitivity can be a cause of an insufficient increase in hardness after ageing. Most billet homogenizing treatments on this alloy are done at temperatures of about 450°C-480°C. However, it is shown that when a lower temperature of 400°C is selected as a homogenizing treatment parameter, the sharp sensitivity to quenching can be restrained.

272F. DRAWING

11A345. Numerical and failure analysis on the drawing of a circular cylindrical cup. - CK Chao, CH Liu, HJ Wu *(Dept of Mech Eng, Natl Taiwan IT, Taipei, Taiwan 106, ROC).* Eng Fracture Mech 45(4) 439-450 (Jul 1993).

The incremental theory of plasticity is applied in conjunction with FEs for modeling of the circular cylinder cup. A punch-die system is prescribed such that a circular blank is displaced at constant increments of 0.005 mm until a cup of 16 mm deep is formed. Based on the strain energy density failure criterion, failure initiation accompanied by large dilation is located by the maximum of the minimum local strain energy density function, $(dW/dV)^{max}{}_{min}$, while yielding initiation accompanied by large distortion is located by the maximum strain energy density function, $(dW/dV)^{max}{}_{min}$. For a punch displacement of 16 mm, $(dW/dV)^{max}{}_{max}$ is near the critical value $(dW/dV)_c$ of the metal sheet which suggests the possibility of fracture initiation. The influence of material drawability and punch movement on the rate of cup formation could be evaluated from analytical simulation of the deep drawing process. Computer software developed in the present study can also be applied to evaluate the drawing characteristics of non-axisymmetric cups.

11A346. Square shell drawing characteristics of aluminum alloy sheet A5182-O. - T Kuwabara, K Akiyama, Y Nakayama *(Mech Syst Eng, Fac of Eng, Tokyo Univ of Agri and Tech, 2-24-16, Naka-cho, Koganei-shi, Tokyo 184, Japan).* J Mat Processing Tech 38(4) 737-749 (Jul 1993).

Deep-drawing experiments on aluminum alloy sheet A5182-O of 0.48 mm thickness have been conducted using square punches with the geometrical ratios r_c/l = 0.1, 0.15, 0.238, 0.25, and 0.5 (l is the side length of the punch, r_c is the corner radius of the horizontal section of the punch). Two types of fracture, punch-profile fracture and wall breakage, were found to limit the drawable heights, and the map which clarifies the relationship between blank shapes and the types of fracture was generated for all the punches. The optimum blank shape to give the deepest shell was determined also for each punch shape. The deep-drawing conditions which affect the wall breakage were discussed. The wall breakage was found to be restrained by preventing the blank-holding force from concentrating on the corner portions in the flange; in this case by sticking strips of stainless-steel tape onto the blank-holding plate, in front of the sides of the die cavity.

11A347. Tensile ductility and deep drawability of rate dependent sheet materials. - H Ohsawa *(Dept of Mech Eng, Col of Eng, Hosei Univ, Kajino chiyo, Koganei City, Tokyo, Japan)* and M Ikeda *(Olympus Optical, Kuboyama chiyo, hachioji City, Tokyo, Japan).* J Mat Processing Tech 38(4) 703-722 (Jul 1993).

The aim of this work is to clarify the role of appreciable rate dependency of the flow stress in practical sheet metal stamping operated at room temperature. The uniaxial ductility of rate-dependent sheet materials which have the ability of strain hardening as well as strain-rate sensitivity is examined. An analytical description combined with conventional instability theories predicts the significance of the rate of change of strain rate during uniaxial deformation in estimating the ductility. In accordance with the prediction, an Instron test machine is improved so as to be able to accelerate and decelerate the strain rate. Computational mechanics is introduced also to simulate the test. The precise examination on the influence of the rate dependency on the total elongation clarifies the nature of the rate of change of strain rate but results in a somewhat diverse conclusion. In deep drawing where the ductility of sheet metals is of little concern, the effect of continuous change of punch speed on the limiting drawing ratio (LDR) is investigated experimentally also. Sheet metals of pure aluminum and zinc are used in the test and the LDR is determined for each tool geometry. Measured LDRs show distinct differences, depending upon the punch-speed conditions, but systematic explanation of the trends displayed has not yet been accomplished.

272G. SHEET METAL FORMING AND STAMPING

11A348. Development of an all-aluminum automotive body. - Y Muraoka *(Honda R&D, 321-33, 4630 Shimotakanezawa Haga-machi,* *Haga-gun Tochigi Pref, Japan)* and H Miyaoka *(Honda Eng, 350-13, 1-10-1, Shinsayama Sayama-shi, Saitama Pref, Japan)*. J Mat Processing Tech 38(4) 655-674 (Jul 1993).

To develop Honda's all-aluminum automotive body, many technical problems have had to be overcome, amongst which, the establishing of a press-forming technology was one of the most difficult. The aim was to give aluminum plate the same level of formed quality as that of steel plate, even though aluminum plate has a poorer formability than that of steel plate. For this purpose, it was required to develop and advance suitable technologies concerning the material, the die and the forming plan, with each of these items being closely related. This paper describes the detailed development and the various technical problems overcome, both up to the start of mass production of the all-aluminum body, and in the development concept.

11A349. Forming limit curves of aluminum and aluminum alloy sheets and effects of strain path on the curves. - S Kohara *(Dept of Mat Sci and Tech, Sci Univ of Tokyo, Noda, Chiuba 278, Japan)*. J Mat Processing Tech 38(4) 723-735 (Jul 1993).

For the applications of aluminum to automobile bodies, sheet forming is an essential process. The formability of sheet materials can be assessed by the forming-limit curve. However, little has been reported on the forming-limit curves of aluminum alloys. In this study, the forming-limit curves of aluminum and non-heat treatable aluminum alloy sheets were determined and the effects of the strain path on the curves were investigated. It was shown that larger limit strains without failure can be achieved by selecting a proper strain path.

11A350. Numerical simulation technology for lightweight aluminum can. - H Takeuchi *(Aluminum Res Dept, Aluminum and Copper Div, Kobe Steel, 15, Kinugaoka Moka-city, Tochigi 321-43, Japan)*. J Mat Processing Tech 38(4) 675-687 (Jul 1993).

About twenty years have passed since aluminum D&I cans were firstly produced in Japan. In this period, as the thickness of aluminum sheets for can bodies and can ends has become thinner, the weight of cans has become correspondingly lighter. In this paper, several recent technologies to lighten cans are described. In the material field, the new aluminum can stock 3004-H191, with high strength, has been developed. Numerical simulation by computer has been applied to optimize both the can profile and the can-manufacturing condition. Can bottom profiles resisting high internal pressure are clarified for one example of optimizing the can profile. Two numerical simulations in the can manufacturing process are also demonstrated. In the necked-in process, an optimum die profile to reduce the necking load and prevent the occurrence of buckling of the thin sidewall is obtained. In the scoring process on the can end, a desirable scoring-punch profile and punch-surface condition are investigated for the attainment of a good scoring performance.

11A351. Plain strain rigid plastic FE formulation for sheet metal forming process. - PAF Martins *(Dept de Eng Mec, Inst Superior Tec, Lisboa, Portugal)* and MJM Barata Marques *(Inst Nacional de Eng Tec Indust, Lisboa, Portugal)*. Proc Inst Mech Eng B 207(B3) 167-171 (1993).

A rigid plastic FE model for analyzing 2D plane strain sheet metal forming processes is described. The model is based on the large strain formulation using membrane theory, and the material is assumed to be rigid plastic, work hardening and conforms to Hill's anisotropic yield criterion and associated flow rules. The theoretical development follows the work of Kobayashi and Kim on the axisymmetric modeling of sheet metal forming. An application of the model for plane strain cylindrical punch stretching is presented. The results obtained are compared with those provided through an analytical membrane solution described in this work. The agreement found between both solutions is excellent.

272P. RAPID SOLIDIFICATION

11A352. Molecular-dynamics simulation of rapid solidification of aluminum. - J Lu and JA Szpunar *(Dept of Mining and Metall Eng, McGill Univ, 3450 University St, Montreal, PQ, H3A 2A7 Canada)*. Acta Metall Mat 41(8) 2291-2295 (Aug 1993).

A constant pressure molecular-dynamics simulation is used to examine changes in the structural characteristics of aluminum during rapid solidification. The glass formation and the crystallization from the liquid are predicted. The structure transformations which occur during solidification are described using the mean atomic volume, the internal energy, the radial distribution function and the surface tension. Changes in these parameters calculated as function of temperature display anomalies associated with a change in the structural ordering and change in the phase transformation.

274B. CRACK INITIATION

11A353. Calculations of crack widths under pure torsion. - T Ciezak *(Fac of Civl and Sanitary Eng, Lublin Univ of Tech, Poland)*. Arch Civil Eng 38(3) 239-248 (1992).

A method to calculate widths of skew cracks generated by the action of twisting moment in the conditions of pure torsion is presented. Slip of both longitudinal reinforcement and stirrups with respect to concrete is allowed for. At the first stage of loading the width of the first crack is determined. At the stage of working load an average width of cracks is assumed to be dependent upon the stress increments in primary bars and stirrups above the stresses causing first cracks and upon a bond parameter. Further research is discussed necessary to apply the method in the practice of dimensioning of elements under torsion.

274C. SUBCRITICAL CRACK PROPAGATION

11A354. Aspects of fatigue affecting the design and maintenance of modern military aircraft. - SA Barter, JQ Clayton, G Clark *(DSTO Aeronaut Res Lab, Melbourne, Australia)*. Int J Fatigue 15(4) 325-332 (Jul 1993).

Over recent years, Australian aircraft operators have gained substantial experience with the early detection and management of cracking in critically stressed aircraft components. In the military sphere, the RAAF have been able to operate high-performance aircraft with cracks in specific locations in the airframe, by recognizing that an appropriate safety-by-inspection approach to cracking in critical components could permit continued operation, life extension, and maintenance efficiences. This approach has worked well in older aircraft, where cracks tend to initiate in well-defined high-stress areas, such as at fastener holes or similar design features, and where crack growth is sufficiently localized to allow crack length monitoring using established non-destructive inspection (NDI) techniques. Extension of this approach to newer aircraft, however, presents certain problems; in particular, the use of a variety of life-enhancing treatments (such as shot peening or cold expansion of fastener holes) in combination with high levels of average component stress has led to greater uncertainty about the number of potential cracking sites, their exact location within the structure, and the crack growth rates at these sites once cracks develop. This paper reviews the changing trends in aircraft design with respect to fatigue and fracture resistance, and discusses the influence of factors such as design approach, surface treatment technique, material behavior and NDI capability on life extension and the management of cracking in a fleet of military aircraft.

11A355. Creep-fatigue properties of Mod 9Cr-1Mo steel under variable straining. - M Miyahara and K Tokimasa *(Iron and Steel Res Lab, Sumitomo Metal Indust, Amagasaki 660, Japan)*. J Pressure Vessel Tech 115(3) 235-241 (Aug 1993).

Two-step variable straining tests, which included CP- (slow-fast) type and PC- (fast-slow) type tests, were conducted at 600°C in air for Mod 9Cr-1Mo steel. In the tests, CP and PC-type strain range level varied from high to low for the high-low test and from low to high for the low-high test. The deviations of the experimental data from the linear damage rule prediction were observed. These experimental results and the effect of the strain waveform on the creep-fatigue properties under variable straining were explained by the life prediction model previously proposed by the authors in which the strain range partitioned crack growth rate equations were applied.

11A356. Fatigue crack growth and closure behavior of semicircular and semi-elliptical surface flaws. - RG Chermahini, B Palmberg, AF Blom *(Struct Dept, Aeronaut Res Inst of Sweden FFA, PO Box 1102, S-161 11 Bromma, Sweden)*. Int J Fatigue 15(4) 259-263 (Jul 1993).

The growth behavior of semi-elliptical and semicircular cracks subjected to crack extensions due to tensile constant amplitude loading ($R = 0.1$) was investigated using a 3D elastic-plastic FE analysis of fatigue crack growth and closure. Based on this analysis, for both semicircular and semi-elliptical meshes, the crack first closed on the exterior (free) surface ($\theta = 0°$) and then closed towards the interior region upon further unloading of the cyclic loading. The closure and opening behavior of crack surfaces for both semicircular and semi-elliptical geometries are investigated. An experimental investigation of semi-elliptical flaws under fin spectrum loading was conducted to simulate relastic growth rate behavior for the semi-ellipticl geometry.

11A357. Multiple crack model for fatigue in welded joints. - S To *(FMG Timberjack, Woodstock, ON, N4S 7X1, Canada)*, SB Lambert, DJ Burns *(Dept of Mech Eng, Univ of Waterloo, Waterloo, ON, N2L 3G1, Canada)*. Int J Fatigue 15(4) 333-340 (Jul 1993).

Several linear elastic fracture mechanics models have been developed to simulate the fatigue performance of welded joints, particularly for offshore structures. Such models are used to estimate residual life when cracks are discovered in service. These models are also used to interpret available experimental results and may eventually be used in design. A key element to the success of such models is the realistic modeling of fatigue crack shape development. In all fatigue testing of welded T-plate, pipe-plate, and tubular joints in the Canadian Offshore Research Programme, care was taken to monitor crack shape development using beach marks and potential-drop techniques. Crack shape development was significantly influenced by specimen thickness, stress distribution and environment. A fatigue model is proposed which explicitly models the growth and coalescence of multiple semi-elliptic fatigue cracks. Such a model has the potential of modeling geometry and environmental effects through their influence on crack shape development. The basics of this model, including coalescence and the calculation of stress intensity factors, are discussed. Verification studies involving both T-plate and pipe-plate specimen geometries are presented.

11A358. Stable crack growth in ceramics at ambient and elevated temperatures. - JY Pastor, J Llorca, J Planas, M Elices *(Dept of Mat Sci, Polytech Univ, 28040-Madrid, Spain)*. J Eng Mat Tech 115(3) 281-285 (Jul 1993).

Quasi-static, stable crack propagation tests in ceramics are presented. The tests are performed using a recently developed technique in which the crack mouth opening displacement is continuously monitored during the test by means of a laser extensometer, and this signal is employed to control a servo-hydraulic testing machine. The advantages of such tests to characterize the fracture behavior of ceramics at high temperature are described, and the technique is used to study the fracture behavior of an ytria-partially stabilized zirconia ceramic at ambient and elevated temperatures.

11A359. Studies of mixed mode crack propagation in D16AT aluminium alloy. - V Srinivas and P Vasudevan *(Dept of Mech Eng, Indian IT, Bombay 400 076, India)*. Eng Fracture Mech 45(4) 415-430 (Jul 1993).

Mixed mode crack behavior was studied. Experiments were conducted on Compact Tension Shear (CTS) specimens at different angles including both mode I and mode II test conditions, and in both static and fatigue conditions. In addition to these tests overload tests were carried out to study the effect of mode I, mixed mode and mode II overload on subsequent mode I fatigue crack propagation. The experiments were conducted on D16AT Al alloy. Fractured specimens were analyzed under a scanning electron microscope. The effect of frequency and load ratio was analyzed at the microscopic scale in terms of striation spacing.

274D. DYNAMIC PROCESSES

11A360. High strain rate deformation and damage in ceramic materials. - G Raiser and RJ Clifton *(Div of Eng, Brown Univ, Providence RI 02912)*. J Eng Mat Tech 115(3) 292-299 (Jul 1993).

The objective of this investigation is to use a plate impact recovery experiment to identify the dominant failure mechanisms in conventional α-Al_2O_3 ceramics and thereby gain insight into the most promising, failure-resistant microstructurers. A "soft-recovery" configuration is used where in a star-shaped flyer imnpacts a square specimen. The impedances, shapes, thicknesses and orientation of all plates are designed to ensure a known history of longitudinal, planar stress waves throughout a central octagonal region of the specimen. The plane waves generated from this experiment are monitored by a laser interferometer system that allows data to be collected at four separate locations. The validity of the approach is demonstrated by a shot in which all plates were stressed within their elastic range. Subsequently, several experiments were conducted at nearly the same stress level with commercially sintered aluminas having different grain size and different glass content. These experiments, taken as a whole, demonstrate that improvement in alumina's dynamic compressive properties is obtained by reducing the grain size. In compression, a reduction in grain size lowers average residual stresses at triple junctions and grain boundaries and makes the material less susceptible to inelastic deformation and sliding at triple junctions and grain boundaries. A reduction in the weight percent of pre-processing impurities (and therefore the amount of intergranular glassy phase) yields strong improvements in the dynamic tensile strength of the ceramic. A decrease in the amount of glassy phase tends to make tensile damage less likely by improving grain boundary strength. These trends were tested by conducting recovery experiments on a high-purity, small-grain alumina, processed in-house through hot pressing. Both the compressive resistance and, especially, the tensile resistance were superior to those found for all other tested specimens. The overall results suggest that the best failure resistance will be obtained for new, high-purity, ultrafine-grain ceramics that are prepared by hot pressing of nanometer scale powders.

274E. FATIGUE CHARACTERISTICS OF MATERIALS

11A361. Application of a new model for fatigue threshold in a structural steel weldment. - L Bartosiewicz, AR Krause *(Ford Motor, PO Box 2053 MD-3083, Dearborn MI 48121)*, A Sengupta *(Dept of Mat Sci and Eng, Wayne State Univ, Detroit MI 48202)*, SK Putatunda *(Dept of Chem and Metall Eng, Wayne State Univ, Detroit MI 48202)*. Eng Fracture Mech 45(4) 463-477 (Jul 1993).

A new model for fatigue threshold has been proposed. The model takes into consideration the influence of material strength, grain size, and load ratio on fatigue threshold. Fatigue crack growth behavior of a structural steel weldment (ASTM Grade A 514) was investigated to examine the applicability of this model. The investigation also examined the influence of welding procedure [submerged arc welding (SMAW) versus metal inert gas welding (MID)] on the resultant microstructure and near the threshold fatigue crack growth behavior of the material in room temperature ambient atmosphere. The results of the present investigation demonstrated that the near threshold fatigue crack growth rates was lowest and fatigue threshold was highest when the crack propagated through the weldment. The fatigue threshold values predicted by the model were in good agreement with the experimentally determined values. The MIG welding process was found to be beneficial compared to the SMAW process as far as the fatigue threshold is concerned for weldment.

11A362. Cyclic fatigue-crack growth in grain bridging ceramics. - RH Dauskardt *(Center for Adv Mat, Mat Sci Div, LBL, UCB)*. J Eng Mat Tech 115(3) 244-251 (Jul 1993).

Cyclic fatigue degradation is contemplated in polycrystalline ceramics exhibiting grain bridging as the principle toughening mechanism. A frictional-wear-mechanism based on repetitive sliding wear degradation of frictional grain bridges is discussed. A micromechanical model is developed which provides an insight into the effects of salient mechanical and microstructural variables such as wear rate at the grain-matrix interface and initial residual stress of bridging grains, on fatigue-crack growth behavior. Results of the analysis are compared to experimentally observed fatigue-crack growth rates in coarse grained alumina and silicon nitride.

11A363. Cyclic near-tip fields for fatigue cracks along metal-metal and metal-ceramic interfaces. - C Woeltjen *(Des and Producibility Eng Div, Electron Syst Group, Westinghouse Elec, PO Box 746-MS336, Baltimore MD 21203)*, C.F. Shih, S Suresh *(Div of Eng, Brown Univ, Providence RI 02912)*. Acta Metall Mat 41(8) 2317-2335 (Aug 1993).

FE analyses were conducted with the objective of determining the cyclic near-tip fields ahead of a stationary tensile fatigue crack lying along the interface between two dissimilar solids. The model systems analyzed are (i) a metal-metal bimaterial whose components have the same elastic properties but different plastic deformation characteristics, and (ii) a metal-ceramic bimaterial. In both cases, monotonic loading to the peak tensile load results in a predominantly mode 1 field ahead of the crack. However, unloading in one or both components of the bimaterial with prior plastic deformation generates mixed-mode conditions at the crack tip. The mode mixity persists during a significant portion of the next loading phase and is gradually removed upon reloading to the peak stress. The cyclic plastic zone size directly ahead of the fatigue crack is approximately one-fifth the size of the monotonic plastic zone. The residual compressive stresses within the cyclic plastic zone are computed. The implications of reversed yielding and mixed-mode near-tip fields to constant-amplitude and variable-amplitude fatigue fracture are discussed.

11A364. Effect of mission cycling on the fatigue performance of SiC-coated carbon-carbon composites. - H Mahfuz, PS Das, S Jeelani *(Mat Res Lab, Tuskegee Univ, Tuskegee AL)*, DM Baker, SA Johnson *(General Dyn, Ft Worth TX)*. Int J Fatigue 15(4) 283-291 (Jul 1993).

The response of quasi-isotropic laminates of SiC-coated carbon-carbon (C-C) composites under flexural fatigue was investigated at room temperature. Virgin as well as mission-cycled specimens were tested to study the effects of thermal and pressure cycling on the fatigue performance of C-C. Tests were conducted in three-point bending with a stress ratio of 0.2 and frequency of 1 Hz. The fatigue strength of C-C has been found to be quite high: approximately above 90% of the ultimate flexural strength. The fatigue strength appears to be decreasing with the mission cycling of the specimens. This lower strength with the mission-cycled specimens is attributed to the increase in interfacial bond strength due to thermal and pressure cycling of the material. C-C is also found to be highly sensitive to the applied stress level during cyclic loading, and this sensitivity is observed to increase with the increase in the amount of mission cycling. Weibull characterization of the fatigue data has been performed, and a wide scatter in the Weibull distribution is discussed. Fractured as well as untested specimens were C-scanned, and the progressive damage growth during fatigue is presented. Optical microscopy including scanning electron microscopy for the failed specimens was also performed, to analyze the failure behavior. Degradation and separation of the porous matrix structure, localized damage and filament splitting within the yarns, complete failure of the fibre bundle, and delamination near the loading zone was observed.

11A365. Effect of temperature on the behavior of short fatigue cracks in Waspaloy using an *in situ* SEM fatigue apparatus. - RR Stephens *(Mech Eng Dept, Univ of Idaho, Moscow ID 83843)*, L Grabowski *(Rolls Royce, PO Box 31, DE2 8BJ, Derby)*, DW Hoeppner *(QIDEC, Univ of Utah, Salt Lake City UT 84112)*. Int J Fatigue 15(4) 273-282 (Jul 1993).

Short fatigue crack growth behavior was studied in Waspaloy at 25°C, 500°C, and 700°C under cyclic loading conditions at a stress ratio of 0.1. Specimens were tested within an elevated temperature fatigue apparatus coupled to a scanning electron microscope which allowed *in situ* observations to be made of the fatigue process. Crack formation was dominated by slip band cracking at 25°C and 500°C, while at 700°C cracks formed along slip bands and twin boundaries. Crack propagation proceeded by means of slip band cracking at 25°C and 500°C, while at 700°C crack growth was primarily stage II-mode

I type growth. Short fatigue crack growth rates were faster at 500°C than at 25°C for an equivalent stress intensity range, ΔK_1, owing to a change in slip character. Short crack growth rates tended to be lower at 700°C than at 500°C, owing to changes in the material leading to precipitate coarsening. As the temperature was increased, mircrostructural contributions to crack growth decreased, resulting in a reduced microstructural short crack effect.

11A366. Fatigue deformation of silver single crystals: STM evidence for crack nucleation, measurements of slip irreversibility and verification of a new scaling relationship for fatigue life. - TS Sriram *(Digital Equip, 77 Reed Rd, MS HL02-3 J12, Hudson MA 01769)*, Chih-Ming Ke, YW Chung *(Dept of Mat Sci and Eng, McCormick Sch of Eng and Appl Sci, NWU)*. Acta Metall Mat 41(8) 2515-2521 (Aug 1993).

Silver single crystals oriented in the single glide orientation were fatigued in air and in vacuum. The surface morphology was observed using a scanning tunneling microscope. A gold film deposited on the silver surface was used as a reference marker so that the same region can be observed upon repeated fatigue cycling. Pit-shaped features were observed to form within a narrow range of cycles and to eventually develop into micron-sized cracks, lending support to the notion that cracks are formed by a nucleation process. In addition, by measuring the slip band height and spacing as a function of cycling, we were able to determine the slip irreversibility and the Coffin-Manson exponents in both environments. With these two sets of data, we were able to verify a new scaling relationship for fatigue life based on our earlier theoretical work.

11A367. Fatigue process in short carbon-fiber reinforced polyamide 6.6 under rotating-bending and torsional fatigue. - H Nisitani, H Noguchi *(Fac of Eng, Kyushu Univ, Fukuoka 812, Japan)*, Y-H Kim *(Dept of Mat Eng, Korea Maritime Univ, Pusan 606-791, Korea)*. Eng Fracture Mech 45(4) 497-512 (Jul 1993).

Rotating-bending fatigue and torsional fatigue tests of the injection moulded short carbon-fiber reinforced polyamide 6.6 were carried out to investigate the fatigue characteristics. The fatigue mechanism in the composites was clarified through successive surface observations using the replica method. Moreover, the mechanism of the torsional fatigue was compared with that of the rotating-bending fatigue. The failure cracks in both fatigue tests are nucleated along the fibers aligued in the direction of the maximum principal stress. In the case of the rotating-bending fatigue test, the fatigue crack propagates at right angles to the direction of the principal stress. On the other hand, in the case of torsional fatigue, the cracks nucleated along the fibers cannot propagate under the low stress amplitude. However, the fatigue cracks nucleated from the fibers which are aligued in the direction of the principal shear stress can propagate, and lead to the final fracture.

11A368. In-service loading of AlSiII aluminium cast alloy in the very high cycle regime. - SE Stanzl-Tschegg, HR Mayer *(Inst for Met and Phys, Univ for Agri, Turkenschanzstr 1, A 1180 Vienna, Austria)*, EK Tschegg *(Inst for Appl and Tech Phys, Tech Univ, Karlsplatz 13, A 1040 Vienna, Austria)*, A Beste *(Audi AG, W 8070, Ingolstadt, Germany)*. Int J Fatigue 15(4) 311-316 (Jul 1993).

The fatigue properties of two AlSiII cast alloys as used for car wheels have been tested in the regime of 10^8-10^9 cycles. An AlSiII aluminium alloy with 0.12-0.20% Mn and one with 0.05% Mn and increased H_2 content during the pouring procedure are compared. It is shown that mainly cast voids determine the fatigue properties. These material inhomogeneities reduce the fatigue strength and lead to early fracturing. The number of cycles to failure decreases with increasing void cross-section. With a statistical analysis of the fatigue [illegible], it is shown that the mean number of cycles to failure is higher for the alloy with fewer large cast voids and a higher Mn content. This alloy is less susceptible to cast voids, and the threshold stress intensity value is approximately 10% higher.

11A369. Modeling of loading rate effect on fatigue crack growth. - KM Golos *(Warsaw Univ of Tech, Warszawa, Poland)*, HP Stuwe, R Pippan *(Erich Schmid Inst fur Festkorperphysik, Vienna, Austria)*. Eng Trans 41(2) 167-175 (1993).

A mechanical model of fatigue crack growth at low and intermediate ΔK values is presented. In the model the effect of the loading rate on the fatigue crack growth is considered. The local stress and strain are calculated based on the Hutchinson, Rice, and Rosengren solution. The required data for predicting fatigue crack growth rate can be found in standard material handbooks where cyclic and fatigue properties of the materials are presented.

11A370. Multiple-site damage in 2024-T3 alloy sheet. - O Partl and J Schijve *(Fac of Aerospace Eng, Univ of Tech, 2629 HS Delft, Netherlands)*. Int J Fatigue 15(4) 293-299 (Jul 1993).

A simple computational procedure, using the principles of fracture mechanics and a compounding K-solution method, was developed for predicting fatigue crack growth if multiple-site damage is present. The prediction method was verified using the results of a series of fatigue crack growth tests performed on 2024-T3 alloy sheet specimens with a row of collinear open holes and artificially introduced flaws at the three central holes. Three different geometrical configurations were adopted. A good agreement was found between the test results and the predictions. An obvious crack interaction effect was found, but it occurred mainly in the last part of the fatigue crack growth lives. The relative size of MSD cracks depends significantly on scatter of the size of the initial crack nuclei.

11A371. Study on threshold fatigue crack growth characteristics of electron beam welding in AISI 4130 steel. - Jiun-Ren Hwang and Hsiu-Hung Chang *(Dept of Mech Eng, Natl Central Univ, Chung-li, Taiwan 320, ROC)*. Eng Fracture Mech 45(4) 519-527 (Jul 1993).

Near-threshold fatigue crack growth of an electron beam weldment in AISI 4130 steel is studied. To increase the fatigue resistance ability, two different post-weld heat treatment processes are adopted to compare the near-threshold fatigue crack growth data with that of an as-welded specimen. The electron beam tempering in the vacuum chamber immediately after the welding and the traditional furnace tempering treatment are chosen for comparison. Strength of the welded joints is evaluated by a tensile test and near-threshold fatigue properties are investigated by K-decreasing method. The resistance to near-threshold fatigue crack growth is improved with post-weld heat treatment, due to the residual stress relief effect and existence of a toughened tempered structure. For electron beam post-weld heat treatment with 6 mm dot pattern width, the threshold stress intensity factor range increases by 14% compared to that of an as-welded specimen and the data of furnace post-weld heat treatment of 550°C can be improved by as much as 26%.

274F. STRESS OR STRAIN LIFE ANALYSIS OF FATIGUE

11A372. Estimating the vibration fatigue life of quad leaded surface mount components. - DB Barker, YS Chen, A Dasgupta *(CALCE Electron Packaging Res Center, Univ of Maryland, College Park MD 20742)*. J Electron Packaging 115(2) 195-200 (Jun 1993).

This paper discusses the assumptions and details of the fatigue life calculations required to predict the fatigue life of a quad leaded surface mount components operating in a vibration environment. A simple approximate stress analysis is presented that does not require complex FE modeling, nor does it reduce the problem to a simple empirical equation or rule of thumb. The goal of the new method is to make PWB vibration solder joint reliability information available to the designer as early as possible and in an easily understood and implemented manner.

274G. OTHER ASPECTS OF FATIGUE

11A373. Constitutive behavior and low cycle thermal fatigue of 97Sn-3Cu solder joints. - Y-H Pao, S Badgley, E Jih, R Govila *(Res Lab, Ford Motor, Dearborn MI 48121-2053)*, J Browning *(RPI)*. J Electron Packaging 115(2) 147-152 (Jun 1993).

The thermal cyclic shear stress-strain hysteresis response and associated steady-state creep parameters of 97Sn-3Cu solder joints have been determined using a beam specimen previously developed by Pao et al, (1992a). The solder joint was subjected to a 40-minute thermal cycling from 40°C to 140°C. A constitutive equation based on elastic and steady-state creep deformation for the solder has been formulated and implemented in a FE program, ABAQUS, to model the experiment. The results show that the constitutive equation based on one single creep mechanism cannot fully account for the deformation during cooling, as opposed to the case of 90Pb-10Sn where the entire cyclic deformation can be well modeled by a similar constitutive equation (Pao et al, 1992c). This suggests that another creep mechanism is dominant for lower stresses and higher temperature. The thermal fatigue results show that the failure mechanism of 97Sn-3Cu joints is similar to that of 90Pb=10Sn joints, but the number of cycles to failure of 97Sn=Cu solder joints is at least 5 times longer than 90Pb-10Sn solder joints. This indicates the potential application of 97Sn-3Cu in place of 90Pb-10Sn solder.

11A374. Influence of the cycle frequency and wave shape on the fatigue life of leaded chip carrier printed wiring board interconnections. - HD Solomon *(GE Corp R&D Center, Schenectady NY 12301)*. J Electron Packaging 115(2) 173-179 (Jun 1993).

This study employed different cycle frequencies, to determine the influence of cycle frequency on the fatigue life of leaded chip carrier to printed wiring board (LCC-PWB) interconnections. Real LCC-PWB interconnections were mechanically cycled at 35° C or 125° C. The cycle frequency was varied by varying the ramp loading and unloading rates or by introducing hold times. Tests were run with equal hold times at the maximum and minimum displacements or only at the maximum displacement. The use of slower ramp cycling or the introduction in the hold times increased the plastic displacement and this decreased the fatigue life. The plastic displacement increase was corrected for, to unveil the underlying material response. The corrected data was similar to that observed in previous tests on simple, single, solder joints, where the plastic strain was kept constant while the cycle frequency was reduced. At 125° C there was a small influence of wave shape, with maximum displacement hold time tests showing the shortest fatigue lives and symmetric (maximum and minimum) hold time tests showing the longest fatigue lives. The fatigue lives of the tests run with ramp cycling were intermediate. This wave shape effect is relatively small, especially compared to the large overall influence of the cycle frequency.

11A375. Stress-based liftime prediction method for a general state of cyclic stress. - J Kolenda *(Poland)*. Marine Tech Trans 3 127-135 (1992).

Fatigue lifetime of constructional steels under multiaxial cyclic stress is considered. It is assumed that the design life consists of periods during which the stress components are synchronous, in-phase and have constant amplitudes. The case of combined load in cyclic bending and torsion is analyzed. The analysis is restricted to the failure subregion for elastic applications. It is concluded that the formulae for calculation of the safety factor in the safe region and in the failure subregion differ only in the definitions of partial safety factors. This permitted to use the known safety factor formula for a general state of cyclic stress in the safe region also for the considered failure subregion.

274H. CORROSION AND EMBRITTLEMENT

11A376. BE model of cathodic well casing protection. - SH Lee, DW Townley, KO Eshun *(Chevron Oil Field Res, PO Box 446, La Habra CA 90633-0446)*. J Comput Phys 107(2) 338-347 (Aug 1993).

An efficient BEM was developed to study cathodic protection of a well casing in a formation with layered conductivities. Even though the electrical potential in soil is governed by the linear Laplace equation, electrochemical reactions at the well casing introduce complex, nonlinear boundary conditons. Furthermore, the complexity of boundary geometries makes the numerical computation nontrivial. Use of Green's function allows a general solution of the Laplace equation to be expressed in the form of a Fredholm integral equation of the second kind. The present formula employs a fundamental solution that eliminates the discretization of the top ground surface. Because the potential distribution within the well casing metal greatly affects the current distribution, the model includes the potential change along the axial direction of the well casing. A Newton-Raphson method was employed to estimate iteratively the current distribution at the well casing, and then the integral equations of the BEM were numerically solved by a collocation technique. This BE model was used to investigate the effects of soil conductivities, well casing geometry, well casing resistivity, and the location of a current source on the current and potential distribution at the well casing.

11A377. Crack length effect on corrosion fatigue crack propagation. (Polish). - M Jakubowski *(Poland)*. Marine Tech Trans 3 97-108 (1992).

The crack length effect has been tested for a shipbuilding steel in saltwater at different, but constant for each specimen levels of the stress intensity factor range ΔK, at a loading frequency of 0.1 Hz, stress ratio R = 0.15. The ΔK values from the Paris Law range of the fatigue diagram, and the cracks longer than so-called "short cracks" have been chosen for testing. The crack growth rate and the coefficient of the relative corrosion effect β (ratio of the crack growth rate in saltwater to that in the air at the very same ΔK) has been evaluated as a function of the crack length a. Crack growth rates and coefficients β increased directly proportional to log a up to the maximum at a certain length. For cracks longer than 15-20 mm they approached a constant level, independent on the crack length, but lower than the maximum. In the shorter cracks range the corrosion effect was controlled mainly by crack length, not ΔK. According to British suggestion β = 6 can be used in conservative calculations of the corrosion fatigue life for offshore and ship structures. Mechanisms of the crack length effect have been discussed.

11A378. Effects of grain size and phosphorus on the corrosion of nanocrystalline Ni-P alloys. - R Rofagha, U Erb, D Ostrander *(Dept of Mat and Metall Eng, Queen's Univ, Kingston, K7L 3N6, Canada)*, G Palumbo *(Ontario Hydro Res Div, 800 Kipling Ave, Toronto, M8Z 5S4, Canada)*, KT Aust *(Dept of Metall and Mat Sci, Univ of Toronto, Toronto, M5S 1A4, Canada)*. Nanostruct Mat 2(1) 1-10 (Jan-Feb 1993).

The effects of grain size and phosphorous content on the corrosion characteristics of nanocrystalline Ni-P alloys tested in 0.1M H_2SO_4 by anodic polarization is evaluated and compared with the corrosion behavior of amorphous Ni-P and high purity conventional polycrystalline Ni. It is found that in contrast to conventional polycrystalline nickel neither nanocrystalline (grain sizes 22.6 and 8.4 nm) nor amorphous Ni-P passivate during potentiodynamic polarization. The electrochemical response and corrosion morphologies observed for the different materials are discussed in terms of their microstructural differences.

274I. FRETTING, WEAR, AND EROSION

11A379. Influence of the mass flux and impact angle of the abrasive on the erosion resistance of materials used in pulverized fuel bends and other components in thermal power stations. - PR Krishnamoorthy, S Seetharamu, P Sampathkumaran *(Mat Tech Div, Central Power Res Inst, Bangalore 560 094, India)*. Wear 165(2) 151-157 (1 Jun 1993).

This paper presents laboratory results and field data obtained on the erosion resistance of metallic and ceramic wear parts of low alloy steel, Nihard, high chromium cast iron, 85% alumina ceramic, and 91% alumina ceramic. The influence of the mass flux and impact angle is evaluated in the laboratory tests. The applicability of laboratory tests to predict wear life in the field is also discussed.

11A380. Machine for fretting wear testing of plasma surface modified materials. - PW Sandstrom, K Sridharan, JR Conrad *(Eng Res Center for Plasma Aided Manuf, Univ of Wisconsin, 1410 W Johnson Dr, Madison WI 53706)*. Wear 166(2) 163-168 (1 Jul 1993).

Microscopic damage caused by fretting wear is of significant concern in many engineering applications. We report the design and performance of a versatile fretting wear testing machine that uses an electromagnetic actuator under closed-loop control to provide a constant slip amplitude over a wide frequency range. The machine is equipped with a mechanism that allows for gradual sample contact and precise relocation of the stylus. An innovative method for monitoring frictional forces during the course of a test is incorporated. The machine has been successfully applied to materials by three types of plasma surface modification: nitrogen ion implantation, thin film alloy deposition and diamond-like carbon film deposition.

274J. CREEP

11A381. Compressive failure of fiber composites: The roles of multiaxial loading and creep. - WS Slaughter, NA Fleck *(Eng Dept, Cambridge Univ, Cambridge CB2 1PZ, UK)*, B Budiansky *(Div of Appl Sci, Harvard Univ, Cambridge MA 02138)*. J Eng Mat Tech 115(3) 308-313 (Jul 1993).

The roles of multiaxial loading and creep in compressive failure of aligned fiber composites are considered. Analytical models are developed based on the model given by Budiansky and Fleck (1992). The critical microbuckling stress in multiaxial loading is calculated for a rigid-perfectly plastic solid and an elastic-plastic strain hardening solid. The rigid-perfectly plastic results predict a plane compressive failure surface in stress space. The rigid-perfectly plastic results are sufficiently accurate, when compared to the strain hardening results, so long as the remote shear stress and stress normal to the fiber direction are not too large relative to the remote stress in the fiber direction. The model given for creep microbuckling is suitable for power-law viscous composite behavior. Deformation within a localized kink band is computed as a function of time. A creep life is predicted, based on a critical strain failure criterion.

11A382. Solder joint creep and stress relaxation dependence on construction and environmental-stress parameters. - RG Ross Jr, LC Wen, GR Mon *(JPL)*. J Electron Packaging 115(2) 165-172 (Jun 1993).

Creep strain is probably the most important time-dependent damage accrual factor affecting solder joint reliability. Under typical multi-hour loading conditions, creep-induced strain is a complex function of solder metallurgical structure, solder temperature, loading time per cycle, the applied stress, and the spring constant of the combined part-lead-board system. The complex system level creep-fatigue interactions involved in electronic part solder joints are shown to be a strong function of the relative stress ratio $_\kappa$, which is the ratio of the stiffness of the combined solder-lead system to the stiffness of the solder element by itself. For a leadless chip package, $_\kappa$ is close to unity. For a compliant leaded package, $_\kappa$ is typically in the 0.01 to 0.0001 range. Important environmental stress dependencies, including the effects of operating temperature, displacement amplitude due to thermal and mechanical cycling, and cyclic frequency of loading are investigated for different levels of $_\kappa$. Understanding the sensitivity of solder strain range to relative stiffness and these key environmental parameters is important to understanding the behavior of alternative packaging concepts and to achieving robust electronic packaging designs and testing approaches.

274K. ABLATION, SPALLATION, DELAMINATION

11A383. Delamination cracks originating from transverse cracking in cross-ply laminates under various loadings. - Yujun Kim and Seyoung Im *(Dept of Mech Eng, Korea Adv Inst of Sci and Tech, Sci Town, Taejon 305-701, Korea)*. Int J Solids Struct 30(16) 2143-2161 (1993).

Delamination cracks originating from transverse cracking in two types of cross-ply lamiantes $[90/0]_s$ and $[0/90]_s$ are analyzed for three types of loadings: plane strain extension, plane strain bending and antiplane shear. The asymptotic solution for stress and displacement field is constructed based upon the Stroh formalism for anisotropic elasticity and the method of eigenfunction expansion. Its structure is determined from appropriate near-field conditions leading to the eigenvalue equation, and then the singular hybrid FEM in conjunction with a quadratic programming procedure for treating the partial contact of crack faces is employed to complete the field solution. The stress intensity factor properly defined for anisotropic interfacial cracks and the energy release rate are computed from the complete solution. The stability of crack growth and the effect of the relative ply thickness upon the crack growth stability are examined in terms of the energy release rate and the phase angle.

274X. STOCHASTIC ASPECTS

11A384. Damage and fuzzy risk assessment in steam plants. - SKP Cheung-Mak and IL May *(Metall Consult Services, PO Box 5006, Saskatoon, SK, S7K 4E3, Canada)*. Trans Can Soc Mech Eng 17(2) 111-125 (1993).

The various methods of damage assessment in steam plants are reviewed. An example of estimating the remaining life of steam pipe welds containing cracks is discussed. Modeling techniques provide a quantitative evaluation of the risk of failure. However, damage assessment is not an exact science. Thus the fuzzy set method of risk assessment is introduced. Most material data for creep are obtained from accelerated tests, and the extrapolation of shorter time data to longer times at different stresses and temperatures is used in the prediction of remaining life. Inexact knowledge of load and temperature variations in the operation of actual steam plant further complicates overall risk assessment. Estimation of the overall risk of failure in the plant using the fuzzy set method requires identification of critical areas in different components at which damage may have accumulated, together with nondestructive testing, microstructural evaluation and other methods to define the extent of the damage. The importance of the particular component to the operation of the whole system must be assessed before a judgement can be made to provide a prediction of the plant's remaining life.

11A385. Fatigue reliability in uniaxial state of stress produced by synchronous loads. - J Kolenda *(Univ of Tech, Gdansk, Poland)*. Eng Trans 41(1) 21-30 (1993).

The paper deals with the stress-based fatigue analysis of structural members subjected to synchronous and in-phase loads. The uniaxial state of stress produced by combined bending and tension-compression is considered. Attention is focused on the failure subregion for high cycle fatigue where the linear logarithmic models for fatigue behavior are applicable. The relationships for calculation of fatigue reliability and number of cycles to failure are proposed. For the assessment of the probability of fatigue failure under the stress with normally distributed amplitudes of its components, the reliability index is determined.

11A386. Load-history sensitive cyclic curve concept in random load fatigue life predictions. - S Petinov and N Yermolaeva *(Div of Ship Struct, Marine Tech Univ, Lotsmanskaya str 3, St Petersburg 190008, Russia)*. Ship Tech Res 40(2) 107-111 (May 1993).

The results of two-level strain control tests of cyclic hardening aluminium alloy were used to derive the load-sensitive cyclic curve model (LHSCC). It incorporates effects of material cyclic strain hardening and of loading sequence. A computer algorithm for generating random load sequences is developed. It takes account of the statistical distribution of amplitudes and of autocorrelation properties of the process. A numerical example of a fatigue damage calculation based on the LHSCC concept is presented.

11A387. Rainflow analysis: Markov method. - M Frendahl and I Rychlik *(Dept of Math Stat, Univ of Lund, PO Box 118, S-22100 Lund, Sweden)*. Int J Fatigue 15(4) 265-272 (Jul 1993).

In this paper we discuss rainflow cycle counting methods and linear fatigue damage accumulation for stationary loads. The expected damage is computed by approximating the sequence of local extremes by a Markow chain. The algorithm is implemented as part of a "fatigue toolbox". Several examples illustrate the results.

11A388. Statistical theory of ceramic damage and fracture. - Xiaoxue Diao *(Dept of Mech Eng, Univ of Sydney, NSW 2006, Australia)* and Xiusan Xing *(Dept of Appl Phys, Beijing IT, PO Box 327, Beijing 100081, Peoples Rep of China)*. Eng Fracture Mech 45(4) 513-518 (Jul 1993).

The shortcomings of continuum damage mechanics are discussed. A new universal statistical definition of damage of ceramic materials is given from the viewpoint of stochastic evolution of microcracks. The kinetic equation and the accumulative rule of damage are derived. The connection between the micromechanisms of damage and macroscopic properties of ceramics is discovered.

11A389. Stochastic aspects of matrix cracking in brittle matrix composites. - SM Spearing *(BP Res Dept, BP America, Cleveland OH 44128-2837)* and FW Zok *(Mat Dept Col of Eng, UC, Santa Barbara CA 93106-5050)*. J Eng Mat Tech 115(3) 314-318 (Jul 1993).

A computer simulation of multiple cracking in fiber-reinforced brittle matrix composites has been conducted, with emphasis on the role of the matrix flaw distribution. The simulations incorporate the effect of bridging fibers on the stress required for cracking. Both short and long (steady-state) flaws are considered. Furthermore, the effects of crack interactions (through the overlap of interface slip lengths) are incorporated. The influence of the crack distribution on the tensile response of such composites is also examined.

11A390. FE alternating approach to the bending of thin plates containing mixed mode cracks. - Wen-Hwa Chen and Chih-Ming Shen *(Dept of Power Mech Eng, Col of Eng, Natl Tsing Hua Univ, Hsinchu, Taiwan 30043, ROC)*. Int J Solids Struct 30(16) 2261-2276 (1993).

A FE alternating procedure developed to deal with the cracked plate in symmetric bending is extended to analyze the more realistic case with single or multiple mixed mode cracks. This modified procedure involves the new derivation of the analytical solution for an infinite thin plate containing a crack subjected to arbitrary antisymmetric equivalent shear force on crack surfaces. Due to the natural limitation of Kirchhoff assumptions for a thin plate in bending, the appropriate treatment of constant twisting moments on the crack surfaces is devised. The interaction effect among cracks on the calculation of bending (symmetric) and shear (antisymmetric) stress intensity factors is also discussed. Several numerical examples are solved to demonstrate the validity and efficiency of the approach.

11A391. Integrity assessment of thick walled industrial furnace tubes. - RK Kizhatil and R Seshadri *(Indust Syst Eng, Univ of Regina, Regina, SK, S4S 0A2, Canada)*. Trans Can Soc Mech Eng 17(2) 127-143 (1993).

This paper examines various simplified methods proposed to analyze stresses and predict damage and remaining life in furnace tubes subjected to sustained primary pressure stresses and cyclic secondary thermal stresses resulting from a typical furnace operation. Operational effects such as tube fouling, firing rates, startup-shutdown cycles are considered. Component integrity assessments are carried out using some recently developed techniques. A numerical example of a furnace tube made of HK-40 material is presented, and results obtained using a nonlinear FE analysis are compared with predictions obtained using the elastic-core method.

276A. GENERAL THEORY

11A392. Role of mechanics in plex: A technical perspective. - YS Garud *(S Levey Inc, 3425 S Bascom Ave, Campbell CA 95008)*. Trans Can Soc Mech Eng 17(2) 97-109 (1993).

The mechanics of materials and structures plays an important role in majority of life prediction and structural integrity evaluations. In many industrial systems this role gets integrated with effects of service environment and material aging; corrosion, oxidation, and irradiation are examples of such effects which require an interdisciplinary approach. Degradation mechanisms related to these effects have been identified as potentially significant to plant life extension (PLEX). In-service inspection and component monitoring are some of the cost effective steps emphasized in the life extension works; usefulness of the results of these steps can be enhanced through the methods needed for the component condition assessment. These methods, therefore, demand an ever increasing accuracy and improvements requiring a better appreciation and integration of the mechanics. The above aspects of PLEX are critically examined in this paper with a review of key degradation mechanisms elucidating the role of mechanics. Current design basis and recent developments in the life prediction techniques are discussed identifying areas of further work. Stress corrosion cracking, corrosion fatigue, pressurized thermal shock, and long term material stability under thermal and irradiation aging are some of the phenomena emphasized in this work. The significance of mechancis in treating the subcritical crack growth due to these phenomena is discussed. Also, from the point of view of final failure step, the role of impact energy and fracture toughness is examined with consideration of the time dependent changes in these properties. The additional objective of this presentation is to provide a perspective on the assessment of remaining life and safety margins with particular reference to the needs and challenges of the plant life extension.

276B. LINEAR ELASTIC FRACTURE MECHANICS

11A393. Equivalent elastic crack 1. Load-Y equivalences. - M Elices and J Planas *(Dept de Ciencia de Mat, Escuela de Ing de Caminos, Univ Politec, Ciudad Univ, 28040 Madrid, Spain)*. Int J Fracture 61(2) 159-172 (15 May 1993).

The use of crack growth resistance curves (R-δ a) to predict the behavior of cracked specimens is a well established practice for ceramic and cementitious materials. When the cohesive crack model can be applied to these materials it is shown that the use of R-δ a curves is equivalent to setting up an *elastic equivalence* that greatly simplifies the computations. This equivalence has its drawbacks and limitations. This paper analyzes a class of equivalences - the load (P) versus another variable - between cracked cohesive materials and linear elastic ones, ascertaining its applicability to the interpretations of fracture data.

276D. STRESS INTENSITY FACTOR CALCULATIONS

11A394. FEM modeling of stress intensity factors for fatigue crack growth at ultrasonic frequencies. - HR Mayer, SE Stanzl-Tschegg, DM Tan *(Inst for Meteorol and Phys, Univ of Agri, Turkenschanzstr 18, A-1180 Vienna, Austria)*. Eng Fracture Mech 45(4) 487-495 (Jul 1993).

The inverse iteration FEM is used to determine the stress intensity factor of a single edge notched specimen as used in ultrasonic resonance testing of fatigue crack growth. The stress intensity factor is determined as a function of velocity or amplitude at the specimen ends. Resonance frequency and tension-compression ratio R are calculated for different crack lengths. It is shown that the R-value increases from R = -1 to R = -0.90 when the relative crack length (a/W) increases from 0.067 to 0.4. The stress intensity factor for high frequency resonance loading is compared with the stress intensity amplitude for two static loading conditions. Significant differences are found in comparison with static concentric loading and similarities with static uniform displacement loading.

11A395. Frequency domain stress intensity calibration of damped cracked panels. - JF Doyle *(Sch of Aeronaut and Astronaut, Purdue)* and SA Rizzi *(Struct Acoust Branch, NASA Langley Res Center, Hampton VA 23665)*. Int J Fracture 61(2) 123-130 (15 May 1993).

This paper discusses two schemes for doing FE K calibration in the frequency domain. The baseline scheme uses the definition of K as a limit toward the crack tip. The limiting process requires using a very fine mesh around the crack tip making the scheme computationally very expensive. It is shown that the behavior of K as a function of frequency is very similar to a modal response. Taking advantage of this, a more efficient scheme involves a modal analysis of the cracked sheet and scaling the response to that of the static stress intensity. In this way, only a static K calibration need be performed. All the examples shown are for a frequency range spanning multiple resonances and with two levels of damping.

11A396. Shearing effects on a shaft with circular surface crack under rotary bending. - Ching-Hwei Chue, Ming-Long Wu, Chih-Hsiang Chang *(Dept of Mech Eng, Natl Cheng-Kung Univ, Tainan 701, Taiwan, ROC)*. Eng Fracture Mech 45(4) 479-486 (Jul 1993).

The shearing effects on the failure behavior of a rotating shaft with a cicular surface crack subjected to transverse concentrated load and torsion are investigated by employing FEM combined with strain energy density theory. Results of stress intensity factors and minimum strain energy density factor at an arbitrary point on the crack front are obtained for three different crack sizes. The plane strain condition has been assumed in order that the onset and direction of the mixed mode crack propagation can be determined. It is shown that the crack will distort and extend preferentially in a direction opposite to that of rotation and swing a small angle depending on the shearing stress effects.

11A397. Stress intensity factor of a subsurface inclined crack subjected to dynamic impact loading. - Chwan-Huei Tsai *(Dept of Mech Eng, Huafan IT, Taipei, Hsien, Taiwan 223, ROC)* and Chien-Ching Ma *(Dept of Mech Eng, Natl Taiwan Univ, No 1 Roosevelt Rd Section 4, Taipei, Taiwan 10764, ROC)*. Int J Solids Struct 30(16) 2163-2175 (1993).

To gain insight into the phenomena of the interaction of stress waves with a material defect, the transient problem of a half-space containing a subsurface inclined semi-infinite crack subjected to normal impact on the boundary of the half-space is studied. The solutions are determined by linear superposition of the fundamental solution in the Laplace transform domain. The fundamental solution is the exponentially distributed traction on crack faces proposed by Tsai and Ma. Due to the nature of the crack geometry, a combination of transient mixed mode I and II deformation fields in induced near the crack tip. The exact closed form solutions of stress intensity factor histories are obtained. These solutions are valid for the time interval from initial loading until the first wave scattered at the crack tip returns to the crack tip after being reflected by the free boundary. The probable crack propagation direction is predicted from different fracture criteria.

11A398. Stress intensity factors of the eccentric and edge cracked cylinders. - Wei-jiang Chen *(Lanzhou Univ, Lanzhou, China)*, Kai Wang *(Nantong Vocational Univ, Nantong, China)*, Ren-ji Tang *(Shanghai Jiaotong Univ, Shanghai, China)*. Appl Math Mech 14(4) 307-312 (Apr 1993).

Using the single crack solution and the regular solution of harmonic function, the torsion problem of a cracked cylinder is reduced to solving a set of mixed-type integral equations which can be solved by combining the numerical method of singular integral equation with the BEM. Several numerical examples are calculated and the stress intensity factors are obtained.

11A399. Failure of structures due to crack growth and damage. - LV Nikitin *(Geomech Div, Inst of Earth Phys, Russian Acad of Sci, 10 B Gruzinskaya 123810, Moscow, Russia)*. Struct Safety 12(2) 123-128 (Jun 1993).

Crack growth and damage in viscoelastic bodies are studied. Using the Sih criterion of fracture the safe and critical loads as well as delaytime of rupture for structure with a crack are determined. Damage is studied on the base of the energy approach. Evolution of damage, the threshold stress, delay time and limiting damage and strain in a rod under action of a constant load are found.

11A400. Stable crack growth in rate-dependent materials with damage. - L-O Fager *(Ericsson Network Eng AB, S-175 26 Jarfalla, Sweden)* and JL Bassani *(Dept of Mech Eng and Appl Mech, Univ of Pennsylvania, Philadelphia PA 19104)*. J Eng Mat Tech 115(3) 252-261 (Jul 1993).

A cohesive zone model of the Dugdale-Barenblatt type is used to investigate crack growth under small-scale-creep and damage conditions. The material inside the cohesive zone is described by a power-law viscous overstress relation modified by a one-parameter damage function of the Kachanov type. The stress and displacement profiles in the cohesive zone and the velocity dependence of the fracture toughness are investigated. It is seen that the fracture toughness increases rapidly with the velocity and asymptotically approaches the case that neglects damage.

276F. CRACK TIP PLASTICITY PROBLEMS

11A401. Applicability of local approaches for the determination of the failure behavior of ductile steels. - K Kussmaul, U Eisele, M Seidenfuss *(Staatiche Materialprufungsanstalt (MPA), Univ of Stuttgart, Stuttgart, Germany)*. J Pressure Vessel Tech 115(3) 214-220 (Aug 1993).

The strength and deformation behavior of specimens and components is, on the one hand, influenced by the local state of stress and strain, and on the other hand, by the chemical composition and the microstructure of the material used. Using two different steels, it was investigated in how far it is possible to predict the failure behavior of specimens and components equalitatively and quantitatively by means of local approaches. For this purpose, two methods differing considerably from the basic idea were chosen. For the description of the failure behavior, so-called damage models were used. These damage models try to describe numerically the process developing microscopically and finally leading to fracture by means of continuum mechanical approaches in order to calculate the macroscopical failure behavior. The results show that for ductile materials, the damage models allow a very accurate calculation of smooth and notched specimens and components. The efforts presently required for the calculation are, however, still very high. Analyses using fracture mechanics approaches (J-integral) in combination with the local stress states (multiaxiality) were performed to describe the failure behavior. With this approach, it was attempted to calculate crack initiation and maximum load of pre-cracked specimens and components. The fracture mechanics methods are to be preferred for cracked components if an engineering estimation of crack initiation and maximum load only is required since the calculation efforts of the fracture mechanics methods are much lower than those of the damage models.

11A402. Assessment of fully plastic J and Cx-integral solutions for application to elastic-plastic fracture and creep crack growth. - DR Lee and JM Bloom *(Struct Mech Section R&D Div, Babcock & Wilcox, Alliance OH 44601)*. J Pressure Vessel Tech 115(3) 228-234 (Aug 1993).

A critical part of the assessment of defects in power plant components, both fossil and nuclear, is the knowledge of the crack driving force (K_1, J, or Cx). While the determination of the crack driving force is possible using FE analyses, crack growth analyses using FEM can be expensive. Based on work by Il'yushin, it has been shown that for a power law hardening material, the fully plastic portion of the J-integral (or the Cx-integral) is directly related to an "h_1" calibration function. The value of h_1 is a function of the geometry and hardening exponent. The FE program ABAQUS was used to evaluate the fully plastic J-integral and determine the h_1 functions for various geometries. The Ramberg-Osgood deformation theory plasticity model, which may be used with the J-integral evaluation capability, allows the evaluation of fully plastic J solutions. Once it was established that the grid used to generate the h_1 functions was adequate (based on the more recent work of Shih and Goan), additional runs were made of other configurations given in the EPRI Elastic-Plastic Fracture Handbook. Differences as great as 55% were found when compared to results given in the Handbook (single edge crack plate under tension and plane stress with $a/b = 0.5$). Effects of errors in h_1 on predicted failure load and creep crack growth are discussed.

11A403. Precise and new analysis for a mode III growing crack in an elastic-perfectly plastic solid. - Zhi-jian Yi *(Bridge and Struct Eng, Chongqing Jiaotong Inst, Chongqing, China).* Appl Math Mech 14(4) 345-352 (Apr 1993).

The near crack line field analysis method has been used to investigate into Mode III quasistatically propagating crack in an elastic-perfectly plastic material. The significance of this paper is that the usual small scale yielding theory has been broken through. By obtaining the general solutions of the stresses and the displacement rate of the near crack line plastic region, and by matching the general solution with the precise elastic fields (not the usual elastic K-dominant fields) at the elastic-plastic boundary, the precise and new solutions of the stress and deformation fields, the size of the plastic region and the normal vector of the elastic-plastic boundary have been obtained near the crack line. The solutions of this paper are sufficiently precise near the crack line region because the roughly qualitative assumptions of the small scale yielding theory have not been used and no other roughly qualitative assumptions have been taken, either. The analysis of this paper shows that the assumingly "steady-state case" for stable crack growth, which has been discussed attentively in previous works, do not exist, and the plastic strains near the crack line do not have singularities. Two most important cases for stable crack growth have been discussed.

11A404. Rigid body rotation near mode I crack in infinite orthotropic plate. - A Bhattacharya *(Dept of Mech Eng, IT, Banaras Hindu Univ, Varanasi 221 005, India).* Eng Fracture Mech 45(4) 451-461 (Jul 1993).

Rigid body rotation is obtained at the points near the crack tip of a mode I crack in an infinite orthotropic plate. Using Lekhnitskii's complex analysis procedure the rotation is expressed in terms of complex potentials. A relation of rigid body rotation is presented by incorporating the stress intensity factor and material constants of orthotropic material. Crack opening displacement is obtained from the rotation of points lying on crack edges and the crack tip opening angle is shown to depend only on material parameters. The region of constant rotation around the crack tip plastic zone is described in the light of the difference between isotropic and orthotropic materials.

11A405. Supplementary study on anisotropic plastic stress fields at a stationary plane-stress crack-tip. - Bai-song Lin *(Central S Univ of Tech, Changsha, China).* Appl Math Mech 14(5) 429-436 (May 1993).

The results in Ref [1] are not suitable for the cases of $a \geq 2$. For this reason, we use the method in Ref [1] to derive the general expressions of the anisotropic plastic stress fields at a stationary plane-stress crack-tip for both the cases of $\alpha=2$ and $\alpha>2$. As an example, we give the analytical expressions of the anisotropic plastic stress fields as the stationary tips of mode I and mode II plane-stress cracks for the case of $\alpha=2$.

11A406. Time dependent fracture and cohesive zones. - WG Knauss *(Graduate Aeronaut Lab, California IT, Pasadena CA).* J Eng Mat Tech 115(3) 262-267 (Jul 1993).

This presentation is concerned with the fracture response of materials which develop cohesive or bridging zones at crack tips. Of special interest are concerns regarding crack stability as a function of the law which governs the interrelation between the displacement(s) or strain across these zones and the corresponding holding tractions. It is found that for some materials unstable crack growth can occur, even before the crack tip has experienced a critical COD or strain across the crack, while for others a critical COD will guarantee the onset of fracture. Also shown are results for a rate dependent nonlinear material model for the region inside of a craze for exploring time dependent crack propagation of rate sensitive materials.

276J. COMPOSITES

11A407. Criterion for splitting crack initiation in unidirectional fiber-reinforced composites. - Keiichiro Tohgo *(Dept of Mech Eng, Shizuoka Univ, Hamamatsu 432, Japan),* Albert SD Wang *(Dept of Mech Eng and Mech, Drexel Univ, Philadelphia PA 19104),* Tsu-Wei Chou *(Center for Composite Mat and Dept of Mech Eng, Univ of Delaware, Newark DE 19716).* J Composite Mat 27(11) 1054-1076 (1993).

Unidirectional fiber-reinforced composites exhibit a high degree of anisotropy in strength. Crack initiation from a pre-existing crack almost always occurs along the fiber direction; it is known as the *splitting crack*. One criterion for the splitting crack initiation under mixed mode condition is proposed. In this criterion, the splitting crack initiation is characterized by a unique interaction curve on the K^f_σ-K^f_τ plane, where K^f_σ and K^f_τ are the tensile and shear stress intensity factors along the fiber direction. Fracture toughness tests under mixed mode loading are systematically carried out on two graphite-epoxy systems: AS4/3501-6 and IM7/8551-7. For both composites, the condition of the splitting crack initiation can be characterized by a vertical line of K^f_σ = constant on the K^f_σ-K^f_τ plane. This means that the tensile stress intensity factor along the fiber direction is responsible for the splitting crack initiation. Furthermore, it is found that under the conditions of $K^f_\sigma = 0$ or $K^f_\sigma < 0$, damage occurs at locations away from the tip of the preexisting crack initiation and that the fracture toughness under such conditions is high.

11A408. Fracture Mech of Ti/Al_2O_3 interfaces. - HF Wang, WW Gerberich *(Dept of Chem Eng and Mat Sci, Univ of Minnesota, Minneapolis MN 55455),* CJ Skowronek *(Metal Matrix Composites Program, 3M, St Paul MN 55144).* Acta Metall Mat 41(8) 2425-2432 (Aug 1993).

Measurement of mixed mode interfacial fracture toughness in Ti/Al_2O_3, bimaterial couples has been accomplished by four-point bending tests of sandwich specimens with symmetrical cracks for different processing temperatures and thickness of Ti interlayers. Fracture surfaces and sample cross sections were analyzed by SEM, XPS, EDAX, EPMA and AES. The interfacial fracture toughness measured with four-point bending tests increases with increasing applied bonding temperature up to 950°C. Above this temperature toughness decreases. The deterioration of toughness is found to be due to an intermetallic phase (Ti_3Al) produced by diffusion at high temperature. The interfacial fracture toughness also increases when the Ti interlayer is thicker. The measured critical strain energy release rate (or interfacial fracture energy) ranges from 10 to 45 J/m^2. This is much larger than the estimated true work of adhesion which is about 2 J/m^2. This is because of plastic energy dissipation in the Ti interlayer during the fracture process.

11A409. Fracture mechanics of orthotropic laminated plates I. The through crack problem. - Binghua Wu and F Erdogan *(Dept of Mech Eng, Lehigh Univ, Bldg No 19, Bethlehem PA 18015).* Int J Solids Struct 30(17) 2357-2378 (1993).

In this paper a laminated plate which consists of an arbitrary number of dissimilar orthotropic layers under membrane and bending loads is considered. The plate is assumed to have a through crack. The problem is formulated by using Mindlin's first order shear deformation theory and a higher order theory due to Reddy. The sample solutions obtained from these two theories, from the classical theory, and from Reissner's stress-based first order theory shows that the stress intensity factors given by the classical theory are highly inaccurate and the three transverse shear deformation theories give roughly the same results. Because of the nonhomogeneous nature of the medium under consideration, the simpler of the two displacement-based shear deformation theories was adopted to carry out the solution of the crack problem in the laminated plates. The main objective of the study is to investigate the influence of the material orthotropy, various stiffness ratios, and relative dimensions concerning the crack size and laminae thicknesses on the stress intensity factors. Only the mode I crack problem is considered. It is shown that if the laminate has a material symmetry with respect to the midplane of the plate, then the membrane and bending solutions of the problem are fully uncoupled.

11A410. Fracture mechanics of orthotropic laminated plates II. The plane strain crack problem for two bonded orthotropic layers. - Binghua Wu and F Erdogan *(Dept of Mech Eng, Lehigh Univ, Bldg No 19, Bethlehem PA 18015).* Int J Solids Struct 30(17) 2379-2391 (1993).

In this paper the plane strain problem for two bonded orthotropic layers containing a crack perpendicular to the laminate surfaces is considered. After deriving the integral equation for the general problem, the solution is obtained for three main crack geometries, namely an embedded crack, a surface crack and a crack terminating at the interface under a remotely applied membrane load or bending moment. For the crack terminating at the interface the necessary asymptotic analysis is carried out, the characteristic equation to determine the power of stress singularity β is obtained, and the influence of the material parameters on β is examined. The main results given in the paper consist of the stress intensity factors obtained for various crack geometries, material combinations and loading conditions.

11A411. Fracture mechanics of orthotropic laminated plates III. The surface crack problem. - Binghua Wu and F Erdogan *(Dept of Mech Eng, Lehigh Univ, Bldg No 19, Bethlehem PA 18015).* Int J Solids Struct 30(17) 2393-2406 (1993).

In this paper the line spring model originally developed to treat the surface crack problems in homogeneous plates is extended to laminates which may consist of bonded isotropic or orthotropic dissimilar elastic layers. By using the two fundamental solutions for a laminate with a through crack and the corresponding plane strain problem for an edge crack, the surface crack problem in laminates is reduced to a system of singular integral equations. Sample results showing the stress intensity factors are given for bonded orthotropic and isotropic layers which correspond to fiber-reinforced structural composites and ceramic-coated metal substrates, respectively.

11A412. Influence of grain size on the toughness of monolithic ceramics. - AF Bower and M Ortiz *(Div of Eng Solid Mech Program, Brown Univ, Providence RI 02917).* J Eng Mat Tech 115(3) 228-236 (Jul 1993).

Experiments have shown that there may be an optimal grain size which maximizes the toughness of polycrystalline ceramics. In this paper, we attempt to develop a theoretical model which can predict the effect of grain size on the toughness of ceramics. We assume that three principal mechanisms affect the toughness of the material: distributed microcracking; crack trapping by tough grains; and frictional energy dissipation as grains are pulled out in the wake of the crack. The grain size influences these mechanisms in several ways. The energy dissipated due to frictional crack bridging increases with the size of the bridging grains, tending to improve toughness. However, as the grain size increases, the density of microcracks in the solid also increases, which eventually weakens the material. In addition, the level of inter-granular residual stress is also reduced by microcracking, which as a detrimental effect on the toughening due to bridging. We have developed a simple model to quantify these effects. However, the model does not predict the dramatic loss of strength which has been observed to occur beyond a critical grain size. We have therefore proposed an alternative explanation for the apparent decrease in toughness in coarse grained ceramics. Calculations indicate that in a coarse grained material, the main contribution to toughness is due to frictional crack bridging. However, to produce this toughening, the bridging zone must be over 500 grains long. In practice, the length of the bridging zone in a coarse grained solid may be comparable to the dimensions of the specimen used to measure its toughness. Under these conditions, it is not appropriate to use the concept of a geometry independent toughness to characterize the strength of the specimen. We have therefore developed a simple model of a double cantilever beam fracture specimen, which accounts for the effects of large scale bridging. Using this model, we are able to prdict the apparent decrease in toughness measured in coarse grained specimens.

11A413. **Notch ductile-to-brittle transition due to localized inelastic band.** - Z Suo, S Ho, X Gong *(Mech and Env Eng Dept, UC, Santa Barbara CA 93106-5070)*. J Eng Mat Tech 115(3) 319-326 (Jul 1993).

Holes are often drilled in a panel for cooling or fastening. For a panel made of a monolithic ceramic, such a hole concentrates stress, reducing load-carrying capacity of the panel by a factor of 3. By contrast, for a ductile alloy panel, plastic flow relieves stress concentration so that the small hole does not reduce load-carrying capacity. A panel made of ceramic-matrix composite behaves in the middle: matrix cracks permit unbroken fibers to slide against friction, leading to inelastic deformation which partially relieves stress concentration. Load-carrying capacity is studied in this paper as an outcome of the competition between stress concentration due to the notch, and stress relaxation due to inelastic deformation. The inelastic deformation is assumed to be localized as a planar band normal to the applied load, extending like a bridged crack. The basic model is large-scale bridging. A material length, $\delta_0 E/\sigma_0$, scales the size of the inelastic band, where σ_0 is the unnotched strength, δ_0 the inelastic stretch at the onset of rupture, and E Young's modulus. Load-carrying capacity is shown to depend on notch size a, measured in units of $\delta_0 E/\delta_0$. Calculations presented here define the regime of notch ductile-to-brittle transition, where ceramic-matrix composites with typical notch sizes would lie. Both sharp notches and circular holes are considered. The shape of the bridging law, as well as matrix toughness, is shown to be unimportant to load-carrying capacity.

11A414. **Role of crack wake toughening on elevated temperature crack growth in a fiber reinforced ceramic composite.** - SV Nair and Tsung-Ju Gwo *(Dept of Mech Eng, Univ of Massachusetts, Amherst MA 01003)*. J Eng Mat Tech 115(3) 273-280 (Jul 1993).

Theoretical models were developed to predict the nature of the elevated temperature failure behavior in composites containing bridged cracks both for the case where crack front creep is absent (brittle regime) and for the case where a frontal creep process zone is present (ductile regime). The nature of the thermally activated time-dependent bridging of matrix cracks was first briefly reviewed from an earlier study and then applied to the case where crack front creep was present. Stable crack growth was predicted both in the presence and absence of crack front creep after an initial delay period, or initiation, which depends on crack size and wake parameters, such as, fiber diameter, volume fraction and interface properties. The dependence of the initiation time and crack growth rates on flaw size and wake parameters as well as on composite microstructure was derived both for the presence and absence of crack front creep. The implications of the results for elevated temperature composite component design are discussed.

11A415. **Stochastic viscoelastic delamination onset failure analysis of composites.** - HH Hilton *(Dept of Aeronaut and Astronaut Eng, Univ of Illinois, 18 Transportation Bldg, Urbana IL 61801-2997)* and Sung Yi *(Natl Center for Supercomput Appl, Univ of Illinois, 4113 Beckman Institute, Urbana IL 61801)*. J Composite Mat 27(11) 1097-1113 (1993).

The previously formulated deterministic viscoelastic quadratic time dependent delamination onset criterion is generalized to complete 3D stochastic environments. The analysis includes stochastic processes due to combined random loads and random delamination failure stresses as well as random anisotropic viscoelastic material properties including the influence of stochastic temperature fields, moisture contents and boundary conditions. It is shown that times for delamination onset occurrences in composites can be predicted probabilistically depending on any one or all of the above conditions. Illustrative examples are presented showing the relationship in terms of parametric variations between times to delamination and corresponding probabilities that such events will occur. Since uniaxial tension, compression, and shear viscoelastic delamination failure stresses decrease in time, the loading history is of significant importance. For cases where deterministic criteria predict no delamination failures, the present stochastic failure theory indicates high probabilities of failure at either early or long times depending on the load-time relations. The early time high probabilities of delamination onset predict short lifetimes and occur in conditions where the composite internal stresses relax at faster rates than the failure stresses are degrading. The effects of fiber orientation and of number of plies on delamination probabilities are also examined.

11A416. **Thermally induced interfacial microcracking in polymer matrix composites.** - DL Hiemstra *(Prince Corp, 1 Prince Center, Holland MI 49423)* and NR Sottos *(Dept of Theor and Appl Mech, Univ of Illinois, Urbana IL 61801)*. J Composite Mat 27(10) 1030-1051 (1993).

Novel experiments on a cluster of fibers combined with FE analysis was utilized to investigate the influence of both inter-fiber spacing and interphase properties on thermally induced microcracking. Local thermal stresses were predicted and microcracking observed as fiber spacing was systematically decreased and interphase properties were varied. Both the computational and experimental results demonstrated that interphase properties and fiber spacing alter the location of the maximum equivalent stress and the initiation of microcracks. Microcracks were predicted and observed to initiate first (at the lowest thermal load) in the case of a higher modulus interphase. The cracks initiated at the fiber-interphase interface at a lower thermal load than if no interphase were present. In contrast, computations for a low modulus interphase predicted the maximum equivalent stress to be lower than the case of no interphase and to occur in the matrix. Experimentally, microcracks were observed to initiate in the matrix at the interphase-matrix interface with higher thermal loads. The presence of the low modulus coating prevented cracks from reaching the fiber surface. Overall, the investigation demonstrated the ability of the interphase to enhance or hinder microcracking in a cluster of fibers. The interphase can be tailored to reduce the local stress state and reduce the initiation of microcracks in the composite.

11A417. **Thermally-induced interlaminar crack-tip singularities in laminated anisotropic composites.** - HJ Choi *(Korea Power Eng, Seoul, Korea)* and S Thangjitham *(Dept of Eng Sci and Mech, VPI)*. Int J Fracture 60(4) 327-347 (15 Apr 1993).

Thermally-induced stress singularities of an interlaminar crack in a fiber-reinforced composite laminate under a state of generalized plane deformation are examined within the framework of steady-state anisotropic thermoelasticity. The crack is assumed to be embedded within a matrix-rich interlaminar region of the composite. The Fourier integral transform technique and the flexibility-stiffness matrix method are introduced to formulate the current mixed boundary value problem. As a result, two sets of simultaneous Cauchy-type singular integral equations of the first kind are derived for the heat conduction and thermoelasticity. Within the context of linear elastic fracture mechanics, the mixed-mode thermal stress intensity factors are defined in terms of the solution of the corresponding integral equations. Numerical results are presented, addressing the effects of laminate stacking sequence, crack location and crack surface partial insulation on the values of thermal stress intensity factors.

11A418. **Toughening mechanisms in quasi-brittle materials.** - SP Shah and C Ouyang *(NSF Center for Sci and Tech of Adv Cement-Based Mat, NWU)*. J Eng Mat Tech 115(3) 300-307 (Jul 1993).

Fracture processes in cement-based materials are characterized by a large-scale fracture process zone, localization of deformation, and strain softening. Many studies have been conducted to understand the toughening mechanisms of such quasi-brittle materials and to theoretically model their nonlinear response. This paper summarizes two innovative experimental techniques which are being developed at the ACBM Center to better define the fracture process zone in cement-based materials. A brief summary is also given of two types of theoretical approaches which attempt to simulate some of the observed nonlinear fracture response of these materials.

11A419. **Transverse cracking in fiber-reinforced brittle matrix, cross-ply laminates.** - ZC Xia, RR Carr, JW Hutchinson *(Div of Appl Sci, Harvard Univ, Cambridge MA 02138)*. Acta Metall Mat 41(8) 2365-2376 (Aug 1993).

The topic addressed in this paper is transverse cracking in the matrix of the 90° layers of a cross-ply laminate loaded in tension. Several aspects of the problem are considered, including conditions for the onset of matrix cracking, the evolution of crack spacing, the compliance of the cracked laminate, and the overall strain contributed by release of residual stress when matrix cracking occurs. The heart of the analysis is the plane strain problem for a doubly periodic array of cracks in the 90° layers. A fairly complete solution to this problem is presented based on FE calculations. In addition, a useful, accurate closed form representation is also included. This solution permits the estimation of compliance change and strain due to release of residual stress. It can also be used to predict the energy release rate of cracks tunneling through the matrix. In turn, this energy release rate can be used to predict both the onset of matrix cracking and the evolution of crack spacing in the 90° layers as a function of applied stress. All these results are used to construct overall stress-strain behavior of a laminate undergoing matrix cracking in the presence of initial residual stress.

276L. OTHER ANISOTROPIC AND NONHOMOGENEOUS MEDIA

11A420. Coplanar cracks in a finite rectangular anisotropic elastic slab under antiplane shear stresses: A hypersingular integral formulation. - WT Ang and G Noone *(Dept of Appl Math, Univ of Adelaide, Adelaide SA 5001, Australia)*. Eng Fracture Mech 45(4) 431-437 (Jul 1993).

An antiplane crack problem concerning an arbitrary number of pairs of coplanar cracks in a finite rectangular anisotropic elastic slab is considered. Using Fourier integral transforms and Fourier series, the problem is reduced to a system of Hadamard finite-part singular (hypersingular) integral equations which can be solved numerically by using a collocation technique. Once these integrals are solved, the relevant crack energy and stress intensity factors can be readily computed. Numerical results for a specific case of the problem are given.

11A421. Observation of deformation and damage at the tip of cracks in adhesive bonds loaded in shear and assessment of a criterion for fracture. - H Chai *(Dept of Mech Mat and Struct, Sch of Eng, Tel-Aviv Univ, Tel-Aviv, Israel)*. Int J Fracture 60(4) 311-326 (15 Apr 1993).

The evolution of damage at the tip of cracks in adhesive bonds deforming in shear was monitored in real time using a high-magnification video camera. Brittle and a ductile epoxy resins were evaluated, with the bond thickness t being an experimental variable. An extensive zone of plastic deformation developed ahead of the crack tip prior to fracture. In the case of the brittle adhesive, for relatively thick bonds tensile microcracks formed within that zone. Increased loading caused the microcracks to grow from the interlayer to the interface, which led to a complete bond separation after interface cracks emanating from adjacent microcracks linked. In contrast, for the ductile adhesive the crack always grew away from the tip. Strain gradients tended to develop there when the bond thickness was large. The adhesive shesr strain was determined from fine lines scratched on the specimen edge. For both adhesives, the average crack tip shear strain at crack propagation rapidly decreased with increasing t. This effect was attributed to the changing sensitivity of the bond to the presence of flaws; thicker bonds can accommodate large microcracks or mircovoids which cause greater stress concentration. For a given bond thickness, the critical crack tip shear strain agreed well with the ultimate shear strain of the unflawed adhesive γ_f previously determined using the napkin ring shear test. This suggests that the ultimate shear strain is a key material property controlling crack growth. The critical distortional strain energy-unit area of the unflawed adhesive W_s was determined from the area under the stress-strain curve in the napkin test ring. Good agreement between W_s and the adhesive mode II fracture energy was found for all joints tested except for relatively thick bonds. For the particular case of an elastic-perfectly plastic adhesive, the agreement above implies $G_{IIC} = W_s = t\tau_y\gamma_f$.

11A422. Rotation at the crack tip and COD of mode I crack in anisotropic plate. - A Bhattacharya *(Dept of Mech Eng, Inst of Tech, Banaras Hindu Univ, Varanasi 221 005, India)*. Int J Fracture 61(2) 131-138 (15 May 1993).

Rigid body rotation is obtained at the points near crack tip of mode I crack in infinite anisotropic plate. Using Lekhnitskii's complex analysis procedure the rotation is expressed in terms of complex potentials and complex parameters of the material. A relation of crack tip rotation is obtained by incorporating the stress intensity factor and complex parameters for the known crack configuration. An equation of crack opening displacement is derived. For the case of plates made of composite materials the features of crack tip rotation and crack edge profiles due to mode I loading are described.

276N. CRACK STABILITY AND BRANCHING

11A423. Fatigue crack growth rate in 63Sn37Pb solder joints. - Z Guo and H Conrad *(Mat Sci and Eng Dept, N Carolina State Univ, Raleigh NC 27695-7907)*. J Electron Packaging 115(2) 159-164 (Jun 1993).

Fatigue crack growth rate (FCGR) was determined in shear (Mode II) on notched 63Sn37Pb solder joints at room temperature. The FCGR data correlated reasonably well with the expression $da/dN = B(\Delta Y)^b$ where ΔY was either ΔK, ΔJ, or ΔW_p. The value of b for ΔJ and ΔW_p was similar to that generally obtained for metals in Mode I loading; however, it was 2-3 times larger in the case of ΔK. Although the fatigue cracks initiated at the centrally located notches, they soon wandered toward the solder-Cu interface and then propagated in the solder adjacent to the intermetallic compound. The fatigue crack mode was transgranular with no clear microstructure preference. The results obtained on the notched specimens are in accord with those reported previously on initially smooth specimens tested in shear.

276S. DYNAMIC CRACK PROPAGATION

11A424. Dynamic crack propagation: A literature study. - MM Banerjee *(Dept of Math, AC Col, Jalpaiguri-735 101, W Bengal, India)*, JN Das *(Dept of Phys, AC Col, Jalpaiguri-735 101, W Bengal, India)*, S Sikdar *(Belakoba HS Sch, Jalpaiguri, India)*. Int J Pressure Vessels Piping 55(3) 495-509 (1993).

Today, analysis in fracture mechanics has become so important that an international collaborative research programme in this field is being carried out. Its importance lies in the fact that the strength or the toughness of a material cannot be measured directly. Moreover, the present structures are often subjected to dynamic loading. Hence the determination of the dynamic fracture toughness values, in particular the crack arrest toughness and the initiation fracture toughness, at high loading rates has become an essential aspect of present investigations. The present work is primarily concerned with a literature survey on dynamic stress analysis, with specific attention to the determination of the stress analysis, with specific attention to the determination of the stress intensity factor K for three-point bending specimens. Future areas of investigation have been discussed.

11A425. FE analysis of plane strain dynamic crack growth in materials displaying the Bauschinger effect. - R Narasimhan *(Dept of Mech Eng, IISc, Bangalore 560012, India)* and CS Venkatesha *(Government Col of Eng, Davangere 577004, India)*. Int J Fracture 61(2) 139-157 (15 May 1993).

In this paper dynamic crack growth in an elastic-plastic material is analyzed under mode I plane strain small-scale yielding conditions using a FE procedure. The main objective of this paper is to investigate the influence of anisotropic strain hardening on the material resistance to rapid crack growth. To this end, materials that obey an incremental plasticity theory with linear isotropic or kinematic hardening are considered. A detailed study of the near-tip stress and deformation fields is conducted for various crack speeds. The results demonstrate that kinematic hardening does not oppose the role of inertia in decreasing the plastic strains and stresses near the crack tip with increase in crack speed to the same extent as isotropic strain hardening. A ductile crack growth criterion based on the attainment of a critical crack opening displacement at a small microstructural distance behind the tip is used to obtain the dependence of the theoretical dynamic fracture toughness with crack speed. It is found that for any given level of strain hardening, the dynamic fracture toughness displays a much more steep increase with crack speed over the quasistatic toughness for the kinematic hardening material as compared to the isotropic hardening case.

11A426. Process region influence on energy release rate and crack tip velocity during rapid crack propagation. - E Johnson *(Dept of Solid Mech, Lund IT, Lund Univ, Box 118, S-221 00 Lund, Sweden)*. Int J Fracture 61(2) 183-187 (15 May 1993).

A FE model of a plate with an edge crack is investigated. A cell mode of the material, with the cell size representing some characteristic intrinsic material length, is adopted. The size of the process region depends on the number of cells that have reached a state which is unstable at load control. The results show that the growth of the process region is a main factor responsible for the lack of a unique relation between the small scale yielding energy release rate and the crack tip velocity and also for the observed constant crack velocities that are significantly below the Rayleigh wave velocity. A rapidly propagating crack appears to meet an increase of the energy flow to the crack edge per unit of time by increasing the size of the process region rather than increasing its edge velocity.

276W. MICROMECHANISMS

11A427. Microcracking of an internally pressurized ceramic ring. - M Olsson and AE Giannakopoulos *(Dept of Solid Mech, RIT, S-100 44 Stockholm, Sweden)*. Acta Metall Mat 41(8) 2353-2364 (Aug 1993).

In the present work we investigated experimentally a thick ring configuration of Al_2O_3 ceramic subjected to internal pressure. Non-transforming ceramic of this type may exhibit stress induced microcracking. We model this possible microcracking process with an anisotropic damage constitutive equation. We solved the appropriate boundary value problem explicitly. Based on the experimental strain-load curve and the predictions of the model, we attemped to resolve the stress-strain behavior of a specific, coarse grained Al_2O_3 ceramic. The present results deal with the mechanics of the test. Some electron microscopy observation will follow. The proposed ring test can be very well used for analysis of transforming ceramics, as well as for biaxial creep.

11A428. Nanometer substructures and its effects on ductility and toughness at room temperature in nickel-rich NiAl. - Tianyi Cheng *(Metal Mat Section, Beijing IT, PO Box 327, Beijing 100081, Peoples Rep of China)*. Nanostruct Mat 2(1) 19-27 (Jan-Feb 1993).

A nanometer substructure in a rapidly solidified Ni-34.6 at% Al alloy with an average grain size of 2.2 μm was achieved and investigated. It was found that the nanometer substructures, in addition to fine grains, led to many interfaces with high density and homogeneous distribution, which played an effective role in improving the ductility and toughness of the NiAl at room temperature. The mechanism and a new definition of the nanostructured materials were discussed.

276Y. COMPUTATIONAL TECHNIQUES

11A429. BE formulation for the inverse elastostatics problem (IESP) of flaw detection. - LM Bezerra and S Saigal *(Dept of Civil Eng, Carnegie Mellon Univ, Pittsburgh PA 15213).* Int J Numer Methods Eng 36(13) 2189-2202 (15 Jul 1993).

A boundary integral formulation is presented for the detection of flaws in planar structural members from the displacement measurements at some boundary locations and the applied loadings. Such inverse problems usually start with an initial guess of the flaw location and size and proceed towards the final configuration of a sequence of iterative steps. A FE formulation will require a remeshing of the object corresponding to the revised flaw configuration in each iteration making the procedure computationally expensive and cumbersome. No such remeshing is required for the BE approach. The inverse problem is written as an optimization problem with the objective function being the sum of the squares of the differences between the measured displacements and the computed displacements for the assumed flaw configuration. The geometric condition that the flaw lies within the domain of the object is imposed using the internal penalty function approach in which the objective function is augmented by the constraint using a penalty parameter. A first-order regularization procedure is also implemented to modify the objective function in order to minimize the numerical fluctuations that may be caused in the numerical procedure due to errors in the experimental measurements for displacements. The flaw configuration is defined in terms of geometric parameters and the sensitivities with respect to these parameters are obtained in the BE framework using the implicit differentiation approach. A series of numerical examples involving the detection of circular and elliptic flaws of various sizes and orientations are solved using the present approach. Good predictions of the flaw shape and location are obtained.

11A430. Collapsed isoparametric element as a singular element for a crack normal to the bimaterial interface. - Yong-Li Wu *(Inst of Mech, Chinese Acad of Sci, Beijing 100080, Peoples Rep of China).* Comput Struct 47(6) 939-943 (17 Jun 1993).

It is shown that the variable power singularity of the strain field at the crack tip can be obtained by the simple technique of collapsing quadrilateral isoparametric elements into triangular elements around the crack tip and adequately shifting the side-nodes adjacent to this crack tip. The collapsed isoparametric elements have the desired singularity at crack tip along any ray. The strain expressions for a single element have been derived and in addition to the desired power singularity, additional singularities are revealed. Numerical examples have shown that triangular elements formed by collapsing one side lead to excellent results.

11A431. Compliance of three-point bend round beam specimens calculated with the slice synthesis method. - Wang Qizhi and Xian Xuefu *(Dept of Resources and Env Eng, Chongqing Univ, Sichuan 630044, Peoples Rep of China).* Eng Fracture Mech 45(4) 547-550 (Jul 1993).

The compliance of two kinds of three-point bend (3PB) round bend specimens is calculated with the slice synthesis method. In this method, the round beam is divided into a number of slices, and every slice is considered as a 3PB beam with a rectangular cross-section for which the compliance is known, then these slices are combined together to give the compliance of the round beam. The calculated results have shown good accuracy. It is postulated that the slice synthesis method can be used to obtain the compliance of bend specimens with a circular cross-section and various crack front shapes.

11A432. Cracks of fractal geometry with unilateral contact and friction interface conditions. - PS Theocaris *(Natl Acad of Athens, PO Box 77230, 17510 Athens, Greece)* and PD Panagiotopoulos *(Dept of Civil Eng, Aristotle Univ, 54006 Thessaloniki, Greece).* Int J Fracture 60(4) 293-310 (15 Apr 1993).

Structures involving cracks of fractal geometry are studied here, on the assumption that at the interface unilateral contact and friction boundary conditions hold. Approximating the fractal by a sequence of classical surfaces or curves and combining this procedure with a two-level contact-friction algorithm based on the optimization of the potential and of the complementary energy, we get the solution of the problem after some appropriate transformations relying on the SVD-decomposition of the equilibrium matrix. Numerical examples, using singular elements for the consideration of the crack singularity, illustrate the theory.

11A433. Finite-part integral and BEM to solve embedded planar crack problems. - TY Qin and RJ Tang *(Shanghai Jiao Tong Univ, Shanghai, Peoples Rep of China).* Int J Fracture 60(4) 373-381 (15 Apr 1993).

Using the Somigliana formula and concepts of the finite-part integral, a set of hypersingular integral equations to solve the arbitrary flat crack in 3D elasticity is derived, then its numerical method is proposed by combining the finite-part integral method with the BEM. In order to verify the method, several numerical examples are carried out. The results of the displacement discontinuities of the crack surface and the stress intensity factors at the crack front are in good agreement with the theoretical solutions.

11A434. Interface crack under combined loading: An eigenvalue problem for the gap. - AK Gautesen *(Ames Lab and Dept of Math, Iowa State Univ, Ames IA 50011).* Int J Fracture 60(4) 349-361 (15 Apr 1993).

To avoid the ductility of overlapping material near the crack tips, the tips of the crack are assumed to be closed (the Comninou model). The exact series solution to the problem of the interface crack under combined loading is complicated, and it is difficult to take advantage of the smallest of the left contact zone to obtain simple asymptotic approximations to the quantities of physical interest. Here, the gap is shown to satisfy an eigenvalue problem. The method of matched inner and outer expansions is used to obtain a simple uniform approximation to this quantity. Similar results are obtained for the tangential shift, which satisfies the same differential equation as the gap. The tractions at the interface also satisfy a second order differential equation and simple uniform approximations are obtained for these quantities.

11A435. Simple models of rapid fracture. - M Marder *(Center for Nonlinear Dyn and Dept of Phys, Univ of Texas, Austin TX 78712).* Physica D 66(1-2) 125-134 (Jun 1993).

The purpose of this article is to introduce the physics of fracture through simple scaling analysis and 1D models. Two 1D models are discussed. The first is a continuum model, for which it is simple to find the steady states and establish linear stability. The second model is a lattice version of the first, and its steady states can be found by the Wiener-Hopf technique. The lattice model steady states involves large quantities of radiation, and may help to explain dynamics observed in some recent unexplained experiments.

11A436. Strain energy release rates for internal cracks in rubber blocks. - Y-W Chang, AN Gent, J Padovan *(Inst of Polymer Eng, Univ of Akron, Akron OH 44325-0301).* Int J Fracture 60(4) 363-371 (15 Apr 1993).

Strain energy release rates have been calculated by FE analysis for growth of a small crack in a cylindrical rubber block under tension. The crack was assumed to lie in the center of the block in a plane perpendicular to the axis. The rubber was taken to be virtually incompressible in bulk and non-linearity elastic. Only small changes were found in the stress-concentrating effect of the crack for imposed tensile strains of up to 150%. Secondly, the rubber cylinder was assumed to be bonded between two parallel flat rigid plates. The stress-concentrating effect of the crack was found to increase markedly as the thickness of the bonded rubber block was reduced, but again it was only slightly dependent on the applied tensile strain.

276Z. EXPERIMENTAL TECHNIQUES

11A437. Automated procedure for determining crack opening level from differential displacement signal data. - Chung-Youb Kim and Ji-Ho Song *(Dept of Autom and Design Eng, Korea Adv Inst of Sci and Tech, 207-43, Cheongryangridong, Dongdaemoongu, Seoul 130-012, Korea).* Int J Fatigue 15(4) 301-309 (Jul 1993).

The crack opening point is commonly measured from load-displacement records or load-differential displacement records. In this study, an automated method is developed to determine the crack opening point from differential displacement signal curves. To improve measurement precision, a noise reduction method using a digital low-pass filter was employed. In order to assess the measurement accuracy and precision of the proposed method, computer simulation was extensively performed, generating differential displacement signals of various S-N ratios. The measured results of crack opening points for these simulated signals show good accuracy and precision. The proposed method was applied in practice to constant-amplitude loading, and two kinds of random loading: narrow- and wide-band random loading. As a result, the method is found to be very effective even for random loadings.

11A438. Comparison of standard measurement methods for critical stress intensity factor K_{Ic} for metals and rock. - M Sklodowski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland).* Arch Civil Eng 38(3) 223-238 (1992).

Methodology of measurements of critical stress intensity factors K_{Ic} as given in ASTM E399 for metals is compared with that suggested by the Commission on Testing Methods ISRM for rocks. Standard geometries of specimens are shown. Special attention is drawn to the differences in the methodology of measurements, important for the interpretation of experimental results and evaluation of their correctness.

11A439. Revisit to the determination of stress-intensity factors and J-integrals using the caustics method. - OS Lee, SK Hong, YS Kim *(Inha Univ, 253 Yong-Hyun Dong, Nam-Ku, Inchon 402-751, Korea).* Exp Mech 33(2) 133-138 (Jun 1993).

Applications of the optical (shadow) method of reflective caustics to measurement of the stress-intensity factor and J integral in various specimens are investigated. The necessary experimental requirements to help determine accurate stress-in-tensity factor and J integral are described. The ratios of r_0 (radius of initial curve)-r_p(plastic-zone size) and r_0-t(thickness of specimen) are found to be very important experimental parameters to obtain meaningful stress and/or strain intensities surrounding crack tips. The appropriate ranges to determine accurate values of stress-intensity factor and J integral for polycarbonate (compact tension) and aluminum (c-shaped tension) specimens are presented.

11A440. Test specimen with constant stress intensity factor for prescribed displacement. - HL Groth *(R&D, Avesta Sheffield AB, S-774 80 Avesta, Sweden)* and D Zenkert *(Dept of Aeronaut Struct and Mat, RIT, S-100 44 Stockholm, Sweden)*. Int J Fracture 61(2) 173-181 (15 May 1993).

A test specimen has been developed that gives a constant value of the stress intensity factor in mode I under fixed displacement loading conditions. The test specimen is a double contoured cantilever beam specimen whose shape is derived from engineering beam theory. A final shape for a range of crack extensions where stress intensity is constant was established using a FE analysis. It is believed that this specimen could be useful for many applications where a constant stress intensity factor is needed over a range of crack extension for constant displacment loading, eg, viscoelastic crack growth in an adhesive layer of stress corrosion cracking.

11A441. Filtering of the experimental data in plane stress and strain fields. - SA Lukasiewicz *(Univ of Calgary, 2500 University Dr, Calgary, AB, T2N 1N4, Canada)*, M Stanuszek *(Comput Center, Tech Univ, Cracow 21-155, Poland)*, JA Czyz *(NOWSCO Pipeline Surveys and Services, Calgary, AB, Canada)*. Exp Mech 33(2) 139-147 (Jun 1993).

The paper presents a filtering algorithm which corrects the results of measurements of strain and stress fields in order to satisfy the fundamental equations of the continuum. It is proved that the algorithm is very efficient and requires small computational time. The developed filter can be used to correct the measuring data from any experiments provided some additional information about the measured system is available.

11A442. Micromechanical fatigue testing. - JA Connally *(Cummins Engine, 1900 McKinley Ave, Columbus IN 47202)* and SB Brown *(Rm 8-106, MIT)*. Exp Mech 33(2) 81-90 (Jun 1993).

This paper describes the design, modeling, and experimental test results of a single crystal silicon micromechanical device developed to evaluate fracture and fatigue of silicon based micromechanical devices. The structure is a cantilever beam, 300 microns long, with a large silicon plate and gold inertial mass at the free end. Torquing and sensing electrodes extend over the plate, and with associated electronics, drive the structure at resonance. Fatigue crack propagation is measured by detecting the shift in the natural frequency caused by the extension of a preexisting crack introduced near the fixed end of the cantilever. Experimental data are presented demonstrating time-dependent crack growth in silicon. Crack extensions of 10 to 300 nm have been measured with a resolution of approximately 2.5 nm, and crack tip velocities as low as 2.1×10^{-14} m-s. It is postulated that static fatigue of the native surface silica layer is the mechanism for crack growth. The methodology established here is generic in concept, permitting sensitive measurement of crack growth in larger fatigue specimens as well.

11A443. Photovisco-elastoplastic behavior of polycarbonate material under creep and tension tests. - MI Ait El Ferrane and A Lagarde *(Lab de Mec des Solides, 40 Ave du Recteur Pineau, 86022 Potiers Cedex, France)*. Exp Mech 33(2) 148-152 (Jun 1993).

Polymers are widely used as photomechanical models of a prototype material (often a metal). Photoplasticity is one of the methods used in order to show the behavior of plastic materials stressed beyond the linear elastic limit. To illustrate this process we have analyzed the photovisco-elastoplastic behavior of polycarbonate as a photoplastic material. In this paper a technique for local and simultaneous measurement of birefringence and principal strains is presented. The mechanical and optical properties, at room temperature, have been evaluated by means of uniaxial tension tests. A series of creep tests has been carried out in order to study the photovisco-elastoplastic behavior of polycarbonate. In two different experiments we analyzed nonlinear birefringence and the amplitude of the corresponding strains. We could thus evaluate the distribution of strains and the distribution of uniaxial stress for each birefringence state and vice versa.

280N. HARDNESS, ABRASION, AND WEAR TESTING

11A444. Effect of residual stresses on hardness measurements. - J Frankel, A Abbate *(SMCAR-CCB-RA, Benet Labs, Watervliet Arsenal, Watervliet NY 12189-4050)*, W Scholz *(SUNY, Albany NY 12222)*. Exp Mech 33(2) 164-168 (Jun 1993).

The Rockwell C hardness, R_C, was measured as a function of position on steel rings with different residual-stress profiles through the thickness. An experimental correlation between residual stress and R_C was obtained. A relationship between the average pressure p of a spherical indenter, the yield strength Sy and the residual stress of the material was conceived and used in fitting the experimental data. In order to model the effects of residual stresses on the measured hardness, the von Mises-Hencky (power) yield criterion was utilized, together with an adaptation for residual stresses of the expression for the stress state under a spherical indenter, given in Shaw, Hoshi and Henry. A parameter α was introduced in our calculations to account for the effect of the nonperpendicularity of the residual stresses to the pressure p of the spherical indenter. The proposed model in large measure fits experimental hardness versus residual stress data, and results are consistent with different samples. This model can be used as a basis for the measurement of residual stresses in steel or other materials.

280R. OPTICAL NONDESTRUCTIVE TESTING (NDT)

11A445. Dual beam laser vibrometer for measurement of dynamic structural rotations and displacements. - MW Trethewey, HJ Sommer, JA Cafeo *(Dept of Mech Eng, Penn State)*. J Sound Vib 164(1) 67-84 (8 Jun 1993).

A novel non-contacting system for multiaxis vibration measurements (one translation and two angular deflections) is described. The system is based on monitoring the reflections of two laser beams from a planar reflective target. By utilizing the geometry of the beams and their respective reflections: range, pitch and roll of the target can be determined. The theory behind the system is discussed along with the development of a prototype device. Static and dynamic experiments are performed to determine the system's operational limits and utility. The prototype system demonstrated the capability of measuring motions up to 1 kHz with absolute accuracies of 0.04 mm for the translation variable and 0.03 degrees for the rotation variables. Measurement precision of 0.01 mm and 0.01 degrees approached the precision of the test stand and the theoretical resolution limits of the system over a usable workspace of ±2.5 mm and ±5 degrees.

11A446. New trends in optical methods for experimental mechanics Part I. Moire and grating projection techniques for shape and deformation measurement. - M Kujawinska and K Patorski *(Fac of Fine Mech, Warsaw Univ of Tech, Poland)*. J Theor Appl Mech 31(3) 539-561 (1993).

The influence of dynamic development in the field of personal computers and video techniques on optical methods used in the experimental mechanics is described. New methods of computer aided processing of the information encoded in the interferogram-moiregram patterns with special emphasis put on so-called phase methods are presented. The benefits of various modifications of the phase-stepping method are emphasized and illustrated by exemplary experimental results in the field of moire and grating projection topography used for the shape and deformation studies. The description of the equipment developed and sensitivity considerations are included.

11A447. New trends in optical methods for experimental mechanics Part II. High sensitivity grating interferometry for in-plane displacement measurement. - K Patorski and M Kujawinska *(Fac of Fine Mech, Warsaw Univ of Tech, Poland)*. J Theor Appl Mech 31(3) 563-582 (1993).

Recent developments in the high sensitivity grating interferometry for sub-micron in-plane displacement studies aiming at the automation of the data reduction process are presented. The implementation of phase methods of interferogram analysis using the polarized light approach together with the spatial carrier method are described. The versatility, speed, and accuracy of the methods and instrumentation developed are illustrated by the results of recent applications in plastic-elastic range of mechanics, fracture mechanics, and studies of composite materials.

11A448. Scanning Moire at high magnification using optical methods. - DT Read *(Mat Reliability Div, NIST, 325 Broadway, Boulder CO*

80303), JW Dally *(Mech Eng Dept, Univ of Maryland, College Park MD 20742)*, M Szanto *(Ben Gurion Univ, Beer Sheva, Israel)*. Exp Mech 33(2) 110-116 (Jun 1993).

Methods of employing scanning moire at high magnification are developed and demonstrated. Modern lithographic techniques for producing custom moire gratings with a frequency up to 250 l/mm are described. On a probing station equipped with a video system, pseudo-color moire fringes are produced using the scanning lines of the color charge-coupled-device camera. Fringe multiplication from 1 to 5 is possible with correct combinations of magnification and grating pitch. An analysis is given to show that strain sensitivity depends only on the number of scanning lines used to record the image. The grating pitch and the magnification are important because they reduce the gage length of strain measurement. The high-magnification scanning moire was used to study plastic- strain fields in an aluminum tensile specimen. Local disturbances in the strain field were observed at 2 to 2.5% applied strain. These discontinuities became more significant at high levels of applied strain.

11A449. Application of nondestructive techniques for the prediction of elastic anisotropy of a textured polycrystalline material. - CJ Yu *(Concurrent Technologies, PA 15904)*, JC Conway Jr *(Penn State)*, J Hirsch *(VAW Aluminum, Bonn, Germany)*, CO Ruud, KJ Kozaczek *(Penn State)*. J Nondestruct Eval 12(1) 79-95 (Mar 1993).

Effect of processing parameters including cold work and grain size on texture development in copper and 68:32 α-brass thin sheets is investigated. The preferred orientation of grains (texture) is represented quantitatively by the orientation distribution function (ODF) as derived either by X-ray diffraction or by ultrasonic velocity measurements. The texture-induced elastic moduli are derived in the sheet plane at various orientations to the rolling direction. The predicted values of elastic moduli are compared with the mechanically measured ones. An attempt is made to empirically correlate ODF coefficients to the mechanically measured elastic modulus and plastic strain ratio (r-value). The sources of discrepancies such as the limitations of the measuring techniques and the models applied are discussed.

11A450. Identification of partial plugging in a gas-transport pipeline by an acoustic method. - Hiroshi Koyama, Kajiro Watanabe *(Dept of Instrument and Control Eng, Col of Eng, Hosei Univ, 3-7-2 Kajinocho, Koganei, Tokyo 184, Japan)*, DM Himmelblau *(Dept of Chem Eng, Univ of Texas, Austin TX 78712)*. Appl Acoust 40(1) 1-19 (1993).

This paper describes how to locate and estimate accurately the degree of partial plugging in a gas-transport pipeline by acoustic methods. The acoustic method proposed is one of the indirect methods that identifies the inner structure of the pipeline from the acoustic standing waves introduced at one end of the pipeline by a source of noise. Both simulations and experiments have been carried out to validate the proposed technique. The method applies to straight sections of pipe without branches or leaks, and in the experiments we used pipe of length 4.113 m and uniform diameter of 16.0 mm (the cross-sectional area was 201 mm^2). Results of the experiments and simulations yielded very similar time responses, which showed clear pulses due to a partial plugging. From the shape of the pulse and the occurrence times of the pulse, the location and degree of the partial plugging could be calculated. A partial plug with an open diameter of 95% of the cross-sectional area of the pipeline was clearly located and estimated with reasonable accuracy.

11A451. Measurement of texture and formability parameters with a fully automated, ultrasonic instrument. - RB Thompson, EP Papadakis *(Center for NDE, Iowa State Univ, Ames IA 50011)*, DD Bluhm *(Ames Lab USDOE, Iowa State Univ, Ames IA 50011)*, GA Alers *(NIST)*, K Forouraghi *(Center for NDE, Iowa State Univ, Ames IA 50011)*, HD Skank *(Ames Lab, USDOE, Iowa State Univ, Ames IA 50011)*, SJ Wormley *(Center for NDE, Iowa State Univ, Ames IA 50011)*. J Nondestruct Eval 12(1) 45-62 (Mar 1993).

A fully automatic, ultrasonic instrument to measure texture and formability parameters on metal sheet is described. Arrays of EMAT transducers are used to transmit and receive S_0 Lamb waves propagating at 0°, 45°, and 90° with respect to the rolling direction. By analyzing the frequency dependence of this phase of the received signals, the long wavelength limit of the velocities is obtained. Included is a discussion of this algorithm, and subsequent processing steps to predict the ODC's W_{400}, W_{420}, and W_{440}. On steel, the prediction of drawability parameter r and Δ r based on a correlation developed previously by Mould and Johnson is also discussed. Results of blind field trials at facilities of three suppliers-users of steel sheet for automotive applications and one supplier of aluminium sheet for beverage can production are reported. The former confirmed the Mould-Johnson correlation for low r materials but indicated that refinement are needed for modern steels with high r. The aluminum data suggest a correlation between W_{440} and the degree of four-fold earing.

11A452. Methods to improve the accuracy of on-line ultrasonic measurement of steel sheet formability. - AV Clark *(Mat Reliab Div, NIST, 325 S Broadway, Boulder CO)*, Y Berlinsky *(NIST, 325 S Broadway, Boulder CO)*, N Izworski *(Ford Motor, Dearborn MI)*, Y Cohen, DV Mitrakovic *(NIST, 325 S Broadway, Boulder CO)*, SR Schaps *(Mat Res Div, NIST, 325 S Broadway, Boulder CO)*. J Nondestruct Eval 12(1) 33-43 (Mar 1993).

We report here on an ultrasonic system which quantifies factors which could degrade the resolution of the plastic strain ratio, or r-value, in sheet steel. We also present means to suppress these artifacts. We have developed a moving sheet device (MSD) to be used as a test bed to demonstrate the feasibility of on-line measurement of r-value in a steel mill. The device can move specimens at speeds comparable to those in industrial practice. An automated velocity measurement system has also been developed and integrated with the MSD. This allows ultrasonic measurements to be made with an array of transducers. Measurements were made in both static and dynamic mode. Artifacts due to sheet motion were small, and should not significantly degrade r-value resolution.

11A453. On-line measurement of plastic strain ratio of steel sheet using resonance mode EMAT. - K Kawashima, T Hyoguchi, T Akagi *(Appl Electron Lab, Electron Res Lab, Nippon Steel, 5-10-1 Fuchinobe Sagmihara, Kanagawa 229, Japan)*. J Nondestruct Eval 12(1) 71-77 (Mar 1993).

We have developed an on-line system for the measurement of plastic strain ratio of steel sheet using a thickness resonance EMAT that measures the thickness resonance frequencies of three different modes of bulk ultrasonic waves. The effective size of the EMAT is small, about 20 mm in diameter. A good correspondence was obtained between the in-plane average Young's modulus measured by this method and the in-plane average plastic strain ratio measured by tensile testing, with a standard deviation smaller than 0.04 in units of plastic strain ratio. The effects of temperature, lift-off, tensile stress, speed of the moving sheet and zinc coats were experimentally and theoretically analyzed. We show that none of them have a sizable effect on the measurement accuracy.

11A454. On-line measurement of steel sheet r-value using magnetostrictive-type EMAT. - M Hirao, H Fukuoka *(Fac of Eng Sci, Osaka Univ, Toyonaka, Osaka 560, Japan)*, K Fujisawa, R Murayama *(Syst Eng Div, Sumitomo Metal Industries, Amagasaki, Hyogo 660, Japan)*. J Nondestruct Eval 12(1) 27-32 (Mar 1993).

An ultrasonic on-line system to measure r values in cold rolled steel sheets has been developed with electromagnetic acoustic transducers (EMATs). These EMATs are composed of meanderline coils with electromagnets and operate with the magnetostrictive mechanism. The EMAT instrument measures the propagation times of the fundamental symmetrical Lamb (S_0) wave at a low frequency and relates them to the r values through a calibrated regression curve. Preliminary tests indicate that the on-line monitoring of r is quite feasible with a standard deviation of 0.07 for various low carbon steel sheets; the thicknesses range from 0.5 to 2.5 mm. The measuring time is 20 msec per data. The liftoff is allowed to 5 mm with 2 mm thick sheet. The r evaluation is independent of the line speed up to 325 m/min. These promising results promote installation of ultrasonic r-value measurement systems in steel production lines.

11A455. Ultrasonic assessment of interfacial oxidation damage in ceramic matrix composites. - YC Chu, SI Rokhlin *(Dept of Welding Eng, Ohio State Univ, Columbus OH 43210)*, GY Baaklini *(NASA Lewis Res Center, Cleveland OH 44135)*. J Eng Mat Tech 115(3) 237-243 (Jul 1993).

A new approach to characterizing oxidation damage in ceramic matrix composites using ultrasonic techniques is proposed. In this approach the elastic constants of the composite are determined nondestructively by measuring the angular dependence of both longitudinal and transverse wave velocities. A micromechanical model for composites with anisotropic constituents is used to find the anisotropic properties of an effective fiber which is a combination of the fiber and the interface. Interfacial properties are extracted from the properties of this effective fiber by analyzing the difference between effective and actual fiber properties. Unidirectional $[0]_{28}$ SiC/Si_3N_4 composites with 30% fiber volume fraction and 30% matrix porosity are used. The samples are exposed in a flowing oxygen environment at elevated temperatures, up to 1400°C, for 100 hours and then measured by ultrasonic methods at room temperature. The Young's modulus in the fiber direction of the sample oxidized at 600°C decreased significantly but it was unchanged for samples oxidized at temperatures above 1200°C. The transverse moduli obtained from ultrasonic measurements decrease continuously up to 1200°C. The shear stiffnesses show behavior similar to the transverse moduli. The effective elastic moduli of the interfacial carbon coating are determined from the experimental data and their change due to thermal oxidation is discussed.

11A456. Ultrasonic predictions of R-value in deep drawing steels. - J Savoie *(Dept of Metall Eng, McGill Univ, 3450 University St, Montreal H3A 2A7, Canada)*, D Daniel *(Centre de Rech de Voreppe SA, Pechiney, Voreppe, France)*, JJ Jonas *(Dept of Metall Eng, McGill Univ, 3450 Univ St, Montreal H3A 2A7, Canada)*. J Nondestruct Eval 12(1) 63-69 (Mar 1993).

The textures of five types of deep drawing steels were measured and analyzed using the series expansion method. Electromagnetic acoustic techniques were employed to determine the elastic anisotropy in terms of the angular variation of the ultrasonic variations. The series expansion formalism was employed for predicting the elastic and plastic anisotropies from texture data. Comparison with experimental measurements of Young's modulus indicates that the elastic energy method can accurately reproduce the elastic anisotropy if the single crystal elastic constants are appropriately chosen. The angular variation of the r-value in the rolling plane was calculated from the ODF coefficients by means of the pancake relaxed constraint model using an appropriate CRSS ratio for glide on the [112]<111> and [110]<111> slip systems. The fourth order and first sixth order ODF coefficients were calculated *nondestructively* from the anisotropy of the ultrasonic velocities. The calculated pole figures based on the ODF coefficients obtained in this way are similar to those derived from complex X-ray data. It is shown that the plastic properties of commercial deep drawing steels are predicted more accurately when the 4th- *and* 6th-order ODF coefficients are employed than when the 4th-order ones are used.

11A457. Ultrasonic technique for investigation of residual stresses in cylindrical forgings. - J Deputat, M Adamski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*, J Goljasz, J Kalisiewicz *(Warszawa, Poland)*. Eng Trans 41(1) 61-76 (1993).

An ultrasonic method to examine statical stress fields in the subsurface layers of cylindrical steel forgings is described. The values of stresses are calculated from precise measurements of traveltimes of subsurface pulses of longitudinal and transverse waves propagating in the direction of generating line. Suitable apparatus is described and some results of investigation of a shipborne shaft forging with favorable and unfavorable distributions of residual stresses are shown. Longitudinal and hoop stresses in a steel mill roll are also examined.

11A458. Finite element simulation of eddy-current flaw detection systems. - KM Gawrylczyk *(Szczecin Univ of Tech, Szczecin, Poland)*. J Tech Phys 34(2) 145-159 (1993).

A number of methods of computer simulation of eddy-current flaw detection systems have been described. As regards 2D cases, model of axial and plane-parallel symmetry have been discussed. Solutions were based on the Helmholtz equation for the magnetic vector potential A. The 3D model is based on the scalar potential ϕ. An essential novelty is the use of an impedance boundary condition for modeling eddy currents in the conducting plate and for modeling a flaw. The use of infinite elements for tetrahedrons, reduces considerably the error caused by cutting-off a part of the region. The examples shown prove the usefulness of numerical simulation of eddy-current flaw detection systems for the design and optimization of sensors. They are also applied in the domain of modern microcomputer-aided defectometers.

11A459. Development of methods for on-line texture analysis. - P Blandford and JA Szpunar *(Dept of Mining and Metall Eng, McGill Univ, Montreal, PQ, Canada)*. J Nondestruct Eval 12(1) 21-26 (Mar 1993).

This work presents results obtained recently as part of the ongoing design of laboratory-scale equipment which will be used to develop and test methods for on-line texture analysis. The equipment is in the process of being built. A range of cold rolled and annealed IF deep-drawing steels were fully characterized using standard X-ray diffraction texture methods. They were then analyzed to obtain information which will be used to help optimize the measurement configuration of the laboratory-scale equipment for both a transmission and a reflection X-ray diffraction geometry. Texture measures in both geometries were then identified which are sensitive to texture changes produced by both cold rolling and annealing. The measures were then used to attempt some correlation between them and plastic properties calculated from the coefficients of the orientation distribution function. Satisfactory agreement between the texture measures and the average plasticity, R, were obtained for both the transmission and reflection geometries.

11A460. Industrial on-line texture determination in rolled steel strips. - H-J Kopineck *(Dortmund, Germany)*, R Loffel *(Loffel Verfahrenstechnik GmbH, Karlsruhe, Germany)*, H-B Otten *(Hoesch Stahl AG, Dortmund, Germany)*. J Nondestruct Eval 12(1) 13-19 (Mar 1993).

In the manufacture of sheet meal, it is of great importance that the quality should be homogeneous over the entire length of a strip. This can only be monitored using a continuous, on-line measuring method. A new X-ray transmission measuring technique has been developed for the nondestructive determination of texture-dependent technological data of rolled strip. It can be applied on-line for both hot and cold rolled metal strip, especially steel strip. The paper describes the measuring principle and gives information on the application for measuring the r_m-values and the earing-values of cold rolled steel strip. With the data from these values, the user can control the deep drawing characteristics of his strips. The extension of the basic measuring principle to a condition-free determination system will be demonstrated with its application for measuring textron dependent technological data of hot and cold rolled steel strip. Long term experience at Hoesch Stahl AG, typical results measured over the total strip length, integration in quality assurance systems, questions of maintenance etc, will be discussed.

11A461. Model for accelerated life testing. - H Strelec *(Dept of Stat, Univ of Tech Vienna, Wiedner Hauptstr 8-10, A-1040 Wien, Austria)*. Struct Safety 12(2) 129-136 (Jun 1993).

After a short motivation for the problem of extremely high reliability a nonparametric model for accelerated life testing is described. Besides well introduced classical models for high reliabilities are mentioned. Finally a stress-dependent model for crack growth based on fatigue accumulation is discussed.

11A462. Accurate measurement of 3D deformations in deformable and rigid bodies using computer vision. - PF Luo, YJ Chao, MA Sutton, WH Peters III *(Dept of Mech Eng, Univ of S Carolina, Columbia SC 29208)*. Exp Mech 33(2) 123-132 (Jun 1993).

Recently, digital-image-correlation techniques have been used to accurately determine 2D in-plane displacements and strains. An extension of the 2D method to the acquisition of accurate, 3D surface-displacement data from a stereo pair of CCD cameras is presented in this paper. A pin-hole camera model is used to express the transformation relating 3D world coordinates to 2D computer-image coordinates by the use of camera extrinsic and intrinsic parameters. Accurate camera model parameters are obtained for each camera independently by (a) using several points which have 3D world coordinates that are accurate within 0.001 mm and (b) using 2D image-correlation methods that are accurate to within 0.05 pixels to obtain the computer-image coordinates of various object positions. A nonlinear, least-squares method is used to select the optimal camera parameters such that the deviations between the measured and estimated image positions are minimized. Using multiple orientations of the cameras, the accuracy of the methodology is tested by performing translation tests. Using theoretical error estimates, error analyses are presented. To verify the methodology for actual tests both the displacement field for a cantilever beam and also the surface, 3D field displacement and strain fields for a 304L stainless-steel compact-tension specimen were experimentally obtained using stereo vision. Results indicate that the 3D measurement methodology, when combined with 2D digital correlation for subpixel accuracy, is a viable tool for the accurate measurement of surface displacements and strains.

282. Structures (basic)

282A. GENERAL THEORY

11A463. Applications of generalized variational principles in nonlinear structural analysis. - Xiang-sheng Cheng *(Tonghi Univ, Shanghai, China)*. Appl Math Mech 14(5) 417-428 (May 1993).

This paper discusses the generalized variational principles founded by the technique of Lagrangian multipliers in structural mechanics and analyzes the nonlinear statically indeterminate structures. It is assumed that the stress-strain relationship of the materials of structures has the form of $\sigma = B\epsilon^{1/m}$ or $\tau = C\gamma^{1/m}$, namely, the physical equations of structures have the shape of exponential functions. Several examples are given to illustrate the statically indeterminate structures such as the trusses, beams, frames, and torsional bars.

11A464. FEM for predicting equilibrium shapes of solder joints. - NJ Nigro *(Dept of Mech Eng, Marquette Univ, Milwaukee WI 53233)*, SM Heinrich *(Dept of Civil and Env Eng, Marquette Univ, Milwaukee WI 53233)*, AF Elkoub, X Zou, R Fournelle *(Dept of Mech Eng, Marquette Univ, Milwaukee WI 53233)*, Ping S Lee *(Allen-Bradley Co, Rockwell Int, Milwaukee WI 53204)*. J Electron Packaging 115(2) 141-146 (Jun 1993).

This paper discusses the development and application of a FEM for determining the equilibrium shapes of solder joints which are formed during a surface mount reflow process. The potential energy governing the joint formation problem is developed in the form of integrals over the joint surface, which is discretized with the use of FEs. The spatial variables which define the shape of the surface are expressed in a parametric form involving products of interpolation (blending) functions and element nodal coordinates. The nodal coordinates are determined by employing the minimum potential energy theorem. The method described in this paper is very general and can be employed for those problems involving the formation of 3D joints with complex shapes. It is well suited for problems in which the boundary region is not known a priori (eg. "infinite tinning" problems). Moreover, it enables the user to determine the shape of the joint in parametric form which facilitates meshing for subsequent FE stress and thermal analyses.

282C. STRUCTURAL OPTIMIZATION

11A465. Accuracy tests for various sensitivity analysis methods with respect to shape variables in planar cantilever beams. - G-J Park *(Mech Des and Prod Eng, Col of Eng, Hanyang Univ, 17 Haengdang-Dong Seongdong-Ku, Seoul 133-791, Korea)*. Comput Struct 47(6) 1057-1063 (17 Jun 1993).

Sensitivity information is required in the optimal design process. In structural optimization, sensitivity calculation is a bottleneck due to its complexities. Various schemes have been proposed for the calculation. Analytic and finite difference methods are the most popular at the present time; however, they have their advantages and disadvantages. The semi-analytic method has been suggested to overcome these difficulties. In spite of its excellence, the semi-analytic method has been found to possess numerical errors with respect to shape variables. In this research, the errors from each method are evaluated and compared using a shape variable. A planar beam is selected as an example since it has a mathematical solution. An efficient method is suggested for the structural optimization which utilizes the FEM.

11A466. Analysis and shape optimization of variable thickness prismatic folded plates and curved shells Part 2. Shape optimization. - E Hinton and NVR Rao *(Dept of Civil Eng, Univ College, Singleton Park, Swansea SA2 8PP, UK)*. Thin-Walled Struct 17(3) 161-183 (1993).

This paper deals with the development of computational tools for structural shape optimization of shells and folded plates in which the strain energy or the weight of the structure is minimized subject to certain constraints. Both thickness and shape variables defining the cross-section of the structure are considered. The analysis is carried out using curved, variable thickness finite strips formulated and tested in Part I of this paper. Optimal shapes are presented for several shells and folded plates of variable thickness including plates on elastic foundation. The changes in the relative contributions of the bending, membrane and shear strain energies are monitored during the whole process of optimization. The tools developed in the present work can be used as an aid to structural engineers in designing novel forms for shells and folded plates and provide valuable insight into the structural behavior. It is concluded that the finite strip method offers an accurate and inexpensive tool for the optimization of a wide class of structures having regular prismatic-type geometry with diaphragm ends.

11A467. Compressive bars with bounded displacement at the task of optimal control. - L Mikulski *(Krakow Univ of Tech, Krakow, Poland)*. Eng Trans 41(2) 123-137 (1993).

The beam with bounded displacement compressed by the axial force is considered as an optimal control task. The constraints relative to displacement of the bar axis could be active pointwise or in some domain. To solve the task, maximum principle shall be used; necessary conditions reduce the problem of optimal control to a multipoint boundary value problem for ordinary differential equations. The boundary value problems with jump conditions are solved by multiple-shooting techniques.

11A468. Exact least-weight truss layouts for rectangular domains with various support conditions. - T Lewinski, M Zhou, GIN Rozvany *(FB 10, Essen Univ, D-4300 Essen 1, Germany)*. Struct Optim 6(1) 65-67 (Jun 1993).

A comprehensive review of both previously known and newly derived exact optimal layouts for rectangular domains with point loads and either line or point supports is given in this note.

11A469. Improved approximation for stress contraints in plate structures. - GN Vanderplaats and HL Thomas *(VMA Eng, 5960 Mandarin Ave Ste F, Goleta CA 93117)*. Struct Optim 6(1) 1-6 (Jun 1993).

An improved approximation for stresses (and strains) in plate structures is presented. This approximation is highly accurate because it is based on approximations of the element forces, which are more invariant than the element stresses and strains, and because it captures the nonlinearity in the stress recovery calculations. Both sizing and shape design problems are used as examples to show the increased accuracy and robustness of this approximation function.

11A470. Isoperimetric inequalities in optimal structural design. - VV Kobelev *(Muhr und Bender KG, W-5952 Attendorn, Germany)*. Struct Optim 6(1) 38-51 (Jun 1993).

Isoperimetric inequalities arising in exactly solvable structural optimization problems are discussed in this article. Most isoperimetric inequalities of mechanical problems have been proved using one of three known methods. The first tool is the variational method, which is a powerful way to prove inequalities for systems described by ordinary differential equations. For the systems described by equations with partial derivatives, the symmetrization method can be applied. Methods based on positivity properties of operators, for example, Hopf's maximum principle, are used to prove the inequalities for local functionals. Using these algorithms, the new isoperimetric inequalities for engineering problems were investigated. Classical examples, namely the St Venant-Polya inequality rigidity, the Faber-Krahn inequality for vibrating membranes, the Banichuk-Wheeler inequality for maximum stress in a perforated plane and the Keller-Ting inequality for static moments of a bar are treated. The inequalities for the maximum stress in twisted isotropic and orthotropic elastic bars are proved. For the perfectly-plastic solid, the inequalities for collapse load are considered. The other class of inequalities, associated with eigenvalue problems, arises in vibration, conservative, and non-conservative stability problems. The new inequalities for the bimodal critical axial compression load for bars with clamped ends, a generalized Pfluger column and a circular ring under hydrostatic pressure are stated.

11A471. Mixed variational formulation for shape optimization of solids with contact conditions. - HC Rodrigues *(CEMUL, Inst Superior Tecnico, Av Rovisco Pais, Lisbon, Portugal)*. Struct Optim 6(1) 19-28 (Jun 1993).

This paper is concerned with the development of a mixed variational formulation and computational procedure for the shape optimization problem of linear elastic solids in possible contact with a rigid foundation. The objective is to minimize the maximum value of the von Mises equivalent stress in a body (non-differentiable objective function), subject to a constraint on its volume and bound constraints on the design. For design purposes, the contact boundary is considered fixed. A FE model that is appropriate for the mixed formulation is utilized in the discretization of the state and adjoint state equations. An elliptical mesh generator was used to generate the FE mesh at each new design. The computational model is tested in several example problems.

11A472. Multiparameter structural optimization using FEM and multipoint explicit approximations. - VV Toropov *(Dept of Civil Eng, Univ of Bradford, Bradford, W Yorkshire BD7 1DP, UK)*, AA Filatov, AA Polynkin *(Dept of Solid Mech, Nizhny Novgorod Univ, 23 Gagarin Ave, 603600 Nizhny Novgorod, Russia)*. Struct Optim 6(1) 7-14 (Jun 1993).

A unified approach to various problems of structural optimization, based on approximation concepts, is presented. The approach is concerned with the development of the iterative technique, which uses in each iteration the information gained at several previous design points (*multipoint approximations*) in order to better fit constraints and/or objective functions and to reduce the total number of FE analyses needed to solve the optimization problem. In each iteration, the subregion of the initial region in the space of design variables, defined by move limits, is chosen. In this subregion, several points (designs) are selected, for which response analyses and design sensitivity analyses are carried out using FEM. The explicit expressions are formulated using the weighted least-squares method. The explicit expressions obtained then replace initial problem functions. They are used as functions of a particular mathematical programming problem. Several particular forms of the explicit expressions are considered. The basic features of the presented approximations are shown by means of classical test examples, and the method is compared with other optimization techniques.

11A473. Optimal design of rigid-plastic structures under dynamic loading. - U Lepik *(Dept of Theor Mech, Tartu State Univ, EE2400 Tartu, Estonia)*. Struct Optim 6(1) 15-18 (Jun 1993).

The optimal design of rigid-plastic beams with piecewise constant thickness under impulsive or dynamic pressure loading is considered. Such dimensions of the structure for which the beam of constant volume attains a minimum of local or mean residual deflection are sought. The equations of motion are integrated (i) exactly and (ii) approximately by making use of the method of mode form solutions. The method of solution is applied also to reinforced beams. The stiffness of the beam can be increased if we provide it with additional supports. The locations of such supports must be chosen so as to minimize the global compliance of the beam. Optimality conditions for this problem are discussed.

11A474. Optimum design of a composite structure with manufacturing constraints. - DP Costin and BP Wang *(Dept of Mech Eng, Univ of Texas, PO Box 19023, Arlington TX 76019)*. Thin-Walled Struct 17(3) 185-202 (1993).

Composite designs produced by multidisciplinary optimization computer programs are often expensive or impossible to produce. In this paper, constraints needed in the optimization process to reduce manufacturing cost or reduce the need for post-optimization design changes are presented. The interactions of the manufacturing constraints with other constraints and the design variable scheme are investigated. Additionally, a design case study is performed, comparing wings designed with a conventional method and the method described in this paper. The designs were built and tested to verify modeling assumptions and the effectiveness of the manufacturing constraints.

11A475. Structural modeling and sensitivity analysis of shape optimization. - Y Gu and G Cheng *(Res Inst of Eng Mech, Dalian Univ of Tech, Dalian 116024, Peoples Rep of China)*. Struct Optim 6(1) 29-37 (Jun 1993).

It is presented in this paper that the structural modeling of shape optimization is composed of, in general cases, four distinct processes on geometry, design, analysis, and perturbation models. The relationships between these models are discussed. An integrated modeling approach based on geometric shape parameterization and automatic mesh generation is proposed. In cooperation with this modeling approach, the semi-analytic sensitivity analysis has been effectively employed. These techniques join shape optimization with FEM and CAD packages and apply it versatilely to optimum designs of general structures. The implementation and applications of the integrated modeling approach and semi-analytic sensitivity analysis to shape optimization of structures with coupling of stress and temperature fields are illustrated.

11A476. Crack initiation, propagation and arrest criteria for steel structure safety assessment. - T Varga *(Inst for Testing and Res in Mat Tech, Tech Univ, Vienna, Austria)*. Struct Safety 12(2) 93-98 (Jun 1993).

Linear Elastic Fracture Mechanics constitutes a numerical correlation between the acting tensile stress, the defect size and the fracture toughness. Usually initiation of material separation is considered to be the critical conditon. This, however, holds only for those cases, in which the weakest microstructural area can be located and tested. If this is not the case, a crack will be initiated somewhere else and the fact that it will grow from there onwards has to be considered. Crack propagation is possible in ductile or in cleavage manner. If ductile propagation is present, an R-curve approach may be adequate to be applied. However, if cleavage is triggered, timely arrest of the running crack becomes the only possibility to prevent the separation of the piece.

11A477. Generalized safety factor and reliability index in a multiaxial state of static stress. - J Kolenda *(Poland)*. Marine Tech Trans 3 111-118 (1992).

The problem of strength calculations in design of engineering components subjected to multiaxial static stress is considered. On the basis of the distortion-energy theory the formula for calculation of the generalized safety factor for aniostropic materials is derived. The dimensionless safety margins is defined, which is a function of safety factor. This permits calculations to be made of the failure probability when the stress components are random variables. Under assumption that the stress components are normally distributed and statistically independent the reliability index is determined.

11A478. Safety factor and reliability index in a general state of cyclic stress. - J Kolenda *(Poland)*. Marine Tech Trans 3 119-125 (1992).

Fatigue strength of constructional steels under multiaxial cyclic stress is considered. It is assumed that the stress components are synchronous and in-phase. The known result of fatigue tests at combined bending and torsion that the fatigue limits are correlated best by the distortion-energy theory is taken into account. Under assumption that this theory is applicable in a 3D state of cyclic stress, the generalized factor of safety and the reliability index at random fluctuations of amplitudes of the stress components are determined.

11A479. Solder joint reliability of surface mount connectors. - J Lau, T Marcotte, J Severine, A Lee, S Erasmus, T Baker, J Moldaschel, M Sporer, G Burward-Hoy *(Hewlett-Packard, Palo Alto CA 94304)*. J Electron Packaging 115(2) 180-188 (Jun 1993).

The solder joint reliability of five different surface mount connectors has been studied by eleven different experimental methods. A set of test methods and specifications for determining the reliability of the solder joints of surface mount connectors has been recommended.

282H. CONCRETE (REINFORCED)

11A480. Pullout tests of epoxy-coated reinforcement in concrete. - AR Cusens *(Dept of Civil Eng, Univ of Leeds, Leeds LS2 9JT, UK)* and Z Yu *(British Rail Res, PO Box 2, Derby DE24 8YB, UK)*. Cement & Concrete Composites 14(4) 269-276 (1992).

The bond strength and slip of epoxy-coated reinforcing bars in concrete have been evaluated by carrying out single pullout and double pullout tests. In extended single pullout tests, slip measurements were made while tensile force was applied to reinforcing bars embedded in concrete. In double pullout tests, 20 cycles of load were applied at levels of steel stress between zero and 0.5 times characteristic steel strength. Strains were measured by electrical resistance strain gauges glued inside the bars. Both epoxy-coated and uncoated bars were used in the investigation, to obtain comparative results. The strain gradient along the bar was found to be less for the coated reinforcement. In general, the epoxy coating was found to increase slip in bond and thereby reduce the bond performance of coated bars.

11A481. Ultimate moment capacity of ferrocement reinforced with weldmesh. - G Singh and GJ Xiong *(Dept of Civil Eng, Univ of Leeds, Leeds LS2 9JT, UK)*. Cement & Concrete Composites 14(4) 257-267 (1992).

An improved qualitative mechanical model which is thought to reflect more realistically the behavior of ferrocement in flexure is presented. In light of this model, three types of existing typical quantitative models of ultimate moment capacity based on yield strength of wire, nonlinear stress-strain function for cold-worked wire and ultimate wire strength have been evaluated. For singly weldmesh reinforced ferrocement the model based on ultimate wire strength is found to be simpler, more reliable and more economical than the other two types of models. For uniformly reinforced ferrocement a new model based on yield strength proposed by the authors appears to be more reliable and economical, and simpler than other models based on yield wire strength. A simpler and more economical model based on ultimate wire strength for uniformly weldmesh reinforced ferrocement is also put forward by the authors. This model shows a closer agreement with test results than the existing models based on yield wire strength or nonlinear stress-strain function of cold-worked wire.

282M. THERMAL LOADING

11A482. Analytical solutions of stresses in a cylindrical plate due to polynomial radial temperature distributions. - FFH Wu *(IBM TP, E Fishkill, Hopewell Junction NY)*. J Electron Packaging 115(2) 214-218 (Jun 1993).

Thermal stress is a significant contributor to a component's failure during manufacturing processes. In the electronic industry, for example, it is very common that components experience an extensive number of nonuniform, local heating cycles throughout its lifetime. In order to promote reliability, components are put through burn-in which creates a very nonuniform temperature distribution. In order to reduce cost, reworkability is considered to be a necessary option for the manufacturing processes to achieve high yield; these rework processes usually require localized heating. In addition, due to certain functionality requirements, materials with different coefficients of thermal expansion are cast together. The thermal mismatch caused by nonuniform temperature and/or different coefficients of thermal expansion will create thermal stress which could result in the cracking of the components. The fracture often initiates on the interface between the different materials or at the free edge of the surface. To make the problems mathematically tractable, the problems here are simplified as linear thermo-elastic and axisymmetric. It is concluded that the displacement distribution is one order higher than the temperature distribution if the temperature is a polynomial function of the radial distance from the center of a disk.

11A483. Effects of inclined free edges on the thermal stresses in a layered beam. - Wan-Lee Yin *(Georgia Tech)*. J Electron Packaging 115(2) 208-213 (Jun 1993).

A stress-function-based variational method is used to determine the thermal stresses in a layered beam with inclined free edges at the two ends. The stress functions are expressed in terms of oblique Cartesian coordinates, and polynomial expansions of the stress functions with respect to the thickness coordinate are used to obtain approximate solutions. Severe interlaminar stresses act across end segments of the layer interfaces. Local concentration of such stresses may be significantly affected by the inclination angle of the end planes. Variational solutions for a two-layer beam show generally beneficial effects of free-edge inclination in dispersing the concentration of interlaminar stresses. The significance of these effects is generally not indicated by the power of the stress singularity as compared from an elasticity analysis of a bimaterial wedge.

11A484. Error estimate and step size control method for nonlinear solution techniques. - MM Abdel-Ghaffar, DW White, Wai-Fah Chen *(Dept of Struct Eng, Sch of Civil Eng, Purdue)*. Finite Elements Anal Des 13(2-3) 137-148 (Jun 1993).

The condition number of the tangent stiffness matrix is shown to reflect the error encountered in the solution of nonlinear structural systems. Due to the linearization process in the incremental solution, two sources of error exist: (1) the error associated with the solution of the linearized set of equations; and (2) the error associated with the unbalanced force residual. While the condition number itself reflects the first error, its change from step to step represents the second error. Being an expensive quantity to compute, only an estimate of the condition number that is based on the L_1-norm of the tangent stiffness matrix has been effectively used in guiding the solution algorithm in adjusting the step size according to the degree of nonlinearity of the system. It is also used to identify the stable from the unstable paths of the response curve. Several examples are solved to show the applicability of the proposed step size control with different solution techniques.

282Z. EXPERIMENTAL TECHNIQUES

11A485. Development of a flexible, multiple-configuration structural test facility. - RA Shenoi, PJCL Read, CL Walters, SCM Thelu *(Dept of Ship Sci, Univ of Southampton, Southampton SO9 5NH, UK)*. Int J Fatigue 15(4) 317-323 (Jul 1993).

This paper deals with the development of a novel facility for testing relatively large structural specimens. It outlines the design process adopted in arriving at the final specification for the structural framework to hold the test specimens, the hydraulic power-pack with associated valves and pipework, and the data acquisition and control system based around a microcomputer. A brief mention is also made of the static and cyclic fatigue tests conducted to verify the workings of the facility.

11A486. Limit loads of framed structures and arches using the gloss r-node method. - CPD Fernando and R Seshadri *(Indust Syst Eng, Univ of Regina, Regina, SK, S4S 0A2, Canada)*. Trans Can Soc Mech Eng 17(2) 197-214 (1993).

An approximate method for determining limit loads of mechanical components and structures on the basis of two linear elastic FE analyses is described. The load-control nature of the redistribution nodes (r-nodes) leads to considerable simplifications. The combined r-node equivalent stress, which can be obtained by invoking an appropriate multibar mode, can be identified with the reference stress. The method is applied to beam, framed and arched structures, and the limit load estimates obtained are reasonably accurate.

11A487. Fundamental of dynamical analysis of the blast-resistant underground structures. - Yu-xiang Zhao, Xi-tai Song, Er-xuan Qian *(Luoyang Inst of Hydraul Eng, Luoyang, China)*. Appl Math Mech 14(5) 407-415 (May 1993).

In this paper, the generalized variational principle of dynamic analysis for the blast-resistant underground structures is established, and the corresponding generalized functionals of elastoplastic analysis for underground structures is derived, and the generalized variational principle of nonconservative system is given, thus the fundamental of dynamical analysis for underground structures to resist blast is proposed. Finally, for the underground cylindrical structure to resist blast, dynamical calculations are made, and compared with the test results.

11A488. Numerical calculations and structural analysis of a 150 m high cooling tower for various types of wind load. - J Dulinska and A Flaga *(Inst of Struct Mech, Krakow Univ of Tech, Poland)*. Arch Civil Eng 38(3) 205-222 (1992).

The paper presents quasistatic, deterministic approach to the wind load acting on a hyperboloidal cooling tower. Static component of the wind load is assumed with the allowance for the global gust wind load coefficient. Taking into account various aspects of geometry, structure and location of the cooling tower, various pressures of quasistatic wind loads were obtained. The investigations are limited to three cases of exposure factor depending on the types of the nearest buildings and the category of terrain roughness. Two cases of external wind pressure distribution along the circumference are assumed, one for a cooling tower with and the other without meridional ribs. Moreover, two values of internal wind pressure factor are adopted and two combinations of dead load and wind load are analysed concerning the characteristic loads and the design loads. Numerical calculations for wind and dead load acting on a cooling tower with the height H = 150 m were performed according to the author's program.

11A489. Static analysis of the influence of thermal load on hyperboloidal reinforced concrete cooling tower. - J Dulinska and A Flaga *(Inst of Struct Mech, Cracow Univ of Tech, Krakow, Poland)*. Arch Civil Eng 38(4) 301-322 (1992).

Thermal influences could be significant in the shell structures design. Polish Standards do not give guidelines to static calculations of hyperboloidal cooling towers under thermal load. The paper presents a short analysis of Polish Standard recommendations for adopting values of thermal load with regard to peculiar character of cooling tower structures. Obtained distributions of winter and summer temperatures were compared with distributions calculated or measured by other authors. The investigations were limited to two cases. 1. Working cooling tower in summer, nonsymmetric distribution of temperature along the circumference of the shell. 2. Working cooling tower in winter, axisymmetric distribution of temperature along the circumference of the shell. Numerical calculations of thermal load stresses for a representative cooling tower H = 150 m were performed according to the author's own program.

11A490. Affecting reliability of rail traffic vehicles in the phase of design and manufacturing. - J Marciniak *(Centrum Naukowo-Tech, Kolejnictwa ul Chlopickiego 50, 04-275 Warsaw, Poland)*. Zagadnienia Eksploatacji Maszyn 26(4) 487-498 (1991).

Demands for rail traffic vehicles in the range reliability and utility properties are presented. Different variants of operational properties of a vehicle (its strength) X_r and its loads X_0 are considered. Practical problems concerning reliability possible to solve in the design, were underlined. Methods of rail vehicles technical stand up prognosis were presented - the gradient method and the method of generalized parameter. Methods of increase of rail traffic vehicles reliability in the design phase were also considered with a vehicle service technological demands taken on account. In the final part of work conclusions are presented which should be fulfilled, to obtain high level of reliability of object in the phase of design, manufacture and exploitation.

11A491. Aspects of interation between the hull and hatch covers of containerships. - AN Rodionov *(Tech Univ Hamburg-Harburg, Arbeitsbereigh Schiffstechnische Konstruktionen und Berechnungen, Lauenbruch Ost 1, 3100 HH90, Germany)*. Ship Tech Res 40(2) 59-70 (May 1993).

Damages caused by the interaction of hatch covers and hull in open-deck ships during torsional deformations are analyzed. Special emphasis is placed on the stopper system. Its traditional function is to keep covers with cargo on top from slipping during the ship's motion, and simultaneously to eliminate forces on covers due to hull deformations. However, stoppers may be used also to include the hatch covers, having large rigidity in their plane, into the hull rigidity and strength. Different versions of stopper systems are proposed, and the corresponding clearances are investigated. A special method of calculating joint deformations of hulls and covers is elaborated. Results are compared with experimental data. Some advantages of involving the hatch covers into the hull torsional resistance are shown.

11A492. Applied mechanics of a lunar base. - H Benaroya *(Lab for Extraterrestrial Struct Res, Dept of Mech and Aerospace Eng, Rutgers Univ, New Brunswick NJ)*. Appl Mech Rev 46(6) 265-357 (Jun 1993).

This special issue of *Applied Mechanics Reviews* was created as a testimony, by the authors, to the importance of a continued presence in Space by representatives of this Nation. We have tried to examine some, but obviously not all, issues which are pertinent to the establishment of a permanent manned facility on the Moon. Hopefully, the interested reader will come away with enough information to permit a further, more advanced study. We have endeavored to provide broad perspectives rather than too narrow a focus. Structural concepts for the Moon are in flux. The first generation of bases will most likely be brought almost intact from Earth orbit, ready for habitation. More advanced bases, like those envisioned here by NASA artists, built of indigenous materials, will require many decades of research and development, analysis, design, and construction.

11A493. Applied mechanics of lunar exploration and development. - MB Duke *(NASA, Johnson Space Center, Houston TX 77058)* and H Benaroya *(Dept of Mech and Aerospace Eng, Rutgers Univ, Piscataway NJ 08855)*. Appl Mech Rev 46(6) 272-277 (Jun 1993).

An overview of current concepts for lunar outposts is provided, with emphasis on identifying design issues that are also prospective research problems in applied mechanics. The authors believe that the conjugation of new applications and the unique features of the lunar environment will provide many interesting problems whose solution will provide fundamental insights into problems in applied mechanics.

11A494. Engineering elements for transportation on the lunar surface. - BE Wallace and NS Rao *(Boeing Defense and Space Group, Huntsville AL)*. Appl Mech Rev 46(6) 301-312 (Jun 1993).

Major aspects of engineering planetary transportation vehicles are discussed. Emphasis is placed on the mechanics of mobility and mobility system design, including considerations for designing the wheels, drive, steering, and suspension systems. Because mobility performance of any vehicle is extremely sensitive to environmental (eg, soil properties) and design (eg, vehicle weight) parameters, the mechanics of mobility are addressed by parametric application as well as empirical (derived relationships and equations) form. Finally, and more philosophical in nature, discussions of the key considerations for designing and analyzing each of the components of mobility (locomotion, steering, suspension, and stability) are also included. These discussions include some general guidelines to assist in determining the values of key design parameters.

11A495. Indigenous materials for lunar construction. - JA Happel *(JR Harris, 1580 Lincoln, Denver CO 80203)*. Appl Mech Rev 46(6) 313-325 (Jun 1993).

An important step in the exploration and colonization of the solar system is to build a permanently inhabited base on the Moon. The lunar environment is stark and hostile to unprotected humans. Structures are needed that protect the inhabitants from vacuum, radiation, extreme temperatures, dust, and meteoroids. Transporting the necessary construction materials from Earth is extremely expensive. Fortunately, lunar structures can be built utilizing indigenous materials. The locally available materials include lunar regolith, cast regolith, glass and glass composites, metals and concrete. Their mechanical properties are summarized and their suitability for lunar construction is evaluated. The most promising materials are cast regolith and lunar glass. Several lunar bases concepts utilizing indigenous materials are described and evaluated. Precast modules and large cast in place structures can be fabricated from lunar concrete. Large cylindrical modules, curved and flat panels and arches cast from lunar regolith are also feasible. A tied arch system is considered very promising because of its structural efficiency.

11A496. Lunar environment. - LR Utreja *(Dynacs Eng, Huntsville AL 35806)*. Appl Mech Rev 46(6) 278-284 (Jun 1993).

As one of the key elements of the Space Exploration Initiative, the Moon provides a waypoint for scientific exploration and travel to Mars. The Moon's stable ground in the vacuum of space is an ideal platform for astronomical observatories. Conditions on the Moon are similar to what human beings will face on other planets, so it is a natural test bed to prepare for a manned mission to Mars. A knowledge of the lunar environment is therefore important before undertaking any missions of construction, operations, and habitation on the lunar surface. The purpose of this paper is to review and assemble information on the lunar environment so that engineers and scientists can refer to this as they begin lunar-based engineering studies. The lunar environment is categorized into three major elements: lunar physical constants, lunar atmosphere, and lunar surface. The description of lunar size, orientation, period of rotation, and lunar month are all treated as part of lunar physical constants. Lunar atmosphere includes gas composition, pressure and density, solar flux and radiation, micrometeorite flux, and lunar dust. The geophysical and geochemical properties are provided as lunar surface characteristics. The geophysical properties include terrain characteristics, topography and surface tremors; soil and rock characteristics; mechanical, thermal, electrical, magnetic, and optical properties. The chemical composition of the regolith and rocks are described in geochemical properties.

11A497. Mechanics of materials in lunar base design. - A Smith *(Eng and Mat Div, Eng Res Lab, US Army Construct, Champaign IL 61826-9005)*. Appl Mech Rev 46(6) 268-271 (Jun 1993).

The construction of a lunar base has been thought about for almost five decades. The earliest concepts dealt with size and shape concepts rather than actual design of structures and equipment. As the exploration of space has received emphasis in more recent times, the need to consider the factors of design and design approaches have received more attention. It still is not possible to completely rationalize the design of a habitat, for example, but we are now very aware of the need to include the fracture and fatigue properties of the materials of which the hardware of a lunar infrastructure is constructed. It is reasonably certain that the same techniques used for terrestrial designs can be used for lunar bases provided the space environment is taken into account. The extensive amount of research on fracture and fatigue that has been and is being conducted, along with the ease and speed of computation of their effects on alternative design features will be invaluable in providing a highly reliable, safe lunar base.

11A498. Properties and mechanics of the lunar regolith. - SW Johnson *(BDM Int, 1801 Randolph Rd, Albuquerque NM 87106)* and Koon Meng Chua *(Dept of Civil Eng, Univ of New Mexico, Albuquerque NM 87131)*. Appl Mech Rev 46(6) 285-300 (Jun 1993).

Knowledge of the lunar regolith is essential to success in lunar missions whether crewed or robotic. The regolith is the loose material overlying more intact strata on the Moon. It varies in thickness from several meters on the maria or lunar seas to many meters on the highlands of the Moon. The regolith is the material humans walked and drove on from 1969 to 1972. In the future, people will use it for radiation protection and as a resource for recovery of oxygen, silicon, iron, aluminum, and titanium. Implanted in the regolith by the solar wind are recoverable amounts of volatiles such as hydrogen and helium. Increasing our knowledge of the mechanical properties of the regolith will enable constructors of the 21st Century to build habitats, do mining, establish manufacturing, and erect telescopes on the Moon. We already know much of the regolith from robotic and astronaut missions to the Moon. There is much more to be learned.

11A499. Structural concepts for lunar-based astronomy. - Koon Meng Chua *(Dept of Civil Eng, Univ of New Mexico, Albuquerque NM 87131)*, SW Johnson *(Adv Basing Syst, BDM Int, 1801 Randolph Rd SE, Albuquerque NM 87106)*, ME Nein *(Program Dev, NASA Marshall Space Flight Center, Huntsville AL 35812)*. Appl Mech Rev 46(6) 336-357 (Jun 1993).

Lunar-based astronomy requires structures that provide the required stiffness, strength, and dimensional stability in the challenging lunar vacuum, thermal, radiation, micrometeorite, secondary ejecta, and dust environments. Materials used in the structures must be durable to provide extended service life. They must not outgas and thereby interfere with optics. Structures must function as part of an integrated system involving detectors, metrology, and optics. The thermal environment of the lunar surface is particularly taxing because the long-duration exposures to extremes of temperature. Designers must cope with transient thermal gradients associated with passing from sunlight to darkness and back to sunlight. Also, the shape of mirrors and other components at night-time low temperatures may differ from shape at day-time high temperatures because of material properties varying significantly over the range from about 70 K to nearly 400 K. Materials for structural components include several types of glass, metals and their alloys (eg, aluminum, beryllium, and titanium), graphite epoxy and the associated class of materials, and metal matrix composites (eg, graphite magnesium and graphite aluminum). Examples of material properties are presented. Structural design concepts for several possible observatories are presented. Structural configurations will be partially determined by the need to reduce direct human involvement in the construction process. Concepts discussed include the 16-meter optical-ultraviolet telescope and a small telescope with 0.8-m aperture intended to be landed on the Moon by a robotic spacecraft. For lunar-based astronomy, structures must rest on the lunar regolith with loads transferred to the regolith through a foundation. The overall response of the structure is dependent on the interaction of the foundation and the regolith.

11A500. Tensile-integrity structures for the moon. - H Benaroya *(Dept of Mech and Aerospace Eng, Rutgers Univ, PO Box 909, Piscataway NJ 08855)*. Appl Mech Rev 46(6) 326-335 (Jun 1993).

A brief review of lunar base structural concepts is presented followed by a discussion of tensile structural concepts. Specifically, tensile integrity (tensegrity) structures are suggested for study for possible use on the lunar surface due to their efficiencies and advantages. Such application could conceivably be for second generation structures. These structures, like pneumatic and truss structures, are self-sustaining and can be designed not to require any significant foundation structure. One exciting advantage of the class of structure discussed here is the possiblity of designing deployable versions.

290. Structures (containment)

11A501. Integral hydro-bulge forming of single and multi-layered spherical pressure vessels. - J Hashemi, J Rasty, S Li *(Dept of Mech Eng, Texas Tech Univ, Lubbock TX 79409)*, AA Tseng *(Dept of Mech Eng and Mech, Drexel Univ, Philadelphia PA 19104)*. J Pressure Vessel Tech 115(3) 249-255 (Aug 1993).

The recently developed integral hydro-bulge forming (IHBF) process was utilized in the manufacturing of single and multi-layered spherical pressure and storage vessels. Single-layered spherical vessels of 1.6-mm thickness and diameters of 316.5, 634.1, and 953.2 mm were manufactured. As an alternative means of manufacturing thick-walled spherical pressure vessels, the IHBF procedure was modified and used in forming double-layered composite pressure vessels with an effective thickness of 15 mm. The results showed that the modified IHBF process may successfully be applied in the manufacturing of multi-layered spherical vessels of various thicknesses and diameters. In this paper, the conventional and modified IHBF procedure will be outlined and the experimental results and analysis will be presented. Finally areas where further work is needed are identified.

11A502. Design procedure for flexibility factors of 90-deg curved pipe having various tangent lengths. - DJ Nordham *(Machinery R&D Directorate, Carderock Div, Naval Surface Warfare Center, Annapolis MD 21402-5067)* and LM Kaldor *(Arnold MD 21012)*. J Pressure Vessel Tech 115(3) 319-324 (Aug 1993).

A simple design procedure, based on 175 FE analyses, was derived to predict the flexibility factor due to an in-plane or out-of-plane moment for a 90° curved pipe with end constraints composed of tangents of any length terminated by rigid flanges and no internal pressure loads. The results of this design procedure were then compared to flexibility factors obtained from additional FE analyses and experimental work. Flexibility factors calculated using the design equations in the Power Piping Code were also compared to all FE and experimental work. It was found that this design procedure more accurately predicts the flexibility factors than the Power Piping Code.

11A503. Design procedure for stress intensification factors of 90-deg curved pipe having various tangent lengths. - DJ Nordham *(Machinery R&D Directorate, Carderock Div, Naval Surface Warfare Center, Annapolis MD 21402-5067)* and LM Kaldor *(Arnold MD 21012)*. J Pressure Vessel Tech 115(3) 313-318 (Aug 1993).

A simple design procedure, based on 114 FE analyses, was derived to predict the stress intensification factor for 90-deg curved pipe with end constraints composed of tangents of any length terminated by rigid flanges and no internal pressure loads. The results of this design procedure were then compared to stress intensification factors obtained from additional FE analyses and experimental work. Stress intensification factors calculated using the design equations in the Power Piping Code were also compared to all the FE and experimental work. It was found that this design procedure more accurately predicts the stress intensification factors than the Power Piping Code.

11A504. Elastic analysis of a circular flange joint subjected to axial force. - J Cao and AJ Bell *(Dept of Civil and Struct Eng, UMIST, PO Box 88, Manchester M60 1QD, UK)*. Int J Pressure Vessels Piping 55(3) 435-449 (1993).

In this paper the general use of a thin circular flange joint is analyzed and an exact elastic solution is derived. Formulae which enable the maximum stresses in the joint to be calculated easily are presented. Results obtained using the formulae are compared with those obtained from FE analyses and with results obtained using other common methods in regular use. The formulae presented are shown to be reliable, accurate and convenient for use in the design of various circular flange joints.

11A505. Behavior of GRP smooth pipe bends with tangent pipes under flexure or pressure loads: A comparison of analyses by conventional and FE techniques. - DR Hose *(Dept of Aeronaut and Mech Eng, Univ of Salford, UK)* and R Kitching *(Dept of Mech Eng, UMIST, PO Box 88 Sackville St, Manchester M60 1QD, UK)*. Int J Mech Sci 35(7) 549-575 (Jul 1993).

A detailed FE analysis has been carried out for a smooth pipe bend with straight pipe attachments made from glass reinforced polyester. The shell was modelled as a composite laminate made up of discrete isotropic laminae. The inside pipe diameter was 250 mm, the thickness was 9.52 mm and the bend radius was 250 mm. For in-plane flexural loading the deformation patterns were studied, especially in the vicinity of the smooth bend-straight pipe discontinuity. Warping of sections is reported, together with its influence on pipe bend flexibility for various bend angles. Comparisons of flexibilities and strain distributions are made with those calculated by making the frequently used assumption that the flattening sections along the entire pipe bend is uniform. The discontinuity effects for out-of-plane flexural and internal pressure loadings, treated separately, are also considered.

11A506. Pressure vessel manufacutring: Mechanical analysis of gas bottles with convex end-plates. - M Nicolich *(Istituto di Fisica Tecnica e di Tecnologie Indust, Univ di Udine, viale Ungheria 43, 33100 Udine, Italy)*. Int J Pressure Vessels Piping 55(3) 423-433 (1993).

The three-centre geometry design for the bottom end-plates of gas bottle cylinders is analyzed using an approximate method involving FE techniques. Shell elements are adopted to obtain the equivalent stress distribution along a generatrix of the bottle. The maximum stress profile in the bottom zone is plotted versus normalized geometrical parameters. The area which bounds acceptable solutions according to basic Standards Codes is outlined in the diagrams. Experimental measurements by means of electrical resistance strain gauges are compared with the numerical forecasts. The good correlation which was obtained confirms the validity of the proposed approach in dealing with industrial applications.

11A507. Stress analysis of a cylinder with a partition plate subjected to internal pressure. - Degui Fan *(Equipment Dept, Chengdu Chem Eng Corp of China, Chengdu, Peoples Rep of China)*. J Pressure Vessel Tech 115(3) 330-333 (Aug 1993).

This paper presents a method to calculate stresses of a cylinder with a partition plate, whose equations for determining bending stresses of a cylinder and its partition plate are different (less conservative) from those in ASME Boiler and Pressure Vessel Code, Section VIII, Division 1. The paper contains: 1) the derivation of equations for calculating bending stresses of a cylinder and its partition plate; 2) the comparisons between the method in ASME Code VIII-I and the author's method, and commentary on the equations for determining bending stresses of a cylinder and its partition plate in ASME Code VIII-I. Also, the recommendation to modify the equations for determining bending stresses of a cylinder and its partition plate in ASME Code VIII-I has been put forward.

11A508. Behavior of a granular medium in a silo. Model tests in a plane silo with parallel walls. Part I. - J Tejchman *(Fac of Civil Eng, Gdansk Univ of Tech, Poland)*. Arch Civil Eng 38(4) 375-394 (1992).

The paper deals with some phenomena occurring during flow of granular media out of a silo (shear zones formation, increase of lateral pressure on the silo wall, scale effect). Quasi-static problems during the onset of a mass flow in a plane strain model silo with parallel walls and a slowly moveable bottom are investigated. Experiments were carried out for different wall roughness (smooth, rough, very rough), sand density (from dense to loose) and silo width. The displacement of the upper surface of a silo fill were measured. The obtained results were compared with some silo formulae based on a slice equation by Janssen. It turns out that many available silo formulae are not realistic because they do not consider the real deformations in a silo fill during silo emptying. It is very important to consider the formation of wall shear zones with a definite thickness and the realistic boundary conditions along silo walls. That can be achieved with the FEM based on the elastoplastic Cosserat approach proposed by Muhlhaus in which grain rotations and couple stresses are considered using the mean grain diameter as a characteristic length.

11A509. Behavior of a granular medium in a silo. Model tests in a plane silo with convergent walls. Part II. - J Tejchman *(Fac of Civil Eng, Gdansk Univ of Tech, Poland)*. Arch Civil Eng 38(4) 395-414 (1992).

The paper deals with model tests carried out in a plane strain silo with convergent walls and a slowly moveable bottom. Quasi-static problems during the onset of a mass flow are investigated. Experiments are made for different wall roughness (smooth, rough, very rough) sand density (from dense to loose) and wall inclination. The resultant forces on the wall and on the bottom plate, the bottom displacements and the displacements of the upper surface of a silo fill are measured. The profiles of a moving sand are determined with the aid of horizontal colored sand layers. The experimental results are compared with the silo formulae by Drescher (based on a slice method), by Enstad (assuming the circular distribution of major principal stresses) and to the German Silo Code. The obtained test results show that an increase of wall stresses after bottom displacement is caused mainly by the deformations inside the moving material due to the wall inclination. For stress calculations it is important to take into account the formation of shear zones in the silo fill.

292. Friction and wear

292A. GENERAL THEORY

11A510. Quantitative investigation of displacement accommodations in third-body contact. - Y Sun *(CNRS CPPM, IN2P3, 163 Ave Luminy, 13228 Marseilles Cedex 9, France)*, Y Berthier, B Fantino, M Godet *(INSA Lab Mec Contacts, CNRS URA 856, Bat 113 20 Ave Albert Einstein, 69621 Villeurbanne Cedex, France)*. Wear 165(2) 123-131 (1 Jun 1993).

Recently, the "velocity accommodation" concept was introduced in tribology. In third-body contacts, velocity accommodation can occur in five sites and according to four modes, giving rise to 20 possible combinations, ie, 20 velocity accommodation mechanisms. The present paper addresses the role of third and first bodies in elastic and/or plastic deformations in velocity accommodation. For this, a simplified model is first proposed to represent third-body contacts separated by wear debris or solid lubricants. Then, by using the FEM, the relative movement between first bodies in contact under different types of loading is simulated and the deformation of the model as well as the stress and strain field in the third body is determined numerically. Results quantify the role of the third and first bodies in either elastic or plastic deformation. When only relative tangential displacement is imposed, a simple analytical formula based upon a model of two compliances in series is suggested in order to estimate the displacement accommodation of the third and first bodies.

292B. FRICTION

11A511. Elastic hysteresis in rolling elements which are loaded with normal force. - W Caban *(Politech Lodzka, Inst Maszyn, ul Stefanowskiego 1-15, 90-924 Lodz, Poland)*. Zagadnienia Eksploatacji Maszyn 26(4) 405-416 (1991).

Hysteresis losses in rolling friction have been written in this article. Author presents method of valuation rolling friction factor which depends of hysteresis losses. This method permits to use the characteristic of logarithmic amplitude decrement for construction materials. In this way we should get more true results, also that method helps to choose a material of rolling elements.

11A512. Mechanical and tribological behavior of Cu-Nb *in situ* composites. - P Liu *(Sch of Tech, E Illinois Univ, Charleston IL 61920)*, S Bahadur *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*, JD Verhoeven *(Ames Lab USDOE, Dept of Mat Sci and Eng, Iowa State Univ, Ames IA 50011)*. Wear 166(2) 133-139 (1 Jul 1993).

The mechanical and tribological properties of Cu-Nb *in situ* composites were studied. The composites were prepared by consumable arc melting of Cn and Nb electrodes, by casting, and by successive deformation of the cast ingot. Dry sliding friction and wear tests were performed in a pin-on-disk set-up, with the composite pin rubbing under atmospheric conditions against a hardened tool steel disk surface. The effect of Nb proportion on the tribological behavior of Cu-Nb composites was studied. It was found that the coefficient of friction decreased with increasing Nb proportion in the composite and that Cu-20vol%Nb composite had the best wear resistance. The effect of prior deformation strain on the coefficient of friction and wear of Cu-15vol%Nb composites was also investigated. The micromechanisms of wear were studied by scanning electron microscopy. It was concluded that cracking in the severely work hardened regions led to the generation of wear particles.

11A513. Wear and friction properties of prosthetic joint materials evaluated on a reciprocating pin-on-flat apparatus. - V Saikko *(Lab of Machine Des, Helsinki Univ of Tech, SF-02150 Espoo, Finland)*. Wear 166(2) 169-178 (1 Jul 1993).

A three-station reciprocating pin-on-flat apparatus was constructed for tribological studies of materials for total replacement joints. Flat-ended cylindrical ultra-high molecular weight polyethylene (UHMWPE) pins were worn against Co-Cr-Mo, Al_2O_3, ZrO_2 and Si_3N_4 counterfaces in distilled, de-ionized water. The temperature of the test environment was 37 ± 1 °C. The nominal contact pressure was 4.8 MPa, sliding distance per cycle 50 mm, frequency 1 Hz and test length 7×10^6 cycles with ZrO_2 and 5×10^6 cycles with all other counterfaces. The wear of the pins were measured gravimetrically at intervals of 5×10^5 cycles. The frictional forces were recorded continuously. The average wear factors of UHMWPE against Co-Cr-Mo, Al_2O_3, ZrO_2 and Si_3N_4 were of the order of 10^{-7}, 10^{-9}, 10^{-9} and 10^{-8} mm^3 N^{-1} m^{-1}, and the average coefficients of static friction were 0.10, 0.11, 0.13 and 0.13, respectively. The results indicate that Al_2O_3 and ZrO_2 are distinctly superior to Co-Cr-Mo as counterfaces for UHMWPE in prosthetic joints. The difference between the wear of UHMWPE against Co-Cr-Mo and that against Al_2O_3 is consistent with clinical observations. The apparatus will be a useful tool in the screening of new materials, surface treatments with coatings for prosthetic joints.

292D. WEAR (UNINTENTIONAL)

11A514. Abrasion and abrasion-corrosion properties of a 9% chromium steel. - GE Gatzanis and A Ball *(Dept of Mat Eng, Univ of Cape Town, Library Rd, Univ Private Bag, Rondesbosch 7700, S Africa)*. Wear 165(2) 213-220 (1 Jun 1993).

A 9Cr2Ni0.7Mo steel was assessed for its dry abrasions and abrasion-corrosion performance using a laboratory test which simulates the conditions experienced by rock conveyors in S African gold mines. The alloy is found to exhibit abrasion and abrasion-corrosion properties comparable with most and better than several higher chromium containing alloys designed for mining applications. The good dry abrasion performance of the alloy is attributed to the good combination of high hardness, strength and toughness imparted to the alloy by its duplex microstructure of lath martensite and thin film of interlath retained austenite. The good abrasion-corrosion results are in a product of the good dry abrasion performance coupled with the excellent corrosion properties in the simulated mine water. The favorable corrosion properties are linked to the effect of the Ni and Mo additions on suppressing pitting tendencies thereby imparting corrosion resistance equivalent to higher chromium containing steels. Experimental evidence however shows that the alloy is operating at the limit of its passivity for the 46 h corrosion period employed in the corrision-abrasion test. Exposure for periods much in excess of this figure will lead to breakdown and poor corrosion-abrasion performance relative to higher chromium containing steels. The production variables of prior cold working and plate thickness are found to exert negligible influence on dry abrasion and abrasion-corrosion properties.

11A515. Effect of head wear and tape shear on the head-tape interface. - C Lacey and FE Talke *(UCSD)*. Trib Trans 36(3) 387-392 (Jul 1993).

The effects of transverse shear deformation in the tape and wear on the head profile are incorporated into a numerical simulation of the longitudinal head-tape interface. These effects can cause a significant change of the head-tape interface behavior for geometries that experience head-tape contact. The numerical implementation is described and results are compared to experimental measurements of head-tape spacing.

11A516. Sliding-wear behavior of ceramic particle-reinforced high-speed steel obtained by powder metallurgy. - M Vardavoulias, C Jouanny-Tresy, M Jeandin *(Ecole Mines de Paris, Centre des Mat PM Fourt, BP 87, 91003 Evry Cedex, France)*. Wear 165(2) 141-149 (1 Jun 1993).

The wear behavior of sintered high-speed steel-type particulate composites depends significantly on microstructural parameters, such as those of the metallic matrix and primary carbides, but also on some additional parameters related to the powder metallurgy processing. Pin-on-disc results, coupled with scanning electron microscopy observation of the wear tracks and microstructure image analysis, indicated the prominent role of the added ceramic particles. More precisely, the size, the mechanical resistance and the cohesion with the metallic matrix of TiC, uncoated Al_2O_3, and TiN-coated Al_2O_3 particles, largely determine the wear behavior of such materials. In addition, the roles of the residual porosity and of the presence of copper as a solid lubricant are pronounced in this investigation.

11A517. Study of abrasive wear resistance of transformation toughened ceramics. - Dongfang Wang, Jian Li, Zhiyuan Mao *(Dept of Math Sci and Eng, Zhejiang Univ, 310027 Hangzhou, China)*. Wear 165(2) 159-167 (1 Jun 1993).

The decreasing abrasive wear rate of tetragonal zirconia polycrystal ceramic (TZP) with increasing load under experimental conditions is believed to be caused by the martensitic transformation of t-ZrO_2 to m-ZrO_2 in the abraded surface. The transformation toughened ceramics (TZP) appeared to give the best abrasive wear resistance among the ceramics studied in this experimental work. The surface failure of these ceramics was mainly due to the microfractural dropping and powder-type polishing scratches resulting from the brittle microfracturing part of the grain(s). Raising the fracture toughness wherever possible, in conjunction with a suitable hardness, will be beneficial in improving the abrasive wear resistance of ceramics.

11A518. Wear transition diagram for silicon nitride. - X Dong *(Dept of Mech Eng, Univ of Maryland, College Park MD 20742)* and S Jahanmir *(Ceramics Div, NIST)*. Wear 165(2) 169-180 (1 Jun 1993).

In the present study, unlubricated wear tests were conducted on a hot isostatically-pressed silicon nitride under various test conditions in self-mated sliding tests in air. Following the tests, scanning electron microscopy was used to elucidate the wear mechanisms and particularly to delineate the effects of load and temperature on wear. The results of the tests and observations were used to construct a wear transition diagram, with load and temperature as the two axes. This diagram is divided into five regions plus one transition zone. The controlling mechanism and tribological data, ie, friction coefficient and wear coefficient, in each region are unique. At low loads and relatively low temperatures, the tribological behavior is controlled by tribochemical reactions between silicon nitride surface and water vapor in the environment. In the temperate range 400-700°C at low loads, selective oxidation of WC inclusions controls the wear behavior. Formation of crystalline precipitates from the amorphous magnesium silicate grain boundary phase controls the wear process from 700 to 900°C at low loads. At higher temperatures, oxidation of silicon nitride dominates the wear process.

292E. CONTACT FATIGUE

11A519. Surface topography and fatigue life of rolling contact bearings. - RS Zhou *(Timken Co, Canton OH 44706-2798)*. Trib Trans 36(3) 329-320 (Jul 1993).

The contact stresses of bearings were analyzed by a micro-macrocontact model in which the macrocontact was elastic, and the microcontact was elastic-plastic. Subsurface stress maps were calculated for real contact surfaces, by including roughness, waviness, and profile. The predicted subsurface stress maps display the local stress levels for various elastohydrodynamic lubrication (EHL) film thicknesses and show why enhanced-finish bearings have longer lives than the standard-finish bearings. It is believed that the present approach provides an alternative to the empirical methods that are used for predicting life under thin-film EHL conditions.

292H. SURFACE EFFECTS, TOPOGRAPHY, COATINGS

11A520. Contribution of EXAFS-like techniques to the determination of local order. Application to tribology. - J Lopez, JC Le Bosse, G Hansali *(Lab Tribologie Dyn Syst CNRS URA 855, Ecole Natl Ing St Etienne, 58 rue Jean Parot, 42023 St Etienne, France)*, M Belin, JM Martin *(Lab Tribologie Dyn Syst CNRS URA 855, Ecole Centrale de Lyon, 36 ave Guy de Collongue BP 163, 69131 Ecully, France)*. Acta Phys Polonica A 83(5) 551-566 (May 1993).

The determination of local order of atomic scale becomes more and more fundamental for understanding superficial phenomena such as tribology and catalysis. Among a few techniques available in this field, we are only concerned with the EXAFS-like ones (EXAFS, SEXAFS, EXELFS, SEELFS, etc). The difficulties appearing all along the numerical treatment of such spectra are carefully analysed and a methodology is proposed in view to obtain reliable radial distribution functions. Some applications of these techniques are presented in two fields connected with tribology: friction induced amorphisation in high vacuum and characterization of interfacial solid bodies created during a wear process including an antiwear additive.

11A521. Determination of proper frequency bandwidth for 3D topography measurement using spectral analysis Part I. Isotropic surfaces. - TY Lin, L Blunt, KJ Stout *(Sch of Manuf and Mech Eng, Univ of Birmingham, Birmingham, Edgbaston B15 2TT, UK)*. Wear 166(2) 221-232 (1 Jul 1993).

Areal spectral analysis is applied to achieve proper frequency bandwidth for topography measurements from machined surfaces. The effect of aliasing on the spectrum of surface features due to a large sample spacing is evaluated. The characteristics of low-frequency components of a surface are also investigated. The low-frequency limit of measurement for obtaining the genuine features of a surface can be decided from the spectral analysis of low-frequency components of the surface. The guidelines for topography measurements are proposed for selecting an appropriate sampling bandwidth of surfaces with due consideration of limited computer memory. The guidelines developed are applied to study the general patterns of spectra from a range of isotropic engineering surfaces. An example is given to demonstrate the selection of a temporary sample spacing for a further measurement search for the low-frequency cut-off of a surface, which may be in turn used to determine the high-frequency limit with an estimate of aliasing influence. In spectral analysis, circular spectra and/or accumulation spectra have been shown to be suitable for the analysis of sample surfaces from isotropic machining processes.

11A522. Effects of real contact area and topographical features of wear surfaces on abrasive wear of metals. - T Hisakado, H Suda, H Ariyoshi, S Sakano *(Dept of Mech Eng, Fac of Eng, Gunma Univ, 1-5-1 Tenjincho Kiryu, Gunma 376, Japan)*. Wear 165(2) 181-191 (1 Jun 1993).

The aim of this study is to clarify various cross-sectional shapes and areas of wear grooves and ridges which are formed under multi-point contacts and to study the effect of the real contact area on the friction and wear properties in the two-body abrasive wear of metals. Two kinds of tests were performed: (1) the scratching test on an actual abrasive paper under two short sliding distances (less than 1 mm or 5mm), and (2) the friction and wear test under a long sliding distance (about 65 mm). The effects of the real contact area and surface topographical features of the wear surface of the pin on the friction and wear properties of abrasive wear are investigated systematically, and the friction and wear mechanisms are discussed. The following main results were obtained. (1) The mean area of the real contact point is affected by the existence of the embedded abrasive grains and the surface layer which is harder than the bulk material of the pin. (2) The mean cross-sectional area of the grooves on the worn surface of the pin, which is calculated from the profile curve measured perpendicular to the sliding direction, is a factor that has a direct effect upon the specific wear rate of a pin and that measured parallel to the sliding direction is the factor which affects the friction coefficient. (3) The specific wear rate for lead pins is approximately proportional to the real contact area for abrasive wear.

11T523. Experimental study of the parameters that determine take-off velocity and CSS performance of thin film disks. - S Suzuki, I Hayashi *(Asahi Glass America, Milpitas CA 95035)*, K Matsushita *(Asahi Glass, Yokohama 221, Japan)*. Trib Trans 36(3) 411-416 (Jul 1993).

11A524. Fast 2D-3D optical profilometer for wide range topographical measurement. - M Zahidi, M Assoul, J Mignot *(Lab Metrologie Interfaces Tech, Inst Univ Tech, 25009 Besancon, Cedex, France)*, B Bellaton *(Digital Surf SARL, Valparc Valentin, 29 route d'Epinal 25048, Besancon Cedex, France)*. Wear 165(2) 197-203 (1 Jun 1993).

An optical profilometer, based on a triangulation principle, has been designed to measure the topography of surfaces. It uses a laser diode source (λ = 0.788 μm) and position sensing detectors. Response is obtained with a minimum of error due to a double detection system. Sensitivity is about ±3 μm for a vertical range of 1 mm. Vertical range can attain 5 mm, and more than 10 mm with a wide range numerical arrangement. Non-contact with the surface means a scanning speed of about 4 mm s^{-1}, and a 512 × 512 matrix (with a 12 bit definition) can be created in 9 min.

11A525. Function: Hardness-load as surface layer characteristics. - F Rudol *(Politechnika Swietkrzyska, Zaklad Odlewnictwa, Kielce, Poland)*. Zagadnienia Eksploatacji Maszyn 26(4) 417-430 (1991).

A new method of estimation of surface layer depth and quality is presented with special regard to its tribological properties. This method is based on analysis of hardness as load function. The methods used here to hardness measurement were only those with geometrically similar indentations: mainly unified HU method and Vickers HV method. Tests with different loads bring hardness of particular zones of material surface layer and so called "essential hardness". The method worked out is a substitution of perpendicular and skew microsections and is complementation to existing layer ganges as those may be accurately calibrated. The tested detail is not destructed. Besides measurements of "zone hardness" it makes possible precise determination of finish treatment allowance. Examples given show advantages and usefulness of the method.

11A526. Influence of microgeometry of surfaces on the contact approach of elements with a surface layer. - A Polijaniuk and Z Handzel-Powierza *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 41(1) 51-60 (1993).

Effects of the microgeometry of surfaces on the contact approach of steel elements of joints at rest are investigated in the paper. A case of elements with nominally flat surfaces subjected to quasi-statical load is considered. The results of experiments are presented made with the use of an original device for studying contact phenomena, designed and constructed in the Inst of Fundamental Technologies Research of PAS (IPPT PAN). It is shown to what extent the contact approach depends on the microgeometry of a surface obtained in the machining process.

11A527. Interfacial mechanics of a tape wrapped around a flexible bumpy roll. - RC Benson *(Dept of Mech Eng, Univ of Rochester, Rochester NY 14627)*. Trib Trans 36(3) 375-380 (Jul 1993).

This paper presents a mathematical model and numerical solution for axisymmetic contact between an elastic tape and a flexible, bumpy roll. Regions of tape-roll contact and gap are identified. It is shown that slight imperfections in the roll's geometry can lead to extremely large deviations from the expected nominal values for interfacial pressure and hoop stress of the tape.

11A528. Physics of solids and morphology of surfaces. - J Rosseau *(Lab Tribologie Dyn Syst URA CNRS 855, Ecole Natl Ing, St Etienne, France)* and TG Mathia *(Lab Tribologie Dyn Syst URA CNRS 855, Ecole Centrale, Lyon, France)*. Acta Phys Polonica A 83(5) 535-550 (May 1993).

The morphology of surfaces is now an important field of research because of its direct connection with the industrial activity like manufacturing and optimizing of functional criteria through complicated interfacial phenomena. Presently, characterization of the surface morphology, via the profile metrology, is well modelled by a statistical description. The use of shape morphological parameters allows to identify features of the surface structures generated by the process techniques and the emergence of the different phases of the condensed matter. Starting from the solid state background knowledge, prediction of the surface morphology appears as a tedious way.

11A529. A simple model for the surface phenomena. - L Wojtczak *(Ecole Natl Ing St Etienne, St Etienne, France)*. Acta Phys Polonica A 83(5) 685-699 (May 1993).

The simplicity of the present model consists in the construction of the Hamiltonian based on the models of quasi-harmonic oscillators coupled to quasi-free electrons with the effective parameters which are estimated by means of the pseudoharmonic approach and coherent potential approximation, respectively. The geometry of the sample is determined by the topological disorder at the surface reflecting the surface roughness. The model is discussed in connection with the friction related to the melting and pre-melting phenomena. The backscattering of electrons seems to be a testing tool useful not only for decorated surfaces but also for quasi-liquid layers.

11A530. Some statistical properties of the rough surface. - T Balcerzak *(Solid State Phys Dept, Univ of Lodz, Pomorska 149-153, 90-236 Lodz, Poland)*. Acta Phys Polonica A 83(5) 597-610 (May 1993).

The temperature induced roughening of the solid surface is described by means of a discrete Gaussian model, using integral operator technique. On the basis of the exact statistical identities, the formulae for several local moments, ie, $\langle h_i \rangle$, $\langle (h_i)^2 \rangle$ and $\langle h_i h_j \rangle$ are derived. The results of computer calculations including surface specific heat, are presented for three lattices with z = 3,4, and 6. In discussion, some further applications of the presented method are suggested.

11A531. Three-body abrasion of brittle materials as studied by lapping. - M Buijs and K Korpel-van Houten *(Philips Res Lab, PO Box 80.000, 5600 JA Eindhoven, Netherlands)*. Wear 166(2) 237-245 (1 Jul 1993).

Lapping experiments on glass were performed to verify a model for three-body abrasion of brittle materials. The model is based on material removal by rolling abrasive particles. The particles indent the workpiece surface and remove material by lateral cracking. Median cracking introduces subsurface damage. The model leads to expressions for removal (or wear) rate, surface roughness, subsurface damage and load per particle as a function of particle shape, particle size, material parameters of workpiece and lapping plate, applied pressure and relative velocity between plate and workpiece. The model was found to give a good description of the experimental results, allowing among other things the calculation of removal rate, surface roughness or damage penetration from the measurement of either one of these parameters.

11A532. Tribochemical studies by XPS analysis of transfer films of Nylon 11 and its composites containing copper compounds. - S Bahadur, Deli Gong *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*, JW Anderegg *(Ames Lab, Iowa State Univ, Ames IA 50011)*. Wear 165(2) 205-212 (1 Jun 1993).

The transfer films of Nylon 11 and its composites with CuS, CuAc and CuF_2 formed on the steel disk surfaces were studied by X-ray photoelectron spectroscopy. The study revealed that CuS and CuF_2 decomposed under the rubbing conditions and produced copper, FeF_6 group and $FeSO_4$. The analysis at different depths in the transfer films indicated higher concentrations of these species closer to the transfer film-counterface interface. There was no chemical change detected when unfilled Nylon 11 and CuAc-Nylon composite rubbed against the steel disk surfaces. These results have been used to hypothesize the mechanism by which the transfer films of these materials influence wear.

292I. WEAR MONITORING

11A533. Effect of niobium on wear resistance of 15%Cr white cast iron. - He-Xing Chen, Zhe-Chuan Chang, Jin-Cai Lu, Huai-Tao Lin *(Wear Res Center, Guangzhou Inst of Nonferrous Metals, Wushan, Guangzhou 510651, China)*. Wear 166(2) 197-201 (1 Jul 1993).

Niobium addition to 15%Cr white cast iron can increase its wear resistance because (1) Nb forms extremely hard carbides (NbC) of hardness around HV 2400, (2) Nb can raise the matrix hardness of 15%Cr iron from HV 693 to HV 899, (3) Nb shifts the eutectic point to the right, therefore the iron can have a high carbon content without the danger of forming brittle hyper-eutectic carbides, and (4) the morphology of NbC is block-hook-like. The NbC particles can be kept firmly in the matrix during the wear process. The wear resistance was tested by wet rubber wheel abrasion tests. The optimum chemical composition of the iron found in these tests was used for making slurry pump components, which were field tested in a mineral mine. The field test confirmed the laboratory test results.

292Y. COMPUTATIONAL TECHNIQUES

11A534. Rudimentary considerations for adaptive gap-friction element based on the penalty method. - SH Lee *(MacNeal - Schwendler, 815 Colorado Blvd, Los Angeles CA 90041)*. Comput Struct 47(6) 1043-1056 (17 Jun 1993).

One of the major areas in nonlinear analysis that poses difficulties in convergence is known to be the application of penalty GAP elements, particularly with friction. The GAP element simulates a point-to-point contact, and is often used to simulate surface contact problems. Numerical difficulty is inherent in nature for the penalty method. Difficulties of the penalty GAP element are coped with by implementing an adaptive GAP element in MSC-NASTRAN. The adaptability comprises algorithms to subdivide the increment in the local process, to update the stiffness at an appropriate time, to bisect load or time step size when the increment is excessive, and to adjust penalty stiffnesses to the proper values in concert with the nonlinear and dynamic environment.

11A535. Vibroacoustic monitoring of bearing points failures in the driving system of the mining main ventilation fans. - T Zakrzewski *(Silesian Univ of Tech, 44-100 Gliwice, Poland)*. Arch Acoust 18(1) 47-66 (1993).

The purpose of the examinations carried out on separated bearing points was to evaluate the range of sensitivity of the introduced, relatively simple, estimates to the recorded vibratory signals, to changes of the degree of wear in the conditions of constant loading and increasing period of operation. The obtained results, and the analysis of these results, served as the basis for elaborating the criteria for the evaluation of the technical state of bearing points. Here, such diagnostic estimates were selected that their values determined at the moment of checking, allowed to draw conclusions on the functional characteristics of the bearing points.

11A536. High cycle fatigue strength of butt welded joints of small diameter pipes. - K Kishida, M Higuchi, M Fukuzawa *(Ishikawajima-Harima Heavy Indust, 1 Shin-nakahara-cho, Isogo-ku, Yokohama 235, Japan)*. Int J Pressure Vessels Piping 55(3) 375-383 (1993).

Fillet welds are usually used for joints of small pipelines with 2-inch nominal outer diameter or smaller. The fillet welded joints might not be strong enough to withstand the high cycle fatigue produced by steady-state vibrations, because they have inherent crack-like discontinuities in the root portion. The fatigue strength of butt welded joints is believed to be higher than that of fillet welded joints, so that it is desirable to use butt welded joints for small pipelines under steady-state vibrations. However, there are no available data on high cycle fatigue strength of small diameter piping butt welded joints. This paper presents new data on high cycle fatigue strength of butt welded joints in small diameter pipes and development of their fatigue strength reduction factors for design use.

11A537. Rotordynamic characteristics of flexure-pivot tilting-pad journal bearings. - RW Armentrout *(California Consultants, Danville CA)* and DJ Paquette *(KMC Div of Cookson America, Coventry RI)*. Trib Trans 36(3) 443-451 (Jul 1993).

Many of today's modern turbomachines, especially those running at high speeds and high power ratings, require the superior stability characteristics of tilting-pad journal bearings to prevent rotordynamic instabilities. Until now, the design complexity of tilting-pad bearings has precluded their use in many small, high-volume applications where cost and size are important. This paper introduces a new one-piece journal bearing design, the flexure-pivot bearing, that offers many of the beneficial rotordynamic advantages of tilting-pad bearings, without the complexities of a multi-piece design. Performance data for a flexure-pivot bearing is shown for an application requiring a highly stable design, illustrating the effectiveness of the flexure-pivot bearing in offering rotordynamic stability approaching that of a tilting-pad bearing.

11A538. Simplified method of bearing material fatigue strength investigation. - A Rigall and J Sikora *(Politech Gdanska, Wydzial Budowy Maszyn ul Majakowskiego 11-12, 80-952 Gdansk-Wrzeszcz, Poland)*. Zagadnienia Eksploatacji Maszyn 26(4) 387-404 (1991).

Fatigue strength investigation of slide bearing is extremely time-consuming and involves special difficulty in design, performing and analysis of the experiments. A new sequential procedure of the research, proposed in this article, is based on the principle of the two-point strategy and makes it possible to achieve effectively an assessment of important part of cumulative distribution function of bush sliding surface fatigue strength. A main statistical parameter which is estimated is a median of the distribution.

11A539. Tilting pad journal bearings: Measured and predicted stiffness coefficients. - DW Parkins *(Cranfield IT, Bedford, UK)* and D Horner *(Michell Bearings, Newcastle-upon-Tyne, UK)*. Trib Trans 36(3) 359-366 (Jul 1993).

This paper presents measured and calculated characteristics of a tilting pad journal bearing suitable for high speed machinery. Descriptions are given of the experimental techniques used with this variety of bearing and the theoretical model for predicting performance. Measured values of pad temperature, eccentricity, attitude angle, and the four stiffness coefficients are given for a range of loads and rotational speeds. Data are given for both load on pad and between pad configurations, the two principal loading arrangements. Comparisons are made between the measured and predicted bearing temperatures and stiffness coefficients over a wide range of values.

11T540. Importance of labyrinth seal through-flow deflection for enlarging clearance without increasing leakage. - DL Rhode and MJ Guidry *(Mech Eng Dept, Texas A&M Univ, College Station TX 77843)*. Trib Trans 36(3) 477-483 (Jul 1993).

11A541. Three-dimensional computations of rotordynamic force distributions in a labyrinth seal. - DL Rhode, SJ Hensel, MJ Guidry *(Turbomachinery Lab, Mech Eng Dept, Texas A&M Univ, College Station TX 77843)*. Trib Trans 36(3) 461-469 (Jul 1993).

A numerical method employing a finite volume approach for calculating the rotordynamic force on eccentric, whirling labyrinth seals has been presented. The SIMPLER algorithm is used to calculate the 3D flowfield within a seal. The modified bipolar coordinate system used accurately describes the geometry of an eccentric seal. The turbulent flow form of the fully elliptic Navier-Stokes equations was solved. A 3% eccentric, single labyrinth cavity rotating at 7000 cpm was investigated for three different inlet swirl conditions, each with and without a whirl orbit frequency of 3500 cpm. It was found that the circumferential pressure variation around the downstream tooth periphery is by far the most important contribution to both rotordynamic force components. Thus the flowfield details near each tooth throttling should be carefully considered. Further, a substantial increase of shaft whirl frequency was found to decrease and increase the effect of cavity inlet swirl on F_t and F_r, respectively.

11A542. Distribution of coupler curves for crank-rocker linkages. - De Lun Wang and Da Zhun Xiao *(Dept of Mech Eng, Dalian Univ of Tech, Dalian 116024, Peoples Rep of China)*. Mech Machine Theory 28(5) 671-684 (Sep 1993).

Based on a differential geometry approach, the basic equations for the coupler curve of the four-bar linkage are concisely derived. The geometric properties of coupler curves for the crank-rocker linkage are analyzed, and the distribution law of various shapes of coupler curves is revealed. The moving centrode, Ball's curve and the self-tangent curve divide the coupler plane into several areas. The points in each of these areas trace a specific shape of curves. Therefore, any shape of coupler curves with a cusp, inflection point, Ball's point, crunode, tacnode or oval shape, etc, for the first time, could be readily located.

11A543. Kinematic-kinetic performance analysis and synthesis measures of multi-dof mechanisms. - Ming-Yih Lee, AG Erdman, Y Gutman *(Productivity Center, Dept of Mech Eng, Univ of Minnesota, Minneapolis MN 55455)*. Mech Machine Theory 28(5) 651-670 (Sep 1993).

This paper discusses kinematic-kinetic performance characteristics of multi-dof mechanisms and proposes analytical and graphical representations for them. These performance characteristics are kinematic cross-coupling, directional motion mobility, force manipulability, and motion efficiency. Properties of the proposed analytical-graphical measures are elaborated on for the purpose of kinematic synthesis. Graphical performance distribution over the mechanism's reachable workspace enables the designer to view the performance as a whole. Critical performance points representing extreme conditions of these performance characteristics are identified and used for design. The proposed performance tools will be demonstrated for the performance analysis of various robotic mechanisms.

11A544. Synthesizing spatial 7R mechanism with 16-assembly configurations. - Qizheng Liao, Chonggao Liang *(Beijing Univ of Posts and Telecommun, Beijing 100088, Peoples Rep of China)*, Qixian Zhang *(Beijing Univ of Aeronaut and Astronaut, Beijing, Peoples Rep of China)*. Mech Machine Theory 28(5) 715-720 (Sep 1993).

Using complex numbers, a special case of a spatial 7R mechanism is discussed. The computer calculations show that the input-output equation of this mechanism is still 16 degree in tan-half-angle of the output angular displacement. By adjusting a group of dimensions of this mechanism, a general 7R mechanism with 16-assembly configurations is discovered.

11A545. Modeling of a torsion-bar cam mechanism. - KSH Sadek *(Sch of Mech and Manuf Eng, Sunderland Univ, Chester Rd, Sunderland SR1 3SD, UK)* and A Daadbin *(Dept of Mech Eng and Manuf Syst, Northumbria Univ, Ellison Build, Newcastle upon Tyne NE1 8ST,* *UK)*. Mech Machine Theory 28(5) 631-640 (Sep 1993).

In high-speed disc-cam mechanisms, vibration of the linkage is harmful in that the end motion deviates from the required schedule; but more importantly, the vibration may result in the loss of contact between the cam and the follower. This causes an increase in noise levels and excessive wear. A simplified mathematical model was developed to predict the dynamic behavior of a mechanism. Fed by the cam profile and the parameters of the mechanism, a computer program yields the output motion of the mechanism as well as the contact force between the cam and its follower. Since it has interactive features, the program can be used to help in the design of such systems.

11A546. Optium design of the RSS'R flexible space mechanism via multiplier techniques. - Yue-Qing Yu *(Section of the Theory of Machines and Mech, Beijing Polytech Univ, Beijing 100022, Peoples Rep of China)*. Mech Machine Theory 28(5) 625-630 (Sep 1993).

This paper presents a new procedure for the optimum design of a flexible space mechanism. An advanced optimization technique for the multiplier method is applied to design a completely elastic linkage having minimum mass while keeping stresses and deflection in the links under prescribed limits. Numerical solutions for the example of the RSS'R spatial mechanism, using the new procedure, are found to be more valid than those of the previously published works.

11A547. Flanged joint analysis: A simplified method based on elastic interaction. - A Bouzid and A Chaaban *(Dept of Mech Eng, Ecole Polytech, Case postale 6079, Succ A, Montreal, PQ, H3C 3A7, Canada)*. Trans Can Soc Mech Eng 17(2) 181-196 (1993).

Structurally sound bolted joints often fail due to loss of tightness. This is because the clamping load is affected by the application of the internal fluid pressure. A good design technique should therefore encompass most aspects of joint behavior and produce efficient sealing performance within the clearly defined limits of the method used. This paper presents a simple analytical model based on an extension of the Taylor Forge approach taking into account flange rotation, flexibility of both the gasket and the bolts and, when applicable, the stiffness of the end closure. Examples will be discussed based on experimentally determined gasket properties.

11A548. Improving toughness of electron beam welds of heavy Mn-Mo-Ni steel plates for pressure vessels. - Y Tomita *(Nagoya R&D Lab, Nippon Steel, Tokai City, Aichi, Japan)*, K Tanabe, K Koyama *(Steel Res Lab, Nippon Steel, Futtsu City, Chiba, Japan)*. J Pressure Vessel Tech 115(3) 242-248 (Aug 1993).

Electron beam welding melts and solidifies steel plate without using any welding material, unlike the conventional welding. Therefore, the toughness at the weld metal can decrease, depending on the chemical composition of the steel plate. Toughness at the electron beam weld can be increased by turning the microstructure from upper bainite into lower bainite and making the effective grain size finer. The microstructure can be controlled by the addition of alloy elements and optimization of impurity elements. In case the chemical compositions cannot be varied, largely because of the specification for their ranges, and the weld metal microstructure remains as upper bainite even after the application of microstructure control, methods to improve the toughness of electron beam weld itself, regardless of steel grades, becomes necessary. Phenomena peculiar to the electron beam weld are segregation during solidification and intergranular segregation over the dendrite surface. The fracture initiation is accelerated by the microcracks caused by the segregations during solidification. The fracture propagation is promoted by intergranular cracking caused by the intergranular segregation. By reducing these segregations, the fracture initiation and propagation are restrained and toughness increases despite the upper bainite microstructure. This can be achieved by the higher purification of steel. Through the foregoing investigations, ASTM A533 Type B Class 2 steel plate of 100 mm in thickness for electron beam welds has been developed for pressure vessels. Various welding tests as pressure vessels have been conducted, and it becomes clear that the developed steel plate has excellent toughness at the weld superior to those obtainable by conventional welding. The use of this steel greatly reduces the welding period compared to the conventional welding method.

11A549. Materials data for high-temperature design of ferritic steel pressure vessel weldments. - ZP Wang and DR Hayhurst *(Dept of Mech and Process Eng, Univ of Sheffield, Mappin St, PO Box 600, Sheffield S1 4DU, UK)*. Int J Pressure Vessels Piping 55(3) 461-479 (1993).

To aid material selectors and engineering designers in the design of ferritic pressure vessel weldments, a data bank has been created of the creep deformation and rupture properties of weld materials and heat affected zone (HAZ) materials. The generated data are based on the properties of well-characterized typical materials and on information supplied by plant engineers. The presentation style allows the data to be used in materials selection at the earlier stages of design, or in Continuum Damage Mechanics based FE analysis at the detailed design stage.

11A550. Advances in bonding technology for electronic packaging. - Chin C Lee, Chen Y Wang, G Matijasevic *(Elec and Comput Eng, UC, Irvine CA 92717)*. J Electron Packaging 115(2) 201-207 (Jun 1993).

Recent progress in bonding materials is briefly reviewed with highlights of some of the advantages and disadvantages of the various attachment processes. The principle and experimental results of bonding with multilayer structures of Au-Sn and Au-In are presented. Using solid state as well as liquid phase diffusion of the multilayers, bonding temperatures less than the final melting point of the alloy can be used. This technique therefore allows reversal of the conventional soldering step hierarchy allowing a higher temperature process to follow the multilayer bonding step. Proper deposition of the multilayers inhibits oxidation of tin or indium. Die attachment experiments confirmed that high quality bonding can be obtained as seen in the void-free bonding layer image done by scanning acoustic microscopy. Cross-section examinations with SEM and EDX show near-eutectic alloy formation of good uniformity. Thermal shock tests confirmed the high strength of these solder alloys.

11A551. Comparison of 2 and 3D FE analyses of adhesive joints. - G Richardon, AD Crocombe *(Dept of Mech Eng, Univ of Surrey, Guildford GU2 5XH, UK)*, PA Smith *(Dept of Mat Sci and Eng, Univ of Surrey, Guildford GU2 5XH, UK)*. Int J Adhesion Adhesives 13(3) 193-200 (Jul 1993).

The validity of modeling adhesive joints as 2D problems has been assessed. Results are presented from a series of 3D adhesive joint analyses and, using these, modifications to 2D analyses are proposed which yield results that compare favorably with their 3D counterparts. This is achieved primarily by adjusting the 2D loading and is shown to be extremely effective. Comparison of both the adhesive stress distributions and the energy release rates associated with crack growth from the 2D and 3D analyses have been made.

11A552. Extended Maxwell Garnett formalism for composite adhesives for microwave-assisted adhesion of polymer surfaces. - B Shanker and A Lakhtakia *(Dept of Eng Sci and Mech, Penn State)*. J Composite Mat 27(12) 1203-1213 (1993).

Adhesives with dielectric loss are needed for microwave-assisted joining of polymeric substances. The dielectric loss in an otherwise suitable adhesive may be enhanced by doping it with fine metallic particles. Here we use a recently extended Maxwell Garnett formalism to estimate the complex dielectric constant of a metal-doped composite adhesive, with specific focus on the imaginary part of the dielectric constant of the composite adhesive.

11A553. Nondestructive evaluation of model adhesive joints by PVDF piezoelectric film sensors. - B Tang *(Wyle-Lab, Build 8252A Edwards AFB CA 93253-5000)*, J Mommaerts, RK Duncan, JC Duke Jr, DA Dillard *(Dept of Eng Sci and Mech, VPI)*. Exp Mech 33(2) 102-109 (Jun 1993).

Metallized poly(vinylidene fluoride) (PVDF) films can be etched into nondestructive evaluation (NDE) sensor devices. Since these sensors are relatively inexpensive, thin and lightweight, they can be attached permanently to adhesively bonded joints, laminated composites, and other structures to measure structural integrity. The present study has addressed techniques to design, attach, and utilize such sensors for adhesive joint and laminated composite applications. PVDF sensors have been successfully used as NDE transducers in pulse-echo, through-transmission, and acousto-ultrasonic techniques to monitor curing, and to detect porosity and crack propagation in different model joint geometries. Feasibility of several applications has been demonstrated, although several problems remain. The potential of using these techniques for practical bonded structures is also suggested.

11A554. Study of the cure of adhesives using dynamic mechanical analysis. - RW Cook and DA Tod *(Military Div, DRA, ET5 Ft Halstead, Sevenoaks Kent TN14 1BP, UK)*. Int J Adhesion Adhesives 13(3) 157-162 (Jul 1993).

Adhesives are being used extensively in fabrication as they offer many advantages over standard joining methods. As the adhesive forms an integral part of the structure, it is necessary to fully understand the initial mechanical properties of the material and how these change with ageing. Formal testing of materials often involves a considerable number of tensile tests. These are not only expensive but time consuming. One method of speeding up the process is to study the small strain mechanical properties of materials and therefore avoid the statistical uncertainty involved in fracture tests. The aim of this paper is to show how the technique of dynamic mechanical spectrometry can be applied to the study of adhesives and adhesive joints.

V. MECHANICS OF FLUIDS

350. Rheology

11T555. Best fit for differential constitutive model parameters to nonlinear oscillation data.

- RS Jeyaseelan and AJ Giacomin *(Rheology Res Lab, Mech Eng Dept, Texas A&M Univ, College Station TX 77843-3123)*. J Non-Newtonian Fluid Mech 47 267-280 (Jun 1993).

11A556. Microscopic studies of static and dynamic contact angles. - PA Thompson *(Dept of Mech Eng and Mat Sci, Duke Univ, Durham NC 27708-0300)*, WB Brinckerhoff *(Dept of Phys, Ohio State Univ, 174 W 18th Ave, Columbus OH 43210)*, MO Robbins *(Dept of Phys and Astron, Johns Hopkins Univ, Baltimore OH 21218)*. J Adhesion Sci Tech 7(6) 535-554 (1993).

Molecular dynamics simulations are used to test macroscopic theories for static and dynamic contact angles. Young's equation is verified by comparing observed static contact angles to angles calculated from the independently measured surface tensions between phases. Laplace's relation between the interfacial curvature and pressure is also checked. Both equations agree with simulation results within statistical errors. Hydrodynamic theories of dynamic contact angles are less well defined because they produce diverging stresses at the contact line between the solid and fluid interfaces if the usual no-slip boundary condition is assumed. Our simulations show that slip occurs within about two molecular diameters of the contact line, and that local hydrodynamics breaks down in the slip region. The slip results from large tangential stresses along the solid wall. A surprising result is that changes in the boundary condition for single-fluid flow at molecular scales produce dramatic changes in the dynamic contact angle.

11A557. Brownian dynamics simulation of finitely extensible bead-spring chains. - BHAA van den Brule *(Shell Res BV, PO Box 60, 2280AB Rijswijk, Netherlands)*. J Non-Newtonian Fluid Mech 47 357-378 (Jun 1993).

The behavior of infinitely dilute solutions of finitely extensible nonlinear elastic (FENE) bead-spring chains in shear flow and uniaxial elongational flow is analyzed under both steady-state and transient conditions, using the method of Brownian dynamics. Three FENE chain models are considered: the original model using the Warner spring force law and models using the Peterlin approximation and the recently proposed PM approximation. It is shown that the two approximate models, which are based on pre-averaging of the spring constant, perform reasonably well in elongational flow but fail in describing shear flow.

11A558. Rheology of polydisperse polymers: Relationship between intermolecular interactions and molecular weight distribution. - P Cassagnau, JP Montfort, G Marin, P Monge *(Univ Pau et des Pays de l'Adour, Pau, France)*. Rheol Acta 32(2) 156-167 (Mar/Apr 1993).

An expression of the relaxation function of linear polydisperse polymers is proposed in terms of intermolecular couplings of reptative chains. The relaxation times of each molecular weight are assumed to be shifted according to a tube renewal mechanism accounting for the diffusion of the surrounding chains. The subsequent shift is applied to the relaxation function of each molecular weight obtained from an analytical expression of the complex compliance Jx(ω). Therefore the complex shear modulus Gx(ω) is derived from the overall relaxation function using the probability density accounting for the molecular weight distribution and four species-dependent parameters: a front factor A for zero-shear viscosity, plateau modulus G^0_N, activation energy E and characteristic temperature T_∞. All the main features of the rheology of polydisperse polymers are described by the proposed model.

11A559. Simultaneous solution for fiber orientation in axisymmetric radial flow. - S Ranganathan and *(Dept of Mech Eng, Center for C... Univ of Delaware, Newark DE 19716)*. J Non-Newtonian Fluid Mech 47 107-136 (Jun 1993).

The effect of the changing microstructure during the flow of fiber suspensions on the flow kinematics is studied. The suspension is assumed to consist of rigid cylindrical particles immersed in a highly viscous Newtonian fluid. Further, the suspension is modeled as an anisotropic fluid whose rheological properties are functions of the local microstructure. The effect of inertia is neglected during the flow of the suspension. The orientation of the particles is assumed to be governed by the flow field and the fiber-fiber interactions. The governing equations for the flow field and fiber orientation are coupled and are simultaneously solved in an axisymmetric radial-flow configuration. These solutions are compared to those obtained using the conventional decoupled approximation where the bulk flow field is assumed to be unaffected by the presence of the suspended particles.

11A560. Unsteady flow of a power-law dusty fluid with suction. - AJ Chamkha *(Fleetguard, Cookeville TN 38502)*. J Fluids Eng 115(2) 330-333 (Jun 1993).

Equations governing flow of a particulate suspension exhibiting finite volume fraction in non-Newtonian power-law fluids are developed and applied to the problem of unsteady flow past an infinite porous flat plate with suction. Numerical results for small volume fraction for the displacement thicknesses for both phases and the skin-friction coefficient for the fluid phase are obtained using an implicit finite difference scheme and presented graphically to elucidate interesting features of the solutions.

11A561. Electrorheological fluids applied to an automotive engine mount. - EW Williams, SG Rigby *(Dept of Appl Math and Theor Phys, Liverpool Univ, PO Box 147, Liverpool L69 3BX, UK)*, JL Sproston, R Stanway *(Dept of Mech Eng, Liverpool Univ, PO Box 147, Liverpool L69 3BX, UK)*. J Non-Newtonian Fluid Mech 47 221-238 (Jun 1993).

This paper is concerned with the mathematical modeling of electrorheological fluids when used in oscillating squeeze-flow mode; in a prototype automotive engine mount. A solution of the problem is found for the situation in which the non-Newtonian behavior of the fluid is represented by a Bi-Viscous characteristic. This permits the prediction of the vibration damping characteristics of the device. Finally these results are compared with recently published experimental values.

11A562. Prediction of viscosities using chemical graph theory. - EW Pitzer *(Aero Propulsion and Power Directorate, Wright Lab, WPAFB)*. Trib Trans 36(3) 417-420 (Jul 1993).

The viscosities of three groups of lubricant basestock molecules are predicted using chemical graph theory. Alkyl diphenylphosphates, trimethyloethane esters, and oligomers of chlorotrifluoroethylene are modeled. These compounds are similar for graph theoretical modeling purposes in that all are aliphatic in nature or vary only by aliphatic substituents. The graph theoretical approach for the modeling of these compounds uses summations of the shortest topological distances between atoms in the molecule. A new topological index is introduced that weights chlorine molecules in the chlorotrifluoroethylene oligomers. For each group modeled, the coefficient of determination γ^2 was in excess of 0.99 with a standard error of estimate well below five percent of the average value modeled.

11A563. Squeezing flow of a Bingham material. - SDR Wilson *(Dept of Math, Univ of Manchester, Manchester M13 9PL, UK)*. J Non-Newtonian Fluid Mech 47 211-219 (Jun 1993).

The "squeeze-flow paradox" for a Bingham material is investigated. The space between two parallel discs is filled with liquid material of the Bingham viscoplastic type and the discs are squeezed together; the paradox arises from the requirement that the material between the discs should move radially outwards, together with the observation that the shear stress on the midplane is zero so that the material should be solid. Here we argue that the Bingham model should be regarded as a limiting case of some other model (the biviscosity model, here) and that this limit clashes with the other limit process, in which normal stresses are neglected, giving rise to lubrication theory. A distinguished limit is demonstrated and a corrected theory is derived which contains the "paradoxical" theory as a special case.

352A. GENERAL THEORY

11A564. Rheo-optical study of shear-thickening and structure formation in polymer solutions Part II. Light scattering analysis. - AJ Kishbaugh and AJ McHugh *(Dept of Chem Eng, Univ of Illinois, Urbana IL)*. Rheol Acta 32(2) 115-131 (Mar/Apr 1993).

Light scattering calculations based on Anomalous Diffraction Theory (AD), Rayleigh spheroids, and flexible macromolecules are used to propose a phenomenological explanation for the relationship between shear-thickening and structure formation in polymer solutions. Quantitative comparisons are made to experimental data for the rheo-optical behavior of fractionated polystyrene solutions presented in part I of this paper. Results from the ADA calculations suggest that the viscosity and dichroism behavior can be attributed to the production and growth of micron-size, optically isotropic structures during flow. The saturation dichroism behavior exhibited by the solutions which shear thin can be attributed to the formation of entanglement regions which achieve a fixed size and act as Rayleigh spheroids in their scattering behavior. The magnitude and shear rate dependence of the observed birefringence can be accounted for on the basis of the nonlinear, flexible macromolecule model, implying that birefringence is governed by the polymer chains remaining in solution which do not take part in the structure formation. The latter result is consistent with the experimental observation that the birefringence dependence on shear rate is the same whether the solution exhibits shear thickening or shear thinning in its viscosity behavior.

352B. CLOSED CONDUIT FLOW

11A565. Use of subdomains for inverse problems in branching flow passages. - AK Agrawal, S Krishnan, Tah-teh Yang *(Dept of Mech Eng, Clemson Univ, Clemson SC 29634-0921)*. J Fluids Eng 115(2) 227-232 (Jun 1993).

For inverse problems in complex flow passages, a calculation procedure based on a multizone Navier-Stokes method was developed. A heuristic approach was employed to derive wall shape corrections from the wall pressure error. Only two subdomains sharing a row of control volumes were used. The grid work in the common region was identical for both subdomains. The flow solver, inverse calculation procedure, multizone Navier-Stokes method and subdomain inverse calculation procedure were validated independently against experimental data or numerical predictions. Then, the subdomain inverse calculation method was used to determine the wall shape of the main duct of a branching flow passage. A slightly adverse pressure gradient was prescribed downstream of the sidebranch. Inverse calculations resulted in a curved wall diffuser for which the wall pressure distribution matched the design (prescribed) wall pressure distribution. The present method was illustrated for laminar, incompressible flows in branching passages. However, the method presented is flexible and can be extended for turbulent flows in multiply connected domains.

352C. OPEN CHANNEL FLOW (INCL HYDRAULIC JUMPS)

11A566. Motion resistance and pressure distribution in a delivery conduit during pumping of a concrete mixture. - A Halicka and M Krol *(Politechnika Lubelska, Poland)*. Inzynieria Budownictwo 50(7) 290-292 (1993).

The analytical description is proposed for a stationary motion of a concrete mixture in horizontal pipes. Resistances to such a motion are discussed.

352F. STRATIFIED FLOW

11A567. Diurnal stratification and its effects on wind-induced currents and water qualities in Lake Kasumigaura, Japan. - T Ishikawa *(Dept of Civil Eng, Tohoku Univ, Aoba, Aramaki, Sendai 980, Japan)* and M Tanaka *(Hydraul Eng Dept, Kajima Tech Res Inst, 19-1 Tobitakyu 2-Chome Chofu-shi, Tokyo 182, Japan)*. J Hydraul Res 31(3) 307-322 (1993).

Diurnal stratification and its effects on wind-induced current and water qualities in a shallow eutrophicated lake are discussed based on the field data obtained in Lake Kasumigaura. Diurnal stratification makes a weak thermocline with the temperature difference of about 1°C. Because a thermocline prevents the vertical momentum transport, it inevitably creates the two-layered flow pattern. The temperature profile has double-thermocline when the thermocline formed one day remains in the following morning. Then, the old thermocline tends to stay near the bottom for several days because the wind mixing works only on the new thermocline developed at upper elevation. DO concentration near the bottom markedly decreases under such condition, because the vertical DO transport is suppressed by the thermocline. PO_4-P is released at high rate from the bed sediments after DO concentration falls below 4 ppm. The entrainment rate is discussed with reference to the basic models which are the turbulent erosion model (TEM) and the dynamic instability model (DIM). It is concluded that DIM, rather than TEM, is suitable to explain the mixing of diurnal stratification observed in this study. The entrainment rate $E[U_m]$ is found to vary as $R_i[U_x]^{-1}$, where $E[U_m] = W_e/U_m$, W_e is the entrainment velocity, U_m is the vertically averaged velocity in the mixed layer, $R_i[U_x] = B/U^2_x$, B is the buoyancy of the mixed layer and U_x is the friction velocity at the water surface.

11A568. Numerical solutions of a nonlinear density current: A benchmark solution and comparisons. - JM Straka *(Sch of Meteor, Univ of Oklahoma, Energy Center Room 1310 100 E Boyd St, Norman OK 73019)*, RB Wilhelmson, LJ Wicker *(Univ of Illinois, Urbana IL 61801)*, JR Anderson *(Univ of Wisconsin, Madison WI 53706)*, KK Droegemeier *(Univ of Oklahoma, Norman OK 73019)*. Int J Numer Methods Fluids 17(1) 1-22 (Jul 1993).

A comparison between solutions from simulations of a nonlinear density current test problem was made in order to study the behavior of a variety of numerical methods. The test problem was diffusion-limited so that a grid-converged reference solution could be generated using high spatial resolution. Solutions of the test problem using several different resolutions were computed by the participants of the "Workshop on Numerical Methods for Solving Nonlinear Flow Problems", which was held on 11-13 September 1990 at the National Center for Supercomputing Applications. In general, it was found that when the flow was adequately resolved, all of the numerical schemes produced solutions that contained the basic physics as well as most of the flow detail of the reference solution. However, when the flow was marginally resolved, there were significant differences between the solutions produced by the various models. Finally, when the flow was poorly resolved, none of the models performed very well. While higher-order and spectral-type schemes performed best for adequately and marginally resolved flow, solutions made with these schemes were virtually unusable for poorly resolved flow. In contrast, the monotonic schemes provided the most coherent and smooth solutions for poorly resolved flow, however with noticeable amplitude and phase speed errors, even at finer resolutions.

11A569. Vertical distribution of particles in stratified lake. - X Casmitjana *(Phys Dept and Inst of Aquatic Ecology, Univ of Girona, P Hospital 6, 17071 Girona, Spain)* and G Schladow *(Center for Water Resources, Dept of Civil and Env Eng, Univ of W Australia, Nedlands 6009, Australia)*. J Env Eng 119(3) 443-462 (May-Jun 1993).

A model to account for the distribution of particulate matter in a lake is presented. This model represents the coupling of a stratified lake mixing model with a particle settling, coagulation, and diffusion model. Using parameterizations of the fundamental and mixing processes, the lake model simulates the response of the stratified water column to external forcing. At the same time, the particle model simulates the settling, aggregation, and diffusion of a given distribution of particles within this changing water column. Three different situations have been chosen in order to test the model. In the first, an input of mineral particles for different size classes has been attributed to an inflow. In the second, the evolution of a distribution of particles initially set up in equilibrium of a strongly stratified lake has been described and in the third, the same initial distribution of particles has been set up for a weakly stratified lake. These cases show the importance of the different mechanisms (settling, aggregation and diffusion) affecting the dynamics of the particles in natural waters.

352H. ORIFICES, NOZZLES, VALVES, AND GATES

11A570. Hydraulics-based-optimization methodology for gating design. - FJ Bradley, S Heinemann *(Dept of Mat Sci and Eng, Univ of Wisconsin, 1509 University Ave, Madison WI 53706)*, JA Hoopes *(Dept of Civil and Env Eng, Univ of Wisconsin, 1509 University Ave, Madison WI 53706)*. Appl Math Model 17(8) 406-414 (Aug 1993).

Advantages and disadvantages of the differential momentum balance and macroscopic control volume approaches to the analysis of flow during mold filling and the computer-aided design of gating systems are discussed. A gating design methodology based on a control volume hydraulics-based flow model and nonlinear optimization is described. Mathematical formulation of the model yields a system of equations that ensures mass continuity at nodes and conservation of energy along paths. In addition to computational efficiency, the hydraulics approach to flow analysis utilizes pipe-node-path representation of gating systems that facilitates the analysis of complex 3D configurations. Example simulations of flow distribution in water modeling systems and of flow distribution and mold filling in molten metal experiments are presented. It is concluded that good agreement between model-predicted and experimental results is obtainable if pertinent loss coefficient data are available. However, application of the hydraulics-based methodology to accurate analysis of flow in gating systems requires knowledge of loss coefficients that specifically relate to the flow conditions and types of runner-ingate geometric configurations encountered in industrial castings. An example formulation illustrating the application of nonlinear optimization to gating design is presented.

352K. STILLING BASINS AND OTHER ENERGY DISSIPATORS

11A571. Velocity measurements within high velocity air-water jets. - H Chanson *(Dept of Civil Eng, Univ of Queensland, St Lucia QLD 4072, Australia)*. J Hydraul Res 31(3) 365-382 (1993).

High velocity turbulent jets are often used in hydraulic structures to dissipate energy and to induce or enhance air entrainment. Examples include ski jumps and bottom aeration devices. This article presents new air concentration and velocity measurements performed in the flow development region of high velocity water jets. The measurements were obtained using a two-tips conductivity probe. The data are compared with analytical air concentration profiles derived from the diffusion equation, and theoretical velocity profiles of turbulent shear layers. The results highlight that the lower jet interface defined as C = 90% coincides with the streamline of maximum velocity gradient.

352L. CAVITATION

11A572. Scale effects for incipient cavitation under consideration of water quality. - G Eickmann *(Hydraul Res Lab Obernach, Munich Tech Univ, Munich, Germany)*. J Hydraul Res 31(3) 347-364 (1993).

By combined measurements of incipient cavitation and water quality, characterized by its tensile strength, the enormous influence of differences in water quality on cavitation data is demonstrated. After eliminating these water quality effects from the test results general similarity relations for velocity and size scale effects become clearly apparent. The knowledge of the effects of water quality and the application of these relations can help to predict cavitation performance more precisely.

11A575. Seasonal cycle of a groundwater dominated lake. - X Casamitjana, E Roget *(Dept of Phys, Inst of Water Ecology, Univ of Girona, Spain)*, G Schladow *(Center for Water Res, Univ of W Australia, Perth, Australia 6009)*. J Hydraul Res 31(3) 293-306 (1993).

Lake Banyoles is a multibasin lake dominated by groundwater derived inflows. It is composed of three major basins, two of them being meromictic. The relatively warm and saline groundwater inflows, together with the basin morphometry, give rise to characteristic thermal structures in each basin, with different thermocline levels and temperature inversions distinguishing the basins. A 1D lake mixing model has been adapted to include the form of mixing associated with the groundwater inflows, and the results are compared with data collected from the lake.

11A576. Study on modeling the morphology of torrents on volcano slopes. - CJ Sloff *(Fac of Civil Eng, Delft Univ of Tech, Delft, The Netherlands)*. J Hydraul Res 31(3) 333-345 (1993).

An exploratory study is done to modeling of rivers on volcano slopes. Beside the occurrence of mud flows or lahars these rivers are characterized by unsteady supercritical flow and large suspended-sediment concentrations. A fully coupled 1D model is presented for the rivers, provided that lahars do not occur. It can simulate unsteady supercritical flow (Froude numbers between about 1 and 1.8) with volumetric sediment concentrations less than about 10%. The redistribution of the suspended-sediment concentration (ie, the lag between concentration and transport capacity due to sediment relaxation) causes instabilities of the bed conformable to antidunes. Calculations with a numerical model using Preissmann's implicit scheme, and applied to a river on the Kelud Volcano in Indonesia, show the rapidity of bed-level variations and the upstream propagation and growth of bed disturbances. These results offer a deeper understanding of the problems of the rivers on the Kelud. Furthermore, it yields a base for investigating the efficacy of sabo works.

352P. COASTS, BEACHES, HARBORS

11A577. Design method of armour Grate Plates for sloping breakwaters. - Guiqiu Wu *(First Inst of Oceanog, State Oceanic Admin, Qingdao 266003)*, Zaihua Ji, Xuexin Sun, Jiuzi Zhang *(Dept of Ocean Eng, Ocean Univ of Qingdao, Qingdao 266003)*. China Ocean Eng 7(1) 45-60 (1993).

Laboratory tests have been conducted on the basis of theoretical analysis of stability of armour Grate Plates with reference to 20 structures. Some empirical formulas of stability thickness of Grate Plates have been obtained in consideration of the effects of water depth in front of the structures and critical wave period. The test results have been compared with field data.

352Y. COMPUTATIONAL TECHNIQUES

11A578. Explicit approach for modeling closed pipes in water networks. - PF Boulos *(Dept of Computer-Aided Eng, Montgomery Watson, 301 N Lake Ave, Ste 900, Pasadena CA 91101)* and T Altman *(Dept of Comput Sci and Eng, Univ of Colorado, Denver CO)*. Appl Math Model 17(8) 437-443 (Aug 1993).

An explicit approach has been developed for use in modeling closed pipes in water distribution networks. The explicit approach is able to directly incorporate the zero-flow effect of closed pipes into the overall network modeling process. The resulting method is based on an analytical reformulation of the quasilinear set of flow continuity and energy equations governing the network hydraulics in terms of energy displacement for the individual closed pipes that exactly meet the corresponding zero-flow boundary constraint imposed. The proposed algorithm is shown to be robust and efficient, and is guaranteed to converge in an expeditious manner. The method compares favorably with others by eliminating numerical diffusion and computational instability or repetitive network topology alterations suffered by the previous procedures. An example application is presented. Enhancement of mathematical modeling of water distribution networks is a principal benefit of this methodology.

354A. GENERAL THEORY

11A579. Effect of mean flows on enhanced diffusivity in transport by incompressible periodic velocity fields. - AJ Majda and RM McLaughlin *(Dept of Math and Program in Appl and Comput Math, Princeton)*. Stud Appl Math 89(3) 245-279 (Aug 1993).

Avellaneda and one of the authors, have recently established that an upper bound for the enhanced diffusivity in the large scale, long time advection-diffusion with periodic steady incompressible velocity fields has the form CPe^2/κ where Pe is the Peclet number and κ is the reciprocal of the Prandtl number. In this paper, flow fields with maximal and minimal enhanced diffusion are studied. Maximal enhanced diffusion requires that in some directions, the enhanced diffusion tensor also has the lower bound CPe^2/κ. For minimal enhanced diffusion, the effect of the velocity field is to boost the enhanced diffusivity by a negligible amount that is bounded by a fixed constant times the bare diffusivity regardless of Peclet number. Stieltjes measure formulas are used to develop a simple, necessary, and sufficient condition for maximal enhanced diffusion and also to characterize minimal enhanced diffusion.

354B. IRROTATIONAL FLOW

11T580. Evidence for a singularity of the 3D incompressible Euler equations. - RM Kerr *(Geophys Turbulence Program, Natl Center for Atmos Res, PO Box 3000, Boulder CO 80307-3000)*. Phys Fluids A 5(7) 1725-1746 (Jul 1993).

11A581. Numerical solutions of Euler equations by using a new flux vector splitting scheme. - G-C Zha and E Bilgen *(Ecole Polytech, Univ of Montreal, PO Box 6079, St A Montreal, PQ, H3C 3A7, Canada)*. Int J Numer Methods Fluids 17(2) 115-144 (30 Jul 1993).

A new flux vector splitting scheme has been suggested in this paper. This scheme uses the velocity component normal to the volume interface as the characteristic speed and yields the vanishing individual mass flux at the stagnation. The numerical dissipation for the mass and momentum equations also vanishes with the Mach number approaching zero. One of the diffusive terms of the energy equation does not vanish. But the low numerical diffusion for viscous flows may be ensured by using higher-order differencing. The scheme is very simple and easy to be implemented. The scheme has been applied to solve the 1D and multidimensional Euler equations. The solutions are monotone and the normal shock wave profiles are crisp. For a 1D shock tube problem with the shock and the contact discontinuities, the present scheme and Roe scheme give very similar results, which are the best compared with those from Van Leer scheme and Liou-Steffen's advection upstream splitting method (AUSM) scheme. For the multidimensional transonic flows, the sharp monotone normal shock wave profiles with mostly one transition zone are obtained. The results are compared with those from Van Leer scheme, AUSM and also with the experiment.

354D. VISCOUS FLOW

11A582. Kinetic theory solution method for the Navier-Stokes equations. - MN Macrossan and RI Oliver *(Dept of Mech Eng, Univ of Queensland, St Lucia, Qld 4072, Australia)*. Int J Numer Methods Fluids 17(3) 177-193 (Aug 1993).

The kinetic-theory-based solution methods for the Euler equations proposed by Pullin and Reitz are here extended to provide new finite volume numerical methods for the solution of the unsteady Navier-Stokes equations. Two approaches have been taken. In the first, the equilibrium interface method (EIM), the forward- and backward-flowing molecular fluxes between two cells are assumed to come into kinetic equilibrium at the interface between the cells. Once the resulting equilibrium states at all cell interfaces are known, the evaluation of the Navier-Stokes fluxes is straightforward. In the second method, standard kinetic theory is used to evaluate the artificial dissipation terms which appear in Pullin's Euler solver. These terms are subtracted from the fluxes and the Navier-Stokes dissipative fluxes are added in. The new methods have been tested in a 1D steady flow to yield a solution for the interior structure of a shock wave and in a 2D unsteady boundary layer flow. The 1D solutions are shown to be remarkably accurate for cell sizes large compared to the length scale of the gradients in the flow and to converge to the exact solutions as the cell size is decreased. The steady-state solutions obtained with EIM agree with those of other methods, yet require a considerably reduced computational effort.

354G. UNSTEADY FLOW

11A583. Wavy mode of the streaked flow around an oscillating cylinder in a stratified fluid at rest. - M Tatsuno and T Karasudani *(Res Inst for Appl Mech, Kyushu Univ, Kasuga 816, Japan)*. Fluid Dyn Res 11(6) 313-318 (Jun 1993).

The structures of the flow induced by a vertical circular cylinder performing transverse oscillations in a linearly stratified fluid at rest are investigated. The density gradient inhibits the onset of the 3D instability. The instability appears as regularly spaced streaked flows along the cylinder axis. Each streaked flow follows a wavy path in the horizontal plane in a certain range of amplitude and frequency of the oscillations.

354J. STRATIFIED FLOW AND FREE SURFACE FLOW

11T584. Calculation of interfacial flows and surfactant redistribution as a gas-liquid interface moves between two parallel plates. - F Wassmuth, WG Laidlaw *(Dept of Chem, Univ of Calgary, 2500 University Dr NW, Calgary, AB, T2N 1N4, Canada)*, DA Coombe *(Comput Model Group, Research Park, 3512-33 St NW Calgary, AB, T2L 2A6, Canada)*. Phys Fluids A 5(7) 1533-1548 (Jul 1993).

11T585. Computations of free surface flows Part 2: 2D unsteady bore diffraction. - JY Yang and CA Hsu *(Inst of Appl Mech, Natl Taiwan Univ, Taipei, Taiwan ROC)*. J Hydraul Res 31(3) 403-413 (1993).

11A586. Upstream stagnation points in stratified flow past obstacles. - PG Baines *(Div of Atmos Res, CSIRO, Aspendale Vic 3195, Australia)* and RB Smith *(Dept of Geol and Geophys, Yale Univ, New Haven CT 06511)*. Dyn Atmos Oceans 18(1-2) 105-113 (Jun 1993).

An experimental study has been made of stagnation points and flow splitting on the upstream side of obstacles in uniformly stratified flow. A range from small to large values of Nh/U (where N is the buoyancy frequency, h_m is the maximum obstacle height and U is the undisturbed fluid velocity) has been covered, for three obstacle shapes which are, respectively, axisymmetric, and elongated in the across-stream and in the downstream directions. Upstream stagnation for the first two of these models does not occur until $Nh_m/U>1.05$, where it occurs at $z \approx h_m/2$. On the central line below this point the flow descends and diverges, and we term this "flow splitting". For the third model (elongated in the downstream direction), upstream stagnation first occurs at $Nh_m/U \approx 1.43$, at $z \approx 0$. Results for this obstacle are not consistent with the "Sheppard criterion", and this upstream flow stagnation is not apparently related to lee wave overturning, in contrast to flow over 2D obstacles.

354K. ROTATING FLOW OR SURFACES

11A587. Fluid flow and heat transfer between finite rotating disks. - VK Garg *(NASA Lewis Res Center, MS 5-11, Cleveland OH 44135)* and AZ Szeri *(Dept of Mech Eng, Univ of Pittsburgh, Pittsburgh PA)*. Int J Heat Fluid Flow 14(2) 155-163 (Jun 1993).

The laminar flow between finite rotating disks with a shroud has been analyzed using a velocity and a stream function formulation, employing Galerkin's method with B-spline basis. Though results from both formulations are in good agreement with the LDV data on velocity profiles, and with each other, we find the stream function formulation clearly superior computationally, and we employ it subsequently to study heat transfer between the disks. The calculations show strong boundary-layer character near the disks. The Nusselt number depends upon both geometry and the Reynolds number.

11A588. Transient interface shape of a two-layer liquid in an abruptly rotating cylinder. - Tae Gyu Lim, Sangmin Choi, Jae Min Hyun *(Dept of Mech Eng, Korea Adv Inst of Sci and Tech, Yusungku, Taejon 305-701, South Korea)*. J Fluids Eng 115(2) 324-329 (Jun 1993).

A description is made of the transient shape of interface of a two-layer liquid in an abruptly rotating circular cylinder. The density of the lower layer is higher than that of the upper layer, but the viscosities may assume arbitrary values. The overall Ekman number is much smaller than unity, and the cylinder aspect ratio is O(1). The classical Wedemeyer model, which deals with the spin-up from rest of a homogeneous fluid, is extended to tackle the two-layer liquid system. If the upper-layer fluid is of higher viscosity, the interface, at small and intermediate times, rises (sinks) in the center (periphery). After reaching a maximum height at the center, the interface tends to the parabolic shape characteristic of the final-state rigid-body rotation. If the lower-layer fluid is of higher viscosity, the interface, at small and intermediate times, sinks (rises) in the center (periphery). The deformation at the center reaches a minimum height, after which the interface approaches the final state parabola. The gross adjustment process is accomplished over the spin-up time scale, $E_n^{-1/2}\Omega^{-1}$, where E_n and Ω denote the lower value of the Ekman numbers of the two layers and the angular velocity of the cylindrical container, respectively. These depictions are consistent with the physical explanations offered earlier. A turntable experiment is performed to portray the transient interface shape. The model predictions of the interface form are in satisfactory agreement with the lab measurements.

354O. FLOW AROUND BODIES

11A589. Added mass coefficient for rows and arrays of spheres oscillating along the axes of tubes. - Xiaolong Cai *(Fluid Flow Projects, Tulsa Univ, Tulsa OK 74104)* and GB Wallis *(Thayer Sch of Eng, Dartmouth Col, Hanover NH 03755)*. Phys Fluids A 5(7) 1614-1629 (Jul 1993).

Rows of single spheres were attached to springs and oscillated in water-filled tubes of several diameters and lengths with various boundary conditions at the ends of the tubes. Similar tests were performed using arrays of spheres in a closed-end tube. The added mass coefficient was deduced from the measured natural frequency. Results for finite systems were systematically extrapolated to predict the coefficient for an infinite system. The results are closely described by adapting the spheres-in-tube potential flow theory of Cai and Wallis and the image method applied to arrays by Wallis *et al.* The coefficient of added mass is shown to depend on the external impedance of a fluid circuit to which the system is connected. Wallis' and Zuber's coefficients are recovered as limiting cases.

11A590. Flow past a needle in a cylindrical tube. - Phan-Thien Nhan, Jin Hao, Zheng Rong *(Dept of Mech Eng, Univ of Sydney, NSW 2006, Australia)*. J Non-Newtonian Fluid Mech 47 137-155 (Jun 1993).

In this paper, the uniform flow past a needle place at the center-line of a tube is analyzed for a class of constitutive equations of the Maxwell type using a FE implementation of the explicitly elliptic momentum equation formulation. In the coupled FE approach, the Galerkin method is applied to the modified momentum equations and the continuity equation, while the treamline upwind Petrov-Galerkin method is applied to the constitutive equations of the viscoelastic fluids. For the power-law and the Phan-Thien-Tanner (PTT) fluids, an asymptotic analysis valid for slender needles is also given. The flow is of practical importance since it forms the basis of an existing commercial viscometer. The viscometer would provide the true shear stress-shear rate relationship if the nominal shear rate is given by KU/R, where U is the falling speed of the needle, R is the radius of the tube, and K is a constant. For the PPT model and the geometry used in this paper, this constant is approximately 4, which is also the value for power-law fluids with power-law index $n = 1/3$.

11A591. Point vortex model of the unsteady separated flow past a semi-infinite plate with transverse motion. - L Cortelezzi *(Dept of Math, UCLA)* and A Leonard *(Graduate Aeronaut Lab, California IT, Pasadena CA 91125)*. Fluid Dyn Res 11(6) 263-295 (Jun 1993).

Two-dimensional unsteady separated flow past a semi-infinite plate with transverse motion is considered. The rolling-up of the separated shear-layer is modeled by a point vortex whose time-dependent circulation is predicted by an unsteady Kutta condition. A power-law starting flow is assumed along with a power law for the transverse motion. The effects of the motion of the plate on the starting vortex circulation and trajectory are presented. A suitable vortex shedding mechanism is introduced and a class of flows involving several vortices is presented. Finally, some possibilities for actively controlling the production of circulation by moving the plate are discussed.

354P. SURFACE TENSION FLOW (EG IN LOW GRAVITY ENVIRONMENTS)

11A592. Computer modeling of transient thermal flows on non-Newtonian fluids. - D Ding, P Townsend, MF Webster *(Dept of Comput Sci, Univ of Wales Inst of non-Newtonian Fluid Mech, Univ Col, Swansea SA2 8PP, UK)*. J Non-Newtonian Fluid Mech 47 239-265 (Jun 1993).

In this report two axisymmetric transient thermal non-Newtonian fluid problems are studied. The first is a capillary flow model problem for a thermal power-law fluid and Graetz number up to 60, governed by a derivative temperature boundary condition. The second is a glass oven flow problem for thermal, Newtonian and power-law fluids, flowing in a complex shaped domain driven by a gravitational body force for thermal Peclet numbers up to 100. The flow domain in this case is a straight pipe with a constriction formed from an axisymmetric angled obstruction on the wall. The results obtained for these problems provide good agreement with both experimental and numerical results supplied by industrial collaborators. Of particular concern here is the nature of the transient development of the flows involved under varying material properties. To this end the code has been validated under typical industrial conditions and found to be robust up to Peclet numbers of at least 100, and involving up to 1000 dof.

11A593. Thermocapillary convection in a multilayer system. - P Georis, M Hennenberg *(Univ Libre de Bruxelles, Brussels, Belgium)*, IB Simanovskii *(Perm State Pedagogical Inst, Perm, Russia)*, A Nepomniaschy *(Perm State Pedagogical Inst, Technion, Haifa, Israel)*, II Wertgeim *(Ural's Branch of Acad of Sci, Perm, Russia)*. Phys Fluids A 5(7) 1575-1582 (Jul 1993).

The Marangoni-Benard instability for a symmetrical three-layer system is examined theoretically. Linear stability analysis and nonlinear numerical simulations show that the ratio of the heat diffusivities determines the nature of the instability. Monotonic disturbances exist only when this parameter is far enough from one, the motion being driven by one interface. When the heat diffusivity ratio is close to one, oscillatory convection is observed. This is explained on a physical base: the oscillation rests on the coupling of both interfaces, which creates a flip-flop mechanism leading to a double inversion of the vortices rotation during one period of oscillation.

11A594. Thermocapillary migration of a small chain of bubbles. - Huailiang Wei and RS Subramanian *(Dept of Chem Eng, Clarkson Univ, Potsdam NY 13699-5705)*. Phys Fluids A 5(7) 1583-1595 (Jul 1993).

The quasistatic thermocapillary migration of a chain of two or three spherical bubbles in an unbounded fluid possessing a uniform temperature gradient is investigated in the limit of vanishing Reynolds and Peclet numbers. The line of bubble centers is permitted to be either parallel or perpendicular to the direction of the undisturbed temperature gradient. The governing equations are solved by a truncated-series, boundary-collocation technique. Results are presented which demonstrate the impact of the presence of other bubbles on a test bubble. In the three-bubble case, a simple pairwise-additive approximation is constructed from the reflections solution, and found to perform well except when the bubbles are close to each other. Also, features of the flow topology in the fluid are explored. Separated reverse flow wakes are found in the axisymmetric problem and other interesting structures are noted for case in which the line of centers is perpendic to the applied temperature gradient. The obs flow structure is shown to be the result of position of simpler basic flows.

11T595. Thermocapillary motion in a spinning vaporizing droplet. - D Lozinski and M Matalon *(Dept of Eng Sci and Appl Math, McCormick Sch of Eng and Appl Sci, NWU)*. Phys Fluids A 5(7) 1596-1601 (Jul 1993).

11A596. Investigation of possible mechanisms of heterogeneous drag reduction in pipe and channel flows. - H-W Bewersdorff, A Gyr, K Hoyer *(Inst of Hydromech and Water Resources Man, Swiss Fed IT, Zurich, Switzerland)*, A Tsinober *(Fac of Eng, Tel-Aviv Univ, Israel)*. Rheol Acta 32(2) 140-149 (Mar/Apr 1993).

This study presents experimental results on the mechanism of this type of drag reduction. The experiments were carried out to find out whether this drag reduction is caused by small amounts of polymer removed from the thread and dissolved in the near-wall region of the flow or by an interaction of the polymer thread with the turbulence. The friction behavior of this type of drag reduction was measured for different concentrations in pipes of different cross-sections, but of identical hydraulic diameter. The parameters of the injection, ie, injector geometry as well as the ratio of the injection to the bulk velcoity, were varied. In one set of experiments the polymer thread was sucked out through an orifice and the friction behavior in the pipe was determined downstream of the orifice. In another experiment, near-wall fluid was led into a bypass in order to measure its drag reducing properties. Furthermore, the influence of a water injection into the near-wall region on the drag reduction was studied. The results provide a strong evidence that heterogeneous drag reduction is in part caused by small amount of dissolved polymer in the near-wall region as well as by an interaction of the polymer thread with the turbulence.

11A597. New approach to the pulsating and oscillating flows of viscoelastic liquids in channels. - R Steller *(Inst of Organic and Polymer Tech, Tech Univ, Wroclaw, Poland)*. Rheol Acta 32(2) 192-205 (Mar/Apr 1993).

An approximate method for mathematical description of unsteady flows of polymeric liquids in channels generated by pulsating pressure gradient or vibration channel wall is presented. The method is based on integration of the equation of motion and determination of the shear stresses and shear rates at channel walls, assuming the inertia effects to be suitably small. The approximate results have been compared with exact solutions using as examples the Newtonian fluid and a special form of a generalized Maxwell model. The applibility conditions of the proposed method have been extensively discussed.

11A598. Two-dimensional planar flow of a viscoelastic plastic medium. - A Isayev and YH Huang *(Inst of Polymer Eng, Univ of Akron OH)*. Rheol Acta 32(2) 181-191 (Mar/Apr 1993).

The present study is concerned with FE simulation of the planar entry flow of a viscoelastic plastic medium exhibiting yield stress. The numerical scheme is based on the Galerkin formulation. Flow experiments are carried out on a carbon black filled rubber compound. Steady-state pressure drops are measured on two sets of contraction or expansion dies having different lengths and a constant contraction or expansion ratio of 4:1 with entrance angles of 90°, 45°, and 15°. The predicted and measured pressure drops are compared. The predicted results indicate that expansion flow has always a higher pressure drop than ... ow. This prediction is in agreement ... al data only at low flow rates, but ... rates. The latter disagreement is ... ication that the assumption of ... low in the upstream and down... not realistic at high flow rates, ... length-to-thickness ratio channels employed. The evolution of the velocity, shear stress, and normal stress fields in the contraction or expansion flow and the location of pseudo-yield surfaces are also calculated.

11A599. Boundary integral equations for contact problems of plane quasi-steady viscous flows. - LK Antanovskii *(MARS Center, Via Diocleziano 328, 80125 Naples, Italy)*. European J Appl Math 4(2) 175-187 (Jun 1993).

Plane, quasi-steady, free-boundary flows of an incompressible viscous fluid with surface tension in a container are considered. The mathematical problem is decomposed into an auxiliary elliptic problem for the Stokes system in a fixed flow domain, whose solution leads to the Cauchy problem for the free boundary with the so-called normal velocity operator. By introducing the complex stress-stream function and applying time-dependent conformal mapping, the auxiliary problem is reduced to a boundary integral equation via consideration of two Hilbert problems for analytic functions in a unit disc. As an application, plane capillary flow with moving contact points is investigated asymptotically for small capillary numbers. We prove that in the case when a dynamic contact angle is equal to π, this problem is well-posed for a filling regime, and ill-posed for a drying one.

11A600. Determination of the stream function and pressure distribution in some plane discrete velocity fields. - WJ Prosnak and JM Elszkowski *(Lab of Numer Fluid Mech, Inst of Fluid Flow Machinery, Polish Acad of Sci, Fiszera 14 Pl-80-952, Gdansk, Poland)*. Bull Polish Acad Sci Tech Sci 41(2) 79-97 (1993).

The paper deals with the plane flow of viscous liquid. It contains a method for construction of a continuous stream function and a continuous pressure field. The both functions correspond to a plane, discrete, instantaneous velocity field, the rectangular velocity components u_{ij}, v_{ij} being given only in nodes i, j of a rectangular grid, introduced in the domain of the flow. The paper can be regarded as a complement.

11A601. Hele-Shaw flows with a free boundary produced by multipoles. - VM Entov *(Inst for Problems in Mech, Russian Acad of Sci, prosp Vernadskogo 101, Moscow, Russia)*, PI Etingof, DY Kleinbock *(Dept of Math, Yale Univ, 2155 Yale Sta, New Haven CT 06520)*. European J Appl Math 4(2) 97-120 (Jun 1993).

We study Hele-Shaw flows with a moving boundary and multipole singularities. We find that such flows can be defined only on a finite time interval. Using a complex variable approach we construct a family of explicit solutions for a single multipole. These solutions turn out to have the maximal possible lifetime in a certain class of solutions. We also discuss the generalized Hele-Shaw model in which surface tension at the moving boundary is considered, and develop a method of finding steady shapes. This method yields new one-parameter families of stationary solutions. In the Appendix we discuss a connection between these solutions and a variational problem of potential theory.

11A602. Improved implicit residual smoothing for steady state computations of first-order hyperbolic systems. - R Enander *(Dept of Sci Comput, Uppsala Univ, PO Box 120, Uppsala*

751 04, Sweden). J Comput Phys 107(2) 291-296 (Aug 1993).

In this paper we introduce a method to accelerate the computation of steady state solutions of first-order hyperbolic problems such as the Euler equations. The acceleration method is an improved version of the so-called *implicit residual smoother*. The new version, the *implicit explicit residual smoother* improves damping properties and numerical examples are presented showing considerably reduction in number of iterations needed to reach a steady state soluton.

11A603. Nonreflecting outlet boundary condition for incompressible unsteady Navier-Stokes calculations. - G Jin and M Braza *(Transferts en Ecoulements Laminaires et Turbulents, Inst de Mec des Fluides Toulouse, Lab Associe CNRS, URA D0005, Ave du Professeur Camille Soula, 31400 Toulouse Cedex, France).* J Comput Phys 107(2) 239-253 (Aug 1993).

The goal of this work is to adapt a nonreflecting outlet boundary condition, derived from a wave equation, to the numerical solution of the full incompressible Navier-Stokes equations, for an elliptic unsteady free shear flow. The numerical results show that a significant improvement is achieved with this nonreflecting boundary condition, in comparison with the results obtained by using free boundary layer type conditions. The physical phenomena studied concern the onset of the Kelvin-Helmholtz instability in the free (nonforced) shear layer and certain 2D characteristics of transition towards turbulence. These phenomena are simulated naturally, without imposing perturbations. The frequency of the organized vortices and the spread of the mixing layer are correctly predicted. The performances of the method are shown through comparison with the physical experiments. Owing to the nonreflecting boundary conditions, the feedback noises are inhibited effectively, so that the computation domain can be reduced and the dynamic characteristics of the flow are maintained up clearly to the outlet boundary.

11A604. Upwind finite-volume method with a triangular mesh for conservation laws. - San-Yih Lin, Tsuen-Muh Wu, Yan-Shin Chin *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan, ROC).* J Comput Phys 107(2) 324-337 (Aug 1993).

A new upwind scheme has been developed and analyzed for a finite-volume solution of the conservation laws on triangular meshes. The scheme is an upwind second-order extrapolation with simple local limiters, and it is weakly second-order accurate and satisfies maximum principles. In one dimension, the scheme reduces to a fully upwind second-order scheme with a simple local limiter. Preliminary numerical results demonstrating the performance of the scheme on a variety of initial-boundary value problems are presented. The order of convergence of the scheme is found to vary from 1.6 to 1.9 in L^1.

11A605. A functional approach to the solution of the Karman-Guderley equation. - M Pogu *(Service Math, ECN, 1 Rue La Noe, 44072 Nantes, France)* and G Tournemine *(Lab d'Anal Numer et Mec IRMAR, Univ De Rennes I, Campus Beaulieu, 35042 Rennes Cedex, France).* Bull Polish Acad Sci Tech Sci 40(4) 335-344 (1992).

The expansion procedure for transonic flows, in the first, leads to the Karman-Guderley equation (K-GE). The aim of the article is to propose a functional approach to the K-GE using the Sobolev spaces and an iterative algorithm. From the mathematical point of view there are two fundamental dilemmas. Firstly the equations become locally hyperbolic or elliptic which does not warrant the monotonicity of the associated operators. This lack of monotonicity has been already observed when solving exact equations (EE). Secondly, the expansion procedure implies that the nonlinear term is not so easy to be bounded as in the case of EE. The Kutta-Joukowski condition causes a new difficulty which is avoided here, since symmetrical flows are considered.

11A607. Compression process in a free-piston shock-tunnel. - L Labracherie, MP Dumitrescu, Y Burtschell, L Houas *(Univ de Provence, Lab IUSTI, CNRS ura 1168 Dept MHEQ Fac Saint Jerome, 13397 Marseille Cedex 13, France).* Shock Waves 3(1) 19-23 (1993).

Preliminary results in the Marseille free-piston shock-tunnel facility are presented. The compression of the driver gas by the piston is studied experimentally for two different geometries of the end of the compression tube. Peak pressures obtained with the end of the compression tube closed, and with bursting of the diaphragm separating the high pressure from the low pressure chamber, are compared with calculated values in the cases of N_2 and He as driver gases. A phenomenon of accoustic resonance has been uncovered, generating strong pressure oscillations which, if not properly dealt with, could impair the quality of the useful flow in such a facility.

11A608. Damping of surface pressure fluctuations in hypersonic turbulent flow past expansion corners. - Kung-Ming Chung and Frank K Lu *(Aerodyn Res Center, Mech and Aerospace Eng Dept, Univ of Texas, Arlington TX 76019).* AIAA J 31(7) 1229-1234 (Jul 1993).

Surface pressure fluctuations of Mach 8 turbulent flow past a 2.5- and a 4.25-deg expansion corner maintained a Gaussian distribution but were severely attenuated by the expansion process. The pressure fluctuations did not recover to those of an equilibrium turbulent flow even though the mean pressures reached downstream inviscid values in four to six boundary-layer thicknesses. The fluctuations were convected with a velocity comparable to that on a flat plate, and they maintained their identities longer for the stronger expansion. The damping of pressure fluctuations at hypersonic Mach numbers, even by small corner angles, may be exploited in fatigue design.

11A609. Evaluation of thermochemical models for particle and continuum simulations of hypersonic flow. - ID Boyd and T Gokcen *(Eloret Inst, NASA Ames Res Center, MS 230-2, Palo Alto CA 94035).* J Thermophys Heat Transfer 7(3) 406-411 (Jul-Sep 1993).

Computations are presented for 1D, strong shock waves that are typical of those that form in front of a re-entering spacecraft. The fluid mechanics and thermochemistry are modeled using two different approaches. The first employs traditional continuum techniques in solving the Navier-Stokes equations. The second approach employs a particle simulation technique, the direct simulation Monte Carlo method. The thermochemical model employed in these two techniques are quite different. The present investigation presents an evaluation of thermochemical models for nitrogen under hypersonic flow conditions. Four separate cases are considered that are dominated in turn by vibrational relaxation, weak dissociation, strong dissociation, and weak ionization. In near-continuum, hypersonic flow, the nonequilibrium thermochemical model employed in continuum and particle simulations produce nearly identical solutions. Furthermore, the two approaches are evaluated successfully against available data for weakly and strongly dissociating flows.

11A610. Accuracy of flux-split algorithms in high-speed viscous flows. - D Gaitonde and JS Shang *(Flight Dyn Directorate, WL-FIMM, Wright Lab, WPAFB).* AIAA J 31(7) 1215-1221 (Jul 1993).

The flux-vector split methods of MacCormack and Candler (MC) and of van Leer (vL) and the flux-difference split method of Roe are investigated in problems representative of complex flows under laminar conditions: the blunt-body flow at Mach 16 and the flow past a 24-deg compression corner at Mach 14. Higher order accuracy is obtained with the monotonic upwind-centered scheme for conservation laws approach, viscous terms are centrally differenced, and an implicit relaxation method is employed for time integration. Emphasis is placed on evaluating the accuracy in prediction of surface quantities of engineering interest. The performance of the schemes is problem dependent. For the flow past the blunt body, the surface pressure is insensitive to the method as well as mesh resolution. Both the MC and Roe schemes predict accurate heat transfer rates whereas results with the vL method are dependent on the limiter employed. The overall distinction between the schemes is diminished for the compression corner especially on finer meshes. The extent of the separation region is notably influenced by the choice of the limiter. Several issues relating to the components of the calculation method are examined.

11A611. Central difference TVD schemes for time dependent and steady state problems. - P Jorgenson *(NASA Lewis Res Center, Cleveland OH 44135)* and E Turkel *(Sackler Fac of Exact Sci, Tel-Aviv Univ, Tel-Aviv 69978, Israel)*. J Comput Phys 107(2) 297-308 (Aug 1993).

We use central differences to solve the time dependent Euler equations. The schemes are all advanced using a Runge-Kutta formula in time. Near shocks a second difference is added as an artificial viscosity. This reduces the scheme to a first-order upwind scheme at shocks. The switch that is used guarantees that the scheme is TVD. For steady state problems it is usually advantageous to relax this condition. Then small oscillations do not activate the switches and the convergence to a steady state is improved. To sharpen the shocks different coefficients are needed for different equations, so a matrix-valued dissipation is introduced and compared with the scalar viscosity. The connection between this artificial viscosity and flux limiters is shown. Any flux limiter can be used as the basis of a shock detector for an artificial viscosity. We compare the use of the van Leer, van Albada, minmod, superbee, and the "average" flux limiters for this central difference scheme. For time dependent problems we need to use a small enough time step so that the CFL is less than one even though the scheme is linearly stable for larger time steps. Using a TVB Runge-Kutta scheme yields minor improvements in the accuracy.

11A612. Inviscid finite-volume lambda formulation. - F Casalini and A Dadone *(Inst Macchine Energetica, Politec di Bari, Via Re David 200, Bari 70125, Italy)*. J Propulsion Power 9(4) 597-604 (Jul-Aug 1993).

A finite-volume lambda formulation for solving Euler equations and able to handle compressible as well as transonic flow computations is presented. The easy extension of the methodology to the solution of Navier-Stokes equations is indicated. The integration scheme is in nonconservative form in smooth flow regions in order to take advantage of its superior accuracy and computational efficiency. It automatically switches to conservative form in shock regions, in order to capture them correctly. Computations of 2D and 3D shockless source flows prove the superior accuracy and computational efficiency of the proposed technique in comparison with a classical conservative upwind methodology. Moreover, computed results referring to some 2D and 3D test cases are compared with numerical or experimental published ones, thus showing the capabilities of the proposed formulation to deal with inviscid subsonic as well as transonic flow cases.

11A613. New artificial viscosity method for compressible viscous flow simulations by FEM. - S Boivin *(Dept Info Math, Univ du Quebec a Chicoutimi, G7H 2B1, Canada)* and M Fortin *(Dept of Math, Univ Laval, G1K 7P4, Canada)*. Int J Comput Fluid Dyn 1(1) 25-41 (1993).

A new artificial viscosity method is presented in the context of the resoltuion of the compressible Navier-Stokes equations. The method is used to solve the 2D time dependent equations by FEMs. The results of numerical experiments for the flow around a NACA0012 airfoil are presented and compared to results from a GAMM workshop in order to show the possibilities of the method.

11A614. Nonlinear relaxation Navier-Stokes solver for 3D, high-speed internal flows. - JR Edwards *(Dept of Mech Eng, N Carolina A&T State Univ, Greensboro NC 27411)* and DS McRae *(Dept of Mech and Aerospace Eng, N Carolina State Univ, PO Box 7910, Raleigh NC 27695)*. AIAA J 31(7) 1222-1228 (Jul 1993).

An efficient implicit Navier-Stokes method for computing steady, 3D flowfields characteristic of high-speed propulsion systems is presented. A nonlinear iteration strategy based on planar Gauss-Seidel sweeps is used to drive the solution toward a steady state, with approximate factorization errors within a crossflow plane reduced by the application of a quasi-Newton technique. A hybrid discretization approach is employed, with flux-vector splitting used in the streamwise direction and central differences with artificial dissipation used for the transverse fluxes. Convergence histories and comparisons with experimental data are presented for several 3D shock-boundary-layer interactions. Turbulent closure is provided by a modification of the Baldwin-Barth one-equation model. For the problems considered (206,000-335,000 mesh points), the algorithm provides steady-state convergence in 900-1700 CPU s on a single processor of a Cray Y-MP.

11A615. Pressure-based composite grid method for the Navier-Stokes equations. - JA Wright and W Shyy *(Dept of Aerospace Eng, Mech and Eng Sci, Univ of Florida, Gainesville FL 32611-2031)*. J Comput Phys 107(2) 225-238 (Aug 1993).

In this work, a pressure-based composite grid method is developed for solving the incompressible Navier-Stokes equations on domains composed of an arbitrary number of overlain grid blocks, where a conservative internal boundary scheme is devised to ensure that global conservation is maintained. Issues concerning the differences between the conservative internal boundary scheme developed for the pressure correction method with a staggered grid and that commonly used for density-based methods for compressible flow with nonstaggered grids are discussed. An organizational scheme is developed in order to provide a general and more flexible means for handling arbitrarily overlain grid blocks. Applications of the composite grid method to various model problems with complex geometry are used to illustrate the characteristics of the present procedure.

11A616. Spectral multigrid methods for the reformulated Stokes equations. - W Heinrichs *(Math Inst Heinrich-Heine, Univ Dusseldorf, Universitatsstr 1, D-4000 Dusseldorf 1, Germany)*. J Comput Phys 107(2) 213-224 (Aug 1993).

We present a spectral multigrid method for the reformulated Stokes equations. Here the continuity equation is replaced by a Poisson equation for the pressure. This system is discretized by a spectral collocation method without introducing a staggered grid. We observed no spurious modes except the physical one which is identical to a constant. Hence no filtering techniques are needed. We present an effective finite difference preconditioner which is employed for relaxation inside of the spectral multigrid method. Numercial results are presented which show the efficiency of our method.

11A617. Spectral solution of the viscous blunt-body problem. - DA Kopriva *(Dept of Math and Supercomput Comput Res Inst, Florida State Univ, Tallahassee FL 32306)*. AIAA J 31(7) 1235-1242 (Jul 1993).

The viscous blunt-body problem is solved with a shock-fitted Chebyshev spectral method. No explicit artificial viscosity or filtering is needed to obtain smooth, converged solutions. The method is applied to two problems. First, results for the flow over a right circular cylinder in the Mach number range of 5.5 - 6.0 are compared with experimental data. Second, a solution for a Mach 25 flow over a hyperbolic cone is compared with a viscous shock-layer calculation.

11A618. Vibrations of compressible fluid in a container closed by an elastic cover set in a baffle. - P Capodanno *(Lab Mec Theor UFR, Sci des Tech, F-25030 Besancon Cedex)*. Bull Polish Acad Sci Tech Sci 41(2) 99-110 (1993).

The author considers a 2D system formed by compressible fluid filling a container closed by an elastic cover set in an elastic finite baffle, regarded as a string. He gives a variational formulation of the vibration problem and proves the existence of the eigenfrequencies of the system by means of the functional analysis. He gives an analytical solution in the case of a symmetrical weightless system and a rectangular container.

11A619. Slip effects in a confined rarefied gas I. Temperature slip. - DC Wadsworth *(Dept of Aerospace Eng, Univ of S California, Los Angeles CA 90089-1191)*. Phys Fluids A 5(7) 1831-1839 (Jul 1993).

The model problem of a gas confined between stationary heated plates is analyzed numerically to quantify slip effects for gas densities ranging from near-continuum to highly rarefied conditions. Calculations are performed with the direct simulation Monte Carlo technique using two gas-surface interaction models and with a finite-difference Navier-Stokes method using slip boundary conditions. Comparisons are made with experimental density profiles and with previous discrete ordinate calculations using a model form of the Boltzmann equation. To the resolution of the experimental data, both direct simulation Monte Carlo and the Navier-Stokes equations with slip provide very good agreement for essentially all cases considered, while the discrete ordinate results are less accurate. The calculated pressure and temperature profiles show slightly larger differences. The details of the gas-surface interaction model have a relatively small effect on calculated density profiles. The direct simulation Monte Carlo and no-slip Navier-Stokes results are found to agree quantitatively for all properties at very small Knudsen number [$O(10^{-3})$]. Detailed direct simulation Monte Carlo quantities near the plates are used to quantify discrepancies in the continuum slip models and suggest possible improvements.

11A620. Models of thermal relaxation mechanics for particle simulation methods. - BL Haas *(NASA Ames Res Center, MS 230-2, Moffett Field CA 94035-1000)*, JD McDonald *(MasPar Comput, 749 N Mary Ave, Sunnyvale CA 94086)*, L Dagum *(Comput Sci, NASA Ames Res Center,* *MS T045-1, Moffett Field CA 94035-1000).* J Comput Phys 107(2) 348-358 (Aug 1993).

An improved phenomenological microscopic model is introduced in the present study and compared to existing models for simulating molecular vibrational relaxation in rarefied flows. These models are employed in statistical particle simulation methods such as the direct simulation Monte Carlo technique. In the traditional Borgnakke-Larsen model, collision energies are partitioned among contributing energy modes as dictated by fractions sampled from equilibrium distributions. Application of this method to fully excited continuous energy modes alone, such as in translation-rotation exchange, promotes the equilibrium state. However, application to translation-vibration exchange is afforded by unrealistically approximating the quantized distribution as continuous and partially excited, and employing individual collision "temperatures" in an attempt to capture the temperature-dependence of the necessary distributions. As proven in theoretical and numerical analyses, such an implementation of the Borgnakke-Larsen method may fail to promote the equilibrium relaxed state exactly and poses computational difficulties. The improved technique of the present work iterates between translation-rotation and rotation-vibration exchanges which does promote equilibrium exactly if the model for the latter process is compatible with quantized oscillators. This may be achieved by quantizing the total internal energy of a molecule and dividing the quanta randomly among the rotational and vibrational energy modes. This iteration-equipartition model retains computational simplicity and promotes thermal equilibrium even when applied to multi-species gas mixtures of non-degenerate anharmonic quantized oscillators.

11A621. Optimization of numerical algorithms for internal coordinate molecular dynamics. - VE Dorofeyev and AK Mazur *(Pacific Inst of Bioorganic Chem, Russian Acad of Sci, Vladivostok 690022, Russia).* J Comput Phys 107(2) 359-366 (Aug 1993).

Different computational procedures are compared for numerical solution of equations of motion for molecular dynamics of semi-rigid polymeric molecules with internal coordinates as general variables and an optimal method is proposed. The method uses forced conservation of momentum and angular momentum of the system and a predictor-corrector scheme with several iterations of correction for only generalized velocities at each time step. Variation of the accuracy of numerical solution with the time step and the order of the predictor-corrector algorithm is studied on three different partially fixed models of the oligopeptide $(Ala)_9$. The maximum possible time step gradually increases as fast dof are frozen. For dynamics in torsion angles the method provides a reasonable accuracy for the time step as large as 0.02 ps. The difference between the results obtained here and the earlier estimates made by using Newtonian molecular dynamics with constraints is discussed.

11A622. Application of multi-phase model to the pipe flow of fresh concrete. - Kazumasa Ozawa *(Dept of Civil Eng, Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Japan),* Anura SM Nanayakkara *(Dept of Civil Eng, Univ of Moratuwa, Sri Lanka, Japan),* Koichi Maekawa *(Eng Res Inst, Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Japan).* Proc JSCE 466(V-19) 121-131 (May 1993).

This paper is to propose the mechanical modeling in terms of the collisional and frictional interaction of constituent particles for flowing fresh concrete through pipelines. The multi-phase formulation was adopted as the basis of computing the resistant force to the deformation arising in tapered and bent pipes. The effects of cement paste existing in fresh concrete on the particle interaction of sands and gravels was taken into account. Approximately 20 different mixtures of concrete were examined for verification of the numerical modeling. The analytical model was proved to be versatile to wider variety of fresh concrete having 3-27 cm by slump and any type of deformed pipe unit with different dimensions. It was emphasized that the pump pressure of concrete being driven through the deformed pipe units can be predicted well chiefly by the particle interaction model of aggregates and the multi-phase scheme.

11T623. Dynamics of small, heavy, rigid spherical particles in a periodic Stuart vortex flow. - Kek-Kiong Tio *(Dept of Appl Mech and Eng Sci, UCSD),* AM Ganan-Calvo *(Dept Ing Energetica Fluidomec, ETS Ing Indust Univ, 41012 Sevilla, Spain),* JC Lasheras *(Dept of Appl Mech and Eng Sci, UCSD).* Phys Fluids A 5(7) 1679-1693 (Jul 1993).

11A624. Multi-phase model for flow of liquid-solid assembly through pipelines. - Koichi Maekawa, Kazumasa Ozawa *(Eng Res Inst, Univ of Tokyo, 7-3-1 Hongo Bunkyo-ku, Tokyo 113, Japan),* Anura SM Nanayakkara *(Dept of Civil Eng, Univ of Moratuwa, Sri Lanka, Japan).* Proc JSCE 466(V-19) 109-120 (May 1993).

This paper is to propose the liquid-solid two phase modeling for simulating the flow and segregation of fresh concrete with the authors' intention of getting the mathematical background for mixture design concept serving super fluidized fresh concrete. The multi-component structure of solid phase was newly introduced into the frame of conventional liquid-solid two-phase model in fluid dynamics. The partial stresses carried by gravel, sand, and cement powder were implemented and the compatibility equations derived from experimental works were incorporated in the scheme of formulation for multi-component solid suspended by liquid. For verifying the capability of the physical model concerned, the trial model for particle-to-particle interaction was combined with the entire frame of formulation. It was examined that the model can follow the behaviors qualitatively in terms of the fluidity and segregation of particulate flow.

11T626. Correlation of adiabatic two-phase pressure drop data using the frictional law of corresponding states. - NT Obot, MW Wambsganss, DM France, JA Jendrzejczyk *(Mat and Components Tech Div, ANL).* J Fluids Eng 115(2) 317-323 (Jun 1993).

11A627. Extension and modification of Wohl equation of state. - A Hackel *(OMV Aktiengesellschaft, A-2214 Auersthal, Austria).* Arch Gornictwa 37(4) 447-490 (1992).

The Wohl fourth degree equation of state was modified in order to describe not only as in the past the gas-phase low density region but also and additionally the liquid and the liquid-gas two-phase region. The former negatively considered curvature downwards or the fourth degree Wohl function at high densities was interpreted positively in this work and utilized for the representation of the liquid volume along the two phase envelope. The modification was made in two steps: A-1: A general correlation parameter $t_cP_c(RT_c$ was introduced to correct the first constant b). A-2: The temperature dependent auxiliary functions for the second, ie, $f_a = f(T_r, w)$ and the third term, ie, $f_c = f(T_r, w)$ of the equation of state were newly defined on the bases of the Vetere-Pitzer-Curl correlation. A new definition of the third term is also capable to estimate the general third virial coefficient. The extension of the original Wohl functions was made in one step: B: Its symmetrical function was defined in a manner that the saturation pressure line in the two-phase region becomes the axis of symmetry of both functions in the two-phase region. The application of the Maxwell-Clausius criterion is outlined in detail for this case. The Wohl EQS describes now the liquid and the liquid-gas two-phase envelope besides the low density partition of the gas phase. For the not described rest of the high density gas phase region the modification steps (A 1-2) may be also applied to the constant (b) and the auxiliary temperature dependent function f_a of cubic equations of state especially the common widespread used Redlich-Kwong EQS or other socalled covolume equations of state - without a reflection of the worst of any equation. The limit of validity of the Wohl EQS between the low and high density region in the gas phase may be evenly described analytically by application of the principles of the proposed (A 1-2) to the Joffe-Dieterici EQS. A general application of the outlined modification is therefore possible. The verification of the solved problem was based on the examples of Argon and Nitrogen. For case of comparison all equations were presented in the reduced form.

11A628. Film-thickness, pressure-gradient, and turbulent velocity profiles in annular dispersed flows. - AN Skouloudis and J Wurtz *(Process Eng Div, JRC, Ispra, Commission of the European Communities, 21020 Ispra, Italy).* J Fluids Eng 115(2) 264-269 (Jun 1993).

A regional model has been described for dispersed turbulent two-phase flow which accounts for the transverse variation of velocity. The two-phase turbulence parameters are introduced in direct analogy to well-known single-phase flow parameters which are then correlated to experimental data. The advantages of this approach are its simplicity and the absence of arbitrary parameters which need calibration at different experimental ranges. Its generality has been tested by comparisons at high and low operating pressures with air-water and steam-water mixtures. Comparisons between calculated and measured values have been carried out for the film thickness and the pressure gradient at different experimental setups.

11A630. Discrete particle model for bubble-slug two-phase flows. - JA Trapp *(Colorado and Idaho Natl Eng Lab, Univ of Colorado, Idaho Falls ID 83415)* and GA Mortensen *(Idaho Natl Eng Lab, EG&G Idaho, Idaho Falls ID 83415)*. J Comput Phys 107(2) 367-377 (Aug 1993).

Most two-phase flow models are based on the fully averaged two-fluid concept. This paper describes a new discrete particle model that is intermediate between the numerically intractable local instant description and the fully averaged two-fluid model, thereby providing a more detailed but still tractable description of dynamical two-phase flow phenomena. The new model uses a Lagrangian description for a single dispersed bubble phase and a 1D Eulerian description for a single continuous liquid phase. In contrast to many other particle simulation models, the present model includes compressible phases and large bubbles whose size may be comparable to the computational cell size. The discrete Lagrangian description of the dispersed phase allows the particles to have a distribution of sizes, shapes, etc, thereby capturing the important statistical aspects of dispersed two-phase flow. In contrast to the two-fluid models, the discrete particle model allows the use of more mechanistic models for dispersed phase coalescence and breakup, wakes, etc, thereby allowing the dynamic prediction of flow regime evolution and transitions without the use of flow regime maps inherent in two-fluid models. Numerical simulations for two test problems are presented. Agreement with experimental data is generally satisfactory. Extensions of the model to heat transfer and to two discrete and two continuous phases will be described elsewhere.

11A631. Motion of long bubbles in tubes of square cross section. - WB Kolb and RL Cerro *(Dept of Civil Eng, Univ of Tulsa, Tulsa OK 74104-3189)*. Phys Fluids A 5(7) 1549-1557 (Jul 1993).

The flow of a long bubble in an otherwise liquid-filled tube is a hydrodynamics problem with interesting practical applications in enhanced oil recovery, the coating of monolithic structures, and more recently the design and operation of three-phase monolithic reactors. For intermediate to large capillary numbers the "bubble" is axisymmetric and the theoretical approach of Bretherton can be applied if the velocity profile of the fluid flowing between the bubble and the square tube wall is known. The velocity profile can be computed using an infinite series expansion of harmonic polynomials. A film evolution equation - which includes all the terms that are important throughout the entire bubble profile - is integrated using a parametric representation as a function of arclength and free-surface angle. The flow is analyzed and complete bubble profiles are generated. The results are shown to be in good agreement with experiment.

One of the most important processes that dominate spray combustion efficiency is spray drop deformation and breakup. Krzeckowski has conducted an experimental study of the deformation mechanisms of spray drops. These may be characterized as bag-type shear-type, with some transition in between. The present work is only concerned with the shear-type mechanism. Existing theoretical models for shear-type breakup may be categorized under two main categories. These are the 1) semianalytical and 2) the Taylor analogy models.

360Y. COMPUTATIONAL TECHNIQUES

11A633. Numericl study on the two-phase flow distribution in a T-junction. - LFM Moura *(Mech Eng Dept, Univ of Campinas, Campinas 13081, Brazil)* and KS Rezkallah *(Mech Eng Dept, Univ of Saskatchewan, Saskatoon, S7N 0WO, Canada)*. Int J Numer Methods Fluids 17(3) 257-270 (Aug 1993).

The main objective of this paper is to investigate the ability of a 2D two-fluid computer code to predict the phase separation in a T-junction. A new semi-implicit numerical scheme is developed for solving the two-fluid model equations. Special attention is directed to the modeling of the constitutive equations for the interfacial friction term. Detailed distribution of void fraction, pressure and velocities are obtained for an air-water mixture in a vertical tee. Good agreement was obtained between the computer code results and the experimental data for the phase separation in the T-junction.

11A634. Combined drag effects of riblets and polymers in pipe flow. - GW Anderson, JJ Rohr, SD Stanley *(Naval Ocean Syst Center, San Diego CA 92152)*. J Fluids Eng 115(2) 213-221 (Jun 1993).

The additional skin friction effect produced by a 3M riblet surface, used in conjunction with low concentration polymer solutions, is investigated in fully developed, turbulent pipe flow. Generally at the low concentrations of Polyox 301 and guar gum studied, the absolute drag reduction of the 3M riblets appears to be independent of the polymer presence, with a maximum between 5 and 7 percent occurring around $h^+ = 12$. Comparisons with previous polymer studies with 3M riblets, sand roughened and commercially rough surfaces are made.

In this paper peculiarities of the laminar hypersonic (Mach numbers 4 - 16) boundary layer stability and its transition to the turbulent one are studied experimentally and numerically at different facilities. The influence of various factors on the boundary-layer stability and the transition is considered.

362D. TURBULENT LAYERS

11A636. Frictional drag reduction by injecting high-viscosity fluid into turbulent boundary layer. - H Kato, Y Fujii, H Yamaguchi, M Miyanaga *(Dept of Naval Architec and Ocean Eng, Univ of Tokyo, Bunkyo, Tokyo 113, Japan)*. J Fluids Eng 115(2) 206-212 (Jun 1993).

This paper presents a new method to reduce turbulent frictional drag by injectiug high-viscosity fluid into the boundary layer. When the turbulent region of the boundary layer is filled with high-viscosity fluid, and the viscosity of the viscous sublayer is kept low, the Reynolds stress in the turbulent region is reduced and therefore requires a greater velocity gradient to transfer the momentum. The greater velocity gradient in the turbulent region results in a reduction of the velocity gradient at the viscous sublayer, which causes a drop in shear stress at the wall. Such a boundary-layer structure could be created by injecting two different fluids from double slits on a wall. Sugar syrup and water were used as the high-viscosity fluid and the low-viscosity fluid, respectively. The shear stress was directly measured by shear stress pick-ups mounted flush on the wall. The shearing stress was reduced by more than 50 percent at the optimum injection condition. A water-water injection experiment was also performed to show the effect of injection itself.

11A637. Strong vortex-boundary layer interactions Part II. Vortices low. - AD Cutler *(George Washington Univ, JIAFS NASA Langley Res Center, Hampton VA 23681)* and P Bradshaw *(Dept of Mech Eng, Stanford)*. Exp Fluids 14(6) 393-401 (May 1993).

This is the second of two papers on the interaction between a longitudinal vortex pair, produced by a delta-wing at angle of attack, and a turbulent boundary layer developing on a flat plate. In the first paper only the outer parts of the vortices entered the boundary layer whereas in this paper the vortices merge with it. In the resultant interaction, the boundary layer between the vortices is kept thin by lateral divergence and a 3D separation line is formed outboard of each vortex. Turbulent, momentum-deficient fluid containing longitudinal vorticity is entrained from the boundary layer along these lines and wrapped around the vortices. As a consequence, the turbulent region of the vortices increases in size and the circulation slowly decreases. It is shown that the flow near the separation line and in the vortices is complicated, and this interaction is expected to be more difficult to calculate than the first. Detailed mean flow and turbulence measurements are reported.

11A638. Finite amplitude steady waves in the Blasius boundary layer. - JM Rotenberry *(Dept of Math, S Methodist Univ, Dallas TX 75275)*. Phys Fluids A 5(7) 1840-1842 (Jul 1993).

The stability of the flow over a flat plate to finite amplitude disturbances is studied using a model by Milinazzo and Saffman. The traveling wave solutions which bifurcate from the Orr-

Sommerfeld neutral stability curve to the Blasius profile are calculated numerically. The curve is the intersection of the zero energy plane with a neutral stability surface in energy, Reynolds number, and wave-number space. Although the bifurcation is supercritical at the "nose" of this curve, it is shown that it is subcritical elsewhere and that the minimum Reynolds number for the existence of traveling waves is less than the critical Reynolds number of the Orr-Sommerfeld neutral stability curve. This result suggests that finite amplitude disturbances can initiate transition.

11A639. Nonlinear evolution of secondary instabilities in boundary-layer transition. - JD Crouch *(Boeing Commercial Airplane Group, Seattle WA 98124)* and T Herbert *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. Theor Comput Fluid Dyn 4(4) 151-175 (1993).

Methods of nonlinear stability theory are applied to analyze the evolution of disturbances in the 3D stage immediately preceding the breakdown of a laminar boundary layer. A perturbation scheme is used to solve the nonlinear equations and to develop a dynamical model for the interaction of primary and secondary instabilities. The first step solves for the 2D primary wave in the absence of secondary disturbances. Once this finite-amplitude wave is calculated, it is decomposed into a basic-flow component and an interaction component. The basic-flow component acts as a parametric excitation for the 3D secondary wave, while the interaction component captures the resonance between the secondary and primary waves. Results are presented in two principal forms: amplitude growth curves and velocity profiles. Our results agree with experimental data and the few available results of transition simulations, and moreover, reveal the origin of the observed phenomena. The method described establishes the basis for physical transition criteria in a given disturbance environment.

11A640. Optimization of multiple-panel compliant walls for delay of laminar-turbulent transition. - PW Carpenter *(Dept of Eng, Univ of Warwick, Coventry CV4 7AL, UK)*. AIAA J 31(7) 1187-1188 (Jul 1993).

Previous theoretical work has led to the development of methods for optimizing compliant-wall properties to achieve the greatest possible transition delay for flat-plate boundary-layer flows. It was found that the optimum wall properties for locally reducing the growth of disturbances depend quite strongly on the Reynolds number. This suggests that it would be advantageous to use multiple-panel walls with each compliant panel optimized for a particular Reynolds number range. Accordingly, the optimization procedure is extended to two-panel compliant walls, and the optimum wall properties are determined that correspond to the greatest transition delay. It is found that, based on a conservative value of n = 7, the e^n method predicts that the greatest transitional Reynolds number achievable using single- and two-panel compliant walls is respectively 4.6 and 6.05 times the rigid-wall value. The corresponding wall properties are readily realizable for operation in water, but are probably not feasible in air.

362F. COMPRESSIBLE AND HYPERSONIC LAYERS

11A641. New test cases in compressible thermo-fluid-dynamics. - A Pozzi *(Istituto di Gasdin, Univ di Napoli, Piazzale V Tecchio, Napoli 80-80125, Italy)*, A Bianchini *(Dept of Math, Univ di Ancona, Ancona, Italy)*, AR Teodori *(Dept of Math and Phys, Univ di Camerino, Camerino, Italy)*. Int J Heat Fluid Flow 14(2) 201-205 (Jun 1993).

This paper studies the thermo-fluid-dynamic field generated by a fast stream impinging on a plane. The Mach number is less than one, but not so small that compressibility effects can be neglected. The analysis requires first the nonviscous solution of the basic equation, obtained by assuming the velocity components as independent variables, and then the viscous solution in the boundary-layer approximation. The Dorodnitzin-Stewartson transformation is used to eliminate the dependence of the transport coefficients on the temperature. The values of 1 and 0.74 (air case) for the Prandtl number are considered. The viscous solution, obtained by means of a MacLaurin series of the Pade approximant technique, gives practically exact results.

362G. SHOCK WAVE BOUNDARY LAYER INTERACTION

11A642. High-speed turbulence modeling of shock-wave-boundary-layer interaction. - F Grasso and D Falconi *(Dept di Mec e Aeronaut, Univ di Roma La Sapienza, Via Eudossiana 18, Rome 00184, Italy)*. AIAA J 31(7) 1199-1206 (Jul 1993).

In the present paper some of the recent theoretical developments in compressible turbulence modeling are analyzed, and a model that accounts for compressibility and low Reynolds-number effects is developed. The leading compressibility terms have been identified in the dilatation-dissipation, pressure-dilatation, and the scalar product of the Favre velocity and mean pressure gradient. For the dilatation-dissipation a model similar to that of Zeman has been assumed; the pressure-dilatation is modeled according to Sarkar's model; and the "Favre" contribution has been modeled with a gradient law. The model also accounts for compressibility effects on the von Karman's constant and on the turbulence length scale, which affects the heating rates. A study of hypersonic boundary-layer flows and shock-wave and boundary-layer interactions shows that the effects of compressibility depend on the flow complexity.

11A643. Investigation of a hypersonic crossing shock wave-turbulent boundary layer interaction. - N Narayanswami, DD Knight *(Dept of Mech and Aerospace Eng, Rutgers Univ NJ)*, CC Horstman *(NASA Ames Res Center, Moffett Field CA)*. Shock Waves 3(1) 35-48 (1993).

A combined theoretical and experimental study is presented for the interaction between crossing shock waves generated by (10°, 10°) sharp fins and a flat plate turbulent boundary layer at Mach 8.3. The theoretical model is the full 3D mean compressible Reynolds-averaged Navier-Stokes equations incorporating the algebraic turbulent eddy viscosity model of Baldwin and Lomax. A grid refinement study indicated that adequate resolution of the flowfield has been achieved. Computed results agree well with experiment for surface pressure and surface flow patterns and for pitot pressure and yaw angle profiles in the flowfield. The computations however, significantly overpredict surface heat transfer. Analysis of the computed flowfield results indicates the formation of complex streamline and wave structures within the interaction region.

362M. SEPARATION AND REATTACHMENT

11A644. Investigation of turbulent separation-reattachment flow in a curved-wall diffuser. - Jun-Fei Yin *(Dept of Power Eng, Nanjing Aeronaut Inst, Nanjing 210016, Jiangsu Province, Peoples Rep of China)* and Shao-Zhi Yu *(Dept of Power Eng, Nanjing Aeronaut Inst, Nanjing, Jiangsu Province, Peoples Rep of China)*. Int J Heat Fluid Flow 14(2) 129-137 (Jun 1993).

A 2D laser velocimeter was employed to study the turbulent separation-reattachment flow field in a 2D diffuser, which is a lower curved wall and upper flat plate. There is a parallel channel connected with the exit of the diffuser. In the inlet of the diffuser, the Reynolds number is 5,000 based on the momentum thickness, and the inlet velocity is 25.2m-s. Mean velocity and Reynolds stresses were measured from upstream of the separation to downstream of the reattachment. The minimum distance from the surface is .3 mm. The significant features were that after transitory detachment, within the reversing flow, there exist the second extreme of u^2 and minus of -uv. Normal stresses and the cross-stream pressure gradient are important immediately in the separating flow and are associated with strong streamline curvature. The maximum of the displacement thickness curvature K^x_{max} corresponds to the intermittency transitory detachment. Several velocity profiles and Cebeci and Smith algebraic eddy-viscosity are compared with the experiment. A new approximate correction of the effect of normal stress is proposed and yields results in agreement with the experiment before the transitory detachment.

364B. LAMINAR FLOW

11A647. Laminar, unidirectional flow of thixotropic fluid in a circular pipe. - J Billingham and JWJ Ferguson *(Schlumberger Cambridge Res, High Cross, Madingley Rd, Cambridge CB3 0EL, UK)*. J Non-Newtonian Fluid Mech 47 21-55 (Jun 1993).

In this paper we study the unidirectional, axisymmetric flow of a bentonite mud in a circular pipe. Bentonite mud is an inelastic, thixotropic, generalized-Newtonian fluid. We use a rheological model that characterizes this behavior in terms of a single parameter λ which is a measure of the amount of structure in the fluid. The behavior of λ is determined by a single rate equation which models the tendency of fluid structure to increase whilst being limited by the imposed shear rate. We find that, for certain parameter ranges, the model is not structurally stable, but that this problem can be eliminated by including diffusion of fluid structure. A graph of the equilibrium shear stress for a given shear rate (the rheogram) is not monotonic, yet no mechanical instability occurs in pipe flow. We contrast this with recent work on the pipe flow of a Johnson-Segalman-Oldroyd fluid which displays spurting and oscillatory behavior. The difference lies in the relative magnitude of normal stress effects in the two fluids. There appear to be no grounds for discarding the constitutive model studied here simply because of the nonmonotonicity of the equilibrium rheogram.

364C. TURBULENT FLOW

11A648. Comparison of numerical and experimental results for a turbulent flow field with a longitudinal vortex pair. - JX Zhu, M Fiebig, NK Mitra *(Inst fur Thermo und Fluiddyn, Ruhr-Univ Bochum, 4630 Bochum 1, Germany)*. J Fluids Eng 115(2) 270-274 (Jun 1993).

A numerical simulation of a 3D turbulent flow with longitudinal vortices embedded in the boundary layer on a channel wall is presented. The flow is described by the unsteady incompressible Reynolds averaged Navier-Stokes equations and the standard κ-ε turbulence model. A finite difference scheme based on the SOLA-algorithm is developed for the numerical solution of the governing equations. Comparison with the experimental data of Pauley and Eaton shows that the numerical computations predict the general characteristics of the flow correctly. Agreement to within 13 percent is obtained for the worst location in mean velocity fields. The average deviation of predicted mean streamwise velocity from the experimental data is 3.6 percent.

Generation of tripolar vortical structures on the beta plane. - JS Hesthaven, JP Lynov, JJ Rasmussen *(Optics and Fluids Dyn Dept, Assoc EURATOM, Riso Natl Lab, PO Box 49, DK-4000 Roskilde, Denmark)*, GG Sutyrin *(PP Shirshov Inst of Oceanog, Russian Acad of Sci, 23 Krasikova St, Moscow 117218, Russia)*. Phys Fluids A 5(7) 1674-1678 (Jul 1993).

11A650. Predicting equilibrium states with Reynolds stress closures in channel flow and homogeneous shear flow. - R Abid *(High Tech Corp, NASA Langley Res Center, Hamtpon VA 23681)* and CG Speziale *(Dept of Aerospace and Mech Eng, Boston Univ, Boston MA 02215)*. Phys Fluids A 5(7) 1776-1782 (Jul 1993).

Turbulent channel flow and homogeneous shear flow have served as basic building block flows for the testing and calibration of Reynolds stress models. In this paper, a direct theoretical connection is made between homogeneous shear flow in equilibrium and the log layer of fully developed turbulent channel flow. It is shown that if a second-order closure model of the standard type is calibrated to yield good equilibrium values for homogeneous shear flow, it will also yield good results for the log layer of channel flow provided that the Rotta coefficient is not too far removed from one. Most of the commonly used second-order closure models introduce an *ad hoc* wall reflection term in order to mask deficient predictions for the log layer of channel flow that arise either from an inaccurate calibration of homogeneous shear flow or from the use of a Rotta coefficient that is too large. Illustrative model calculations are presented to demonstrate this point which has important implications for turbulence modeling.

11A651. Analytical solution of flow of second-order non-Newtonian fluids through annular pipes. - Wen-hui Zhu *(Natl Univ of Defence Tech, Changsha, China)* and Ci-qun Liu *(Inst of Porous Flow and Fluid Mech, Langfang, Hebei, China)*. Appl Math Mech 14(3) 209-215 (Mar 1993).

This paper presents an analytical solution to the unsteady flow of the second-order non-Newtonian fluids by the use of integral transformation method. Based on the numerical results, the effect of non-Newtonian coefficient Hc and other parameters on the flow are analyzed. It is shown that the annular flow has a shorter characteristic time than the general pipe flow while the correspondent velocity, average velocity have a smaller value for a given H_c. Else, when radii ratio keeps unchanged, the shear stress of inner wall of annular flow will change with the inner radius compared with the general pipe flow and is always smaller than that of the outer wall.

364K. ROTATING FLUIDS OR SURFACES

364N. ROUGHNESS EFFECT

11A653. Evaluation of open channel flow with varying aspect ratio and roughness ratio. - Yongdi Yang and Atsuyuki Daido *(Dept of Civil Eng, Ritsumeikan Univ, 56-1 Kitamachi Tojin Kitaku, Kyoto 603, Japan)*. Proc JSCE 467(II-23) 103-113 (May 1993).

A flow pattern with varying aspect ratio (breadth-depth) and boundary roughness ratio (bed roughness-side wall roughness) in open channel is proposed in this paper. The distribution of boundary shear and the mean boundary shear are studied. On the basis of this, velocity distribution and flow resistance are further discussed. The evaluation formulate of boundary shear, velocity distribution, and flow resistance are derived systematically. The results are suitable for all aspect ratio and roughness ratio, and are better in agreement with a wide range of experimental data. These are much helpful to the study of sediment transport, flow diffusion, river engineering, etc.

364P. OBSTRUCTIONS

11A654. Experimental study of two flows through an axisymmetric sudden expansion. - WJ Devenport and EP Sutton *(Eng Dept, Cambridge Univ, Trumpington St, Cambridge, UK)*. Exp Fluids 14(6) 423-432 (May 1993).

Two turbulent separated and reattaching flows produced by a sudden expansion in a pipe have been studied. The first was produced by a simple axisymmetric sudden enlargement from a nozzle of diameter 80 mm to a pipe of diameter 150 mm. The second was the flow at the same enlargement with the addition of a center-body 90 mm downstream of the nozzle exit. Detailed measurements of velocity and skin friction (made primarily using pulsed wires) and of wall static pressure are presented. Without the centerbody the flow structure is similar to that observed in other sudden pipe expansions and over backward-facing steps. A turbulent free shear layer, bearing some similarity to that of a round jet, grows from separation and then reattaches to the pipe wall downstream. Reattachment is a comparatively gradual process, the shear layer approaching the wall at a glancing angle. The introduction of the centerbody causes the shear layer to curve towards the wall and reattach at a much steeper angle. Reattachment is much more rapid; gradients of skin friction and pressure along the wall are many times those without the centerbody. The high curvature of the shear layer strongly influences its turbulent structure, locally suppressing turbulence levels and reducing its growth rate.

11A655. Prediction of pressure drop for incompressible flow through screens. - E Brundrett *(Dept of Mech Eng, Univ of Waterloo, Waterloo, ON N2L 3G1, Canada)*. J Fluids Eng 115(2) 239-242 (Jun 1993).

A new pressure loss correlation predicts flow through screens for the wire Reynolds number range of 10^{-4} to 10^4 using the conventional orthogonal porosity and a function of wire Reynolds number. The correlation is extended by the conventional cosine law to include flow that is not perpendicular to the screen. The importance of careful specification of wire diameter for accurate predictions of porosity is examined. The effective porosity is influenced by the shape of the woven wires, by any local damage, and by screen tension.

364R. SECONDARY FLOW, EFFECTS OF CURVATURE

11T656. Behavior of flow in a channel bend with a side overflow (flood relief) channel. - YR Fares *(Dept of Civil Eng, Univ of Surrey, Guildford, UK)* and JG Herbertson *(Dept of Civil Eng, Univ of Glasgow, Glasgow, UK)*. J Hydraul Res 31(3) 383-402 (1993).

11A657. Numerical study of fully developed laminar flow and heat transfer in a curved pipe with arbitrary curvature ratio. - Ru Yang and Sung Fa Chang *(Inst of Mech Eng, Natl Sun Yat-Sen Univ, Kaohsiung, Taiwan, ROC)*. Int J Heat Fluid Flow 14(2) 138-145 (Jun 1993).

A finite-difference numerical method is applied to solve the full Navier-Stokes equations for the fully developed flow and heat transfer in an axially uniformly heated curved pipe with arbitrary curvature ratio (the ratio of the pipe radius to the pipe curvature). Previous studies were restricted to within a range of the curvature ratio less than 0.3. In this study, the ranges of the parameters are the curvature ratio varying from 0.01 to 0.9, the Reynolds number varying from 1 to 2,000, and the Prandtl number varying from 0.7 to 300. The results of the friction ratio and the Nusselt-number ratio are correlated with the parameters of the curvature ratio, the Dean number, and the Prandtl number.

11A658. Reconstruction of 3D particle trajectories in flows through curved circular tubes. - ML Lowe *(Phys Dept, Loyola Col, Baltimore MD 21210)*, PH Kutt *(Phys Dept, Univ of Pennsylvania, Philadelphia PA 19104)*, T York, LA Kazanov, B Leavy *(Phys Dept, Loyola Col, Baltimore MD 21210)*. Exp Fluids 14(6) 402-408 (May 1993).

An automated technique is described for reconstructing 3D trajectories of tracer particles in curved circular ducts. Individual particles are tracked in real time by a rotating camera under computer control. A digital imaging system enables the computer to locate the particle, adjust the speed of rotation, and store position and calibration data. By viewing the tube from approximately orthogonal directions, 3D information on the position of the particle is obtained. Its precise location is calculated by tracing rays from the camera to the interior of the tube. This technique yields detailed 3D position and velocity data along a trajectory.

11A659. Steady, inviscid shock waves at continuously curved, convex surfaces. - B Koren and E van der Maarel *(Center for Math and Comput Sci, PO Box 4079, 1009 AB Amsterdam, Netherlands)*. Theor Comput Fluid Dyn 4(4) 177-195 (1993).

An accurate and efficient numerical method for steady, 2D Euler equations is applied to study steady shock waves perpendicular to smooth, convex surfaces. The main subject of study is the flow near both ends of the hock wave: the shock-foot and shock-tip flow. A known analytical model of the inviscid shock-foot flow is critically investigated, analytically and numerically. The results obtained agree with those of the existing analytical model. For the inviscid shock-tip flow, two existing analytical solutions are reviewed. Numerical results are presented which agree with one of these two solutions. Good numerical accuracy is achieved through a monotone, second-order accurate, finite-volume discretization. Good computational efficiency is obtained through iterative defect correction iteration and a multigrid acceleration technique which employs local grid refinement.

11A660. Torsion effect on fully developed laminar flow in helical square ducts. - Wen-Hwa Chen and R Jan *(Dept of Power Mech Eng, Natl Tsing Hua Univ, Hsinchu 30043, Taiwan ROC)*. J Fluids Eng 115(2) 292-301 (Jun 1993).

The continuity equation and Navier-Stokes equations derived from a nonorthogonal helical coordinate system are solved by the Galerkin FEM in an attempt to study the torsion effect on the fully developed laminar flow in the helical square duct. Since high-order terms of curvature and torsion are considered, the approach is also applicable to the problems with finite curvature and torsion. The interaction effects of curvature, torsion, and the inclined angle of the cross section on the secondary flow, axial velocity, and friction factor in the helical square duct are presented. The results show that the torsion has more pronounced effect on the secondary flow rather than the axial flow. In addition, unlike the flow in the toroidal square duct, Dean's instability of the secondary flow, which occurs near the outer wall in the helical square duct, can be avoided due to the effects of torsion and/or inclined angle. In such cases, a decrease of the friction factor is observed. However, as the pressure gradient decreases to a small value, the friction factor for the toroidal square duct is also applicable to the helical square duct.

364Y. COMPUTATIONAL TECHNIQUES

11A661. Streamwise computation of 3D flows using two stream functions. - MS Greywall *(Dept of Mech Eng, Wichita State Univ, Wichita KS 67208)*. J Fluids Eng 115(2) 233-238 (Jun 1993).

An approach to compute 3D flows using two stream functions is presented. The independent variables used are χ, a spatial coordinate, and ξ and η, value of stream functions along two sets of suitably chosen intersecting stream surfaces. The dependent variables used are the streamwise velocity, and two functions that describe the stream surfaces. Since the value of a stream function is constant along the solid boundaries, this choice of variables makes it easy to satisfy the boundary conditions. To illustrate the approach, computations of incompressible potential flow through a circular-to-rectangular transition duct are also presented.

11A663. Bubbly flows through a converging-diverging nozzle. - R Ishii, Y Umeda, S Murata, N Shishido *(Dept of Aeronaut Eng, Kyoto Univ, Kyoto 606, Japan)*. Phys Fluids A 5(7) 1630-1643 (Jul 1993).

Characteristics of bubbly flow through a vertical, 2D, converging-diverging nozzle are investigated theoretically and experimentally. First, a new model equation of motion governing a dispersed bubble phase is proposed. This is compared in detail with those proposed previously by several researchers. Next, hyperbolicity of the resultant systems of governing equations for the bubbly flow is investigated in detail. Numerical simulations of bubbly flows through a converging-diverging nozzle are carried out by using the proposed system of model equations. In order to check the validity of the numerical results and then the proposed system, they are compared with the experiments which were performed previously in the authors' laboratory in a water-nitrogen blow-down facility. It will be shown that the numerical results obtained by using the proposed system of model equations agree well with the experiments.

11A664. Flow structures and their relevance to passive scalar transport in fume cupboards. - IB Ozdemir, JH Whitelaw *(Dept of Mech Eng, Imperial Col of Sci Tech and Med, London, UK)*, AF Bicen *(Invent UK Ltd, Imperial Col of Sci Tech and Med, London, UK)*. Proc Inst Mech Eng C 207(C2) 103-115 (1993).

This paper describes an experimental investigation of air flow patterns and related passive scalar transport inside an open-fronted containment facility, with emphasis on the interaction with the laboratory environment. Time-averaged and instantaneous structures of the turbulent flow were examined by visualization and local measurements inside the enclosure and at the front aperture of 1200mm × 500mm cross-section. The cabinet was scavenged at an extract flowrate of 0.310 m^3/s with 95% of the air passing through the front aperture at a spatially averaged air velocity of 0.5 m/s and 5% supplied through an auxiliary aperture of 1200mm × 15mm cross-section located at the front edge of the ceiling of the enclosure. Sulphur hexafluoride was used to mark the flow and the distributions of its time-averaged concentration over the front aperture and inside the cabinet were used to deduce the degree of mixing and passive scalar transport. The geometrical features of the cabinet provided a flow field with a spanwise vortex at the upper frontal part of the enclosure, whose cross-sectional dimension was larger close to the side walls where the velocity of the inflowing air was lower than in the central region. The spanwise vortex implemented to improve capture efficiency at low inflowing air velocities can be detrimental to the stability of the inflowing air stream along the sash handle, leading to severe leakage of the passive scalar encapsulated within the vortex itself.

11A665. Spatially resolved birefringence studies of planar entry flow. - SR Galante *(Calgon Water Man, Pittsburgh PA 15230)* and PL Frattini *(Eifle, 11465 Clayton Rd, San Jose CA 95127)*. J Non-Newtonian Fluid Mech 47 289-337 (Jun 1993).

Stress distributions near the re-entrant corners in 2D, 4:1 contraction flows of weakly elastic and more highly elastic poly(dimethylsiloxane) (PDMS) melts were investigated with a high-resolution, polarization modulated flow birefringence method. Measurements were taken at the limiting spatial resolution of 100 μm length scales, and

Weissenberg numbers We of the flows ranged from 0.12 to 0.91. For the weakly elastic liquid, measured profiles of the stress $\tau_{r\theta}$ were in general agreement with predictions of Second Order Fluid theory.

11A666. Flow in the Stirling regenerator characterized in terms of complex admittance Part 1: Theoretical development. - AJ Organ *(Dept of Eng, Univ of Cambridge, UK)*. Proc Inst Mech Eng C 207(C2) 117-125 (1993).

A wire mesh regenerator is studied, with one end closed and the other subject to a harmonic variation of flow. The methods of linear wave analysis are used to determine a *complex input admittance*, Y, for the system. Y is the ratio of the volume flow to pressure excess for a given frequency, and permits piston face pressure waveform to be determined directly in terms of prescribed velocity waveforms. A computational procedure is developed for finding the pressure waveform at the closed end. Computed waveforms are presented and discussed. Energy dissipated per cycle is calculated.

11A667. Flow in the Stirling regenerator characterized in terms of complex admittance Part 2: Experimental investigation. - AJ Organ *(Dept of Eng, Univ of Cambridge, UK)*. Proc Inst Mech Eng C 207(C2) 127-139 (1993).

Experiments are described that support the analysis of the practical Stirling cycle in terms of linear waves. All aspects of the theoretical approach are corroborated, including the incidence of amplitude attenuation and marked phase shift between pressure-time records on either side of the matrix, together with the overriding importance of the dimensionless groups N_{MA} and N_{SG} in characterizing these features.

11A668. Analysis of hypersonic nozzles including vibrational nonequilibrium and intermolecular force effects. - PW Canupp *(Dept of Mech and Aerospace Eng, N Carolina State Univ, Raleigh NC 27695)*, GV Candler *(Dept of Aerospace Eng and Mech, Univ of Minnesota, Minneapolis MN 55455)*, JN Perkins *(Dept of Mech and Aerospace Eng, N Carolina State Univ, Raleigh NC 27695)*, WD Erickson *(Hypersonic Tech Office, NASA Langley Res Center)*. AIAA J 31(7) 1243-1249 (Jul 1993).

A computational fluid dynamics technique is developed for the study of high-pressure, axisymmetric hypersonic nozzle flows. The effects of intermolecular forces and vibrational nonequilibrium are included in the analysis. The numerical simulation of gases with an arbitrary equation of state is discussed. Simulations for high-pressure nitrogen nozzles (p_0 = 138 MPa) demonstrate that both intermolecular forces and vibrational nonequilibrium affect the flow significantly. These nonideal effects tend to increase the Mach number at the nozzle exit plane. In addition, these effects may introduce weak expansion and compression waves in the nozzle that degrade test section flow quality. Thus, they must be included in the design and analysis of high-pressure hypersonic nozzles.

11A669. Multigrid calculation of 3D viscous cascade flows. - A Arnone *(Dept of Energy Eng, Univ of Florence, Via S Marta 3, Florence 50139, Italy)*, M-S Liou *(Internal Fluid Mech Div, NASA Lewis Res Center, Via S Marta 3, Cleveland OH 44135)*, LA Povinelli *(Internal Fluid Mech Div, NASA Lewis Res Center, Cleveland OH 44135)*. J Propulsion Power 9(4) 605-614 (Jul-Aug 1993).

A 3D code for viscous cascade flow prediction has been developed. The space discretization uses a cell-centered scheme with eigenvalue scaling to weigh the artificial dissipation terms. Computational efficiency of a four-stage Runge Kutta scheme is enhanced by using variable coefficients, implicit residual smoothing, and a full-multigrid method. The Baldwin-Lomax eddy-viscosity model is used for turbulence closure. A zonal, nonperiodic grid is used to minimize mesh distortion in and downstream of the throat region. Applications are presented for an annular vane with and without end wall contouring, and for a large-scale linear cascade. The calculation is validated by comparing with experiments and by studying grid dependency.

11A670. Turbulent flow through bifurcated nozzles. - DE Hershey, BG Thomas, FM Najjar *(Dept of Mech and Indust Eng, Univ of Illinois, 1206 W Green St, Urbana IL 61801)*. Int J Numer Methods Fluids 17(1) 23-47 (Jul 1993).

A FE model has been used to study steady-state turbulent flow through bifurcated submerged entry nozzles with oversized ports typical of those used in the continuous casting of steel. Both 2D and 3D simulations have been performed with the commercial code FIDAP, using the standard κ-ϵ turbulence model. Predicted velocities from 3D simulations compare reasonably with experimental measurements using a hot-wire anemometer conducted in a physical water model, where severe turbulent fluctuations are present. Results show that a 2D simulation can also capture the main flow characteristics of the jet existing the nozzle and requires two orders of magnitude less computer time than the 3D simulation. A model combining the nozzle and mould was set up to study the effect of the outlet boundary conditions of the nozzle on the jet characteristics. This modeling technique will assist in the design of submerged-entry nozzles, especially as applied to enhance steel quality in the continuous casting process. Further, the model will provide appropriate inlet boundary conditions for a separate numerical model of the mould.

368. Free shear layers (mixing layers, jets, wakes, cavities, plumes)

368B. LAMINAR INCOMPRESSIBLE

11A671. Experiments on the nonlinear stages of excited and natural planar jet shear layer transition. - FO Thomas and HC Chu *(Hessert Center for Aerospace Res, Dept of Aerospace and Mech Eng, Univ of Notre Dame, Notre Dame IN 46556)*. Exp Fluids 14(6) 451-467 (May 1993).

An experimental investigation focusing on the nonlinear stages of planar jet shear layer transition is presented. Experimental results for transition under both "natural" and low level artificial forcing conditions are presented and compared. The local spectral dynamics of the jet shear layer is modeled as a nonlinear system based upon a frequency domain, second-order Volterra functional series representation. The local linear and nonlinear wave coupling coefficients are estimated from time-series streamwise velocity fluctuation data. From the linear coupling coefficient, the mean dispersion characteristics and spatial growth rates may be obtained. With the estimation of the nonlinear power transfer function, the total, linear and quadratic nonlinear spectral energy transfer may be locally estimated. When these measures are used in conjunction with the local quadratic bicoherency and linear-quadratic coupling bicoherency, the local system output power may be completely characterized and the effect of nonlinearity on local mean flow distortion assessed.

11A672. Periodic flow in the near wake of straight circular cylinders. - P Plaschko *(Dept Fis, Univ Autonoma Metropolitana, Iztapalapa, CP 09340 Mexico DF)*, E Berger *(Hermann-Fottinger Inst, Tech Univ, D-1000 Berlin 12, Germany)*, R Peralta-Fabi *(Fac Ciencias, Dept Fisica, Univ Nacional Autonoma, CP 04510 Mexico DF)*. Phys Fluids A 5(7) 1718-1724 (Jul 1993).

The formation of periodic waves in the near wake of straight circular cylinders with arbitrary aspect ratios in crosswise flows at low Reynolds numbers (Re) is analyzed. Using a semiempirical model it is shown that raising of the Reynolds number beyond a critical value of about $Re^{(1)}$ = 22 yields a supercritical Hopf bifurcation preceding the known onset of the von Karman vortex flow at about $Re^{(2)}$ = 46.7. In agreement with experimental trends a stable periodic, secondary transversal motion arises in the previously steady crosswise flow.

11A673. Structure and flow patterns in turbulent wakes. - F Giralt and JA Ferre *(Escola Tecnica Superior Eng, Univ Rovira i Virgili, Crt de Salou S/n, 43006 Tarragona Catalunya, Spain)*. Phys Fluids A 5(7) 1783-1789 (Jul 1993).

A pattern recognition technique is used to detect and identify patterns and structures embedded in the velocity field of a turbulent wake behind a cylinder. Two component velocities u and v or u and w are measured with eight X-wire anemometers aligned with the vertical and spanwise directions in the wake at x/D = 420 and Re = 1600. The velocity patterns educed as averaged patterns or instantaneous structures are consistent with the presence of double-roller eddies, whose legs are continuously stretched by the rate of strain. Experimental u and v data suggest that the rollers are connected at the top, with vorticity parallel to the cylinder axis, forming a horseshoe vortex. The fine-scale activity, estimated by the envelope of the second derivatives, with respect to time of the velocity signals, confirms that this kind of structure can account for both the uv correlation and the continuous entrainment of potential flow into the wake.

11A674. Vortex shedding and lock-on in a perturbed flow. - MS Hall *(Sci Appl Intl, McLean VA 22102)* and OM Griffin *(Naval Res Lab, Washington DC 20375-5351)*. J Fluids Eng 115(2) 283-291 (Jun 1993).

Vortex shedding resonance or lock-on is observed when a bluff body is placed in an incident mean flow with a superimposed periodic component. Direct numerical simulations of this flow at a Reynolds number of 200 are compared here with experiments that have been conducted by several investigators. The bounds of the lock-on or resonance flow regimes for the computations and experiments are in good agreement. The computed and measured vortex street wavelengths also are in good agreement with experiments at Reynolds numbers from 100 to 2000. Comparison of these computations with experiments shows that both natural, or unforced, and forced vortex street wakes are nondispersive in their wave-like behavior. Recent active control experiments with rotational oscillations of a circular cylinder find this same nondispersive behavior over a three-fold range of frequencies at Reynolds numbers up to 15,000. The vortex shedding and lock-on resulting from the introduction of a periodic inflow component upon the mean flow exhibit a particularly strong resonance between the imposed perturbations and the vortices.

11A675. Wave interactions in the far wake of a body. - CHK Williamson and A Prasad *(Dept of Mech and Aerospace Eng, Upson Hall, Cornell)*. Phys Fluids A 5(7) 1854-1856 (Jul 1993).

There has been some question recently as to whether the far-wake structure of a bluff body is dependent on, or "connected" with, the precise details of the near-wake structure. Indeed, it has previously been assumed that there is no direct connection in scale or frequency. In the present work, observations are shown of a honeycomb-like 3D pattern in the far wake, which is caused by an interaction between the decaying oblique shedding waves from upstream, and large-scale 2D waves in the far wake. A clear "connection" between the 3D scales of the near and far wakes is thereby demonstrated. The symmetry and spanwise wavelength of Cimbala *et al's*, 3D pattern are precisely consistent with such wave interactions. In the presence of parallel shedding, the lack of a honeycomb pattern shows that the pattern is clearly dependent on oblique vortex shedding. It also follows that for oblique shedding, the far-wake 2D waves cannot possibly be the result of vortex pairing.

11T676. Discrete shedding modes in the von Karman vortex street. - M Konig, BR Noack, H Eckelmann *(Max-Planck-Inst Stromungsforschung, Bunsenstr 10, 3400 Gottingen, Germany)*. Phys Fluids A 5(7) 1846-1848 (Jul 1993).

368D. TURBULENT INCOMPRESSIBLE

11A677. Adequacy of the the thin-shear-flow equations for computing turbulent jets in stagnant surroundings. - A el Baz, TJ Craft, NZ Ince *(Mech Eng Dept, UMIST, Manchester, M60 1QD, UK)*, BE Launder *(Mech Eng Dept, UMIST, PO Box 88, Manchester, M60 1QD, UK)*. Int J Heat Fluid Flow 14(2) 164-169 (Jun 1993).

This paper reports that the usual parabolic truncation of the Reynolds equations, used in conjunction with second-moment closure, leads to rates of growth in the self-similar region of the axisymmetric jet in stagnant surroundings that are some 12 percent greater than when the complete (elliptic) equation set is solved. The differences between the Reynolds stress profiles are relatively small, however. A term-by-term examination indicates that the omission of the normal-stress terms in the streamwise momentum equation and of the streamwise diffusion from the ε equation has the greatest effect on the spreading rate, the former raising the rate of spread by about 4.5 percent and the latter by 6 percent. The stress-generation terms associated with streamwise gradients have little effect on spreading rate but modify the stress profiles, particularly in the near-axis region. A comparable exploration for the plane jet shows qualitatively similar behavior, though the influence of the secondary terms arising from streamwise gradients is much less for this flow.

11A678. Flow structure and statistics of a passive mixing tab. - WJ Gretta *(Fluid Syst Eng, Morristown NJ 07960)* and CR Smith *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*. J Fluids Eng 115(2) 255-263 (Jun 1993).

Water channel flow visualization and anemometry studies were conducted to examine the flow structure and velocity statistics in the wake of a passive mixing tab designed for enhancement of cross-stream mixing by generation of flow structures characteristic of turbulent boundary layers. Flow visualization reveals that the mixing tab generates a wake comprising a combination of counterrotating, streamwise vortices enveloped by distinct hairpin vortex structures. The counterrotating streamwise vortices are observed to stimulate a strong ejection of fluid along the symmetry plane, which results in very rapid cross-stream mixing. The hairpin vortices are found to undergo successive amalgamation and coalescence downstream of the device, which aids in the streamwise mixing and outward penetration of ejected fluid. After an initially intense mixing process, the mixing tab wake rapidly develops mean velocity, turbulence intensity, and boundary layer integral properties characteristic of a significantly thickened turbulent boundary layer.

11A679. Observations of large-scale structures in wakes behind axisymmetric bodies. - S Cannon *(McDonnell Douglas Elec Syst, 1801 E St Andrew Pl, Santa Ana CA 92705)*, F Champagne *(Dept of Aerospace and Mech Eng, Univ of Arizona, Tucson AZ 85721)*, A Glezer *(Woodruff Sch of Mech Eng, Georgia Tech)*. Exp Fluids 14(6) 447-450 (May 1993).

Wakes behind disk-shaped axisymmetric bodies of varying solidity are studied using flow visualization and 2D Fourier decomposition of velocity measurements. Evidence of a reverse flow region behind some of the bodies is observed to coincide with the presence of large-scale structures in the near and far wake. Fourier analysis shows that these large-scale structures are predominantly helical ($m = \pm 1$) and occur at a characteristic frequency which corresponds to their wavelength as observed from flow visualization. Our measured value for this characteristic frequency agrees with vortex shedding frequencies observed for these types of wakes.

11A680. Partial cavities: Global behavior and mean pressure distribution. - Q Le *(Natl Polytech Inst, Hanoi, Vietnam)*, JP Franc, JM Michel *(Lab des Ecoulements, Geophys et Indust, Inst de Mec de Grenoble, 38041 Grenoble Cedex, France)*. J Fluids Eng 115(2) 243-248 (Jun 1993).

The results of an experimental work concerning the behavior of flows with partial cavities are presented. The tests were carried out using the plano-convex foil placed in the free surface channel of the IMG Hydrodynamic Tunnel. The experimental conditions concerning ambient pressure, water velocity, and body size were such that various and realistic kinds of flows could be realized. The main flow regimes are described and correlated to the values of foil incidence and cavitation parameter. Attention is paid to the shedding of large vapor pockets into the cavity wake and its possible periodic character. Aside from classical considerations to the cavity length and shedding frequency in the periodic regime, results concerning the wall pressure distribution in the rear part of the cavity are given. They lead to distinguish thin, stable, and closed cavities from the thick ones in which the reentrant jet plays a dominant role for the shedding of vortical structures and the flow unsteadiness.

11A681. Partial cavities: Pressure pulse distribution around cavity closure. - Q Le *(Natl Polytech Inst, Hanoi, Vietnam)*, JP Franc, JM Michel *(Inst de Mec de Grenoble, 38041 Grenoble Cedex, France)*. J Fluids Eng 115(2) 249-254 (Jun 1993).

Pressure pulse height spectra are measured in the case of partial cavitation attached to the leading edge of a hydrofoil. It is shown that the distributions of pressure pulses around cavity closure may significantly differ according to the type of cavity. In the case of a thin, well-closed and stable cavity, the pressure pulse distributions exhibit a strong maximum centered on the visible cavity termination. As the cavity becomes thicker and increasingly open and unsteady, the pressure pulse distribution widens. In the limit case of a cavity periodically shedding bubble clusters, no definite maximum in the pressure pulse distribution is observed. In addition, scaling of pressure pulse height spectra is approached from measurements at two different velocities. It is shown that the pressure pulse height spectra can be correctly transposed from a velocity to another one from two basic scaling rules concerning pulse heights and production rates of bubbles.

11A682. Steady laminar flow of liquid-liquid jets at high Reynolds numbers. - JR Richards, AN Beris, AM Lenhoff *(Dept of Chem Eng, Univ of Delaware, Newark DE 19716)*. Phys Fluids A 5(7) 1703-1717 (Jul 1993).

The axisymmetric steady-state laminar flow of a Newtonian liquid jet injected vertically into another immiscible Newtonian liquid is investigated for various Reynolds numbers. The steady-state solution was calculated by solving the axisymmetric transient equations of motion and continuity using a numerical scheme based on the volume of fluid method combined with the new continuum surface force algorithm. The analysis takes into account pressure, viscous, inertial, gravitational, and surface tension forces. Comparison with previous experimental measurements, performed on a xylene-water system, under conditions where all of these forces are important, shows good agreement over the entire range of conditions studied. Comparisons of the present numerical method with the numerical results of previous boundary-layer methods help establish their range of validity.

11A683. Prediction of turbulent coaxial streams of constant and variable density. - RW Johnson *(Idaho Natl Eng Lab, EG&G Idaho, Idaho Falls ID 83415)*. J Propulsion Power 9(4) 588-596 (Jul-Aug 1993).

The present study investigates the accuracy of well-known turbulence models in simulating the mean velocity, turbulence, and concentration fields for the cases of constant and variable density, turbulent, low Mach number, isothermal, confined coaxial streams of different bulk mean velocities, or axisymmetric mixing layers. The standard $\kappa \sim \varepsilon$ eddy viscosity model and an anisotropic thin shear algebraic stress model (ASM) are employed for the constant density care. Results for the $\kappa \sim \varepsilon$ model are determined to be qualitatively satisfactory and superior to those for the thin shear ASM, though both show excessive radial diffusion of axial momentum. Based on these conclusions, the $\kappa \sim \varepsilon$ model extended for variable density, is used for numerical simulations for a similar flow where the inner stream gas has a density four times that of the outer stream gas. Simulations for the velocity using the $\kappa \sim \varepsilon$ model are again found to be qualitatively accurate. Predictions for the concentration field, however, are in good agreement with the data. The flow fields studied are idealizations of a particular configuration once proposed for a gas core reactor nuclear propulsion engine. Nuclear propulsion for space travel, once considered in the 1960s and early 1970s, is being reconsidered, especially for manned interplanetary travel.

368J. JET-FLOW INTERACTION

11A684. Studies on the flowfield of multijet with square configuration. - GH Moustafa *(Dept of Mech Power Eng, Col of Eng and Tech, Menoufia Univ, Menoufia, Egypt)* and E Rathakrishnan *(Dept of Aerospace Eng, Indian IT, Kanpur 208 016, India)*. AIAA J 31(7) 1189-1190 (Jul 1993).

Measurements of mean velocity, spread rate, and merging point location were made to investigate the flowfield generated by four identical jets of air in a square configuration, issuing from axisymmetric nozzles in a common end wall and mixing with the ambient air. The effect of stagnation pressure ratios as well as the nozzle spacings on the flowfield behavior were investigated. The effect of nozzle configurations was also studied. The results show that the nature of the mean velocity profile as well as the mean velocity decay are unaffected by the pressure ratio. The nozzle spacing effect on the mean velocity decay is only marginal. The four jets interact with axis switching at the midpoint between them, which implies better mixing.

11A685. Visual observations of supersonic transverse jets. - D Papamoschou and DG Hubbard *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717)*. Exp Fluids 14(6) 468-471 (May 1993).

We present experimental results on penetration of round sonic and supersonic jets normal to a supersonic cross flow. It is found that penetration is strongly dependent on momentum ratio, weakly dependent on free-stream Mach number, and practically independent of jet Mach number, pressure ratio, and density ratio. The overall scaling of penetration is not very different from that established for subsonic jets. The flow is very unsteady, with propagating pressure waves seen emanating from the orifice of helium jets.

368K. HEAT OR MASS ADDITION

11A686. Computation of convective heat transfer in rotating cavities. - H Iacovides *(Mech Eng Dept, UMIST, PO Box 88, Manchester, M60 1QD, UK)* and JW Chew *(Design Sci Group, Rolls Royce, Derby, UK)*. Int J Heat Fluid Flow 14(2) 146-154 (Jun 1993).

In this paper, numerical solutions of the Reynolds-averaged Navier-Stokes equations are presented for convective heat transfer inside axisymmetric rotating disc cavities. The study involves the examination of three different disc-cavity configurations and the use of four different mathematical models of turbulence. The three configurations are a rotating cavity with flow entering axially at the center and leaving radially through the outer shroud, a rotating cavity with central axial throughflow, and a rotor-stator system with axial flow injection through the stator center and outflow through the annulus formed between the rotor disc and the outer shroud. Of the four turbulence models, three are based on the zonal modeling approach with the κ-ε model in the main flow region and alternative low-Reynolds number treatments across the near-wall regions. These near-wall alternatives consist of two versions of the mixing-length hypothesis and a one-equation κ-transport model. The fourth turbulence model is the mixing-length hypothesis applied over the entire cavity. Comparisons with available heat transfer measurements show that none of the models is successful in all cases examined. Considering overall performance, the κ-ε model with the one-equation near-wall treatment is preferred.

368Z. EXPERIMENTAL TECHNIQUES

11A687. Measurement and analysis of a small nozzle plume in vacuum. - PF Penko *(Aerospace Eng, NASA Lewis Res Center, Cleveland OH 44135)*, ID Boyd *(Aerospace Eng, Cornell)*, DL Meissner *(Owens Illinois, Toledo OH)*, KJ DeWitt *(Dept of Chem Eng, Univ of Toledo, Toledo OH 43606)*. J Propulsion Power 9(4) 646-648 (Jul-Aug 1993).

There is continuing development of small thrusters that operate on electrical power for both primary and auxiliary satellite propulsion. As a part of this development, a study is in progress to gain a better understanding of thruster-satellite interaction and design considerations in placing electric thrusters on satellites. Of particular interest is the prediction of thruster-plume expansion, especially in the off-axis region where the plume may impinge on spacecraft surfaces. The problem is being approached numerically, by modeling the nozzle flow and plume on both the continuum and molecular level, and experimentally by making plume flowfield measurements in a vacuum facility.

11A688. Mechanism of mode selection in Rayleigh-Benard convection with free-rigid boundaries. - Jiro Mizushima *(Dept of Mech Eng, Fac of Eng, Doshisha Univ, Imadegawa-Dori, Karasuma-Higashi-ru, Kamigyo-ku, Kyoto 602, Japan)*. Fluid Dyn Res 11(6) 297-311 (Jun 1993).

Higher harmonic resonances with wavenumber ratio of 1:2, 1:2:3 and so on are shown to take place in Rayleigh-Benard convection under free-rigid boundary condition. Bifurcation diagrams for 2D motion are obtained for the Prandtl number P = 7. The subharmonic instability is explained by a couple of amplitude equations obtained from weakly nonlinear stability theory. A straightforward extension of the coupled amplitude equations leads to a model which consists of n amplitude equations. The mechanism of mode selection is illustrated by numerical simulations of the model equations.

11A689. Oblique and parallel wave interaction in the near wake of a circular cylinder. - Pan-Mei Yang, Hussein Mansy, DR Williams *(Dept of Mech and Aerospace Eng, Illinois IT, Chicago IL 60616)*. Phys Fluids A 5(7) 1657-1660 (Jul 1993).

Detailed velocity measurements have been made to investigate the structure of the low-frequency vortex dislocations that appear in the indigenous wake of a circular cylinder. It is shown that one mechanism for the production of vortex dislocations is the *superposition* of two waves with slightly different frequencies, where the higher frequency wave is parallel to the cylinder axis and the lower frequency is an oblique wave. In contrast to the discrete vortex concept that implies discontinuous shedding frequencies, the measured amplitude and phase distribution of the interacting waves are shown to be continuous along the span of the cylinder. Both waves (parent modes) exist simultaneously and overlap in the wake. The difference mode associated with the vortex dislocations is produced by the nonlinear interaction of the parent modes, and its maximum amplitude is at the location where the parent modes have comparable magnitude. The spanwise phase and amplitude distributions of the difference modes are "predicted" by taking the product of the complex wave amplitudes of the parent modes.

11A690. Linear stability analysis of cone and plate flow of an Oldroyd-B fluid. - DO Olagunju and LP Cook *(Dept of Math Sci, Univ of Delaware, Newark DE 19716)*. J Non-Newtonian Fluid Mech 47 93-105 (Jun 1993).

A linear stability analysis of the cone and plate flow of an Oldroyd-B fluid is carried out. We show that the base flow is stable to a class of axisymmetric perturbations provided that the Deborah number is less than a critical value and that at the critical value there is exchange of stability. The value of the critical Deborah number for both creeping and non-creeping flow is obtained. The critical value of the Deborah number at which instability is predicted for non-creeping flows is shown to be less than the value for creeping flows, indicating that inertia is destabilizing.

11T691. Linearized approximation of the Benard convection problem. - JC Song *(Dept of Math, Hanyang Univ, Ansan, Kygunggido, 425-791, Seoul, Korea)*. Stability Appl Anal Continuous Media 2(1) 1-11 (Mar 1992).

11A692. Kelvin-Helmholtz instability for surface waves in currents of uniform vorticity. - I Brevik and H Sund *(Dept of Appl Mech, Univ of Trondheim NTH, N-7034 Trondheim, Norway)*. Phys Fluids A 5(7) 1644-1650 (Jul 1993).

The Kelvin-Helmholtz instability is investigated for the case when linear monochromatic water waves of wave number k are propagating in a current whose undisturbed horizontal velocity profile is linear down to some depth h, and zero beneath. The present paper generalizes the work of Esch to the case of finite water depth D. Surface tension is neglected. The result of the analysis is a quartic equation for the phase velocity. The presence of a finite water depth tends to stabilize the flow field. The interval in kh, for which complex roots of the dispersion equation occur, becomes narrower as the depth increases. Also, the growth rate of the flow decreases. The main results are illustrated graphically, and supplemented by analytic approximations in the limiting case when D/h lies close to unity.

372. Turbulence

372A. GENERAL THEORY

11A693. Investigation of the turbulent model for pressure fluctuations with spectral theory. - Sheng Jin and Han-gen Ni *(Dalian IT, Dalian, China)*. Appl Math Mech 14(4) 353-360 (Apr 1993).

The pressure fluctuations in turbulent shear flows are investigated with the theory of spectral analysis. An expression for pressure spectra is analytically derived in terms of velocity spectra. This deviation is based on a formal solution of the Navier-Stokes equation and the quasi-normal assumption to express the third and fourth order velocity correlations in terms of double velocity correlation. Then, a turbulent model for the computation of pressure fluctuation intensity with Reynolds stress and mean flow velocity gradients is established. The turbulent constants in the model are calculated from the assumptions that the general behavior of velocity spectra in high Reynolds number flows. Comparison with direct simulation of turbulent boundary-layer is made. It is found that the turbulent-turbulent, cross correlation, and turbulent-shear source terms for mean square value of pressure fluctuation are about the same magnitude.

11A695. Analysis of subgrid-scale interactions in numerically simulated isotropic turbulence. - J Andrzej Domaradzki, Wei Liu *(Dept of Aerospace Eng, Univ of S California, Los Angeles CA 90089-1191)*, ME Brachet *(Lab Phys Stat, Ecole Normale Superieure, 75231 Paris, Los Angeles, Cedex 05, France)*. Phys Fluids A 5(7) 1747-1759 (Jul 1993).

Using a velocity field obtained in a direct numerical simulation of isotropic turbulence at moderate Reynolds number the subgrid-scale energy transfer in the spectral and the physical space representation is analyzed. The subgrid-scale transfer is found to be composed of a forward and an inverse transfer component, both being significant in dynamics of resolved scales. Energy exchanges between the resolved and unresolved scales from the vicinity of the cutoff wave number dominate the subgrid-scale processes and the energetics of the resolved scales are unaffected by the modes with wave numbers greater than twice the cutoff wave number. Correlations between the subgrid-scale transfer and the large-scale properties of the velocity field are investigated.

11A696. Study of multiscalar mixing. - SS Girimaji *(ASM, Hampton VA 23666)*. Phys Fluids A 5(7) 1802-1809 (Jul 1993).

A model for passive mixing of multiple scalars in homogeneous turbulence is developed. This model is based on the time-evolving mapping closure methodology. Calculations from the model are compared against heat conduction simulations (HCS) data. The agreement is excellent at the early stages of mixing and at the later stages it is fair.

11T697. Universal form of energy spectra in fully developed turbulence. - Zhen-Su She *(Dept of Math, Univ of Arizona, Tucson AZ 85721)* and E Jackson *(Program in Appl and Comput Math, Princeton)*. Phys Fluids A 5(7) 1526-1528 (Jul 1993).

372F. FREE SHEAR LAYERS

11A698. Behavior of streamwise rib vortices in 3D mixing layer. - JM Lopez *(Dept of Math, Penn State)* and CJ Bulbeck *(Defence Sci and Tech Org, Air Operations Div, Aeronaut Res Lab, Melbourne, Australia)*. Phys Fluids A 5(7) 1694-1702 (Jul 1993).

The structure and behavior of a streamwise rib vortex in a direct numerical simulation of a time-developing 3D incompressible plane mixing layer is examined. Where the rib vortex is being stretched, the vorticity vector is primarily directed in the vortex axial direction and the radial and azimuthal velocity distribution is similar to that of a Burgers vortex. In the region where the vortex stretching is negative, there is a change in the local topology of the vortex. The axial flow is decelerated and a negative azimuthal component of vorticity is induced. These features are characteristic of vortex breakdown. The temporal evolution of the rib vortex is similar to the evolution of an axisymmetric vortex in the early stages of vortex breakdown. The effect of vortex breakdown on the other parts of the flow is, however, not as significant as the interaction between the rib vortex and other vortical structures.

372G. BOUNDARY LAYERS

11A699. Kolmogorov behavior of near-wall turbulence and its application in turbulence modeling. - Tsan-Hsing Shih *(Center for Model of Turbulence and Transition, ICOMP, NASA Lewis Res Center)* and JL Lumley *(Cornell)*. Int J Comput Fluid Dyn 1(1) 43-56 (1993).

The near-wall behavior of turbulence is re-examined in a way different from that proposed by Hanjalic and Launder and followers. It is shown that at a certain distance from the wall, all energetic large eddies will reduce to Kolmogorov eddies (the smallest eddies in turbulence). All the important wall parameters, such as friction velocity, viscous length scale, and mean strain rate at the wall, are characterized by Kolmogorov microscales. According to this Kolmogorov behavior of near-wall turbulence, the turbulence quantities, such as turbulent kinetic energy, dissipation rate, etc at the location where the large eddies become "Kolmogorov" eddies, can be estimated by using both direct numerical simulation (DNS) data and asymptotic analysis of near-wall turbulence. This information will provide useful boundary conditions for the turbulent transport equations. As an example, the concept is incorporated in the standard κ-ε model which is then applied to channel and boundary layer flows. Using appropriate boundary conditions (based on Kolmogorov behavior of near-wall turbulence), there is no need for any wall-modification to the κ-ε equations (including model constants). Results compare very well with the DNS and experimental data.

11A700. Measurements in a pressure-driven 3D turbulent boundary layer during development and decay. - WR Schwarz *(Dept of Mech Eng, Stevens IT, Hoboken NJ 07030)* and P Bradshaw *(Dept of Mech Eng, Stanford)*. AIAA J 31(7) 1207-1214 (Jul 1993).

Measurements of the turbulence structure in the outer layer of a 3D turbulent boundary layer were made in an open-circuit low-speed blower tunnel. The 3D turbulent boundary layer on the floor of the tunnel was generated by a cross-stream pressure gradient using a 30-deg bend in the horizontal plane. Downstream of the bend, the 3D turbulent boundary layer gradually relaxed toward a 2D turbulent boundary layer as the crossflow decayed slowly after the cross-stream pressure gradient was removed. Mean velocities were measured with a three-hole pressure probe, and turbulence quantities, which included the Reynolds-stress tensor and the triple products, were measured with a cross-wire hot-wire anemometer. The experiment provides new data that isolate the effects of crossflow from the effects of an adverse streamwise pressure gradient that may have clouded the interpretations of previous 3D turbulent boundary-layer experiments. Another advance over previous work is that enough turbulence quantities were measured for all terms in the Reynolds-stress transport equations to be evaluated, allowing term-by-term tests of stress-transport turbulence models.

11A701. New time scale based κ-ε model for near-wall turbulence. - Z Yang and TH Shih *(Center for Model of Turbulence and Transition, Inst for Comput Mech in Propulsion, NASA Lewis Res Center, Cleveland OH 44135)*. AIAA J 31(7) 1191-1198 (Jul 1993).

A κ - ε is proposed for wall-bounded turbulent flows. In this model, the eddy viscosity is characterized by a turbulent velocity scale and a turbulent time scale. The time scale is bounded from below by the Kolmogorov time scale. The dissipation equation is reformulated using this time scale, and no singularity exists at the wall. The damping function used in the eddy viscosity is chosen to be a function of $R_y = (\kappa^{1/2}y/\nu)$ instead of y^+, as in the Lam and Bremhorst model. Hence, the model could be used for flows with separation. The model constants used are the same as in the high Reynolds number standard κ - ε model. Thus, the proposed model will also be suitable for flows far from the wall. Turbulent channel flows at different Reynolds numbers and turbulent boundary-layer flows with and without pressure gradient are calculated. Results show that the model predictions are in good agreement with direct numerical simulation and experimental data.

11A702. One-equation near wall turbulence modeling with the aid of direct simulation data. - W Rodi *(Univ of Karlsruhe, Karlsruhe, Germany)*, NN Mansour *(NASA Ames Res Center, Moffett Field CA 94035)*, V Michelassi *(Univ of Florence, Florence, Italy)*. J Fluids Eng 115(2) 196-205 (Jun 1993).

The length scales appearing in the relations for the eddy viscosity and dissipation rate in one-equation models were evaluated from direct numerical (DNS) simulation data for developed channel and boundary-layer flow at two Reynolds numbers each. To prepare the ground for the evaluation, the distribution of the most relevant mean-flow and turbulence quantities is presented and discussed, also with respect to Reynolds-number influence and to differences between channel and boundary-layer flow. An alternative model is examined in which $(v'^2)^{1/2}$ is used as velocity scale instead of $k^{1/2}$. With this velocity scale, the length scales now appearing in the model follow closely a linear relationship near the wall. The resulting length-scale relations together with a DNS based relation between v'^2/k and $y\times = k^{1/2}y/\nu$ form a new one-equation model for use in near-wall regions. The new model was tested as near wall component of a two-layer model by application to the developed-channel, boundary-layer and backward-facing-step flows.

11A703. Two-way interaction between homogeneous turbulence and dispersed solid particles I. Turbulence modification. - S Elghobashi and GC Truesdell *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717)*. Phys Fluids A 5(7) 1790-1801 (Jul 1993).

The modification of decaying homogeneous turbulence due to its interaction with dispersed small solid particles ($d/\eta < 1$), at a volumetric loading ratio $\phi_u \leq 5 \times 10^{-4}$, is studied using direct numerical simulation. The results show that the particles increase the fluid turbulence energy at high wave numbers. This increase of energy is accompanied by an increase of the viscous dissipation rate, and, hence, an increase in the rate of energy transfer T(k) from the large-scale motion. Thus, depending on the conditions at particle injection, the fluid turbulence kinetic energy may increase initially. But, in the absence of external sources (shear or buoyancy), the turbulence energy eventually decays faster than in the particle-free turbulence. In gravitational environment, particles transfer their momentum to the small-scale motion but in an *anisotropic* manner. The pressure-strain correlation acts to remove this anisotropy by transferring energy from the direction of gravity to the other two directions, *but at the same wave number*, ie, to the small-scale motion in directions normal to gravity. This input of energy in the two directions with lowest energy content causes a *reverse cascade*. This reverse cascade tends to build up the energy level at lower wave numbers, thus reducing the decay rate of energy as compared to that of either the particle-free turbulence or the zero-gravity particle-laden flow.

An evaluation of some numerical methods for turbulent reacting flows in furnace-like geometries is carried out. The Reynolds averaged Navier-Stokes equations and the two-equation κ - ε model together with either finite-rate or infinite-rate reaction models are solved numerically. Either single- or multiple-step reactions together with the "eddy dissipation concept" (EDC) are used to model reacting flows with finite reaction rates. The numerical scheme is finite difference based, together with a multi-grid method and a local grid refinement technique. These methods have been used to calculate the combustion of propane in a single- and multiple-burner configurations. In the former case, the sensitivity of the solution to variations in some model parameters (determining the reaction rate) and numerical parameters (mesh spacing) has been studied. It is noted that different dependent variables exhibit different levels of sensitivity to the variation in model parameters. Thus, calibration and validation of models for reacting flows require that one compares that most *sensitive* variables. For engineering purposes, on the other hand, one may calibrate and validate models with respect to the most *relevant* variables. Our conclusion is that since sensitivity of the temperature distribution is relatively mild, one can still use EDC-like methods in engineering applications where details of the temperature field are of minor importance.

11A707. Three-dimensional mesh embedding for the Navier-Stokes equations using upwind control volumes. - BL Lapworth *(Rolls Royce, PO Box 31, Derby DE2 8BJ, UK)*. Int J Numer Methods Fluids 17(3) 195-220 (Aug 1993).

A numerical model for the compressible Navier-Stokes equations using local mesh embedding is presented. The model solves for 3D turbulent flow using an algebraic mixing length model of turbulence. The technique of control volume upwinding is used to produce a novel treatment, whereby the hanging nodes on the mesh interfaces are left with null control volumes. This yields an efficient discretization scheme which ensures second-order accuracy, flux conservation and stability at the mesh interfaces, whilst retaining a simple interpolative treatment for the hanging nodes. The discrete flow equations are solved using the semi-implicit pressure correction method. The accuracy of the embedded mesh solver is demonstrated by modeling the 3D flow through a cascade of turbine vanes at design and off-design conditions. Mesh embedding gives a saving of 48% in the number of nodes. The embedded mesh solutions compare well with fine structured mesh solutions and experimental measurements. The capability of the embedded mesh solver to perform solution adaptive calculations is demonstrated using a 2D mid-height section of the cascade at the off-design flow conditions.

372Z. EXPERIMENTAL TECHNIQUES

11A708. Note on secondary flows in oscillating-mixing-box experiments. - HJS [illegible] IPD De Silva *(Dept of Mech and [illegible] Arizona State Univ, Tempe AZ)* [illegible]hys Fluids A 5(7) 1849-1851 (Jul 1993).

Oscillating-grid induced turbulence in confined geometries (tanks) is commonly used in the study of turbulence with zero-mean shear. It is demonstrated that the mean secondary circulation generated during such experiments can be reduced by selecting conditions that lessen the Reynolds-stress gradients within the fluid. A simple power law for the spatial decay of turbulent velocity fluctuations is realized only in the absence of such mean circulation.

11A709. Modified theory of ferroelectric liquid crystals as micropolar medium on bundle space constitutive equations. - CZ Rymarz *(Military Univ of Tech, Warszawa, Poland)*. J Tech Phys 34(2) 185-197 (1993).

In this paper the verification and extension of the paper has been presented. The verification concerns the kinematics and, mostly, the conservation law and equations of evolution of the considered medium. The extension concerns the construction of the constitutive equations for nondissipative stresses and internal body force. The paper contains some necessary remarks on the kinematics of the considered medium, which supplement the results presented, derivation of the evolution equations from the conservation laws, both in the Euclidean space and in the fibre space, and the construction of the constitutive equations for the ferroelectric liquid crystalline medium. In the kinematics the components of directors d_k are presented as functions of the Euler angles ϕ, μ, ψ, which are microstructural dof. The simplified relations of the components of directors corresponding to the straight or slightly bent smectic layers have been presented. The generalized momentum conservation law in fibre space is introduced and the role of the angular momentum conservation law is discussed. The set of constitutive arguments is established, the integrity base and the set of invariants of the group of material symmetry are obtained. The constitutive relations for nondissipative stresses and internal body force are constructed.

11A710. Electromagnetic billards. - R Bolcato, J Etay, Y Fautrelle *(MADYLAM-ENSHMG-BP95-38402, St Martin D'Heres, Cedex, France)*, HK Moffatt *(DAMTP-Cambridge Univ, Silver St, Cambridge CB3 9EW, UK)*. Phys Fluids A 5(7) 1852-1853 (Jul 1993).

Moffatt has argued that it should be possible to control the motion of a metallic sphere immersed in a nonconducting fluid using the electromagnetic force and couple generated by means of a traveling and/or rotating magnetic field applied externally. Such a system has been realized experimentally: one or more aluminum spheres are placed in a vessel containing fluid (air, water, or silicone oil), the whole being placed in an inductor which provides an upward-traveling magnetic field. The spheres move in response to the induced electromagnetic forces, the motion being influenced by gravity, viscous drag, vessel boundary reaction, and collisions. A range of possible behaviors, stable, unstable, and chaotic, are identified and discussed. The term "electromagnetic billiards" seems appropriate to describe this phenomenon.

11A711. Bounded multi-scale plasma simulation: Application to sheath problems. - SE Parker *(Electron Res Lab, UCB)*, A Friedman, SL Ray *(LLNL)*, CK Birdsall *(Electron Res Lab, UCB)*. J Comput Phys 107(2) 388-402 (Aug 1993).

In our previous paper we introduced the *multi-scale* method, a self-consistent plasma simulation technique that allowed particles to have independent timesteps. Here we apply the method to 1D electrostatic bounded plasma problems and demonstrate a significant reduction in computing time. We describe a technique to allow for variable grid spacing and develop consistent boundary conditions for the direct implicit method. Also discussed are criteria for specifying timestep size as a function of position in phase space. Next, an analytically solvable sheath problem is presented, and a comparison to simulation results is made. Finally, we show results for an ion acoustic shock front propagating toward a conducting wall.

11A712. Implementation of a semi-implicit orbit-averaged gyrokinetic particle code. - BI Cohen and TJ Williams *(LLNL)*. J Comput Phys 107(2) 282-290 (Aug 1993).

A semi-implicit orbit-averaged time-integration algorithm has been successfully implemented in a gyrokinetic particle simulation code for the study of self-consistent phenomena in a strongly magnetized plasma. The semi-implicit aspect of the integration scheme relaxes the timestep constraints required to ensure numerical stability. The orbit averaging is useful in reducing statistical noise and relaxes the statistical constraints for kinetic simulation. For appropriate applications, the semi-implicit orbit-averaged algorithm should be more efficient than are traditional particle-in-cell plasma simulation algorithms with explicit time-integration schemes. Both a linear numerical dispersion analysis and illustrative simulation examples are presented.

11A713. Partially linearized algorithms in gyrokinetic particle simulation. - AM Dimits *(LLNL)* and WW Lee *(Plasma Phys Lab, Princeton)*. J Comput Phys 107(2) 309-323 (Aug 1993).

In this paper, particle simulation algorithms with time-varying weights for the gyrokinetic Vlasov-Poisson system have been developed. The primary purpose is to use them for the removal of the selected nonlinearities in the simulation of gradient-driven microturbulence so that the relative importance of the various nonlinear effects can be assessed. It is hoped that the use of these procedures will result in a better understanding of the transport mechanisms and scaling in tokamaks. Another application of these algorithms is for the improvement of the numerical properties of the simulation plasma. For instance implementations of such algorithms (1) enable us to suppress the intrinsic numerical noise in the simulation, and also (2) make it possible to regulate the weights of the fast-moving particles and, in turn, to eliminate the associated high frequency oscillations. Examples of their application to drift-type instabilities in slab geometry are given. We note that the work reported here represents the first successful use of the weighted algorithms in particle codes for the nonlinear simulation of plasmas.

376. Naval hydromechanics

11A714. SES Dynamics in the vertical plane. - AJ Sorensen, S Steen *(Div of Marine Hydrodyn, Norwegian IT, N7034 Trondheim, Norway)*, OM Faltinsen *(Postfach 52 03 65 Elbschaussee 277, 2000 Hamburg 52, Germany)*. Ship Tech Res 40(2) 71-94 (May 1993).

The dynamic response of Surface Effect Ships (SES) advancing at high speed in waves is studied. The results show dominating vertical accelerations in a frequency range of importance for passenger comfort and crew workability. These vibrations are analyzed using a mathematical model for the air cushion. It accounts for the motions and accelerations in heave and pitch induced by both the dynamic uniform and the spatially varying air cushion pressure. The latter is described by a modal representation. High ride quality can be achieved by compensating for these vibrations using a ride control system. Based on a mathematical model of such a system it is shown that optimal placement of the fan and the ride control system gives a significant improvement in ride quality.

378. Aerodynamics

11A715. Control of vortices on a delta wing by leading-edge injection. - W Gu, O Robinson *(Lehigh Univ, Bethlehem PA 18015)*, D Rockwell *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*. AIAA J 31(7) 1177-1186 (Jul 1993).

This experimental investigation addresses the control of flow past a half-delta wing at high angle of attack. Application of steady blowing, steady suction, or alternate suction-blowing in the tangential direction along the leading edge of the wing can retard substantially the onset of vortex breakdown and stall. The most effective period of the alternate suction-blowing is on the order of one convective time scale of the flow past the wing. As a result of this type of control, the vortex structure in the crossflow plane is modified from a fully stalled condition to a highly coherent leading-edge vortex. This transformation to a restabilized vortex is represented by instantaneous velocity fields, streamline patterns, and vorticity contours.

11A716. Major linear control problem. - AA Baloev and TK Sirazetdinov *(Izvestiya VUZ, Aviatsionnaya Tekhnika, Russia)*. Russian Aeronaut 35(4) 12-19 (1992).

We consider the stochastic alternate of solution of the major problem of control in the linear stationary formulation. We perform the numeric search method using as the base the method for constructing the linear differential equations.

11A717. Aerodynamic design and investigation of a high-loaded turbine. - J Guiming *(Marine Boiler and Turbine Res Inst, PO Box 77 Harbin, Heilongjiang Province 150036, Peoples Rep of China)*. Int J Turbo Jet Engines 10(1) 19-30 (1993).

This paper presents a design method with its specific features of a high-loaded turbine stage through a design practice to change a two-stage marine power turbine to a one-stage one. The design was conducted by using the meridional streamline curvature method based on a full radial equilibrium. In the design, a controlled vortex concept was adopted so as to attain a high-loaded stage. The advantages and disadvantages of the high-loaded turbine design are discussed through an analysis and comparison of both design results. In particular, some views and comments are made in this paper with respect to marine power turbine engine.

11A718. Complete thrust vectoring flight control for future civil jets, F-22 superiority fighter and cruise missiles Part I. Vectored F-22, F-16, and F-15. - B Gal-Or, V Sherbaum, M Lichtsinder, M Turgemann *(Jet Lab Technion, Israel IT, Haifa 32000, Israel)*. Int J Turbo Jet Engines 10(1) 1-17 (1993).

Tailless vectored F-22, F-16, F-15, stealth cruise missiles, stealth unmanned vehicles and civil-cargo designs are investigated. The fastest possible "Cobra" and Herbst-turn-back maneuvers are flight-demonstrated via new unique thrust-vectoring techniques. Maximized vectoring agility-controllability is flight-demonstrated by scaled F-22, F-16, F-15, and other prototypes. Introducing vectoring control laws and laboratory and flight-tests proves that new, fast-responding, roll-yaw-pitch nozzles, provide alternative flight-control for military and civil vehicles. Unaffected by flow on conventional fight control (CFC) surfaces, complete thrust-vectoring flight control (TVFC) dramatically enhances safety-agility-effectiveness during critical take-off, landing, spin, CFC-damage, and offensive-defensive, air-to-ground and air-to-air, post-stall combat maneuvers. Vulnerability, accuracy, terrain-following, range, payload, stealth limits, and final maneuverability of manned and unmanned vehicles, including cruise missiles, are expected to be significantly improved via proper CFC-TVFC.

11A719. Propulsion system flight test analysis using model techniques. - SJ Khalid *(Pratt & Whitney, PO Box 109600, W Palm Beach FL 33410-9600)* and MF Faherty *(General Dyn, Ft Worth TX)*. Int J Turbo Jet Engines 10(1) 31-43 (1993).

This paper presents the use of these analytical tools in emulating the in-flight performance and operation of a modern fighter engine designed to meet stringent operational requirements. The pre-flight predictions and accurate post-flight analyses contributed to the successful flight test evaluation of the F100-PW-229 (PW229) engine, which is an increased thrust derivative of the highly successful F100-PW-220 (PW220) engine. The use of simulation in the thorough pre-flight checkout of every logic path of the digital control is illustrated with the example of an enhanced failure mode accommodation of the PW229 Improved Digital Electronic Control. This increased capability control and its thorough verification, adds to the confidence in the safety and dependability of single engine installations. The suitability of the state-variable piece-wise linear model for the functional checkout of the control logic and for continuous engine performance synthesis over long periods of thermal non-equilibrium is explained. For applications requiring increased accuracy, use of test data driven nonlinear dynamic engine model is preferred and is illustrated by determining in-flight thrust response to small throttle movements. The significance of this analysis is that it helps identify small perturbation response requirements which greatly influence airplane handling during formation flying, refueling, approach, and landing. In addition, the paper includes calculation of quasi-steady net propulsive force and specific excess power which is substantiated by measured airplane acceleration.

11A720. Cryogenic wind tunnel. - MJ Goodyer *(Dept of Aeronaut and Astronaut, Univ of Southampton, Southampton, UK)*. Prog Aerospace Sci 29(3) 193-220 (1992).

Until recently engineers have been unable to reach full scale Reynolds number in most wind tunnel tests. The cryogenic wind tunnel has been introduced to provide the aerospace community with the means to test models at near-full-scale Reynolds numbers, satisfying a particular need at transonic speeds. The background to the need for high Reynolds number wind tunnels is outlined together with options. The main advantages of the cryogenic option are highlighted which led to this type being adopted for transonic testing. The novel technology is described together with brief descriptions of several of the more major tunnel projects.

11A721. Conservation of rothalpy in turbomachines. - FA Lyman *(Dept of Mech and Aerospace Eng, Syracuse Univ, Syracuse NY 13244-1240)*. J Turbomachinery 115(3) 520-526 (Jul 1993).

The conditions under which rothalpy is conserved are investigated by means of the energy and moment-of-momentum equations for unsteady flow of a viscous, compressible fluid. Differential and integral equations are given for the total enthalpy and rothalpy in both stationary and rotating coordinates. From the equations in rotating coordinates it is shown that rothalpy may change due to: (1) pressure fluctuations caused by flow unsteadiness in the rotating frame; (2) angular acceleration of the rotor; (3) work done by viscous stresses on the relative flow in the rotating frame; (4) work done by body forces on the relative flow; (5) changes in entropy due to viscous dissipation and heat transfer. Conclusions of this investigation are compared with those of previous authors, some of whom have stated that rothalpy is conserved even in viscous flows. A modified Euler's turbomachine equation, which includes viscous effects, is derived and errors in previous derivations noted.

11A722. Discs and drums: The thermo-fluid dynamics of rotating surfaces. - FJ Bayley, CA Long, AB Turner *(Thermo-Fluid Mech Res Centre, Univ of Sussex, Brighton)*. Proc Inst Mech Eng C 207(C2) 73-81 (1993).

This paper reviews long-term experimental and theoretical research programs concerned with flow and heat transfer over the large rotating surfaces, commonly discs, often drums but sometimes conical, used to support the blades in turbomachinery. The account begins with a geometry found in turbomachinery from the oldest steam plant to the most modern gas turbine, in which a disc rotates near a stationary, usually coaxial member. The flow in the intervening "wheel-space" is well understood, but external conditions can affect the extent and nature of ingress from the surrounding fluid. In the gas turbine this fluid is the mainstream hot gas, an inflow of which could have serious consequences, so that the study of ingress has become the principal subject of research for rotor-stator systems and recent work is fully reported here.

11A723. Rotordynamic coefficients of incompressible flow damping seals using Colebrook's formula. - JK Scharrer, N Rubin *(Rocketdyne Div, Rockwell Int, Canoga Park CA 91304)*, CC Nelson *(Texas A&M Univ, College Station TX 77843)*. Int J Mech Sci 35(8) 669-673 (Aug 1993).

The basic equations are derived for incompressible flow in an annular seal with large-scale roughness. The flow is assumed to be completely turbulent in the axial and circumferential directions with no separation, and is modeled using Colebrook's friction factor relationship. Linearized zeroth- and first-order perturbatio[n] equations are developed for small motion abo[ut] an arbitrary position by an expansion in the eccentricity ratio. The zeroth-order continuity and momentum equations are integrated, yielding the axial and circumferential velocity components and the pressure distribution. The first-order equations are integrated to satisfy the boundary conditions and yield the perturbation pressure distribution. This resultant pressure distribution is integrated along and around the seal to yield the force developed by the seal and the corresponding dynamic coefficients. Results of this analysis are compared with one using Moody's equation and with experimental data for leakage and rotordynamic coefficients.

11A724. Aerodynamic design of turbomachinery blading in 3D flow: An application to radial inflow turbines. - YL Yang, CS Tan, WR Hawthorne *(Gas Turbine Lab, MIT)*. J Turbomachinery 115(3) 602-613 (Jul 1993).

A computational method based on a theory for turbomachinery blading design in 3D inviscid flow is applied to a parametric design study of a radial inflow turbine wheel. As the method requires the specification of swirl distribution, a technique for its smooth generation within the blade region is proposed. Excellent agreements have been obtained between the computed results from this design method and those from direct Euler computations, demonstrating the correspondence and consistency between the two. The computed results indicate the insensitivity of the pressure distribution to a lean in the stacking axis and a minor alteration in the hub-shroud profiles. Analysis based on a Navier-Stokes solver shows no breakdown of flow within the designed blade passage and agreement with that from a design calculation; thus the flow in the designed turbine rotor closely approximates that of an inviscid one. These calculations illustrate the cause of a design method coupled to an analysis tool for establishing guidelines and criteria for designing turbomachinery blading.

11A725. Aerodynamic performance of a transonic low aspect ratio turbine nozzle. - SH Moustapha *(Turbine Aerodyn, Pratt & Whitney, Montreal, PQ, Canada)*, WE Carscallen *(Combust and Fluid Eng Lab, NRC, Ottawa, ON, Canada)*, JD McGeachy *(Dept of Mech Eng, Queen's Univ, Kingston, ON, Canada)*. J Turbomachinery 115(3) 400-408 (Jul 1993).

This paper presents detailed information on the 3D flow field in a realistic turbine nozzle with an aspect ratio of 0.65 and a turning angle of 76°. The nozzle has been tested in a large-scale planar cascade over a range of exit Mach numbers from 0.3 to 1.3. The experimental results are presented in the form of nozzle passage Mach number distributions and spanwise distribution of losses and exit flow angles. Details of the flow field inside the nozzle passage are examined by means of surface flow visualization and Schlieren pictures. The performance of the nozzle is compared to the data obtained for the same nozzle tested in an annular cascade and a stage environment. Excellent agreement is found between the measured pressure distribution and the prediction of a 3D Euler flow solver.

11A726. Aeroloads and secondary flows in a transonic mixed-flow turbine stage. - KR Kirtley, TA Beach *(LeRc Group, Sverdrup Tech, Cleveland OH 44135)*, C Rogo *(Teledyne CAE, Toledo OH 43612)*. J Turbomachinery 115(3) 590-601 (Jul 1993).

A numerical simulation of a transonic mixed-flow turbine stage has been carried out using an average passage Navier-Stokes analysis. The n[...] turbine stage considered here consists [...]ozzle vane and a highly loaded [...]tion was run at the design pressure ratio and is assessed by comparing results with those of an established through flow design system. The 3D aerodynamic loads are studied as well as the development and migration of secondary flows and their contribution to the total pressure loss. The numerical results indicate that strong passage vortices develop in the nozzle vane, mix out quickly, and have little impact on the rotor flow. The rotor is highly loaded near the leading edge. Within the rotor passage, strong spanwise flows and other secondary flows exist along with the tip leakage vortex. The rotor exit loss distribution is similar in character to that found in radial inflow turbines. The secondary flows and nonuniform work extraction also tend to redistribute a nonuniform inlet total temperature profile significantly by the exit of the stage.

11A727. Incidence angle and pitch-chord effects on secondary flows downstream of a turbine cascade. - A Perdichizzi *(Dipt Meccanica, Univ Brescia, 25060 Brescia, Italy)* and V Dossena *(Dipt Energetica, Politec Milano, 20100 Milano, Italy)*. J Turbomachinery 115(3) 383-391 (Jul 1993).

This paper describes the results of an experimental investigation of the 3D flow downstream of a linear turbine cascade at off-design conditions. The tests have been carried out for five incidence angles from -60 to +35°, and for three pitch-chord ratios: s/c = 0.58, 0.73, 0.87. Data include blade pressure distributions, oil flow visualizations, and pressure probe measurements. The secondary flow field has been obtained by traversing a miniature five-hole probe in a plane located at 50% of an axial chord downstream of the trailing edge. The distributions of local energy loss coefficients, together with vorticity and secondary velocity plots, show in detail how much the secondary flow field is modified both by incidence and by cascade solidity variations. The level of secondary vorticity and the intensity of the crossflow at the endwall have been found to be strictly related to the blade loading occurring in the blade entrance region. Heavy changes occur in the spanwise distributions of the pitch-averaged loss and of the deviation angle when incidence or pitch-chord ratio is varied.

11A728. Investigation of rotor blade roughness effects on turbine performance. - JL Boynton, R Tabibzadeh *(Rocketdyne Div, Rockwell Int, Canoga Park CA 91303)*, ST Hudson *(NASA Marshall Space Flight Center, Huntsville AL 35812)*. J Turbomachinery 115(3) 614-620 (Jul 1993).

The cold air test program was completed on the SSME (Space Shuttle Main Engine) HPFTP (High-Pressure Fuel Turbopump) turbine with production nozzle vane rings and polished coated rotor blades with a smooth surface finish of 30 μin (0.76 μm) rms (root mean square). The smooth blades were polished by an abrasive flow machining process. The test results were compared with the air test results from production rough-coated rotor blades with a surface finish of up to 400 μin (10.16 μm) rms. Turbine efficiency was higher for the smooth blades over the entire range tested. Efficiency increased 2.1% points at the SSME 104% RPL (Rated Power Level) conditions. This efficiency improvement could reduce the SSME HPFTP turbine inlet temperature by 57 R (32 K), increasing turbine durability. The turbine flow parameter increased with the midspan outlet swirl angle became more axial with the smooth rotor blades.

11A729. Measurement and prediction of the tip clearance flow in linear turbine cascades. - FJG Heyes *(European Gas Turbines, Lincoln, UK)* and HP Hodson *(Whittle Lab, Cambridge Univ Eng Dept, Cambridge CB3 0DY, UK)*. J Turbomachinery 115(3) 376-382 (Jul 1993).

This paper describes a simple 2D model for the calculation of the leakage flow over the blade tips of axial turbines. The results obtained from calculations are compared with data obtained from experimental studies of two linear turbine cascades.

One of these cascades has been investigated by the authors and previously unpublished experimental data are provided for comparison with the model. In each of the test cases examined, excellent agreement is obtained between the experimental and predicted data. Although ignored in the past, the importance of pressure gradients along the blade chord is highlighted as a major factor influencing the tip leakage flow.

11A730. Progress towards understanding and predicting heat transfer in the turbine gas path. - RJ Simoneau and FF Simon *(NASA Lewis Res Center, Cleveland OH 44135)*. Int J Heat Fluid Flow 14(2) 106-128 (Jun 1993).

A new era is dawning in the ability to predict convection heat transfer in the turbine gas path. We feel that the technical community now has the capability to mount a major assault on this problem, which has eluded significant progress for a long time. In this paper we hope to make a case for this bold statement by reviewing the state of the art in three major and related areas, which we believe are indispensable to the understanding and accurate prediction of turbine gas path heat transfer: configuration-specific experiments, fundamental physics and model development, and code development. We begin our review with the configuration-specific experiments, whose data have provided the big picture and guided both the fundamental modeling research and the code development. Following that, we will examine key modeling efforts and comment on what will be needed to incorporate them into the codes. In this region we will concentrate on bypass transition, 3D endwalls, and film cooling. We will then review progress and directions in the development of computer codes to predict turbine gas path heat transfer. Finally, we will cite examples and make observations on the more recent efforts to do all this work in a simultaneous, interactive, and more synergistic manner. We will conclude with an assessment of progress, suggestions for how to use the current state of the art, and recommendations for the future.

11A731. Statistical approach to the experimental evaluation of transonic turbine airfoils in a linear cascade. - ML Shelton, BA Gregory *(Turbine Aero and Cooling Tech, General Elec Aircraft Engines, Cincinnati OH 45208)*, RL Doughty, T Kiss, HL Moses *(Dept of Mech Eng, VPI)*. J Turbomachinery 115(3) 366-375 (Jul 1993).

In aircraft engine design (and in other applications), small improvements in turbine efficiency may be significant. Since analytical tools for predicting transonic turbine losses are still being developed, experimental efforts are required to evaluate various designs, calibrate design methods, and validate CFD analysis tools. However, these experimental efforts must be very accurate to measure the performance differences to the levels required by the highly competitive aircraft engine market. Due to the sensitivity of transonic and supersonic flow fields, it is often difficult to obtain the desired level of accuracy. In this paper, a statistical approach is applied to the experimental evaluation of transonic turbine airfoils in the VPI and SU transonic cascade facility in order to quantify the differences between three different transonic turbine airfoils. This study determines whether the measured performance differences between the three different airfoils are statistically significant. This study also assesses the degree of confidence in the transonic cascade testing process at VPI and SU.

11A732. Aerodesign and performance analysis of a radial transonic impeller for a 9:1 pressure ratio compressor. - S Colantuoni *(Alfa Romeo Avio, Societa Aeromotoristica pA R&D, Napoli, Italy)* and A Colella *(Alta Romeo Avio, Societa Aeromotoristica pA R&D, Napoli, Italy)*. J Turbomachinery 115(3) 573-581 (Jul 1993).

The aerodynamic design of a centrifugal compressor for technologically advanced small aeroengines requires more and more the use of sophisticated computational tools in order to meet the goals successfully at minimum cost development. The objective of the present work is the description of the procedure adopted to design a transonic impeller having 1.31 relative Mach number at the inducer tip, 45° back-swept exit blade angle, and a tip speed of 636 m-s. The optimization of the blade shape has been done by analyzing the aerodynamic flowfield by extensive use of a quasi-3D code and a fully 3D Euler solver based on a time-marching approach and a finite volume discretization. Testing has been done on the impeller-only configuration, using a compressor rig that simulates real engine hardware, ie, having an S-shaped air-intake. The overall performance of the impeller is presented and discussed.

11A733. Experimental and computational investigation of the NASA low-speed centrifugal compressor flow field. - MD Hathaway *(US Army Res Lab, Vehicle Propulsion Directorate, Cleveland OH 44135)*, RM Chriss, JR Wood, AJ Strazisar *(NASA Lewis Res Center, Cleveland OH 44135)*. J Turbomachinery 115(3) 527-542 (Jul 1993).

An experimental and computational investigation of the NASA Low-Speed Centrifugal Compressor flow field has been conducted using laser anemometry and Dawes' 3D viscous code. The experimental configuration consists of a backswept impeller followed by a vaneless diffuser. Measurements of the 3D velocity field were acquired at several measurement planes through the compressor. The measurements describe both the throughflow and secondary velocity field along each measurement plane. In several cases the measurements provide details of the flow within the blade boundary layers. Insight into the complex flow physics within centrifugal compressors is provided by the computational analysis, and assessment of the CFD predictions is provided by comparison with the measurements. Five-hole probe and hot-wire surveys at the inlet and exit to the rotor as well as surface flow visualization along the impeller blade surfaces provide independent configuration of the laser measurement technique. The results clearly document the development of the throughflow velocity wake, which is characteristic of unshrouded centrifugal compressors.

11A734. Experimental and theoretical analysis of the flow in a centrifugal compressor volute. - E Ayder, R Van den Braembussche *(von Karman Inst for Fluid Dyn, Rhode St Genese, Belgium)*, JJ Brasz *(Carrier, Syracuse NY 13221)*. J Turbomachinery 115(3) 582-589 (Jul 1993).

Detailed measurements of the swirling flow in a centrifugal compressor volute with elliptical cross section are presented. They show important variations of the swirl and throughflow velocity, total and static pressure distribution at the different volute cross sections and at the diffuser exit. The basic mechanisms defining the complex 3D flow structure are clarified. The different sources of pressure loss have been investigated and used to improve the prediction capability of 1D mean streamline analysis correlations. The tangential flow loss model under decelerating flow conditions and the friction loss model are confirmed. New empirical loss coefficients are proposed for the exit cone loss model and the tangential flow loss model for the case of accelerating flow in the volute.

11A735. Investigation of compressor rotor wake structure at peak pressure rise coefficient and effects of loading. - J Prato and B Lakshminarayana *(Dept of Aerospace Eng, Penn State)*. J Turbomachinery 115(3) 487-500 (Jul 1993).

This paper reports an experimental study of the 3D characteristics of the mean velocity in the trailing-edge, near-wake, and far-wake regions of a highly loaded low-speed compressor rotor. The wake structure and decay characteristics are compared with the wake data in the same compressor with moderate loading. The experimental investigation was carried out using a rotating five-hole probe. The flow field was surveyed at various radial and axial locations downstream of the compressor rotor. Variations in the axial, tangential, and radial components of mean velocity at various axial and radial locations were derived from the data and compared with earlier data at lower loading to discern the effects of loading. It was found that the higher loading had the following effects: Higher total velocity defects were observed in the hub-wall region, increased wake growth rate in the tip region, faster decay of static pressure difference in the trailing-edge region, larger initial wake width in the trailing-edge region, increased rate of growth in the semi-wake width in the trailing-edge region, increased decay rate of radial velocity in the trailing-edge region, and decreased decay rate of radial velocity in the far wake region. Far wake properties were almost identical in both cases.

11A736. Investigations on a radial compressor tandem-rotor stage with adjustable geometry. - B Josuhn-Kadner *(Lehrstuhl Fluidenergemaschinen, Ruhr-Univ, Bochum, Germany)* and B Hoffmann *(Inst Antriebstech, DLR Koln, Germany)*. J Turbomachinery 115(3) 552-559 (Jul 1993).

A radial compressor stage has been investigated mainly experimentally for aerodynamic stage optimization. The rotor ($\pi_t = 3.9$) consists of a profiled axial inducer and a conventionally designed radial impeller. Inducer and impeller can be locked at different circumferential positions relative to each other, thus forming a tandem wheel with adjustable geometry. Conventional and Laser-2-Focus system measurements for the tandem rotor and the stage were performed at different operating points to study the influence of the circumferential clearance geometry between inducer and impeller with respect to compressor characteristics and performance. Furthermore, 3D Navier-Stokes calculations are being developed at design point condition to analyze the flow field. A small influence of the inducer adjustment on the rotor characteristics is observed. The maximum rotor efficiency of 93.5% varies in a range of less than 1% depending on the different inducer positions.

11A737. Numerical simulation of compressor endwall and casing treatment flow phenomena. - AJ Crook *(Allison Gas Turbine Div, Indianapolis IN 46206)*, EM Greitzer, CS Tan *(MIT)*, JJ Adamczyk *(NASA Lewis Res Center, Cleveland OH 44135)*. J Turbomachinery 115(3) 501-512 (Jul 1993).

A numerical study is presented of the flow in the endwall region of a compressor blade row, in conditions of operation with both smooth and grooved endwalls. The computations are first compared to velocity field measurements in a cantilevered stator-rotating hub configuration to confirm that the salient features are captured. Computations are then interrogated to examine the tip leakage flow structure since this is a dominant feature of the endwall region. In particular, the high blockage that can exist near the endwalls at the rear of a compressor blade passage appears to be directly linked to low total pressure fluid associated with the leakage flow. The fluid dynamic action of the grooved endwall, representative of the casing treatments that have been most successful in suppressing stall, is then simulated computationally and two principal effects are identified. One is suction of the low total pressure, high blockage fluid at the rear of the passage. The second is energizing of the tip leakage flow, most notably in the core of the leakage vortex, thereby suppressing the blockage at its source.

11T738. Probabilistic simulation of fragment dynamics and their surface impacts in the SSME turbopump. - A Hamed and H Moy *(Dept of Aerospace Eng and Eng Mech, Univ of Cincinnati, Cincinnati OH 45221)*. J Fluids Eng 115(2) 302-308 (Jun 1993).

11A739. Relative flow and turbulence measurements downstream of a backward centrifugal impeller. - M Ubaldi, P Zunino, A Cattanei *(Dipt Ing Energetica, Univ Genova, Genova, Italy)*. J Turbomachinery 115(3) 543-551 (Jul 1993).

The paper presents the results of an experimental investigation on the 3D relative flow at the exit of the backward bladed centrifugal impeller of the high-pressure stage of a two-stage biregulating pump-turbine model, operating at the pump nominal point. Mean velocity, Reynolds stress tensor, and total pressure of the relative flow have been measured with stationary hot-wire probes and fast response miniature pressure transducers, by means of a phase-locked ensemble-average technique. The results, shown in terms of secondary vector plots and contours of mean flow characteristics and Reynolds stress components, give a detailed picture of the flow kinematic structure and of the complex relative total pressure loss and turbulence distributions. In spite of strongly backswept blades, the flow leaving the impeller presents a jet and wake structure and an intense secondary flow activity. Large relative total pressure losses affect the wake and the region where secondary vortices interact. The turbulence data analysis provides information about the effects of the impeller rotation on the turbulence structure and about the mechanisms of the flow mixing process and of the secondary flow decay downstream of the impeller.

380I. AXIAL FANS, PUMPS, COMPRESSORS

11A740. Experimental study on the 3D flow within a compressor cascade with tip clearance Part I. Velocity and pressure fields. - S Kang and C Hirsch *(Dept of Fluid Mech, Vrije Univ, 1050 Brussel, Belgium)*. J Turbomachinery 115(3) 435-443 (Jul 1993).

Experimental results from a study of the 3D flow in a linear compressor cascade with stationary endwall at design conditions are presented for tip clearance levels of 1.0, 2.0, and 3.3% of chord, compared with the no-clearance case. In addition to five-hole probe measurements, extensive surface flow visualizations are conducted. It is observed that for the smaller clearance cases a weak horseshoe vortex forms in the front of the blade leading edge. At all the tip gap cases, a multiple tip vortex structure with three discrete vortices around the midchord is found. The tip leakage vortex core is well defined after the midchord but does not cover a significant area in transverse planes. The presence of the tip leakage vortex results in the passage vortex moving close to the endwall and the suction side.

11A741. Experimental study on the 3D flow within a compressor cascade with tip clearance Part II. Tip leakage vortex. - S Kang and C Hirsch *(Dept of Fluid Mech, Vrije Univ, 1050 Brussel, Belgium)*. J Turbomachinery 115(3) 444-452 (Jul 1993).

An analysis of the experimental data of a linear compressor cascade with tip clearance is presented with special attention to the development of the tip leakage vortex. A method for determining the tip vortex core size, center position, and vorticity or circulation from the measured data is proposed, based on the assumption of a circular tip vortex core. It is observed that the axial velocity profile passing through the tip vortex center is wakelike. The vorticity of the tip vortex increases rapidly near the leading edge and reaches its highest values at a short distance downstream, from which it gradually decreases. In the whole evolution, its size growing and its center is moving away from both the suction surface and the endwall, approximately in a linear way.

11A742. Investigation of tip clearance phenomena in an axial compressor cascade using Euler and Navier-Stokes procedures. - RF Kunz, B Lakshminarayana, AH Basson *(Dept of Aerospace Eng, Penn State)*. J Turbomachinery 115(3) 453-467 (Jul 1993).

Three-dimensional Euler and full Navier-Stokes computational procedures have been utilized to simulate the flow field in an axial compressor cascade with tip clearance. An embedded H-grid topology was utilized to resolve the flow physics in the tip gap region. The numerical procedures employed is a finite different Runge-Kutta scheme. Available measurements of blade static pressure distributions along the blade span, dynamic pressure and flow angle in the cascade outlet region, and spanwise distributions of blade normal force coefficient and circumferentially averaged flow angle are used for comparison. Several parameters that were varied in the experimental investigations were also varied in the computational studies. Specifically, measurements were taken and computations were performed on the configuration with and without: tip clearance, the presence of an endwall, inlet endwall total pressure profiles, and simulated relative casing rotation. Additionally, both Euler and Navier-Stokes computations were performed to investigate the relative performance of these approaches in reconciling the physical phenomena considered. Results indicate that the Navier-Stokes procedure, which utilizes a low Reynolds number κ-ε model, captures a variety of important physical phenomena associated with tip clearance flows with good accuracy. These include tip vortex strength and trajectory, blade loading near the tip, the interaction of the tip clearance flow with passage secondary flow, and the effects of relative endwall motion. The Euler computational provides good but somewhat diminished accuracy in resolution of some of these clearance phenomena. It is concluded that the level of modeling embodied in the present approach is sufficient to extract much of the tip region flow field information useful to designers of turbomachinery.

11A743. Measurement of the 3D tip region flow field in an axial compressor. - RC Stauter *(United Tech Res Center, E Hartford CT 06108)*. J Turbomachinery 115(3) 468-476 (Jul 1993).

A two-color, five-beam LDV system has been configured to make simultaneous three-component velocity measurements of the flow field in a two-stage axial compressor model. The system has been used to make time-resolved measurements both between compressor blade rows and within the rotating blade passages in an axial compressor. The data show the nature and behavior of the complex, 3D flow phenomena present in the tip region of a compressor as they convect downstream. In particular, the nature of the tip leakage vortex is apparent, being manifested by high blockages as well as the expected vortical motion. The data indicate that the radial flows associated with the tip leakage vortex begin to decrease while within the rotor passage, and that they temporarily increase aft of the passage.

11A744. Radial transport and momentum exchange in an axial compressor. - RP Dring *(United Tech Res Center, E Hartford CT 06108)*. J Turbomachinery 115(3) 477-486 (Jul 1993).

The objective of this work was to examine radial transport in axial compressors from two perspectives. The first was to compare the mixing coefficient based on a secondary flow model (using measured radial velocities) with that based on a turbulent diffusion model. The second was to use measured airfoil pressure forces and momentum changes to assess the validity of the assumption of diffusive radial transport, which is common to both models. These examinations were carried out at both design and off-design conditions as well as for two rotor tip clearances. In general it was seen that radial mixing was strongest near the hub and that it increased dramatically at near-stall conditions. It was also seen that radial transport could cause large differences ($\approx$ 100%) between the force on an airfoil and the change in momentum across the airfoil at the same spanwise location.

380L. ROTOR AND INDUCER BLADING

11A745. Blade loading and shock wave in a transonic circular cascade diffuser. - H Hayami *(Inst of Adv Mat Study, Kyushu Univ 86, Kasuga 816, Japan)*, M Sawae *(Nikko Kyodo, Chita 478, Japan)*, T Nakamura *(Toshiba, Yokohama 230, Japan)*, N Kawaguchi *(Inst of Adv Mat Stud, Kyushu Univ 86, Kasuga 816, Japan)*. J Turbomachinery 115(3) 560-564 (Jul 1993).

A low-solidity circular cascade, conformally transformed from a high-stagger linear cascade of double-circular-arc vanes with solidity 0.69, was tested as a part of diffuser systems of a transonic centrifugal compressor and the static pressures were measured around a vane of the cascade and on the side wall between cascade vanes in detail. The blade loading of cascade vane was discussed by integrating the pressure distribution around the vane. The experimental data for lift-coefficient of vane were almost on a single straight line with positive gradient against angle-of-attack over a wide range of inflow Mach number and inflow angle. The maximum lift coefficient reached about 1.5 and the vane worked well to the surge condition of the compressor. The structure of shock wave was also discussed by drawing a contour map of the flow Mach number between cascade vanes. The normal shock wave was observed on the suction surface of vane and it moved upstream along the suction surface with the decrease inflow angle. The vane did not fall in stall even though the Mach number upstream of the shock was over 1.4.

11A746. Design and rotor performance of a 5:1 mixed-flow supersonic compressor. - R Monig *(Siemens AG, KWU Group, Gas Turbine Tech, Mulheim, Ruhr, Germany)*, W Elmendorf, HE Gallus *(Inst Strahlantriebe and Turboarbeitsmaschinen Rheinisch Westfalische, Tech Hochsch, Aachen, Germany)*. J Turbomachinery 115(3) 565-572 (Jul 1993).

In consideration of further jet-engine developments required by applications for supersonic travel aircraft, airbreathing propulsion of space vehicles, or only the improvement of conventional high-performance turbo-engines, highly loaded supersonic compressors seem to meet the future demands. Particularly mixed-flow compressor stages with moderate supersonic rotor and stator inlet flow reveal the potential of high pressure rise and mass flow as well as favorable performance characteristics and efficiency. The first part of this paper presents analytical considerations for mixed-flow supersonic compressors with strong shock waves. This theoretical approach proves to be essential besides established design tools in order to ensure safe rotor and stage operation in accordance with the design objectives. In this context, the conditions for shock wave stabilization within a diagonal rotor passage are discussed in detail for design and off-design rotational speeds. The main part of this paper, however, presents the results and flow analysis obtained by extensive experimental investigations of the designed mixed-flow compressor rotor. The investigations were restricted to operation without stator in order to strictly separate rotor performance from rotor-stator interactions. The results reveal the design goals to be met in general. Mass flow, total pressure rise, and efficiency in particular show a good agreement with the design properties for near-surge operation at design and off-design conditions.

11A747. Off-design performance prediction for radial-flow impellers. - SC Lee *(Dept of Mech and Aerospace Eng, Univ of Missouri, Rolla MO)* and D Chen *(Univ of Missouri, Rolla MO)*. Int J Turbo Jet Engines 10(1) 45-60 (1993).

A numerical method was developed to consider the 2D flowfield between impeller blades of a given geometry. Solution of the laminar Navier-Stokes equations in geometry-oriented coordinates was obtained for stream functions and vorticities. Velocities and pressures were calculated to determine the output fluid-energy head. The circumferential components of the normal and shear stresses along the blade were evaluated to give the input mechanical-energy head. Performance predictions were obtained for different load conditions. Comparisons were made with the measured velocity vectors of the flowfield of an air-pump impeller and with the measured performance of a production water pump; good agreements were reached.

11A748. Separated flow in a low-speed 2D cascade Part I. Flow visualization and time-mean velocity measurements. - AM Yocum *(Appl Res Lab, Penn State Univ, State College PA 16804)* and WF O'Brien *(VPI)*. J Turbomachinery 115(3) 409-420 (Jul 1993).

This study was conducted for the purpose of providing a more fundamental understanding of separated flow in cascades and to provide performance data for fully stalled blade rows. Cascades of a single blade geometry and a solidity of unity were studied for three stagger angles and the full range of angle of attack, extending well into the stalled flow region. Results are presented from flow visualization and time-mean velocity measurements of stalled flow in the cascade. Surface and smoke flow visualization revealed that the blade stagger angle is a key parameter in determining the location of the separation line and the occurrence of propagating stall. Time-mean velocity measurements obtained with a dual hot split-film probe also showed that the separated velocity profiles within the blade passages and the profiles in the wake have distinctly different characteristics depending on the stagger angle.

11A749. Separated flow in a low-speed 2D cascade Part II. Cascade performance. - AM Yocum *(Appl Res Lab, Penn State)* and WF O'Brien *(VPI)*. J Turbomachinery 115(3) 421-434 (Jul 1993).

This study was conducted for the purpose of providing a more fundamental understanding of separated flow in cascades and to provide performance data for fully stalled blade rows. Cascades of a single blade geometry and a solidity of unity were studied for three stagger angles and the full range of angle of attack extending well into the stalled flow regime. The Reynolds number was also varied for a limited number of cases. Results from velocity and pressure measurements made in the cascade and the overall cascade performance evaluated from these measurements are presented. In addition, results from a numerical simulation of the flow through a cascade of flat plate airfoils are used to illustrate further the effects of blade stagger and to define the correct limits for the cascade performance. The results indicate that the slope of the total pressure loss versus angle of attack curve for the flow immediately downstream of the cascade is steeper for cascades with greater stagger. The normal force coefficient was found to increase to a peak value near the angle of attack where full leading edge stall first occurs. A further increase in angle of attack results in a decline in the normal force coefficient. The peak value of the normal force coefficient is greater and occurs at a higher angle of attack for the cascades with smaller stagger.

11A750. Shock formation in overexpanded tip leakage flow. - J Moore *(Dept of Mech Eng, VPI)* and KM Elward *(Gas Turbine Eng and Dev, General Elec, Schenectady NY 12345)*. J Turbomachinery 115(3) 392-399 (Jul 1993).

Shock formation due to overexpansion of supersonic flow at the inlet to the tip clearance gap of a turbomachine has been studied. The flow was modeled on a water table using a sharp-edge rectangular channel. The flow exhibited an oblique hydraulic jump starting on the channel sidewall near the channel entrance. This flow was analyzed using hydraulic theory. The results suggest a model for the formation of the jump. The hydraulic analogy between free surface water flows and compressible gas flows is used to predict the location and strength of oblique shocks in analogous tip leakage flows. Features of the flow development are found to be similar to those of compressible flow in sharp-edged orifices. Possible implications of the results for high-temperature gas turbine engine design are considered.

11A751. Supersonic turbomachine rotor flutter control by aerodynamic detuning. - KM Spara *(Tech Dept, Aerospace Corp, Los Angeles CA)* and S Fleeter *(Sch of Mech Eng, Thermal Sci and Propulsion Center, Purdue)*. J Propulsion Power 9(4) 561-568 (Jul-Aug 1993).

A mathematical model is developed to analyze the flutter stability characteristics of an aerodynamically detuned rotor operating in a supersonic inlet flowfield with a supersonic axial component. Alternate-blade aerodynamic detuning is considered, accomplished by alternating the circumferential spacing of adjacent rotor blades. The unsteady aerodynamics are determined by developing an influence coefficient technique which is appropriate for both aerodynamically tuned and detuned rotor configurations. The effects of this detuning on the flutter stability characteristics of supersonic axial flow rotors are then demonstrated by applying this model to baseline 12-bladed rotors. Results show that, dependent on the specific blade row and flowfield geometry, alternate blade aerodynamic detuning is a viable flutter control mechanism for supersonic through-flow rotors.

380R. PROPELLERS AND HELICOPTER ROTORS

11A752. Aeroelastic response, loads, and stability of a composite rotor in forward flight. - EC Smith *(Aerospace Eng Dept, Penn State)* and I Chopra *(Dept of Aerospace Eng, Center for Rotorcraft Educ and Res, Univ of Maryland, College Park MD 20742)*. AIAA J 31(7) 1265-1273 (Jul 1993).

The aeroelastic response, blade and hub loads, and shaft-fixed aeroelastic stability are investigated for a helicopter with elastically tailored composite rotor blades. A new FE-based structural analysis including nonclassical effects such as transverse shear, torsion related warping, and in-plane elasticity is integrated with the University of Maryland Advanced Rotorcraft Code. The structural dynamics analysis is correlated against both experimental data and detailed FE results. Correlation of rotating natural frequencies of coupled composite box-beams is generally within 5 - 10%. The analysis is applied to a soft-in-plane hingeless rotor helicopter in free flight propulsive trim. Changes in blade loads are relatively small; however, aeroelastic stability can be significantly improved by the use of elastic pitch-lag coupling. For example, lag mode damping can be increased 300% over a range of thrust conditions and forward speeds. The influence of attached flow unsteady aerodynamics on the blade response and vibratory hub loads is also investigated. The magnitude and phase of the flap response is substantially altered by the unsteady aerodynamic effects. Vibratory hub loads increase up to 30% due to unsteady aerodynamic effects.

380Y. COMPUTATIONAL TECHNIQUES

11A753. Practical application of solution-adaption to the numerical simulation of complex turbomachinery problems. - WN Dawes *(Whittle Lab, Cambridge Univ, Cambridge, UK)*. Prog Aerospace Sci 29(3) 221-269 (1992).

This paper describes some recent developments in the application of unstructured mesh, solution-adaptive methods to the solution of the 3D Navier-Stokes equations in turbomachinery flows. By adopting a simple, pragmatic but systematic approach to mesh generation, the variety of simulations which can be attempted ranges from simple turbomachinery blade-blade primary paths towards complex secondary gas paths and can include the interactions between the two paths. By adopting a hierarchical data structure, mesh refinement and derefinement can be preformed sufficiently economically that it becomes practical to perform unsteady flow simulations with zones of mesh refinement "following" unsteady flow features, like vortices and wakes, through a coarse background mesh. The combined benefits of the approach result in a powerful analytical ability. Solutions for a wide range of steady flows are presented including a transonic compressor rotor, a centrifugal impellor, the internal coolant passage of a radial inflow turbine and a turbine disc-cavity flow. Unsteady solutions are presented for a cylinder shedding vortices and for a turbine wake-rotor interaction.

380Z. EXPERIMENTAL TECHNIQUES

11A754. Blade row interaction effects on compressor measurements. - T Shang *(Gas Turbine Lab 31-256, MIT)*, AH Epstein *(Gas Turbine Lab 31-266, MIT)*, MB Giles *(Gas Turbine Lab 31-264, MIT)*, AK Sehra *(Compressor Aerodyn Dept LSD-10, Textron Lycoming, 550 Main St, Stratford CT 06497)*. J Propulsion Power 9(4) 569-578 (Jul-Aug 1993).

The influence of a downstream stator row on the measurement of compressor rotor performance has been examined using a 2D computational fluid dynamic code backed by laser anemometry data on a transonic fan stage. The upstream potential influence of the stator causes unsteady circulation about the rotor blades which is a function of the rotor circumferential position. This, in turn, results in a nonuniform circumferential pattern of time-averaged temperature and pressure in the stationary frame. A relatively fast calculational procedure using a linearized, potential flow approach coupled with an analytical theory relating the temperature and pressure variations to the circulation perturbation is developed and shown to give good agreement with the numerical calculations. The results of a parametric study show that the magnitude of this effect is a strong function of rotor-stator blade row spacing and relative blade counts. The effects range from negligible for large spacings typical of high bypass ratio fans, to several percent of the stage pressure and temperature rise for closely spaced blade rows typical of high compressors. Because the temperature and pressure perturbation are in spatial phase, the net effect on measured rotor efficiency is negligible so long as the pressure and temperature measurements are made in the same location relative to the stators. If they are not, errors of ±1.5% can result. The effects of axial position and stator loading are shown to be relatively small.

11A755. Investigation of factors influencing the calibration of five-hole probes for 3D flow measurements. - RG Dominy *(Sch of Eng and Comput Sci, Univ of Durham, Durham, UK)* and HP Hodson *(Whittle Lab, Cambridge Univ, Cambridge, UK)*. J Turbomachinery 115(3) 513-519 (Jul 1993).

The effects of Reynolds number, Mach number, and turbulence on the calibrations of commonly used types of five-hole probe are discussed. The majority of the probes were calibrated at the exit from a transonic nozzle over a range of Reynolds number ($7 \times 10^3 < Re < 80 \times 10^3$ based on probe tip diameter) at subsonic and transonic Mach numbers. Additional information relating to the flow structure were obtained from a large-scale, low-speed wind tunnel. The results confirmed the existence of two distinct Reynolds number effects. Flow separation around the probe head affects the calibrations at relatively low Reynolds numbers while changes in the detailed structure of the flow around the sensing holes affects the calibrations even when the probe is nulled. Compressibility is shown to have little influence upon the general behavior of these probes in terms of Reynolds number sensitivity but turbulence can affect the reliability of probe calibrations at typical test Reynolds numbers.

382. Lubrication

382A. GENERAL THEORY

11T756. Effect of fluid compressibility on journal bearing performance. - F Dimofte *(NASA Lewis Res Center, Cleveland OH 44135)*. Trib Trans 36(3) 341-350 (Jul 1993).

11A757. Effect of inertia forces on the performance of externally pressurized conical thrust bearings under turbulent flow conditions. - MF Khalil, SZ Kassab, AS Ismail *(Dept of Mech Eng, Fac of Eng, Alexandria Univ, Alexandria 21544, Egypt)*. Wear 166(2) 155-161 (1 Jul 1993).

The effects of convective and centrifugal inertia forces on the performance of externally pressurized conical thrust bearings, working under turbulent flow conditions, are studied. The study makes use of an algebraic Reynolds stress model proposed for turbulent lubrication. The governing equations are solved iteratively using the finite difference method. The study reveals that the effect of the convective inertia force on the conical bearing performance is opposite to the effect of the centrifugal force. Further, the effect of combined inertia forces is to decrease both the dimensionless pressure and the load of the bearing.

11A758. Lubrication in cold rolling: Elasto-plastic-hydrodynamic lubrication of smooth surfaces. - PM Lugt, AW Wemekamp, WE ten Napel *(Univ of Twente, PO Box 217, Enschede, Netherlands)*, P van Liempt, JB Otten *(Hoogovens Res Lab, PO Box 10000, IJmuiden, Netherlands)*. Wear 166(2) 203-214 (1 Jul 1993).

A model has been developed with respect to hydrodynamic lubrication in cold rolling. The basic model describes the configuration of a rigid, perfectly plastic sheet rolled by a rigid work roll. The governing equations have been solved throughout the complete contact area, ie, the inlet, the work zone and the outlet zone. Multi-level techniques have been applied to solve these equations together with boundary conditions, resulting in an algorithm solving the problem in O(n) operations. This means that the distribution of the pressure and the traction force in the lubricant film, and the shape of this film, as well as the plastic deformation of the sheet, can be accurately calculated for a large number of nodal points on a minicomputer. Subsequently elastic deformation, work hardening and dynamic behavior of the flow stress have been incorporated in the model. It will be shown that the influence of these effects on the film thickness or the pressure distribution is considerable.

11A759. Performance of externally pressurized conical thrust bearing under laminar and turbulent flow conditions. - MF Khalil, SZ Kassab, AS Ismail *(Dept of Mech Eng, Fac of Eng, Alexandria Univ, Alexandria 21544, Egypt)*. Wear 166(2) 147-154 (1 Jul 1993).

In the present theoretical investigation, the effect of turbulent lubrication, represented by Reynolds stresses, on the performance of externally pressurized circular and conical thrust bearings is studied. A recent algebraic Reynolds stress model is employed. The governing equations are solved iteratively using the finite difference method. Both the inertia forces and thermal effects are neglected in the present analysis. The effects of recess radius ratio, film thickness ratio and Poiseuille and Couette Reynolds numbers on the performance characteristics of the circular and conical bearinga are studied. The bearings' performances under laminar flow condition are also presented and compared with the turbulent condition. The present study reveals that the circular bearing has slightly higher dimensionless pressure, load and torque than the conical bearing. Further, the turbulent flow solution gives higher dimensionless pressure, load and torque than the laminar flow solution. Finally, increasing the film thickness ratio or the recess radius ratio has the effect of decreasing both the dimensionless load and torque.

382C. HYDRODYNAMIC AND HYDROSTATIC LUBRICATION

11A760. Dynamic characteristics of hydrostatic bearings. - Zhicheng Pang, Jingwu Sun, Wenjie Zhai, Qingming Liu, Wei Chi *(Dept of Mech Eng, Harbin IT, 802 Div, Harbin, China)*. Wear 166(2) 215-220 (1 Jul 1993).

The characteristics of hydrostatic bearings have been theoretically studied in terms of the compressibility of the air-contained oil. A formula for the stability criterion of a hydrostatic bearing system and a dynamic stiffness formula have been derived. The theory has been verified by experimental research, and provides a basis for hydrostatic bearing design.

11A761. Non-Newtonian effects on the coastdown phenomenon of hydrodynamic journal bearings. - D Sheeja and BS Prabhu *(Dept of Appl Mech, Indian IT, Madras 600 036, India)*. Trib Trans 36(3) 405-410 (Jul 1993).

The behavior of a rotating system after its power supply is cut off is called the coastdown phenomenon. An experimental investigation of the coastdown characteristics was carried out on a rotor rig, with different types of lubricants including a Newtonian oil, a blend of ISOVG 32 and hydrogenated styrene isoprene, multigrade oils, and aqueous polymer solutions in a hydrodynamic journal bearing. The characteristics were plotted in terms of deceleration vs speed, which resembled the Stribeck diagram of friction due to viscous drag. Thus, the apparent Stribeck diagrams of friction for the above oils were obtained by plotting the derived coefficient of friction against the reciprocal Sommerfeld number.

11T762. Nonlinear study of a misaligned hydrodynamic journal bearing. - FK Choy, MJ Braun, Y Hu *(Dept of Mech Eng, Univ of Akron, Akron OH 44325)*. Trib Trans 36(3) 421-431 (Jul 1993).

382D. ELASTOHYDRODYNAMIC LUBRICATION

11A763. Elastohydrodynamic lubrication of elliptical contacts with pure spin. - D Dowson, CM Taylor *(Dept of Mech Eng, Univ of Leeds, UK)*, H Xu *(T&N Tech, Cawston Rugby, Warwickshire, UK)*. Proc Inst Mech Eng C 207(C2) 83-92 (1993).

In a lubricated, non-conformal piezoviscous effects associated with the lubricant and elastic distortion of the bounding surfaces can have a significant influence upon the generation of the lubricant film and consequently upon the oil pressure distribution. In many widely studied cases which have been concerned with surface motions of rolling-sliding, it has been shown that these effects enhance the load-generating capability of the oil-film. However, some machine elements experience more complicated bearing surface motions. For example, spinning as well as entraining occurs in the elliptical contact regions of angular contact bearings and some forms of continuously variable speed drives. In this paper, results from a study on the elastohydrodynamic lubrication of elliptical contacts with pure spin are reported. In contrast to the former situation, an unfavorable influence of the surface deflection upon the generation of the fluid film has been observed. Comparison with experimental observation demonstrated encouraging agreement.

11A764. Experimental study on oil supply in a space bearing with an oil-impregnated retainer. - Jianhai Liu, Youwen Fan, Shizhu Wen *(Natl Trib Lab, Tsinghua Univ, Beijing 10084, Peoples Rep of China)*. Wear 165(2) 193-196 (1 Jun 1993).

Parched elastohydrodynamic lubrication (EHL) film thickness in a space ball bearing is measured by electrical capacitance and resistance, and parched transients of oil film and lubricant breakdown are observed. With different oil-impregnated polymer retainers, which are employed as oil supply resources, parched degradation is restricted to some degree, even lubricant breakdown disappears and a steady state of the oil film is produced. A long-term space ball bearing demands both the lowest driving torque and a steady state oil film, which depends on a strictly controlled oil supply from oil-impregnated retainers. The results of this experimental research describe the effects of oil supply by amounts of oil in retainers on parched EHL.

382E. LIQUID LUBRICANTS

See the following:

11A562. Prediction of viscosities using chemical graph theory

11T756. Effect of fluid compressibility on journal bearing performance

382F. GAS LUBRICANTS

11A765. Modeling supersonic inlet boundary-layer bleed roughness. - GC Paynter, DA Treiber, WD Kneeling *(Boeing, Seattle WA 98124)*. J Propulsion Power 9(4) 622-627 (Jul-Aug 1993).

Boundary-layer mass removal (bleed) through spanwise bands of holes on a surface is used to prevent or control separation in supersonic inlets. The rough wall algebraic turbulence model of Cebeci and Chang was added to both boundary-layer and Navier-Stokes analyses to simulate the overall effect of bleed on the growth of a boundary layer. Roughness values were determined for seven bleed configurations, a range of Mach numbers between 1.3-4, and bleed rates between zero and choked values. For the bleed experiments considered, the roughness was found to be a function of the fraction of the upstream boundary-layer mass flux removed. Choked bleed flow through holes at a low angle, with respect to the surface, minimized the roughness effect and gave the best improvement in the boundary-layer velocity distribution for separation control.

382H. OTHER LUBRICANTS

11A766. Laser chemical vapor deposition of fluorinated diamond thin films for solid lubrication. - PA Molian *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*, B Janvrin, AM Molian *(Laser Sci, Ames IA 50010)*. Wear 165(2) 133-140 (1 Jun 1993).

A laser chemical vapor deposition process for growing fluorinated diamond thin films and the solid lubrication behavior of such films on two bearing materials (SiC and 440C stainless steel), were investigated. Raman spectroscopy analysis revealed that the films deposited on SiC consisted of a mixture of diamond and graphite, while the films deposited on 440C steel were composed of diamond-like carbon and graphite X-ray photoelectron spectroscopy analysis revealed the presence of significant amounts of C-F compounds, both in the surface and subsurface layers, in addition to carbon. Tribological tests (ball-on-disc and pin-on-disc) of laser-grown films under ambient environmental indicated a friction coefficient in the range of 0.1-0.3, depending on the wear couple, sliding speed and load, confirming the effectiveness of these films as solid lubricants for moving mechanical assemblies in space structures. Fluorination of carbon films has the following attributes: passivation of the surface of diamond-graphite films from absorption of water or oxygen, reduction of surface energy needed for shearing of the film during solid lubrication and protection from corrosive environments.

382Y. COMPUTATIONAL TECHNIQUES

11A767. Analysis of hydrodynamic journal bearings considering lubricant supply conditions. - JCP Claro and AAS Miranda *(Univ of Minho, Guimaraes, Portugal)*. Proc Inst Mech Eng C 207(C2) 93-101 (1993).

A method of analysis of steadily loaded hydrodynamic journal bearings with a single axial groove (either on the load line or at 90° to the load line) or two diametrically opposed axial grooves is described. The method is based on Elrod's cavitation algorithm (which ensures conservation of mass flow in both the full film and the cavitated regions) and is able to accommodate specified lubricant supply conditions, namely groove size and location and supply pressure. Special attention has been given to the determination of flowrate. The equation governing the distribution of pressure around the bearing has been solved numerically using a finite difference approximation and multi-grid techniques to accelerate the convergence of the solution. Performance predictions of the analysis are compared with published experimental data and with experimental measurements obtained in laboratory tests carried out by the authors. The data used cover all grooving arrangements studied.

382Z. EXPERIMENTAL TECHNIQUES

11A768. Possibilities of ultrasound cavitation application to estimation utility properties of power fluid Part II. Estimation of thermo-oxidation properties. - B Wislicki *(Inst Lotnictwa, Aleja Krakowska 110-114, 02-256 Warszawa, Poland)*. Zagadnienia Eksploatacji Maszyn 26(4) 431-440 (1991).

Examples of results of comparative tests of gear oil oxidation resistance acc FTM std No 791-5308 in toothed gear and by use of ultrasound cavitation are presented in the part II. Thirty percent higher effectiveness of cavitation methods has been stated. Similarity of oxidation processes by compared methods is confirmed by results of IR absorption spectrum tests. The possibility of development of effective method of laboratory estimation operational fluids oxidation resistance has been stated.

384. Flow measurements and visualization

11A769. Reconstruction of a quasi-instantaneous image of coherent structures from hotwire signals obtained by a multi-point simultaneous measurement system. - M Hino *(Katase-Yama 4-20-6, Fujisawa-Shi 251, Japan)* and Yan Meng *(Fluid Dyn Group, Env Eng Dept, IT, Shimizu Corp, Etchujima 3-chome, Koto-ku, Tokyo 135, Japan)*. Fluid Dyn Res 11(6) 245-261 (Jun 1993).

The turbulent velocity components (u,v) at 11 points in a reciprocating oscillatory turbulent flow have been measured simultaneously by a set of eleven X-type hotwire probes located in a plane perpendicular to the mean flow. Using a conditional sampling technique and a new method of data analysis for the inverse estimation of flow fields called "virtual plate-load and MASCON model", a quasi-instantaneous 3D image of coherent structures of turbulence was first reconstructed directly from the experimental velocity data. The quasi-instantaneous image was expressed in terms of the velocity components u, v, w and the vorticity components ω_x, ω_y, ω_z and we found that the large-scale coherent structure was composed of a pair of counter-rotating fluid motions with asymmetry which was quite different from that of the ensemble-averaged one. Flow patterns induced by the large-scale structure have been clarified by perspective representations visualized by computer simulations that produce timelines and streaklines of fluid particle traces. Results showed that the new experimental method was applicable for investigating the 3D feature of coherent structures including asymmetry.

11A770. Verification of the theoretical discharge coefficient of a subcritical airflow meter. - DJ Lahti *(Aerothermo Syst Integration, GE Aircraft Engines, Cincinnati OH 45215)* and A Hamed *(Dept of Aerospace and Eng and Appl Mech, Univ of Cincinnati, Cincinnati OH 45221)*. J Propulsion Power 9(4) 615-621 (Jul-Aug 1993).

Since many modern high bypass ratio turbofan engines have flow rates that exceed the capacity of most of the worlds airflow calibration facilities, their airflow metering bellmouth inlets cannot be calibrated, but rather their discharge coefficients must be determined theoretically. The objective of this program was to verify the theoretically derived discharged coefficient for a scale model of such a bellmouth which was small enough to allow its calibration in an existing laboratory facility. Extensive flowfield measurements were also made to further validate theoretical predictions. Thus, this program provides a "calibration" of the theoretical method used, and establishes a link between a traceable airflow metering standard and large engine bellmouth inlets that cannot be calibrated any other way.

11A771. Flow visualization in a circular-to-rectangular transition duct. - CK Lin *(Chung-Shan Inst of Sci and Tech, Taichung, Taiwan, ROC)*, JJ Miau, QS Chen *(Inst of Aeronaut and Astronaut, Natl Cheng-Kung Univ, Tainan, Taiwan, ROC)*, JH Chou *(Dept of Eng Sci, Natl Cheng-Kung Univ, Tainan, Taiwan, ROC)*, D Pan, SF Lin *(Inst of Aeronaut and Astronaut, Natl Cheng-Kung Univ, Tainan, Taiwan, ROC)*. Int J Turbo Jet Engines 10(1) 61-74 (1993).

This work reports on flow behaviors near the wall and secondary flow structures in a circular-to-rectangular transition duct at Reynolds number of 10^4. Flow visualization experiments were conducted under the conditions of uniform and swirling inlet flows. As found, flow structures observed at the rectangular exit under the swirling inlet condition appear very differently from those observed under the uniform inlet condition. In the former case the secondary flows are developed due to the detachments of the swirling flow from the contoured wall, while in the latter cases the secondary flows are known due to the mechanism of mean-flow straining in the corner regions.

11A772. Application of numerical and optical evaluation schemes for particle image velocimetry. - PV Farrell *(Dept of Mech Eng, Univ of Wisconsin, 1514 University Ave, Madison WI 53706)*. Exp Fluids 14(6) 433-446 (May 1993).

This paper will compare the performance of optical and numerical Fourier transform analysis of Young's fringes using speckle images. The repeatability and an estimate of the accuracy of the particle displacement will be shown for each method. A brief examination of the effects of small particle number density of PIV evaluation will also be presented. Finally, for a small part of an actual unsteady flow, the optical and numerical Fourier transform analysis methods will be compared.

11A773. Infrared imagery of an air-CO_2 axisymmetric jet. - DN Gordge *(SETD ACS SY73, Naval Air Warfare Center, Patuxent River MD 20670)* and RH Page *(Mech Eng Dept, Texas A&M Univ, College Station TX 77843-3123)*. Exp Fluids 14(6) 409-415 (May 1993).

This experiment uses an infrared imaging system to investigate a subsonic, non-isoenergetic, air-CO_2 axisymmetric jet. The classical limitations of using IR imagery with hot gases are presented and a novel approach to overcome these limitations is proposed. The results suggest that radial and axial irradiant profiles measured with the IR imager, when non-dimensionalized, collapse onto curves of similarity. This behavior could allow temperature, velocity, and concentration profiles to be deduced from the IR image.

11A774. Large-field high-brightness focusing schlieren system. - LM Weinstein *(Fluid Mech Div, Exp Methods Branch, NASA Langley Res Center, Hampton VA 23665)*. AIAA J 31(7) 1250-1255 (Jul 1993).

The analysis and performance of a large-field high-brightness focusing schlieren system is described. Techniques are described that allow the system to be used even through slightly distorting optical elements. The system can be used to examine complex 2D and 3D flows.

11T775. Absolute intensity measurements of impurity emissions in a shock tunnel and their consequences for laser-induced fluorescence experiments. - PC Palma, AFP Houwing, RJ Sandeman *(Dept of Phys and Theor Phys, Fac of Sci Austral Natl Univ, PO Box 4, Canberra 2601, Australia)*. Shock Waves 3(1) 49-53 (1993).

11A776. Indirect temperature determination of a hot gas stream. - A Kogan *(Technion, Haifa, Israel)* and I Hodara *(Solar Res Fac Unit, Weizmann Inst of Sci, Rehovot 76100, Israel)*. Exp Mech 33(2) 99-101 (Jun 1993).

The method for indirect temperature measurement of hot flowing gas presented in this paper evolved out of the need to determine experimentally the temperature of hot gas leaving a hydrogen production solar thermal water dissociation reactor. The method is based on Fanno line choked flow theory. It enables gas-temperature determination from gas flow rate and pressure measurement. The reliability of the method was tested by applying it to determine the temperature of a relatively cold gas stream and by comparing the result with gas temperature measured directly with a thermocouple.

VI. HEAT TRANSFER

400. Thermodynamics

11A777. Numerical modeling of turbulent flow and heat transfer in rotating cavities. - R Schiestel, L Elena, T Rezoug *(Inst Mec des Fluides Marseille IM2, Unite Mixte CNRS 34, 1 Rue Honnorat, 13003 Marseille, France)*. Numer Heat Transfer A 24(1) 45-65 (Jul-Aug 1993).

The present work considers the numerical modeling of turbulent flow in rotating cavities with a radial imposed flux and a preliminary examination of heat transfer prediction. Two turbulence models are studied: the standard κ-ε low-Reynolds-number approach and a zonal approach using second-order algebraic stress model in the core region adapted to rotating flows. The computational procedure is based on a finite volume method. Predictions are compared with experimental data in the literature. The results bring to light the importance of a detailed near-wall treatment in order to properly capture the Ekman layer region. Second-order modeling seems to be necessary to attain a wider practical value, particularly in the presence of recirculation zones and 3D effects in strong rotation.

11A778. Geometrical aspect of symmetric conservative systems of partial differential equations. - S Piekarski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(5-6) 603-614 (1992).

In mathematical physics, one often encounters systems of the first-order conservation laws which imply the additional conservation law and, as their special cases, symmetric conservative and symmetric hyperbolic systems. In particular, systems of the first-order conservation laws which imply the additional conservation are interesting from the point of view of phenomenological thermodynamics, where the additional conservation law is interpreted as the entropy law. In this paper the geometrical description of such systems, based on the geometrical approach proposed by Peradzynski and Piekarski is discussed. It should be stressed that this description is different from that usually applied in the theory of conservation laws (HH Johnson). The applications of the discussed formalism to the symmetric systems are also mentioned.

402B. FORCED CONVECTION (EXTERNAL)

11A779. Convection heat transfer of closely-spaced spheres with surface blowing. - C Kleinstreuer *(Dept of Mech and Aerospace Eng, N Carolina State Univ, Raleigh NC 27695-7910)* and H Chiang *(Thermofluid Tech Div, Indust Tech Res Inst, Chutung, Taiwan, ROC)*. Warme Stoffubertragung 28(5) 285-293 (May 1993).

A validated computer simulation model has been developed for the analysis of colinear spheres in a heated gas stream. Using the Galerkin FEM, the steady-state Navier-Stokes and heat transfer equations have been solved describing laminar axisymmetric thermal flow past closely-spaced monodisperse spheres with fluid injection. Of interest are the coupled nonlinear interaction effects on the temperature fields and ultimately on the Nusselt number of each sphere for different free stream Reynolds numbers ($20 \leq Re \leq 200$) and intersphere distances ($1.5 \leq j \leq 6.0$) in the presence of surface blowing ($0 \leq v_b \leq 0.1$). Fluid injection (ie, blowing) and associated wake effects generate lower average heat transfer coefficients for each interacting sphere when the Reynolds number increases ($Re > 100$). Heat transfer is also reduced at small spacings especially for the second and third sphere. A Nusselt number correlation for each interacting (porous) sphere has been developed based on computer experiments.

11A780. Computational study of coolant flow of liquid hydrogen through an externally heated duct. - RG Carlisle and HG Wood III *(Dept of Mech and Aerospace Eng, Univ of Virginia, Charlottesville VA 22903)*. J Thermophys Heat Transfer 7(3) 418-425 (Jul-Sep 1993).

The computational modeling of the 2D flow of liquid hydrogen coolant within the leading edge of the National Aerospace Plane engine structure is described. The model includes consideration of the effects of the variable thermophysical properties of hydrogen, axial conduction within the leading-edge material, and the coupling of the energy and momentum equations in the flow. The reduced Navier-Stokes equations are solved by parabolic marching of the discretized finite difference equations down the coolant passage. The importance of the consideration of the above factors was demonstrated as the calculated temperatures agreed with those predicted by earlier empirical methods for moderate heat transfers, but differed for the heat transfer magnitude of interest. The form of the expression of the solid-fluid interface condition was found to be an important factor in determining the accuracy and speed of convergence of the algorithm. The ability of the hydrogen coolant system to cool the incident heat load was found to be marginal: moderately increased incident heat loads would exceed the capabilities of the modeled system. Parametric studies were done to show the relative importance of the temperature, pressure, and velocity of the coolant fluid on the cooling capabilities of the system.

11A781. Convective heat transfer in a curved annular-sector duct. - G Yang and MA Ebadian *(Dept of Mech Eng, Florida Int Univ, Miami FL 33199)*. J Thermophys Heat Transfer 7(3) 441-446 (Jul-Sep 1993).

A numerical analysis of heat transfer behavior in a curved annular-sector duct is presented in this article. A uniform axial heat flux and constant peripheral wall temperature boundary condition are applied in this study. The effects of three major parameters on the heat transfer process (the axial pressure gradient, the dimensionless radius ratio, and the dimensionless curvature) are systematically studied. The results indicate that completely different temperature distribution patterns are evident among the segmented duct in different locations relative to the symmetric centerline. The Nusselt number significantly increases as the pressure gradient increases. Furthermore, an increase of the dimensionless curvature will also enhance heat transfer because of strong secondary flow. Finally, the results indicate that heat transfer is improved dramatically as the duct radius ratio decreases, especially when the duct radius ratio is smaller than 0.6.

11A782. Flow of supercritical hydrogen in a uniformly heated circular tube. - B Youn and AF Mills *(Dept of Mech, Aerospace and Nucl Eng, UCLA)*. Numer Heat Transfer A 24(1) 1-24 (Jul-Aug 1993).

Turbulent flow of supercritical hydrogen through a uniformly heated circular tube has been investigated using numerical methods, for the range of $4 \times 10^5 \leq Re \leq 3 \times 10^6$, $5 \leq q_w \leq 10$ MW/m^2, $30 \leq T_{in} \leq 90$ K, and $5 \leq P_{in} \leq 15$ MPa. The purpose is to validate a turbulence model and calculation method for the design of active cooling systems of hydrogen-fueled hypersonic aircraft, where the hydrogen fuel is used as coolant. The PHOENICS software package was used for the computations, which required special provision for evaluation of the thermophysical properties of the supercritical hydrogen, and a low Reynolds number form of the κ-ε turbulence model. Pressure drop and heat transfer data were compared with experiment and existing correlations, and good agreement was demonstrated. For the pressure range considered here a "thermal spike" was observed and shown to be due to the secondary peak in specific heat, rather than the primary peak.

11A783. Heat transfer and pressure drop of a transversely finned concentric annulus with longitudinal flow. - Yuanyue Jin, Changming Ling, Zhongqi Chen, Ye Tian *(Dept of Power Machinery Eng, Xi'an Jiaotong Univ, Xi'an 710049, China)*. Warme Stoffubertragung 28(5) 243-249 (May 1993).

The characteristics of heat transfer and pressure drop have been experimentally studied for the fully developed concentric annular flow with transverse fins normal to the flow direction by the naphthalene sublimation technique. Correlations for calculating the heat transfer coefficient with different inner diameters D_o of the outer tube are presented. A "characteristic Reynolds number" has been proposed, by which the predominant role of the transverse fins can be evaluated. It has been indicated that the inner diameter D_o has much more effect on pressure drop than on heat transfer. The effect of D_o on the overall performance is also compared under the same flow velocity or flow rate. It has been found that the effect of developing flow on heat transfer is significant and should be taken into account during experiment.

402D. NATURAL CONVECTION (EXTERNAL)

11A784. Effect of blowing or suction on laminar free convective heat transfer on flat horizontal plates. - HJH Brouwers *(Dept of Civil Eng and Man, Univ of Twente, PO Box 217, 7500-AE Enschede, Netherlands)*. Warme Stoffubertragung 28(6) 341-344 (Jun 1993).

In the present paper laminar free convective heat transfer on flat permeable horizontal plates is investigated. To assess the effect of surface suction or injection on heat transfer a correction factor, provided by the film model (or "film theory"), is applied. Comparing the film model predictions with numerical results of previous boundary layer analysis yields good agreement for a wide range of dimensionless transpiration levels.

402E. NATURAL CONVECTION (ENCLOSURES)

11A785. Comparison of natural convection of water and air in a partitioned rectangular

enclosure. - Jamil A Khan and Guang-Fa Yao *(Dept of Mech Eng, Univ of S Carolina, Columbia SC 29208)*. Int J Heat Mass Transfer 36(12) 3107-3117 (Aug 1993).

A numerical solution comparing steady natural convection of water and air in a 2D, partially divided, rectangular enclosure is presented. Rayleigh numbers investigated range from 10^6 to 10^8, and the opening ratios studied are 0, 1/4, 1/6, and 1/8 respectively. To obtain a comparative study, Prandtl number of 7.0 (for water) and Prandtl number of 0.71 (for air) are used for the two working fluids. This study demonstrates that the conventional use of water to model air convection in partitioned enclosures gives reasonable heat transfer results. The average Nusselt number obtained for water is only 2 ~ 5% larger than that for air at the same conditions. The flow configuration and exchange flow rates for water and air are, however, different. The exchange flow rate for water is found to be 10 ~ 20% larger than that for air. It is observed that for the opened partition the average Nusselt number is 13 ~ 24% larger than that for unopened partition. On the other hand, an opening in the partition reduces the exchange volume flow rates by 5.68 ~ 15.2% for water and 1 ~ 11.4% for air, depending on the Rayleigh number and the opening ratio.

11A786. Conjugate natural-convection-conduction heat transfer in enclosures divided by horizontal fins. - CJ Ho and JY Chang *(Dept of Mech Eng, Natl Cheng Kung Univ, Tainan Taiwan ROC)*. Int J Heat Fluid Flow 14(2) 177-184 (Jun 1993).

This article presents a numerical study concerning conjugate heat transfer across a vertical rectangular water-filled enclosure divided by multiple horizontal fins. The objective of the study is mainly to explore the effects of the conducting horizontal fins on heat transfer due to conjugate natural convection-conduction in the finned enclosure. Numerical results via a finite-difference method for the governing differential equations of the problem considered have been obtained for two different conductive fins with Ra = 10^3 to 10^7, AR = 1, 5, 8, and 10, N = 1 to 4, and t = 0.00001 to 0.125. The results demonstrate that the feasibility and effectiveness of using horizontal fins to enhance heat transfer across a vertical rectangular enclosure depend strongly on the aspect ratio, the Rayleigh number, the thermal conductivity, and the number of fins in the enclosure.

11A787. Laminar free convection in a nonrectangular inclined cavity. - GN Facas *(Dept of Mech Eng, Trenton State Col, Trenton NJ 08650)*. J Thermophys Heat Transfer 7(3) 447-453 (Jul-Sep 1993).

Numerical calculations are presented for 2D natural convection flow in a nonrectangular inclined cavity. The governing equations in the stream function-vorticity formulation are solved using finite differences. Arakawa's differencing scheme is used to represent the convection terms. Flow characteristics are investigated for Grashof numbers and inclination angles in the range of 9.0 $\times 10^3$ to 1.25×10^5, and -30 to 30° (from the vertical), respectively. A multicellular flow structure is found to exist for all angles of inclination considered. Although steady-state solutions were achieved for all Grashof numbers and angles of inclination considered, the flow structure that was predicted (steady vs unsteady) was found to depend strongly on the initial condition and, in some cases, unsteady flows were predicted if the "wrong" initial condition was specified.

11A788. Laminar natural convection in a horizontal rhombic annulus. - F Moukalled, H Diab *(Fac of Eng and Architec, American Univ, Beirut, Lebanon)*, S Acharya *(Dept of Mech Eng, Louisiana State Univ, Baton Rouge LA 70803)*. Numer Heat Transfer A 24(1) 89-107 (Jul-Aug 1993).

This paper presents the simulation of heat transfer and flow patterns in an enclosure between two isothermal concentric cylinders of rhombic cross sections. Four different values of the enclosure gap (E_g = 0.875, 0.75, 0.5, and 0.25) and three different rhombic angles (Ω = 10°, 20°, and 30°) are considered. At low Rayleigh numbers (10^3-10^5) the flow is weak and conduction is the dominant mode of heat transfer. Convection plays a key role starting at higher Rayleigh numbers (10^6-10^7). For all cases studied, there is no tendency for flow separation at the horizontal corners. The flow strength is found to increase with increasing rhombic angle, increasing enclosure gap, and increasing Rayleigh number. The critical Rayleigh number at which the heat transfer is influenced by convection decreases with increasing gap values and increasing rhombic angle; it is as high as 10^6-10^7 for E_g = 0.25 and decreases to about 10^4, for E_g = 0.875.

11A789. Laminar natural convection in internally finned horizontal annuli. - JC Chai and SV Patankar *(Dept of Mech Eng, Univ of Minnesota, Minneapolis MN 55455)*. Numer Heat Transfer A 24(1) 67-87 (Jul-Aug 1993).

An analysis is made of laminar natural convection in two internally finned horizontal annuli. The governing equations were solved numerically by a control-volume-based finite difference method. Information about the flow patterns and temperature distributions is presented through velocity vectors, streamlines, and isotherm plots. The effects of Rayleigh number and fin height on the Nusselt numbers are presented for two selected fin orientations. Variations of the local Nusselt numbers along the inner cylinder are also presented. In the cases studied, orientations of the internal fins are found to have insignificant effects on the average Nusselt number.

11A790. Numerical study of laminar and turbulent natural convection in an inclined square cavity. - RA Kuyper, TH van der Meer, CJ Hoogendoorn, RAWM Henkes *(Fac of Appl Phys, Univ of Tech, Lorentzweg 1, 2628 CJ Delft, Netherlands)*. Int J Heat Mass Transfer 36(11) 2899-2911 (Jul 1993).

Two-dimensional numerical simulations of the natural convection flow of air in a differentially heated, inclined square cavity were performed for both laminar and turbulent flows. The angle of inclination of the cavity was varied from 0° (heated from below) to 180° (heated from above). For Rayleigh numbers between 10^4 and 10^{11} the natural convection flow has been calculated. A detailed analysis was made for Rayleigh numbers of 10^6 and 10^{10}. The standard κ - ε model for turbulence was used in the prediction of turbulent flows. Numerical predictions of the heat flux at the hot wall and the influence of the angle of inclination on the Nusselt number are presented. The Nusselt number shows strong dependence on the orientation of the cavity and the power law dependence on the Rayleigh number of the flow. Flow patterns and isotherms are shown to give greater understanding of the local heat transfer. For the high Rayleigh number calculations hysteresis of the solution was found at a transient of flow patterns.

11A791. Scaling of the laminar natural-convection flow in a heated square cavity. - RAWM Henkes and CJ Hoogendoorn *(JM Burgers Centre for Fluid Mech, Fac of Appl Phys, Delft Univ of Tech, PO Box 5046, 2600 GA Delft, Netherlands)*. Int J Heat Mass Transfer 36(11) 2913-2925 (Jul 1993).

The steady laminar natural-convection flow of air and water in a square heated cavity is calculated for increasingly large Rayleigh number. The flow is calculated by solving both the Navier-Stokes equations and the boundary-layer equations. The results are used to determine the proper scalings of the flow in the different asymptotic flow regions: vertical boundary layers, core region, corner region and horizontal boundary layers. In particular the scalings according to the Navier-Stokes equations agree with the asymptotic model for the core and vertical boundary layers as proposed by Gill.

11A792. Transition to time-periodicity of a natural-convection flow in a 3D differentially heated cavity. - RJA Janssen, RAWM Henkes, CJ Hoogendoorn *(JM Burgers Centre, Dept of Appl Phys, Univ of Tech, PO Box 5046, 2600 GA Delft, Netherlands)*. Int J Heat Mass Transfer 36(11) 2927-2940 (Jul 1993).

The steady and time-periodic flow of air in a differentially heated cubical cavity has been studied numerically, using the finite-volume method. In the steady flow regime, the scaling in the boundary layer along the wall has been investigated. In the periodic flow regime, the calculated frequency was almost the same as for the 2D square cavity, suggesting that the same instability mechanism is in both cases responsible for the bifurcation. There was, however, a strong 3D in the distribution of the amplitude of the oscillations.

402F. THERMALLY UNSTABLE CONFIGURATIONS

11A793. Instability of radiation-induced flow in an inclined slot. - Wen-Mei Yang and Mou-Chang Leu *(Dept of Mech Eng, Natl Chiao Tung Univ, Hsinchu, Taiwan 30049, ROC)*. Int J Heat Mass Transfer 36(12) 3089-3098 (Aug 1993).

The instability of radiation-induced flow of a participating fluid in an inclined slender slot irradiated from one boundary is studied numerically for the inclination from 0° to 90°. The Eddington approximation is employed for the equation of transfer, and the pseudospectral method is used to solve the linearized perturbed equations. At an angle smaller than the transition angle the instability sets in as stationary longitudinal rolls. At an angle greater than the transition angle the instability occurs in the form of traveling transverse waves. The transition angle for the fluid of Pr = 0.71 is found to be minimum at the optical thickness near unity. Increasing optical thickness decreases the penetration of radiant energy, consequently increases the stability. The critical Rayleigh number increases rapidly with increasing the optical thickness as the optical thickness is greater than one.

11A794. Thermally unstable convection with applications to chemical vapor deposition channel reactors. - G Evans *(Comput Mech Div, Sandia)* and R Greif *(Mech Eng Dept, UCB)*. Int J Heat Mass Transfer 36(11) 2769-2781 (Jul 1993).

The 3D, thermally unstable flow and heat transfer of a gas have been studied in a horizontal channel with applications to chemical vapor deposition. The cases examined include flows that exhibit a longitudinal roll instability and a combination of both transverse, traveling waves and longitudinal rolls. Detailed results are presented for two values of the temperature ratio $\varepsilon = (T_1 - T_0)/T_0$ = 0.01 and 2.33 (helium), Grashof number $Gr = g\varepsilon H^3/\nu^2_0$ = 125,000, Prandtl number $Pr = \nu_0/\alpha_0$ = 2/3, aspect ratios L/H = 10 and W/H = 2. For ε = 0.01 and Reynolds number $Re = uH/\nu_0$ = 250, longitudinal rolls result whereas for Re = 100 a combination of transverse waves and longitudinal rolls occurs. For ε = 2.33 and Re = 100 the longitudinal roll instability is present.

402G. COMBINED NATURAL AND FORCED CONVECTION

11A795. Cool-down of a vertical line with liquid nitrogen. - A Hedayatpour *(Adv Program Dev and Prod Support, McDonnell Douglas Space Syst, 689 Discovery Dr, Huntsville AL 35806)*, BN Antar *(Dept of Eng Sci and Mech, Univ of Tennessee Space Inst, Tullahoma TN 37388)*, M Kawaji *(Dept of Chem Eng and Appl Chem, Univ of Toronto, ON, Canada)*. J Thermophys Heat Transfer 7(3) 426-434 (Jul-Sep 1993).

Analytical and numerical modeling is presented for predicting the thermofluid parameters of the cool-down process of an open-to-air vertical tube carrying liquid nitrogen. A two-fluid mathematical model is employed to describe the flowfield. In this model, four distinct flow regions were analyzed: 1) fully liquid, 2) inverted annular film boiling, 3) dispersed flow, and 4) fully vapor. These flow regimes were observed in an experimental investigation constructed for validating the mathematical model, and also in previous experiments by other investigators. For the single-phase regions, the 1D form of mass, momentum, and energy equations were used. For the two phase regions, the volume-averaged, phasic 1D form of conservation equations were applied. The 1D energy equation was formulated to determine the tube wall temparature history. The numerical procedure is based on the semi-implicit, finite-difference technique. The calculations for the inverted annular film boiling were performed implicitly. The computations for the tube wall, fully liquid, and dispersed flow regions were performed implicitly. The computations for the tube wall, fully liquid, and dispersed flow regions were performed explicitly. In each region, the appropriate models for heat transfer and shear stress rates are used. Results and comparisons of the predicted numerical models with the experimental data for several constant inlet flow rates of liquid nitrogen into a vertical, insulated tube are presented.

11T796. Correlation formulas for mixed convection heat transfer in saturated porous media. - DA Nield *(Dept of Eng Sci, Univ of Auckland, Auckland, New Zealand)*. Int J Heat Fluid Flow 14(2) 206 (Jun 1993).

11A797. Investigation of transient mixed convection heat transfer of cold water in a tall vertical annulus with a heated rotating inner cylinder. - CJ Ho and FJ Tu *(Dept of Mech Eng, Natl Cheng Kung Univ, Tainan, Taiwan 701, ROC)*. Int J Heat Mass Transfer 36(11) 2847-2859 (Jul 1993).

The transient buoyant rotating convective flow and heat transfer in a tall vertical annulus containing cold water near the density inversion have been investigated via a finite difference procedure. Simulations are carried out by solving axisymmetric Navier-Stokes equations adhering to the Boussinesq approximation coupled to the energy equation for an aspect ratio A = 8 and radius ratio RR = 2, two density inversion parameters $\theta_m = 0.4$ and 0.5, three Reynolds numbers Re = 50, 100, and 150, and varying Rayleigh number (up to 10^6). Numerical results demonstrate that the transient mixed convective flow and heat transfer may evolve into sustained oscillation over a certain range of Rayleigh number at given θ_m and Re; outside such unstable Ra-range, the transient evolution converges to steady-state solution. The transition into oscillatory convection arises at higher Rayleigh number with higher Reynolds number. Within the unstable convection regimes, simple as well as complex periodic oscillation, and chaotic oscillations have been detected. Moreover, the unstable Ra-ranges under fixed Re for $\theta = 0.5$ are found to be wider than those for $\theta_m = 0.4$, clearly reflecting the effects of the density inversion on the transient buoyant rotating convective flow and heat transfer in the wall vertical annulus.

11A798. Laminar mixed convection in a duct with a backward-facing step: The effects of inclination angle and Prandtl number. - B Hong, BF Armaly, TS Chen *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)*. Int J Heat Mass Transfer 36(12) 3059-3067 (Aug 1993).

Mixed convective heat transfer results for 2D laminar flow in an inclined duct with a backward-facing step are presented for both the buoyancy assisting and the buoyancy opposing flow conditions. The wall downstream of the step is maintained at a uniform heat flux, while the straight wall that forms the other side of the duct is maintained at a constant temperature equivalent to the inlet fluid temperature. The wall upstream of the step and the backward-facing step are considered as adiabatic surfaces. The inlet flow is fully developed and is at a uniform temperature. The effects of the inclination angle and Prandtl number on the velocity and temperature distributions are reported.

11T799. Mixed convection flow in a curved annulus: Effect of radius ratio. - SO Park and HK Choi *(Korea Adv Inst of Sci and Tech, Kusong-Dong Yusung-Ku, Taejon, Korea)*. Phys Fluids A 5(7) 1843-1845 (Jul 1993).

11A800. Mixed convection heat transfer in open ended inclined channels with discrete isothermal heating. - C Yucel, M Hasnaoui, L Robillard, E Bilgen *(Ecole Polytech, Univ of Montreal, CP 6079 St A, Montreal, PQ, H3C 3A7, Canada)*. Numer Heat Transfer A 24(1) 109-126 (Jul-Aug 1993).

A numerical study is carried out on mixed convection heat transfer (laminar natural and forced convection) in inclined open ended channels. The isothermal discrete heating elements are equally distanced and placed on one side, while isothermal conditions are imposed on the other. The governing equations are solved using the finite difference method. Normalized average and local Nusselt numbers are calculated as functions of the Rayleigh number ($10^3 \le Ra \le 10^5$), Reynolds number ($10 \le Re \le 50$), inclination angle ($0 \le \theta \le 90$), various heat sources ($0.1 \le A \le 1$), and various aspect ratios ($5 \le B \le 20$). These include, as limiting cases, horizontal and vertical positions. Flow and temperature fields for various cases are also produced.

11A801. Mixed convection in an inclined channel with a discrete heat source. - CY Choi and A Ortega *(Dept of Aerospace and Mech Eng, Univ of Arizona, Tucson AZ 85721)*. Int J Heat Mass Transfer 36(12) 3119-3134 (Aug 1993).

The effects of laminar forced flow on buoyancy-induced natural convection cells throughout the regions of natural, mixed, and forced convection have been numerically investigated for a parallel planes channel with a discrete heat source. Emphasis is placed on the influence of the inlet flow velocity and the inclination angle of the channel, and the local buoyancy induced by the discrete source. The results indicate that the overall Nusselt number of the source strongly depends on the inclination angle (γ) in the natural and mixed convection regimes when $\gamma > 45°$. On the other hand, the changes in Nu and $\theta_{s,max}$ are negligible when the channel is from 0 to 45°, there is no significant penalty in heat transfer due to the inclination of the channel up to $\gamma = 45°$. As Gr increases at a fixed Re, the entrainment of the air from the downstream exit is observed for the case of aiding flow.

11A802. Mixed convective flow with mass transfer in a horizontal rectangular duct heated from below simulated by the conditional Fourier spectral analysis. - I Hosokawa, Y Tanaka *(Dept of Mech and Control Eng, Univ of Electro-Commun, Chofu, Tokyo 182, Japan)*, K Yamamoto *(Natl Aerospace Lab, Chofu, Tokyo 182, Japan)*. Int J Heat Mass Transfer 36(12) 3029-3042 (Aug 1993).

With application to a horizontal chemical vapor deposition apparatus in mind, mixed convection and mass transfer in a horizontal rectangular duct heated from below are numerically investigated. 11A803. Forced convection heat transfer to an elastic fluid of constant viscosity flowing through a channel filled with a Brinkman-Darcy porous medium. - AV Shenoy *(Dept of Energy and Mech Eng, Shizuoka Univ, 3-5-1 Johoku, Hamamatsu 432, Japan)*. Warme Stoffubertragung 28(5) 295-297 (May 1993).

An analysis is presented of fully developed flow and heat transfer in a channel confined by two parallel walls subjected to uniform heat flux in a highly porous medium saturated with an elastic fluid of constant viscosity. The Brinkman-extended Darcy model is used for studying the effect of the boundary viscous frictional drag on the heat transfer characteristics. The approximate integral method is employed to obtain a solution.

402M. LIQUID METAL FLOWS

11A804. Low Prandtl number convection in layers heated from below. - V Kek and U Muller *(Kernforschungszentrum Karlsruhe, Inst Angewandte Thermo- and Fluiddyna, Postfach 36 40, W-7500 Karlsruhe 1, Germany)*. Int J Heat Mass Transfer 36(11) 2795-2804 (Jul 1993).

Experimental results are presented for the heat transfer across a horizontal layer of liquid sodium heated from below. The experiments show that up to a Rayleigh number of Ra ~ 7000 heat is mainly transferred by conduction for this low Prandtl number fluid. Beyond this threshold value the heat transport by convection increases significantly. For higher values of the Rayleigh number the measured Nusselt numbers follow a power law $Nu \sim Ra^{0.2}$ which is slightly smaller than the one predicted for the so-called flywheel convection as suggested by Jones *et al.*

11A805. Modeling of turbulent buoyant flow and heat transfer in liquid metals. - AA Mohamad and R Viskanta *(Sch of Mech Eng, Purdue)*. Int J Heat Mass Transfer 36(11) 2815-2826 (Jul 1993).

Turbulent convection in a cavity filled with low Prandtl number fluids is investigated. The cavity is either heated from below and cooled from above or heated differentially and the other connecting walls are assumed to be thermally insulated. Direct numerical simulations, and 2D and 3D low Reynolds number κ-ε turbulence models are used. It is shown that the turbulent Prandtl number equal to one or slightly greater than one produces useful results, regardless of the value of molecular Prandtl number. A correlation is suggested for the Nusselt number as a function of Ra Pr (Boussinesq number) for natural convection in a differentially heated cavity. The flow becomes turbulent for $Ra\,Pr > 4.8 \times 10^3$.

402P. TRANSPORT MECHANISMS

...06. **Impinging jet studies for turbulence ...ssessment I. Flow-field experiments.** - ...per, DC Jackson, BE Launder, GX Liao *...Mech Eng, UMIST, Manchester, UK)*. Int ... Mass Transfer 36(10) 2675-2684 (Jul

The paper reports an extensive set of measurements of a turbulent jet impinging orthogonally onto a large plane surface. Two Reynolds numbers have been considered, 2.3×10^4 and 7×10^4, while the height of the jet discharge above the plate ranges from two to ten diameters, with particular attention focused on two and six diameters. The experiment has been designed so that it provides hydrodynamic data for conditions the same as those for which Baughn and Shimizu have recently reported Nusselt number data (at Re = 23,000). In both experiments, before discharge the air passed along a smooth pipe sufficiently long to give fully developed flow at the exit plane of the jet - a feature that is helpful in using the data for turbulence-model evaluation. Hot-wire measurements have been made with pipes of nominally one-inch (26 mm) and four inches (101.6 mm) diameter. Data are reported of the mean velocity profile in the vicinity of the plate surface and also of the three Reynolds-stress components lying in the x-r plane. Computational results reported in a companion paper indicate a good degree of internal consistency between the mean and turbulent field data in the models predicting the mean flow poorly (or well) also predict the turbulence data poorly (well).

11A807. Impinging jet studies for turbulence model assessment II. An examination of the performance of four turbulence models. - TJ Craft, LJW Graham, BE Launder *(Dept of Mech Eng, UMIST, Manchester, UK)*. Int J Heat Mass Transfer 36(10) 2685-2697 (Jul 1993).

Four turbulence models are applied to the numerical prediction of the turbulent impinging jets discharged from a circular pipe measured by Cooper *et al*, Baughn and Shimizu and Baughn *et al*. They comprise one κ-ε viscosity model and three second-moment closures. In the test cases selected, the jet discharge was two and six diameters above a plane surface orthogonal to the jet's axis. The Reynolds numbers were 2.3×10^4 and 7×10^4, the flow being fully developed at the discharge plane. The numerical predictions, obtained with an extended version of the finite-volume TEAM code, indicate that the κ-ε model and one of the Reynolds stress models lead to far too large levels of turbulence near the stagnation point. This excessive energy in turn induces much too high heat transfer coefficients and turbulent mixing with the ambient fluid. The other two second-moment closures, adopting new schemes for accounting for the wall's effect on pressure fluctuations, do much better though one of them is clearly superior in accounting for the effects of the height of the jet discharge above the plate. None of the schemes is entirely successful in predicting the effects of Reynolds number. It is our view, however, that the main cause of this failure is the two-equation eddy viscosity scheme adopted in all cases to span the near-wall sublayer rather than the outer layer models on which the present study has focused.

11A808. Multiple jet impingement cooling. - MR Pais, LC Chow *(Dept of Mech Eng, Univ of Kentucky, Lexington KY 40506)*, ET Mahefkey *(Aerospace Power Div, Aero Propulsion and Power Lab. Wright R&D Center, WPAFB)*. J Thermophys Heat Transfer 7(3) 435-440 (Jul-Sep 1993).

Experiments were performed to study the effect of nozzle rotation, flow rate, degrees of subcooling, number of jets, and velocity on the heat flux in jet impingement cooling using deionized distilled water. The heat flux is a strong function of the flow rate and degree of subcooling, attaining a maximum value of the order of 600 W/cm^2 at the highest flow rates. The heat flux shows no significant dependency on velocity and number of jets for fixed flow rates. The rate of rotation shows no significant effects on the heat flux within the forced convective and early nucleate boiling region. At temperatures close to the critical heat flux the rotation retards the heat flux (compared with a stationary jet) diminishing it by 20%. Comparisons with published results are presented.

11A809. Ohmic heating of complex fluids. - A Ould El Moctar, H Peerhossaini *(Lab de Thermocinetique URA de CNRS No 869, ISITEM, La Chantrerie, CP 3023, 44087 Nantes, France)*, P Le Peurian *(EDF-DER Dept ADE, Centre des Renardieres, BP No 1, 77250, Moret sur Loing, France)*, JP Bardon *(Lab de Thermocinetique URA de CNRS No 869, ISITEM, La Chantrerie, CP 3023, 44087 Nantes, France)*. Int J Heat Mass Transfer 36(12) 3143-3152 (Aug 1993).

This paper describes the basic principles and physical modeling of systems based on the ohmic heating of liquids by passage of mains frequency electric current through the liquid itself, in order to heat it on a continuous flow regime. Preliminary numerical results for non-Newtonian fluids of Herschel-Bulckley type (Carbopol 940) are presented and the effect of natural convection, and shear and temperature dependence are emphasized.

402S. POROUS MEDIA

11A810. Conduction and convection heat transfer in composite solar collector systems with porous absorber. - M Mbaye and E Bilgen *(Ecole Polytech, CP 6079 St A, Montreal, PQ, H3C 3A7, Canada)*. Warme Stoffubertragung 28(5) 267-274 (May 1993).

Steady natural convection and conduction heat transfer has been studied in composite solar collector systems. The system consists of a glazing, a porous layer and a massive wall installed in a room. The heat transfer in this system is studied by assuming the glazing and the vertical bounding wall isothermal at different temperatures, two horizontal bounding walls adiabatic and porous layer without vents. The aspect ratio A was from 0.1 to 1.0 but the detailed study was carried out with A = 1. The thickness of the porous wall F_p varied from 1/3 to 1, while the solid wall thickness was kept constant. The conductivity ratio of porous layer was from 10^{-2} to 10^{-2}, Ra from 10^3 to 10^7. The results are presented in terms of thermal parameters as function of Ra and non-dimensional geometrical parameters. The isotherms and stream lines within the system are produced.

11A811. Natural convection and heat transfer in a vertical cavity filled with an ice-water saturated porous medium. - Xiaoli Zhang *(Dept of Mech Eng, Ecole Polytech, Montreal, PQ, H3C 3A7, Canada)*. Int J Heat Mass Transfer 36(11) 2881-2890 (Jul 1993).

A numerical study is made of natural convection and heat transfer in a rectangular porous cavity filled with an ice-water saturated porous medium. The two vertical sides of the cavity are cooled and heated at temperatures below and above the fusion point. The remaining sides of the cavity are assumed perfectly insulated. Special attention is focused on the influence of the heating temperature on the steady solutions. The Landau-transformation is used to immobilize the ice-water interface and the Darcy-Boussinesq equations are solved by the finite-difference technique. It is found that local maximum and minimum average Nusselt numbers occur at heating temperatures of 5 and 8°C, respectively. The melt region is wider at the bottom if the heating temperature is less than 8°C while the inverse is true for heating temperatures higher than 8°C. The 4°C isotherm is the boundary between the two counter-rotating flows at a heating temperature of 8°C only, otherwise the dominant flow crosses the 4°C isotherm and penetrates into the other layer as the heating temperature is higher than 4°C.

11A812. Natural convection in vertical porous enclosures due to prescribed fluxes of heat and mass at the vertical boundaries. - F Alavyoon *(Vattenfall Utveckling AB, S 810-70 Alvkarleby, Sweden)*. Int J Heat Mass Transfer 36(10) 2479-2498 (Jul 1993).

Unsteady and steady convection in a fluid-saturated, vertical and homogeneous porous enclosure has been studied numerically on the basis of a 2D mathematical model. The buoyancy forces that induce the fluid motion are due to cooperative and constant fluxes of heat and mass on the vertical walls. For the steady state, an analytical solution, valid for stratified flow in slender enclosures, is presented. Scale analysis is applied to the two extreme cases of heat-driven and solute-driven natural convection. Comparisons between the fully numerical and analytical solutions are presented for $0.1 \le R_c \le 500$, $2 \le Le \le 10^2$, $10^{-2} \le N \le 10^4$ and $1 \le A \le 10$, where R_c, Le, N and A denote the solutal Rayleigh-Darcy number, Lewis number, inverse of buoyancy ratio and enclosure aspect ratio, respectively. The numerical results show that for any value of Le > 1, there exists a minimum A below which the concentration field in the core is rather uniform and above which it is linearly stratified in the vertical direction. For sufficiently high aspect ratios, the agreement between the numerical and analytical solutions is good. The results of the scale analysis agree well with approximations of the analytical solution in the heat-driven and solute-driven limits. The numerical results indicate that for Le > 1 the thermal layers at the top and the bottom of the enclosure are thinner than their solutal counterparts. In the boundary layer regime, and for sufficiently high A, the thickness of the vertical boundary layer of velocity, concentration and temperature are shown to be equal, regardless of the value of Le.

402Y. COMPUTATIONAL TECHNIQUES

11A813. Natural convection in a cylindrical cavity heated by an internally-located strong source. - J Slomczynska *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 41(2) 187-208 (1993).

Stationary natural convection caused by a strong source of heat centrally located in a cylindrical cavity is analyzed by a finite-difference method. Since gradients of pressure are much smaller than gradients of both the temperature and density, the axisymmetric flow is treated as incompressible while, for the same reason, variable density is fully accounted for. Viscosity and thermal conductivity are assumed to be functions of temperature. Coupled stationary equations of continuity, motion, and energy are formulated in the framework of primitive variables. Line integration of the equation of motion over a closed contour is used to eliminate pressure. The solution, ie, temperature (hence, density) and velocity distributions in the cavity, is found by a two-step iterative procedure based on line successive over-relaxation. Examples of computation showing the effects of change in the source heat-rate, mean value of pressure and the aspect ratio of the cavity are provided.

404. Two phase convection

404H. FLOW BOILING, PEAK HEAT FLUX (EXTERNAL)

11A814. CHF mechanism in flow boiling from a short heated wall I. Examination of near-wall conditions with the aid of photomicrography and high-speed video imaging. - JE Galloway

(Cummins Engine, Columbus IN 47202) and I Mudawar *(Boiling and Two-Phase Flow Lab, Sch of Mech Eng, Purdue)*. Int J Heat Mass Transfer 36(10) 2511-2526 (Jul 1993).

Results of flow visualization experiments are presented to clearly identify the trigger mechanism for critical heat flux (CHF) in flow boiling. It is shown that discrete bubbles which form following the onset of nucleation coalesce into a wavy vapor layer at fluxes well below CHF. Depressions in the layer interface were observed to touch the heater surface periodically, painting a thin liquid sub-film on the surface beneath the vapor layer. This sub-film was consumed by a combination of vigorous boiling and interfacial evaporation. As CHF was approached, boiling became more concentrated toward the leading edge of the heater surface and around regions where the vapor layer interface touched the surface, while the remaining parts of the surface were dry. CHF was exceeded when severe vapor effusion from the sub-film normal to the heater surface lifted the wavy interface away from the surface, precluding any sustained wetting and resulting in a global dry-out.

11A815. CHF mechanism in flow boiling from a short heated wall II. Theoretical CHF model. - JE Galloway *(Cummins Engine, Columbus IN 47202)* and I Mudawar *(Boiling and Two-Phase Flow Lab, Sch of Mech Eng, Purdue)*. Int J Heat Mass Transfer 36(10) 2527-2540 (Jul 1993).

A theoretical CHF model is presented which is based upon the flow visualization of the wavy liquid-vapor interface near the heated surface as reported in Part I of this study. At approximately 90% of CHF, bubbles coalesced into a continuous wavy vapor layer and vigorous boiling was observed in a liquid sub-film beneath the vapor layer. This efficient boiling mechanism was transformed to boiling at isolated regions, wetting fronts, at approximately 95% of CHF. Wetting fronts were established when minimum points in the wavy vapor interface made contact with the heater surface. Regions surrounding the wetting fronts remained dry as the supply of liquid was consumed. CHF was triggered by intense vapor production which lifted the upstream wetting front away from the heater surface, cutting the supply of liquid locally and causing the heat flux to become more concentrated at the remaining wetting fronts. Soon after, remaining wetting fronts were also lifted from the heater surface and the surface temperature increased more rapidly. The new mechanistic CHF model incorporates classical interfacial instability theory for a confined 2D wave, a separated two-phase flow model and a criterion for separation of the liquid-vapor interface from the heater surface. The model predictions show good agreement with the experimental data.

404J. FILM BOILING (FLOW)

11A816. Similarity solution for laminar film boiling over a moving isothermal surface. - J Filipovic, R Viskanta, FP Incropera *(Heat Transfer Lab, Sch of Mech Eng, Purdue)*. Int J Heat Mass Transfer 36(12) 2957-2963 (Aug 1993).

Forced film boiling arises when a liquid flows over a highly superheated surface or when the surface moves through a liquid which is stationary or is itself in motion. As a result of the vapor layer separating the surface and the liquid, there is a significant reduction in the drag force and heat transfer. In this study, a similarity solution of the boundary layer equations is obtained, and for a wide range of subcooling parameters and surface velocities, related numerical results are shown to be in excellent agreement with predictions based on an integral method.

11A817. Vapor-film-unit model and heat transfer correlation for natural-convection film boiling with wave motion under subcooled conditions. - Shigefumi Nishio and Hiroyasu Ohtake *(Inst of Indust Sci, Univ of Tokyo, 7-22-1 Roppongi Minato-ku, Tokyo 106, Japan)*. Int J Heat Mass Transfer 36(10) 2541-2552 (Jul 1993).

This report presents a heat transfer model and correlation of natural-convection film-boiling heat transfer with interfacial wave motion under subcooled conditions. First, the vapor-film-unit model developed for saturated film boiling in our previous report was extended to subcooled film boiling along inclined and vertical flat-plates and also around horizontal cylinders of large diameter. Next, based on the vapor-film-unit model, a general form of heat transfer correlation of film boiling with wave motion was developed. Comparisons with experimental data showed that the present heat transfer model and correlation can predict the effects of the fluid properties, liquid subcooling, wall superheat, the geometry, and the size of the heat transfer surface on film-boiling heat transfer with wave motion.

404L. TRANSITION BOILING

11A818. Second-order instability on an electrically heated temperature-controlled test section under forced convective boiling conditions. - XC Huang and G Bartsch *(Inst Energietech, TU Berlin, Marchstr 18, 1000 Berlin 10, Germany)*. Int J Heat Mass Transfer 36(10) 2601-2612 (Jul 1993).

During boiling experiments with electrically heated temperature-controlled test sections it was observed by many researchers that although stability conditions can be satisfied in the ordinary sense, wall temperature distribution may tilt over from one form to another quite different form near the CHF and the minimum film boiling conditions. The measured local boiling curves appeared to be discontinuous. By solving the heat conduction problem of the test section with a simplified continuous boiling topography as one of its boundary conditions it is shown that the discontinuous phenomena may be caused by the experimental construction rather than by boiling characteristics. Using an unsteady-state measurement system the two types of second-order instability are observed. Possible ways of getting a fully stable operation of the test section are proposed.

404M. CONDENSATION (STATIC VAPOR)

11A819. Condensation and evaporation of liquid droplets at arbitrary Knudsen number in the presence of an inert gas. - JB Young *(Whittle Lab, Univ of Cambridge, Madingley Rd, Cambridge CB3 0DY, UK)*. Int J Heat Mass Transfer 36(11) 2941-2956 (Jul 1993).

A new set of equations describing the growth and evaporation of stationary liquid droplets in a mixture of pure vapour and inert gas is presented. The equations, which model the heat and mass transfer between the droplet and its environment, are presented in a simple algebraic form and are suitable for practical calculations of droplet growth at any Knudsen number and at any concentration of inert gas. In particular, they are not restricted to the so-called \quasi-steady\rm regime of droplet growth when the droplet surface temperature has relaxed to its steady-state value. The physical model on which the theory is based is essentially that of Langmuir but some novel features are incorporated. Thus, the velocity distribution functions for vapour and inert gas molecules approaching the liquid surface are assumed to correspond to simplified Grad thirteen-moment distributions and this allows correct representation at a molecular level of the heat and mass fluxes at the outer edge of the Knudsen layer. In contrast to most simple models of condensation and evaporation, the theory predicts finite (as opposed to zero) temperature and vapour pressure jumps across the Knudsen layer in the continuum limit and shows that the former is directly proportional to the concentration of vapour present. The analysis also provides a physical interpretation for the origins of the *reversed temperature gradient phenomenon* in the Knudsen layer, an unusual feature predicted by more complex solutions of the Boltzmann equation itself. The transition from diffusion to kinetic control as the pure vapour limit is approached is also modeled by the theory which shows that the range of Knudsen numbers over which this occurs is of the same order as the mole fraction of inert gas present.

404O. EVAPORATION

11A820. Multicomponent droplet evaporation at intermediate Reynolds numbers. - M Renksizbulut and M Bussmann *(Dept of Mech Eng, Univ of Waterloo, ON, N2L 3G1, Canada)*. Int J Heat Mass Transfer 36(11) 2827-2835 (Jul 1993).

The convective evaporation of a binary hydrocarbon droplet (decane-hexadecane) in air at 1000 K and at a pressure of 10 atmospheres has been studied using numerical methods. All transient effects including droplet size and velocity variations, heat and mass transfer within the liquid phase, and thermophysical property variations with temperature and concentration in both phases are included in the analysis. As the rate controlling process, liquid phase mass transfer is examined in detail. It is demonstrated that the existing drag coefficient, Sherwood number, and Nusselt number correlations originally developed for single-component droplets can be used for multicomponent droplets as well.

11A821. Single droplet vaporization including thermal radiation absorption. - PLC Lage *(Dept of Chem Eng, COPPE-UFRJ, PO Box 68502, 21945 Rio de Janeiro, Brazil)* and RH Rangel *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717)*. J Thermophys Heat Transfer 7(3) 502-509 (Jul-Sep 1993).

Total hemispherical absorption distributions for n-decane and water droplets irradiated by a blackbody under spherically symmetric conditions are used in the calcualtion of transient droplet heating and vaporization. The gas model used is based on the extended film theory. Three liquid-phase models have been extended to include thermal radiation absorption. The results show that radiation absorption can be as important as, or more important than, the choice of liquid-phase model. Based on the effective-conductivity model, two dimensionless parameters expressing the ratios of radiation absorption and gas-liquid heat transfer to liquid conductive and convective heat transfer are defined. It is shown that the first parameter determines the droplet heating regime. Over 200 numerical calculations using the effective-conductivity model and various initial and ambient conditions have been performed for water and n-decane droplets. It is shown that the ratio of the 2D parameters evaluated at the initial time can be used to correlate and predict the radiation absorption influence on the droplet lifetime. All cases investigated correspond to the slow heating regime. Under the conditions analyzed, the nonuniformity of the radiation absorption has little effect on the overall droplet heating and vaporization process.

11A819. Condensation and evaporation of liquid droplets at arbitrary Knudsen number in the presence of an inert gas

404P. SURFACE TENSION EFFECTS

11A822. Role of surface tension and ellipticity in laminar film condensation on a horizontal elliptical tube. - Sheng-An Yang and Cha'o-Kuang Chen *(Dept of Mech Eng, Natl Cheng-Kung Univ, Tainan, Taiwan, ROC)*. Int J Heat Mass Transfer **36**(12) 3135-3141 (Aug 1993).

An analytical study is made into the process of heat transfer with the vapor condensation on a horizontal elliptical tube under the simultaneous effects of the forces of surface tension and gravity on the condensate film. Analytical expressions for both local condensate film thickness and heat transfer coefficient around the elliptical periphery have been derived under the effects of gravity and surface tension for various values of ellipticity, respectively. The dimensionless mean heat transfer coefficient - Nu for any ellipticity e and various Bond numbers Bo has been obtained; however, it is almost unaffected by surface tension force due to surface curvature changing. For special objects (vertical plate e = 1, circular tube e = O), the results are identical to some classical Nusselt-type solutions.

404R. SOLID-FLUID FLOWS

11A823. Interaction between liquid droplets and heated surface. - BI Nigmatulin, NI Vasiliev, VV Guguchkin *(Res Eng Centre, LWR Nucl Plants Safety, Bezymyannaya 6 142530 Elektrogorsk, Moscow Region, Russia)*. Warme Stoffubertragung **28**(6) 313-319 (Jun 1993).

In this paper, experimental methods and investigation results of interaction between droplets of different liquids and a heated surface are presented. Wetted area, contact time period and transition boundary from wetted to non-wetted interaction regimes are experimentally evaluated. A simple connection of the wetted area value and contact line period with the heat removal efficiency is shown.

11A824. Kinetic and heat transfer-controlled solidification of highly supercooled droplets. - M Epstein and HK Fauske *(Fauske & Assoc, 16W070 W 83rd St, Burr Ridge IL 60521)*. Int J Heat Mass Transfer **36**(12) 2987-2995 (Aug 1993).

An efficient integral profile computational method is used to solve the problem of the solidification of highly subcooled droplets. The effects of surface cooling by radiation and convection, interface crystallization kinetics and fully time-dependent heat conduction are included in the method. Particular attention is focused on the predicted drop surface temperature-time histories as these, together with available experimental luminosity-time traces for solidifying microspheres of Al_2O_3 and ZrO_2, are used to infer the coefficient of the kinetic law for Al_2O_3 crystallization - one of the crucial parameters in a recently proposed theory of underwater aluminum ignition.

404S. ELECTRIC FIELD EFFECTS

11A825. Magnetorheological control of heat transfer. - WI Kordonsky, SP Gorodkin, SA Demchuk *(AV Lukov Heat and Mass Transfer Inst, Acad of Sci, Minsk 220072, Belarus)*. Int J Heat Mass Transfer **36**(11) 2783-2788 (Jul 1993).

Results of experimental investigation of the effect of magnetic fields on thermal processes taking place in magnetorheological suspensions (MRS) are presented. It is shown that by varying the orientation and strength of the field it is possible to control heat transfer within a wide range. Anisotropy of the thermal conductivity of MRS is established. In the case of the field lines being co-directional with a heat flux, the thermal conductivity coefficient increases by about 70%, whereas with their normal relative orientation it decreases by about 50%. The effect of a rotating magnetic field on MRS shear flow in a gap causes an almost 15-fold enhancement of heat transfer. Heat transfer of a turbulent suspension flow in a channel is intensified by an order of magnitude on superposition of a homogeneous field, transversely to the channel axis, and is suppressed twice as much in the case of parallel orientation. Examples and recommendation for practical application of the regularities revealed are given.

404V. POROUS MEDIA

11A826. Two-phase mixture model of liquid-gas flow and heat transfer in capillary porous media I. Formulation. - Chao-Yang Wang and C Beckermann *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*. Int J Heat Mass Transfer **36**(11) 2747-2758 (Jul 1993).

A model for two-phase transport in capillary porous media is presented, in which the two phases are viewed as constituents of a binary mixture. The conservation equations are derived from the classical separate flow model without invoking additional assumptions. The present formulation, owing to its analogy for conventional multicomponent mixture flow theories and to a considerable reduction in the number of the differential equations required for the primary variables, provides an alternative for the theoretical analysis and numerical simulation of two-phase transport phenomena in porous media. Several complicated problems such as boundary layer two-phase flows, conjugate two- and single-phase flows in multiple regions and transient flows are shown to become more tractable within the framework of this new formulation.

11A827. Two-phase mixture model of liquid-gas flow and heat transfer in capillary porous media II. Application to pressure-driven boiling flow adjacent to a vertical heated plate. - Chao-Yang Wang and C Beckermann *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*. Int J Heat Mass Transfer **36**(11) 2759-2768 (Jul 1993).

The two-phase mixture model developed in Part I is applied to investigate a pressure-driven two-phase boiling flow along a heated surface embedded in a porous medium. The general governing equations in Part I for the transport of mass, momentum and liquid (constituent) mass for the two-phase mixture are simplified for the above system. The present formulation, owing to its strong analogy to the classical description of multicomponent convective flows, suggests that a thin capillary layer exists over the solid surface at high Peclet numbers and that the two-phase flow is confined only to this boundary layer. Using approximations analogous to the classical boundary layer theory, a set of boundary layer equations for two-phase flow is derived and solved by a similarity transformation. The resulting ordinary differential equations are numerically integrated using a combination of the Gear stiff method and a shooting procedure. Numerical results for the saturation field and the flow fields of the two-phase mixture and the individual phases are presented and discussed.

404Y. COMPUTATIONAL TECHNIQUES

11A828. Time-marching method for the prediction of 2D, unsteady flows of condensing steam. - AJ White and JB Young *(Dept of Eng, Whittle Lab, Univ of Cambridge, Madingley Rd, Cambridge CB3 0DY, UK)*. J Propulsion Power **9**(4) 579-587 (Jul-Aug 1993).

A time-accurate, 2D time-marching technique is presented which can predict unsteady phenomena in condensing steam flows. Conservation equations for the mixture are solved using a variation of a well-established Euler solver, while nucleation and droplet growth calculations are performed in a Lagrangian framework by tracking particle pathlines. A special averaging technique is used to retain a polydispersion of droplet sizes, necessary for the accurate modeling of the condensation processes, without consuming excessive storage or CPU time. The basic Euler solution technique has been validated by comparison with predictions from an independent source for the unsteady flow of air in a channel. The full scheme has been used to compute nucleating flows in convering-diverging nozzles for which agreement with experiment for both steady and unsteady cases is extremely good. All the results presented are for flows in nozzles for which experimental data are available, but the scheme may also be applied to turbine cascade geometries.

404Z. EXPERIMENTAL TECHNIQUES

11A829. Theory and measurement of local interfacial area using a four sensor probe in two-phase flow. - ST Revankar and M Ishii *(Sch of Nucl Eng, Purdue)*. Int J Heat Mass Transfer **36**(12) 2997-3007 (Aug 1993).

A theoretical foundation of the measurement method for the time averaged local interfacial area using a four sensor resistivity probe is presneted. Based on this theory, the four sensor resistivity probe was developed and employed to measure the interfacial velocity, local interfacial area concentration and void fraction in a vertical air-water cap bubbly flow. The four sensor probe measurements were checked against the global void measurement using a differential pressure. The results were very satisfactory. Theoretical profiles of the void fraction and interfacial area concentration were obtained using the pictures of cap bubbles. The theoretical predictions of the cap bubbles and the interfacial area concentration profiles compared very well with the four sensor data.

406. Conduction

406A. GENERAL THEORY

11A830. Transmittances and frequency characteristics of wave and diffusion heat transfer in the flat slab. - J Golebiowski and AJ Jordan *(Tech Univ, 15-893 Bialystok, Poland)*. Int J Heat Mass Transfer **36**(12) 3099-3105 (Aug 1993).

This paper on conduction heat transfer in a slab presents a frequency domain comparison between the usual diffusion model and a wave model which includes the effect of non-instantaneous heat propagation. This is accomplished using a transfer function approach. Additionally, transfer functions relating the temperature distribution to heat flux are presented for various cases. The limit frequency, f_{ij}, is developed as that frequency below which the difference between the diffusion model and the wave model is negligible. Above this frequency, the difference between the two models increases rapidly. The work of this paper is an essential generalization of various specific cases found in the previous literature. It also refers to previous papers written by the authors.

406C. TRANSIENT PROBLEMS

11A831. Heat conduction in a semi-infinite solid subject to time-dependent surface heat fluxes: An analytical study. - SM Zubair *(Mech*

Eng Dept, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia) and MA Chaudhry *(Math Sci Dept, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)*. Warme Stoffubertragung **28**(6) 357-364 (Jun 1993).

A closed-form model for the computation of the transient temperature and heat flux distribution in the case of a semi-infinite solid of constant properties is investigated. The temperature and heat flux solutions are presented for time-dependent, surface-heat flux of the forms: (i) $Q_1(t) = Q_0(t/t\kappa)^{v-1}$, (ii) $Q_2(t) = Q_0\exp(-\lambda t)$, and (iii) $Q_3(t) = Q_0(t/t\kappa)\exp(-\lambda t)$, where λ is a real number and v is a positive real number. The dimensionless (or reduced) temperature and heat flux solutions are presented in terms of the Whittaker function, the generalized representation of an incomplete Gamma function $I_\alpha(b,x)$ which can also be expressed by the complementary error functions. It is also demonstrated that the present analysis covers some well known (classical) solutions as well as a family of new solutions for the heat transfer through a semi-infinite solid.

11A832. Transient heat conduction with uniform heat generation in a slab subjected to convection and radiation cooling. - N Onur and M Sivrioglu *(Dept of Mech Eng, Gazi Univ, 06570 Maltepe Ankara, Turkey)*. Warme Stoffubertragung **28**(6) 345-349 (Jun 1993).

A finite difference scheme with fourth-order Runge-Kutta method is employed to determine the unsteady state temperature distribution in a plane slab with uniform heat generation. The plane slab is insulated on one face and subjected to convective and radiative cooling at the other face. The plane slab has a uniform initial temperature and the ambient environment as well as the fluid temperatures are assumed to be constant. Heat conduction is considered to be 1D. Results are presented in dimensionless charts over a wide range of parameters.

11A833. Transient heat transfer from a solid sphere translating at low Reynolds number: Perturbation solution for low Peclet number. - SS Sadhal *(Dept of Mech Eng, Univ of S California, Los Angeles CA 90089-1453)*. Warme Stoffubertragung **28**(6) 365-370 (Jun 1993).

In this paper the heat transfer from a solid spherical particle translating at low Reynolds number is analytically examined for the limit of vanishing Peclet number. The temperature distribution within the solid sphere is treated as fully transient while the fluid phase is considered to be quasisteady. The temperature field in the dispersed phase is obtained by a singular perturbation expansion of the Acrivos-Taylor type. The time-dependence in the solid phase is handled by means of the Laplace transform. This approach allows the temperature and heat flux continuity conditions at the solid-liquid interface to be exactly satisfied. The solution in the time domain appears in the form of infinite series which have associated with them a set of eigenvalues for every order of the perturbation expansion. The Nusselt number to order Pe, however, depends only on the leading order eigenvalues. An analytical limit of the Nusselt number for large values of time is also obtained.

11A834. Two-dimensional linear transient inverse heat conduction problem: Boundary condition identification. - B Guerrier and C Benard *(URA 871 FAST, Natl Center for Sci Res, Batiment 502, Campus Univ, Orsay 91405, France)*. J Thermophys Heat Transfer 7(3) 472-478 (Jul-Sep 1993).

This article deals with the identification of unknown time- and space-dependent boundary conditions for systems driven by the heat equation. We first consider a 1D and single-input problem dealing with the identification of the time-dependent heat flux on one side of a 1D linear thermal wall, from temperature and heat flux measurements on the other side. We then focus on a quenching process; our interest is to identify the time- and space-dependent heat flux on the boundary of a metal piece from temperature measurements performed inside the material (2D geometry). Those inverse problems are solved by use of a regularization method, and the solution is obtained by minimization of a quadratic criterion. Because of the linearity of the input-output relationship, the solution of this minimization is derived from the linear quadratic optimal control theory (resolution of a nonstationary Riccati equation). The robustness of the method for very small signal-to-noise ratio is shown. In the 2D multi-input problem, the identification sensitivity to the localization of the measurement points is analyzed. In both cases, we consider input that are discontinuous in time, in order to show the method accuracy in the high-frequency domain.

406F. ANISOTROPIC MEDIA

11A835. Discrete element method for composite media: 1D heat conduction. - S Hou, AC Cogley *(Dept of Mech Eng, Kansas State Univ, Manhattan KS 66506)*, A Sharma *(IBM Corp Res, Yorktown Heights NY 10598)*. Int J Heat Mass Transfer **36**(12) 3009-3016 (Aug 1993).

Green's functions for steady-state, 1D heat conduction for discretely inhomogeneous media are found by using an interactive principle. Exact solutions can therefore be expressed by Green's representation. An unsteady problem is solved numerically by treating the time derivative as a source term. The results demonstrate accuracy, stability, and efficiency.

11A836. Double conductivity media: A comparison between phenomenological and homogenization approaches. - JL Auriault and P Royer *(Lab Sols, Solides, Struct, Inst Mec, Lab Assoc CNRS, BP 53X, Grenoble Cedex, France)*. Int J Heat Mass Transfer **36**(10) 2613-2621 (Jul 1993).

The heat transfer model for the double conductivity medium is investigated. The medium is composed of two homogeneous materials which differ considerably in their conductivity characteristics. The aim of this paper is to compare the descriptions obtained by a phenomenological and a homogenization approach. The first one, which introduces two temperature fields, is shown to be inefficient for a large range of phenomena. The latter gives the rigorous description. The study enables us to improve the phenomenological description. It provides an approximation which is valid for the quasi-static conditions.

11A837. Optimal experimental design for estimating thermal properties of composite materials. - R Taktak, JV Beck *(Heat Transfer Group, Dept of Mech Eng, Composites and Struct Center, Michigan State Univ, E Lansing MI 48824-1226)*, EP Scott *(VPI)*. Int J Heat Mass Transfer **36**(12) 2977-2986 (Aug 1993).

Design of optimal transient experiments is needed for the efficient estimation of thermal conductivity and volumetric heat capacity of composite materials. One criterion for optimal experiments is minimization of the area (or volume) of the confidence region. The experimental designs are transient and involve both finite and semi-finite geometries with finite duration heating. Two cases are considered for the finite body: 1D heat conduction within cured composite materials and 1D heat conduction within composite materials undergoing curing. The optimal dimensionless heating and experimental times at the heated boundary and the optimal location of the temperatures sensors are determined.

11A838. Thermal diffusion in cyclic laminated composites: Spectral properties and application to the homogenization. - M Bouzidi and P Duhamel *(Lab Thermique, CNAM, 292 rue Saint-Martin 75141, Paris Cedex 03, France)*. Int J Heat Mass Transfer **36**(11) 2715-2723 (Jul 1993).

The eigenvalue problem associated with thermal diffusion studies in cyclic multilayered composites is considered. The transfer matrix of these walls can be made explicit with the help of Chebycheff's polynomials. This general property is exploited in a detailed study of the first group of eigenvalues in order to propose a homogenization process for these media. By this way it is possible to find a homogeneous medium which has approximately the same first eigenvalues as the actual multilayered composite. The application to a binary composite leads to an interpretation of the time scale of the homogenized medium. This example reveals a very good accuracy in the temperature calculations. A corrective term which takes into account the finite number of the pattern repetitions, when determining the physical characteristics of the homogenized wall, is at the origin of that remarkable accuracy.

406G. POROUS AND GRANULAR MATERIAL

11A839. Heat transfer in evacuated crinkled or embossed multilayer foil insulations. - K Georg Degen, S Rossetto, J Fricke *(Physikalisches Inst, Universitat, Am Hubland, D-8700 Wurzburg, Germany)*. J Thermal Insulation Build Envelopes 16 340-355 (Apr 1993).

Evacuated multilayer insulations with crinkled or embossed foils without spacers were investigated in a guarded hot plate apparatus. In order to quantify the heat transfer mechanisms as well a their interaction, temperature and dependent measurements of the total heat transfer coefficient were performed. The mean temperature was varied between 260 and 550 K. Important parameters were type, coating, and crinkling treatment of the foils as well as the number of foil layers at a given thickness. The radiative heat transfer contribution is characterized by an effective emissivity εx of the foils; εx is greater than the emissivity ε of the smooth foil depends on the ε as well as on the crinkling or embossing intensity. For 30 nm double-sided aluminized polyimide foils with $\varepsilon = 0.020$ at T = 300 K, effective emissivities of $\varepsilon x = 0.022$ to 0.040 were obtained. Foils with aluminum coating thickness $\delta < 30$ nm showed a much higher εx; for $\delta \approx 17$ nm and $\delta \leq 10$ nm, emissivities of $\varepsilon x \geq 0.05$ and $\varepsilon x \geq 0.18$, respectively, were determined.

11A840. Measured thermal resistance of frame walls with defects in the installation of mineral fibre insulation. - WC Brown, MT Bomberg, JM Ullett *(Build Performance Lab, Inst for Res in Construct, NRC (IRC-NRCC), Ottawa, ON, K1A 0R6, Canada)*, J Rasmussen *(Rockwool Int A-S, Hedehusene, Denmark)*. J Thermal Insulation Build Envelopes **16** 318-339 (Apr 1993).

Studies have shown that convective air flow can significantly reduce the thermal resistance of frame walls insulated with mineral fibre insulation (MFI). It has also been shown that convective air flow can be avoided if the MFI products are installed with at least one face against an air impermeable material. The evolution of MFI products has seen the introduction of products with small fibre diameters and lighter densities, and there is a dominance of the frame wall insulation market by friction fit products. The effect of these changes on the installed (field) performance of MFI products is unknown, as the effect of "minor" installation defects on the performance of frame wall insulation systems. This article examines, through a program of full scale laboratory measurements, the effect of corner installation defects and product density on the thermal resistance of frame walls insulated with MFI products.

406I. PHASE CHANGE (FREEZING, MELTING)

11A841. Freezing of aqueous sodium chloride solution saturated packed bed from a vertical wall of a rectangular cavity. - J Choi and R Viskanta *(Heat Transfer Lab, Sch of Mech Eng, Purdue)*. Int J Heat Mass Transfer 36(11) 2805-2813 (Jul 1993).

Freezing of an aqueous solid chloride (H_2O-NaCl) solution saturating a packed bed of glass spheres is investigated experimentally. Experiments are conducted on the hypoeutectic side, and the cold wall temperature is lower than the eutectic point. Spherical soda-lime glass beads 2.85 mm and 6 mm in average diameter constituted the packed bed. The effects of initial salt concentration, superheat and bead diameter are investigated. Three distinct regions came into existence during the freezing process. Supercooling was observed only at early times of the freezing process for an experiment with 5% initial salt concentration. However, small supercooling was observed throughout the freezing process for the 15% initial salt concentration experiment. Reheating of the mixture was intensified with an increase in the bead diameter, initial salt concentration, and near the vertical hot wall. At the end of the freezing process, remelting was observed only at the mush-liquid interface for the 10-15% initial salt concentration experiments. Flow visualization experiment and mush-liquid observations revealed natural convection in the upper part of the liquid region. An enriched and stratified fluid layer existed in the bottom of the liquid region. The intensity of natural convection was affected by both the Darcy and modified Rayleigh numbers.

11A842. Melting around a shaft rotating in a phase-change material. - AM Morega, AM Filip, A Bejan *(Dept of Mech Eng and Mat Sci, Duke Univ, Box 90300, Durham NC 27708-0300)*, PA Tyvand *(Dept of Agri Eng, Agri Univ, PO Box 5065, N-1432 As, Norway)*. Int J Heat Mass Transfer 36(10) 2499-2509 (Jul 1993).

In this paper we describe the thin-film melting of a block of solid phase-change material (the bearing) around a rotating cylinder (the shaft). We determine the relation between the force applied on the shaft and the speed with which the shaft migrates into the bearing, the relation between the applied force and the torque, and the angle between the applied force and the direction of migration into the bearing. The method is based on contact melting theory, which combines the Reynolds thin-film lubrication theory with an analysis of phase-change heat transfer in the melt. The paper addresses three limiting regimes of the contact melting phenomenon: (1) the long bearing with melting due to frictional heating in the melt layer; (2) the short bearing with melting due to frictional heating in the melt layer, and (3) the short bearing with melting due to a temperature difference imposed between the hot cylinder and the cold phase-change material.

11A843. Two-dimensional freezing of water filled between vertical concentric tubes involving density anomaly and volume expansion. - Charn-Jung Kim, Sung Tack Ro, Joon Sik Lee, Moo Geun Kim *(Dept of Mech Eng, Seoul Natl Univ, Seoul 151-742, Korea)*. Int J Heat Mass Transfer 36(10) 2647-2656 (Jul 1993).

Freezing of an initially superheated water filled with an axisymmetric enclosure is studied numerically. Simulation is carried out using a computational method recently developed by the authors to treat moving boundary problems in axisymmetric geometries. Emphasized is the influence of both volume expansion and density anomaly upon freezing via natural convection. Two distinctive types of thermal boundary conditions are identified and utilized to guide our efforts to investigate the freezing process. Due to the density anomaly of pure water, fluid flow direction reverses depending on the initial superheat of water and thereby the interface slope exhibits an inversion behavior. By assuming that the water does not flood over the ice surface, the volume-change-induced rise of ice formed results in a substantially curved surface. Effects of several parameters characterizing phase-change process of interest are investigated. Numerical results clearly reveal that freezing undergoes multiple stages and proceeds in a complicated manner especially when the water is superheated over the density-extremum temperature.

406Y. COMPUTATIONAL TECHNIQUES

11A844. Explicit vs implicit schemes for the spectral method for the heat equation. - GE Schneider and K Wittich *(Dept of Mech Eng, Univ of Waterloo, Waterloo, ON, Canada)*. J Thermophys Heat Transfer 7(3) 454-461 (Jul-Sep 1993).

Three different boundary condition enforcement and time-stepping formulations are detailed for the Chebyshev collocation spectral method. Application is made to the 1D heat equation with a saw-tooth initial condition and several boundary condition combinations. It is observed that for a small time step, the explicit time stepping-strong boundary condition implementation method and the implicit time-stepping method give essentially the same solutions for various numbers of collocation points. The explicit time-stepping and weak boundary condition enforcement scheme has significantly large error at low numbers of collocation points, and requires considerably more collocation points to achieve convergence. While implicit schemes can employ significantly larger time steps than can the explicit schemes, implicit schemes require some form of matrix inversion, and this can be costly. Conversely, the explicit schemes can exploit the use of fast transform techniques to economize each time-step solution, but stability considerations limit the size of the time step that can be employed. A series of parametric studies are conducted to assess the relative economies of explicit vs implicit time-stepping schemes. The 1D heat equation is used as the basis problem and Robin boundary conditions are considered. The maximum explicit time-step limit is determined and a correlation provided that includes the dependence on boundary condition parameter values.

11A845. Numerical analysis for hyperbolic heat conduction. - Han-Taw Chen and Jae-Yuh Lin *(Dept of Mech Eng, Natl Cheng Kung Univ, Tainan, Taiwan 701, ROC)*. Int J Heat Mass Transfer 36(11) 2891-2898 (Jul 1993).

A new numerical simulation of the hyperbolic heat conduction problem is investigated. The primary difficulty encountered in the numerical solution of such a problem is numerical oscillations in the vicinity of sharp discontinuities. In this work, it is shown that the hybrid technique based on the Laplace transform and control volume methods can successfully be applied to suppress these oscillations. The Laplace transform method is used to remove the time-dependent terms, and then the transformed equations are discretized by the control volume scheme. Various comparative examples involving a nonlinear problem with surface radiation and the hyperbolic heat conduction in a composite region are illustrated to verify the accuracy of the present method. Due to the application of the Laplace transform method, the present technique does not need to consider the effects of the Courant number on the numerical results.

11A846. Numerical solution of axisymmetric heat conduction problems using finite control volume technique. - BF Blackwell *(DMTS, Thermophys Dept 1553, Sandia)* and RE Hogan *(SMTS, Thermal and Fluid Eng Dept 1513, Sandia)*. J Thermophys Heat Transfer 7(3) 462-471 (Jul-Sep 1993).

A finite control volume technique is developed to solve 2D axisymmetric heat condition problems using an arbitrary quadrilateral mesh. In this technique, the integral form of the conservation of energy equation is applied to control volumes of finite size. The boundary conditions considered include specific flux, aerodynamic heating, convection, and radiation. Two example problems involving a specified heat flux boundary condition and a specified temperature in conjunction with a temperature-dependent source are presented to demonstrate quadratic convergence as the mesh is spatially refined. The temperature-dependent source problem is solved using both a rectangular and a skewed mesh; the method is capable of producing accurate results on both rectangular and skewed meshes. Numerical comparisons with a Galerkin FE code are also presented.

408. Radiation and combined modes

11A847. Improved thermal radiation extinction in metal coated polypropylen microfibers. - R Caps, MC Arduini-Schuster, H-P Ebert, J Fricke *(Univ Wurzburg, Am Hubland, 8700 Wurzburg, Germany)*. Int J Heat Mass Transfer 36(11) 2789-2794 (Jul 1993).

If polypropylen microfibers with 2-3 μm diameters are coated with aluminum the infrared extinction increases by a factor of 20 as compared to the non-coated fibers. This has been shown by Mie scattering calculations and infrared optical transmission and reflection measurements using an integrating sphere. Large infrared extinction is important for the reduction of thermal radiative heat transfer in low density insulations. Insulation systems with Al-coated polypropylen microfiber fleeces can be expected to provide the same excellent insulation performances as natural downs.

11A848. Optimum finned space radiators. - SS Kumar, V Nayak, SP Venkateshan *(Heat Transfer and Thermal Power Lab, Dept of Mech Eng, Indian IT, Madras 600036, India)*. Int J Heat Fluid Flow 14(2) 191-200 (Jun 1993).

The present study considers a space radiator with uniform area fins standing vertically on a nonisothermal parent surface to enhance heat transfer. The numerical study shows that the finned radiator exhibits an optimum number of fins for which the heat lost from the finned radiator is a maximum, for given values of N_{R-C}, N_{F-C}, ε, and r_{OPT}. The numerical data has been used to derive correlations, respectively, between the optimum heat loss ratio and the optimum fin number with the other influencing parameters. These formulas are useful to the designer for a quick calculation of the performance of the optimum configuration.

11A849. Inverse radiation problem in axisymmetric cylindrical scattering media. - MP Menguc and S Manickavasagam *(Dept of Mech Eng, Univ of Kentucky, Lexington KY 40506)*. J Thermophys Heat Transfer 7(3) 479-486 (Jul-Sep 1993).

A semianalytical technique has been developed to solve the inverse radiation problem in absorbing and scattering cylindrical media. The radiative properties in the medium are allowed to vary radially. Isotropic, linearly anisotropic, and Rayleigh scattering phase functions are considered, and both the first- and second-order scattering of radiation are accounted for in the analysis. The angular radiosity distribution obtained from the solution of the forward problem is employed as input to the inverse angle. A numerical inversion scheme is followed to determine the profiles of extinction coefficient in the single-scattering albedo. For an anisotropically scattering medium, the asymmetry factor is also recovered. It is shown that the method is simple and accurate, even though the inversion is limited to three- or four-layer media. This inversion procedure can easily be used in experiments to determine the effective radiative property distributions in cylindrical systems.

11A850. Monte-Carlo simulation of a radiative transfer problem in a random medium: Application to a binary mixture. - S Audic and H Frisch *(Lab DG Cassini, CNRS URA 1362 Observatoire de la Cote d'Azur, BP 229, 06304 Nice Cedex 4, France)*. J Quant Spectros Radiative Transfer 50(2) 127-147 (Aug 1993).

This paper considers monochromatic radiative transfer in a diffusive 3D random binary mixture. The absorption coefficient, along any line-of-sight is a homogeneous Markov process, which is described by a 3D Kubo-Anderson process. The transfer equation is solved numerically by Monte-Carlo simulations on a massively parallel computer (a Connection Machine) by attaching one or several photons to each processor. The implementation of the simulations on the machine is discussed in detail, in particular the association between photons and processors and the storage of the data concerning the photons and the realizations of the statistics. With a CM-2 having 8000 processors, it is possible, with an adequate strategy, to follow simultaneously millions of photons in hundreds of realizations and to reach optical thicknesses up to 100 with dispersions of order 10^{-2} for the reflection and transmission coefficients. The simulations are validated, in the case of the 1D rod geometry, by comparison with the exact analytical solution, constructed by averaging the solution of the non-stochastic problem (diffusion in a rod of given optical thickness) over the probability density of the optical thickness. The latter obeys a stochastic Liouville equation which is solved by a Green's function method. The influence of the dimension of the Kubo-Anderson process is studied for the case of a slab and it is shown that a slab consisting in a pile of layers (1D process) is more transparent than one which consists in a stack of lumps (3D process). A strategy for improving the efficiency of Monte-Carlo simulations, based on the distribution of the lengths of the individual steps of the photons, is presented and discussed.

11A851. Radiative transfer by the YIX method in nonhomogeneous, scattering, and nongray media. - Pei-feng Hsu *(Dept of Mech Eng, Univ of Texas, Austin TX 78712)*, Zhiqiang Tan *(Aerospace Eng and Eng Mech Dept, Univ of Texas, Austin TX 78712)*, JR Howell *(Dept of Mech Eng, Univ of Texas, Austin TX 78712)*. J Thermophys Heat Transfer 7(3) 487-495 (Jul-Sep 1993).

A numerical solution of the integral equation of radiative heat transfer using the YIX method involving a mixture of highly anisotropic scattering particles and a nongray absorbing gas is presented. To validate the 3D calculation, bench mark solutions are established on a model problem using a high-order accuracy method, the product integration method (PIM). Various effects, eg, the discrete ordinates sets, first integration point of the YIX quadrature, optical thickness of the medium, grid sizes, and spectral resolution on the accuracy of the 3D calculation are discussed. Results for 3D calculations are presented. For all cases, the pressure variation has less significant effect on the results than those by particle density or temperature variations. The 3D nonhomogeneous cases have different trends of variation in radiative flux and divergence due to their nonuniform particle density distribution and nonisothermal participating medium. The use of the YIX method with discrete ordinates for the multidimensional calculations of highly anisotropic scattering and spectrally-dependent medium is shown to be accurate and flexible.

11A852. Benchmark results for particle transport in binary non-Markovian mixtures. - Bingjing Su and GC Pomraning *(Sch of Eng and Appl Sci, 38-137 H Eng IV, UCLA)*. J Quant Spectros Radiative Transfer 50(2) 211-226 (Aug 1993).

Numerical benchmark results are reported for particle transport in a randomly mixed binary medium, with the stochastic mixing described by a variety of stationary and homogeneous renewal statistics. Such statistics are quantified by chord length distributions for the two immiscible components of the mixture. A simple Monte Carlo procedure is used to generate physical realizations of the statistics, and the transport equation is solved numerically for each realization. The ensemble-averaged solutions and certain variance results are obtained by appropriately averaging over a large number of such calculations. The geometry considered is the rod model of transport, in which particles are constrained to move along a single axis.

11A853. Combined conduction and correlated-radiation heat transfer in packed beds. - K Kamiuto, M Iwamoto, Y Nagumo *(Dept of Prod Syst Eng, Oita Univ, Dannoharu 700, Oita 870-11, Japan)*. J Thermophys Heat Transfer 7(3) 496-501 (Jul-Sep 1993).

A quasihomogeneous model for heat transfer in a plane-parallel packed bed of opaque spheres is presented. The proposed model takes into account the variable porosity distribution within a packed bed and the correlated radiative properties of packed spheres having gray diffuse surfaces. On the basis of the proposed model, combined conductive and radiative heat transfer through comparatively thin packed layers of cordierite spheres or oxidized steel spheres are analyzed numerically and the obtained results are compared with the experimental ones. Additionally, the adequacy of a simplified analytical formula for the total effective thermal conductivities of a packed bed is discussed. It is found that the detailed theoretical model accurately predicts the heat transfer characteristics and the temperature profiles of the plane-parallel packed beds, and the predictions derived from the approximate formula well-correlate with the present experimental data for the total effective thermal conductivities.

11A854. Measurement of local heat flow in flat evacuated glazing. - RE Collins, CA Davis, CJ Dey, SJ Robinson, J-Z Tang, GM Turner *(Sch of Phys, Univ of Sydney, Sydney 2006, Australia)*. Int J Heat Mass Transfer 36(10) 2553-2563 (Jul 1993).

A guarded hot-plate apparatus has been developed for measuring the local thermal conductance of flat evacuated glazing. Parasitic heat flows in the apparatus have been reduced to below an equivalent thermal conductance of 0.01 W $m^{-2} K^{-1}$. Techniques are described for determining the separate contributions to heat flow through the sample from pillar conduction, conduction through residual gas, and radiation. The accuracy of the measurement system is estimated to be better than ±2% and the reproducibility for sequential measurements is better than ±0.004 W $m^{-2} K^{-1}$ for a measurement area of approximately 1.7 cm^2.

11A855. Analytical solution for transient response of counter flow heat exchanger with finite wall capacitance. - DD Gvozdenac *(Inst of Thermal Energy and Process Eng, Univ of Novi Sad, 21000 Novi Sad, Yugoslavia)*. Warme Stoffubertragung 28(6) 351-356 (Jun 1993).

The Laplace Transform Method is applied to solve the transient response of the counter flow heat exchanger with finite wall capacitance problem. The mathematical model is based on three local energy balance equations which are solved assuming that only the fluid 1 inlet condition is perturbed (step change). As any counter flow problem could be reduced to an adequate integral equation, collocation method is used for solving such equation in the presented case. Results are given for the outlet temperatures of both fluids and temperature distributions for both fluids and the wall as an explicit analytical formula.

410D. EXTENDED SURFACES

11A856. Effect of dehumidification of air on the performance of eccentric circular fins. - H Kazeminejad, MA Yaghoubi, M Sepehri *(Dept of Mech Eng, Univ of Shiraz, Iran)*. Proc Inst Mech Eng C 207(C2) 141-146 (1993).

A theoretical analysis of the performance of cooling and dehumidifying an eccentric circular fin has been carried out. Numerical results for fin temperature distribution and fin efficiency were obtained for various ranges of physchometric conditions and compared with those of a dry fin. The effect of eccentricity on the fin efficiency was also investigated. It was found that the fin efficiency decreases as dehumidification or eccentricity is increased.

11A857. Performance analysis and optimization of convective annular fins with internal heat generation. - E Georgiou *(Dept of Mech Eng, Univ of Patras, Patras, Greece)* and P Razelos *(Dept of Appl Sci, College of Staten Island, CUNY, Staten Island NY 10301)*. Warme Stoffubertragung 28(5) 275-284 (May 1993).

An analysis of the thermal performance for convective annular fins, having a general trapezoidal profile and internal heat generation, is presented. The solution of the optimal problem is also given when either the heat dissipation rate or the volume of the fin is specified. The results are expressed in suitable nondimensional variables that are specified by the problem, and presented graphically. The effect of the fin's profile and thermal conductivity upon the optimum dimensions is discussed. It is shown that the presence of heat generation reduces the ability of the fin to convect heat. Furthermore, certain limiting values of the heat generation that may be imposed on the fin for a feasible optimization are also derived.

410E. OTHER AUGUMENTATION TECHNIQUES

11A858. Augmentative heat transfer in a vertical 2-pass tube through an air box by use of strip type inserts. - Shou-Shing Hsieh and Mao-Yu Wen *(Dept of Mech Eng, Natl Sun Yat-Sen Univ, Kaohsiung, Taiwan 80424, ROC)*. Int J Heat Mass Transfer 36(12) 3043-3057 (Aug 1993).

This work presents and discusses an experimental information of the augmentation of heat transfer in a vertical 2-pass tube through an air box by use of different inserts (strip type inserts-longitudinal strip, crossed-strip, and regularly interrupted strip in a crossflow heat exchanger. Flow visualization as well as the interferogram of the temperature field inside-outside the tube were made and analyzed. Correlations for Nusselt number and pressure drop factor are reported and comparisons of these results with those of smooth tubes are also discussed. In addition, the performance has been evaluated by two different criteria based on both constant pumping power and constant heat duty, which suggest the use of these inserts in certain ranges of the Reynolds numbers in the present crossflow heat exchanger.

11A859. Enhanced heat transfer in channels with staggered fins of different spacings. - MA Habib *(Mech Eng Dept, King Fahd Univ of Pet and Minerals, PO Box 1570, Dhahran 31261, Saudi Arabia)*, AM Mobarak, AM Attya, AZ Aly *(Mech Eng Dept, Faculty of Eng, Cairo Univ, Cairo, Egypt)*. Int J Heat Fluid Flow 14(2) 185-190 (Jun 1993).

The flow pattern and heat transfer across staggered fins inside a rectangular duct are presented. The influence of Reynolds number, fin spacing, fin material, and wall heat flux on local and average heat transfer coefficients are studied. Fin spacings ranged from 0.8 to 2.0 times the channel height. The fin height was 0.7 times the channel height. The investigated Reynolds number ranged from 8,000 to 18,000. The experimental results show that the flow must pass over three to six fins before it appears to be a thermally periodic, fully developed flow. The fins enhance the heat transfer significantly due to flow deflection and impingement upon the fins. Augmentation of heat transfer was obtained with increase in Reynolds number, thermal conductivity of fins, and decrease in fin spacing and wall heat flux.

11A860. Heat transfer enhancement in a serpentine channel. - B Snyder, KT Li, RA Wirtz *(Mech Eng Dept, Univ of Nevada, Reno NV 89557)*. Int J Heat Mass Transfer 36(12) 2965-2976 (Aug 1993).

Forced-convection heat transfer rates and pressure drops were measured in the thermally fully developed region of a serpentine channel over Reynolds numbers ranging from 250 to 10 000. The wall geometry was similar to #17.8-3/8W of Kays and London, but carefully designed to minimize the extent of flow separation. The spatially-periodic wall impingement currents and high shear stresses combined to make a more uniform streamwise variation in local heat flux compared with corrugated surfaces. On an equal-Re basis, the heated surface of the serpentine channel outperformed the baseline parallel-plate channel by about a factor of 9 in air and 14 in water. Thus wavy-walled channels may prove effective for enhancing heat transfer in laminar and transitional flow regimes.

11A861. Performance evaluation of a vortex generator heat transfer surface and comparison with different high performance surfaces. - U Brockmeier *(Inst Energeitech, Ruhr-Univ, Bochum, Germany)*, T Guentermann, M Fiebig *(Inst Thermo- and Fluiddyn, Ruhr-Univ, Bochum, Germany)*. Int J Heat Mass Transfer 36(10) 2575-2587 (Jul 1993).

A comparative assessment of five different heat transfer configurations for operation in compact heat exchangers is presented. The configurations under consideration are four standard heat exchanger surfaces - two plain fins, an offset strip and a louvered fin geometry - and one surface with so called vortex generators for heat transfer augmentation. In the case of the standard surfaces, the basic performance characteristics in the form of heat transfer and friction data versus the Reynolds number have been taken from published experimental results. In the case of the vortex generator surface, the performance characteristics have been derived from a numerical prediction of the flow and temperature field in a closely spaced parallel plate channel with vortex generators in the form of delta wings mounted on the channel walls. In comparison to the plain fin surface with a rectangular cross section, the vortex generator surface shows best performance characteristics allowing a reduction in heat transfer surface area of 76%, for fixed heat duty and for fixed pumping power.

410G. DRYING AND FREEZING

11A862. Advances in transport phenomena during convective drying with superheated steam and moist air. - P Perre *(ENGREF, 14 rue Girardet, 54042 Nancy, France)*, M Moser, M Martin *(LEMTA, URA CNRS n°875, av de la Foret de Haye 54516, Vandoeuvre, France)*. Int J Heat Mass Transfer 36(11) 2725-2746 (Jul 1993).

The latest developments in high temperature convective drying are presented. The process has been investigated experimentally and theoretically for two drying fluids; moist air and superheated steam, and for two materials: light concrete and softwood. The experimental investigation was made in an aerodynamic return flow wind-tunnel, using a new type of sensor which enables measurement of both temperature and pressure at the same point. The numerical model of heat and mass transfer developed over several years has been used to simulate the experimental test, in 1D for concrete and in 2D for softwood. Good agreement is obtained between the calculations and experiments. An analytical model taking into account the transfer mechanisms between the exchange surface and an assumed drying-front has also been developed, and enables the explanation of most of the phenomena observed, both in the experiments and the simulation. The main purpose of the present work was not only to determine the differences on the pressure and temperature fields, but also to give a good physical explanation for the moisture migration at temperatures when the wet bulb is other than the boiling point. Finally, it is shown that the process can be divided into three domains: (a) an initial drying period, where the medium is at the wet bulb temperature; (b) a second phase with stage more or less pronounced, at a temperature which depends on the air flow and on the material; and (c) a final stage, during which all the temperatures approach the dry bulb temperature.

410I. ENVIRONMENTAL CONDITIONING AND CONTROL

11A863. Comparative performance study of CFC502, HCFC22 and HCF125. - SM Sami, J Schnotale *(Mech Eng, Sch of Eng, Univ of Moncton, Moncton NB, E1A 3E9, Canada)*, JG Smale *(Du Pont Canada, Box 2200, Streetsville Mississauga, ON, L5M 2H3, Canada)*. Int J Energy Res 17(3) 143-151 (Apr 1993).

In the paper, the performance of HCF125 as an alternative to CFC502 and R22 is assessed under different operating conditions. Cycle characteristics, such as thermal capacity, coefficient of performance, pressure ratio, system pressures, temperatures, and compressor power are also discussed. Results obtained after extensive detailed experimental work indicate that the performance is degraded on using HCF125, relative to that obtained with HCFC22.

11A864. Residential space conditioning with solid sorption technology. - SV Shelton *(Sch of Mech Eng, Georgia Tech)*. Heat Recovery Syst CHP 13(4) 353-361 (July 1993).

Approximately 50% of residential energy use in the US is for space heating and cooling. The most popular type of system installed in US houses is a central air-circulating system combining a natural-gas-fired direct-air-heating furnace and an electric-driven vapor compression cooling system. Natural-gas-driven heat pump technology offers considerable benefits over these exciting technologies including a reduction in energy use, improved environmental impact, and reduced investment in electric power plant construction. However, over the past 30 years, more than 100 major natural-gas-driven heat pump development projects have been undertaken without a currently successful product. These past projects have focused on engine-driven vapor compression refrigeration cycles and liquid sorption refrigeration cycles. New solid sorption technology offers significant advantages over these engines and liquid sorption technologies. The fundamental advantages of solid sorption refrigeration technology in natural gas residential heat pumps are presented and the societal benefits over existing residential systems discussed.

11A865. Sorption refrigeration research at JPL-NASA. - JA Jones *(JPL)*. Heat Recovery Syst CHP 13(4) 363-371 (July 1993).

Since 1979, long-life, reliable heat-powered sorption refrigeration systems have been developed for spacecraft use at the JPL. JPL has successfully built and tested a series of cryogenic sorption refrigeration systems for spacecraft sensor cooling and is presently assembling a -263°C (10K) hydride sorption refrigerator, which will fly on the Space Shuttle in 1994. With the addition of novel regenerative heating techniques, this same technology has more recently been applied to design high efficiency, ground-based adsorption heat pumps. Using actual sorption isothermm data and detailed analytic thermal computer models, analysis has predicted that the cooling and heating COPs will be significantly better than for any other single stage, heat-powered heat pump. Specifically the cooling COP (COP_c) with the new regenerative system using ammonia is predicted to be as high as about 1.16. Recent tests on a signal carbon sorbent canister compressor have been performed with R22, R134a, and ammonia. Transient thermal response of the sorption compressor has compared well with computer predictions. With ammonia, the total amount of average cooling from the 0.51 kg bed of carbon has been measured to be about 1038 Btu h^{-1} (304 W) for a 6 min full cycle including both heating and cooling.

410L. THERMAL ENERGY STORAGE SYSTEMS

11A866. Thermal performance of roof evaporative cooling and floor coupled evaporatively cooled underground water storage tank systems. - MS Sodha, U Mahajan, RL Sawhney *(Sch of Energy Stud and Centre of Energy Stud and Res Dept, Devi Ahilya Univ, Indore-452 001, India)*. Int J Energy Res 17(2) 127-140 (Mar 1993).

The thermal performance of a room with two indirect evaporative cooling systems (operating independently and jointly) is analyzed. The two evaporative systems considered are a water-film roof evaporative cooling system, and an underground water storage tank beneath the floor of the room. The water in the tank is evaporatively cooled through a suitable aeration system. The performance of the room is analyzed in the hot-dry climate of Jodhpur and the composite climate of Delhi. It is found that the underground water storage system is marginally better than the roof evaporative cooling system for the Jodhpur and Delhi climates. A detailed parametric performance analysis of the room has also been carried out.

412. Thermomechanics of solids

11A867. One-dimensional quasi-static contact problem in linear thermoelasticity. - MIM Copetti and CM Elliott *(Sch of Math and Phys Sci, Univ of Sussex, Brighton BN1 9QH, UK)*. European J Appl Math 4(2) 151-174 (Jun 1993).

The existence, uniqueness and regularity of the solution to a 1D linear thermoelastic problem with unilateral contact of the Signorini type are established. A FE approximation is described, and an error bound is derived. It is shown that if the time step if $O(h^2)$, then the error in L^2 in the temperature and in L^∞ in the displacement is $O(h)$. Some numerical experiments are presented.

11A868. Computer simulation of thermo-mechanical fatigue of solder joints including microstructure coarsening. - P Hacke, AF Sprecher, H Conrad *(Mat Sci and Eng Dept, N Carolina State Dept, Raleigh NC 27695-7907)*. J Electron Packaging 115(2) 153-158 (Jun 1993).

Thermo-mechanical cycling (-30°/130°C) tests were performed on 63Sn37Pb solder joints with cycle periods of 12-48 min. The effect of phase (grain) size was incorporated into the integrated matrix creep damage concept to take into account the coarsening which occurred during the thermal cycling. It was thereby determined that failure (50% load drop) results at a total integrated matrix plastic strain (creep) of 1.39 and that the measured fatigue life is only 21% of that predicted assuming no coarsening. The coarsening during the thermo-mechanical cycling was in reasonable accord with the cubic coarsening law. However, it was more rapid than occurred during isothermal aging at zero stress.

11A869. Perturbation solution for thermal expansion buckling of no expansion joint slope pavement plate. - Jian-kang Chen *(Jiangsu Agri Col, Yangzhou, China)* and Ru-peng Wang *(Shanghai Col of Architec and Municipal Eng, Shanghai, China)*. Appl Math Mech 14(3) 277-284 (Mar 1993).

In this paper, the mechanical mechanism of thermal expansion buckling of no expansion joint slope pavement undergoing the action of a temperature field is analyzed. By using regular perturbation method, the formula of perturbation solution for this problem is derived, the relationship between critical laying temperature difference of slope pavement and of level straight pavement is studied, and the unified solution and its numerical results are also obtained. In terms of this research, rational laying temperature of no expansion joint slope pavement is given.

11A870. High temperature fracture toughness in silicon nitride and sialon. - Y Mutoh, N Miyahara, K Yamaishi *(Nagaoka Univ of Tech, Nagaoka-shi 940-21, Japan)*, T Oikawa *(NKK Corp, Kawasaki-ku, Kawasaki-shi 210, Japan)*. J Eng Mat Tech 115(3) 268-272 (Jul 1993).

Fracture Toughness of HIP-sintered silicon nitride decreased with increasing temperature up to 1200°C. The brittle-to-ductile transition was observed in the temperature range from 1200°C to 1275°C: the fracture toughness rapidly increased in the transition region. Above the transition temperature, the fracture toughness decreased with increasing temperature. Fracture toughness of sialon increased with increasing temperature. Transition of fracture mechanism was observed in sialon around 1300°C. The differences of temperature dependence of fracture toughness between two materials are interpreted in terms of the effects of grain-boundary glass phase on fracture.

11A871. Thermally induced stress intensity factor of a semi-circular surface crack in a half-space. - An-Yu Kuo, SS Tang *(Structural Integrity, 3150 Almaden Expressway, Ste 226, San Jose CA 95118)*, TP Yu *(Univ of Houston, Houston TX 77004)*. Int J Fracture 61(2) 101-122 (15 May 1993).

This paper presents thermal stress intensity factor solutions for a semicircular surface crack in a semi-infinite space, ie, a semicircular crack of radius a in a semi-infinite space $y \geq 0$. The cracked semi-infinite space is subjected to point heat sources with arbitrary time history $Q(t)$ at any points (x',y',z') in the region $y \geq 0$.

11A872. Formation of castings with complex geometry. Thermomechanical effects, growth and influence of the air gap. - JR Popov and IH Katzarov *(Inst for Metal Sci and Tech, Bulgarian Acad of Sci, Chapaev 53, 1574 Sofia, Bulgaria)*. Int J Heat Mass Transfer 36(11) 2861-2867 (Jul 1993).

In previous works we have proposed a method for mathematical modeling of the processes of heat and mass transfer in castings, which includes the construction of a boundary fitted coordinate system in a Riemannian coordinate space. Within this approach we obtain the deformations, stresses and strains in the casting-mould system within a linear thermoelastic model. The equations of stresses and deformations are derived from the corresponding laws of conservation in the coordinate space. Secondly, we consider the problem of heat transfer between the casting and the mould, while the boundary conditions change during the crystallization and formation of the crust due to the thermochemical interaction there. We describe the evolution of the air gap and consider its influence on the process of crystallization. Some consequences from this model, which may allow a more subtle description of the casting formation, like the segregation behavior in the two-phase region, are also discussed.

11A873. Predicting high temperature ultimate strength of continuous fiber metal matrix composites. - EJ Barbero *(Mech and Aerospace Eng Dept, W Virginia Univ, 315 Eng Bldg, Morgantown WV 26506-6101)* and KW Kelly *(Sci Appl Int, 1710 Goodridge Dr, McLean VA 22102)*. J Composite Mat 27(12) 1214-1235 (1993).

A model to predict the high temperature ultimate strength of a continuous fiber metal matrix composite (CFMMC) has been developed. The model extends the work of Rosen by including high temperature processes such as matrix creep, fiber-matrix debond, and the effects of randomly spaced fiber breaks which typically exist in the MMC prior to loading. A FE model (FEM), developed in the form of a representative volume element (RVE), is used to calculate the time-dependent stress field surrounding a fiber break. Variables included in the calculation are process-related parameters such as the fiber diameter, the fiber-matrix interface strength, and interface roughness. Statistical analysis is used to infer the strength of a large composite sample from the stress analysis of a single break provided by the FEM.

11A874. Linear birefringence changes in betaine phosphite crystal. - B Kosturek, J Przeslawski, Z Czapla *(Inst of Exp Phys, Univ of Wroclaw, Cybulskiego 36, 50-205 Wroclaw, Poland)*. Acta Phys Polonica A 83(6) 769-775 (Jun 1993).

Linear birefringence temperature changes are measured in the betaine phosphite crystal. The linear birefringence increments induced by antiferrodistortive, structural and ferroelectric phase transitions are analyzed. Temperature derivatives of the linear birefringences are shown for comparison. Critical exponents are determined for both transitions. The antiferrodistortive phase transition is close to a tricritical one.

414E. CONVECTION WITH DIFFUSION

11A876. Convection-driven growth in fluctuating velocity field. - A Gadomski *(Dept of Polymer Phys, Silesian Univ, Sniezna 2, 41-200 Sosnowiec, Poland)* and J Luczka *(Dept of Theor Phys, Silesian Univ, Bankowa 14, 40-007 Katowice, Poland)*. Acta Phys Polonica B B24(4) 725-732 (Apr 1993).

The growth process of an initially ideal sphere in a convective fluctuation velocity field is considered. The influence of fluctuations of the velocity field on the growth process is examined.

11A877. Near-field solution for heat and mass transfer from buried nuclear waste canisters. - K Muralidhar *(Dept of Mech Eng, Indian IT, Kanpur-208 016, India)*. Int J Heat Mass Transfer 36(10) 2665-2674 (Jul 1993).

A numerical study of heat and mass transfer from cylindrical containers filled with nuclear waste and buried under the surface of the earth is reported here. For prescribed heat flux and leach rates the temperature and concentration distributions on the surface of the containers are determined under a variety of conditions. These conditions include the diffusion limit, the effect of superimposed flow, the multi-canister problem and radioactive decay of a parent-daughter chain. The equations governing unsteady transport are solved using a Galerkin FEM. Results using this method are compared with those obtained from boundary-layer analysis.

11A878. Spectral approximation to advection-diffusion problems by the fictitious interface method. - A Frati, F Pasquarelli *(Dept Matematica, Univ Cattolica, Brescia, Italy)*, A Quarteroni *(Dept Matematica, Politecnico di Milano, Milano, Italy)*. J Comput Phys 107(2) 201-212 (Aug 1993).

In this work we face the numerical approximation by spectral methods of advection-diffusion equations for convective dominated regimes. For either boundary and internal layer problems, it has been recently pointed out that effective methods can be based on dropping the viscous terms far from the thin layer. This yields a problem that couples two different model equations (one of hyperbolic type, the other one of parabolic type) through suitable matching conditions at subdomain interfaces. An extensive theory has been developed and effective algorithms have been derived. Here we apply this theory to spectral approximations to 2D steady problems. In particular, we investigate the issues of stability and convergence, and we propose effective algebraic solvers to face both the hyperbolic and elliptic problems.

414F. DOUBLE DIFFUSION AND OTHER COMBINED EFFECTS

11A879. Inverse segregation for a unidirectional solidification of aluminum-copper alloys. - JH Chen and HL Tsai *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)*. Int J Heat Mass Transfer 36(12) 3069-3075 (Aug 1993).

A mathematical model has been developed to simulate the inverse segregation for a unidirectional solidification of Al-Cu alloys cooled from the bottom. It is found from the present study that the fluid flow of solute-rich liquid in the mushy zone caused by solidification shrinkage is the main driving force for the formation of inverse segregation. The predicted copper concentration in the solidified alloys is in good agreement with the published experimental data. Several interesting transient behaviors of solute redistribution in the mushy zone, which were not reported before, are also discussed.

11A880. Investigation of solutal convection during the dissolution of silicon in a sandwich system. - S Erbay, HA Erbay, N Djilali, S Dost *(Centre for Adv Mat and Related Tech and Dept of Mech Eng, Univ of Victoria, Victoria, BC, V8W 3P6, Canada)*. Int J Heat Mass Transfer 36(12) 3017-3027 (Aug 1993).

This paper considers natural convection due to solutal gradients during the dissolution of silicon in a substrate-solution-substrate "sandwich" system under isothermal conditions. This work is motivated by the need to understand the role of convection in liquid-phase epitaxial growth of semiconductor crystals. Unsteady 2D numerical simulations are presented for two dissolution experiments. Solutal convection is found to be predominant during the initial phase of the process and causes a rapid increase in the dissolution depths of both substrates. However, because convection is mostly confined to the lower half of the sandwich system, lower substrate dissolution depths are about twice as large. This result is in good agreement with available experimental data. Another interesting consequence of convection is the development of a wavy irregular surface along the lower substrate.

414I. POROUS MEDIA

11A881. Exact solution of coupled heat and mass transfer with double moving interfaces in a porous half-space Part 3. Effect of surface pressure and permeability on rates of sublimation and desorption. - S-W Peng *(Dept of Power Eng, Huazhong Univ of Sci and Tech, Wuhan, Hubei 430074, Peoples Rep of China)* and G-Q Chen *(Dept of Mech, Peking Univ, Beijing 100871, Peoples Rep of China)*. Int J Energy Res 17(3) 193-202 (Apr 1993).

Coupled heat and mass transfer with double moving interfaces, taking place in a porous half-space, is defined, and exact solutions for the temperature and moisture distributions, as well as the position of two moving fronts, are obtained. As in Part 2 of the paper, the interest is focused on the case of moderate vacuum environment pressure, where the moisture transfer is due to the result of the vapor concentration and pressure gradients. The temperature of sublimation is assumed to be unknown, whereas the temperature of desorption is still assumed to be known, and the pressure of desorption is determined by a linear assumption among pressures of sublimation, desorption and surface. The Clapeyron equation is incorporated on the sublimation front to close the equation system. The effects of the surface pressure and the permeability on the sublimation and desorption are analyzed. Conclusions are drawn on the basis of the results.

11A882. Heat and humidity transfer in non saturated porous media: Capillary hysteresis effects under cyclic thermal conditions. - CHA Molenda, P Crausse, D Lemarchand *(Inst de Mec des Fluides, Ave du Prof Camille Soula, 31400 Toulouse Cedex, France)*. Int J Heat Mass Transfer 36(12) 3077-3088 (Aug 1993).

An analysis of the influence of capillary hysteresis in the humidity migration in porous media is presented. Several situations have been considered: experimental and numerical study of transfer phenomena in porous media at impermeable boundaries, numerical simulation of the thermo-hydraulic behavior of the cellular concrete wall under cyclic thermal conditions. Effects of temperature on capillary properties and the relaxation time of the liquid flux by capillary effects, are also taken into account and studied.

11A883. Solidification of porous medium saturated with aqueous solution in a rectangular cell. - K Matsumoto, M Okada *(Dept of Mech Eng, Aoyamagakuin Univ, 6-16-1 Chitosedai Setagaya-ku, Tokyo 157, Japan)*, M Murakami *(Toshiba, 1-1-1 Shibaura Minato-ku, Tokyo 105-01, Japan)*, Y Yabushita *(Dept of Mech Eng, Aoyamagakuin Univ, 6-16-1 Chitosedai Setagaya-ku, Tokyo 157, Japan)*. Int J Heat Mass Transfer 36(11) 2869-2880 (Jul 1993).

Beads saturated with NaCl-solution used as porous medium were packed in a rectangular cell. The porous medium was solidified by cooling one of the vertical walls of the cell. The above solidification process was studied analytically and experimentally. The temperature and concentration distributions were measured for three kinds of beads and almost the same mean diameters. From both experimental and analytical results, the analysis, where permeability within the mushy region was expressed as the n-th power of the volume fraction of the liquid phase, was found to simulate approximately the solidification process. The characteristics of the solidification process were clarified herein.

414Y. COMPUTATIONAL TECHNIQUES

11A884. Eulerian-Lagrangian localized adjoint methods for linear advection or advection-reaction equations and their convergence analysis. - RE Ewing and H Wang *(Dept of Math, Univ of Wyoming, Laramie WY 82071)*. Comput Mech 12(1-2) 97-121 (Jun 1993).

In this paper, we develop Eulerian-Lagrangian localized adjoint methods (ELLAM) to solve the initial-boundary value problems for linear advection or advection-reaction equations. In contrast to many methods for advection-type problems, our ELLAM scheme naturally incorporates the inflow boundary conditions into its formulations and does not need an artificial outflow boundary condition. It does conserve mass. Moreover, optimal-order error estimates for ELLAM have been obtained. In contrast, many methods have only suboptimal-order estimates when applied to solve these problems. Furthermore, our ELLAM scheme provides a systematic approach to treat the interface problems of advection-type equations and can be naturally combined with domain decomposition and local refinement techniques to solve these problems. Numerical results in 1D and 2D are presented and discussed.

11A885. Spectrum enveloping technique for convection-diffusion computations. - VS Manoranjan and R Drake *(Dept of Pure and Appl Math, Washington State Univ, Pullman WA 99164-3113)*. IMA J Numer Anal 13(3) 431-443 (Jul 1993).

In a convection-diffusion equation, if the convection term is very dominant, the linear system of equations which result from either finite-differencing or finite elementing will not have a strictly diagonally dominant coefficient matrix. So, if one tries a standard iteration method (Jacobi or Gauss-Seidel) to solve the linear system of equations, the iteration matrix may not satisfy the spectral radius condition for convergence and hence no converging solution may be obtained. The problem can be overcome, under certain conditions, if one uses the two step iteration-spectrum enveloping procedure of de Pillis in the format of a Jacobi method. This paper extends the two step iteration-spectrum enveloping idea to a Gauss-Seidel format for a model convection-diffusion problem.

414Z. EXPERIMENTAL TECHNIQUES

11A886. Mass flow sensing with heat waves: The effect of gas pressure. - DK Lambert *(Phys Dept, General Motors Res and Env Staff, Warren MI 48090-9055)*. Int J Heat Mass Transfer 36(10) 2623-2634 (Jul 1993).

Two conceptual examples are given of mass flow sensors based on heat waves that have *exact* gas pressure self-compensation in uniform flow: one with a plane heat source through which the flow passes, and one with a line source. Both sensors ratio the heat wave amplitudes detected at equal distances upstream and downstream from the source. Heat wave fronts from either source expand symmetrically upstream and downstream. An automotive air flow sensor based on heat waves is also described and modeled. It is a microelectronic device on silicon. This sensor is approximately, but not exactly, self-compensated for pressure change.

11T887. Coupled complex Ginzburg-Landau type equations in gaseous combustion. - DO Olagunju *(Dept of Math Sci, Univ of DE, Newark DE 19716)* and BJ Matkowsky *(Dept of Eng Sci & Appl Math, Tech Inst NWU)*. Stability Appl Anal Continuous Media 2(1) 32-58 (Mar 1992).

416C. IGNITION (THERMAL AND HETEROGENEOUS)

11A888. Computational and experimental study of a railplug igniter. - JL Ellzey, MJ Hall, X Zhao *(Dept of Mech Eng, Univ of Texas, Austin TX)*, H Tajima *(Dept of Mech Eng, Miyazaki Univ, Japan)*. Exp Fluids 14(6) 416-422 (May 1993).

The plasma plume generated by a new type of high energy igniter known as the railplug is examined. The railplug is a miniaturized railgun that has the potential for improving ignition characteristics of combustible mixtures in engines. The objective of the study is to gain an understanding of the characteristics of the plasma created by a transparent railplug and to validate a multidimensional computer simulation of the plasma and shock fronts. The nature of the plume emitted by the railplug was examined for three levels of electrical energy while firing into air at a pressure of 1 atm. The computer model is to be used to predict trends in railplug performance for various railplug designs, energies, and ambient conditions. The velocity of the plasma movement inside a transparent railplug was measured, as well as the velocity of the plume ejected from the cavity. A shock is produced at the initiation point of the arc and propagates down the cavity, eventually exiting the plug. The velocity of the shock was both measured experimentally and simulated by the model.

416D. LAMINAR FLAME PROPAGATION

11A889. Burning of a spherical fuel droplet in a uniform flowfield with exact property variation. - K Madooglu and AR Karagozian *(Dept of Mech Aerospace and Nucl Eng, UCLA)*. Combust Flame 94(3) 321-329 (Aug 1993).

An analytical and numerical model is developed for single droplet evaporation and burning in a convective flowfield. The model is based on the boundary-layer approach, and chemical reaction kinetics are represented by a one-step, finite-rate reaction mechanism, while variation of gas properties with temperature and gas composition is based on the kinetic theory of gases. Four droplet models differing in the degree of complexity concerning property variation and chemistry are compared. Comparisons are also provided with existing empirical correlations for convective droplet evaporation and burning.

11A890. Burning velocities of hydrogen-air mixtures. - GW Koroll, RK Kumar, EM Bowles *(AECL Res, Whiteshell Lab, Pinawa, MB, Canada)*. Combust Flame 94(3) 330-340 (Aug 1993).

Laminar and turbulent burning velocities of hydrogen-air mixtures have been determined in a 17-L vessel using the double-kernel technique for a range of hydrogen concentrations between 9% and 70% by volume. Over the range of mixtures investigated, simple empirical correlations yield laminar burning velocities that are in good agreement with those measured. A turbulent-burning-velocity correlation that includes the flame-generated turbulence produces burning velocities in good agreement with the values measured experimentally. The data and correlations for the hydrogen burning velocity are used in models to predict hydrogen combustion behaviour in enclosures containing hydrogen-air-diluent mixtures and in combustion systems that employ hydrogen as the fuel.

11A891. Compositional structure and the effects of exothermicity in a nonpremixed planar jet flame. - CJ Steinberger, TJ Vidoni, P Givi *(Dept of Mech and Aerospace Eng, SUNY, Buffalo NY 14260-4400)*. Combust Flame 94(3) 217-232 (Aug 1993).

Results are presented of direct numerical simulation (DNS) of a randomly perturbed compressible, spatially developing 2D planar jet under the influence of a finite rate chemical reaction of the type F + O → Product. The objectives of the simulations are to assess the compositional structure of the flame and to determine the influence of reaction exothermicity by means of statistical sampling of the DNS generated data. It is shown that even with this idalized kinetics model the simulated results exhibit features in accord with experimental data. These results indicate that the Damkohler number is an important parameter in determining the statistical composition of the reacting field and that the results are not very sensitive to the mechanism by which this parameter is varied. It is demonstrated that as the intensity of mixing is increased and the effect of finite rate chemistry is more pronounced, the magnitudes of the ensemble mean and variance of the product mass fraction decrease and those of the reactants' mass fractions increase. Also, at higher missing rates the joint probability density functions of the reactants' mass fractions shift towards higher values within the composition domain, indicating a lower reactedness. These trends are consistent with those observed experimentally and are useful in portraying the statistical structure of non-equilibrium diffusion flames. The DNS-generated data are also utilized to examine the applicability of the "laminar diffusion flamelet model" in predicting the rate of the reactant conversion with finite rate chemistry. This examination indicates that the performance of the model is improved as the value of the Damkohler number is increased. Finally, the simulated results suggest that in the setting of a "turbulent" flame, the effect of the heat liberated by the chemical reaction is to increase the rate of reactant conversion. This finding is different from those of earlier DNS results and laboratory investigations that indicate a suppressed chemical reaction with increasing heat release.

11A892. Liftoff characteristics of methane jet diffusion flames. - JP Seaba *(Dept of Mech Eng and Aerospace Eng, Univ of Missouri, Columbia MO 65211)*, L-D Chen *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*, WM Roquemore *(Aero Propulsion and Power Directorate, Wright Lab, WPAFB)*. J Propulsion Power 9(4) 654-656 (Jul-Aug 1993).

The mechanisms responsible for the liftoff from the burner rim and stabilization of the jet flames are not clearly understood. Early works studied the stability of jet flames in open air and identified four different regimes concerning flame stability. Of the four stability regimes 1) liftoff, 2) blowoff, 3) lifted, and 4) blowout, only the liftoff process will be studied in this Note. The liftoff condition is referred to the instant when the flame detaches from the burner rim in a discontinuous manner. After the flame detaches from the burner rim, it may stabilize at a downstream location (ie, lifted flame) or it may result in flameoff conditions (or the blowoff condition).

416F. FLAME STABILITY AND STABILIZATION

11A893. Feedback control of an unstable ducted flame. - TP Parr, E Gutmark, DM Hanson-Parr, KC Schadow *(Res Dept, Code 3892, Naval Air Warfare Center Weapons Div, China Lake CA 93555)*. J Propulsion Power 9(4) 529-535 (Jul-Aug 1993).

Active control of a naturally unstable ducted flame was realized using acoustic forcing of either the shear layer of the flame jet or the duct itself. The feedback signal was derived from either the duct pressure signal or the CH intensity (related to the flame heat release rate), and delayed in time to produce cancellation of the natural resonant oscillations of the system. Direct driving of the shear layer using the duct pressure signal feedback produced the best control with the lowest power requirements. The controller was able to reduce the acoustic power in the duct at the resonant frequency from 19 Pa to about 0.7 Pa, or nearly 30 dB. When operating in the controlled mode, the driving speaker is producing a sound pressure level more than three orders of magnitude below the natural duct uncontrolled level (both measured in the duct), so the effect is clearly not just acoustic cancellation.

11A894. Review of active control of combustion instabilities. - KR McManus *(Phys Sci, 20 New England Bus Center, Andover MA 01810)*, T Poinsot, SM Candel *(Lab EM2C du CNRS, Ecole Centrale Paris, 92295 Chatenay-Malabry, France)*. Prog Energy Combust Sci 19(1) 1-29 (Aug 1993).

Combustion instabilities in modern high-perfomance propulsion systems are often manifested

compone[illegible] ed
oscillations. Other phenomena which can lead to unstable oscillations have been identified as well, these include naturally occurring hydrodynamic instabilities and convectively coupled oscillations. Due to their potential harm to system performance, it is often necessary to find ways to reduce the magnitude of these oscillations in the course of developing a new combustion system. Historically, the control and suppression of combustion instabilities has been achieved through hardware design changes. These modifications have included changes in the fuel delivery system, including feedlines and pumps, changes in the fuel injection distribution pattern, and modifications to the combustor or the combustor liner geometry. In general, these design modifications have been made in an attempt to change the resonant behavior of the combustion system so as to avoid the resonantly coupled oscillations which lead to combustion instability. In recent years, much attention has been focused on the control and suppression of combustion instabilities by actively and continously perturbng certain combustion parameters in order to interrupt the growth and persistence of resonant oscillations. The strategies used in this field of active control vary greatly in nature, both with respect to the theoretical basis for the control system and the system hardware which is employed. The purpose of this paper is to present a discussin of different methods which can be used to suppress combustion instabilities using active control, as well as to give a review of the work which has recently been performed in this area of combustion research.

416I. KINETICS AND MECHANISMS

11A895. Reduced kinetic mechanisms and their numerical treatment I. Wet CO flames. - W Wang and B Rogg *(Dept of Eng, Univ of Cambridge, Trumpington St, Cambridge CB2 1PZ, UK)*. Combust Flame 94(3) 271-292 (Aug 1993).

In the present article we investigate laminar, premixed freely propagating wet CO flames, ie, flames whose initial mixture contains small amounts of hydrogen and water vapor. Attention is focused on the derivation and validation of reduced kinetic schemes that provide both more computational efficiency in the calculation and the basis for asymptotic analysis of such flames. Specifically, a short detailed mechanism and systematically reduced three-step, two-step, and one-step mechanisms are derived that allow realistic predictions of burning velocities and flame structures over a wide range of stoichiometries. *Inner iteration* is discussed in detail and its *black box* character is identified. Also presented and discussed are numerical tricks for efficient use of reduced kinetic mechanisms in flame calculations. In particular, the so-called *partially explicit* numerical schemes are identified.

11T896. Review of chemical-kinetic problems of future NASA missions I. Earth Entries. - C Park *(NASA Ames Res Center, Moffett Field CA 94035)*. J Thermophys Heat Transfer 7(3) 385-398 (Jul-Sep 1993).

416J. UNSTEADY COMBUSTION AND COMBUSTION ACOUSTICS

11A897. Low-frequency combustion oscillations in a model afterburner. - MA Macquisten *(Combustion Dept, Rolls Royce, Filton, Bristol BS12 7QE, UK)* and AP Dowling *(Eng Dept, Cambridge Univ, Trumpington St, Cambridge CB2 1PZ, UK)*. Combust Flame 94(3) 253-264 (Aug 1993).

Low-frequency combustion oscillations, involving the interaction between longitudinal acoustic waves and unsteady combustion, are investigated for a model afterburner. An experimental rig, in which a confined flame is stabilized in the wake of a conical gutter, is run with inlet conditions representative of an engine afterburner. Results are presented for inlet Mach numbers in the range of 0.15-0.27, with inlet temperatures up to 630 K. Comparison is made between theory and experiment. Although the theory was developed from low Mach number data, it is found to apply equally well at these faster flow rates. The theory is able to predict the frequency of the instability and the mode shape, accurately reproducing the changes due to variations in the inlet Mach number and temperature.The effect of altering the downstream boundary condition by replacing the open end by a choked nozzle is also investigated. Such a change is found to be highly destabilizing, both experimentally and theoretically. Again, predictions from the theory are in good agreement with the observations.

416K. SUPERSONIC COMBUSTION

11A898. Research on supersonic combustion. - FS Billig *(Johns Hopkins Univ, Laurel MD 20723)*. J Propulsion Power 9(4) 499-514 (Jul-Aug 1993).

This paper is not at all representative of the complete body of the research on supersonic combustion. Instead, what is presented is primarily based on material with which the writer has had either direct involvement or a first-hand knowledge. It does not do justice to the exemplary works of many other investigators. Hopefully, this is somewhat rectified by the extensive list of references. The reader is encouraged to. consult these manuscripts to obtain a more balanced perspective. This applied research must be viewed from the perspective of the engineer who is charged with expediting development and is in need of design tools. Exact physics have frequently been abandoned to produce functional models. Much of the experimental verification upon which the models are based has been obtained in facilities which have known imperfections with respect to duplication of flight conditions. Moreover, compromises have been made in the analysis and interpretation of the experimental data, in part due to imperfect or incomplete diagnostic instrumentation, and in part due to a limited understanding of the underlying physics. An example that embodies all of these deficiencies would be a design model that is based on the use of integral techniques to describe combustion in supersonic flow from experiments conducted in an arc-heated tunnel.

416L. HETEROGENEOUS AND MULTIPHASE COMBUSTION

11A899. New results in the theory of filtration combustion. - AP Aldushin *(Inst of Struct Macrokinetics, Russian Acad of Sci, Chernogolovka, Russia)*. Combust Flame 94(3) 308-320 (Aug 1993).

Approximative analytical as well as numerical techniques have been used to study the propagation of a heterogeneous chemical transformation autowave in a dissociating system with filtration of a gas mixture containing an active reaction component. The interaction of heat and reaction waves combined with dissociation results in a complex two-front combustion wave structure with two reaction zones. For simple situations, practically important wave characteristics are estimated analytically. It is shown that filtration combustion of dissociating systems can concentrate energy in the reaction zone by transport gases from the hot product region to the reaction zone. This is referred to as the superadiabatic effect. In contrast to nondissociating system, in which the superadiabatic effect causes a temperature rise in the reaction zone, in dissociating system it causes a decrease in the depth of conversion to product.

416M. FLAME RADIATION

11A900. Total radiative heat loss in jet flames from single point radiative flux measurements. - YR Sivathanu *(Thermal Sci and Propulsion Center, Sch of Mech Eng, 125 Chafee Hall, Purdue)* and JP Gore *(Sch of Mech Eng, Purdue)*. Combust Flame 94(3) 265-270 (Aug 1993).

A method for estimating total radiant output of turbulent jet flames based on the measurement of radiative heat flux at a single location is reported. The radiative flux from a variety of jet flames was measured and plotted in normalized coordinates to establish the feasibility of this approach. In addition, the radiative flux from acetylene-air diffusion flames to representative detector locations, for two different burner geometries and flow conditions, was calculated using the Planck-averaged equation of transfer coupled with a multiray technique. The local temperature and soot volume fractions for the calculations were obtained from emission and absorption measurements. The normalized calculated heat flux for the two flames also collapse with the experimental data. This result shows that scalar property distributions combined with the appropriate view factor for the single location are the basis for the single point technique.

416O. COMBUSTORS AND AFTERBURNERS

11A901. Demonstration of mode transition in a scramjet combustor. - GA Sullins *(Appl Phys Lab, Johns Hopkins Univ, Laurel MD 20723)*. J Propulsion Power 9(4) 515-520 (Jul-Aug 1993).

Direct-connect combustor hardware has been assembled at the Avery Propulsion Research Lab of the Johns Hopkins University Applied Physics Lab to investigate a hydrogen-fueled scramjet combustor. The test hardware was designed to perform tests at simulated Mach 5 to Mach 8 flight conditions. This is done using a combustion heater with H_2 fuel and makeup O_2. The air, H_2 and O_2 flow rates are all supplied through computer-controlled digital values. This system allows rapid changes in conditions and very steady flow rates can be maintained throughout the test. Recently, tests were performed in which the flow rates were systematically varied during the test to simulate an acceleration from $M = 5.9$ to 6.2. During this acceleration the fuel-air equivalence ratio was held constant and the combustor transitioned from a dual mode ramjet with a precombustion shock system creating subsonic flow at the injection plane, to a scramjet with no precombustion shock system. The results of these tests are presented along with descriptions of the hardware and control systems.

11A902. Effects of momentum ratio on turbulent nonreacting and reacting flows in a ducted rocket combustor. - TM Liou, L Chen, YY Wu *(Natl Tsing Hua Univ, Hsinchu, Taiwan 300, ROC)*. Int J Heat Mass Transfer 36(10) 2589-2599 (Jul 1993).

A numerical study of turbulent nonreacting and reacting flows in a ducted rocket combustor with an ASM turbulence model and a finite-rate combustion model is reported. In addition, detailed measurements of flow velocities and turbulence parameters have been conducted by use of a four-beam two-color LDV system. Three different values of the ratio of fuel momentum to air momentum were selected to investigate its effects on the turbulent flow structure, mixing and combustion characteristics. It is found that the momentum ratio has strong effects on the number, size, and rotational direction of dome region recirculation zones, reattachment length, axial fuel-jet spreading rate, and penetration ability, flame temperature distributions and total pressure loss in the ducted rocket combustor. A useful correlation between the reattachment length and momentum ratio is derived. Moreover, a moderate value of the momentum ratio is recommended for better combustion performance and lower total pressure loss. The reported data are believed to provide valuable guidelines for practical design of combustors.

11A903. Flow measurements in a model burner Part 2. - DFG Durao, MV Heitor, ALN Moreira *(Dept of Mech Eng, Inst Superior Tecnico, Tech Univ of Lisbon, 1096 Lisboa, Codex, Portugal)*. J Fluids Eng 115(2) 309-316 (Jun 1993).

The isothermal swirling flow in the vicinity of a model oxy-fuel industrial burner is analyzed with laser Doppler velocimetry together with laser-sheet visualization. The burner consists of a central axisymmetric swirling jet surrounded by sixteen circular jets, simulating the injection of oxygen in practical burners. The results extend those obtained for non-swirling flows, and presented in Part I of this paper, to the analysis of the dependence of the mixing efficiency of the burner assembly upon the swirl motion of the central jet and have the necessary detail to allow to assess the accuracy of calculation procedures of the flow in industrial burners. It is shown that swirl attenuates the 3D structure typical of multijet flows in such a way that turbulence production and transport in the near burner zone are dominated by swirl-induced processes.

416P. SOLID FUELS

11A904. Global rates of devolatilization for various coal types. - S Niksa *(Mol Phys Lab, SRI Int, 333 Ravenswood Ave, Menlo Park CA 94025)* and Chun-Wei Lau *(High Temp Gasdyn Lab, Stanford)*. Combust Flame 94(3) 293-307 (Aug 1993).

This modeling study reports global rate expressions for transient weight loss and yields of tar and gas for coals across the rank spectrum. A novel kinetic analysis demonstrates that the Distributed Activation Energy Model (DAEM) reliability correlates transient weight loss at various heating rates, and makes reasonably accurate extrapolations for pulverized coal (p.c.) firing conditions. This performance motivates solutions of the DAEM for arbitrary thermal histories, including approximate closed-form solutions for transient weight loss along linear temperature ramps and exponential temperature histories. Our analysis also rigorously defines the rate constants in single first order reactions that give the same devolatilization rate as the DAEM at every instant in any thermal history. For devolatilization during heatup at constant rates, frequency factors increase by a factor of 6 for every order-of-magnitude increase in heating rate, while activation energies remain constant. Throughout convective heating, however, both rate parameters decrease continuously, so that straight lines on Arrhenius diagrams do not represent rate constants for coal devolatilization. Rate variations for different coal ranks are modest by comparison. For ranks from lignite to high-volatile bituminous, rates decrease by up to a factor of 3. Low volatility coals are much more resistant to thermal decomposition; they devolatilize at rates up to 5 times slower than all other lower ranks Correlations for different coal types from FLASH2, a more detailed devolatilization model, describe separate gas and tar evolution rates, and replace hypothetical ultimate yield parameters by accurate predictions for ultimate tar and gas yields.

11A905. Slowly varying filtration combustion waves. - MR Booty *(Dept of Math, S Methodist Univ, Dallas TX 75275)* and BJ Matkowsky *(Dept of Eng Sci and Appl Math, NWU)*. European J Appl Math 4(2) 205-224 (Jun 1993).

We describe the slow evolution of the wave speed and reaction temperature in a model of filtration combustion. In the counterflow configuration of the process, a porous solid matrix is converted to a porous solid product by injecting an oxidizing gas at high pressure into one end of a fresh sample of the solid while igniting it at the other end. The solid and gas react exothermically at high activation energy and, under favorable conditions, a self-sustaining combustion travels along the sample, converting reactants to product. Since the reaction rate depends on the gas pressure p in the pores, small gradients p cause variations in the conditions of combustion, which, in turn, cause inhomogeneities in the physical properties of the product. We determine the slow evolution of the wave speed, the reaction temperature, and the mass flux of the gas downstream of the reaction zone. In the absence of a pressure gradient, there is a branch of steadily propagating solutions which has a fold. For planar disturbances on the slow time scale, we show that the middle part of the branch is unstable, with the change of stability occurring at the turning points of the branch. When the pressure gradient is nonzero, there are no steadily propagating solutions and the wave continually evolves. Conditions on the state of gas at the inlet are described such that the variation in the wave speed and reaction temperature throughout the process can be minimized.

416Q. LIQUID FUELS

11A906. Comparison of droplet combustion models in spray combustion. - TL Jiang and W Hsu *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan 70101, ROC)*. J Propulsion Power 9(4) 644-646 (Jul-Aug 1993).

For a spray-burning combustor, experimental observations reveal that different spray combustion modes are present under various atomization conditions. In a fine-droplet spray, fast evaporation of small droplets make gas-phase combustion much more significant than droplet combustion and a diffusion gas-phase flame, with a relatively short spray length with respect to the overall flame length results. As spray droplets become larger, both individual droplet burning of large droplets and group burning of small droplets are possible, and a mixed combustion mode consisting of diffusion gas-phase flame and droplet combustion occurs. Massive droplet combustion with either envelope or wake flames are observed when the spray droplet size is further increased.

11A907. Modeling and simulation of combustion processes of charring and non-charring solid fuels. - C Di Blasi *(Dept di Ing Chimica, Univ di Napoli, Piazzale V Tecchio, 80125 Napoli, Italy)*. Prog Energy Combust Sci 19(1) 71-104 (1993).

Some of the progress that, owing to modeling and numerical simulation, has been made to the understanding of chemical and physical processes, which occur during combustion of solid fuels, is presented. The first part of the review deals with thermal degradation processes of charring (wood and, in general, cellulosic materials) and non-charring (poly-methyl-methacrylate) materials. Gas-phase combustion processes (ignition, flame spread and extinction) are discussed in the second part of the review. Solid fuel degradation has been described by kinetic models of different complexity, varying from a simple one-step global reaction, to multi-step reaction mechanisms, accounting only for primary solid fuel degradation, and to semi-global reaction mechanisms, accounting for both primary solid degradation and secondary degradation of evolved primary pyrolysis products. Semi-global kinetic models have been coupled to models of transport phenomena to simulate thermal degradation of charring fuels under ablation regime conditions. The effects of bubble formation on the transport of volatiles during thermal degradation of non-charring fuels, described through a one-step global reaction, have also been modeled. On the contrary, very simplified treatments of solid phase processes have been used when gas phase combustion processes are also simulated. On the other hand, the latter have also always been described through one-step global reactions. Numerical modeling has allowed controllng mechanisms of ignition and flame spread to be determined and the understanding of the interaction between chemistry and physics during thermal degradation of solid fuels to be improved. However, the chemical processes are not well understood, the few kinetic data are in most cases empirical and variations of solid properties during degradation are very poorly known, so that even the most advanced models do not in general give quantitative predictions.

416S. FLAME AND FIRE (SPREAD AND EXTINCTION)

11A908. Extinction of pool flames by means of a DC electric field. - E Sher, G Pinhasi, A Pokryvailo, R Bar-On *(Dept of Mech Eng, Pearlstone Center for Aeronaut Stud, Ben-Gurion Univ of the Negev, Beer-Sheva, Israel)*. Combust Flame 94(3) 244-252 (Aug 1993).

The application of an electric field to a combustion system can produce large and potentially useful effects, such as reducing carbon formation, affecting flame velocity, extending flammability limits, increasing flame luminosity, and stabilizing and extinguishing flame. The present study is concerned primarily with the corona discharge interaction with pool fires. The fuel surface served as the blunt electrode and several specially designed sharp probes have been examined as the high-voltage electrode. The most effective sharp electrode appeared to be a simple thin wire parallel to the liquid surface situated above it at a distance of several millimeters. The flame was repelled from the probe, thus creating a possible pool flame extinction device. Similar results were achieved with a mechanical blower that reproduced the velocity profile of the electric wind. The gas composition in different locations was examined for both the corona and blower cases. No significant difference was found, and it was concluded that ion pumping has no influence on the extinction performance. It is suggested that extinction by corona discharge is caused solely by the aerodynamic action of the electric wind with its remarkably flat, sharp velocity profile. Fire extinctions under hot and aggressive environments are possible applications of the present device.

416T. COMBUSTION, FLAME, AND FIRE MODELING

11A909. Integral combustion simulation of a turbulent reacting flow in a channel with cross-stream injection. - SL Chang and SA Lottes *(Energy Syst Div, ANL)*. Numer Heat Transfer A 24(1) 25-43 (Jul-Aug 1993).

A new integral one-step reaction submodel has been developed for an Argonne combustion computer code to sir [illegible] ting flows of an advanced cor [illegible] etohydrodynamic power gen [illegible] ombustion code makes n [illegible] a reacting flow more eff [illegible] hile still preserving the major physical effects of the complex combustion processes. Results of the simulation indicate that (1) fluid mixing is mainly responsible for combustion performance and (2) counterflow injection with an injection angle in the range of 120° to 140° yields the best mixing and combustion performance.

11A910. Mixing of multiple jets with a confined subsonic crossflow. - JD Holdeman *(NASA Lewis Res Center, Cleveland OH 44135)*. Prog Energy Combust Sci 19(1) 31-70 (1993).

This paper summarizes experimental and computational results on the mixing of single, double, and opposed rows of jets with an isothermal or variable temperature mainstream in a confined subsonic crossflow. The studies from which these results came were performed to investigate flow and geometric variations typical of the complex 3D flowfield in the dilution zone of combustion chambers in gas turbine engines. The principal observations from the experiments were that the momentum-flux ratio was the most significant flow variable, and that temperature distributions were similar, independent of orifice diameter, when the orifice spacing and the square-root of the momentum-flux ratio were inversely proportional. The experiments and empirical model for the mixing of a single row of jets from round holes were extended to include several variations typical of gas turbine combustors, namely variable temperature mainstream, flow area convergence, noncircular orifices, and double and opposed rows of jets, both inline and staggered. All except the last of these were appropriately modeled with superposition or patches to the basic empirical model. Combinations of flow and geometry that gave optimum mixing were identified from the experimental and computational results. Based on the results of calculations made with a 3D numerical model, the empirical model was further extended to model the effects of curvature and convergence. The principal conclusions from this study were that the orifice spacing and momentum-flux relationships were the same as observed previously in a straight duct, but the jet structure was significantly different for jets injected from the inner wall of a turn than for those injected from the outer wall. Also, curvature in the axial direction caused a drift of the jet trajectories toward the inner wall, but the mixing in a turning and converging channel did not seem to be inhibited by the convergence, independent of whether the contraction was radial or circumferential. The calculated jet penetration and mixing in an annulus were similar to those in a rectangular duct when the orifice spacing was specified at the radius dividing the annulus into equal areas.

11A911. Prediction of the pulsation frequency of flames formed over a semi-infinite horizontal surface. - IK Puri *(Dept of Mech Eng, MC 251, Univ of Illinois, PO Box 4348, Chicago IL 60680)*. Int J Heat Mass Transfer 36(10) 2657-2663 (Jul 1993).

The pulsation frequency of horizontally situated semi-infinite reacting surfaces is studied using linear stability theory. The analysis considers the flow to consist of an initially laminar base flow and a periodic disturbance. The governing equations are cast into a self-similar form analogous to previous analyses of boundary layers. The base flow is analyzed in terms of a flame sheet approximation, the solution to which is required to solve the disturbed flow. Some boundary conditions pertaining to the disturbances are evident but some others are inferred herein. The governing equations are solved for a flame burning n-heptane, and the results of the analysis relate the disturbance frequency of the flame to a Grashof type number, which, in turn, is related to the length of the thermal boundary layer. It is determined that the frequency scales according to a power law expressed as $(\text{length})^{-0.8}$.

11A912. Application of small deflection method in calculation of acceleration time of aircraft turbine engines. - M Orkisz *(Warszawa, Poland).* Biuletyn Wojskowej Akademii Technicznej 42(1) 99-110 (1993).

A method of small declinations was used for linearization the relations describing the turbine and compressor operation and then they were introduced into the equation for acceleration time of the turbine engine. The obtained relation enables the evaluation of influence the departure of turbine as well as the compressor parameters during the acceleration.

11A913. Ballistics of solid rocket motors with spatial burning rate variations. - SD Heister *(Sch of Aeronaut and Astronaut, Purdue).* J Propulsion Power 9(4) 649-651 (Jul-Aug 1993).

The solid rocket motor ballistician has the job of predicting the chamber pressure and thrust history for both new and existing motors utilizing propellant burning rate and grain geometry, ambient conditions, and nozzle geometry. For motors which do not have a test history, ballisticians introduce a constant "scale factor" to force predictions to match actual burn times of test units as well as time varying multiplier to improve "pointwise" matching of the pressure history. This pointwise burning anomaly rate factor, or BARF, is usually established as a function of web distance since it is generally acknowledged that the factor accounts for spatial burning rate variations within the grain. This ubiquitous quantity has gone by several names through the years: hump factor, surface burn rate error, and residual error to name a few.

11A914. Development of a dual-frequency microwave burn-rate measurement system for solid rocket propellant. - DT Foss *(Combust Turbine Eng, Westinghouse Elec, Orlando FL 32826),* RJ Roby, WF O'Brien *(Dept of Mech Eng, VPI).* J Propulsion Power 9(4) 497-498 (Jul-Aug 1993).

A dual-frequency microwave burn-rate measurement system for solid rocket motors has been developed. The system operates in the X-band (8.2-12.4 GHz) and uses two independent frequencies operating simultaneously to measure the instantaneous burn rate in a solid rocket motor. Computer simulation and limited laboratory testing of the system were performed to determine its ability to limit errors caused by secondary reflections and by uncertainties in material properties, particularly the microwave wavelength in the propellant. Simulations showed that the frequency ratio and the initial motor geometry determined the effectiveness of the system in reducing secondary reflections. Overall, the simulations showed that a dual frequency system can provide up to a 75% reduction in burn-rate error over that returned by a single-frequency system. The hardware and software for dual-frequency measurements was developed and tested; however, further instrumentation work is required to increase the data acquisition rate so its full potential can be realized.

11A915. Preliminary assessment of exhaust systems for high-Mach (4-6) fighter aircraft. - AP Kuchar *(Adv Tech Operation, Aircraft Eng Div, GE Aircraft Engines, 1 Neumann Way M-D A330, Cincinnati OH 45215)* and JP Wolf *(Adv Tech Operation, Aircraft Eng Div, GE Aircraft Engines, 1 Neumann Way, Cincinnati OH 45215).* J Propulsion Power 9(4) 636-643 (Jul-Aug 1993).

Exhaust systems designed for high-Mach fighter aircraft will operate at nozzle pressure ratios near 100 for a Mach 4 aircraft to possibly over 600, depending on inlet recovery, for a Mach 6 aircraft. Also, the nozzle pressure loading will be two to four times higher than current Mach 1.5-2.2 exhaust systems, and the exhaust gas temperatures will be significantly higher. These new operating conditions for high Mach nozzles will result in substantial increases in both nozzle size and weight relative to current exhaust systems. Analytical studies have been conducted to assess the internal performance of the conventional axisymmetric nozzle, the 2D, convergent-divergent (2DCD) nozzle, and the single expansion ramp nozzle (SERN) operating at high Mach conditions. Weight estimates have also been complete for the 2DCD nozzle matrix. As expected, results of the studies show that the 2DCD and SERN concepts can achieve desired levels of performance at the expense of size and weight. In general, the exhaust systems for Mach 4-6 aircraft will have to be three to four times as large and four to five times as heavy as those currently employed on Mach 1.5-2.2 aircraft. The axisymmetric nozzle has geometric constraints that limits its performance capability.

11A916. Scramjet nozzle experiment with hypersonic external flow. - S Watanabe *(Aerodyn Div, Natl Aerospace Lab, 7-44-1 Jindaiji-higashi-machi Chofu, Tokyo 182, Japan).* J Propulsion Power 9(4) 521-528 (Jul-Aug 1993).

An experimental study of a scramjet asymmetric nozzle flowfields is conducted to investigate the effects on nozzle performance of interactions between engine exhaust and hypersonic external flow. The test model consists of a flat-plate ramp and a short cowl. Tests are performed in a hypersonic wind tunnel ($M_\infty = 7.1$) whose freestream constitutes the external flow around an aerospace plane. Room temperature air is used to simulate engine exhaust flow. Model surface pressure and pitot pressure distributions in the flowfields are measured, from which nozzle performance is calculated. Flow visualizations are performed using several techniques. It is found that in underexpansion conditions, the external flow affects the model surface pressure only from the ramp sides because the intercepting shock (barrel shock) does not impinge upon the ramp surface. It is shown that the external flow produces an effect which suppresses boundary-layer separation on the ramp surface. When using a long side fence, spanwise expansion of the exhaust flow is restrained, thus, a slight gain of thrust can be obtained relative to that using a shorter side fence. The predicted nozzle performance by the 2D method of characteristics with boundary-layer correction agrees well with the long side fence experimental results.

11A917. Diagnostics and performance of a low-power MPD thruster with applied magnetic nozzle. - TM York, C Zakrzwski, G Soulas *(Aeronaut and Astronaut Eng Dept, Ohio State Univ, Columbus OH 43210).* J Propulsion Power 9(4) 553-560 (Jul-Aug 1993).

This study evaluates the performance of a 50-150-kW thruster which was 1/4-scale of a bench mark magnetoplasmadynamic (MPD) thruster; it was operated with and without applied magnetic nozzle fields. Capacitors (14 μF) and inductors (80 μH) in networks produced relatively constant currents for about 450 μs to generate the applied magnetic nozzle, and currents up to 2.3-kA constant for about 300 μs to drive the thruster. With the solid copper electrode, the applied magnetic field was excluded from the thrust chamber because of the short duration of the experiments. The 1/4-scale device was mass starved below m = 0.135 g/s; this was equivalent to 2 g/s for a full-scale MPD thruster with the same m/A. With m > 0.25 g/s, the device was found to operate smoothly and with little evident erosion. Current-voltage records were similar with and without applied magnetic nozzle fields, indicating little effect of the external nozzles on the power deposition. The current plume in the expansion region outside the thruster chamber was reduced in axial extent with the application of the magnetic nozzle in this transient experiment. Momentum flux in the exhaust flow was measured by the local pressure probes. For the same arc power, impact pressures with magnetic nozzles applied were 3-4 times larger than the self-field cases.

11A918. Thermal nonequilibrium in a low-power arcjet nozzle. - DM Zube *(Inst Raumfahrtsyst, Univ Stuttgart, 7000 Stuttgart 80, Germany)* and RM Myers *(NASA Lewis Res Group, Sverdrup Tech, Cleveland OH 44135).* J Propulsion Power 9(4) 545-552 (Jul-Aug 1993).

Emission spectroscopy measurements were made of the plasma flow inside the nozzle of a 1-kW-class arcjet thruster. The thruster propellant was a hydrogen-nitrogen mixture used to simulate fully decomposed hydrazine. Several 0.25-mm-diam holes were drilled into the 12-mm-long diverging section of the tungsten thruster nozzle to provide side-on optical access to the internal flow. Electron excitation for atomic species and molecular vibrational and rotational temperatures were determined for the expanding plasma using relative line ratio techniques. The atomic excitation temperature decreased from 18,000 K at a location 3-mm downstream of the constrictor to 9000 K at a location 9 mm from the constrictor, while the molecular vibrational and rotational temperatures decreased from 6500 to 3000 K and 8000 to 3000 K, respectively, between the same locations. The electron density, measured using H_β line Stark broadening, decreased from $\approx 10^{21} m^{-3}$ to $2 \times 10^{20} m^{-3}$ during the expansion in the nozzle. The results show that the plasma is in a nonequilibrium state throughout most of the nozzle, with relaxation times close to or larger than the particle residence time.

11A919. Temperature control of a liquid helium propulsion system. - P Wiktor *(Hansen Labs GP-B, Stanford).* J Propulsion Power 9(4) 536-544 (Jul-Aug 1993).

Two spacecraft, gravity probe B (GP-B) and the satellite test of the equivalence principle, incorporating onboard liquid helium cryogenic systems are scheduled to fly around the turn of the century. Effective propulsion systems can be implemented for these spacecraft by directing the helium gas which boils off from the cryogenic systems in specific directions through a set of thrusters. Due to extensive development and testing work, the ultra low flow rate helium thrusters for such a propulsion system are now considered proven technology. This article is concerned with implementing these thrusters into an effective overall propulsion system. A thermodynamic model relating the temperature, pressure, and flow rate of the propulsion system is derived. Based on this model a controller is developed which regulates the liquid helium supply temperature and pressure by varying the net helium mass flow rate through the thrusters. We show how the net mass flow rate can be controlled independently from the desired output thrust. The manifold pressure upstream of the thrusters is shown to remain remarkably stable even with fairly large flow rate variations. Using the GP-B spacecraft as an example we conclude that it is feasible to build a liquid helium based propulsion system with a very stable supply temperature and pressure.

452B. FUNDAMENTALS OF FLUID FLOW

11A920. Modified percolation approach to simulating three-fluid capillary pressure-saturation relationships. - WE Soll *(LANL)* and MA Celia *(Dept of Civil Eng, Princeton)*. Adv Water Resources 16(2) 107-126 (1993).

A computational model was developed for simulating capillary pressure-saturation relationships for porous media systems containing two or three mobile fluids. The model is based on describing fluid displacement on a pore-by-pore basis over a large number of pores to produce bulk saturations in the medium. The computational approach utilizes percolation and network theories to describe fluid movement within the pore space. Percolation theory calls for a set of displacement rules to determine the movement of the fluids under capillary-driven transport. A comprehensive set of rules appropriate for either two-fluid or three-fluid systems is described. These rules account for a variety of processes affecting displacement, such as wetting films, hysteresis, trapping of fluids, and gravity. The model is shown to reproduce the basic characteristics of a two-fluid capillary pressure-saturation curve, and model predictions are shown to agree with both two- and three-fluid experimental data.

11A921. Simultaneous determination of dispersion and nonlinear adsorption parameters from displacement tests by using numerical models and optimization techniques. - CA Grattoni, RA Dawe *(Mineral Resources Eng, Imperial Col, London SW7 2AZ, UK)*, MS Bidner *(Lab de Ingenieria de Reservorios, Univ de Buenos Aires, Pabellon de Indust, Ciudad Universitaria, 1428 Buenos Aires, Argentina)*. Adv Water Resources 16(2) 127-135 (1993).

The determination of the dispersion and adsorption parameters (either for the Freundlich or Langmuir adsorption isothermal models) can be determined by optimizing the matching of the numerical solution of the adsorption-convection dispersion equation with the experimental effluent curves measured on displacement tests in core material using multivariable optimization techniques. The numerical solutions are obtained by solving the convection-disperion-nonlinear adsorption equation by finite differences using the Crank-Nicolson method with iterations to account for nonlinearities. The optimization routines are used to find the parameters that give the global minimum error between predicted and measured effluent curves. The results show that whenever the three parameters (the dispersion coefficient and two adsorption parameters) are simultaneously determined, the solution is not unique and depends on the adsorption model used. The nonuniqueness can be removed by performing an independent test such as a static adsorption test.

11A922. Travelling waves during the transport of reactive solute in porous media. Combination of Langmuir and Freundlich isotherms. - CJ van Duijn *(Fac of Tech Math and Info, Tech Univ, PO Box 356, 2600 AJ Delft, Netherlands)*, P Knabner *(Inst fur Angewandte Anal and Stochastik, Hausvogteiplatz 5-7, D 0-1086 Berlin, Germany)*, SEATM van der Zee *(Dept of Soil Sci and Plant Nutrition, Agri Univ, PO Box 8005, 6700 EC Wageningen, Netherlands)*. Adv Water Resources 16(2) 97-105 (1993).

Recently, it has been shown that in the case of nonlinear solute adsorption the displacement may be in the form of a travelling wave. In this paper, we investigate whether a travelling wave type of behavior can be expected when two different types of sorption sites can be distinguished with different isotherms and kinetics. Illustrations are given for cases where the overall isotherm comprises two contributions that follow the Langmuir and the Freundlich equations, respectively. Boundary conditions are chosen that ensure a decrease in concentration in the direction of flow. Depending on the value of the Freundlich power (p) the travelling wave may exist. For $p \leq 1$, the travelling wave always exists, where as for $1 < p \leq 2$ it depends on the values of the other adsorption parameters and whether a lower bound of the upstream concentration (at $x = -\infty$) is exceeded. For $p \geq 2$, the existence of the travelling wave requires that the upstream concentration does not exceed an (specified) upper bound. Besides illustrating some waves we show that two different rate functions have the Freundlich isotherm as their limit for an infinite rate parameter result in qualitatively different travelling waves.

11A923. BE analysis of contaminant transport in fractured porous media. - CJ Leo and JR Booker *(Sch of Civil and Mining Eng, Univ of Sydney, Sydney 2006, Australia)*. Int J Numer Anal Methods Geomech 17(7) 471-492 (Jul 1993).

A 2D boundary integral method to analyze the flow of contaminant in fractured media having a 2D or 3D orthogonal fracture network is presented. The method assumes that the fractures provide the paths of least resistance for transport of contaminants while the matrix, because of its low permeability, acts as "storage blocks" into which the contaminant diffuses. Laplace transform is used to eliminate the time variable in the governing equation in order to facilitate the formulation of a boundary integral equation in the Laplace transform space. Conventional BE techniques are applied to solve for the contaminant concentrations at specified locations in the spatial domain. The concentration in the time domain is then obtained by using an efficient inversion technique developed by Talbot. The method is able to analyze the behaviour of waste repositories which have diminishing concentration due to the mass transport of the contaminant into the surrounding fractured media.

11A924. FE modelling of transport of organic chemicals through soils. - T Kuppasamy *(Dept of Civil Eng, VPI)*. Int J Numer Anal Methods Geomech 17(7) 457-469 (Jul 1993).

Aquifer contamination by organic chemicals in subsurface flow through soils due to leaking underground storage tanks filled with organic fluids is an important groundwater pollution problem. The problem involves transport of a chemical pollutant through soils via flow of three immiscible fluid phases: namely air, water, and an organic fluid. In this paper, assuming the air phase is under constant atmospheric pressure, the flow field is described by two coupled equations for the water and the organic fluid flow taking interphase mass transfer into account. The transport equations for the contaminant in all the three phases are derived and assuming partition equilibrium coefficients, a single convective-dispersive mass transport equation is obtained. A FE formulation corresponding to the coupled differential equations governing flow and mass transport in the three fluid phase porous medium system with constant air phase pressure is presented. Relevant constitutive relationships for fluid conductivities and saturations as function of fluid pressures lead to non-linear material coefficients in the formulation. A general time-integration scheme and iteration by a modified Picard method to handle the non-linear properties are used to solve the resulting FE equations. Laboratory tests were conducted on a soil column initially saturated with water and displaced by ρ-cyumene (a benzene-derivative hydrocarbon) under constant pressure. The same experimental procedure is simulated by the FE programme to observe the numerical model behaviour and compare the results with those obtained in the tests. The numerical data agreed well with the observed outflow data, and thus validating the formulation. A hypothetical field case involving leakage of organic fluid in a buried underground storage tank and the subsequent transport of an organic compound (benzene) is analyzed and the nature of the plume spread is discussed.

11A925. Modeling coupled heat and contaminant transport in groundwater. - PJ Hensley *(Dept of Civil and Env Eng, Univ of W Australia, Nedlands 2009, W Australia)* and C Savvidou *(Eng Dept, Cambridge Univ, Cambridge CB2 1PZ, UK)*. Int J Numer Anal Methods Geomech 17(7) 493-527 (Jul 1993).

This paper presents the results of a research program conducted on the geotechnical centrifuge at The Univeristy of Western Australia to investigate coupled heat and contaminant transport in the soil surrounding a buried waste source. The phenomena which govern heat and contaminant transport through porous media are discussed, the principles of geotechnical centrifuge modeling are outlines, and relevant scaling laws that govern the relationship between a centrifuge model and the prototype, with respect to the problem of coupled waste transport, are presented. A model test, simulating 2D migration from a buried heat and contaminant source, is described, and the results from four model tests are presented. The experimental data show that hydraulic instability is responsible for the transport of contaminant in the soil around the source and that the mode of instability is determined by the magnitude of the effective Rayleigh number.

11A926. Simulation of groundwater flow and containment transport at a landfill site using models. - TJ Franz *(Dames and Moore, 7560 Airport Rd, Mississauga, ON, Canada)* and RK Rowe *(Geotech Res Center, Fac of Eng Sci, Univ of W Ontario, London, ON, Canada)*. Int J Numer Anal Methods Geomech 17(7) 435-455 (Jul 1993).

Numerical and analytical modeling studies were conducted for the analysis of groundwater flow and contaminant transport at the Innisfil landfill site in the Town of Innisfil, County of Simcoe, in Ontario, Canada. Previously conducted field studies categorized the upper stratigraphy at the site into three units: upper sand unit, upper silt-clay unit, and Intermediate Sand unit. Essentially horizontal groundwater movement in the two sand units and vertical downward flow in the silt-clay unit were reported by the field hydrogeologists. In the following, application of three computer models (FLOWPATH, USGS MOC and POLLUTE) for the simulation of the groundwater flow and contaminant transport processes at the Innisfil landfill site is described. The paper focuses on the calibration of groundwater flow and contaminant transport systems, and demonstrates how the insight gained during the contaminant transport calibration was used to improve the initial groundwater flow characterization of the hydrogeological system.

11A927. Transient infinite elements for seepage problems in infinite media. - Chongbin Zhao and S Valliappan *(Sch of Civil Eng, Univ of New S Wales, PO Box 1 Kensington, NSW 2033, Australia)*. Int J Numer Anal Methods Geomech 17(5) 323-341 (May 1993).

In this paper, a time-dependent infinite element which can be used to simulate transient seepage problems in infinite media is presented. The hydraulic head distribution function of the element has been derived in detail and the property matrices of the element have been formulated. Since both space and time variables are used in the course of constructing the hydraulic head distribution function of the element, the present infinite element can be referred to as a transient one. Using the present infinite element to model the far field of a system, the mechanism of transient seepage problems in infinite media can be rigorously simulated because the property matrices of the element are evaluated at any time of interest in the analysis. Since explicit expressions can be written for the property matrices of the infinite element, they may be evaluated quite easily and this can be carried out by writing a simple subroutine in a computer program. In order to examine the accuracy and efficiency of the present infinite element, both a 1D transient seepage problem in a semi-infinite medium and a 2D transient seepage problem in a full plane have been solved using the finite and infinite element technique. It has been demonstrated that the present infinite element is very useful for the numerical solution of transient seepage problems in infinite media.

11A928. Numerical modeling of circulating fluidized beds. - MK Patel, K Pericleous, M Cross *(Centre for Numer Model and Process Anal, Univ of Greenwich, London SE18 6PF, UK)*. Int J Comput Fluid Dyn 1(2) 161-176 (1993).

The development of the multi-phase flow algorithm MIPSA (Multi-InterPhase Slip-Algorithm) within a 2D Computational Fluid Dynamics (CFD) code called CASCADE is summarized with its application to the modeling of lean phase circulating fluidized beds. The well-known InterPhase Slip Algorithm (IPSA) technique for handling the presence of particles in an air stream is modified and extended, to handle explicitly a range of particle sizes simultaneously. The salient features of IPSA are retained; hence each size family is treated as a separate "phase" and its motion governed by its own momentum equations. The MIPSA algorithm is embedded within CASCADE, in a framework which ensures overall conservation of mass, momentum, and energy. In this paper, the MIPSA algorithm is used to model the hydrodynamic behavior of Circulating Fluidized Beds (CFB). CFB's are increasingly being employed by a wide range of process industries and their design for a specific application can be problematic. The objective of this paper is to show how CFB's can be analyzed to identify their mixing behavior and factors affecting their efficiency of operation. The present study considers hydrodynamic behavior in relation to single and multiple mixing cells in a columnar arrangement, with a range of recirculation rates together with the effect of different riser configurations. The results of the calculations are presented in the form of velocity vecotrs, pressure contours, temperature contours and solid particle distributions for mono- and multi-sized particle simulations. The relative efficiency of single and multiple units is compared, together with the effects of reentry.

This paper evaluates the applicability of nonhomogeneous fibers for improving the thermal insulation properties of the fiber matrix composites. Hollow silica fibers and silica fibers coated with alumina and silicon are considered for enhancing the surface reflectance and thermal radiative resistance of fibrous composites in which fibers are oriented parallel to planar boundaries. Analytical models are developed to determine the influence of coating material and thickness on these radiative characteristics. Numerical results reveal that silicon-coated silica fibers are most effective in increasing the insulation capacity of a fiber matrix. The results also show that the radiative resistance can be tailored to exhibit the desired spectral variation by combining an appropriate proportion of coated fibers with different coating thicknesses. The present results establish the feasibility of utilizing silicon-coated silica fibers to substantially enhance the thermal insulation capacity of fibrous composites.

452L. FLOW STABILITY

11A931. Dispersion, permeability heterogeneity, and viscous fingering: Acoustic experimental observations and particle-tracking simulations. - HA Tchelepi, FM Orr Jr *(Dept of Pet Eng, Stanford)*, N Rakotomalala, D Salin, R Woumeni *(Lab Acoust Optique Matiere Condensee CNRS, Univ Pierre et Marie Curie, Tour 13 Boite 78, 4 pl Jussieu, 75252 Paris Cedex 05, France)*. Phys Fluids A 5(7) 1558-1574 (Jul 1993).

Stable and unstable displacement experiments were performed in millstone and limestone cores. Concentration histories at ten locations along the core samples were obtained by acoustic measurements. Particle-tracking simulations of the displacements were also made utilizing permeability distributions measured with a permeameter. The combination of experimental observations and simulations indicate that superstable ($M < 1$) displacements suppress the influence of heterogeneity; this suppression was reflected in smaller apparent dispersivities as the mobility ratio decreased below unity. In the millstone, which exhibited random heterogeneity, 2D particle-tracking simulations reproduce with reasonable accuracy the growth of the fingered region in unstable displacements. In homogeneous porous media, concentration histories obtained in 3D simulations did not differ significantly from their 2D counterparts. In the more heterogeneous limestone, unstable displacements accentuated the influence of heterogeneity leading to longer transition zones. Two distinct flow regimes were observed in unstable displacements: (1) an initial period of rapid transition zone growth and (2) a subsequent period in which leading and trailing edges of the transition zone travel at nearly constant velocities.

452M. NON-NEWTONIAN FLUIDS

11A932. Non-Newtonian flow in porous media: A laboratory study of polyacrylamide solutions. - S Flew *(11 Foxcombe Court Wyndyke Furlough, Abingdon OX14 1D2, UK)* and RHJ Sellin *(Dept of Civil Eng, Univ of Bristol, Bristol BS8 1TR, UK)*. J Non-Newtonian Fluid Mech 47 169-210 (Jun 1993).

Quantification of the rheological effects of polymer solutions flowing through a porous matrix must be achieved if high molecular weight polymers are to be used to the best effect in augmenting oil recovery. This investigation explores the extensional flow behavior of polyacrylamide solutions, at dilutions around those used in oilfield practice, in a variety of flow geometries including hexagonal-rod arrays and glass-bead packs.

11A933. Determination of drying induced stresses in a prismatic bar. - A Rybicki *(Inst of Fund Tech Res, Polish Acad of Sci, Poznan, Poland)*. Eng Trans 41(2) 139-156 (1993).

In the paper a solution of the 2D problem of convective drying of porous-capillary material is presented. The considered phenomenon is described by a system of coupled differential equations proposed by Kowalski. The problem is solved with the use of the FEM for spatial derivatives and of the three-point finite difference method for derivatives with respect to time. The obtained results with special emphasis on the stress distributions are shown diagrammatically.

11A934. Steady-state plane Lamb's problem for a fluid-saturated poro-elastic medium. - R Staroszczyk *(Inst of Hydroeng, Polish Acad of Sci, Szczecin, Poland)*. Arch Mech 44(5-6) 499-512 (1992).

In the paper the time harmonic plane Lamb's problem for a fluid-saturated porous elastic solid is investigated. The considerations are carried out on the basis of Biot's dynamical theory of consolidation. The problem is solved by means of the Fourier transformation technique. The solutions are derived in the form of improper integrals, which have been evaluated in a numerical way, described in the paper. In a limiting case of no pore fluid in the medium, the solutions obtained are shown to reduce to those known in the classical theory of elasticity. As an illustration, some results of numerical calculations performed for the material parameters corresponding to a water-filled coarse sand are presented.

452Z. EXPERIMENTAL TECHNIQUES

11A935. Measurement technique and a new model for the wall heat transfer coefficient of a packed bed of (reactive) powder without gas flow. - M Pons *(CNRS-LIMSI, BP 133, 91403 Orsay Cedex, France)*, P Dantzer *(CNRS-URA 446 Bat 415, Univ Paris Sud, 91405 Orsay Cedex, France)*, JJ Guilleminot *(CNRS-LIMSI, BP 133, 91403 Orsay Cedex, France)*. Int J Heat Mass Transfer 36(10) 2635-2646 (Jul 1993).

An experimental technique, designed for investigating altogether the effective thermal conductivity and the wall heat transfer coefficient in a packed bed of hydride powder, and the coupling of heat transfer with the hydriding reaction, is presented. It consists of measuring transient temperature evolution in a reactor with only geometrical symmetry and of fitting to the experimental data the numerical solution of the heat equation in the 2D domain including the whole reactor. This method requires only a relatively small powder volume (30 cm^3). As a first step, results on non-reactive packed bed (500 μm glass beads with argon and 20 μm iron powder with hydrogen) validate the experimental technique. A new model for the wall heat transfer coefficient is developed for packed beds without gas flow. This model attempts to unify the current differing approaches of modeling this quantity. It predicts high values for small grain size and large variations in the Knudsen transition domain: this is qualitatively confirmed by experiments, with coefficients at around 3000 W m^{-2} K^{-1} being measured for 20 μm iron powder in hydrogen. Experimental results show that the pressure-dependent thermal resistances on wall and grain surfaces are not negligible.

11A936. Nonlinearity of flow in a porous medium and its origin. - R Skawinski *(Inst Mech Gorotworu, Polska Akad Nauk, 30-059 Krakow ul, Reymonta 27, Poland)*. Arch Gornictwa 37(4) 421-438 (1992).

The subject of the present paper is the consideration on the opinions and results of experiments concerning the flow of liquids in porous media, particularly the nonlinearity of this flow, ie, dependence of permeability on flow velocity. From all theoretical and experimental works it is evident that the assumption of fixed stream lines in flow in a pore space of porous medium is not in accordance with reality and that the deviations from Darcy's law originate in significant participation of the inertial forces in the formation of the velocity field in the pore space realized by changes in the stream lines with the occurrence of flow separation at microscopic points in the pore space where the flow diverges or is curved. For the study of phenomena in a packed bed a model which retains the converging-diverging character of the flow is needed. Such geometric formations as constrictions and expansions of the space embraced by the flow have been used in experimental investigations made in Strata Mechanics Research Institute of Polish Academy of Sciences in Cracow, as the main element in modelling the flow in porous media and in investigation of the velocity field and its changes in such flow. These investigations were performed by the visualization methods.

11A937. Transient method for measuring thermal properties of saturated porous media. - OV Trevisan *(Fac Eng Campinas, Univ Estadual, 13081 Campinas SP, Brazil)*, S Mohanty, MA Miller *(Dept of Pet Eng, Univ of Texas, Austin TX 78712)*. Int J Heat Mass Transfer 36(10) 2565-2573 (Jul 1993).

This paper describes the development of a transient technique to measure thermal diffusivity and conductivity of porous samples. The method uses the film heat sensor to probe heat flux. Temperature and heat flux are measured dynamically allowing conditions to vary in time at the point of measurement. The data are then treated by a deconvolution algorithm, rendering results proper to simpler models for the same geometry. The numerical treatment in the deconvolution procedure was verified for a hypothetical case. The method was finally tested in the laboratory, with experiments made on samples of natural rock.

11A938. Model for nonlinear seismic waves in a medium with instability. - IA Beresnev *(Inst of Earth Sci, Acad Sinica, PO Box 1-55 Nankang, Taipei, Taiwan 11529, ROC)* and VN Nikolaevskiy *(Inst of Phys of the Earth, Bolshaya Gruzinskaya 10, Moscow 123 810, Russian Federation)*. Physica D 66(1-2) 1-6 (Jun 1993).

Experimental investigations show that the earth's crust is elastically nonlinear and contains the sources of accumulated elastic energy, so that it can be considered as a nonlinear active medium. The effects of simulation of narrow- and broad-band seismic emission and the existence of dominant frequencies for which the medium is transparent have been reported. A model evolutionary equation which takes into account nonlinearity, instability, dissipation of energy and dispersion is proposed and solved numerically. The temporal solution of chaotic signals results in the formation of quasi-sinusoidal steady-state wave trains. The dependence of their amplitude on the values of coefficients of nonlinearity and dispersion is found. The mathematical model proposed can be used to describe the observed seismic phenomena.

11A939. Evaluation of seismic hazard of large industrial objects. - Z Droste *(Inst of Geophys, Polish Acad of Sci, 01-452 Warsaw ul Ksiecia, Janusza 64, Poland)*. Acta Geophys Polonica 40(3-4) 247-270 (1992).

Methods for evaluation of seismic hazard in areas in which large industrial objects such as water power plants, nuclear power plants and the like are to be built have been discussed. The discussion is based on the reports prepared at the Institute of Geophysics for the planned nuclear power plant sites.

11A940. Heat flow from Okuniew-IG-1 borehole, Poland. - MAJ Slawomir *(Inst of Geophys, Polish Acad of Sci, 01-452 Warsaw ul, Ksiecia Janusza 64, Poland)*. Acta Geophys Polonica 40(3-4) 213-218 (1992).

The surface heat flow density from Okuniew-IG-1 borehole is estimated to be about 40-50 mW/m^2. Our indirect calculations are based, in general, on an empirical relation between the HF and seismic Pn wave velocity, and on the nonlinear HF-radiogenic heat production relationship for heat flow provinces. Statistical correlations between the thermal conductivities and some physical properties (such as mean velocity, density, and porosity) for sedimentary rocks are also used.

11A941. General relativity in geophysics. - AP Trofimenko *(Astron Section, Minsk Dept, Astron-Geodesical Society of CIS, Minsk-12 Abonent Box 7, 220012 Byelorussia)*. Acta Geophys Polonica 40(3-4) 303-322 (1992).

Geophysical manifestations of otons (objects of general relativity) are discussed. The values of energy and flow of neutrino from a microblack hole which can supply the energy of volcanos are specified. The energy of catastrophic volcano explosions coincides in the order of magnitude with the energy of exploding black holes. The question is put forward about the registration of high energy neutrino from exploding black holes by means of deep-water detectors. Short-time variations of gravitational potential derivatives (otonic gravi-impulses) are described, which are produced by fast moving otons in the Earth. The results of experimental registration of minute variations of the second and first derivatives of gravitational potential are presented.

11A942. Baroclinic instability of the atmosphere due to the nonhomogeneity of zonal flow. - R Brojewski *(Military Tech Acad, Warszawa, Poland)*. J Tech Phys 34(1) 37-43 (1993).

The subject matter of the present paper is the problem of stability of zonal flow of geophysical fluid using an example the two-layer model of baroclinic atmosphere. It has been shown that the occurrence of nonhomogeneity in zonal flow changes the wave range of cylogenesis in the model by moving it in the direction of long waves. Having sufficient degree of nonhomogeneity of flow it is unstable for any wavelength. In addition, the existence of the model is discussed of five parameters influencing its stability and the existence of three parameters having the character of bifurcation parameters has been pointed out.

11A943. Magnetotelluric response on a multilayered earth model with a layer having exponentially varying conductivity. - B Banerjee *(Central Geophys Div, Geol Survey of India, R&D Wing, P-49 CIT Rd, Beliaghata, Calcutta 70010, India)*. Acta Geophys Polonica 40(3-4) 293-302 (1992).

Magnetotelluric response of a horizontally stratified earth in which the conductivity or resistivity of any one of the layers varies exponentially with depth or with or without a discontinuity at the interfaces has been investigated. All previous works regarding this problem are particular cases of the present study.

11A944. Stability of zonal flow in the divergent-barotropic model of a geophysical fluid. - R Brojewski *(Military Tech Acad, Warszawa, Poland).* J Tech Phys 34(1) 45-56 (1993).

The stability of zonal flow in the divergent-barotropic model of the atmosphere is estimated making use of stability criteria connected with the method of disturbances as applied to locally linearized dynamics systems. The result obtained enables us to infer that any nonhomogeneous inviscid flow in the N-S direction is unstable under short-wave disturbances of sufficiently small wavelengths, of the type of Rossby waves. A numerical experiment that was presented shows that there exist, in the system, stable vibration states of a type of nonlinear vibration with modulated frequency.

Dynamic response of deeply embedded structures, such as underground tunnels and deep foundations, in multilayered elastic half-space are analyzed when the structure is excited by a plane P or SV wave propagating at some angle. The scattered field is represented by the sum of three Green's functions, corresponding to two oscillating forces and one oscillating moment at the centroid position of the buried structure. The amplitudes of these two forces and one moment are *a priori* unknown and are obtained by satisfying displacement and stress continuity conditions across the near-field and far-field boundary. The distinguishing feature of this technique from direct or indirect boundary integral techniques is that in these techniques a distribution of sources of unknown amplitude are considered at the near-field and far-field boundary, and a large number of sources are needed for different combinations of source-receiver arrangements. But in this technique the sources of unknown amplitude are placed at the location of the structure, not at the near-field and far-field boundary and, using the Saint Venant's principle, the scattered field is modeled. Thus, the number of sources required is reduced to only three. Two example problems are solved. The first one is for a deeply embedded footing in a three-layer soil mass and the second one is for a rectangular tunnel in a two-layer soil mass.

11A947. Influence of time-domain dam-reservoir interaction on cracking of concrete gravity dams. - DH Wepf *(WWI Wepf and Wepf Eng Services, 9230 Flawil, Switzerland)*, G Feltrin, H Bachmann *(Inst of Struct Eng, Swiss Fed IT, 8093 Zurich, Switzerland).* Earthquake Eng Struct Dyn 22(7) 573-582 (Jul 1993).

Based on a nonlinear dam-reservoir interaction model, a study investigating the earthquake response of concrete gravity dams is presented. For the propagation of cracks in unreinforced mass concrete, a discrete crack approach formulation based on the FEM is applied. A special crack element is used to follow a fictitious crack in order to account for a zone of microcracks developing at the crack tip. The reservoir is modeled using the BEM. At a fictitious boundary dividing the irregular finite part of the reservoir from the regular infinite part, the loss of energy due to pressure waves moving away towards infinity is taken into account rigorously. Analyses are performed on the tallest non-overflow monolith of the Pine Flat Dam located in Kern County, California. The interaction of a dam, which may exhibit cracks in mass concrete, with a reservoir domain of arbitrary geometry extending to infinity is studied. Some main parameters are investigated. The importance of tools capable of handling the non-linear dam-reservoir interaction is emphasized.

11A948. Seismic response of heavily damped base isolation systems. - Hsiang-Chuan Tsai *(Dept of Construct Eng, Natl Taiwan IT, Taipei, Taiwan, ROC)* and JM Kelly *(Dept of Civil Eng, UCB).* Earthquake Eng Struct Dyn 22(7) 633-645 (Jul 1993).

The development of an efficient energy-dissipating mechanism that works in conjunction with laminated elastomeric bearings in order to reduce the lateral deformation of the isolation system has always been a goal of base isolation research. Theoretically, this deformation will be reduced to the minimum if damping augmentation of the isolation system can reach a critical value. However, augmenting the isolation damping may cause some unwanted side effects. The purpose of this paper is to study the influence of isolation damping on the seismic response of heavily damped base-isolated buildings. The base isolation system is assumed to be linearly viscoelastic and is analyzed using the complex mode method. Solutions derived by using perturbation techniques for a 2-dof system and the computer simulation for a multiple-dof system reveal that augmenting the isolation damping can reduce efficiently the deformation of the isolation system, but at the price of increasing the high-frequency vibration in the superstructure. When the damping ratio of the isolation system is beyond some level, increasing the isolation damping will enlarge the extreme values of the base and superstructural accelerations. It is also found that approximate solutions derived from the use of classical damping and classical modes of vibration in the seismic analysis of heavily damped base isolation systems can be substantially in error.

11A949. Design study of an energy-dissipating cladding system. - JM Cohen *(Cladding Res Inst, 6 Commodore Dr, Suite 330, Emeryville CA 94608)* and GH Powell *(Dept of Civil Eng, UCB).* Earthquake Eng Struct Dyn 22(7) 617-632 (Jul 1993).

A design study has been conducted to explore the use of structural cladding panels with energy-dissipating cladding-to-frame connections for seismic-resistant design. The study identifies several issues involved in the modeling and analysis of frames with energy-dissipating cladding-to-frame connections, establishes concepts for design, and provides a preliminary assessment of the force and deformation demands that are likely to be placed on panels and connections. Nonlinear dynamic analyses indicate that the clad frames perform well, based on observations about maximum interstorey drifts, maximum plastic hinge rotations in the frames, and maximum ductility demands on the cladding-to-frame connections.

11A955. Stability analysis of the viscous geophysical fluid flow on a torus in a divergent-barotropic model, including rotation sources. - R Brojewski *(Military Univ of Tech, Warszawa, Poland).* J Tech Phys 34(2) 107-118 (1993).

The subject of the present considerations are some properties of the solution of a set of ordinary differential equations obtained as a result of application of Galerkin's method to the equation of divergent-barotropic model of viscous geophysical fluid on a torus, with sources of rotation. The stationarities of the system have been studied, the relevant stability criteria being found as well as the conditions of the system attractors existence in the form of closed orbits. The parameters of the latter have been determined. It has been demonstrated that there are no attractors of any other type, if the sources of rotation depend on a single variable which governs the Coriolis parameter, and are independent of time. In the case of pulsating sources of rotation it has been shown that resonances may occur in the system.

11A956. The cooling power of mining air cooler. - J Waclawik *(Inst Gornictwa Podziemnego I Bezpieczenstwa Pracy, Akad Gorniczo-Hutnicza, 30-059 Krakow Al, Mickiewicza 30, Poland).* Arch Gornictwa 37(4) 393-408 (1992).

The paper presents a method of calculation of the air temperature and humidity in a working in the case when the air is cooled by air cooler. In the work is assumed, that the thermodynamic process of the humid air cooling is lying on the enthalpy-moisture content diagram on the straight line. The cooling powers of the air cooler is depending on the inlet valves of water temperature, air temperature and humidity, the area of cooled surface and on type of heat exchanger system.

11A957. An empirical study on the functioning of nonbranching air duct lines in mines in the context of airflows with mass and momentum exchange in accordance with the law of growth: The problem of air quantity. - H Bystron *(Glowny Inst Gornictwa, Kopalnia Doswiadczalna "Barbara", 40-951 Katowice Pl, Gwarkow 1, Poland).* Arch Gornictwa 37(4) 491-551 (1992).

The object of this present study, dealing with the problems of air quantity and air pressure, was to verify the hypothesis that the system of equations describing airflows with mass and momentum exchange should include the growth function, in which appears growth intensity expressed by equation. This equation refers to discriminant. Its integrals are not simple functions having corresponding simple antifunctions in the explicit form. For this reason a parameterized growth intensity was introduced and on this is based a family of theoretical growth functions. Making use of empirical data, empirical growth functions together with the corresponding families of theoretical functions are presented in tabular form. Starting from criterion based on standard deviations, appropriate theoretical growth functions were developed and also appropriate growth parameters and intensities.

11A958. Estimate changes of concentration of gases during stoping downcast ventilator in the area of liquidated ventilator gallery of longwall with caving. - H Kaletka *(Kopalina Wegla Kamiennego, Rymer, 44-270 Rybnik-Niedobczyce ul, Rymera 4, Poland).* Arch Gornictwa 37(4) 409-420 (1992).

In this article has been shown bloc scheme of diffusing gases in liquidated ventilation gallery of longwall with caving. The formula has been derived showing the course of concentration particular gases as a function of time during stoping downcast ventilator. Simplified flow of air and gas from cavings (or goaf gas) model, in the area longwall with caving, has been shown. This model allowed measure the influence of natural depression on velocity of changes concentration of gases in time period.

11A959. Creative design-by-analysis solutions applied to high-temperature components. - AK Dhalla *(Nucl Adv Tech Div, Westinghouse Elec, Pittsburgh PA 15230).* J Pressure Vessel Tech 115(3) 221-227 (Aug 1993).

Elevated temperature design has evolved over the last two decades from design-by-formula philosophy of the ASME Boiler and Pressure Vessel Code, Sections I and VIII (Division I), to the design-by-analysis philosophy of Section III, Code Case N-47. The benefits of design-by-analysis procedures, which were developed under a US-DOE-sponsored high-temperature structural design program, are illustrated in the paper through five design examples taken from two US liquid metal reactor (LMR) plants. Emphasis in the paper is placed upon the use of a detailed, nonlinear FE analysis method to understand the structural response and to suggest design optimization so as to comply with Code Case N-47 criteria. A detailed analysis is cost-effective, if selectively used, to qualify an LMR component for service when long-lead-time structural forgings, procured based upon simplified preliminary analysis, do not meet the design criteria, or the operational loads are increased after the components have been fabricated. In the future, the overall costs of a detailed analysis will be reduced even further with the availability of FE software used on workstations or PCs.

11A960. Combination of radiation and hydrogen damage of reactor pressure vessel materials. - K Splichal, M Ruscak, J Zd'arek *(Nucl Res Inst, 250 68 Rez, Czechoslovakia).* Int J Pressure Vessels Piping 55(3) 361-373 (1993).

The hydrogen embrittlement of low-alloyed base steel, austenitic cladding and heat affected zone (HAZ) of a reactor pressure vessel was measured for both unirradiated and irradiated materials. The fracture toughness decreased with both hydrogen charging and neutron irradiation; the shift of the fracture toughness-temperature transient curve is influenced by both damage processes. The plastic zone in hydrogen-charged material becomes smaller. The total elongation of both CrMoV and CrNiMoV HAZ decreases with increasing hydrogen content. This influence is pronounced in the HAZ after a weld process without subsequent annealing, a total loss of plasticity being observed in this case. The properties of the austenitic layer are not influenced at comparable hydrogen contents.

506. Solar and other energy systems

11A961. Heat and fluid flow in rectangular solar air heater ducts having transverse rib roughness on absorber plates. - D Gupta *(Dept of Mech Eng, Eng Col, Kota 324 009, India),* SC Solanki, JS Saini *(Dept of Mech and Indust Eng, Univ of Roorkee, Roorkee 247 667, India).* Solar Energy 51(1) 31-37 (Jul 1993).

An experimental investigation has been carried out to determine the effect of transverse wire roughness on heat and fluid flow characteristics in transitionally rough flow region ($5 < e+ < 70$) for rectangular solar air heater ducts with an absorber plate having transverse wire roughness on its underside. The investigation covered a Reynolds number range of 3000-18000 for a duct aspect ratio of 6.8-11.5, relative roughness height of 0.018-0.052 at a relative roughness pitch of 10 encompassing a range of roughness Reynolds number between 5-70. Simple correlations for a Nusselt number and friction factor have been developed in terms of geometrical parameters of roughness, duct cross section, and the flow Reynolds number.

11A962. Losses in a 3D compound parabolic concentrator as a second stage of a solar concentrator. - N Yehezkel, J Appelbaum *(Fac of Eng, Tel-Aviv Univ, Tel-Aviv 69978, Israel),* A Yogev *(Weizmann Inst of Sci, Rehovot, Israel),* M Oron *(Soreq Nucl Center, Yavne, Israel).* Solar Energy 51(1) 45-51 (Jul 1993).

In this article, the losses due to reflection properties in a 3D compound parabolic concentrator (3D CPC) are calculated and the effect of these losses on the concentration is analyzed. The 3D CPC is used as a second stage in two configurations of a two-stage concentrator: (a) a parabolic dish as a first stage, and (b) a Cassegrainian as a first stage. The nonplanar rays play an important role in 3D CPC losses. Thus, a ray-tracing procedure is needed to evaluate the losses. In this study, a rigorous 3D ray tracing program was specially developed. The reflection losses and their effect on the concentration were determined from the reflection distribution derived by the developed ray-tracing program. As a result, the reflection losses were approximated by a simple empirical linear model useful in practical ranges of the 3D CPC acceptance angles and reflectivities. This model facilitates design and system optimization by analytical methods without resorting to a ray-tracing procedure. The approach presented in this article may be used to compare the performance of the two-system configurations, taking into account the 3D CPC losses.

11A963. Experimental and numerical study of heat transfer in a simulated collector for a solar dryer. - PH Oosthuizen and A Sheriff *(Heat Transfer Lab, Dept of Mech Eng, Queen's Univ, Kingston, ON, K7L 3N6, Canada).* Trans Can Soc Mech Eng 17(2) 145-160 (1993).

Indirect passive solar crop dryers have the potential to considerably reduce the losses that presently occur during drying of some crops in many parts of the "developing" world. The performance so far achieved with such dryers has, however, not proved to be very satisfactory. If this performance is to be improved it is necessary to have an accurate computer model of such dryers to assist in their design. An important element is any dryer model is an accurate equation for the convective heat transfer in the collector. To assist in the development of such an equation, an experimental and numerical study of the collector heat transfer has been undertaken. In the experimental study, the collector was simulated by a 1m long by 1m wide channel with a gap of 4 cm between the upper and lower surfaces. The lower surface of the channel consisted of an aluminium plate with an electrical heating element, simulating the solar heating, bonded to its lower surface. Air was blown through this channel at a measured rate and the temperature profiles at various points along the channel were measured using a shielded thermocouple probe. Local heat transfer rates were then determined from these measured temperature profiles. In the numerical study, the parabolic forms of the governing equations were solved by a forward-marching finite difference procedure.

11A964. Anisotropic sky radiance model based on narrow field of view measurements of shortwave radiance. - AP Brunger *(Solar Thermal Res Lab, Dept of Mech Eng, Univ of Waterloo, Waterloo, N2L 3G1, Canada)* and FC Hooper *(Dept of Mech Eng, Univ of Toronto, Toronto, M5S 1A4, Canada).* Solar Energy 51(1) 53-64 (Jul 1993).

A model for the average anisotropic sky radiance (or intensity) as a function of the position of the sun, the diffuse fraction κ, and the atmospheric clearness index κ_t are presented in this article. The complete range of sky conditions from clear to turbid to overcast is covered. Analysis of the observed data indicates that the model can be used to estimate instantaneous sky radiance values with a mean bias error of -11% and a root mean square error of 65% of the mean. The model is shown to account for 83% of the deterministic part of the variance of the instantaneous sky radiance measurements.

11A965. Geostatistical properties and modeling of random cloud patterns for real skies. - R Perez, R Seals, J Michalsky *(Atmos Sci Res center, SUNY, 100 Fuller Rd, Albany NY 12205),* P Ineichen *(Groupe Phys Appl, Univ of Geneva, Switzerland).* Solar Energy 51(1) 7-18 (Jul 1993).

A new model that synthesizes sky luminance distribution from routine irradiance measurements for all insolation conditions was recently presented by the authors. The model produces continuous sky luminance distribution patterns representative by specific insolation conditions from overcast to clear through partly cloudy. In this article we address the discontinuous aspects of skylight, created by "one of a kind" cloud patterns. We show that these patterns, which are superimposed on the continuous luminance distributions, have predictable physical characteristics that can be parameterized as a function of insolation conditions. We present a method for incorporating these random but predictable luminance effects as an option in the continuous skylight distribution model.

11A966. Blade-pitch-angle-controllable windmill simulator. - T Toumiya *(Dept of Elec Eng, Anan Col of Tech, 265 Aoki Minobayashi Anan-City, Tokushima Prefecture 774, Japan)*, T Sakakibara *(Dept of Elec and Electron Eng, Fac of Eng, Toyahashi Univ of Tech, 1-1 Kumosuzumegaoka Tenpaku-cho Toyohashi-city, Aichi-prefecture 770, Japan)*, T Suzuki *(Dept of Elec and Electron Eng, Fac of Eng, Univ of Tokushima, 2-1 Minamijosanjima, Tokushima-city 770, Japan)*. Int J Energy Res 17(2) 89-104 (Mar 1993).

The paper describes the development of a windmill simulator, to simulate accurately the movement of a windmill. The simulator has a model to facilitate the change of windmill parameters, such as power coefficient or moment of inertia, by overcoming the weak points in the research and development environment for wind utilization, especially with the purpose of improving methods of windmill speed control or output. Also, to determine further the dynamic characteristics of the windmill speed with great accuracy, the simulator has a motor model to compensate for the slow response of the DC motor itself. The simulator is mainly composed of a separately-excited DC motor to directly simulate the movement of the windmill, a high-output DC amplifier to drive the motor, and a personal computer for control. It is ascertained that the developed simulator can fully reproduce the stationary and dynamic characteristics of a windmill from the experimental results. Also, a method is described to control the blade pitch angle to keep a windmill rotational speed constant. The results of the numerical simulation agree with the characteristics of the windmill simulator, and the effectiveness of the blade pitch angle control of the simulator is also affirmed.

11A967. Novel wind-diesel-battery hybrid energy system. - CV Nayar *(Power Electron Res Univ, Sch of Elec & Comput Eng, Curtin Univ of Tech, Perth, W Australia)*, SJ Phillips, WL James, TL Pryor, D Remmer *(Energy Res Inst, Murdoch Univ, S St, Murdoch, W Australia)*. Solar Energy **51**(1) 65-78 (Jul 1993).

In most of the remote areas of Australia and in many other parts of the world, diesel generators are used to provide electrical power. Such systems are often characterized by either poor efficiency and high maintenance costs because of prolonged operation at low load levels, or intermittent power because the unit is only run during period of significant load. The addition of a battery bank and a power conditioner to produce a diesel-battery-inverter hybrid system has been identified as producing a number of benefits. Such systems can be broadly classified according to their configuration as series, switched, or parallel hybrid systems. A new parallel hybrid energy system developed in W Australia is described in this article. The heart of the system is a high quality sinewave inverter which can also be operated in reverse as a battery charger. The system can cope with loads ranging from zero (inverter only operation) to approximately three times the generator capacity (inverter and diesel operating in parallel) with excellent efficiency. The system is fully automatic, provides continuous power, and can readily incorporate input from wind or photovoltaic systems. This article also includes a description of 5 kW wind generator charging a battery bank as part of the hybrid system, and an economic analysis indicates a favorable result for this hybrid system with payback period estimated to be the order of three years.

11A968. Analytical and experimental investigation of thermal stratification in storage tanks. - NM Al-Najem, AM AL-Marafie, KY Ezuddin *(Dept of Mech Eng, Kuwait Univ, PO Box 5969, SAFAT 13060, Kuwait)*. Int J Energy Res 17(2) 77-88 (Mar 1993).

An analytical and experimental investigation of transient turbulent 2D charging and discharging of a sensible heat storage tank has been conducted. Parametric studies showed that the turbulent mixing factor due to hydrodynamic disturbances at the inlet ports is the most significant item in the performance of thermal stratification storage tanks. Furthermore, the effect of the aspect ratio and convection at the walls in promoting stratification have been studied. Comparison with experimental data showed the capability of the present analytic approach to accommodate, with a satisfactory degree of accuracy, such problems.

11A969. Degradation of a stratified thermocline in a solar storage tank. - NM Al-Najem *(Dept of Mech Eng, Kuwait Univ, PO Box 5969, SAFAT 13060, Kuwait)*. Int J Energy Res 17(3) 183-191 (Apr 1993).

The thermal stratification behavior in a solar storage tank is simulated and analyzed using a theoretical model based on an integral transform technique. A comparison with available experimental and theoretical data is used to validate present theoretical results. The accuracy of the model in simulating the thermal behavior of stratification is reasonably good, especially when consideration is given to the complexity of the physical mechanisms involved, and the relative simplicity of the model. The effect of the heat loss parameter is investigated and it is found that initially it is strongly spatially and temporally dependent. Therefore, a functional form that accurately represents the heat loss parameter is needed for closer agreement with experimental results. However, after a relatively long time, the assumption of a constant heat loss parameter is adequate to produce acceptable predictions.

11A970. Disagreements between gradient-diffusion and Lagrangian stochastic dispersion models, even for sources near the ground. - CJ Mooney and JD Wilson *(Univ of Alberta, Edmonton, AB, T6G 2H4, Canada)*. Boundary-Layer Meteorol **64**(3) 291-296 (Apr 1993).

It is well known that if turbulent mass convection is modeled as diffusion, errors result unless trajectories from the source (at h) to the point of observation (z_p) comprise many statistically-independent segments (Taylor, 1921). We show that this is not guaranteed merely by the Lagrangian timescale (τ) at the source being small (eg, source at ground), but that a better criterion is $t \gg \max[\tau(h), \tau(z_p)]$, where t is a typical travel time to z_p.

11A971. Mathematical model for the hydrodynamics and pollutants transport in long and narrow tidal rivers. - V Nassehi and JH Bikangaga *(Dept of Chem Eng, Univ of Tech, Loughborough, Leicestershire LE11 3TU, UK)*. Appl Math Model 17(8) 415-422 (Aug 1993).

This paper deals with the application of the Taylor-Galerkin FEM to the simulation of the tidal dynamics and transport of chemically reactive pollutants in a branching river-estuary system. The adopted mathematical technique is fully described and the derivation of the working equations of the scheme is outlined. To validate the model two case studies, namely, tidal dynamics and salt intrusion in Upper Milford Haven (Wales, UK) and heavy metal dispersion in the Fal estuary (Cornwall, UK) are reported. Results of the model simulation in both cases are in good agreement with the field observations.

11A972. Probability distributions of concentration fluctuations of a weakly diffusive passive plume in a turbulent boundary layer. - E Yee *(Defense Res Est Suffield, Box 4000, Medicine Hat,, AB, T1A 8K6, Canada)*, DJ Wilson, BW Zelt *(Dept of Mech Eng, Univ of Alberta, Edmonton, AB, T6G 2G8, Canada)*. Boundary-Layer Meteorol **64**(4) 321-354 (Jun 1993).

Results are presented from an experimental investigation of turbulent dispersion of a saline plume of large Schmidt number (Sc = 830) in a turbulent boundary-layer shear flow simulated in a laboratory water channel. The dispersion measurements are obtained in a neutrally buoyant plume from an elevated point source over a range of downstream distances where both plume meandering and fine-structure variations in the instantaneous plume are important. High-resolution measurements of the scalar fluctuations in the plume are made with a rake of conductivity probes from which probability distributions of concentration at various points throughout the plume are extracted from the time series.

11A973. Anisotropic, transversely isotropic nonlinear viscosity of rock ice and rheological parameters inferred from homogenization. - L Lliboutry *(Lab de Glaciologie et Geophys del l'Env, CNRS, BP 96, 38402 St-Martin d'Heres, France)*. Int J Plasticity 9(5) 619-632 (1993).

The stress-strain relations for an anisotropic, incompressible viscous body that is orthotropic, transversely isotropic, are drawn from symmetry considerations. This kind of material forms the largest part of polar ice sheets. The 10 parameters entering the rheological law would be extremely difficult to draw from torsion-compression tests, the only ones that are feasible on ice cores. Nevertheless, homogenization allows to infer them from the statistical distribution of the c-axes and only two parameters that are accessible by readily analyzed pure shear tests. Homogenization is done assuming for any crystal embedded in rock ice a rheology that differs from the onset of isolated monocrystals and microscopic stresses at the crystal level equal to the macroscopic stress. Both assumptions are argued, in the light of experimental evidence about a single system of active slip planes, very low dislocation velocities, pile-ups at the grain boundaries, and boundary migrations during strain. These migrations destroy the pile-ups, besides allowing the strains in neighbor crystals to be different.

IX. BIOENGINEERING

550. Biomechanics

11A974. **Mineral-organic interfacial bonding and the mechanical properties of cortical bone tissue.** - WR Walsh *(Biomech Lab, Dept of Orthopaedics, Brown Univ Sch of Med, Providence RI 02912)* and N Guzelsu *(Univ of Med and Dentistry, SOM Biomech & Rutgers Univ, 675 Hoes La, Piscataway NJ 08854)*. Biomimetics 1(3) 199-218 (Sept 1992).

Interfacial bonding between the mineral fibers (a hydroxyapatite-like material) and the organic constituents of bone (collagen and noncollagenous proteins) plays an important role in determining strength and stiffness. This bonding arises, in part, through the strong adsorption affinity between the mineral and the organic phase of bone. Phosphate and fluoride ions can alter the mineral-organic interfacial bonding, causing a dramatic reduction in the mechanical properties. The present study reveals that the phosphate ion effect is reversible when phosphate ions are removed from the equilibrium buffer. The fluoride ion effect is irreversible and the mechanical properties are permanently altered. Mineral-organic interactions in bone may serve as a guide to develop man-made materials based on similar interactions.

11A975. **Boundary layer development of pulsatile blood flow in a tapered vessel.** - Ren-jing Cen and Chan Qin *(S China Univ of Tech, Guangzhou, China)*. Appl Math Mech 14(4) 319-326 (Apr 1993).

Assuming that the tapered angle is small, the problems of developing flow under unsteady oscillatory condition are studied in this paper. The formula of velocity distribution is obtained. The analyses for the results show that the blood flow in a converging tapered vessel remains a developing flow throughout the length, and the effects of tapered angle on the developing flow are increased with the increment of the tapered angle.

11A976. **Effects of body force on the pulsating blood flow in arteries.** - K Haldar *(Electron Univ, Indian Stat Inst, Calcutta, India)* and SN Ghosh *(Dept of Math, Manbhum Mahavidyalaya, Manbazar, India)*. Eng Trans 41(2) 157-166 (1993).

The present investigation deals with the study of pulsating blood flow in single arteries in the presence of body force which usually arises unintentionally during travel in a road vehicle, an aircraft or a spacecraft. A blood vessel considered here is assumed to be rigid. The resulting equation which governs the flow field in the tube is 1D and it is solved using the Fourier analysis. The results obtained in this analysis are the expressions for the local energy dissipation and the amplitude coefficients of mean velocity and wall shear stress. The numerical solutions of these results are shown graphically for better understanding of the problem.

ANNOUNCEMENT

Fifth Conference on Nonlinear Vibrations, Stability, and Dynamics of Structures

June 12-16, 1994

Virginia Polytechnic Institute and State University
Blacksburg, Virginia

GENERAL INFORMATION

The scope of the conference includes

1. Multibody dynamics,
2. Dynamics of composite structures,
3. Adaptive structures,
4. Fluid/structure interactions,
5. Parametric vibrations: single- and multi-frequency excitations of single- and multi-degree-of-freedom systems,
6. Computational techniques: efficient algorithms, use of symbolic manipulators, integration of symbolic manipulation and numerical methods, and use of parallel processors,
7. Experimental methods: benchmark experiments, measurements in hostile environments, and instrumentation techniques,
8. Influence of nonlinearities on control systems, and
9. Identification of nonlinear systems.

Authors will have the option of having their full-length papers considered for publication in *NONLINEAR DYNAMICS*.

The deadline for two-page abstracts is January 15, 1994
The deadline for full-length papers is April 1, 1994.

applied mechanics reviews

AIMS

The primary aim of *AMR* is to serve engineering scientists worldwide by assessing, reviewing, and reporting on advances in a broad range of mechanical engineering sciences. To this end *AMR* publishes (i) state-of-the-art review articles, bibliographic surveys, reviews with a special focus on emerging technology, tutorials, historical perspectives, periodic summaries of trends and advances; (ii) critical reviews of books, software, and databases; (iii) indexed compilations of carefully selected abstracts from high quality research journals; (iv) book-length monographs and symposium proceedings as special issues or supplements; and (v) editorials, announcements, and letters-to-the-editor.

A secondary aim of *AMR* is to serve technical and reference librarians, information specialists, professional engineers, and college professors through reliable, comprehensive, and timely information about all types of books within its subject scope. The annual cumulative index issue of *AMR* together with its monthly classified listings of abstracts is in effect a comprehensive bibliography of the mechanical engineering sciences, including essentially every article in some 50-60 core journals; this core includes all ASME Transaction journals.

SCOPE

The scope of *AMR* encompasses all the engineering sciences represented in the journals and symposia sponsored by the American Society of Mechanical Engineers and is outlined by *AMR*'s Subject Classification Scheme, which is reprinted on the back cover. It includes basic discipline-oriented areas such as dynamics, continuum mechanics, solid and fluid mechanics, structures, heat transfer, tribology, geomechanics, and biomechanics, as well as cross-disciplinary subjects and emerging critical technological areas such as new numerical and computational techniques, systems control technology, engineering design tools, manufacturing technology, materials and energy technology, and environmental engineering.

The American Society of Mechanical Engineers

INFORMATION FOR AUTHORS OF REVIEW ARTICLES

(1) Prospective authors are strongly urged to communicate with one of the Associate Editors or the Editor-in-Chief, Professor Arthur W Leissa, Department of Engineering Mechanics, Ohio State University, 155 W Woodruff Ave, Columbus, Ohio 43210 (TEL 614-457-4337 or 614-292-2680) before submitting an article, and to furnish a one-page outline of the proposed article and information as to its type, audience, and probable length. A form, *Prospectus for a Review Article,* is available for this purpose. Refer to the editorials in the January 1985 and March 1991 issues of *AMR* and the box at left for further discussion of *AMR*'s editorial criteria.

(2) *Submit four clean copies* of the manuscript to one of the Associate Editors or to the Editor-in-Chief. (Hold all separate original artwork until the article has been accepted.) All articles will be reviewed critically by at least two independent and anonymous referees chosen by the editor involved. This procedure will be followed even if the article is the result of solicitation or encouragement by the editors, or if the author is also an *AMR* editor. The final decision on publication is made by the Editor-in-Chief upon recommendation of an Associate Editor. If appropriate, the article will carry a footnote saying "Transmitted by Associate Editor . . ."

(3) Submission of a manuscript is a representation that it has not been published previously nor is currently being submitted for publication elsewhere. The authors will be asked to sign a statement *transferring copyright to ASME.* It is the author's responsibility to obtain permission to copy material from other sources, if needed.

(4) There are *no page charges* in *AMR* and no numerical length limitations. The length of the article should be appropriate to the subject and the audience. It is certainly one factor that will be evaluated by the editors and their referees, who may recommend changes (30-120 manuscript pages is typical). Each author of a review article will receive *a year's free subscription to AMR.* After publication the author will receive *100 free reprints* (to be shared if there are more than one author). In addition, ASME will distribute reprints singly and in bulk.

(5) Along with the final *manuscript* send the *compuscript on diskette,* if available, (with format identified) incorporating all corrections and additions, and with the tables and figure captions *in place within the text.* If the figures are computer graphics, place them also within the compuscript where they belong. Also, send a head-and-shoulders *photograph and short biographical sketch* (100-200 words) of each author, including grades of ASME membership, if any; include the bio at the end of the compuscript.

(6) *Order of parts:* Title of article, authors' names, authors' institutional affiliations, abstract (200-300 words suitable for abstracting services), table of contents (only if the article is so long that it needs one), list of symbols and abbreviations (if necessary), main text incorporating tables (each starting with a caption) and figure captions (in place where you want them in the text), list of references, biographical sketch, and original figures (if computer graphics, place in text above captions).

(7) *Format:* (a) Paper size: A4 or 8.5×11 inch (220×280 mm). (b) Word processor settings: One column of width 3.4 in (87 mm) leaving rest of page for referee and editorial comments; Type size 10 point (72 point = 6 pica = 1 inch = 25.4 mm) Times Roman or similar proportionally spaced style; Line spacing 12 points. These as-printed *AMR* specifications will help to insure that equations, tables, and figures are properly designed for the available space. (c) Use metric SI units; with other units in parentheses, if appropriate. (d) Cite references by last name and year; reference list at end alphabetical by author (in 7-point type). (e) Number figures with arabic numerals; design figures for column width (83 mm or 3.1 in), if possible; they should be professionally drawn or computer generated with lettering of consistent size (not smaller than the printed text after reduction); use your wordprocessor to place an empty box of the correct dimensions (or the figure itself, if a computer graphic) in the text above each figure caption. (f) Number tables with roman numerals. (g) Latin letters used as math symbols should be in italics both in text and in displayed equations. Subscripts and superscripts should be 7 point type. Fractional powers are preferred to root signs, exp(..) to $e^{\cdot\cdot}$, and a solidus (/) for fractions, if that will save vertical space.

(8) *Camera-ready copy:* Typeset (or near-typeset) quality pages or galleys generated by the author (after review and acceptance) are preferred, and could result in faster publication. Reproduce the format of published *AMR* review articles (basically, two of the columns defined above per page). Camera-ready pages along with a diskette (for DOS) is requested. Microsoft Word is suggested. Questions on this should be directed to the Production Editor at 201-882-1170, ext 232.

SPECIAL ISSUES: From time to time Guest Editors are invited to produce Special Issues consisting of three or more articles grouped around a common theme. SUPPLEMENTS are booklength monographs or symposium proceedings published as part 2 of a regular issue. Proposals for Special Issues or Supplements are very welcome. Guest Editorials, Letters-to-the-Editor, Announcements: Contact the Editor-in-Chief.

INTRODUCTION

The Third Pan American Congress of Applied Mechanics (PACAM III) was held at the *Escola Politécnica da Universidade de São Paulo*, in the city of São Paulo, Brazil, during January 4-8, 1993.

The PACAM congresses are sponsored by the American Academy of Mechanics (AAM) and are held every other year, during the first week of January, in one of the countries of the Americas. The objective of each congress is to promote technical interactions between research engineers, scientists, and graduate students.

The organizing and editorial committees of PACAM III accepted nearly 200 short papers from South America, North America, Europe, Africa, and Asia. These four-page papers appear in a 774-page proceedings of the congress, which was printed in Brazil.

This special supplement of *Applied Mechanics Reviews*, edited by the chairman of PACAM III and by the chairman of the local arrangements committee for the congress, contains the extended version of a number of the papers that were presented at PACAM III. These papers were selected by several reviewers who attended the congress.

We gratefully acknowledge the support received from the *Escola Politécnica da Universidade de São Paulo,* Rensselaer Polytechnic Institute, FAPESP (*Fundação de Amparo à Pesquisa do Estado de São Paulo)*, and the National Science Foundation.

The Fourth Pan American Congress of Applied Mechanics (PACAM IV) will be held in Buenos Aires, Argentina, in January 1995.

Theoretical and experimental study on nonlinear response of a rotor blade to a gust

DM Tang and EH Dowell

Department of Mechanical Engineering and Materials Science
Duke University, Durham NC 27706

A rotating slotted cylinder (RSC) gust generator installed in the Duke University low speed wind tunnel was used to generate a gust excitation field and the nonlinear response of a flexible rotor blade to gust excitations was studied theoretically and experimentally. The quantitative agreement between theory and experiment indicates that the assumption of an uniform chordwise gust angle of attack and an approximate solution procedure of the nonlinear equations proposed are allowable for the parameter range considered in this study. For a periodic gust flow field, the effects of geometric structural nonlinearity and aerodynamic nonlinearity on dynamic aeroelastic behavior are significant and lead to aperiodic or chaotic motion when stall occurs.

INTRODUCTION

From an earlier theoretical study of a linear rotor blade structure with a nonlinear aerodynamic model in forward flight, it was found that chaotic or aperiodic responses exist when the parameters of the rotor blade are near the flutter boundary or stall occurs, see Ref.[1]. Subsequent theoretical and experimental studies were conducted for a non-rotating rotor blade with a parabolic or a freeplay pitch stiffness nonlinear element, and using a linear or nonlinear aerodynamic model to determine limit cycle flutter, chaotic stall response and the influence of the initial conditions on response behavior. The experimental results from the wind tunnel test were compared to the theoretical prediction and the agreement was good, see Ref.[2] and [3] which considered a rigid, hinged (articulated) rotor blade. Ref.[4] extended the above studies to a flexible, hingeless (cantilevered) blade with geometric structural nonlinearity included in the analysis and experiment. The nonlinear static deflections, limit cycle flutter oscillation and stall chaotic responses were determined theoretically and experimentally.

The foregoing works considered an external excitation, such as a cyclic pitch control input from a swashplate of the helicopter, or a base harmonic excitation in the pitch and/or chordwise direction at the blade root, in addition to the self-induced aerodynamic forces. The purpose of the present paper is to study the forced response of a non-rotating flexible rotor blade due to an aerodynamic gust without any other external excitation sources. In order to evaluate the results obtained from the present analytical prediction, a gust response experiment with a rotating slotted cylinder (RSC) gust generator has been carried out in the Duke University low speed wind tunnel. The development of the experimental apparatus as well as the associated measurement technique for gust angle and flow field charecteristics are discussed in Ref.[5].

The study of helicopter gust response is important because of the normal conditions for helicopter operation and the successful application of advanced hub designs. Helicopters with hingeless and bearingless rotors are often more sensitive to gusts than articulated rotors. For a helicopter fitted with a wing (e.g. compound configurations), additional gust loads may be generated. These configurations require the accurate determination of rotor blade gust response for both handling qualities and structural loads design.

Linear theoretical gust response calculations and wind tunnel tests of helicopter rotors have been considered by several authors Ref.[6-10]. In this paper fundamental research on nonlinear response to a sinusoidal gust, or a periodic gust with two harmonic frequency components, or a linear frequency sweep gust excitation is described. In the present analysis, both the linear response below stall and nonlinear stall response through the stall angle of attack are described based on the Sears aerodynamic solution [11] and also the nonlinear ONERA aerodynamic model [12]. A comparison between the theoretical and experimental results has been made. The results may be helpful in understanding physically the nonlinear aeroelasticity phenomena.

In this paper, two major issues are discussed. One is the theoretical prediction of the unstalled and stalled gust response. An approximate solution procedure and numerical examples are included. Another issue is the comparison of theory and experiment for a cantilevered blade model with geometric structural nonlinearity. Results from the wind tunnel tests show generally good agreement with theory.

Appl Mech Rev vol 46, no 11, part 2, November 1993

NUMERICAL ANALYSIS

Equations of motion

The present study is based upon a consistently derived system of equations of motion for an elastic hingeless blade model under a sinusoidal gust excition for a non-rotating blade which is cantilevered vertically as shown in Fig.1. v, w and ϕ are the chordwise, flapping bending deflections and twist about deformed elastic axis, respectively. According to the Hodges-Dowell equations [13], for a non-rotating uniform, untwisted elastic blade, neglecting cross-section warping, the equations of motion may be written as

$$EI_2 v'''' + \beta(\phi w'')'' + m\ddot{v} + v_{mg} = \frac{dF_v}{dx} \quad (1)$$

$$EI_1 w'''' + \beta(\phi v'')'' + m\ddot{w} + me\ddot{\phi} + w_{mg} = \frac{dF_w}{dx} \quad (2)$$

$$-GJ\phi'' + \beta w'' v'' + mK_m^2\ddot{\phi} + me\ddot{w} + M_k = \frac{dM_x}{dx} \quad (3)$$

where $\beta = E(I_2 - I_1)$. Note that in Eq.[1]-[3] only the most important geometric structural nonlinear terms, $(\phi w'')''$, $(\phi v'')''$ and $w''v''$ are retained from the Hodges-Dowell equations and the third and higher order geometrically nonlinear terms are neglected here. Also note that ϕ is measured with respect to the deformed elastic axis. For the blade structure with a pitch spring at the root, the torsional motion, ϕ, includes elastic torsional deformation along the blade span and pitch motion at the blade root.

The restoring stiffness terms v_{mg} , w_{mg} and M_k may be deduced by variational methods.

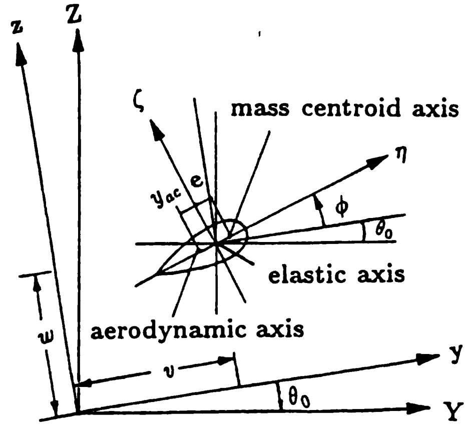

FIG 1. Deflection geometry of a flexible rotor blade

In Eq.(1)-(3), the components of the aerodynamic forces, dF_v, dF_w, and the aerodynamic moment about the elastic axis, dM_x, are obtained from the two-dimensional incompressible strip theory.

For determination of the aerodynamic lift, drag and pitching moment coefficients, C_l, C_d and C_m, in this theory, an ONERA aerodynamic stall model is used. The ONERA model is semi-empirically derived using measured wind tunnel data for an oscillating airfoil in conjunction with a parameter identification scheme as shown in Ref.[12].

For the ONERA aerodynamic stall model, the lift, drag and moment coefficients of each blade section in the differential equations are described in terms of a reduced time. This time scale is not convenient for the dynamic analysis of the blade, however. A more conventional differential operator relative to the real time, d/dt, is used in this paper for comparison with the experimental data.

The ONERA dynamic stall model is based on a blade airfoil element. Here, it is applied to a blade motion problem. A simple assumption is that the blade is divided into several spanwise aerodynamic sections, say NN, and the ONERA model is applied to each section.

When we use the ONERA model, a key consideration is how to express the gust angle of attack for an airfoil entering a sinusoial gust field. A general expression of the effective gust angle of attack, see Ref.[11], pp. 410, is

$$\alpha(t, \bar{y}) = \alpha_{G0}\sin(\omega t - k\bar{y}). \quad (4)$$

where $\bar{y}$ is the nondimensional streamwise coordinate fixed on the airfoil, with the origin $\bar{y} = 0$ located at the mid-chord point. k is the reduced frequency. Now recall that the lift acting on an airfoil at small angles of attack (linear regime) can be expressed as the Sears solution

$$L = \pi\rho c U^2 \alpha_{G0} e^{i\omega t}\phi_S(k), \quad (5)$$

where $\phi_S(k)$ is a Sears function.

In this paper, we assume that the chordwise distribution of the gust velocity may be regarded as constant at any instant of time and equal to the gust at the mid-chord point. The effective angle of attack is thus

$$\alpha(t) = \alpha_{G0}\sin\omega t \quad (6)$$

This assumption is valid for the conditions of the experiments described in this paper. For some helicopter applications, this assumption may need to be overcome by generalizing the present analysis.

The results of numerical simulations indicate that the assumption of an uniform chordwise gust effective angle of attack in the linear ONERA model is in good quantitative agreement with the Sears solution for a convecting gust field at small gust angles, ($\alpha_{G0} < 6^0$) and small reduced frequency k ($k < 0.3$). However, for the nonlinear (stall) ONERA model, the constant chordwise gust distribution assumption has not been verified independently, except through the subsequent comparison between theory and experiment for blade response.

Several periodic gust time histories are considered subsequently including the following:

(1) Continuous sinusoidal gust

$$w_G(t) = w_{G0}\sin\omega t \quad (7)$$

(2) Continuous periodic gust

$$w_G(t) = w_{G01}\sin\omega t + w_{G02}\sin(2\omega t + \epsilon) \quad (8)$$

(3) Continuous frequency sweep gust

$$w_G(t) = w_{G0}\sin(\omega_1 + \frac{\omega_2 - \omega_1}{2T}t)t \quad (9)$$

where ω_1, ω_2 and T are the minimum frequency, maximum frequency, and the sweep duration (in seconds).
An effective angle of attack component , α_G, due to the gust can be represented as

$$\alpha_G(t) = \frac{w_G(t)}{U}. \tag{10}$$

In Eq.(1)-(3), expansions in general mode shape functions are used to obtain ordinary differential equations in terms of generalized modal co-ordinates. They are expressed in series form as follows.

$$\bar{v} = \sum_{j=1}^{N} V_j(t)\psi_j(\bar{x}), \tag{11}$$

$$\bar{w} = \sum_{j=1}^{N} W_j(t)\psi_j(\bar{x}),$$

$$\phi = \sum_{j=1}^{N} \Phi_j(t)\Theta_j(\bar{x}),$$

where $(\bar{\ })$ indicates non-dimensionalization of the spanwise coordinate with respect to the blade span, R, and, ψ_j and Θ_j are the characteristic functions for cantilevered beam bending and torsional vibrations, respectively.
Substituting these expansions into Eq.(1)-(3), and using the Galerkin method one obtains a set of nonlinear modal equations of motion.

Solution procedure

Unstalled gust response solution

For the unstalled gust response problem, the aerodynamic drag and pitching moment coefficients are explicit algebraic functions of the effective angle of attack, but the lift coefficient is described as a first order differential equation which also depends upon the position of aerodynamic element. There are NN degrees of freedom for the aerodynamic model.

A linearized perturbation procedure was used to solve the nonlinear equations. The static equilibrium equations are 3N nonlinear algebraic equations in the static equlibrium values, V_{0j},W_{0j} and Φ_{0j} which are solved by iteration using the Newton-Raphson method. In addition, there is a set of 6N+NN first order linear non-homogeneous perturbation differential equations in the small time dependent structural perturbation variables, ΔV_j,ΔW_j $\Delta\Phi_j$ and the lift coefficient perturbation veriables, $\Delta C_{l\gamma l}$. It is expressed as a matrix equation of first order by:

$$\begin{bmatrix} M_{jj} & M_{jl} \\ M_{lj} & M_{ll} \end{bmatrix} \begin{Bmatrix} \Delta\dot{q}_{a1} \\ \Delta\dot{q}_{a2} \end{Bmatrix} = \begin{bmatrix} K_{jj} & K_{jl} \\ K_{lj} & K_{ll} \end{bmatrix} \begin{Bmatrix} \Delta q_{a1} \\ \Delta q_{a2} \end{Bmatrix} + \begin{Bmatrix} F_{jd} \\ F_{ld} \end{Bmatrix} \alpha_G + \begin{Bmatrix} F_{jv} \\ F_{lv} \end{Bmatrix} \dot{\alpha}_G \tag{12}$$

where

$$\{\Delta q_{a1}\}^T = \lfloor ....\Delta\dot{V}_j, \Delta V_j, \Delta\dot{W}_j, \Delta W_j, \Delta\dot{\Phi}_j, \Delta\Phi_j .... \rfloor$$

$$\{\Delta q_{a2}\}^T = \lfloor ....\Delta C_{l\gamma l} .... \rfloor$$

For the solution using the Sears aerodynamic model, the perturbation equations are expressed as a set of 6N first order linear non-homogeneous differential equations by:

$$[M_s]\{\Delta\dot{q}_{a1}\} = [K_s]\{\Delta q_{a1}\} + \{F_s\}\phi_s(k)\alpha_G + \{F_v\}\dot{\alpha}_G \tag{13}$$

Stalled gust response solution

Stalled gust response can be determined by the following procedure. The structural model are second order, nonlinear differential equations in the variables, V_j, W_j and Φ_j, respectively. Two state variables are required for each jth variable. Thus 2x3xN structural state variables are required. For the ONERA aerodynamic model, a third order system for the lift coefficient and a second order system for both drag and pitch moment coefficients are required. Hence, seven state variables are required per aerodynamic section. The total number of state variables for the aeroelastic system is thus 6N+7NN.

The resulting system of the state variable equations is given by:

$$\begin{bmatrix} \hat{M}_{jj} & \hat{M}_{jl} \\ \hat{M}_{lj} & \hat{M}_{ll} \end{bmatrix} \begin{Bmatrix} \dot{q}_{bj} \\ \dot{q}_{bl} \end{Bmatrix} = \begin{bmatrix} \hat{K}_{jj} & \hat{K}_{jl} \\ \hat{K}_{lj} & \hat{K}_{ll} \end{bmatrix} \begin{Bmatrix} q_{bj} \\ q_{bl} \end{Bmatrix} + \begin{Bmatrix} \hat{F}_j \\ \hat{F}_l \end{Bmatrix} \tag{14}$$

where

$$\{q_{bj}\}^T = \left\{....\dot{V}_j, V_j, \dot{W}_j, W_j, \dot{\Phi}_j, \Phi_j ....\right\}^T,$$

$$\{q_{bl}\}^T = \left\{....\dot{C}_{lbl}, C_{lbl}, C_{l\gamma l}, \dot{C}_{dbl}, C_{dbll}, \dot{C}_{mbl}, C_{mbl}, ...\right\}^T.$$

Eq.(14) is a set of nonlinear differential equations. The solution of the equations can be obtained by numerical time integration. The section angle of attack ,α_l, and section inflow angle ,$\phi_{\lambda l}$, involve the state variables V_j, W_j and Φ_j. The initial values of α_l and $\phi_{\lambda l}$ are determined by the initial values of the state variables that then change during the numerical integration in a time step fashion.

The following calculation results are for the blade divided into 4 equal length spanwise strips. The blade section is a NACA 0012 airfoil. The static lift, drag and pitch moment coefficients are identified from the experimental data using curve fitting.

EXPERIMENT

An experiment for a flexible rotor blade responding to a gust was performed in the Duke University low speed, closed circuit wind tunnel as shown in Fig.2. The gust was created by placing a rotating slotted cylinder (RSC) behind a rigid, fixed airfoil upstream of the flexible blade. The gust generator configuration in the wind tunnel had two airfoils or vanes and two rotating sl[illegible]ers.

The distance between these vanes was 12 inches. For details of the gust generator design, see Ref.[5]. The flexible blade model configuration (Model II), parameters and measurement sensors were described in Ref.[4], and also see Table 1.

Strain gages were used for measurement of flap and elastic torsional deflections. An axial gauge (flap) for bending modes and a 45^0 gauge for torsional modes were glued to the flexible rotor blade spar to measure the bending-torsional deflections of the blade tip. Signals from the strain gages were conditioned and amplified before their measurement through a low-pass filter. A micro-accelerometer was installed at the tip of the blade for measuring the chordwise response. The pitch angular displacement at the blade root was measured by a rotational velocity/displacement transducer, RVDT. The output signals from these strain gauges and transducers were amplified and directly recorded on a Macintosh IIci computer through a data acquisition package, NB-MIO-16, which consisted of a 16-channel analog to digital (A/D) plug-in interface board, a BNC termination box, and data acquisition and analysis software, LabVIEW. The digitized response data could be graphically displayed either on-line or off-line as a time history, phase plane plot, FFT, PSD, or Poincare map. In order to obtain a comparison of the theory with the test, a measurement system calibration was completed before the wind tunnel test. The dynamic calibration coefficients were determined by a ground vibration test. The dynamic calibration assumed that there was no significant coupling between the bending and torsional directions. This is a reasonable assumption for the present test configuration.

The longitudinal gust velocity and gust angle were measured with two differential presure probes mounted on a cylinder which is located at the blade chord position with the blade temporarily removed. The distance between the blade chord and airfoil/RSC system was 7 inches. The blade was placed in the symmetrical plane of the tunnel. The gust flow field measurements were described in Ref.[5].

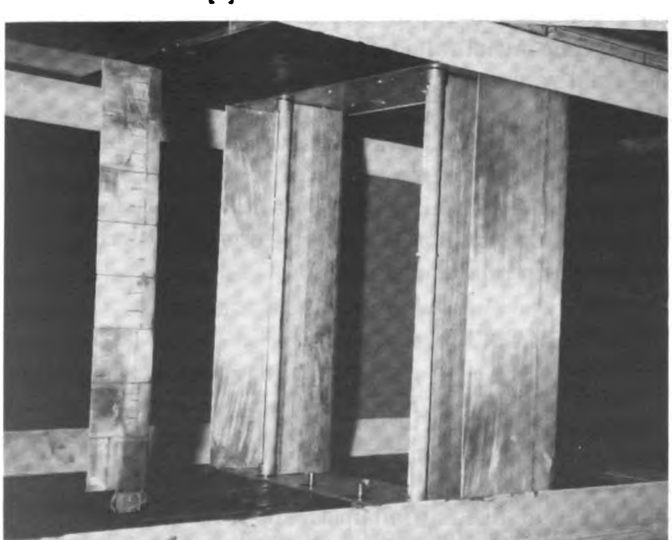

FIG 2. Photograph of experimental apparatus.

RESULTS AND DISCUSSIONS

In the next section, the response behavior of the blade to a single harmonic, a two harmonic or a continuous frequency sweep gust excitation is discussed. The ONERA stall aerodynamic model is used to calculate the gust response of this model for comparison with the experimental results. Two major issues are discussed here. One is the unstalled gust response, i.e. the initial pitch angle, θ_0, is 6^0. Another is the stalled gust response, i.e. $\theta_0 = 13^0$. The free stream velocity is U=15.6 m/s which is lower than the flutter critical speed ($U_{cr} = 24.4m/s$ for $\theta_0 = 13^0$) for the flexible blade model used here.

Single harmonic gust excitation

A typical measured gust angle (lateral gust wave) generated by the RSC gust generator is shown in Fig.3(a) for an airstream velocity of U=15.6 m/s, and cylinder rotation speed of $\omega_s = 5Hz$. The dominant gust frequency has been shown to be $2\omega_s$ [5]. A corresponding FFT plot is shown in Fig.3(b). The gust angle of the first harmonic frequency ($2\omega_s = 10Hz$) is 1.7^0, and the second harmonic ($4\omega_s = 20Hz$) is 0.16^0. A relatively pure tone lateral sinusoidal gust wave is obtained.

In the following, we will discuss unstalled and stalled response behavior for U=15.6m/s and $\alpha_G = 1.7^0$ as displayed in Fig.4-Fig.6. In those figures, (a) is for the theory and (b) for the test.

The theoretical calculations are based on Eq.(14). For unstalled gust response, the theoretical results indicate that the lift coefficient is linear vs the angle of attack. Flap, chord and pitch responses appear to be purely periodic with response primarily at the gust frequency. See Fig.4. The difference between the results for Type=0 (without geometric structural nonlinearity, i.e. $(\phi w'')''$, $(\phi v'')''$ and $w''v''$ in Eq.(1)-(3) are zero) and Type=1 (with geometric structural nonlinearity) is small except for the chordwise response. For Type=0 the chordwise response is much smaller than the one for Type=1. A typical theoretical flap response time history at the blade tip is shown in Fig.4(a) for $\theta_0 = 6^0$ and $\omega_s = 5Hz$. For a comparison, an experimental flap response is shown in Fig.4(b). The experimental results display a little more complex response for flap motion and more complex responses for chordwise and torsional motions than those of theory. This may be because the theoretical calculation did not include the longitudinal gust velocity. The quantitative agreement between theory and experiment is good for flap motion, and the agreement at the the fundamental frequency component ($2\omega_s = 10Hz$) is generally good for the chordwise and torsional motions. For brevity, the latter are not shown.

For stalled gust response, the theoretical results display aperiodic or chaotic behavior for $\theta_0 = 13^0$. This is because the aerodynamic forces are nonlinear functions of the angle of attack due to the airfoil motion arising from the gust. The phase plane plots of the lift, drag and pitch moment coefficients response vs α have substantial hys-

teresis and the hysteresis loops are irregular. Also the effects of geometric structural nonlinearity on the response are significant for flap, lag and twist. The PSD plots of the responses with comparison of the results for Type=0, and Type=1 show that in addition to a dominant excitation frequency component, $2\omega_s = 10Hz$, more harmonic components and broader frequency bandwidth exist in the results for Type=1. A typical theoretical phase plane plot of torsional responses at the blade tip for $\theta_0 = 13^0$ is shown in Fig.5(a) and the experimental result is shown in Fig.5(b). The experimental results display somewhat more complex behavior than the theoretical ones. From the PSD plots (not shown), it is found that the peaks of the PSD are not exactly located at the natural frequencies ($\omega_{x1} = 31.5Hz, \omega_{y1} = 23.5Hz$ and $\omega_{z1} = 10Hz$). The PSD peak frequencies are lower than these natural frequencies. This is because the aerodynamic forces affect the aeroelastic modal behavior of the blade.

When we reduce or relax the constraint condition at the support of the pitch spring in the experimental model, a lower torsional natural frequency may be obtained. It is $\omega_{x1} = 22Hz$ which is near the chordwise natural frequency. Fig.6 shows the PSD plots of torsional response at the blade tip for $\theta_0 = 13^0$, $\omega_s = 10.18Hz$ and U=10.7m/s. An obvious beating oscillation is found. The agreement between theory and experiment for this beating phenomenon is generally good, but the frequency difference and oscillation frequency do not correspond precisely. Given the quite complex response due to the nonlinear aeroelastic effects, the agreement between calculation and test is encouraging.

Two harmonic gust excitation

In order to study how the flexible rotor blade will respond to a more general periodic gust excitation, a continuous periodic gust with two-frequency excitation is considered here. The emphasis is on the effect of the second harmonic component on the gust response. The theoretical calculations are based on Eq.(14) and Eq.(8). The gust response behavior can be described in terms of following parameters: $\kappa_w, \kappa_v, \kappa_\phi, \kappa_{\epsilon w}, \kappa_{\epsilon v}, \kappa_{\epsilon\phi}$ and μ. $\kappa_w(\kappa_v, \kappa_\phi)$ is the gust response ratio of *rms* flap (lag, twist) response amplitude undergoing two harmonic gust excitation to that under only a fundamental harmonic excitation when the phase angle, $\epsilon = 0$. $\kappa_{\epsilon w}(\kappa_{\epsilon v}, \kappa_{\epsilon\phi})$ is the *rms* flap (lag, twist) amplitude ratio for varying phase angle, ϵ, in Eq.(8) for a certain α_{G01} and α_{G02}. μ is the gust angle ratio given by $\alpha_{G02}/\alpha_{G01}$. Theoretical results are shown in Fig.7 for $\theta_0 = 6.5^0, \omega = 14Hz$, U=10m/s , $\omega_{x1} = 17.8Hz$ and Type=1. Fig.7 shows κ_w vs μ for $\epsilon = 0$ and a fundamental frequency gust angle of $\alpha_{G01} = 1^0, 2^0, 3^0$. It is seen that for unstalled gust response, ($\alpha_{G01} = 1^0$), κ_w is greater than 1 as μ increases. The effect of the second harmonic of the gust excitation is to increase the response compared to that for only a fundamental harmonic excitation. This effect is often observed for linear systems. However, for stalled gust response, ($\alpha_{G01} = 3^0$), the effect of the second harmonic gust excitation is to decrease the response amplitude. The above conclusions are also true for κ_v and κ_ϕ vs μ for unstalled and stalled gust responses. This "quenching" of the response by added harmonic excitation is known to be possible in nonlinear systems, see Ref.[16]. This offers possibilities for the control of nonlinear systems with strong harmonic content by imposing oscillations at higher frequencies.

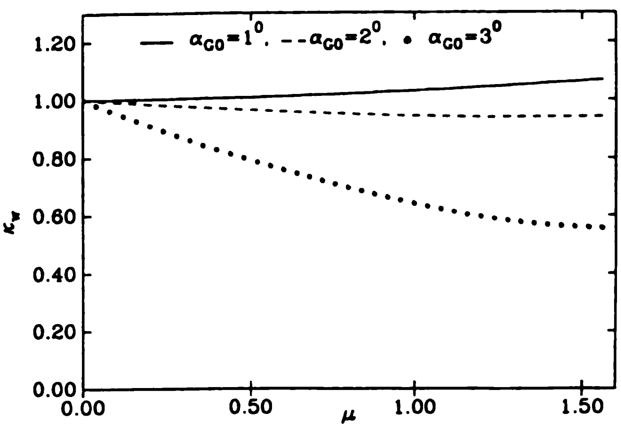

FIG 7. Gust response to two harmonic gust excitation for $\omega = 14Hz$, $\theta_0 = 6.5^0$, $\omega_{x1} = 17.8Hz$ and U=10 m/s: gust response ratio of *rms* flap response amplitude vs gust angle ratio.

More theoretical details are shown in Fig.8. Fig.8 displays the phase plane plots including a comparison with the results obtained from the single sinusoidal gust excitation (Fig.8(a)) for $\mu = 0.5, \epsilon = 0, \omega = 14Hz$ and $\alpha_{G01} = 3^0$, (stalled). The motion is aperiodic or chaotic as described above. In comparing Fig.8(a) and 8(b), it is seen that the effect of the second harmonic of the gust excitation is to decrease the response.

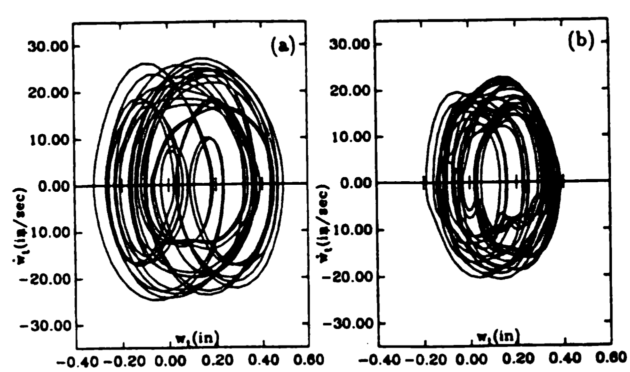

FIG 8(a)(b). Phase plane plot of flap response: (a) for single frequency gust excitation, (b) for two harmonic gust excitation.

In order to obtain experimentally a periodic gust with two harmonic frequency components (a fundamental frequency component plus a double frequency component) for a given motor speed, two distinct pulleys with different groove numbers (12 and 24) are fixed on the shaft end of the motor. A typical measured gust angle wave is shown in Fig.9(a) for an airstream velocity of U=15.6 m/s, and cylinder rotation speeds of $\omega_{s_1} = 3Hz$ and $\omega_{s_2} = 6Hz$. A corresponding FFT plot is shown in Fig.9(b). The gust angles of the first and second harmonic frequencies ($2\omega_{s_{1,2}} = 6Hz$ and $12Hz$) are .7^0 and 1.6^0, respectively . From this figure, the third frequency component ($\omega = 24Hz$) is also not small. Fig.10-11 show the phase plane plots and PSD plot of torsional responses at the blade tip for $\theta_0 = 13^0$. The response appears to be aperiodic or chaotic motion. For the w and v responses, the conclusion is the same. The quantitative agreement between theory and experiment at the dominant driving frequency, 12 Hz , is good as shown in the PSD plot of Fig.11. The experimental PSD has a broader frequency bandwidth. The experimental results are more complex than those of theory. This is because the experimental gust excitation includes more higher harmonic frequency components than the theoretical model as shown in Fig.9(b). In comparing Fig.10 and Fig.5, the response with two-frequency excitation is more chaotic than that with one-frequency excitation both for the theoretical and experimental results. The "quenching" phenomenon has not been found in the present tunnel test. This is because the required minimum first harmonic of the gust, α_{G0}, for generating "quenching" is 1.5^0 from theory, but the available experimental gust generator can only provide 0.7^0 as shown in Fig.9.

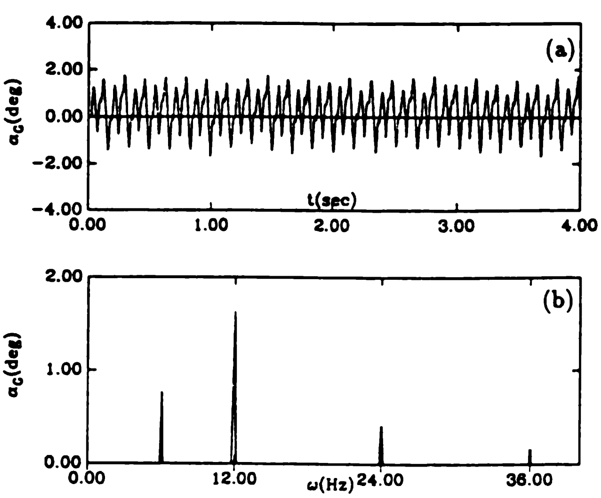

FIG 9(a)(b). Lateral gust of two harmonic gust excitation for $\omega_s = 3Hz$, U=15.6 m/s: (a) for time history, (b) for FFT.

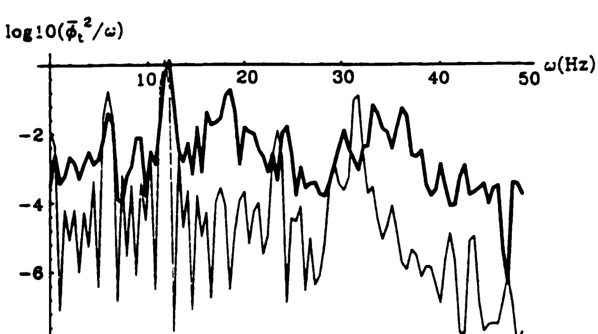

FIG 11. PSD plot of torsional response for two harmonic gust excitation, —, for theory, ▬, for test.

A continuous frequency sweep gust excitation

Theoretical calculations are based on Eq.(14) and (9). The gust excitation is continuous with a period T, i.e, the process is repeated using such a frequency sweep signal. The gust PSD is quite broad in the range of 0-50Hz. For unstalled gust response, the basic parameters of the frequency sweep are $\alpha_{G0} = .5^0, \omega_1 = 2Hz, \omega_2 = 50Hz$, $T = 4sec.$ and $\theta_0 = 6.5^0$, U=10m/sec. The motions are approximately periodic with period, T. A typical PSD plot of the theoretical flap response is shown in Fig.12. A comparison of the results for Type=0 (indicated by the thick solid line) and Type=1 (thin solid line) is also shown in this figure. For the response PSD, resonant behavior is very clear. As shown in Fig.12, there is no peak response at the chordwise natural frequency ($\omega_{y1} = 23.5Hz$) for Type=0, but there is for Type=1. For Type=0 we also find a large response at 5Hz which is equal to half the flap natural frequency. For the chordwise and torsional responses, the result is similar to Fig.12.

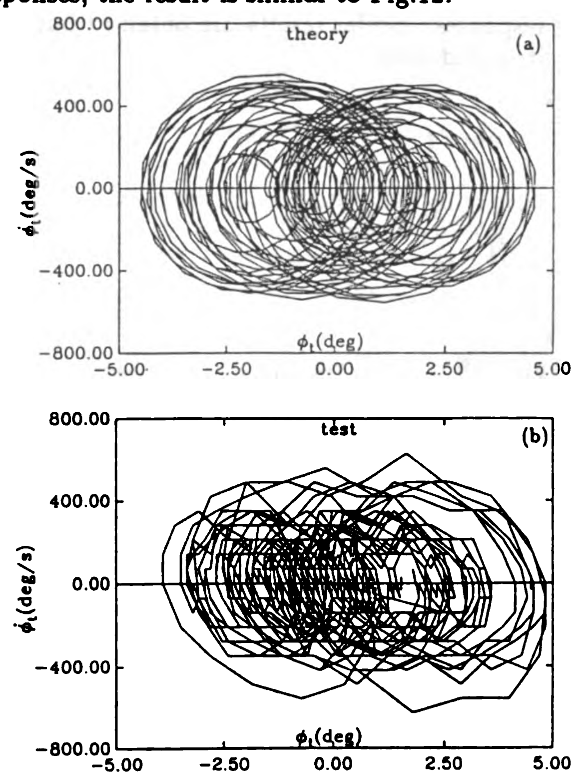

FIG 10(a)(b). Phase plane plot of torsional response for two harmonic gust excitation, $\omega_s = 3Hz$,$\theta_0 = 13^0$, and U=15.6 m/s: (a) theory, (b) test.

An experimental lateral gust wave generated by the linear frequency sweep RSC/airfoil system for an airstream velocity of $U = 10m/s$ and the cylinder rotation speed from 0 Hz to 20 Hz in 2.8 second is shown in Fig.15(a). A corresponding power spectra plot is shown in Fig.15(b) for an average over 200 sweep periods. It is noted that the measured lateral gust has about a 0.9 second time delay, i.e., the restarting time of the DC-motor for each repeated process. This is due to the rotational inertia of the DC-motor. The average angle of the linear frequency sweep gust is about 0.8^0.

Typical experimental results for the flap response of the blade model to this continuous frequency sweep gust excitation are shown in Fig.14-15 for $\theta_0 = 6.5^0$. The flap time history has two oscillation bursts in an approximate period for both the experiment and theory. This means that there are two dominant resonant frequency components, i.e., the flap and torsional components. These results are also found in the PSD plot as shown in Fig.15. In addition to the above components, there is a small peak at 23.5Hz which corresponds to the first lag natural frequency due to the structural nonlinearity. The theoretical results are also plotted in Fig.14(b) and Fig.15 for comparison. It is seen that the experimental PSD has a broader frequency bandwidth between the two peaks of the dominant frequency components. This is because the experimental background has random aerodynamic noise due to the shed vortex sheet behind the RSC/airfoil. The agreement between theory and experiment is reasonably good for the flap frequency component, but not as good for the torsional component (at 17.8Hz). For the torsional and lag responses, similar results are obtained but they are not presented here.

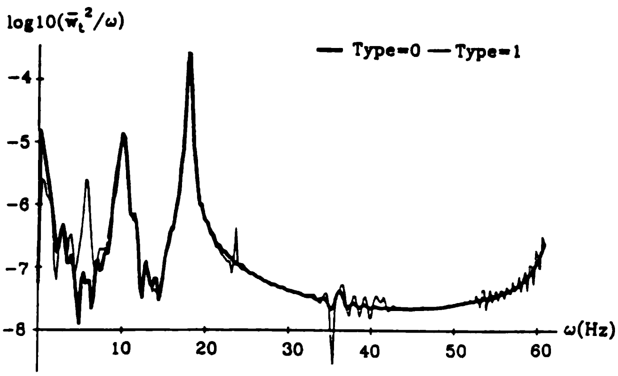

FIG 12. Theoretical PSD plot of flap response for frequency sweep gust excitation, $\theta_0 = 6.5^0$, $\omega_{x1} = 17.8Hz$, $\alpha_{G0} = .5^0$, T=4s and U=10 m/s.

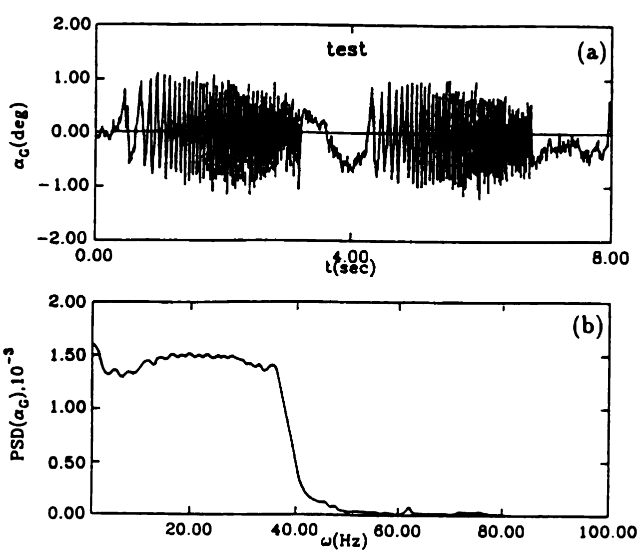

FIG 13(a)(b). Lateral gust of linear frequency sweep gust excitation for $\omega_s = 0 - 20Hz$, U=10 m/s: (a) for time history, (b) for PSD.

For stalled gust response, the basic parameters are $\alpha_{G0} = 1.5^0, \omega_1 = 2Hz, \omega_2 = 50Hz$, $T = 1sec.$ and $\theta_0 = 6.5^0$, U=10m/sec. The response is not repeated with a period, T, but appears chaotic over a long time history. This is because the angle of attack of the blade enters the stall range, and a more complex $C_z - \alpha$ hysteresis loops exists. Fig.16 shows the Poincare section map of the theoretical torsional response for an internal clock, i.e. at those times when $\dot{w}_t \equiv 0$. Over 3493 points for 100 seconds of time are shown. The diffuse nature of the Poincare points indicates the response is highly chaotic. For the chordwise and flap motions, similar maps are also found, see Ref.[15].

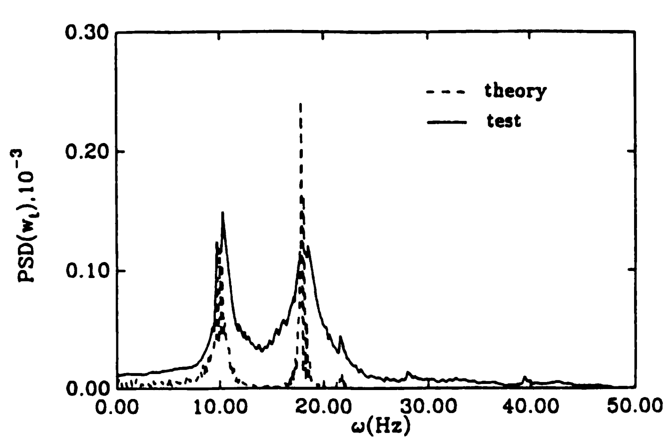

FIG 15. PSD plot of flap response for linear frequency sweep gust excitation, ––, for theory, —, for test.

CONCLUDING REMARKS

A theoretical and experimental study of the nonlinear response of a rotor blade to single and two harmonic, as well as a sweep frequency, gust excitation was made. The conclusions obtained are as follows:

1. The assumptions of a uniform chordwise gust angle of attack and a simple representation for lift forces in a gust flow field are allowable for the parameters of the present study.
2. The effects of geometric structural nonlinearity and aerodynamic nonlinearity on dynamic aeroelastic behavior are significant when stall occurs.
3. At a large pitch angle, the chordwise and twist responses display an aperiodic or possibly chaotic motion, and the flap response displays a more nearly periodic motion.
4. When this nonlinear system undergoes a two harmonic gust excitation, theory predicts a "quenching" phenomenon may occur for a certain combination of parameters. The effect of the second harmonic gust excitation is to decrease the response amplitude under these circumstances.
5. Generally good quantitative agreement between theory and experiment is obtained.

A quasistatic thermoelastoplastic analysis is given for the response of a traction-free plate subject to surface heating. The formulation incorporates temperature-induced phase changes which model experimentally obtained data for X22 CrMoV 12 1 stainless steel. The plate is discretized into layers, with material properties considered homogeneous within each layer. An incremental, iterative approach based upon Kirchhoff bending theory is employed to obtain an approximate solution to the problem. Numerical results illustrate the effects of phase transformations and temperature sensitivity of the material properties upon the transient and residual stress distributions.

INTRODUCTION

The thermal stresses in a free plate of elastoplastic material subject to surface heating were investigated first by Weiner (1956). Landau and Weiner (1958) extended this analysis to the determination of transient and residual stresses due to a temperature distribution which is an arbitrary function of time and of the thickness coordinate. Yuksel (1958) considered the case of a free elastoplastic plate with periodically varying surface temperature. In each of these investigations, all material properties were taken to be independent of temperaure. Later, Landau *et al* (1960) (see also Boley and Weiner, 1960) examined the transient and residual stresses in a viscoelastic-plastic plate having a temperature-dependent yield stress.

In addition to residual stresses which occur as a result of plastic flow during heating followed by elastic response during cooling, residual stresses also may develop if the material experiences phase transformation. In this paper, an investigation is made of the thermoelastoplastic response of a traction-free stainless steel plate, characterized by both temperature-sensitive Young's modulus and yield strength, and temperature-induced phase transformations. Phase change behavior is modeled after experimental data presented in the following section. Temperature and stress fields are determined for a plate which undergoes surface heating followed by convective cooling.

Appl Mech Rev vol 46, no 11, part 2, November 1993

MATERIAL BEHAVIOR

Whereas materials normally expand upon heating and contract during cooling, steel also undergoes phase transformations which alter its thermal expansion behavior over certain temperature ranges. An experimentally obtained plot (Reed, 1990) of longitudinal strain versus temperature for an unconstrained specimen of X22 stainless steel (X22 CrMoV 12 1) is shown in Fig. 1. The strain measurements were made using a quartz push-rod dilatometer.

Over a temperature range of approximately $813\ K<\theta<856\ K$, where θ denotes the rise in temperature from ambient (room) temperature, a phase change from martensite to austenite occurs. Temperature increases during this transformation period result in thermal contraction rather than expansion. Under subsequent cooling of the steel, a transformation from austenite back to martensite takes place. During this phase change, which begins at approximately $\theta = 262\ K$, the metal expands rather than contracts with decreasing temperature. The phase-transformation process is assumed here to be independent of time.

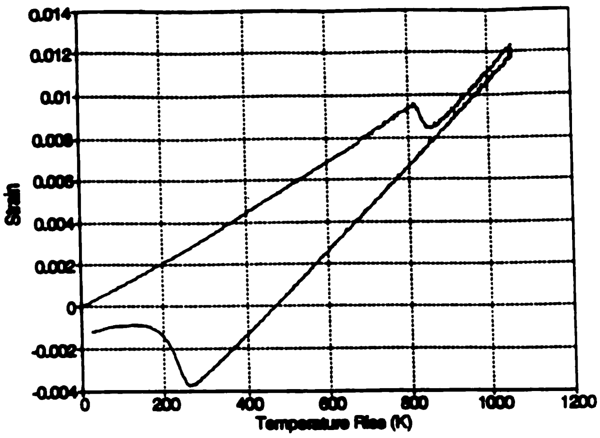

Fig. 1. Strain versus temperature curve for unconstrained specimen of X22 stainless steel.

For the purpose of the present analysis, the measured strain-temperature behavior described by Fig. 1 is represented by the piecewise linear approximation ABCDEF shown in Fig. 2. The slopes of the four line segments in this idealization represent the values of the coefficient of linear thermal expansion $\alpha(\theta)$ over the respective temperature ranges.

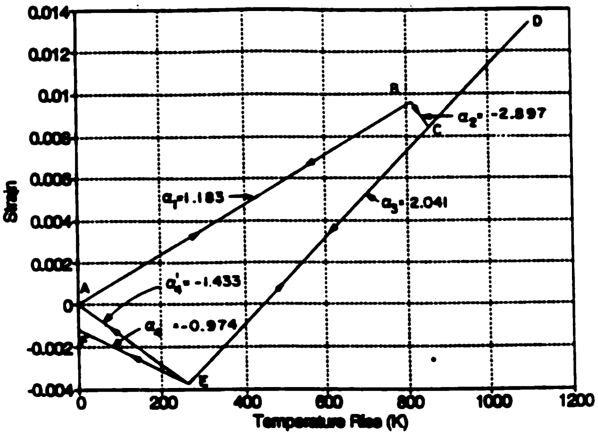

Fig. 2. Strain versus temperature curve used for the analysis (values of α given in 1/100K).

In addition to accounting for the influence of temperature on the thermal expansion coefficient, temperature-dependence of the material's elastic modulus and yield stress is included in this investigation. Other material properties are, however, assumed to be unaffected by temperature.

THEORETICAL ANALYSIS

Temperature Field

The plate under consideration (Fig. 3) is thermally insulated on its lower face (z=-h/2) and along its edges (x=0,a; y=0,b). During the time interval $0 < t < t_o$ there is uniform heat input q_o over the top face z=h/2, while thereafter this face is subject to convective cooling.

The temperature rise $\theta(z)$ in the plate is assumed to satisfy the Fourier heat conduction equation

$$\lambda \frac{\partial^2\theta}{\partial z^2} = \dot{\theta} \qquad (1)$$

in which $\theta = T - T_A$ is the temperature increase from an ambient, stress-free temperature T_A; $\lambda = k/\rho c$ is the thermal diffusivity, where k and ρc denote thermal conductivity and volumetric heat capacity, respectively.

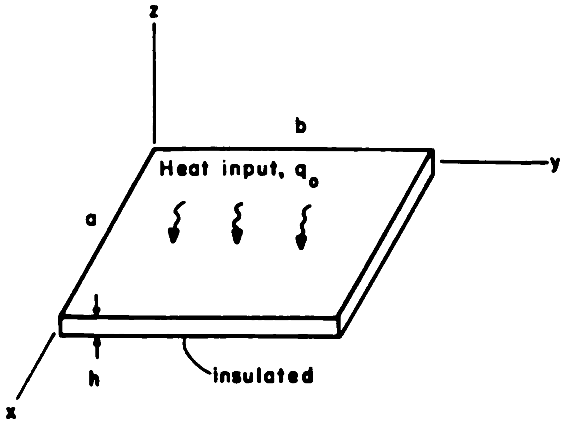

Fig. 3. Stainless steel plate.

The initial and boundary conditions for the problem are expressed mathematically as

$$\theta(z,0) = 0 \tag{2}$$

$$k\,\frac{\partial\theta(-h/2,t)}{\partial z} = 0 \qquad t>0 \tag{3}$$

$$k\,\frac{\partial\theta(h/2,t)}{\partial z} = -q_o \qquad 0<t<t_o \tag{4}$$

$$k\,\frac{\partial\theta(h/2,t)}{\partial z} = -H\,\theta(h/2,t) \qquad t>t_o \tag{5}$$

in which H is the boundary conductance at z=h/2.

The temperature distribution satisfying equations (1)-(5) is (Boley and Weiner, 1960)

$$t<t_o:\ \theta(z,t) = \frac{hq_o}{24k}\left[\frac{24\lambda t}{h^2} + 12\left(\frac{z}{h}\right)^2 + 12\left(\frac{z}{h}\right) - 1 - \frac{48}{\pi^2}\cdot \sum_{m=1}^{\infty}\frac{(-1)^m}{m^2}e^{\frac{-m^2\pi^2\lambda t}{h^2}}\cos m\pi\left(\frac{z}{h}+\frac{1}{2}\right)\right] \tag{6}$$

$$t>t_o:\ \theta(z,t) = \sum_{m=1}^{\infty} a_m e^{\frac{-\alpha_m^2\lambda(t-t_o)}{h^2}}\cdot \cos\alpha_m\left(\frac{z}{h}+\frac{1}{2}\right) \tag{7}$$

in which

$$a_m = \frac{1}{hb_m}\int_{-h/2}^{h/2}\theta(z,t_o)\cos\alpha_m\left(\frac{z}{h}+\frac{1}{2}\right)dz \tag{8}$$

$$b_m = \frac{1}{2}\left(\frac{\sin^2\alpha_m}{Hh/k}+1\right)$$

where α_m are the roots of the equation

$$\alpha\tan\alpha = Hh/k \tag{9}$$

Stress Field

In order to obtain an approximate solution for the stress field, the plate is idealized as a laminate having N layers. Within each layer the material's thermoelastoplastic properties are assumed to be uniform. For those properties which are presumed to vary with temperature, a value based upon the average temperature within the layer is used; i.e., a typical layer (k) occupying the region $z_{k-1} < z < z_k$ and having a mean temperature rise

$$\theta^{(k)} = [\theta(z_k) + \theta(z_{k-1})]/2 \tag{10}$$

has temperature-dependent properties

$$\alpha^{(k)} = \alpha(\theta^{(k)}),\quad E^{(k)} = E(\theta^{(k)}),\quad Y^{(k)} = Y(\theta^{(k)}) \tag{11}$$

The plate material is taken to be elastic-perfectly plastic, and to satisfy a temperature-sensitive von Mises yield criterion defined by the yield function

$$f = s_{ij}\,s_{ij} - \frac{2}{3}Y^2 \tag{12}$$

where s_{ij} denotes the component of the stress deviator. The behavior is assumed to be elastic if

$$f < 0, \text{ or if } f=0 \text{ and } \left(\frac{\partial f}{\partial s_{ij}}\dot{s}_{ij} + \frac{\partial f}{\partial \theta}\dot{\theta}\right) < 0 \tag{13}$$

whereas plastic flow is assumed to occur if

$$f = 0 \text{ and } \left(\frac{\partial f}{\partial s_{ij}}\dot{s}_{ij} + \frac{\partial f}{\partial \theta}\dot{\theta}\right) \geq 0 \tag{14}$$

Assuming that a state of plane stress exists for the traction-free plate under consideration, the stress components are taken to be

$$\sigma_{xx} = \sigma_{yy} = \sigma, \quad \text{all other } \sigma_{ij} = 0 \tag{15}$$

In this case equation (12) yields

$$f = \frac{2}{3}(\sigma^2 - Y^2) \tag{16}$$

and it follows that the stress state is elastic if

$$\sigma^2 < Y^2, \text{ or } \sigma^2 = Y^2 \text{ and } \sigma\dot{\sigma} - Y\dot{Y} < 0 \tag{17}$$

and plastic if

$$\sigma^2 = Y^2 \text{ and } \sigma\dot{\sigma} - Y\dot{Y} \geq 0 \tag{18}$$

The flow conditions (17) and (18) associated with the case $\sigma^2 = Y^2$ can be expressed in terms of incremental changes occurring during a small time interval Δt as follows. For elastic behavior

$$\sigma \ \Delta\sigma - Y \ \Delta Y < 0 \tag{19}$$

and for plastic flow

$$\sigma \ \Delta\sigma - Y \ \Delta Y \geq 0 \tag{20}$$

Considering thermoelastoplastic behavior, the constitutive relation is taken to be

$$\sigma = \frac{E(\theta)}{1-\nu} \cdot \left(e - e^P - \int_0^\theta \alpha(\tau)\, d\tau\right) \tag{21}$$

in which e^P denotes the plastic portion of the total strain component $e_{xx} = e_{yy} = e$. During thermoelastic response $(\Delta e^P = 0)$, the stress increment $\Delta\sigma = \Delta\sigma^E$ becomes

$$\begin{aligned}\Delta\sigma^E &= \frac{\partial\sigma}{\partial e}\Delta e + \frac{\partial\sigma}{\partial\theta}\Delta\theta \\ &= \frac{E(\theta)}{1-\nu}\Delta e + \frac{1}{1-\nu} \cdot \\ &\quad \left[\frac{dE(\theta)}{d\theta}\left(e - e^P - \int_0^\theta \alpha(\tau)\, d\tau\right) - \alpha(\theta)E(\theta)\right]\Delta\theta\end{aligned} \tag{22}$$

or introducing (21),

$$\Delta\sigma^E = \frac{E(\theta)}{1-\nu}(\Delta e - \alpha(\theta)\Delta\theta) + \frac{dE(\theta)}{d\theta}\frac{\sigma}{E(\theta)}\Delta\theta \tag{23}$$

If the usual assumptions of classical (Kirchhoff) theory of plates are employed, the strain component e is related to the middle-surface strain $e^o_{xx} = e^o_{yy} = e^o$ and curvature $(\kappa_x = \kappa_y = \kappa)$ by the expression

$$e = e^o + z\,\kappa \tag{24}$$

The strain increment Δe appearing in equation (23) thus becomes

$$\Delta e = \Delta e^o + z\,\Delta\kappa \tag{25}$$

For the layered idealization of the plate, it is convenient to define a function $g^{(k)}(t)$ (similar to that introduced by Boley and Weiner, 1960) which is equal to unity when layer k is in the elastic state, and zero when the layer is in the plastic state. Thus when $g^{(k)} = 1$:

$$\Delta\sigma^{E(k)} = \frac{E^{(k)}}{1-\nu}\cdot (\Delta\epsilon^{o}+z\Delta\kappa-\alpha^{(k)}\Delta\theta^{(k)}) + \frac{dE^{(k)}}{d\theta}\frac{\sigma^{(k)}}{E^{(k)}}\Delta\theta^{(k)} \tag{26}$$

and when $g^{(k)}=0$:

$$\Delta\sigma^{(k)} = \begin{cases} \Delta Y^{(k)} & \text{if } \sigma^{(k)}>0 \\ -\Delta Y^{(k)} & \text{if } \sigma^{(k)}<0 \end{cases} \tag{27}$$

in which $\Delta Y^{(k)}$ represents the change in magnitude of the yield stress for layer (k), resulting from the temperature change $\Delta\theta^{(k)}$.

Stress resultants are obtained through suitable integrations of the stress with respect to the thickness coordinate z. The resultant incremental in-plane force-per-unit-length ΔN and the incremental bending moment-per-unit-length ΔM are defined as

$$\begin{aligned}(\Delta N, \Delta M) &= \int_{-h/2}^{h/2}\Delta\sigma(1,z)\,dz \\ &= \sum_{k^E}\int_{z_{k-1}}^{z_k}\Delta\sigma^{(k)}(1,z)\,dz \\ &+ \sum_{k^P}\int_{z_{k-1}}^{z_k}\Delta\sigma^{(k)}(1,z)\,dz\end{aligned} \tag{28}$$

where $\sum_{k^E}$ designates a summation over all of the elastic layers, and $\sum_{k^P}$ designates a summation over the plastic layers. Substituting equation (26) into (28) and performing the indicated integration lead to

$$\begin{aligned}\Delta N &= A\Delta\epsilon^{o}+B\Delta\kappa-\Delta N^{\theta}+\Delta N^{P} \\ \Delta M &= B\Delta\epsilon^{o}+D\Delta\kappa-\Delta M^{\theta}+\Delta M^{P}\end{aligned} \tag{29}$$

in which A,B,D are extensional, coupling and bending stiffnesses defined by

$$(A,B,D) = \sum_{k^E}\frac{E^{(k)}}{1-\nu}\left(z_k-z_{k-1}, \frac{z_k^2-z_{k-1}^2}{2}, \frac{z_k^3-z_{k-1}^3}{3}\right) \tag{30}$$

Furthermore we have defined an incremental thermal force ΔN^{θ} and an incremental thermal moment ΔM^{θ} as

$$(\Delta N^{\theta}, \Delta M^{\theta}) = \sum_{k^E}\left[\frac{\alpha^{(k)}E^{(k)}}{1-\nu} - \frac{dE^{(k)}}{d\theta}\frac{\sigma^{(k)}}{E^{(k)}}\right]\left(z_k-z_{k-1}, \frac{z_k^2-z_{k-1}^2}{2}\right)\Delta\theta^{(k)} \tag{31}$$

Also appearing in equations (29) are the contributions to the total force and moment resultants offered by the plastic layers, namely

$$(\Delta N^{P}, \Delta M^{P}) = \sum_{k^P}\Delta\sigma^{(k)}\cdot\left(z_k-z_{k-1}, \frac{z_k^2-z_{k-1}^2}{2}\right) \tag{32}$$

with $\Delta\sigma^{(k)}$ given by equation (27).

In the case of a traction-free plate

$$\Delta N = \Delta M = 0 \tag{33}$$

in which case equations (29) yield

$$\begin{aligned}A\,\Delta\epsilon^{o} + B\,\Delta\kappa &= \Delta N^{\theta} - \Delta N^{P} \\ B\,\Delta\epsilon^{o} + D\,\Delta\kappa &= \Delta M^{\theta} - \Delta M^{P}\end{aligned} \tag{34}$$

The thermal stresses within each layer of the plate are calculated from the preceding equations by means of the iterative procedure described hereafter.

Computational Procedure

At each time increment Δt:

(i) Calculate layer temperature rises $\theta^{(k)}$ and $\Delta\theta^{(k)}$ according to (6) or (7).

(ii) Select appropriate values of $\alpha^{(k)}$, $E^{(k)}$ and $Y^{(k)}$ based upon $\theta^{(k)}$.

(iii) Assume that the quantities $g^{(k)}$ remain unchanged from their values at the preceding time. (Initially

$g^{(k)}=1$ for all k.)

(iv) Calculate incremental middle surface strain $\Delta\varepsilon^{o}$ and curvature $\Delta\kappa$ using (34).

(v) Calculate incremental strains $\Delta\varepsilon^{(k)}$ from (25).

(vi) Calculate incremental stresses according to either (26) or (27), depending upon values of $g^{(k)}$.

(vii) Calculate total stresses $\sigma^{(k)}$ by adding $\Delta\sigma^{(k)}$.

(viii) Calculate incremental elastic stresses $\Delta\sigma^{E(k)}$ from (26).

(xi) Apply yield criterion (19)-(20) to determine $g^{(k)}$.

(x) Compare each $g^{(k)}$ with its previous value. If any is different, repeat steps (iv) to (x); if all remain unchanged, continue.

(xi) Increment time, and repeat procedure.

NUMERICAL RESULTS AND DISCUSSION

As an illustrative example, consideration is given to an X22 steel plate of thickness h=0.1m, characterized by the temperature-induced phase changes described earlier (Fig. 1). The values of the thermal expansion coefficients α_1 employed to model the transformation behavior are those given in Fig. 2. Other material properties taken for this example, based upon data presented by Briggs and Parker (1962), Wegst (1983) and the ASME Boiler and Pressure Vessel Code (1989), are

$$
\begin{aligned}
k &= 26.0 \quad W/mK \\
\lambda &= 6.97 \times 10^{-6}\ m^2/s \\
\nu &= 0.3 \\
E(\theta) &= (216.8 - 0.9083\,\theta)\ GPa \\
Y(\theta) &= (896 + 0.1693\theta - 1.4015 \times 10^{-3}\theta^2)\ MPa
\end{aligned}
\qquad (35)
$$

Heat input over the top surface (z = h/2) of the plate is given by $q_o = 5.0 \times 10^5\ W/m^2$, while the convection coefficient for subsequent cooling is taken to be $H = 156\ W/m^2K$.

The plate is divided into a total of 12 layers. The top 4 layers (k = 9 to 12), which comprise the region where the gradients of temperature and stress are greatest, have thicknesses 0.005m; the remaining layers (k=1 to 8) are 0.01m thick.

Figure 4 shows the variations of stress in the thickness direction at nondimensionalized times $t^*=\lambda t/h^2 = 0.08, 0.4$ and 10.0 for the case of a heating duration $t_o^*=\lambda t_o/h^2=0.18$ and a strain-temperature response given by path ABCDEF (Fig. 2). These and later results were calculated using a time increment $\Delta t^*=0.001$.

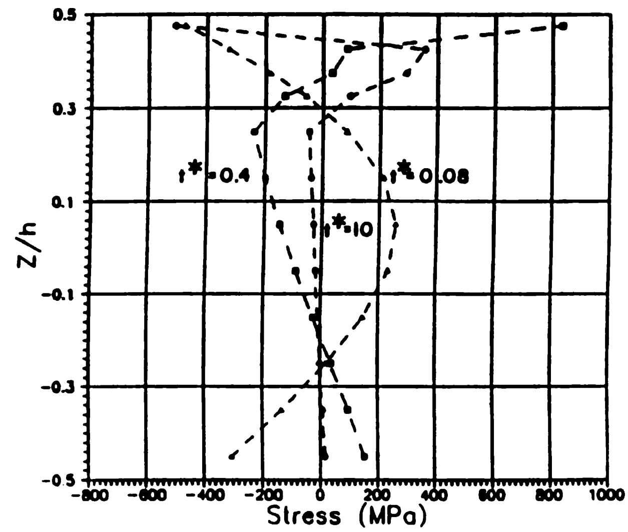

Fig. 4. Stress distributions for heating duration $t_o^*=0.18$.

At $t^*=0.08$ the computed maximum layer temperature rise $(\theta^{(12)}=568K)$ is below the temperature rise at which austenitic transformation begins $(\theta=813.3K)$. At this time no phase transformation or plastic flow has occurred. Observe (Fig. 4) that as a result of the large thermal expansion at the top of the plate, the upper four layers are in compression, the middle layers are in tension, and the bottom two layers are in compression. Force and moment equilibrium conditions are thereby satisfied.

When the applied surface heating ceases at $t^*=0.18$, the temperature rise in layer 12 exceeds the temperature at which full austenitic transformation has occurred $(\theta=856K)$. However the temperature rise in all other layers remains below $813K$. Consequently for this thermal loading condition, layer 12 alone undergoes phase transformation.

At $t^*=0.4$ layer 12 has cooled to a temperature $\theta^{(12)}=267K$, and is in a plastic state. Since the temperature in this layer is then lower than that in the central region of the plate, and since this layer alone has undergone contraction due to austenitizing, it experiences a large tensile stress (Fig. 4).

When $t^*=10.0$ all layer temperature increases $\theta^{(k)}$ are less than $3K$, indicating a near steady-state thermal condition has been reached. The plastic deformation which occurs in layer 12 during heating, followed by elastic response during cooling, results in residual compressive top surface stresses, tensile stresses immediately subsurface, and nearly zero stresses elsewhere.

Figure 5 shows a similar set of results for the stress distributions resulting from a larger heat input time, namely $t_o^* = 0.215$. In this case both layers 11 and 12 undergo phase transformations. Note that while the increased heating time results in a deeper zone of compression at the top of the plate, the magnitudes of the stresses within this zone are much reduced.

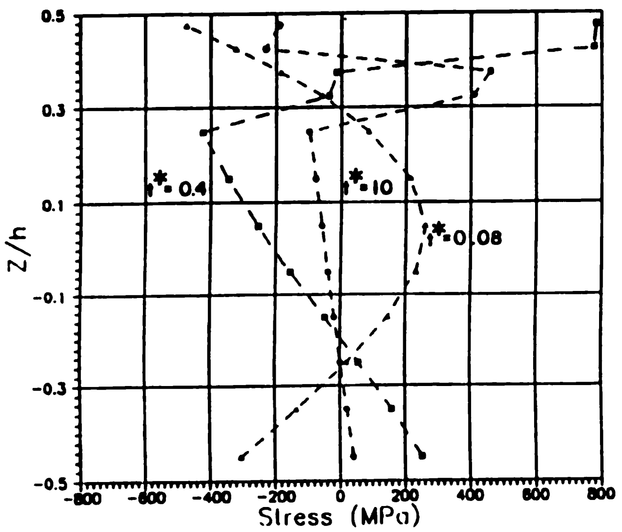

Fig. 5. Stress distributions for heating duration $t_o^*=0.215$.

The degree of martensite formation which takes place during cooling has a pronounced effect upon the residual stress magnitudes. To examine this effect, the calculated stress distributions are compared with those which would occur if the plate material were to return to its original microstructure following the phase transformations; i.e., if the martensitic transformation were represented by line EA rather than EF in Fig. 2. Note that curve ABCDEF characterizes a situation in which the contraction of the affected layers resulting from the austenite formation exceeds the expansion associated with the subsequent martensite formation, whereas for the "closed" curve ABCDEA the net deformation resulting from the two transformations is zero. The residual stress distributions for these two situations are plotted in Figs. 6 and 7, corresponding to heat input durations of $t_o^* = 0.18$ and 0.215, respectively. Since the expansion which occurs during martensitic transformation has the effect of increasing the compressive stresses in the affected layers, the magnitude of the compressive residual surface stresses are greater in the case of "complete" martensite formation (curves b) than in the case of incomplete martensitic transformation (curves a).

Also shown in Figs. 6 and 7, for the purpose of comparison, are residual stress distributions calculated assuming that no phase transformations occur (curves labelled c). In this case the upper region undergoes thermal expansion during heating which is large relative to expansion elsewhere in the plate, resulting in compressive surface stress and plastic flow. Following elastic unloading (cooling) the surface stresses become tensile, as indicated in the figures.

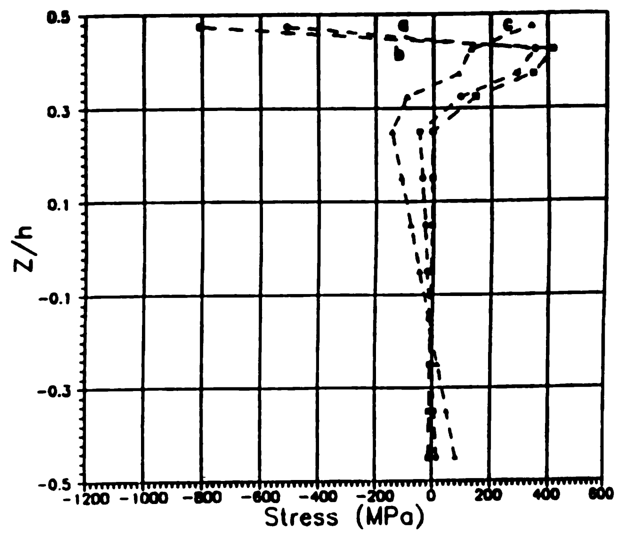

Fig. 6. Residual stress distributions for heating duration $t_o^*=0.18$. (a) incomplete martensitic formation;(b) complete martensitic formation; (c) no phase transformations.

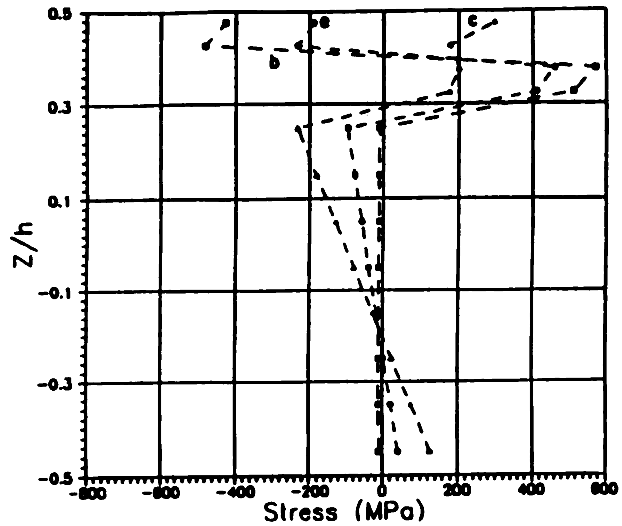

Fig. 7. Residual stress distributions for heating duration $t^*_o = 0.215$. (a) incomplete martensitic formation;(b) complete martensitic formation;(c) no phase transformations.

The effects of the temperature dependence of Young's modulus and yield stress upon residual stress also have been examined. Figures 8 and 9 show stress distributions calculated on the basis of the relations $E(\theta)$ and $Y(\theta)$ given in equation (36), as well as those based on constant modulus E(0) = 216.8 GPa and constant yield stress Y(0) = 896 MPa. For either of the elastic modulus expressions ($E(\theta)$ or $E(0)$), the predicted residual compressive stress at the heated surface is greater when the yield stress decreases with temperature than when it is considered constant (cf. curves a and c, or b and d in the figures). On the other hand, when either of the yield stress relations ($Y(\theta)$ or $Y(0)$) is employed, the compressive residual surface stress based upon a modulus which decreases with temperature is smaller than that based upon a constant value of modulus (cf. curves a and b, or c and d).

Also shown in Figs. 8 and 9 are residual stress distributions obtained from a purely elastic analysis ($Y=\infty$), assuming a temperature-dependent Young's modulus (see curves e). Nearly identical results (not shown) were found when a temperature-independent modulus E(0) was considered. In both cases residual tensile stresses develop at the heated surface as a consequence of overall contraction associated with the material's phase transformations.

CONCLUDING REMARKS

A procedure has been developed for predicting the transient stresses which develop when a steel plate is exposed to heat input over one surface. Plastic deformation which occurs in the higher temperature region of the plate, followed by elastic response during subsequent cooling, results in residual compressive surface stresses and tensile subsurface stresses. Such compressive surface stresses are beneficial from the point of view of reducing the likelihood of fracture due to surface cracking; however this advantage may be partially offset by the presence of tensile subsurface stresses. The numerical results presented indicate that the stress distributions are affected signficantly by the duration of applied heat input, the degree of phase transformation which occurs, and the temperature sensitivity of the thermomechanical properties of the material.

Electroelastic analysis of piezoelectric laminated structures

Horacio Sosa and Marco Castro

Department of Mechanical Engineering and Mechanics
Drexel University, Philadelphia PA 19104

A two-dimensional electroelastic formulation is developed to study the response of piezoelectric laminated structures. The methodology is based on a state space formulation where a particular collection of elastic and electrical variables is used to determine the behavior of layered structures subjected to arbitrary loading conditions. The application of this methodology in the area of multilayer electromechanical devices and of adaptive or smart structures is discussed.

INTRODUCTION

This article is concerned with structures formed by assembling layers of various materials possessing very different elastic and electric characteristics. Of all the components present in the resulting layered system the most important in this study is a piezoelectric material which is placed in a continuous or discrete manner at different locations in the structure. The applications of such arrangements include electronic and electromechanical devices which are being used in spacecrafts, launch vehicles and military equipment. As a first example consider Fig 1 where we show a multilayer electromechanical device, such as a transducer, resonator or capacitor, where electrodes are embedded within a piezoelectric ceramic. If the thickness of the electrodes can not be neglected the structure is regarded as a multilayer system of conducting, rigid or deformable metal sheets and elastic piezoelectric ceramic. A second example is provided by Fig 2 where it is shown a schematic representation of a so-called smart structure. That is, a structure that responds in an autonomously or predetermined manner to external disturbances. This unique characteristic is achieved by embedding within the structure layers of piezoelectric material which are used as sensors and actuators to detect and react, respectively, to an external load.

The analysis of layered structures as the ones shown in Figs 1 and 2 is by no means trivial since phenomena such as material anisotropy and electromechanical coupling tend to introduce formidable mathematical difficulties. In addition, a mathematical method capable of describing the response of such a composite structure should furnish information on local as well as global behavior with equal ease. For example, in the case of the multilayer device of Fig 1 one may be interested on the local behavior of stresses induced in the neighborhood of the electrode's tip where high electric fields tend to occur. On the other hand, when dealing with smart or adaptive structures the main objective is to be able to predict the overall response of the structure to a given load.

In contrast to previous formulations which have been based on ad hoc, and some times unrealistic assumptions, we present a general, two-dimensional methodology to address problems where mechanical and electrical effects occur simultaneously. The method is based on the so-called state space formulation and can be regarded as a generalization of previous works developed within the framework of linear isotropic elasticity (Bahar, 1972 &1975, Sosa and Bahar, 1992). The formulation consists of casting the equations of electroelasticity in a mixed form, where a state vector is formed by collecting not only mechanical variables such as stress and

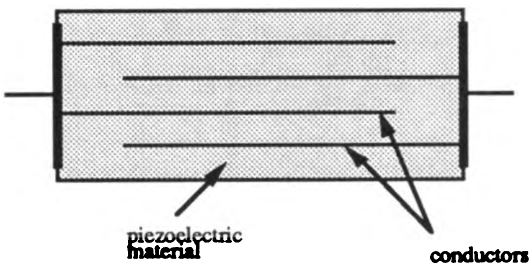

Figure 1: Multilayer electromechanical device

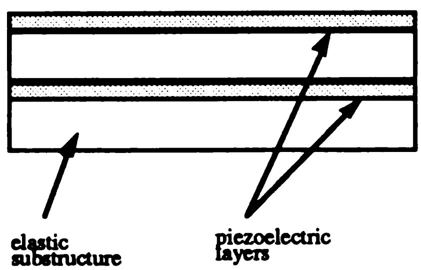

Figure 2: Smart structure

displacement but also electrical variables like induction (also known as the electric displacement) and electric potential. Furthermore, in view of the geometries under study use of the Fourier transform allows us to produce a system of ordinary differential equations which can be written in matrix form with the transform state vector and the depth within the medium playing the role of dependent and independent variables, respectively. The solution of the matrix differential equation is obtained in terms of a transfer matrix that allows us to find the transformed electroelastic variables anywhere in the medium once the state vector on the boundary (also referred to as the initial state vector) is known. Furthermore, the state vector in any layer can be obtained upon multiplication of the initial state vector by a chain of transfer matrices of the individual layers by the transfer matrix of the layer of interest. Finally, by Fourier inversion the electromechanical variables in the physical space are obtained.

The main objective of this article is to present the formalism behind the state space methodology in electroelasticity. Therefore, particular problems are not addressed although remarks are made with respect to the implementation of the method to attack some fundamental electromechanical boundary value problems. Finally, it is shown that despite the inherent complexities due to material anisotropy and coupling effects, the new electroelastic transfer matrix preserves the characteristics of the isotropic elastic transfer matrix found in the original works of Bahar (1972 & 1975).

THE PIEZOELECTRIC EFFECT AND PIEZOELECTRIC CERAMICS

As mentioned previously, within the realm of the present study the piezoelectric material is the most important component in the multilayer structures to be analyzed. Therefore, a brief description of the phenomenon of piezoelectricity is provided in this section as well as how this property can be induced in ceramics.

Piezoelectric materials are anisotropic dielectrics that deform under the effect of an electric field and conversely, they produce an electric voltage when subjected to mechanical loads. The now called direct piezoelectric effect (namely, the inducement of charge in response to applied pressure) was discovered in some crystals by J. and P. Curie in 1880 and its formal mathematical description was provided by Voigt in 1894 (Cady, 1964). Despite the importance of the piezoelectric phenomenon, the first applications did not occur until World War I, where crystal quartz was used for the emission of acoustic waves as a means to locate German submerged vessels.

The main property of a piezoelectric material is its electromechanical coupling parameter which gives an indication of how much mechanical energy can be transformed into electrical and vice versa. Pure crystals have small electromechanical coupling and, as a consequence, the range of their applications remained very limited. In the 1940's it was discovered that piezoelectricity could be induced in isotropic ceramics such as lead zirconate titanate (PZT) and barium titanate (Ba Ti O_3) by subjecting the ceramic to a high DC electric field, a process known as poling (Jaffe et al., 1971). The sequence of events involved in the inducement of piezoelectricity can be described as follows: A piezoelectric ceramic is first manufactured to its final shape and size by conventional methods. A microscopic look at the finished product will reveal a structure as the one shown in Fig 3 where dipoles

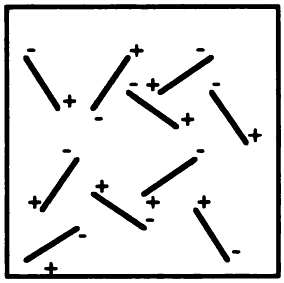

Figure 3: Ceramic before poling

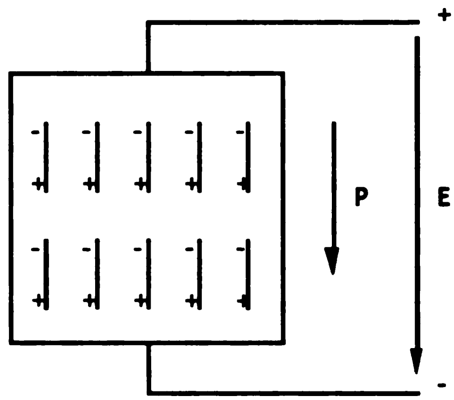

Figure 4: Ceramic after poling

(or molecules) are oriented in a random manner. From a macroscopic point of view, however, the material is regarded as isotropic with a net polarization vector equal to zero and, therefore, with no piezoelectric characteristics. The ceramic is next electroded and subjected to a DC electric field (the poling field) of the order of $10^6 - 10^7$ Volts/m at temperatures below $200^0 - 400^0$ C (known as the Curie temperature). The consequence of this procedure is an alignment of the dipoles in the direction of the applied field as shown in Fig 4. From a macroscopic point of view the ceramic is now transversely isotropic with the axis of transverse isotropy being parallel to the polarization vector **P**. Therefore, piezoelectricity can be manifested only on bulk materials lacking a center of symmetry. An important aspect of this procedure is that the polarization is permanent as long as in practical applications applied or induced fields do not exceed the poling field. Otherwise dielectric breakdown or depolarization may occur.

The popularity of piezoelectric ceramics as components of electromechanical and electronic devices stems from the following three characteristics: first, they have high piezoelectric constants; second, they can be given almost any shape and size with the direction of polarization freely chosen; and third, they are very stiff, therefore, they are capable of exerting and sustaining very large loads. An undesirable characteristic is their brittleness and therefore, low fracture resistance. Consequently, it is clear that studies of the induced stresses in these materials is an important subject to ensure reliable and more efficient structures.

MATHEMATICAL DESCRIPTION OF LINEAR PIEZOELECTRICITY

The mathematical representation of the piezoelectric effect makes use of two mechanical (stress and strain) and two electrical (field and polarization or electric displacement) variables. Depending on which two variables (one mechanical and one electrical) are regarded as independent one can obtain four different constitutive equations by making use of thermodynamic potentials (Cady, 1964). Denoting by $\boldsymbol{\sigma}$, $\boldsymbol{\varepsilon}$, $\mathbf{E}$, and $\mathbf{D}$ the stress tensor, the strain tensor, the electric field vector and the electric displacement vector, respectively, it can be shown that one possible set of constitutive relations is provided by

$$\boldsymbol{\sigma} = \mathbf{C}\,\boldsymbol{\varepsilon} - \mathbf{e}^T\,\mathbf{E}, \quad (1)$$

$$\mathbf{D} = \mathbf{e}\,\boldsymbol{\varepsilon} + \boldsymbol{\epsilon}\,\mathbf{E}, \quad (2)$$

where $\mathbf{C}$ is the fourth order elastic stiffness tensor (measured at constant electric field), $\mathbf{e}$ is third order piezoelectric tensor, $\boldsymbol{\epsilon}$ is the rank two dielectric tensor (measured at constant strain), and the superscript "T" in (1) denotes the transpose of the tensor. Alternate forms of constitutive equations can be obtained by considering different thermodynamic potentials. Numerical values for the material constants of different classes of piezoelectric ceramics can be found in Berlincourt et al. (1964).

In the most general case, Eqs (1) and (2) contain a total of 45 independent material constants (21 elastic, 18 piezoelectric and 6 dielectric). However, most piezoelectric materials used in electromechanical applications are transversely isotropic. As a consequence, only 5 elastic, 3 piezoelectric and 2 dielectric constants need to be considered. For example, if poling of the material occurs in the x_3-direction, the plane perpendicular to this axis remains isotropic. This condition becomes much easier to visualize by writing Eqs (1) and (2) in matrix form with respect to a Cartesian coordinate system (x_1, x_2, x_3). In such a case the electromechanical variables can be represented by column vectors

$$\begin{aligned}
\boldsymbol{\sigma} &= \{\sigma_{11}, \sigma_{22}, \sigma_{33}, \sigma_{32}, \sigma_{31}, \sigma_{12}\}^T, \\
\boldsymbol{\varepsilon} &= \{\varepsilon_{11}, \varepsilon_{22}, \varepsilon_{33}, 2\varepsilon_{32}, 2\varepsilon_{31}, 2\varepsilon_{12}\}^T, \\
\mathbf{D} &= \{D_1, D_2, D_3\}^T, \\
\mathbf{E} &= \{E_1, E_2, E_3\}^T,
\end{aligned}$$

while the material properties have the following matrix representations:

$$\mathbf{C} = \begin{Vmatrix} C_{11} & C_{12} & C_{13} & 0 & 0 & 0 \\ C_{12} & C_{11} & C_{13} & 0 & 0 & 0 \\ C_{13} & C_{13} & C_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & C_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & C_{44} & 0 \\ 0 & 0 & 0 & 0 & 0 & C_{66} \end{Vmatrix}$$

with

$$C_{66} = \frac{1}{2}(C_{11} - C_{22}),$$

$$\mathbf{e} = \begin{Vmatrix} 0 & 0 & 0 & 0 & e_{15} & 0 \\ 0 & 0 & 0 & e_{15} & 0 & 0 \\ e_{31} & e_{31} & e_{33} & 0 & 0 & 0 \end{Vmatrix}$$

and

$$\boldsymbol{\epsilon} = \begin{Vmatrix} \epsilon_{11} & 0 & 0 \\ 0 & \epsilon_{11} & 0 \\ 0 & 0 & \epsilon_{33} \end{Vmatrix}$$

With this representation it is immediate to recognize that a field E_3 induces only normal stresses through the piezoelectric constants e_{31} and e_{33}, while inplane deformations give rise to out-of-plane electric displacement. It is also important to note that if the material is anisotropic but does not possess piezoelectricity (or this effect is neglected) then e=0, leading to elastic and dielectric problems which can be solved independently of each other.

In addition to Eqs (1) and (2) the formulation of piezoelectric problems is based on field equations provided by the equations of motion and Gauss' law of electrostatics, namely

$$\begin{aligned}
\operatorname{div} \boldsymbol{\sigma} + \rho\, \mathbf{b} &= \rho\, \mathbf{a}, && (3) \\
\operatorname{div} \mathbf{D} &= q, && (4)
\end{aligned}$$

where ρ, $\mathbf{b}$, $\mathbf{a}$ and q denote the mass density, the body forces, the acceleration and the density of free charges, respectively. Finally it is convenient to introduce the elastic displacement $\mathbf{u}$ and electric potential ϕ which satisfy the equations

$$\begin{aligned}
\boldsymbol{\varepsilon} &= \frac{1}{2}\left(\nabla \mathbf{u} + \nabla \mathbf{u}^T\right), && (5) \\
\mathbf{E} &= -\nabla \phi. && (6)
\end{aligned}$$

We would like to note that despite the very different physical nature of the elastic and dielectric problems, these two phenomena are governed by equations with the same mathematical structure, that is, there is a one-to-one correspondence between the elastic and the electric variables as is illustrated below:

$$\begin{aligned}
\boldsymbol{\sigma} &\leftrightarrow \mathbf{D} \\
\boldsymbol{\varepsilon} &\leftrightarrow \mathbf{E} \\
\mathbf{u} &\leftrightarrow \phi.
\end{aligned}$$

Combining Eqs (1) through (6) yields a system of four partial differential equations coupling the three components of the displacement vector $\mathbf{u}$ with the electric potential ϕ, which must be solved subject to certain electrical and mechanical boundary conditions. Letting Ω be the piezoelectric solid bounded by $\partial\Omega$, and calling $\partial\Omega_t$, $\partial\Omega_u$, $\partial\Omega_D$ and $\partial\Omega_\phi$ the parts of the boundary where force, displacement, electric displacement, and electric potential can be prescribed, one can write in the most general case

$$\begin{aligned}
\boldsymbol{\sigma}\, \mathbf{n} &= \mathbf{t}_s \quad \text{on } \partial\Omega_t \\
\mathbf{u} &= \mathbf{u}_s \quad \text{on } \partial\Omega_u \\
[\mathbf{D}] \cdot \mathbf{n} &= \omega \quad \text{on } \partial\Omega_D \\
[\phi] &= 0 \quad \text{on } \partial\Omega_\phi
\end{aligned}$$

where $\mathbf{t}_s$ represents the traction (or stress vector), $\mathbf{n}$ is the outward unit normal to $\partial\Omega$, ω is a prescribed surface charge density and [.] indicates the jump of the enclosed quantity across the boundary.

STATE SPACE FORMULATION FOR ELECTROELASTICITY

The analysis of piezoelectric materials is mathematically highly involved because of electroelastic coupling and material anisotropy. A certain degree of simplification can be obtained if the analysis is reduced to two dimensions. However, to retain general coupling characteristics the plane of study can not be chosen arbitrarily. Indeed, as mentioned before if the material is poled in the x_3-direction, the plane (x_1, x_2) is isotropic and no electroelastic interactions take place. On the other hand, suitable planes to study coupling effects are (x_1, x_3) and (x_2, x_3). Choosing the former and renaming the coordinates as (x, z) the plane stress constitutive equation reduces to

$$\left\{\begin{array}{c}\sigma_{xx}\\ \sigma_{zz}\\ \sigma_{xz}\end{array}\right\} = \left\|\begin{array}{ccc}C_{11} & C_{13} & 0\\ C_{13} & C_{33} & 0\\ 0 & 0 & C_{44}\end{array}\right\| \left\{\begin{array}{c}u_{,x}\\ w_{,z}\\ u_{,z}+w_{,x}\end{array}\right\} + \left\|\begin{array}{cc}0 & e_{31}\\ 0 & e_{33}\\ e_{15} & 0\end{array}\right\| \left\{\begin{array}{c}\phi_{,x}\\ \phi_{,z}\end{array}\right\} \tag{7}$$

$$\left\{\begin{array}{c}D_x\\ D_z\end{array}\right\} = \left\|\begin{array}{ccc}0 & 0 & e_{15}\\ e_{31} & e_{33} & 0\end{array}\right\| \left\{\begin{array}{c}u_{,x}\\ w_{,z}\\ u_{,z}+w_{,x}\end{array}\right\} - \left\|\begin{array}{cc}\epsilon_{11} & 0\\ 0 & \epsilon_{33}\end{array}\right\| \left\{\begin{array}{c}\phi_{,x}\\ \phi_{,z}\end{array}\right\}. \tag{8}$$

where u and w are the components of displacement in the x- and z- directions, respectively, and a comma after a variable denotes partial differentiation. Moreover, assuming all physical variables to be independent of time, and neglecting body forces and electric charge density Eqs (3) and (4) become

$$\frac{\partial \sigma_{xx}}{\partial x} + \frac{\partial \sigma_{xz}}{\partial z} = 0 \tag{9}$$

$$\frac{\partial \sigma_{xz}}{\partial x} + \frac{\partial \sigma_{zz}}{\partial z} = 0 \tag{10}$$

$$\frac{\partial D_x}{\partial x} + \frac{\partial D_z}{\partial z} = 0 \tag{11}$$

The set of eight equations given by Eqs (7)-(11) constitutes eight coupled partial differential equations in eight unknowns (three components of stress, two components of electric displacement, two components of elastic displacement, and the electric potential). The state space formulation consists of describing physical phenomena in terms of the minimum possible number of variables. Towards this end, a first step is to reduce the variables involved in (7)-(11) by eliminating the components σ_{xx} and D_x, which renders

$$\begin{aligned}
\frac{\partial u}{\partial z} &= -\frac{\partial w}{\partial x} + \frac{1}{C_{44}}\sigma_{xz} - \frac{e_{15}}{C_{44}}\frac{\partial \phi}{\partial x}\\
\frac{\partial w}{\partial z} &= -\frac{\alpha}{\gamma}\frac{\partial u}{\partial x} + \frac{\epsilon_{33}}{\gamma}\sigma_{zz} + \frac{e_{33}}{\gamma}D_z\\
\frac{\partial \sigma_{zz}}{\partial z} &= -\frac{\partial \sigma_{xz}}{\partial x}\\
\frac{\partial \sigma_{xz}}{\partial z} &= \left(\frac{C_{13}^2}{C_{33}} - C_{11} - \frac{\beta^2}{\gamma C_{33}}\right)\frac{\partial^2 u}{\partial x^2}\\
&\quad + \left(\frac{e_{33}}{C_{33}}\frac{\beta}{\gamma} - \frac{C_{13}}{C_{33}}\right)\frac{\partial \sigma_{zz}}{\partial x} - \frac{\beta}{\gamma}\frac{\partial D_z}{\partial x}\\
\frac{\partial \phi}{\partial z} &= -\frac{\beta}{\gamma}\frac{\partial u}{\partial x} + \frac{e_{33}}{\gamma}\sigma_{zz} - \frac{C_{33}}{\gamma}D_z\\
\frac{\partial D_z}{\partial z} &= -\frac{e_{15}}{C_{44}}\frac{\partial \sigma_{xz}}{\partial x} + \frac{\kappa}{C_{44}}\frac{\partial^2 \phi}{\partial x^2}
\end{aligned} \tag{12}$$

where

$$\alpha = C_{13}\,\epsilon_{33} + e_{31}\,e_{33},\ \beta = C_{13}\,e_{33} - C_{33}\,e_{31},$$

$$\gamma = C_{33}\,\epsilon_{33} + e_{33}^2,\ \kappa = e_{15}^2 + \epsilon_{11}\,C_{44}.$$

Notice that in the process no mixed derivatives are involved in (12). The next step is to reduce this system of partial differential equations into a system of ordinary differential equations. This can be done by taking advantage of the particular geometrical configurations under study. That is, as shown in Figs 1 and 2 the laminated structures can be represented by the infinite strip: $-\infty < x < \infty$, $-h \le z \le h$. Thus, the Fourier transform, defined as

$$\hat{f}(\xi) = \int_{-\infty}^{\infty} f(x)\, e^{i\xi x}\, dx$$

can be used in (12) yielding

$$\frac{d\hat{\mathbf{S}}}{dz}(\xi, z) = \mathbf{A}(\xi)\ \hat{\mathbf{S}}(\xi, z) \tag{13}$$

where $\hat{\mathbf{S}}(\xi, z)$ is the Fourier transform of the state vector $\mathbf{S}(x, z) = \{u, w, \sigma_{zz}, \sigma_{xz}, \phi, D_z\}^T$, and it has been assumed that the quantities $u, u_{,x}, w, \sigma_{zz}, \sigma_{xz}, \phi, \phi_{,x}$ and D_z tend to zero as $x \to \infty$. Furthermore, $\mathbf{A}(\xi)$ is the 6×6 matrix given by

$$\mathbf{A} = \left\| \begin{array}{cccccc} 0 & i\xi & 0 & a_{14} & a_{15}i\xi & 0 \\ a_{21}i\xi & 0 & a_{23} & 0 & 0 & a_{26} \\ 0 & 0 & 0 & i\xi & 0 & 0 \\ a_{41}\xi^2 & 0 & a_{43}i\xi & 0 & 0 & a_{46}i\xi \\ a_{51}i\xi & 0 & a_{53} & 0 & 0 & a_{56} \\ 0 & 0 & 0 & a_{64}i\xi & a_{65}\xi^2 & 0 \end{array} \right\|$$

where the coefficients a_{jk} reflecting the material characteristics can be expressed as

$$\begin{aligned} a_{14} &= \frac{1}{C_{44}}, \; a_{15} = \frac{e_{15}}{C_{44}} \\ a_{21} &= \frac{\alpha}{\gamma}, \; a_{23} = \frac{\epsilon_{33}}{\gamma}, \; a_{26} = \frac{e_{33}}{\gamma} \\ a_{41} &= -\frac{C_{13}}{C_{33}} + C_{11} + \frac{\beta^2}{\gamma C_{33}}, \\ a_{43} &= -\frac{e_{33}}{\beta}\gamma C_{33} + \frac{C_{13}}{C_{33}}, \; a_{46} = \frac{\beta}{\gamma} \\ a_{51} &= \frac{\beta}{\gamma}, \; a_{53} = \frac{e_{33}}{\gamma}, \; a_{56} = -\frac{C_{33}}{\gamma} \\ a_{64} &= \frac{e_{15}}{C_{44}}, \; a_{65} = -\frac{\kappa}{C_{44}}. \end{aligned}$$

The solution to (13) is found to be (Ogata, 1967)

$$\hat{\mathbf{S}}(\xi, z) = \exp[z\mathbf{A}(\xi)]\; \hat{\mathbf{S}}(\xi, 0) \tag{14}$$

where the matrix exponential $\exp[z\mathbf{A}(\xi)]$ is the transfer matrix that propagates the "initial" transformed state vector $\hat{\mathbf{S}}(\xi, 0)$ into the field at any depth z, and whose explicit form can be determined by means of the following steps:

(i) The eigenvalues λ of $\mathbf{A}$ are found from the associated characteristic equation, that is

$$\lambda^6 + p\,\xi^2\lambda^4 + q\,\xi^4\lambda^2 + r\,\xi^6 = 0 \tag{15}$$

where the coefficients p, q and r are given by

$$p = \frac{1}{\gamma C_{44}}\Big[\alpha\, C_{33} + \beta\, e_{31}\,\frac{C_{33}}{C_{13}} - \gamma\, C_{11} + 2\,\beta\, e_{15} - \kappa\, C_{33}\Big],$$

$$\begin{aligned} q &= \frac{1}{\gamma^2 C_{44}}\Big[-(\alpha\, C_{33} + \beta\, e_{31}\,\frac{C_{33}}{C_{13}} - \gamma\, C_{11})(\epsilon_{33}\, C_{44} \\ &+ 2\, e_{15}\, e_{33} + \epsilon_{11}\, C_{33}) + \alpha\,(\gamma\, C_{44} + 2\,\beta\, e_{15} \\ &- \kappa\,(C_{33} + e_{33}) - 2\,\beta\,\kappa\, e_{33} - \beta^2\,\epsilon_{11})\Big], \end{aligned}$$

$$r = \frac{\kappa}{\gamma^2 C_{44}}\Big[\alpha\,(C_{33} - C_{13}) + \beta\, e_{31}\,(\frac{C_{33}}{C_{13}} - 1) - \gamma\, C_{11}\Big].$$

Since (15) is expressed in terms of even powers of λ its roots can be found in closed form. Moreover, it can be shown that for any physically admissible transversely isotropic piezoelectric material the roots can be expressed as

$$\lambda_{1,4} = \pm a|\xi|,\; \lambda_{2,5} = \pm(b + ic)|\xi|,\; \lambda_{3,6} = \pm(b - ic)|\xi|$$

where a, b, and c are real numbers which depend solely on the material constants.

(ii) The matrix exponential is expanded in a matrix polynomial, namely

$$\begin{aligned} \exp[z\mathbf{A}(\xi)] &= a_0\mathbf{1} + a_1\mathbf{A} + a_2\mathbf{A}^2 + a_3\mathbf{A}^3 \\ &+ a_4\mathbf{A}^4 + a_5\mathbf{A}^5 \end{aligned} \tag{16}$$

where no higher powers of $\mathbf{A}$ are needed on account of the Cayley-Hamilton theorem, which asserts that $\mathbf{A}$ satisfies its own characteristic equation, that is

$$\mathbf{A}^6 + p\,\xi^2\mathbf{A}^4 + q\,\xi^4\mathbf{A}^2 + r\,\xi^6\mathbf{1} = \mathbf{0}$$

(iii) The coefficients $a_0, \cdots, a_5$ appearing in (16) are determined in terms of the eigenvalues of $\mathbf{A}$ by noting that each λ satisfies also (16), therefore,

$$\exp[z\,\lambda] = a_0 + a_1\lambda + a_2\lambda^2 + a_3\lambda^3 + a_4\lambda^4 + a_5\lambda^5 \tag{17}$$

(iv) Use of (17) six times, one for each eigenvalue, yields a system of six equations in the unknowns $a_0, \cdots, a_5$, whose solution can be written compactly as

$$a_j = \frac{1}{2}\sum_{k=1}^{3}\Lambda_{jk}\left[e^{\lambda_k z} + (-1)^j e^{-\lambda_k z}\right], \quad j = 0, \cdots, 5 \tag{18}$$

where the coefficients Λ_{jk} are expressed in terms of the eigenvalues as follows:

$$\Lambda_{0k} = \prod_{j=k+1}^{k+2}\frac{\lambda_j^2}{d_k}; \quad \Lambda_{1k} = \prod_{j=k+1}^{k+2}\frac{\lambda_j^2}{\lambda_k d_k};$$

$$\Lambda_{2k} = \sum_{j=k+1}^{k+2}\frac{\lambda_j^2}{d_k}; \quad \Lambda_{3k} = \sum_{j=k+1}^{k+2}\frac{\lambda_j^2}{\lambda_k d_k};$$

$$\Lambda_{5k} = \frac{1}{d_k}; \quad \Lambda_{6k} = \frac{1}{\lambda_k d_k};$$

$$d_k = (\lambda_{k+1}^2 - \lambda_k^2)(\lambda_{k+2}^2 - \lambda_k^2), \quad k = 1, 2, 3$$

where the results $\lambda_1^2 = \lambda_4^2$, $\lambda_2^2 = \lambda_5^2$, and $\lambda_3^2 = \lambda_6^2$ must be used.

(v) Upon substitution of (18) together with the various powers of $\mathbf{A}$ into (16), the final expression for the matrix exponential is obtained, which henceforth will be denoted by $\mathbf{B}(M,\xi,z)$, where the argument M emphasizes the explicit dependence of the transfer matrix on the various material constants.

Finally, Eq (14) is rewritten as

$$\hat{\mathbf{S}}(\xi,z) = \mathbf{B}(M,\xi,z)\ \hat{\mathbf{S}}(\xi,0) \tag{19}$$

which gives the state vector consisting of the transformed stresses, displacements, electric potential and electric displacement at an arbitrary depth z in the field. It should be noted that while $\mathbf{B}$ is a unique matrix for a given material, $\hat{\mathbf{S}}(\xi,0)$ varies from problem to problem according to the prescribed boundary conditions.

To find the physical components of the state vector one must invert (19). This process may vary in difficulty according to the boundary value problem under consideration. In general, the inversion may have to be performed numerically, although some fundamental solutions can be obtained in an exact manner as we show in a forthcoming article. In closing this section we present important properties of the transfer matrix and an outline of the basic procedures to follow in the solution of actual boundary value problems.

Properties of the matrix B

As noted by Bahar (1975) the transfer matrix $\mathbf{B}$ has group properties that here we repeat for the sake of completeness.

(a) Identity property:

$$\text{Since}\ \ \mathbf{B}(\xi,z) = \exp[z\mathbf{A}(\xi)] \implies \mathbf{B}(\xi,0) = \mathbf{1}$$

That is, $\mathbf{B}(\xi,0)$ maps the initial state vector onto itself.

(b) Inversion property:

$$\mathbf{B}(\xi,-z) = \exp[-z\mathbf{A}(\xi)] = \mathbf{B}^{-1}(\xi,z)$$

Which means that the inverse of the transfer matrix carries the state vector in the field back into the initial state vector.

(c) Translation property:

$$\mathbf{B}(\xi,z_1+z_2) = \mathbf{B}(\xi,z_1)+\mathbf{B}(\xi,z_2) = \exp[(z_1+z_2)\mathbf{A}(\xi)]$$

Physically this means that the operation of carrying an input state vector first from 0 to z_1, then from z_1 to z_2 is equivalent to carrying the same vector from 0 directly to $z_1 + z_2$ in a single step. Consequently, the transfer matrix is independent of the choice of origin.

(d) Determinant property: A well established result of the theory of ordinary differential equations is (Coddington and Levinson, 1955)

$$\det\mathbf{B}(\xi,z) = \det\mathbf{B}(\xi,0)\ \exp\left[\int_0^z \mathrm{tr}\ \mathbf{A}(t)\ dt\right]$$

But $\det\mathbf{B}(\xi,0) = 1$, and $\mathrm{tr}\ \mathbf{A} = 0 \implies \det\mathbf{B} = 1$

That is, the transfer matrix is nonsingular.

Solution of Boundary Value Problems

Equation (19) represents the behavior in the transformed domain of a single piezoelectric layer provided the initial state vector is known in its entirety. In general, this is not the case and additional conditions must be imposed. For example, consider the case of a semi-infinite piezoelectric medium $z \geq 0$ subjected to a distributed mechanical or electrical load on the surface $z = 0$. In such a case only the values of the stresses and electric displacement on the surface of the medium will be known. The initial values of the displacement components and electric potential can be obtained by requiring that the state vector vanishes when $z \to \infty$. Once all the initial values are known the physical variables can be determined for all values of z.

When the problem under consideration consists of two or more layers as shown in Figs 1 and 2 it becomes necessary to generalize (19) in an appropriate manner. This is accomplished by using a continued matrix product in which the state vector approach is used to eliminate intermediate state vectors through the conditions existing among the divers variables at the various interfaces. That is, the relation (19) holds between successive interfaces. Letting N denote the number of a layer located at depth

$z = h_N$, (19) can be written as

$$\hat{\mathbf{S}}(\xi, h_N) = \mathbf{B}_N(M_N, \xi, h_N) \cdots \mathbf{B}_1(M_1, \xi, h_1)\ \hat{\mathbf{S}}(\xi, 0) \tag{20}$$

where $\mathbf{B}_1, \cdots, \mathbf{B}_N$ are the transfer matrices of the individual layers. Hence Eq (20) describes the overall response of the layered system in which all intermediate state vectors have been eliminated. Naturally, local information consisting of state vectors at arbitrary interfaces can also be obtained.

We notice at this point that the various layers composing the structure may have different electric and mechanical behavior. For example, one layer could be made of isotropic linear elastic material, in which case only elastic variables need to be used to describe its behavior. Thus, its transfer matrix will be only a 4×4 matrix, making impossible its product with the transfer matrix of a piezoelectric layer. To overcome this difficulty the purely elastic transfer matrix can be augmented and partitioned in a manner that makes explicit the elastic and electrical effects. Thus, it is convenient to write all the transfer matrices as

$$\left\{ \begin{matrix} \hat{\mathbf{S}}^m \\ \hat{\mathbf{S}}^e \end{matrix} \right\} = \left\| \begin{matrix} \mathbf{B}^m & \mathbf{B}^{me} \\ \mathbf{B}^{em} & \mathbf{B}^e \end{matrix} \right\| \left\{ \begin{matrix} \hat{\mathbf{S}}^m \\ \hat{\mathbf{S}}^e \end{matrix} \right\}_{z=0}$$

where $\mathbf{B}^m$, $\mathbf{B}^e$, $\mathbf{B}^{me}$, and $\mathbf{B}^{em}$ are 4×4, 2×2, 4×2 and 2×4 matrices reflecting the purely mechanical, purely electrical, mechanical-electrical and electrical-mechanical interactions, respectively. Furthermore $\hat{\mathbf{S}}^m = \{\hat{u}, \hat{w}, \hat{\sigma}_{zz}, \hat{\sigma}xz\}^T$ and $\hat{\mathbf{S}}^e = \{\hat{\phi}, \hat{D}_z\}^T$ are the transformed mechanical and electrical state vectors. Hence in the case of the isotropic elastic layer we have $\mathbf{B}^{me} = \mathbf{B}^{em} = \mathbf{0}$. An additional advantage of this representation stems from the fact that the matrices $\mathbf{B}^m$ and $\mathbf{B}^e$ are symmetric with respect to their secondary diagonals as a consequence of Maxwell's reciprocity theorem, introducing certain computational simplifications in the final calculations.

Experimental determination of stress intensity factor distributions in engineering problems

CW Smith

Department of Engineering Science and Mechanics
Virginia Polytechnic Institute and State University
Blacksburg VA 24061-0219

Following a brief introduction of the concept of stress intensity factor from fracture mechanics and the frozen stress method from photoelasticity, an algorithm is developed from fracture mechanics equations and the stress-optic law for converting stress fringe measurements into a form useful for determining the stress intensity factor. This algorithm covers all three local modes of deformation and is used to analyse frozen stress slices along the border of cracks to obtain distributions for stress intensity factors K_1, K_2 and K_3. The use of the method is illustrated by three examples from practical engineering problems and results are compared with the literature where possible.

I - INTRODUCTION

The present paper deals with the refinement and use of two old and established concepts for use in measuring the stress intensity factor (SIF) distribution in three dimensional cracked body problems.

A) Fracture Mechanics – Concept of SIF

The basic concepts of plane fracture mechanics were proposed in two papers (Griffith, 1921, 1925) and were prescribed on an energy basis using the solution of a narrow ellipse provided by Inglis (1913). Then Irwin (1948) and Orowan (1948) independently observed a concentration of plastic deformation in the surface layer of fractured steel specimens and extended Griffith's concept to include local plastic flow. Then Irwin (1957), utilizing a solution by Westergaard (1939), which treated the crack as a mathematical branch cut, developed the concept of the stress intensity factor (SIF) as the field strength of the crack tip stress singularity. The same result was obtained by Williams (1957). Irwin (1958) proposed a simple correction for local plasticity by extending the crack length in the computation. The result was known as Linear Elastic Fracture Mechanics (LEFM). Many subsequent developments have extended LEFM to include moderate to large scale plasticity as Elastic-Plastic Fracture Mechanics (EPFM) but these are not included in the present discussion.

In the sixties and seventies, rapid developments in both the hardware and software of digital computers opened the way for attacking three dimensional fracture problems through the use of numerical methods. However, validation of the computer codes was both expensive and difficult, lagging significantly developments in computational methods. Without code validation, some codes were called into question.

Around 1968, the author and his colleagues undertook an initial effort to develop a cost effective modelling technique for providing the needed validation at that time. The method of experimental verification selected for this purpose was known as frozen stress photoelasticity.

B) Photoelasticity – Concept of Frozen Stress

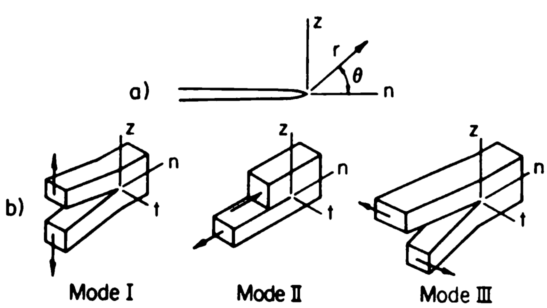
The photoelastic effect was discovered by Maxwell (1853) and current normal useage is described by Burger (1987). The frozen stress method of analysis was introduced by Oppel (1936). The method was subsequently widely used on three dimensional elastic problems for over a quarter of a century. The use of the method required construction of a scale model of a three dimensional body from a transparent photoelastic material of diphase characteristics. That is, at a certain temperature, the critical temperature, the material's elastic modulus dropped to about 0.2% of its room temperature modulus and became about 25 times more sensitive to stress fringes. When loaded above its critical temperature and then cooled slowly to room temperature, the stress fringes associated with the photoelastic effect above critical temperature are trapped permanently in the material along with accompanying deformations. When the load is later removed at room temperature, the recovery exhibited by the material which is 500 times stiffer than above critical temperature can be neglected. Moreover, thin slices can be removed from the "frozen" body without altering either stress fringes or deformations. In other words, no live stresses remain and it is the stress fringes and displacements obtained above critical temperature which remain.

After describing the refinements introduced in the two above concepts, several examples of the use of the resulting method of analysis will be described.

II – REFINEMENTS

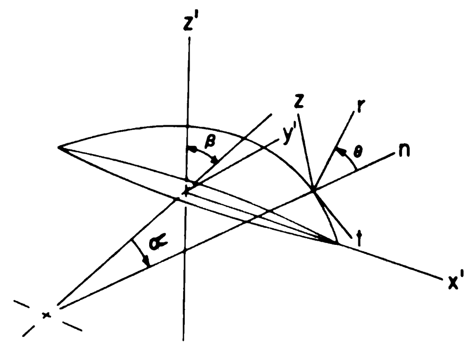
A) The Algorithm for Converting Optical Data Into SIF Values

As a result of the analytical models described above for the plane problem, the local state of stress is usually described in terms of a single parameter, the SIF, for small scale yielding with Mode I loading. If all three local modes are present (Fig. 1) then three parameters K_1, K_2, K_3 are indicated. However, when making photoelastic measurements in the neighborhood of the crack tip, since the stress fringes are proportional to the maximum in plane shear stress, then, if the non-singular shear stress does not vanish near the crack tip, it must be included in the algorithms for converting stresses into K values. On the other hand, if one moves too far from the crack tip, then the contribution to the data from the non-singular stress field increases as the contribution from the singular field decreases. A number of algorithms have been proposed for converting data around the crack tip into K values. Smith and Olaosebikan (1984) have shown that all of these algorithms yield essentially the same results for near tip measurements in plane problems. In three dimensional problems, the singular zone is further constricted by nearby boundary effects. The following analysis has been used successfully in dealing with such problems.



1. Local modes of deformation.

Consider a general mixed mode flaw geometry with notations as pict 2. It has been shown [Kassir and Sih (19 resses near the border of an elliptical ressed in terms of a set of local moving rectangular cartesian coordinates in a plane perpendicular to the flaw border, have the same form as the stresses in a plane perpendicular to the border of a straight front crack. Consider a half-space containing a surface flaw at an angle β to the boundary with remote uniform tension parallel to the z' direction (Figure 2). The local moving orthogonal coordinate system tnz is always oriented such that t is tangent to the flaw border and n is normal to the flaw border but both n and t are in the flaw plane. The z axis is normal to the flaw plane. In such a problem, all three local modes of near field deformation (i.e., Modes I, II and III) will be present as we move around the flaw border. We note that at $\alpha = 0$, however, Mode III will be absent.



2. General problem geometry and notation.

The stress distribution near the part through crack in the data zone, corresponding to the opening mode of deformation can be taken as

$$\sigma_{nn} = \frac{K_1}{(2\pi r)^{1/2}}\cos\frac{\theta}{2}\left[1 - \sin\frac{\theta}{2}\ \sin\frac{3\theta}{2}\right] - \sigma^1_{nn} \quad (1)$$

$$\sigma_{zz} = \frac{K_1}{(2\pi r)^{1/2}}\cos\frac{\theta}{2}\left[1 + \sin\frac{\theta}{2}\ \sin\frac{3\theta}{2}\right] - \sigma^1_{zz} \quad (2)$$

$$\tau_{nz} = \frac{K_1}{(2\pi r)^{1/2}}\sin\frac{\theta}{2}\left[\cos\frac{\theta}{2}\ \cos\frac{3\theta}{2}\right] - \tau^1_{nz} \quad (3)$$

where K_1 is the Mode I SIF and the coordinates r and θ are shown in Figure 2. σ^1_{ij} represent the contribution of the Mode I regular stress field to the measurement zone which is taken far enough from the crack tip to avoid a non-linear zone very near the tip. While they may generally be regarded as expressible in Taylor Series Expansions, it turns out that only the leading terms of said series are normally necessary so that σ^1_{ij} are constants for a given point in the flaw border but vary from point to point. Stresses in the data zone corresponding to the Mode II can be taken as

$$\sigma_{nn} = \frac{K_2}{(2\pi r)^{1/2}}\sin\frac{\theta}{2}\left[2 + \cos\frac{\theta}{2}\ \cos\frac{3\theta}{2}\right] - \sigma^2_{nn} \quad (4)$$

$$\sigma_{zz} = \frac{K_2}{(2\pi r)^{1/2}} \sin\frac{\theta}{2} \cos\frac{\theta}{2} \cos\frac{3\theta}{2} - \sigma^2_{zz} \quad (5)$$

$$\tau_{nz} = \frac{K_2}{(2\pi r)^{1/2}} \cos\frac{\theta}{2} \left[1 - \sin\frac{\theta}{2} \sin\frac{3\theta}{2}\right] - \tau^2_{nz} \quad (6)$$

where K_2 and σ^2_{ij} are analogous to K_1 and σ^1_{ij}.

And finally the stresses in the data zone corresponding to the Mode III loading can be taken as

$$\tau_{nt} = -\frac{K_3}{(2\pi r)^{1/2}} \sin\frac{\theta}{2} - \tau^3_{nt} \quad (7)$$

$$\tau_{zt} = \frac{K_3}{(2\pi r)^{1/2}} \cos\frac{\theta}{2} - \tau^3_{zt} \quad (8)$$

with K_3 and τ^3_{ij} analogous to K_1 and σ^1_{ij}.

If the above modes of loading are superimposed, one gets the following stress distribution in a plane perpendicular to the crack front (the n-z plane)

$$\sigma_{nn} = \frac{K_1}{(2\pi r)^{1/2}} \cos\frac{\theta}{2} \left[1 - \sin\frac{\theta}{2} \sin\frac{3\theta}{2}\right] - \frac{K_2}{(2\pi r)^{1/2}} \sin\frac{\theta}{2} \left[2 + \cos\frac{\theta}{2} \cos\frac{3\theta}{2}\right] - \sigma^0_{nn} \quad (9)$$

$$\sigma_{zz} = \frac{K_1}{(2\pi r)^{1/2}} \cos\frac{\theta}{2} \left[1 + \sin\frac{\theta}{2} \sin\frac{3\theta}{2}\right] + \frac{K_2}{(2\pi r)^{1/2}} \sin\frac{\theta}{2} \cos\frac{\theta}{2} \cos\frac{3\theta}{2} - \sigma^0_{zz} \quad (10)$$

$$\tau_{nz} = -\frac{K_1}{(2\pi r)^{1/2}} \sin\frac{\theta}{2} \cos\frac{\theta}{2} \cos\frac{3\theta}{2} + \frac{K_2}{(2\pi r)^{1/2}} \cos\frac{\theta}{2} \left[1 - \sin\frac{\theta}{2} \sin\frac{3\theta}{2}\right] - \tau^0_{nz} \quad (11)$$

which are independent of equations (7) and (8); (i.e., the local field equations for Modes I and II are completely separate from those for Mode III).

While σ^0_{ij} has no influence upon the singular stress field itself, it does alter the isochromatic fringe pattern, which is proportional to the maximum in-plane shearing stress.

From the stress field given in equations (9)–(11), the maximum shearing stress in the plane perpendicular to the crack front, nz, can be obtained using

$$(\tau)^{nz}_{max} = \left[\left(\frac{\sigma_{zz} - \sigma_{nn}}{2}\right)^2 + \tau^2_{nz}\right]^{1/2} \quad (12)$$

and, truncating to the same order as equations (9)–(11), one gets

$$(\tau)^{nz}_{max} = \frac{A}{r^{1/2}} + B \quad (13)$$

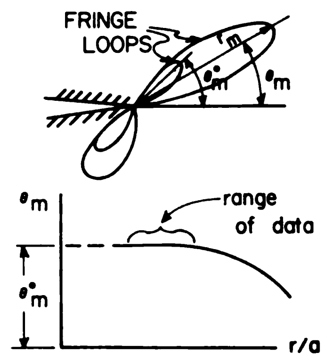
for fringe loops approaching the shape of Fig. 3 where

$$A = \left\{\frac{1}{8\pi}\left[(K_1 \sin\theta + 2K_2 \cos\theta)^2 + (K_2 \sin\theta)^2\right]\right\}^{1/2} \quad (14)$$

and

$$B = B\left(\sigma^0_{ij}\right)$$

The maximum shearing stress in the nz plane, the left side of equations (12) and (13), is determined photoelastically.



3. Determination of θ^0_m for mixed mode.

Now, in general, the effect of σ^0_{ij} involves both a folding and a change in eccentricity of the fringe loops (Figure 3). If folding occurs, θ_m, the angle along which the distance to a fringe from the crack tip is greatest, will vary with the fringe order n and one must plot θ_m vs r/a and extrapolate to the origin in order to obtain θ^0_m, the value of θ_m associated with K_1 and K_2. In the present problem θ_m was constant over the data range in the fashion indicated qualitatively by Figure 3. As noted in Fig. 3, data are always taken from forward leaning loops. In case $K_2 > K_1$, Eq. 13 and Fig. 3 may require modification. Upon computing

$$\lim_{\substack{r_m \to 0 \\ \theta_m \to \theta^0_m}} \left\{(8\pi r_m)^{1/2} \frac{\partial (\tau)^{nz}_{max}}{\partial \theta} \left(K_1, K_2, r_m, \theta_m, \sigma^0_{ij}\right)\right\} = 0 \quad (15)$$

one obtains

$$\left(\frac{K_2}{K_1}\right)^2 - \frac{4}{3}\left(\frac{K_2}{K_1}\right) \cot 2\theta^0_m - \frac{1}{3} = 0 \quad (16)$$

Since θ^0_m can be measured experimentally, (K_2/K_1) can be calculated from equation (16). Then by combining the Stress-Optic Law with a modified form of Equation (13)

$$(\tau)^{nz}_{max} = \frac{fn'}{2t'} = \quad (17)$$

where $K^*_{AP} = (\tau)^{nz}_{max}(8\pi r)^{1/2}$ is the "apparent" SIF, f is the material fringe value, n' is the fringe order, and t' is the slice thickness, hence

$$K^*_{AP} = \Big[(K_{1AP}\sin\theta_m + 2K_{2AP}\cos\theta_m)^2 + (K_{2AP}\sin\theta_m)^2\Big]^{1/2} \tag{18}$$

and one can solve for the individual values of K_1 and K_2.

In order to do this, one must obtain

$$K^* = \Big[(K_1 \sin\theta^0_m + 2K_2 \cos\theta^0_m)^2 + (K_2 \sin\theta^0_m)^2\Big]^{1/2} \tag{19}$$

from K^*_{AP} by plotting $K^*_{AP} = (\tau)^{nz}_{max}(8\pi r)^{1/2}$ vs $(r/a)^{1/2}$ identifying a linear zone, and extrapolating to the origin. This will yield K^*. A typical set of fringe data illustrating such a determination is given in Figure 4. Once K^*, K_2/K_1, and θ^0_m are known, K_1 and K_2 can be calculated which then can be normalized using proper quantities.

Note that the above approach utilizes a two parameter (A,B) model since the linear zone can be located experimentally (Figure 4). However, if one cannot locate such a zone experimentally then additional terms leading to an equation of the form

$$(\tau)^{nz}_{max} = \frac{A}{r^{1/2}} + \sum_{n=0}^{\infty} B_n r^{n/2} \tag{20}$$

with suitable truncation criteria must be considered.

Since such criteria are not yet established independent of experiment, this latter approach is avoided where possible and was not necessary in the studies described in the sequel.

The stress distribution (σ_{tt}), acting in a plane perpendicular to the crack surface and tangent to the crack front (zt plane) or in a plane parallel to the zt plane can be found from equations (9)–(10).

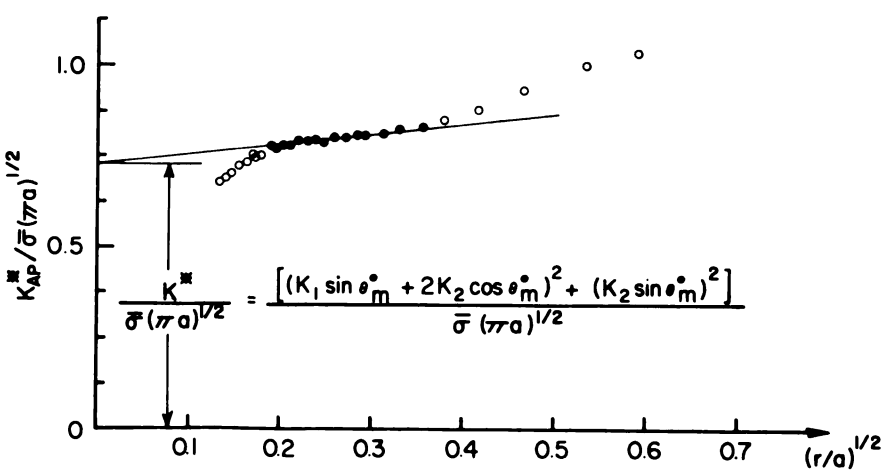
$$\sigma_{zz} = \frac{K_1}{(2\pi r)^{1/2}}\cos\frac{\theta}{2}\left[1+\sin\frac{\theta}{2}\sin\frac{3\theta}{2}\right] + \frac{K_2}{(2\pi r)^{1/2}}\sin\frac{\theta}{2}\left[\cos\frac{\theta}{2}\cos\frac{3\theta}{2}\right] - \sigma^0_{zz} \tag{21}$$

In order to arrive at a value of σ_{tt}, prior experiments by the authors indicate that the usual assumption of plane strain (for the plane problem) may not be valid here. However, if one assumes a state of nearly *generalized* plane strain such that the value of $\mathcal{E}_{tt}$ can be considered constant over a portion of the length of the flaw border, then the observed state of varying transverse contraint along the flaw border can apparently be approximated rather well. Thus, we assume

$$\mathcal{E}_{tt} = \frac{\sigma_{tt} - \nu(\sigma_{nn} + \sigma_{zz})}{E} \simeq \bar{\mathcal{E}} \tag{22}$$

whence $\sigma_{tt} \simeq E\bar{\mathcal{E}} + \nu(\sigma_{nn} + \sigma_{zz})$ where $\bar{\mathcal{E}}$ may be adjusted at intervals along the flaw border and where, again from equation (10),

$$\sigma_{nn} = \frac{K_1}{(2\pi r)^{1/2}}\cos\frac{\theta}{2}\left[1-\sin\frac{\theta}{2}\sin\frac{3\theta}{2}\right] - \frac{K_2}{(2\pi r)^{1/2}}\sin\frac{\theta}{2}\left[2+\cos\frac{\theta}{2}\cos\frac{3\theta}{2}\right] - \sigma^0_{nn} \tag{23}$$



4. Det- -tion of K^* from test data. $\bar{\sigma}$ is the remote normal s' z' direction in Fig. 2.

For $\nu = (1/2)$ (as in the present experiments) we then have

$$\sigma_{tt} = \frac{K_1}{(2\pi r)^{1/2}}\cos\frac{\theta}{2} - \frac{K_2}{(2\pi r)^{1/2}}\sin\frac{\theta}{2} - \sigma_{tt}^0 + E\bar{\mathcal{E}} \quad (24)$$

Moreover, from Mode III, we have

$$\tau_{zt} = \frac{K_3}{(2\pi r)^{1/2}}\cos\frac{\theta}{2} - \tau_{zt}^0 \quad (25)$$

$$(\tau)_{max}^{zt} = \left[\left(\frac{\sigma_{zz} - \sigma_{tt}}{2}\right)^2 + \tau_{zt}^2\right]^{1/2} \quad (26)$$

Consider the line normal to the crack surface which passes through the crack tip in the zt plane. For this case $\theta = (\pi/2)$, and when substituted in equations (21), (24) and (25), there results

$$\sigma_{zz} = \frac{1}{4(\pi r)^{1/2}}[3K_1 - K_2] - \sigma_{zz}^0 \quad (27)$$

$$\sigma_{tt} = \frac{1}{2(\pi r)^{1/2}}[K_1 - K_2] - \sigma_{tt}^0 + E\bar{\mathcal{E}} \quad (28)$$

$$\tau_{zt} = \frac{K_3}{2(\pi r)^{1/2}} - \tau_{zt}^0 \quad (29)$$

then for a two parameter model as before,

$$(\tau)_{max}^{zt} = \frac{C}{r^{1/2}} + D \quad (30)$$

where

$$C = \frac{1}{(4\pi)^{1/2}}\left[\frac{1}{16}(K_1 + K_2)^2 + K_3^2\right]^{1/2} \quad (31)$$

and

$$D = D\left(E\bar{\mathcal{E}},\ \sigma_{ij}^0\right) \quad (32)$$

Now by combining the Stress-Optic Law with a modified form of equation (30)

$$(\tau)_{max}^{zt} = \frac{fn'}{2t'} = \frac{K_{AP}^{**}}{(8\pi r)^{1/2}} \quad (33)$$

where

$$K_{AP}^{**} = \left\{2\left[\frac{1}{16}(K_{1AP} + K_{2AP})^2 + K_{3AP}^2\right]\right\}^{1/2} \quad (34)$$

the value of K_3 can be obtained.

In order to do this, one must obtain

$$K^{**} = \left[2\left\{\frac{1}{16}(K_1 + K_2)^2 + K_3^2\right\}\right]^{1/2} \quad (35)$$

from K_{AP}^{**} by plotting a $K_{AP}^{**} = (\tau)_{max}^{zt}(8\pi r)^{1/2}$ vs $(r/a)^{1/2}$ curve, identifying a linear zone, and extrapolating to the origin. This will yield K^{**}.

At the points where the flaw border intersects the boundary of the plate, SIF values are uncertain and require a boundary layer analysis for an accurate evaluation.

(B) Methods for Increasing Fringe Sensitivity

Due to the lack of stiffness of the material above critical temperature, it is necessary to keep loads small in the frozen stress experiments in order to avoid finite deformations near the crack tip. Moreover, the slices which are removed from the stress frozen body which are oriented normal to the crack plane locally and the t direction will be quite thin ($t' < 0.5mm$). These limitations result in only a few stress fringes near the crack tip. In order to increase the number of fringes, two special techniques, the method of Tardy (1929) and the fringe multiplication method of Post (1966) are applied in tandem. In this way one fiftieth of a fringe is routinely measured, providing ample data near the crack tip.

Finally, as noted earlier, the value of Poisson's Ratio for stress freezing materials is nearly one half. No correction is made for this deviation from metals but it may slightly influence the results towards the locally plastic situation which actually exists in metals.

III - GENERAL APPROACH

Given a general cracked body problem with all three local modes of deformation, the general procedure for obtaining SIF distributions along the flaw border would be the following:

a) Construct transparent model from stress freezing material.

b) Insert crack of desired shape and size in desired location. Natural starter cracks can be made by striking a sharp blade held against the body surface with a hammer. Then the crack may be grown above critical temperature to desired size without knowing the crack shape a-priori. The shape is dictated by body shape and load orientation.

c) Reduce load required to grow the crack to stop growth and cool to room temperature.

d) Remove thin slices mutually orthogonal to flaw border and its surface at intervals along the flaw border and analyze photoelastically with polarized light directed along the t axis as in Fig. 3 for θ_m^0 and K_{AP}^*, and obtain K^* from Fig. 4. Then solve Eqs. 16 and 19 for K_1 and K_2.

e) Then remove a sub-slice from each main slice and analyze photoelastically with the polarized light directed along the n axis. Then using Eqs. (33)–(34) as described above determine K^{**} graphically and finally K_3 from Eq. (35).

Although the method can be applied to artificial cracks of pre-determined shape and size where a sharp (< 30°) vee notch is used to simulate the crack, it can also be used as described in (b) to generate the crack shape and size where neither are known a-priori.

IV - APPLICATION OF THE METHOD TO ENGINEERING PROBLEMS

When cracks grow in isotropic, homogeneous materials, the crack path follows the plane of the maximum principal tensile stress with only rare exceptions (Smith and Weirsma, 1986). Thus, once the crack begins to grow, it exhibits only Mode I locally. However, if a crack is loaded in a different way from that creating it, mixed modes may be present and cause the crack to change direction so as to recover Mode I during growth. In order to illustrate the application of the method to several different kinds of problems, three examples have been selected:

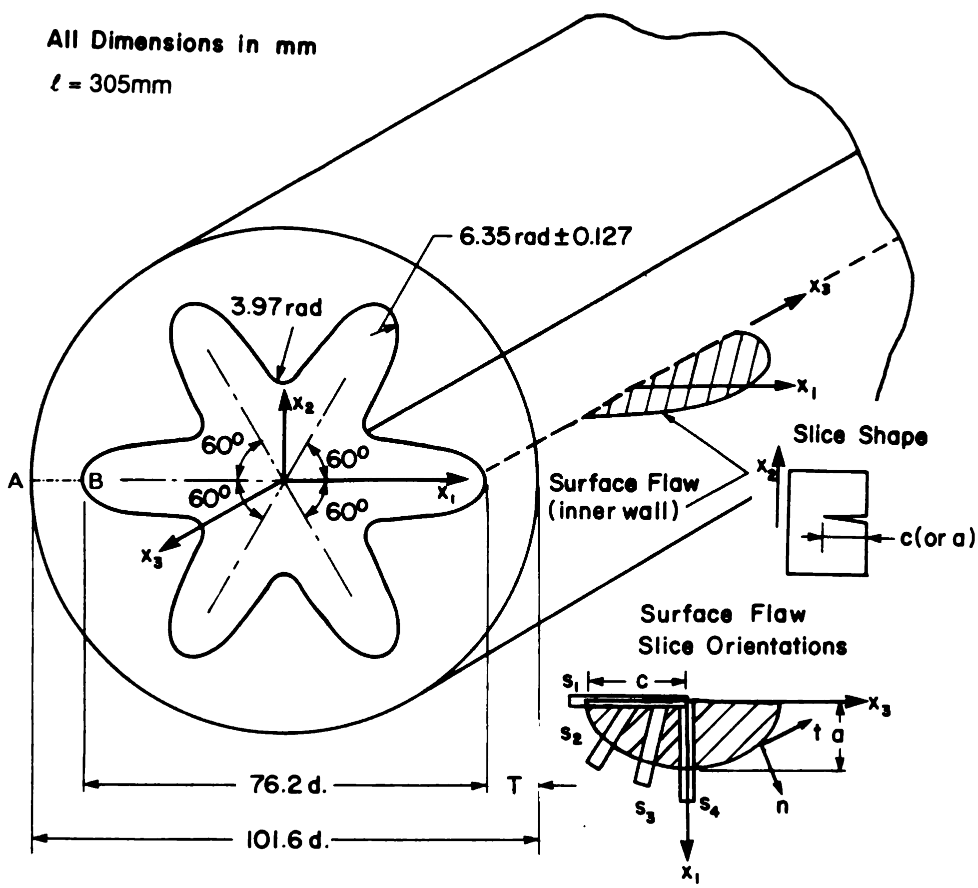
i) Surface crack growing in a rocket motor grain model (Mode I).

ii) Crack emanating from a hole filled with a rigid pin (Modes I and II).

iii) Circumferential crack in cylinder under pure torsion (Mode III).

Example 1

i) Crack in Rocket Motor Grain Model (Mode I)
Cracked test models as shown in Fig. 5 were loaded with internal pressure. This produced pure Mode I loading on the semi-elliptic crack surfaces. A typical Mode I stress fringe pattern for a slice prior to fringe multiplication or further enhancement is shown in

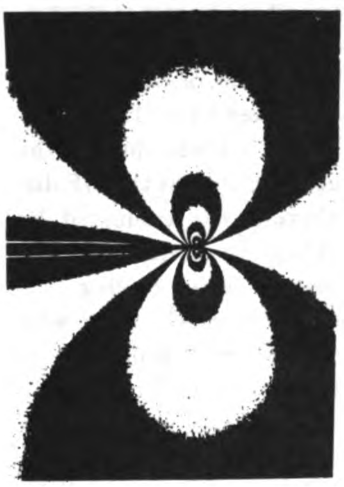


5. Cracked motor grain model and frozen slice orientation.

Fig. 6. Since the fringes spread approximately normal to the crack plane we can set $\theta = \pi/2$ in Eq. (14), and, if we replace σ_{ij}^0 with τ_0, the non-singular maximum shear stress resulting from σ_{ij}^0, Eq. 13 becomes:

$$(\tau)^{nz}_{max} = \frac{K_1}{(8\pi r)^{1/2}} + \tau_0 \quad \text{or} \tag{36}$$

$$(\tau)^{nz}_{max}(8\pi r)^{1/2} = K_1 + (8\pi)^{1/2}\tau_0 r^{1/2} \tag{37}$$

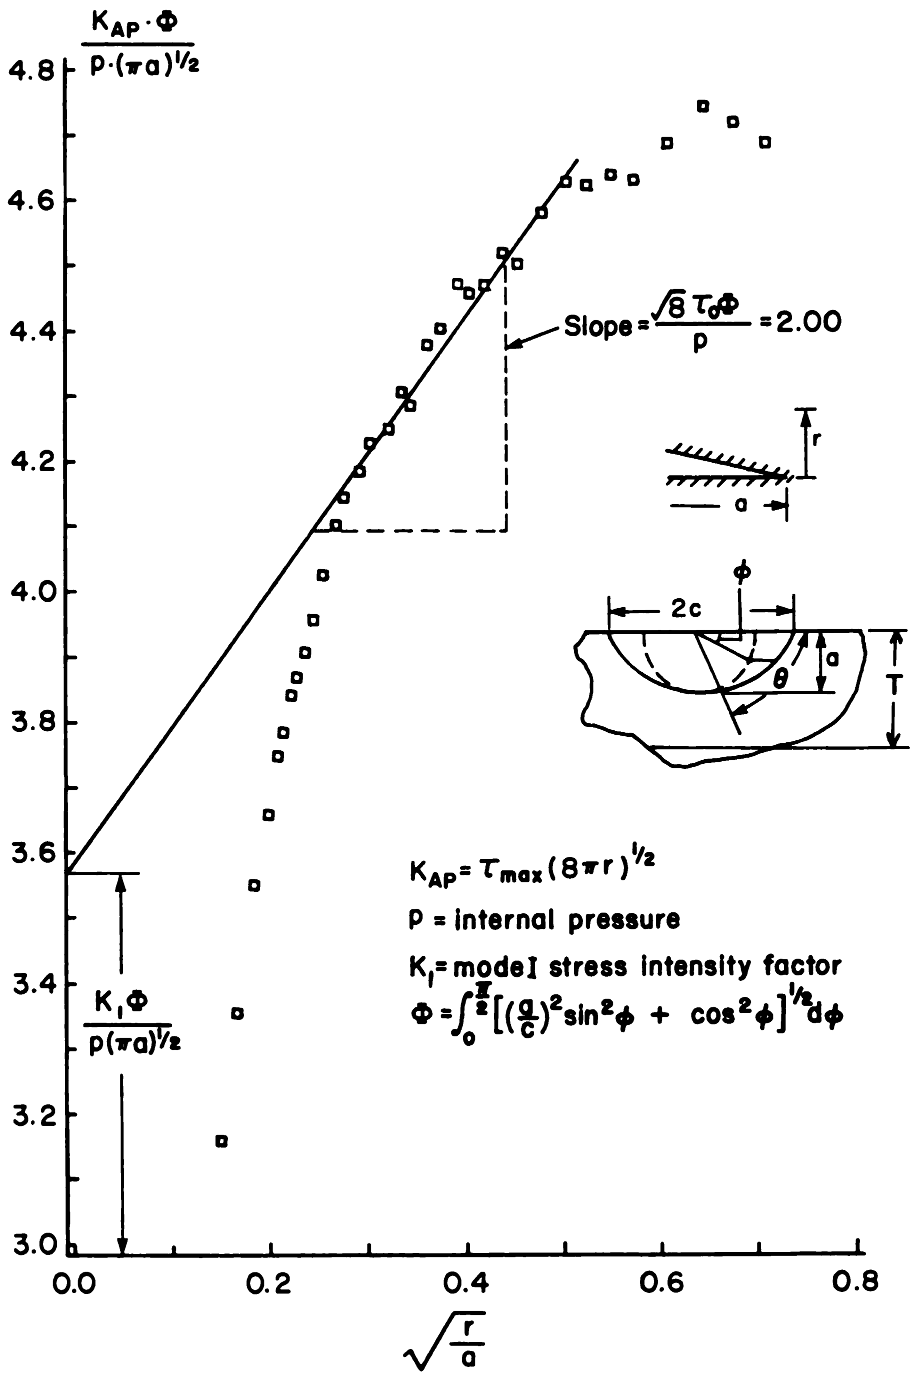


6. Mode I stress fringe pattern.

So if we define $K_{AP} = (\tau)^{nz}_{max}\,(8\pi r^{1/2})$, the apparent SIF, and normalize with respect to $\rho(\pi a)^{1/2}/_{\Phi}$ where ρ is the internal pressure, a the crack depth, and Φ is an elliptic integral defined in Fig. 7 which is known as the shape factor for a semi-elliptic crack, then

$$\frac{K_{AP}\Phi}{\rho(\pi a)^{1/2}} = \frac{K_1\Phi}{\rho(\pi a)^{1/2}} + \frac{(8)^{1/2}}{\rho}\tau_0\Phi\left(\frac{r}{a}\right)^{1/2} \tag{38}$$

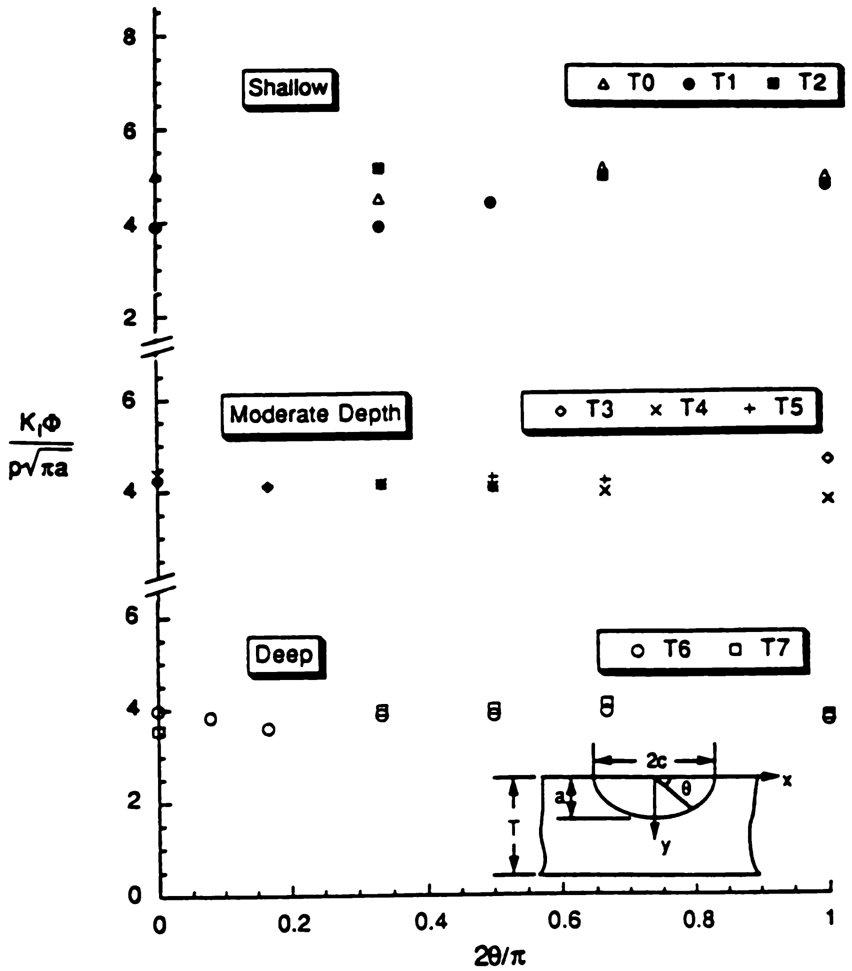
Along $\theta = \pi/2$, we measure n' which determines τ^{nz}_{max} (Eq. 17) and corresponding values of r which allow computation of K_{AP}. Now, if one plots $\frac{K_{AP}\Phi}{\rho(\pi a)^{1/2}}$ vs $\left(\frac{r}{a}\right)^{1/2}$, a straight line results, the intercept of which is the normalized SIF, or K_1. Such a plot is shown in Fig. 7. In order to locate the appropriate linear zone in a three dimensional problem, such plots must be



7. Determination of normalized SIF from test data.

obtained for several slices along the flaw border. The zone which is common to all slices usually lies between $\sqrt{r/a}$ of 0.2 and 0.4 (or greater). (Smith, et al, 1984.)

For cracks located on the axis of symmetry of the star finger, the crack remained planar as it grew but its aspect ratio, (a/c)(Fig. 7) changed somewhat and the data and resulting SIF distributions for several crack sizes are given in Fig. 8, suggesting that the cracks adjust their shapes during growth to maintain a nearly constant SIF along the flaw border. However, if cracks are initiated off of the axis of symmetry of the star finger, (Fig. 9) the surface orientation and SIF curves vary (Fig. 10). Crack E-2 broke through the outer surface but the SIF distribution was estimated by holding the internal pressure constant during cooling. When the crack paths were compared with principal planes obtained from uncracked frozen stress models at the crack midpoints, the paths were found to closely follow principal planes. Some details are found in Smith and Wang, (1992).



Test No.	a(mm)	a/c	a/T	Φ^1	p(KPa)^2
T0	3.6	.54	.28	1.23	26.9
T1	3.2	.52	.25	1.22	47.6
T2	4.1	.55	.32	1.24	47.6
T3	6.2	.46	.45	1.18	47.6
T4	6.6	.52	.52	1.22	42.1
T5	7.3	.43	.56	1.16	47.6
T6	8.4	.44	.66	1.17	47.6
T7	7.9	.45	.62	1.17	47.6

9. Crack shapes and notations for unsymmetric cracks.

Example 2

ii) Crack Emanating From Edge of Pin Loaded Hole (Modes I and II)

The test specimen and loading arrangement for this problem is pictured in Fig. 11. Only two slices [S] and [H] were removed and analyzed for the cracks which were planar as inserted and were not grown. The stress fringe patterns at H revealed a pure Mode I signature as shown in Fig. 6. However, at S, a mixed mode signature was obtained of the form sketched in Fig. 3. A typical set of results showing only the linear data is shown in Fig. 12 where $K_H^* = (K_1)_H$ since $(K_2)_H = 0$. K^* values were obtained as described earlier using Eqs. (17)–(19). Results, when compared with experiments on open holes showed that K_{1S} with the pin was two to four times that without the pin and K_{1H} with the pin was two to five times the value of K_{1H} without the pin. Details are given by Smith, Jolles and Peters, (1977).

Example 3

iii) Circumferential Crack Under Pure Torsional Load (Mode III)

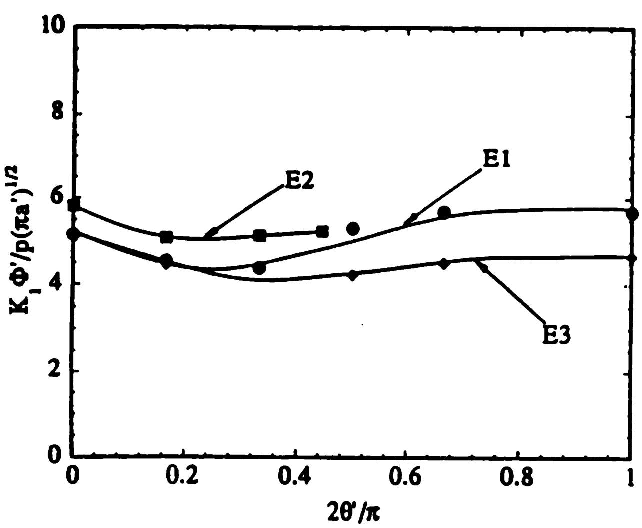
A sharp circumferential notch (Fig. 13a) was cut into a 5.08 cm. diameter cylinder and stress frozen under a torsional load. Thin slices were removed oriented as shown in Fig. 13b. The polarized light field and observations of fringes were made along the n axis. A typical fringe pattern is shown in Fig. 14. Since K_1 and K_2 were zero, K_3 was obtained directly from a plot of Eq. (29) after normalizing with respect to the remote shear stress $\bar{\tau}$ times $(\pi a)^{1/2}$, that is:

$$\frac{K_{AP}}{\bar{\tau}(\pi a)^{1/2}} = \frac{K_3}{\bar{\tau}(\pi a)^{1/2}} - \frac{2\tau_{zt}^{o}}{\bar{\tau}}\left(\frac{r}{a}\right)^{1/2} \quad (39)$$

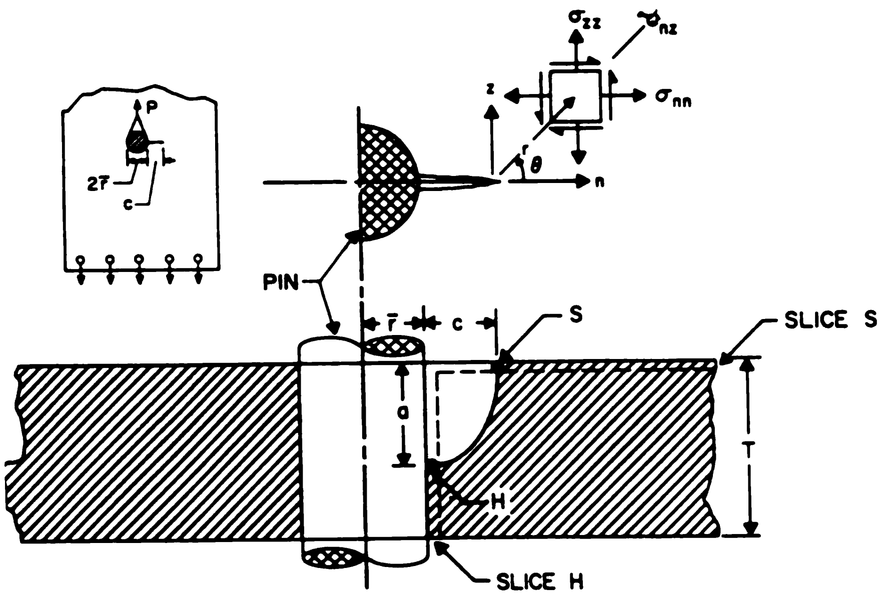
where $K_{AP} = \tau_{max}^{zt}(4\pi r)^{1/2}$. Again the fringe order n' (Eq. 17) and r are measured along $\theta = \pi/2$. Fig. 15 compares the results with other analyses. Details are furnished by Smith and Hardrath (1978).

Test No.	a'(mm)	a'/c	a'/T'[1]	Φ·2	p(Kpa)[3]
E1	11.4	0.62	0.88	1.29	41.4
E2	13.1	0.69	1.0	1.33	41.4
E3	7.95	0.65	0.61	1.30	41.4

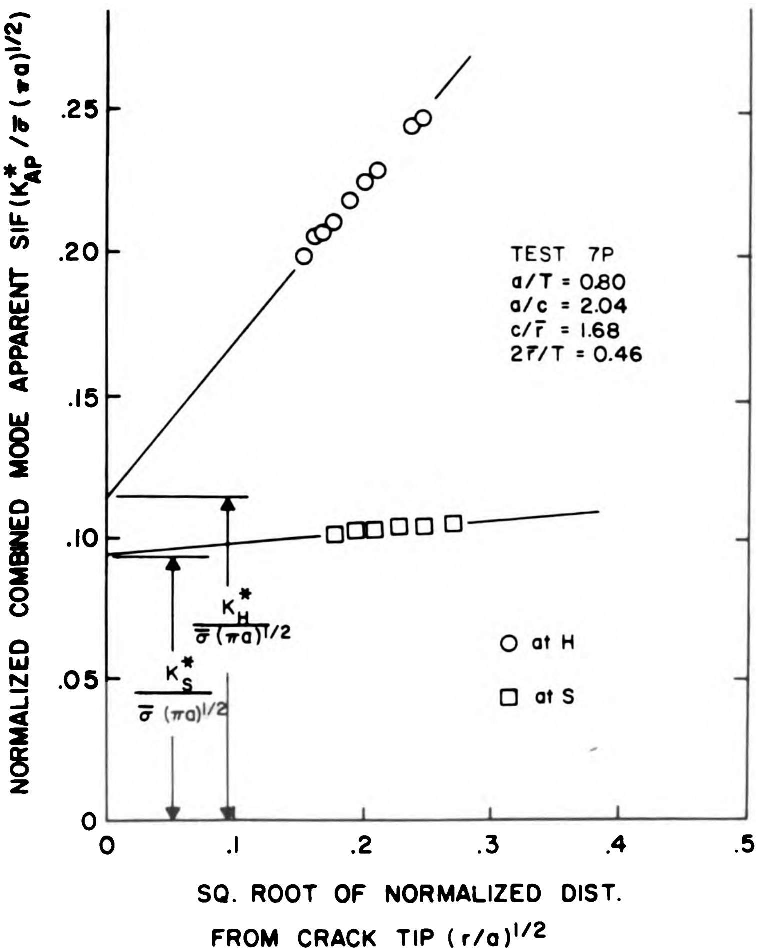
1. T' is measured along a' to the outer boundary of the cylinder.
2. $\Phi' = \int_0^{\pi/2}\left[\left(\frac{a'}{c}\right)^2 \sin^2\phi' + \cos^2\phi'\right]^{1/2} d\phi'$.
3. p is the internal pressure.



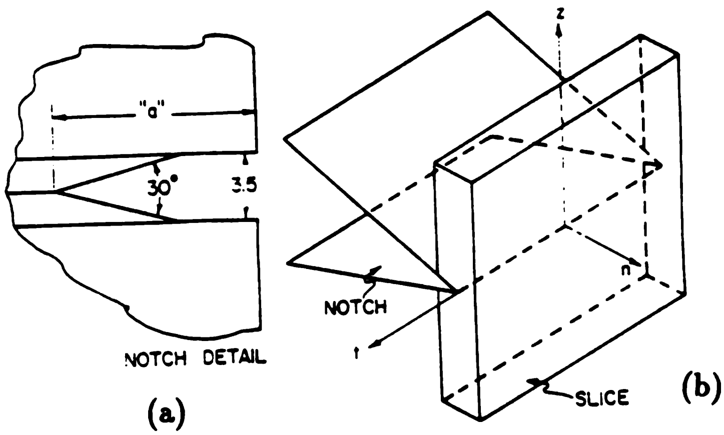
10. Data and SIF distributions for unsymmetric cracks.



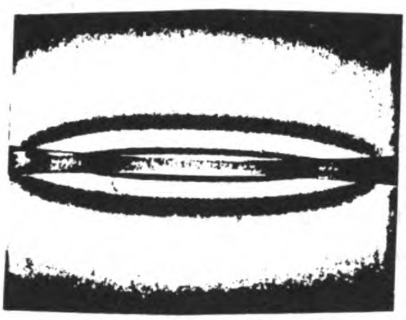
11. Loading and slice locations for pin loaded, cracked hole.



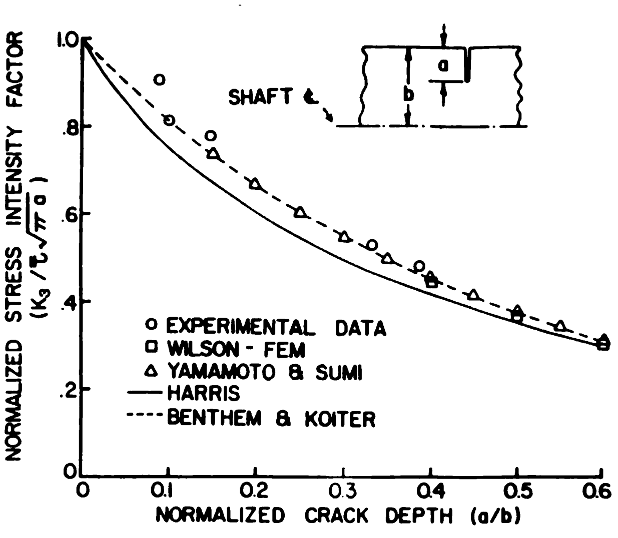
12. Normalized values for K^*_s and K^*_H for pin loaded cracked hole.



13. (a) Notch tip geometry
(b) Slice orientation for circumferentially cracked torsion bar.



14. Mode III stress fringe pattern for slice from circumferentially cracked torsion bar.



15. Comparisons of Mode III results.

SUMMARY

A modelling procedure based on frozen stress photoelasticity which has proven to be cost effective compared to full scale testing was described for estimating stress intensity factor distributions in a variety of three dimensional problems, even when the crack shape was not known a-priori. It is limited to LEFM and, while errors are normally less than 5% for Mode I problems, they may exceed 10% for shear mode results when all three modes are acting. Moreover the method does not accommodate significant amounts of plasticity. Nevertheless, it has found substantial use in supporting numerical analysis and improving the formulation of numerical solutions for a variety of three dimensional problems.

Implementation of viscoelastic behavior in a time domain boundary element formulation

M Schanz and L Gaul

University of the Federal Armed Forces Hamburg
Postfach 70 08 22, D-22008 Hamburg, Federal Republic of Germany

The boundary element method (BEM) provides a powerful tool for the calculation of elastodynamic response in frequency and time domain. Field equations of motion and boundary conditions are cast into integral equations, which are discretized only at the boundary. The boundary data often are of primary interest because they govern the transfer dynamics of members and the energy radiation into a surrounding medium. Formulations of BEM currently include conventional viscoelastic constitutive equations in the frequency domain. In the present paper viscoelastic behaviour is implemented in a time domain approach as well. The constitutive equations are generalized by taking fractional order time derivatives into account.

INTRODUCTION

It is well known that the boundary element method (BEM) reduces the dimension of a boundary value problem by one. The variables in the domain of a 3–d problem are for example governed by the surface variables on the 2–d boundary via the boundary integral equation which includes the boundary conditions. The BEM provides a powerful tool for the 3–d calculation of elastodynamic response in frequency and time domain because in space only the boundary has to be discretized. The boundary data are CAD compatible and detailed constitutive properties can be modelled (Beskos D. E., 1987, Gaul L., 1990). Domain variables can be determined at arbitrary locations from the complete boundary data. If infinite (fullspace 3–d) or semi infinite (halfspace 3–d) domains are treated, no artificial boundaries with non reflecting boundary conditions need to be introduced. This is why the Sommerfeld radiation condition is fulfilled by the so called fundamental solution of the boundary integral equation. Formulations of BEM currently include conventional viscoelastic constitutive equations in the frequency domain. One aim of the present paper is to implement viscoelastic behaviour in a time domain approach as well. The elastic Stokes fundamental solution is converted to a viscoelastic one by adopting a correspondence principle. A novel viscoelastic fundamental solution is obtained analytically by inverse Laplace transformation. Viscoelastic constitutive equations are generalized by taking fractional order time derivatives into account (Gaul L., Schanz M., Fiedler C., 1992).

INTEGRAL EQUATION OF ELASTODYNAMICS

For consistency the boundary integral equation describing elastodynamics in time domain is recalled. The field equations of a homogeneous elastic domain Ω with boundary Γ are given by

$$\left(c_1^2 - c_2^2\right) u_{i,ij} + c_2^2\, u_{j,ii} + b_j = \ddot{u}_j \tag{1}$$

with displacement coordinates u_j and wave speeds

$$c_1^2 = \frac{K + \frac{4}{3}G}{\varrho}, \qquad c_2^2 = \frac{G}{\varrho} \tag{2}$$

with given boundary conditions

$$\begin{aligned} t_{(n)i}(\mathbf{x},t) = \sigma_{ik} n_k = p_i(\mathbf{x},t) \qquad & \mathbf{x} \in \Gamma_t, \\ u_i(\mathbf{x},t) = q_i(\mathbf{x},t) \qquad & \mathbf{x} \in \Gamma_u \end{aligned} \tag{3}$$

and initial conditions

$$\begin{aligned} u_i(\mathbf{x},0) &= u_{0i}(\mathbf{x}), \\ \dot{u}_i(\mathbf{x},0) &= v_{0i}(\mathbf{x}) \qquad \mathbf{x} \in \Omega. \end{aligned} \tag{4}$$

The 3-d Stokes fundamental solution of the Lamé equation (1) in an unbounded space, excited by $b_j(\mathbf{x},t) = \delta(t-\tau)\,\delta(\mathbf{x}-\boldsymbol{\xi})\,e_j$ is given by (e.g. (Eringen A. C., Suhubi E. S., 1975))

$$\begin{aligned} \tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t) = \; & \frac{1}{4\pi\varrho}\left\{\frac{t}{r^2}\left(\frac{3r_ir_j}{r^3} - \frac{\delta_{ij}}{r}\right)\cdot\right. \\ & \cdot \left[H\left(t-\frac{r}{c_1}\right) - H\left(t-\frac{r}{c_2}\right)\right] \\ & + \frac{r_ir_j}{r^3}\left[\frac{1}{c_1^2}\,\delta\left(t-\frac{r}{c_1}\right) - \frac{1}{c_2^2}\,\delta\left(t-\frac{r}{c_2}\right)\right] \\ & \left. + \frac{\delta_{ij}}{rc_2^2}\;\delta\left(t-\frac{r}{c_2}\right)\right\} \end{aligned} \tag{5}$$

where $r = \sqrt{r_ir_i}$, $r_i = x_i - \xi_i$. The corresponding fundamental traction vector components are obtained from

Eq. (3) after replacing the stresses by strains and displacements

$$\tilde{t}_{(n)ij} = \varrho\left(c_1^2 - 2c_2^2\right)\tilde{u}_{jm,m}\delta_{ik}n_k + \varrho c_2^2\left(\tilde{u}_{ji,k}n_k + \tilde{u}_{jk,i}n_k\right) \tag{6}$$

with the outward normal n_k.

The dynamic extension of Betti's reciprocal work theorem combining two states of displacements and tractions $(\tilde{u}_{ij}, \tilde{t}_{(\mathbf{n})ij})$ and $(u_{ij}, t_{(\mathbf{n})ij})$ leads to the integral equation

$$\varepsilon_{ij}(\xi)\, u_j(\xi, t) = \int_\Gamma \left[\tilde{u}_{ij} * t_{(n)j} - \tilde{t}_{(n)ij} * u_j\right] d\Gamma + \int_\Omega \varrho\left[\tilde{u}_{ij} * b_j + \tilde{u}_{ij} v_{0j} + \dot{\tilde{u}}_{ij} u_{0j}\right] d\Omega \tag{7}$$

where $*$ denotes the convolution with respect to time and $\varepsilon_{ij}(\xi) = \frac{\delta_{ij}}{2}$ for a smooth boundary. Initial conditions being zero and vanishing volume forces reduce (7) to a boundary integral equation. As a prerequisite for a later application of a correspondence principle, the Laplace transform of the fundamental solution (5) is given as

$$\begin{aligned} \tilde{u}_{ij}(\mathbf{x}, \xi, s) = \; & \frac{1}{4\pi\varrho}\left\{\frac{1}{r^2}\left(\frac{3r_i r_j}{r^3} - \frac{\delta_{ij}}{r}\right)\cdot\right. \\ & \cdot\left[\frac{s\frac{r}{c_1} + 1}{s^2} \quad e^{-\frac{r}{c_1}s} - \frac{s\frac{r}{c_2} + 1}{s^2} \quad e^{-\frac{r}{c_2}s}\right] \\ & + \frac{r_i r_j}{r^3}\left[\frac{1}{c_1^2} \quad e^{-\frac{r}{c_1}s} - \frac{1}{c_2^2} \quad e^{-\frac{r}{c_2}s}\right] \\ & \left. + \frac{\delta_{ij}}{r c_2^2} e^{-\frac{r}{c_2}s}\right\}. \end{aligned} \tag{8}$$

GENERALIZED VISCOELASTIC CONSTITUTIVE EQUATIONS

Linear constitutive equations are assumed to describe the propagation of small disturbances. Elastic–viscoelastic correspondence principles convert Hooke's law of elasticity

$$s_{ij} = 2Ge_{ij} \qquad \sigma_{ii} = 3K\varepsilon_{ii}, \tag{9}$$

with shear and bulk moduli G, K respectively to viscoelastic laws by adopting the differential operator concept or the hereditary integral concept (Flügge W., 1975). More flexibility in fitting measured data in a large frequency range with less parameters and lower order time derivatives is obtained by replacing integer order time derivatives in differential operator formulations by fractional order time derivatives.

The derivative of fractional order α

$$\frac{d^\alpha \varepsilon(t)}{dt^\alpha} = \frac{1}{\Gamma(1-\alpha)}\frac{d}{dt}\int_0^t \frac{\varepsilon(t-\tau)}{\tau^\alpha}d\tau \qquad 0 \le \alpha < 1 \tag{10}$$

defined with the gamma function

$$\Gamma(1-\alpha) = \int_0^\infty e^{-x} \tag{11}$$

is the inverse operation of fractional integration attributed to Riemann and Liouville (Ross B., 1977). It can be shown that the definition by Grünwald (Grünwald A. K., 1867)

$$\frac{d^\alpha \varepsilon(t)}{dt^\alpha} = \lim_{N\to\infty}\left\{\left(\frac{t}{N}\right)^{-\alpha}\sum_{j=0}^{N-1}\frac{\Gamma(j-\alpha)}{\Gamma(-\alpha)\Gamma(j+1)}\cdot \cdot\varepsilon\left[t\left(1-\frac{j}{N}\right)\right]\right\} \tag{12}$$

is equivalent and more convenient in constitutive equations treated by time–stepping algorithms. The generalized viscoelastic constitutive equations of differential operator type

$$\begin{aligned} \sum_{k=0}^{N} p_k' \frac{d^{\alpha_k}}{dt^{\alpha_k}} s_{ij} &= \sum_{k=0}^{M} q_k' \frac{d^{\alpha_k}}{dt^{\alpha_k}} e_{ij}, \\ \sum_{k=0}^{N} p_k'' \frac{d^{\alpha_k}}{dt^{\alpha_k}} \sigma_{ii} &= \sum_{k=0}^{M} q_k'' \frac{d^{\alpha_k}}{dt^{\alpha_k}} \varepsilon_{ii} \end{aligned} \tag{13}$$

correspond to Hooke's law (9).

As defined by Eq. (10) the fractional derivative appears complicated in time domain. However both Laplace and Fourier transforms reveal the useful results

$$\begin{aligned} \mathcal{L}\{\frac{d^\alpha}{dt^\alpha}\varepsilon(t)\} &= s^\alpha \mathcal{L}\{\varepsilon(t)\} = s^\alpha \bar{\varepsilon}(s), \\ \mathcal{F}\{\frac{d^\alpha}{dt^\alpha}\varepsilon(t)\} &= (i\omega)^\alpha \mathcal{F}\{\varepsilon(t)\}. \end{aligned} \tag{14}$$

Laplace transformation converts Eq. (13) to

$$\begin{aligned} \mathcal{P}'(s)\,\bar{s}_{ij} &= \mathcal{Q}'(s)\,\bar{e}_{ij}, \\ \mathcal{P}''(s)\,\bar{\sigma}_{ii} &= \mathcal{Q}''(s)\,\bar{\varepsilon}_{ii}, \end{aligned} \tag{15}$$

with e.g. $\mathcal{P}' = \sum_{k=0}^{N} p_k' s^{\alpha_k}$ and vanishing initial conditions.

NEW VISCOELASTIC FUNDAMENTAL SOLUTION IN TIME DOMAIN

The correspondence principle replaces the elastic moduli according to

$$3K \to \frac{\mathcal{Q}''(s)}{\mathcal{P}''(s)}, \qquad 2G \to \frac{\mathcal{Q}'(s)}{\mathcal{P}'(s)} \tag{16}$$

and leads to the transformed wave speeds

$$c_{1v}^2 = \frac{1}{\varrho}\left[\frac{1}{3}\frac{\mathcal{Q}''(s)}{\mathcal{P}''(s)} + \frac{2}{3}\frac{\mathcal{Q}'(s)}{\mathcal{P}'(s)}\right], \qquad c_{2v}^2 = \frac{1}{\varrho}\frac{1}{2}\frac{\mathcal{Q}'(s)}{\mathcal{P}'(s)}, \tag{17}$$

for a viscoelastic domain.

The rheological Maxwell model of a spring and dashpot in series (Fig. 1) with spring and damping coefficients $3K, F_K$ respectively corresponds to the constitutive equation (e.g. hydrostatic state)

$$\dot{\sigma}_{ii} + \gamma\sigma_{ii} = 3K\dot{\varepsilon}_{ii} \qquad \gamma = \frac{3K}{F_K}. \tag{18}$$

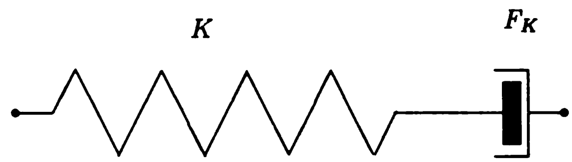

Figure 1: Maxwell model

The correspondence (16) leads to

$$3K \to \frac{3Ks}{s+\gamma}, \qquad 2G \to \frac{2Gs}{s+\gamma} \qquad \gamma = \frac{3K}{F_K} = \frac{2G}{F_G}, \tag{19}$$

if it is assumed for simplicity, that the same damping mechanism holds for the deviatoric and the hydrostatic state. This assumption relates the transformed viscoelastic wave speeds to the elastic ones according to

$$c_{1v}^2 = c_1^2 \frac{s}{s+\gamma}, \qquad c_{2v}^2 = c_2^2 \frac{s}{s+\gamma}. \tag{20}$$

The Laplace transformed viscoelastic fundamental solution is obtained by substituting the elastic wave speeds in (8) by the viscoelastic ones in (20).

A new fundamental solution has been calculated by inverse Laplace transformation. Details of the calculation, based on the theory of residues and integration along a modified Bromwich contour to assure a unique definition of complex roots, are omitted for the sake of brevity. The analytical solution is given by

$$\begin{aligned}\tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t) = \frac{1}{4\pi\varrho}\Bigg\{ & \frac{1}{r^2}\left(\frac{3r_ir_j}{r^3} - \frac{\delta_{ij}}{r}\right) \\ & \cdot\left[C_1(t) + \frac{r}{c_1}D_1(t) - \left(C_2(t) + \frac{r}{c_2}D_2(t)\right)\right] \\ & + \frac{r_ir_j}{r^3}\left[\frac{1}{c_1^2}A_1(t) + \frac{\gamma}{c_1^2}B_1(t) - \left(\frac{1}{c_2^2}A_2(t) + \frac{\gamma}{c_2^2}B_2(t)\right)\right] \\ & + \frac{\delta_{ij}}{rc_2^2}\left(A_2(t) + \gamma B_2(t)\right)\Bigg\}\end{aligned} \tag{21}$$

where the functions $A_\beta, B_\beta, C_\beta$ and D_β are given in the appendix. Inserting the new viscoelastic fundamental solution (21) in Eq. (6) leads to the viscoelastic fundamental solution of the traction vector components.

Different viscoelastic constitutive equations, including those with fractional time derivatives, can be treated as well. In general this requires numerical integration of the inverse Laplace integral.

VISCOELASTIC FORMULATIONS OF BEM IN TIME DOMAIN

The integral equation (7) reduces to a boundary integral equation for vanishing volume forces b_j and initial conditions. Discretization in space and time leads to the boundary element formulation. Only the time discretization by n equal steps Δt is discussed. For simple constitutive equations the aim is to integrate the convolution terms analytically. Linear shape functions for the displacements u_i and constant shape functions for the tractions t_i in time domain

$$\begin{aligned} u_i(\mathbf{x},\tau) &= \left(U_{il}^{m-1}\frac{t_m - \tau}{\Delta t} + U_{il}^m \frac{\tau - t_{m-1}}{\Delta t}\right)\eta_l(\mathbf{x}) \\ t_i(\mathbf{x},\tau) &= 1 \cdot T_{il}^m \cdot \mu_l(\mathbf{x}) \end{aligned} \tag{22}$$

are the simplest choice such that no terms drop out in the boundary integral equation. The actual time step is m; U_{il}^m, T_{il}^m are the nodal values at time $t_m = m\Delta t$ for the corresponding boundary element Γ_l. Inserting (22) reduces the boundary integrals in (7) to

$$\begin{aligned} & \int_0^t \int_\Gamma \Big[t_{(\mathbf{n})i}(\mathbf{x},\tau)\cdot\tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t-\tau) - \\ & \qquad \tilde{t}_{(\mathbf{n})ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\cdot u_i(\mathbf{x},\tau)\Big] d\Gamma d\tau = \\ & \sum_l \sum_{m=1}^n \int_{\Gamma_l} \int_{t_{m-1}}^{t_m} \Big[\tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\cdot 1 \cdot \mu_l(\mathbf{x})\cdot T_{il}^m - \\ & \qquad \tilde{t}_{(\mathbf{n})ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\cdot\eta_l(\mathbf{x})\cdot\left(\frac{\tau}{\Delta t}\left(U_{il}^m - U_{il}^{m-1}\right)\right. \\ & \qquad\qquad \left.+ U_{il}^{m-1}\frac{t_m}{\Delta t} - U_{il}^m\frac{t_{m-1}}{\Delta t}\right)\Big] d\tau d\Gamma. \end{aligned} \tag{23}$$

The associated time integrals

$$\begin{aligned} & \int_{t_{m-1}}^{t_m} \tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\,d\tau, \\ & \int_{t_{m-1}}^{t_m} \tilde{t}_{(\mathbf{n})ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\cdot\tau d\tau, \\ & \int_{t_{m-1}}^{t_m} \tilde{t}_{(\mathbf{n})ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\,d\tau \end{aligned} \tag{24}$$

can be integrated analytically for special constitutive equations (e. g. Maxwell model).

According to the arrival times of the shear wave front $\frac{r}{c_2}$ and the compression wave front $\frac{r}{c_1}$ the time integration of the fundamental solution has to be carried out in five intervals. With the abbreviations

$$\begin{aligned} f_0(r) &= \frac{3r_{,i}r_{,k} - \delta_{ik}}{r^3} \\ f_1(r) &= \frac{r_{,i}r_{,k}}{rc_1^2} \\ f_2(r) &= \frac{\delta_{ik} - r_{,i}r_{,k}}{rc_2^2} \end{aligned} \tag{25}$$

the first integral in (24) for example leads to

$$\int_{t_{m-1}}^{t_m} \tilde{u}_{ij}(\mathbf{x},\boldsymbol{\xi},t-\tau)\,d\tau =$$

$$\frac{1}{4\pi\varrho}\begin{cases} 0 & \textit{interval I} \\ \int_{t_{m-1}}^{t-\frac{r}{c_1}} G_1(r,t-\tau)\,d\tau & \textit{interval II} \\ \int_{t_{m-1}}^{t_m} G_1(r,t-\tau)\,d\tau & \textit{interval III} \\ \int_{t_{m-1}}^{t_m} G_1(r,t-\tau)\,d\tau & \\ -\int_{t_{m-1}}^{t-\frac{r}{c_2}} G_2(r,t-\tau)\,d\tau & \textit{interval IV} \\ \int_{t_{m-1}}^{t_m} \left[G_1(r,t-\tau)\right. & \\ \quad \left.-G_2(r,t-\tau)\right]d\tau & \textit{interval V} \end{cases} \tag{26}$$

with the abbreviations

$$G_1(r,t-\tau) = f_0(r)\left[C_1(t-\tau) + \frac{r}{c_1}D_1(t-\tau)\right] + f_1(r)\left[A_1(t-\tau) + \gamma B_1(t-\tau)\right]$$

$$G_2(r,t-\tau) = f_0(r)\left[C_2(t-\tau) + \frac{r}{c_2}D_2(t-\tau)\right] - f_2(r)\left[A_2(t-\tau) + \gamma B_2(t-\tau)\right] \tag{27}$$

and the time intervals

$$\begin{array}{ll} \textit{interval I} & t < t_{m-1} + \frac{r}{c_1} \\ \textit{interval II} & t_{m-1} + \frac{r}{c_1} < t < t_m + \frac{r}{c_1} \\ \textit{interval III} & t_m + \frac{r}{c_1} < t < t_{m-1} + \frac{r}{c_2} \\ \textit{interval IV} & t_{m-1} + \frac{r}{c_2} < t < t_m + \frac{r}{c_2} \\ \textit{interval V} & t_m + \frac{r}{c_2} < t. \end{array}$$

The time integration of the expressions A_β to D_β in (27)contain the integration of Dirac distribution, constant function or modified Bessel function only.

The modified Bessel functions are defined by

$$I_n(x) = \sum_{k=0}^{\infty} \frac{1}{k!\,(k+n)!}\left(\frac{x}{2}\right)^{2k+n}. \tag{28}$$

By inserting the argument $\frac{\gamma}{2}\sqrt{(t-\tau)^2 - \left(\frac{r}{c_\beta}\right)^2}$ in Eq. (28) the Bessel function becomes

$$I_n\left(\frac{\gamma}{2}\sqrt{(t-\tau)^2 - \left(\frac{r}{c_\beta}\right)^2}\right) =$$

$$\sum_{k=0}^{\infty}\left(\frac{\gamma}{2}\right)^{2k+n}\frac{1}{k!\,(k+ \quad \ldots \quad \frac{r}{c_\beta}\right)^2\Bigg)^{k+\frac{n}{2}} \tag{29}$$

After interchanging integration and summation the analytical time integration within a time step has to be carried out for expressions like

$$\int_{t_{m-1}}^{t_m}\left((t-\tau)^2 - \left(\frac{r}{c_\beta}\right)^2\right)^k e^{-\frac{\gamma}{2}(t-\tau)}d\tau. \tag{30}$$

Analytical integration becomes possible by decomposing the sum according to

$$\left((t-\tau)^2 - \left(\frac{r}{c_\beta}\right)^2\right)^k =$$

$$\sum_{\mu=0}^{k}(-1)^\mu \frac{k!}{\mu!\,(k-\mu)!}\left(\frac{r}{c_\beta}\right)^{2\mu}(t-\tau)^{2(k-\mu)} \tag{31}$$

where the binominal theorem (Bronstein I. N., Semendjajew K. A., 1984) has been used. Thus the integral reduces to

$$\int_{t_{m-1}}^{t_m}\left((t-\tau)^2 - \left(\frac{r}{c_\beta}\right)^2\right)^k e^{-\frac{\gamma}{2}(t-\tau)}d\tau =$$

$$= \sum_{\mu=0}^{k}(-1)^\mu \frac{k!}{\mu!\,(k-\mu)!}\left(\frac{r}{c_\beta}\right)^{2\mu} \int_{t_{m-1}}^{t_m}(t-\tau)^{2(k-\mu)}e^{-\frac{\gamma}{2}(t-\tau)}d\tau. \tag{32}$$

This integral is solved by partial integration n times

$$\int_{t-t_m}^{t-t_{m-1}} x^n e^{-\frac{\alpha}{2}x}dx =$$

$$\sum_{\nu=1}^{n}\left(\frac{2}{\alpha}\right)^\nu \frac{n!}{(n-\nu+1)!}\left[e^{-\frac{\alpha}{2}(t-t_m)}(t-t_m)^{(n-\nu+1)} - e^{-\frac{\alpha}{2}(t-t_{m-1})}(t-t_{m-1})^{(n-\nu+1)}\right]$$
$$+n!\left(\frac{2}{\alpha}\right)^{n+1}\left[e^{-\frac{\alpha}{2}(t-t_m)} - e^{-\frac{\alpha}{2}(t-t_{m-1})}\right]. \tag{33}$$

The above mentioned steps lead to the analytical time integration of Eq. (26).

After time and space integration the integral equation (23) reduces to a set of linear algebraic equations. The integrated fundamental solutions depend on the difference between the observation and impact time only. Because of this property it is possible to use the recursive equation (Steinfeld B., 1993)

$$\mathbf{C}^1\mathbf{y}^m = \mathbf{D}^1\bar{\mathbf{y}}^m + \mathbf{R}^m \tag{34}$$

of the associated elastic boundary integral equation. The algebraic equations in (34) are ordered such that $\mathbf{y}^m$

contains the unknown boundary values and $\bar{\mathbf{y}}^m$ contains the known values at time step m. The matrixes $\mathbf{C}^1$ and $\mathbf{D}^1$ contains the influence functions. The time history is stored in the vector

$$\mathbf{R}^m = \sum_{k=2}^{m} \left(\mathbf{U}^k \mathbf{t}^{m-k+1} - \mathbf{T}^k \mathbf{u}^{m-k+1} \right). \tag{35}$$

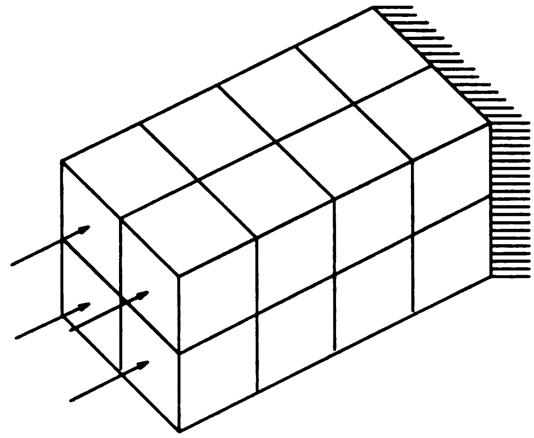
containing the influence functions of the integrated fundamental solutions of the displacements $\mathbf{U}^k$ and the tractions $\mathbf{T}^k$.

NUMERICAL EXAMPLE

The propagation of waves in a 3–d continuum has been calculated by a boundary element formulation in time domain. The problem geometry, with associated boundary discretization is shown in Fig. 3 with chosen viscoelastic material data. Linear shape functions have been used. The free end is excited by a pressure jump according to a unit step function $H(t)$. The opposite end is fixed in welded contact.

Fig. 2 shows the longitudinal displacement in the center of the free end cross section via time. An associated viscoelastic 3–d FE solution has been calculated by the FE–program MARC.

Both BEM and FEM solution are compared with the 1–d analytical elastic solution. Ongoing research analyzes the effect of time step and space discretization with respect to the errors of both discretization methods.



geometry data:

length l = 4 m
heigth = 2 m
width = 2 m

time step BEM:

$\Delta t = 0.002825$

viscoelastic material data:

$E = 100000 \frac{N}{m^2}$
$\nu = 0.25$
$\varrho = 1 \frac{kg}{m^3}$
$\gamma = 0.001$

$$u(l,t)_{\text{analytic}} = -\frac{1}{\varrho c}\left(t + \sum_{n=1}^{\infty} (-1)^n \, 2\left(t - \frac{2nl}{c}\right) H\left(t - \frac{2nl}{c}\right)\right)$$

$$c = \sqrt{\frac{E}{\varrho}}$$

Figure 2: 3–d BEM and FEM solutions comparised with the analytic elastic 1–d solution

SUMMARY

An improved approach has been presented for calculating the elastodynamic response of solids in time domain by BEM. In addition to the so called geometrical damping by energy radiation the energy dissipation described by viscoelastic constitutive equations is taken into account. Conventional viscoelastic laws and those generalized by fractional time derivatives can be treated. An analytical fundamental solution has been derived in time domain for a viscoelastic Maxwell model.

ACKNOWLEDGEMENT

The subject of the paper is related to the authors project in a priority research program on BEM. Support by the German Research Council (DFG) is gratefully acknowledged.

Transient and steady-state operational limits for ship roll

Steven R Bishop and Jesse Rebello de Souza

Centre for Nonlinear Dynamics and its Applications, University College London
Civil Engineering Building, Gower Street, London WC1E 6BT United Kingdom

This paper investigates the safe operational limits of roll for small vessels in regular waves through the use of an archetypal model of ship motion. The technique incorporates steady-state analysis with methods of quantifying the engineering integrity of transient motions. Both analytical and numerical methods are used and compared. The resonant response of the vessel is examined to reveal unacceptable solutions and superimposed on parameter space diagrams which include lower bounds for fractal erosion of basins of attraction.

CONTENTS

INTRODUCTION

The analysis of the motions of a small vessel in ocean waves poses the engineer or naval architect with challenging problems to determine stability and predict extreme excursions. Reports indicate that capsize remains a major problem for fishing boats and small vessels, including loss of life, Jons et al (1987). Studies conducted during the last two decades have identified several physical mechanisms of capsize, including pure resonant rolling, parametric excitation, broaching, and loss of static stability at a wave crest, Paulling et al (1975). This latter mechanism of capsize may be one of the most dangerous in some ways since it offers little or no information of the impending disaster prior to the event, Miller et al (1986). Broaching involves the loss of directional stability in waves, and it is mentioned in reports as a possible explanation for some disasters.

In this paper, however, we shall restrict our attention to resonant rolling motions of ships in regular beam seas. This problem is of particular relevance to vessels that have to keep fixed courses during operations such as towing arrays, digging trenches, or laying submarine pipelines. Those operations may require vessels to be exposed to beam waves that they would otherwise avoid by changing course. As we shall emphasize later in this paper, even a short train of regular waves can be very dangerous to the ship: this fact has been confirmed by experimental studies in wave tanks, Grochowalski (1989), and by reported descriptions of actual capsizings, USCG (1984).

We investigate here the dynamics of ships in waves through an archetypal model equation, Thompson et al (1990). This model represents in a simplified fashion the uncoupled rolling motion of a ship under harmonic forcing. Linear viscous-type damping is assumed, and a static bias due, for instance, to wind loading or cargo imbalance is implicit in the (asymmetric) shape of the restoring moment curve. In physical terms the model assumes the action of a constant lateral force such that capsize towards the direction of this force is very unlikely.

Firstly, we consider numerical methods to evaluate the operational wave conditions that lead to unacceptably large displacements in steady roll. We then introduce analytical and numerical methods to determine the engineering integrity of the vessel by examining its safe basin of attraction. This technique, which applies modern geometrical concepts of dynamical systems theory, is able to capture transient as well as long term behaviour. Bounds can then be placed on the system which ensure structural integrity and when these are coupled with steady-state analysis a guide to the safe operational limits for the vessel is produced.

LIMITS OF STEADY STATE RESONANT MOTION

A full dynamic analysis of the ship's motions is an extremely complicated task involving, at least, the solution of the ship as a rigid body with its full six degrees of freedom. Accurate calculation of ship-wave hydrodynamic interactions imposes yet further difficulties, leading invariably to highly complex mathematical models whose analyses can prove very demanding on computer time, Miller et al (1986). An alternative approach might be to use fundamental (or archetypal) mathematical models derived from first principles. These models have the advantages of being much simpler (thus allowing systematic parametrical studies and some analytical investigation) while, at the same time, being quite general in the sense that they depict fundamental aspects of the behaviour of a whole class of vessels, and indeed systems, Thompson and Stewart (1986). The simplest form of archetypal equation that has been used to study ship motions is a single degree of freedom oscillator which models the roll of a ship in beam seas, Virgin (1987).

A first approach is to consider the response of the vessel in regular waves represented here by a single frequency harmonic excitation. The restoring moment curve can be initially represented by a second order polynomial and the damping can be assumed linear. Normalizing time and the angle of roll to make the linear natural frequency and the angle of vanishing static stability equal to unity yields :

$$\ddot{x} + \beta\dot{x} + x - x^2 = F\sin(\omega t) \qquad (1)$$

In the equation above x is the non-dimensional angle of roll, β is the normalized damping coefficient, F and ω are the non-dimensional amplitude and frequency of the exciting moment, respectively; a dot denotes differentiation with respect to the normalized time t. Equation 1 captures many qualitative features of more complex descriptions, representing motions of a particle in a cubic potential well. It has been extensively studied and has been shown to display a variety of qualitatively distinct types of behaviour, including multiple steady state solutions, jumps to resonance, and period doubling cascades leading to chaos, Thompson (1989). Numerical integration for $\beta=0.1$ was performed and the resulting steady state nonlinear resonance curves for two values of the amplitude of excitation are shown in Fig 1. For the higher value of $F=0.050$ jumps to and from resonance as the system evolves with frequency, as well as the appearance of subharmonic resonances can be observed. From the analysis of such resonance curves it is possible to determine ranges of F and ω such that pre-specified limits of steady state response are exceeded. For pre-specified operational limits of 0.15, 0.40 and 0.70 times the angle of vanishing stability of the boat, Fig 2 shows curves on the (F,ω)-plane that separate acceptable from unacceptable conditions. Operational conditions defined by points lying within each region (i.e above the lines) correspond to unacceptable final amplitude of motion. These ranges of parameters impose a first set of restrictions which will be complemented by the consideration of transient behaviour and other phenomena as we shall discuss in the following section.

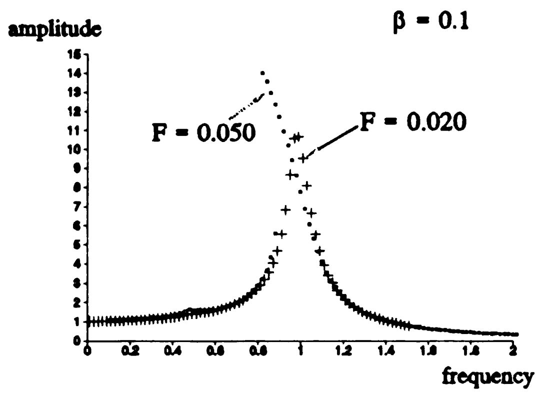

FIG 1. Steady-state resonance curves for Eq 1. The larger F value shows the influence of nonlinearities.

BOUNDS OF TRANSIENT STRUCTURAL INTEGRITY

A boat in a real marine environment will rarely be influenced by a long sequence of regular waves. Therefore the steady states shown in Fig 1, although revealing important dynamical features, are not likely to be reached. Nevertheless a short train of, say, up to 10 regular waves can indeed influence the boat under specific environmental conditions. Transient behaviour will then dominate motions and the analysis of the transient response is essential, Soliman and Thompson (1991). Furthermore, as we have already pointed out, dangerous large-amplitude motions can build up when the vessel is hit even by a short sequence of sufficiently steep waves. Capsize can occur after a small number of, say, less than eight waves have hit the vessel.

The existence of multiple solutions dependent solely on initial conditions requires additional care. In general, small-amplitude stable solution (or solutions) coexists with other solutions associated with unacceptably large -or even infinite- amplitudes. For a given configuration of parameters such as amplitude and frequency of excitation, the size and shape of the safe basin of attraction of the small-amplitude solution(s) is a fundamental measure of the safety of the system from an engineering point of view. Here we note that it has been shown that the local stability analysis traditionally performed in engineering may lead to grossly non-conservative results. This is due to the fact that, well before the small-amplitude solution loses its stability , its basin of attraction can be severely reduced, Thompson et al (1987). In such situations,

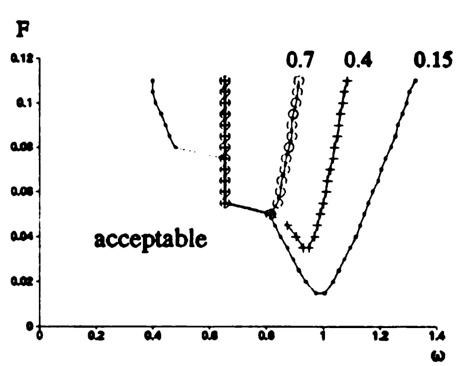

FIG 2. Boundaries of safe steady-state motion for Eq 1.

most trajectories will not be attracted to the safe solution, but to other, possibly unsafe, ones. We shall refer to this point again in the next section.

We identify the set of initial conditions $(x,\dot{x})$ that do not lead to escape as the *safe basin of attraction*, and the changes in shape and/or area experienced by this set as system parameters (amplitude and frequency of excitation, for instance) are varied provide valuable information about the systems structural integrity. Basins of attraction can be generated by various techniques including cell-to-cell mapping, Hsu (1987), and grids-of-starts.

A striking feature of the archetypal Eq 1 (and indeed of many other nonlinear models) is that the safe basin of attraction experiences a process of fractal erosion due to the homoclinic tangling of stable and unstable manifolds of the saddle-type fixed point, Thompson et al (1987). The incursion of fractal striations may cause a sharp decrease of safe area, well before the final loss of stability obtained by conventional steady state analysis, Thompson et al (1990). For relatively simple models the point of homoclinic tangency can be accurately predicted by a Melnikov analysis, Guckenheimer and Holmes (1983), giving rise to a lower bound for basin erosion. Similar boundaries can be generated for more complex systems by the use of numerical methods. In the next two sections we investigate these techniques in more detail.

ANALYTICAL PREDICTION OF BASIN EROSION

To better understand the relevance of basins of attraction in their connection with the steady-state and transient engineering integrity of the system, we adopt here a geometric point of view, proceeding from simpler to more realistic scenarios. We start with the Hamiltonian system associated with Eq 1:

$$\ddot{x} + x - x^2 = 0 \qquad (2)$$

This system has only two fixed points: a stable centre at $(x,\dot{x})=(0,0)$ and an unstable saddle-type point at $(x,\dot{x})=(1,0)$. The homoclinic orbit that connects the unstable fixed point to itself defines the boundary between trajectories that remain bounded for all time and those that escape to infinity. This special orbit is therefore the safe basin boundary for the unforced, undamped system, and it can be determined analytically, Thompson (1989).

Considering now small perturbations $\epsilon F\sin(\omega t)$ and $\epsilon\beta$ for excitation and damping, respectively, yields a different picture in which the fixed points of the unforced, undamped case are substituted by small-amplitude oscillations. The oscillation around the origin is stable, whereas the one around the hill-top saddle is unstable. Once again the inset (stable invariant manifold) of the hill-top saddle cycle is the separatrix between safe and unsafe starting conditions.

As we increase the magnitude of the excitation term, the next qualitative change takes place when the inset and outset (unstable invariant manifold) of the hill-top saddle cycle intersect in what is called a *homoclinic tangency*. Further increase in F generates a much more complex picture, in which an infinite tangling of the invariant sets of the hill-top saddle solution results in the creation of a Smale horseshoe, and the boundary of the safe basin of attraction becomes fractal. Perturbation schemes like the Melnikov method can be used to obtain good analytical approximations for the values at which such homoclinic tangency occurs. See chapter 10 of Barenblatt et al (1983) for an account of Melnikov method, and Thompson (1989) for an application of the method to Eq 1.

The importance of the homoclinic tangling phenomenon for the engineering integrity of the system given by Eq 1 is two-fold. First, the fractal nature of the safe basin boundary implies that there are regions of the phase plane in which an accurate prediction of escape is impossible. This fact alone does not seriously affect *practical* predictability if the fractal region is confined, for example, to the vicinity of the saddle-type fixed point. Studies have shown, however, that fractal areas quickly develop into the bulk of the safe basin, in what is called a *fractal erosion process*, Soliman and Thompson (1989). Moreover, such erosion takes place considerably before (i.e for smaller F values) the final loss of stability predicted by steady-state analysis. The rapid erosion of the safe basin of attraction is therefore the second reason for the interest in predicting the homoclinic tangency. This global phenomenon is a first signal of a complex chain of events, including a heteroclinic tangency, that will quickly result in loss of engineering integrity.

In view of the above it is of interest to compare, or rather combine, the results of steady-state limits of oscillation with a lower boundary for transient integrity as given by the Melnikov method prediction of safe basin erosion. Figure 3 combines steady state operational limits (as given by

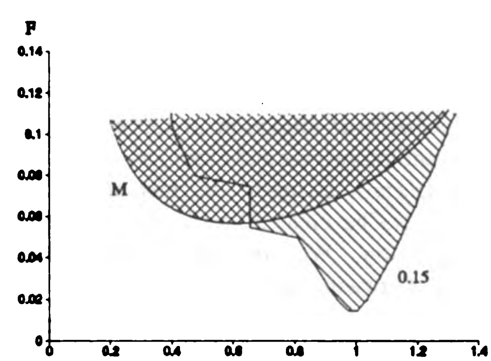

FIG 3. Combination of safe steady-state limits with a lower boundary for transient integrity for Eq 1.

acceptable amplitudes of response, e.g., 0.15 times the angle of vanishing static stability) and a lower bound for transient structural integrity signalled by the Melnikov curve M. The shaded areas above each one of those curves indicate unsafe operational conditions. As Fig 3 shows there are sizeable regions of the (F,ω)-plane that would be regarded as safe by steady state or transient analysis alone. In particular, the double-shaded area on the upper left corner (above Melnikov curve) would be considered safe even by quite stringent steady state criteria, but safe basins of attraction might be considerably eroded in these regions and actual engineering integrity may be reduced. Nonetheless, steady state analysis is able to detect conditions (denoted by the single-hatched area on the lower right corner in Fig 3) under which basins of attraction are smooth but lead to unacceptable final solutions.

NUMERICAL PREDICTION OF BASIN EROSION

Melnikov method is a perturbation technique, and therefore relies upon the knowledge of an exact solution for the unperturbed system. The possibility of obtaining closed-form solutions is limited to relatively simple systems; in the case of ship models, even when just one degree of freedom is considered, only very simplified expressions for the vessel's damping and restoring moments are allowed if analytical methods are to be used.

We propose here the use of a *coarse grid-of-starts* as a means of quickly and effectively detecting the erosion of the vessel's safe basin of attraction. The method is based on much the same geometrical ideas described in the previous section, as we briefly summarize here.

For a statically stable ship, the origin of the phase space (upright position, zero velocity) is clearly a stable fixed point of the unforced system. The basin of attraction for the unforced system is directly connected with the angle of vanishing static stability, beyond which the vessel capsizes from rest (i.e zero velocity initial condition).

A small excitation (sinusoidal forcing) will give rise to small-amplitude oscillations around the origin. The basin of attraction of this new solution can be expected to differ very little from the original, unforced case. For any given frequency of waves, as the amplitude of the excitation increases, the basin of attraction of the safe solution may experience quantitative (size and shape) as well as qualitative (smooth to fractal) changes or metamorphoses. New attractors can also be created, each of them with its own basin of attraction. We are particularly interested in distinguishing between safe and unsafe motions, and therefore we designate the *union* of all basins of attraction that do not lead to capsize as the safe basin of attraction of the system. Moreover, as we have already pointed out, short-term transient motions are more relevant within the context of periodically forced ship motions than their steady-state or long-term transient counterparts. We therefore concentrate here on transients of short duration. Accordingly, the safe basin of attraction is defined as the union of starting conditions that do not lead to capsize *within a given number of waves*.

By performing numerical simulations of trajectories from different starting points around the origin we are able to detect any significant change in the safe basin of attraction, be it in size/shape or nature (smooth to fractal). It should be mentioned that, although we know here, through previous analytical investigation, that the process that will determine safe limits for this specific system is indeed fractal basin erosion, a coarse grid-of-starts is capable of detecting the reduction of transient safe basin for any system that can be numerically integrated. This is important since it is reasonable to imagine that for different systems the sequence of events leading to reductions in safe basins will differ from the one observed for Eq 1. This method is envisaged as a practical means to detect those decreases in safe basin area of transient motions for a much broader class of mathematical models.

We discuss now in more detail the main points involved in the definition of a suitable grid-of-starts. Firstly, it should perhaps be emphasized that, whilst embedded in detailed

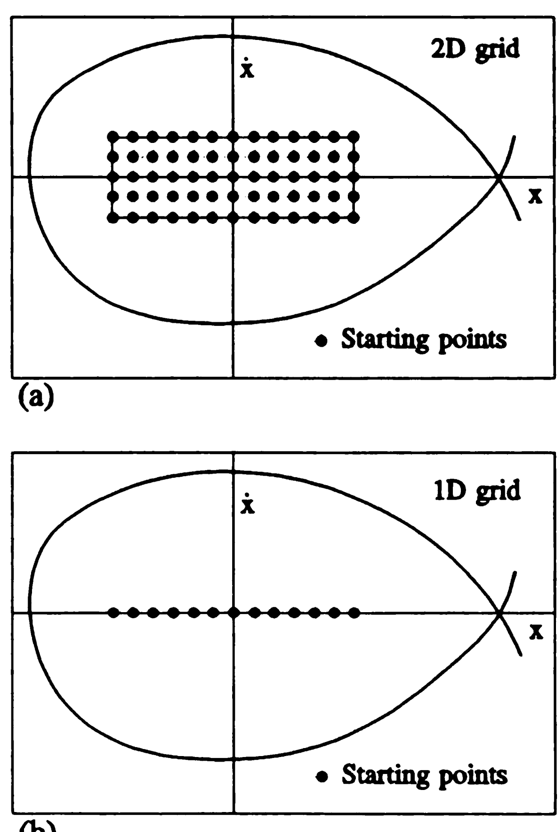

FIG 4. (a) Two-dimensional grid-of-starts in the phase plane of position and velocity. (b) One-dimensional grid-of-starts.

studies of the geometrical and bifurcational structures of the specific system illustrated here, this method is simple to apply, and does not require extensive computational resources. Furthermore, the method lends itself to direct experimental verification, and can be a valuable guide in selecting critical conditions for more detailed (and expensive) studies.

Figure 4a illustrates the idea of placing a coarse grid-of-starts in the phase plane of initial position (roll angle), x, and angular velocity, $\dot{x}$. We suggest here that the grid is placed *around the origin*, which has two basic advantages over placing the grid around fixed points of the associated Poincarè map. Firstly, the choice of a cross section for the definition of the Poincarè map can be a source of ambiguity, and furthermore the fixed point obviously moves in the phase plane as we wind up the amplitude of excitation. Secondly, it is very difficult to reproduce *both* initial angles and angular velocities in experiments with physical models, therefore jeopardizing the direct link of results between numerical and experimental studies. For this same reason, we favour the use of a *one-dimensional grid* (laid along the x axis), which of course has the additional benefit of speeding up computations considerably. For the sake of simplicity we restrict ourselves here to uniform grids, i.e grids formed by equally spaced starting points. Figure 4b shows a one-dimensional grid placed around the origin.

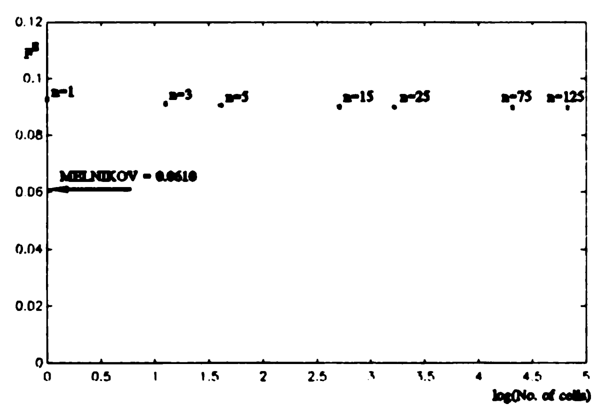

FIG 5. Basic grid parameters: effect of the number of starting points.

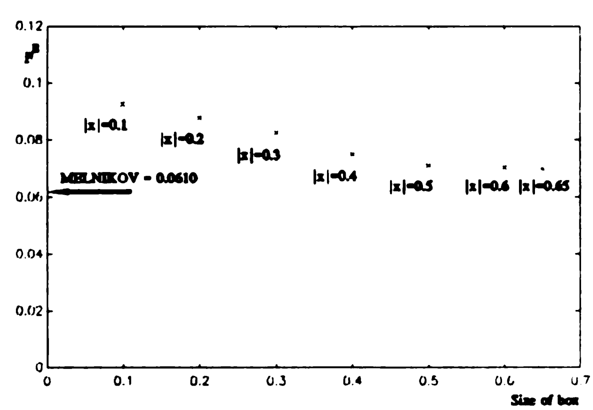

FIG 6. Basic grid parameters: effect of the size of grid in the phase plane.

The two basic parameters defining an uniform grid-of-starts are the number of starting points and the size of the grid in the phase plane. In the case of our one-dimensional grids we relate that second parameter to the *length* of the grid, which in physical terms is given by the difference between minimum and maximum starting roll angles. The first parameter bears direct relevance to the total computing time, and therefore it is of primary interest to keep it to a minimum.

We performed numerical sensitivity tests involving those two parameters. The tests consisted of determining, for a fixed excitation frequency of $\omega=0.80$, the minimum value of amplitude of excitation for escape (F^E) under transient conditions of up to 8 waves. The escape value F^E is defined as the smallest value of F for which escape occurs *for any starting point of the grid*. The idea is to place a sensible grid of starts and to simulate transient motions from each starting point of the grid. The process is repeated for increasingly higher F values until escape is detected for some point of the grid. The method is therefore capable of sensing reductions in safe basin area caused by both shrinkage and/or erosion.

Figure 5 shows the escape value F^E predicted using different number of points in the grid. Results show little sensitivity to the number of points of the grid: grids formed by 3 or 125 points give similar results, provided that they have equal lengths. In this case a range of $-0.1<x<0.1$ was used for all grids. In Fig 6 we show the influence of the length of the grid on the escape values predicted by the method. A fixed number of 3 starting points was used. In contrast with the first set of tests, results now display considerable sensitivity to the length of the grid: the longer the grid the smaller the escape value predicted. This can be readily understood for the specific system under study here if we recall the fractal erosion process that is responsible for early escape in Eq 1. Fractal striations develop from the tangling of invariant manifolds of the hill-top saddle-type cycle. The saddle-type fixed point itself sits near to the

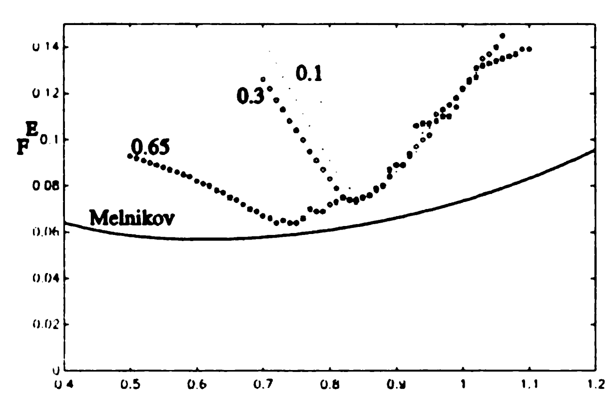

FIG 7. Numerical vs analytical prediction of basin erosion.

original unstable fixed point at $(x,\dot{x})=(0,1)$, and the fractal structures will emanate from that region of the phase space. Therefore, the nearer to saddle-type fixed point the starting point is located, the larger the chances of an early identification of one of the incursive areas of unsafe starting conditions. It can also be observed in Figs 5 and 6 that numerical prediction of escape gives less conservative estimates when compared with Melnikov method. Figure 6 indicates that Melnikov predictions tend to agree with numerical results for long grids.

From the results of the sensitivity study described above we selected three particular combinations of number of points and length of grid for further analysis and comparison with Melnikov method. We adopted grids of just 3 starting points and ranges covering $-0.10<x<0.10$, $-0.30<x<0.30$, and $-0.65<x<0.65$. Using these grids we established estimates for escape values for a range of frequencies, and compared the results with values predicted by Melnikov analysis. The shape and position of the numerically generated safe boundaries agree well with Melnikov curve. As we could expect, the longer grid gave escape values closer to Melnikov results, but always less conservative, as we can see from Fig 7.

With respect to the relation between numerically generated safe transient boundaries and steady-state limits of acceptable motion most of the comments already made in the context of the Melnikov method hold valid. Suitably defined grids reveal regions of the parameter plane in which steady-state limits may be acceptable but transient safe basins are already eroded.

CONCLUSIONS

The continuing loss of life due to the capsize of small vessels implies that attention must be paid to dynamic resonant effects. Transient as well as steady state phenomena play relevant roles in determining safe operational conditions and should both be constituent parts of a sound dynamic stability criterion that is still needed. We have proposed here the use of a *coarse grid-of-starts* as a means of detecting the erosion of the vessel's safe basin of attraction. The method is based on geometrical ideas of nonlinear dynamics, and although based upon detailed studies of the dynamic behaviour of the specific system illustrated here, this method is simple to apply, and does not require extensive computational resources. Furthermore, the method lends itself to direct experimental verification, and can be a valuable guide in selecting critical conditions for more detailed studies.

Passive vibration control: A probabilistic approach

Hector A Jensen

This paper is concerned with the behavior of vibration absorbers attached to systems with uncertain properties. The uncertainties of the main system properties are modeled in a probabilistic sense by means of a Bayesian probabilistic interpretation. The structural systems considered in this study are simple systems modeled as one-degree-of-freedom oscillators subjected to a white noise base excitation. Due to the uncertainty of the main system properties, the classical deterministic minimization problem becomes a stochastic optimization problem. An optimization technique is implemented to solve this non-classical problem, and the absorber parameters as well as the optimum response of the system are obtained. These results are then used to assess the performance of the vibration absorber. It is found that parameter uncertainties may have a significant effect on its effectiveness. Finally, an alternative approach that improves the absorber efficiency, when uncertainties in the main system properties are considered, is presented in this paper.

INTRODUCTION

For many years there has been considerable interest in the study of dynamic vibration absorbers that, when added to a structural system, will reduce significantly the vibration response. A number of publications have discussed the use of vibration absorbers to limit the response of single degree-of-freedom systems subjected to harmonic excitations. The well-known work of Den Hartog (1940) has been the first detailed study in this subject. Thompson (1965) and Anderson (1969) also discussed the use of tuned mass dampers to reduce the absolute motion of simple systems subjected to harmonic forces. Application of vibration absorbers to systems subjected to stochastic excitation has also been investigated by a number of researchers. Crandall and Mark (1963) presented an analysis of a single-degree-of-freedom absorber system subjected to a white noise base acceleration and they showed how to choose the proper absorber parameters. Curtis and Boykin (1961) presented some results concerning the relative displacement response to stochastic excitation and they considered its possible reduction using absorbers.

part of "MECHANICS PAN-AMERICA 1993" edited by MRM Crespo da Silva and CEN Mazzilli ASME Reprint No AMR134

The use of damped vibration absorbers to reduce the level of vibration of simple elastic systems such as rods in extension, beams in flexure, plates, and cylindrical shells has been discussed by several researchers, among them, Neubert (1964), Snowdon (1975) and Jacquot (1978). They represented the vibration of the elastic body by a single normal mode. Warburton and Ayorinde (1979) studied in what circumstances is it impossible, or at least inaccurate, to represent the vibration of such systems by a single mode. Recently, Setareh (1991) has developed a methodology that considers several normal modes explicitly into the analysis. He used the component mode synthesis method as the main tool for implementing such technique. The use of absorbers to limit the structural response to earthquake-like excitation has also been studied by a number of authors, among them, Wirsching and Campbell (1974). They have shown the effectiveness in reducing the structural response even with relatively small values of the absorber mass. In all these studies, the structural properties of the system were assumed to be described with a mathematical precision. Yet, uncertainty in the definition of many real systems does exist to some degree. In fact, to model the dynamic behavior of structural systems, model parameters such as frequencies, mass distributions and damping coefficients, need to be estimated. Different methods are employed in estimating these parameters, from empirical formulas to very detailed methods such as the finite element technique. All these methods lead to parameter values that have associated uncertainties or errors because of the numerous assumptions made when modeling the geometry, material properties and boundary conditions.

It is the objective of this paper to study the effects of uncertain system parameters on the performance of vibration absorbers, when the system is subjected to a white noise base excitation. The structural systems considered in this paper are simple oscillators or simple elastic systems, provided that their dynamic behavior can be represented by a single mode shape. The characterization of the system properties is based on a Bayesian probabilistic interpretation, and it depends on the relevant information available. The study reported in the present paper essentially generalizes the work done by Jensen et al to consider different probabilistic tuning procedures, which are then used to assess the efficiency of the vibration absorber. The performance of the absorber is evaluated and compared with the one obtained for the case of deterministic system properties.

The next section formulates the problem under study in a more formal fashion. The following section discusses the implementation of different optimization problems to be considered in this study. Then, a numerical example is presented to illustrate the effects of uncertainty on the absorber performance. Finally, a stochastic optimization approach is suggested for treating this type of problems.

STATEMENT OF THE PROBLEM

Consider a main system idealized as a single degree-of-freedom oscillator with mass m_m, stiffness k_m and viscous damper c_m. The absorber system, which is also modeled as a simple oscillator, has mass m_a, stiffness k_a and viscous damper c_a. It is easily shown that the stationary response variance for the displacement of the main system when subjected to a stochastic base excitation is

$$\sigma^2_{x_m} = \int_{-\infty}^{+\infty} \| H_{mm}(\omega) \|^2 \; S(\omega)\, dw \;, \quad (1)$$

where $S(\omega)$ is the power spectral density function of the random excitation and $H_{mm}(\omega)$ is the component of the frequency response matrix of the combined system corresponding to the displacement of the main system. For a white noise excitation, equation (1) can be computed analytically and it is given by (Crandall, 1963)

$$\sigma^2_{x_m} = \pi S_0 \frac{(\Gamma_0^2/\Delta_0)(\Delta_2\Delta_3 - \Delta_1\Delta_4)}{\Delta_1(\Delta_2\Delta_3 - \Delta_1\Delta_4) - \Delta_0\Delta_3^2} +$$

$$\pi S_0 \frac{\Delta_3(\Gamma_1^2 - 2\Gamma_0\Gamma_2) + \Delta_1\Gamma_2^2}{\Delta_1(\Delta_2\Delta_3 - \Delta_1\Delta_4) - \Delta_0\Delta_3^2}, \quad (2)$$

where S_0 is the power spectral density of the white noise excitation; $\Delta_0 = \omega_m^2\omega_a^2$; $\Delta_1 = 2\zeta_m\omega_m\omega_a^2 + 2\zeta_a\omega_a\omega_m^2$; $\Delta_2 = \omega_m^2 + (1+\mu)\omega_a^2 + 4\zeta_m\zeta_a\omega_m\omega_a$; $\Delta_3 = 2\zeta_m\omega_m + 2(1+\mu)\zeta_a\omega_a$; $\Delta_4 = 1$; $\Gamma_0 = -(1+\mu)\omega_a^2$; $\Gamma_1 = -2(1+\mu)\zeta_a\omega_a$; $\Gamma_2 = -1$; and where $\omega_m^2 = k_m/m_m$ = the natural frequency of the main system; $\zeta_m = c_m/(2m_m\omega_m)$ = damping ratio of the main system; $\omega_a^2 = k_a/m_a$ = the natural frequency of the absorber; $\zeta_a = c_a/(2m_a\omega_a)$ = damping ratio of the absorber; and $\mu = m_a/m_m$ = the mass ratio.

It is noted that a similar equation to Eq (2) can be obtained for the case of elastic bodies with attached vibration absorbers, provided that their vibration can be represented by a single normal mode. In those cases the parameters that described the main system can be defined by means of a modal analysis approach or by an energy balance approach (Wirsching and Campbell, 1974 ; Warburton and Ayorinde, 1980). In this study, the frequency and damping properties of the main system are assumed to be uncertain and they are described in a probabilistic sense. The mathematical characterization of the frequency parameter ω_m, and damping parameter ζ_m, is based on a Bayesian probabilistic interpretation together with the maximum entropy principle. Then, the probabilistic distributions for these parameters are chosen by the maximum entropy principle that produces the greatest uncertainty in the parameters consistent with the specified constraints. For example, if the set of plausible values for the parameters is a bounded region, then the principle produces uniform distributions. If additional information is available for the parameters, then other probabilistic characterizations can be used as well (Jaynes, 1968). Here, it is assumed that the only available information for the frequency and damping parameters of the main system is that they lie inside an interval. Therefore, the parameters ω_m and ζ_m are modeled as uniform random variables, with mean values $\bar{\omega}_m$ and $\bar{\zeta}_m$, and variances $\sigma_{\omega_m}^2$ and $\sigma_{\zeta_m}^2$, respectively. The mean values of ω_m and ζ_m represent their nominal values while the variances measure the variability of the parameters with respect to their nominal values.

In the classical analysis, the optimum absorber parameters are found by minimizing the response of the main system. Due to the uncertainties of the main system properties, the response of the system, measured by the variance of the displacement response, is itself uncertain. Therefore, the deterministic minimization problem becomes a stochastic optimization problem. The next section presents the optimization techniques that are considered in this study to assess the performance of the vibration absorber.

OPTIMIZATION PROBLEM

In the classical vibration control problem, the optimum absorber parameters, that is, the frequency and damping properties are found for a given value of the absorber mass by minimizing some response function of the main system. Then, the optimization problem can be stated as

$$Minimize_{(\omega_a,\zeta_a)}\,[Response\ \ Function] \quad (3)$$

for a given mass ratio μ.

The response function to be considered in this study is the standard deviation of the stationary displacement response of the main system. This response depends on the properties of the main system as well as the properties of the dynamic absorber. Since the frequency and damping parameters of the main system are assumed to be uncertain, then the response function is also uncertain and the classical minimization problem becomes a stochastic optimization problem. In order to determine the optimum absorber parameters, an equivalent deterministic optimization problem is defined by selecting a new objective function (Rao, 1984). It is defined as a linear combination of the expected value and the standard deviation of the response, that is

$$Response\ \ Function = \alpha_1\, E(\sigma_{x_m}) + \alpha_2\, \sqrt{Var(\sigma_{x_m})}, \tag{4}$$

where $E(\cdot)$ and $Var(\cdot)$ are the expectation and variance operations with respect to the uncertain parameters, respectively, α_1 and α_2 are nonnegative constants whose values indicate the relative importance of the expected value and standard deviation of the response function in the minimization problem. Thus, $\alpha_2 = 0$ indicates that the expected value of the response function is to be minimized without caring for the standard deviation of the response. On the other hand, if $\alpha_1 = 0$, it indicates that the interest is to minimize the variability of the response function about its mean value without considering about what happens to the mean value of the response. Similarly, if $\alpha_1 = 1$ and $\alpha_2 = 1$, it indicates that equal importance is given to the minimization of the mean value as well as the standard deviation of the response function. Therefore, the solution of the stochastic programming problem stated in Eq (3) can be obtained by solving the equivalent deterministic optimization problem

$$Minimize_{(\omega_a,\zeta_a)}\ \ \alpha_1 E(\sigma_{x_m}) + \alpha_2\sqrt{Var(\sigma_{x_m})} \tag{5}$$

for a given mass ratio μ.

The expected value and the standard deviation of the response function σ_{x_m}, which by definition are multiple integrals in the random space, are computed by numerical integration over the range of the uncertain parameters, evaluating the response function at every integration point from Eq (2). Since the uncertain parameters are modeled as uniform random variables, the number of integration points can be minimized by using a Gaussian quadrature in which the zeros of the Legendre polynomials are chosen as abscissas. The actual number of integration points needed in the quadrature depends on the level of uncertainty of the system parameters and on the degree of non-linearity of the response function as a function of the uncertain parameters.

In order to solve the equivalent deterministic optimization problem previously defined, an optimization technique was implemented to obtain the values of the absorber parameters that minimize the corresponding objective function. The response function evaluated at the optimum parameters will be referred as the optimum response.

EXAMPLE OF APPLICATION

Formulation

In this example problem, the nominal value of the stiffness parameter is selected in such a way that the nominal natural frequency of the main system is $1Hz$. The nominal damping coefficients of the main system considered here correspond to 1 and 5 percent of critical, and the mass ratio μ, varies between 0.005 and 0.2. Three levels of uncertainty of the frequency and damping parameters of the main system are considered, and they are given in terms of their coefficients of variation. The selected values are 10%, 20% and 30%, which represent low, moderate, and high variations on the main system properties, respectively. Recall that the coefficient of variation is the ratio between the standard deviation and the mean value of the parameter.

To quantify the effects of uncertain main system parameters on the performance of the vibration absorber, different performance parameters are considered in this study. When deterministic properties are assumed for the main system, the performance parameter is defined as

$$p_1 = \frac{\sigma_{x_m(optimum)}}{\sigma_0}, \tag{6}$$

where $\sigma_{x_m(optimum)}$ is the optimum standard deviation of the stationary displacement response of the main system with the vibration absorber attached to the system, and σ_0 is the standard deviation of the stationary displacement response of the main system without the absorber. The optimum standard deviation response $\sigma_{x_m(optimum)}$, corresponds to the standard deviation response evaluated at the optimum parameters of the vibration absorber. It is noted that if the performance parameter is less than one, the vibration absorber has decreased the level of response of the main system, and vice-versa. When uncertainties in the main system properties are taken into account, four performance parameters are considered in this study, and they are defined as

$$p_2 = \frac{E(\sigma_{x_m(optimum)})}{\sigma_0}, \tag{7}$$

where $E(\sigma_{x_m(optimum)})$ is the expected value of σ_{x_m} evaluated at the optimum parameters of the deterministic optimization problem defined in the previous section with $\alpha_1 = 1$ and $\alpha_2 = 0$, that is

$$Minimize_{(\omega_a,\zeta_a)}\,[E(\sigma_{x_m})]\ . \tag{8}$$

The next two performance parameters, p_3 and p_4, are defined as in Eq (7) but evaluating the expected value of σ_{x_m} at the optimum parameters of the optimization problems

$$Minimize_{(\omega_a,\zeta_a)}\left[\sqrt{Var(\sigma_{x_m})}\right] \tag{9}$$

and

$$Minimize_{(\omega_a,\zeta_a)}\quad E(\sigma_{x_m}) + \sqrt{Var(\sigma_{x_m})}\,, \tag{10}$$

respectively. These problems correspond to the general optimization problem defined in Eq (5) with $\alpha_1 = 0$ and $\alpha_2 = 1$, and $\alpha_1 = \alpha_2 = 1$, respectively. The last performance parameter p_5, is defined as

$$p_5 = \frac{E(\sigma_{x_m(optimum)})}{\sigma_0} + \frac{\sqrt{Var(\sigma_{x_m(optimum)})}}{\sigma_0}, \tag{11}$$

where $E(\sigma_{x_m(optimum)})$ is the expected value and $Var(\sigma_{x_m(optimum)})$ are is the variance of σ_{x_m}, respectively, evaluated at the optimum parameters of the optimization problem given by Eq (10).

Numerical Results

Figs 1,2 and 3 show the performance parameters as a function of mass ratio μ, for different levels of uncertainty of the main system properties. A nominal damping parameter of the main system corresponding to 1% of critical is considered in these figures. The comparison of the performance parameters p_2, p_3 and p_4 with p_1 shows that there is loss of effectiveness of the vibration absorber due to the uncertainty of the main system properties. This loss of effectiveness is particularly significant for high levels of uncertainty and for small mass ratios. That is, as the coefficient of variation of the main system parameters increases the efficiency of the vibration absorber decreases. For example, for a 30% coefficient of variation and for a mass ratio less than 5%, the optimum response of the main system is about twice its nominal response. Therefore, the loss of efficiency of the vibration absorber is quite severe.

The effects of uncertain main system properties on the performance of the vibration absorber are more dramatically illustrated by the performance parameter p_5. According to its definition, the main system response is taken as $E(\sigma_{x_m}) + \sqrt{Var(\sigma_{x_m})}$, evaluated at the optimum parameters of the optimization problem given by Eq (10). Then, the response function is defined as the expected value plus one standard deviation of the standard deviation of the main system stationary displacement response. So, if the response of the main system is measure in this form, the loss of efficiency of the absorber is quite significant, particularly for high levels of uncertainty and small mass ratios. On the other hand, these results indicate that once the level of uncertainty of the main system properties is high, the use of absorbers is not effective for vibration reduction if the system is subjected to a white noise base excitation.

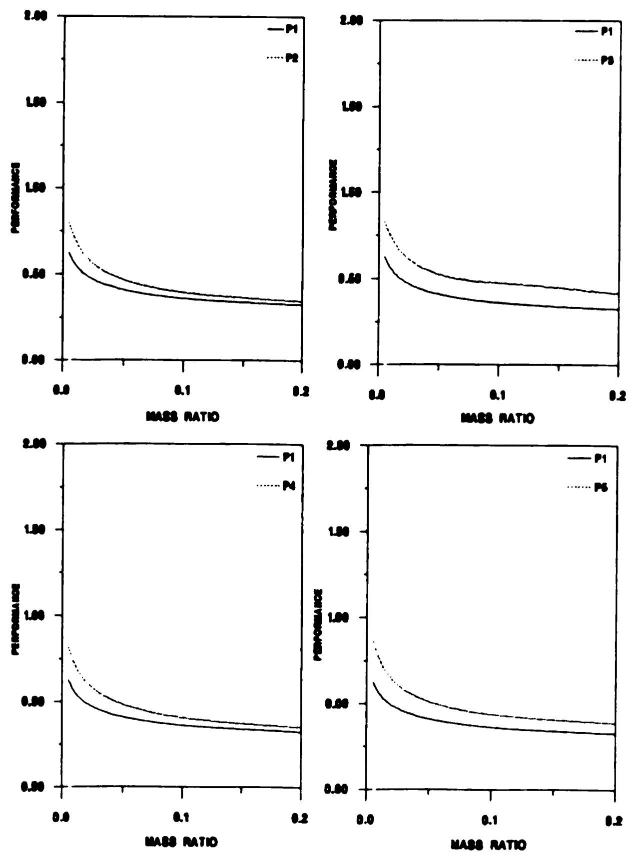

FIG 1. Comparison of performance parameters. Nominal main system damping parameter: 1% of critical. Level of uncertainty of the main system parameters: 10% coefficient of variation.

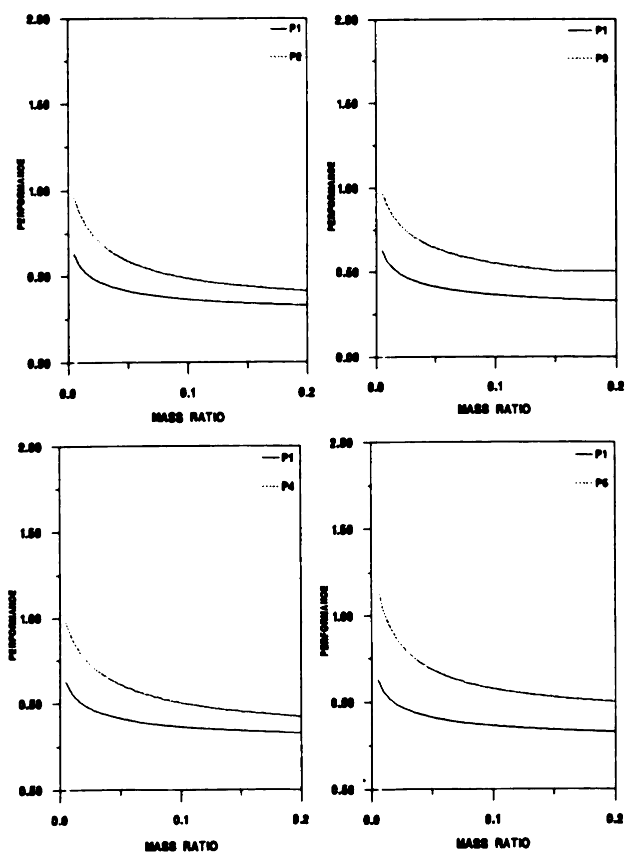

FIG 2. Comparison of performance parameters. Nominal main system damping parameter: 1% of critical. Level of uncertainty of the main system parameters: 20% coefficient of variation.

Figs 4,5 and 6 present the performance parameters when a nominal damping coefficient of the main system corresponding to 5% of critical is considered. The information given by these figures is qualitatively similar to that for the case of 1% of nominal critical damping. That is, uncertainty of the main system parameters produces a loss of efficiency in the performance of the vibration absorber. However, as can be observed, increasing the nominal damping parameter of the main system decreases the loss of efficiency, but for high levels of uncertainty and small mass ratios the effect on the absorber efficiency is still significant.

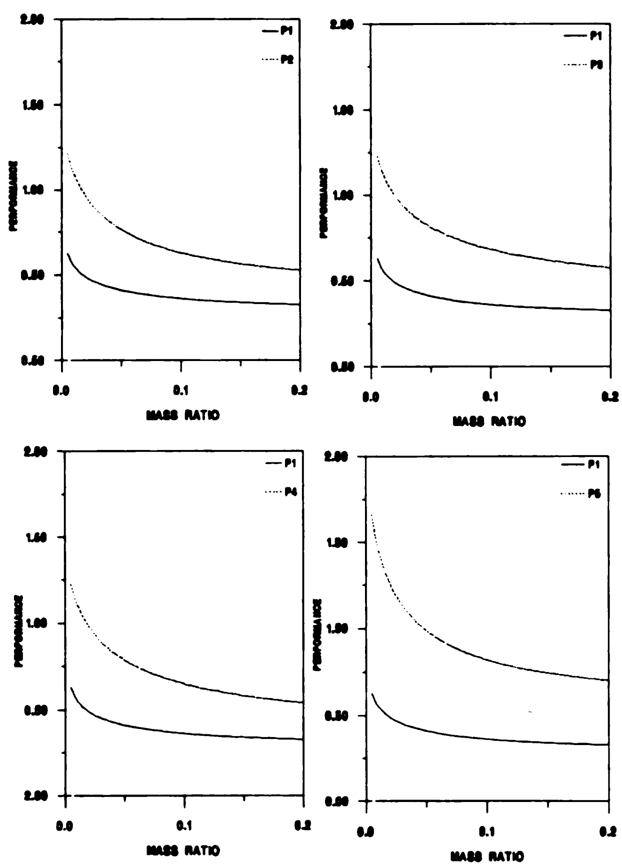

FIG 3. Comparison of performance parameters. Nominal main system damping parameter: 1% of critical. Level of uncertainty of the main system parameters: 30% coefficient of variation.

The results presented in Figs 1-6 show that the loss of effectiveness of the vibration absorber due to uncertain main system properties is invariant with respect to the performance parameter used to quantify the efficiency of the absorber. Thus, the effects of uncertainty on the efficiency of the absorber are qualitatively similar independently of the objective function used for minimization of the system response. The number of Gaussian integration points used throughout this example to compute the expected value and the standard deviation of the response function is the following. A second-order quadrature is used when a 10% coefficient of variation of the uncertain parameters is considered, a fourth-order quadrature is used for a 20% coefficient of variation, and a sixth-order quadrature is

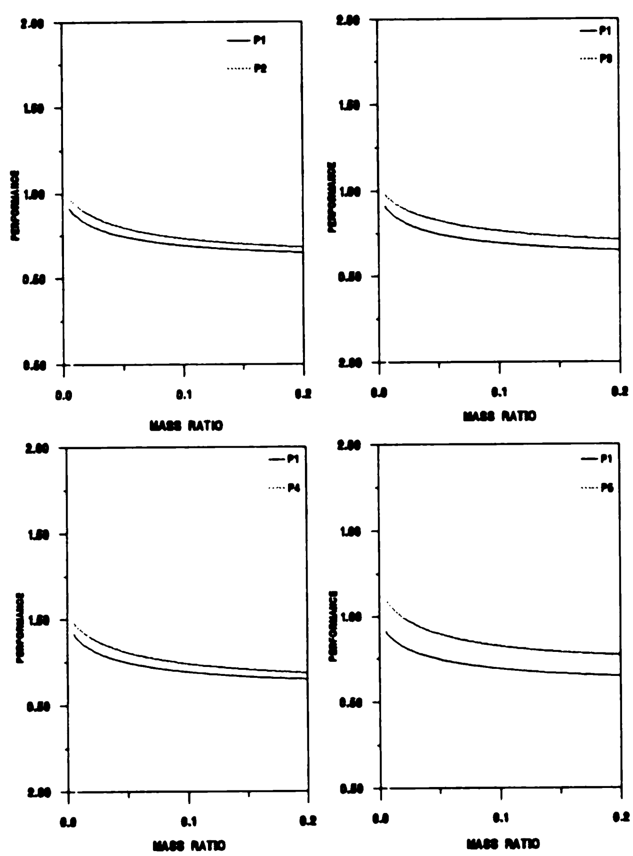

FIG 4. Comparison of performance parameters. Nominal main system damping parameter: 5% of critical. Level of uncertainty of the main system parameters: 10% coefficient of variation.

used for the case of a 30% coefficient of variation. It is found that these orders of integration are adequate for the present application since the use of higher-order quadratures produces essentially the same optimum parameters and therefore the same system response.

It is noted that as the uncertainty of the main system parameters increases, the optimum absorber frequencies, that are obtained from the optimization problems described in the previous section, decrease. Contrarily, the optimum damping parameters increase as the level of uncertainty increases. For low level of uncertainty the optimum absorber parameters are close to those obtained by assuming deterministic properties for the main system. However, for high level of uncertainty, such as 30% coefficient of variation, the difference is quite significant.

As stated before, the classical approach in passive vibration control is to find the optimum absorber parameters assuming nominal properties for the main system. Using this solution as the optimum solution, one can then include the effects of uncertain main system properties to compute different statistics of the solution. For example, the first statistical moment of the system response is given by $E(\sigma_{x_m(optimum)})$, where $\sigma_{x_m(optimum)}$ is the optimum standard deviation response obtained from the classical approach, and $E(\cdot)$ is the expected operation with respect to the uncertain parameters. In this manner, a new performance parameter can be defined as

$$p_6 = \frac{E(\sigma_{x_m(optimum)})}{\sigma_0} \,. \tag{12}$$

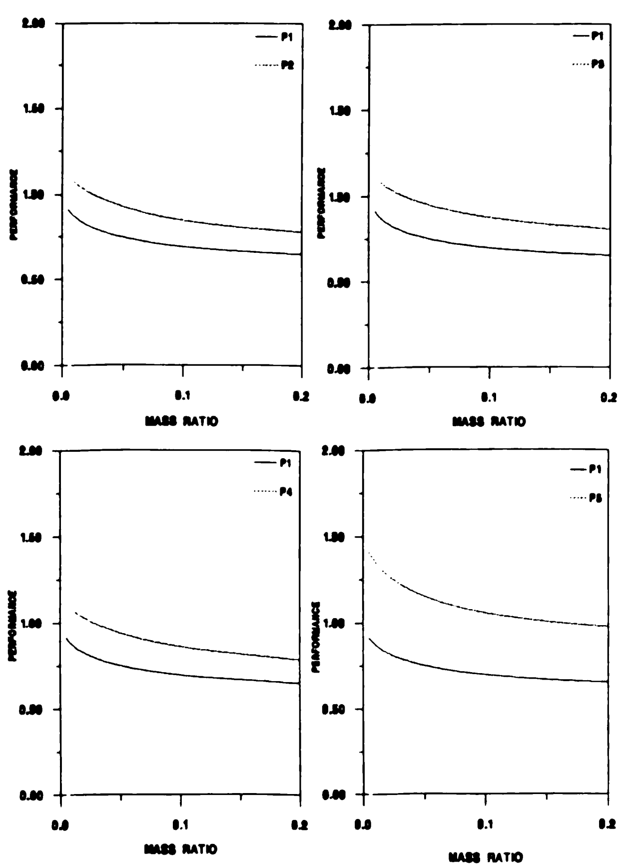

FIG 5. Comparison of perforr ... ters. Nominal main system damping parameter: ... Level of uncertainty of the main system ... % coefficient of variation.

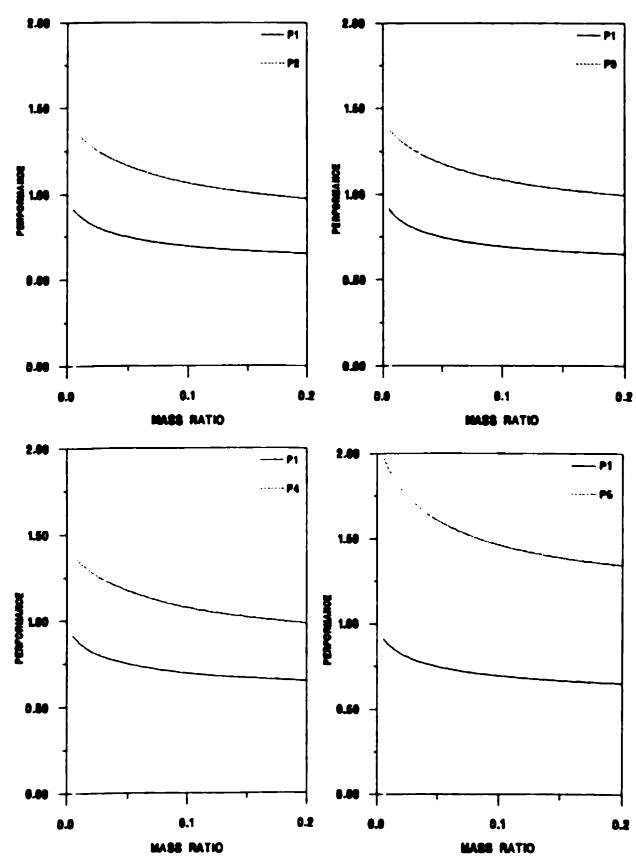

FIG 6. Comparison of performance parameters. Nominal main system damping parameter: 5% of critical. Level of uncertainty of the main system parameters: 30% coefficient of variation.

This performance parameter can be compared with the performance parameter p_2, defined in the previous section. Fig 7 shows a comparison of p_2 and p_6 for different levels of uncertainty of the main system properties. A nominal damping parameter of the main system corresponding to 1% of critical is considered in this case.

For low levels of uncertainty the two performance parameters are very similar. However, for high coefficient of variations, the difference is quite significant. These results show that the efficiency of the vibration absorber obtained from the stochastic approach is greater than the one from the classical approach. The same conclusions are obtained if other performance parameters are considered as well. Therefore, the stochastic approach considered in this study is suggested to be used instead of the deterministic approach if there is some level of uncertainty or error in the specification of the main system properties.

CONCLUDING REMARKS

The present study has shown the effects of uncertainty in the main system properties on the performance of vibration absorbers. Different response functions of the main system have been used to find the optimum absorber parameters and the optimum system response. It was found that the loss of efficiency is qualitatively similar, independently of the objective function used to minimize the system response. The numerical results have shown that uncertainty in the model parameters of the main system may cause significant changes on the response characteristics of the absorber. In these situations, the errors or uncertainties in the specification of the main system properties should be properly accounted for in the vibration control problem. If these uncertainties are not accounted for, then the performance of the vibration absorber can be affected significantly. On the other hand, the results obtained from this study suggest that for large levels of uncertainty, the use of vibration absorbers is not justified for the reduction of the main system response. This is specially true when the absorber mass is only a small fraction of the main system mass. Finally, when there is a moderate level of error in the specification of the main system properties, it is recommended to use the stochastic approach considered in this study instead of the classical deterministic approach. The new method may achieve a substantial improvement on the efficiency of the absorber compared with the one obtained by the classical tuning approach.

Flowing polymers through porous media: An experimental study of flow distribution, polymer degradation, and molecular weight effects

AJ Müller, LI Medina, O Pérez-Martin, S Rodriguez, C Romero, ML Sargenti, and AE Sáez

Grupo de Polimeros USB, Departamentos de Termodinámica y Ciencia de los Materiales, Universidad Simón Bolívar, PO Box 89000, Caracas 1080-A, Venezuela

The flow of aqueous poly(ethylene oxide) solutions through nonconsolidated porous media has been experimentally investigated. Three aspects of practical relevance have been addressed: the effect of polymer on flow distribution under nonuniform flow conditions, the mechanical degradation of the polymer in the porous media, and the effect of molecular weight on flow resistance. The nonuniform flow results indicate that, although the presence of polymer changes the distribution of the flow by affecting the region of the medium that is swept by the fluid, a significant increase in flow resistance is still observed above a critical Reynolds number, as it happens under uniform flow conditions. The degradation experiments show that the polymer is significantly degraded only in the region where a sizable increase in flow resistance is obtained with respect to the Newtonian behavior. The most significant effect of the molecular weight of the polymer is the fact that an increase in that parameter results in a substantial reduction of the Reynolds number at which the increased flow resistance is observed. Furthermore, the rate of change of this onset Reynolds number with polymer concentration appears to be independent of molecular weight. The results presented here indicate that the increase in flow resistance is not exclusively determined by the shear viscosity of the polymer solution.

CONTENTS

INTRODUCTION

In recent years there has been an increased interest in the characterization of the flow of polymer solutions through porous media. This has been motivated by the great importance of this phenomenon in practical applications such as enhanced oil recovery, filtration processes and gel permeation chromatography.

One of the most important hydrodynamic parameters used in the characterization of single phase flow through porous media is the pressure drop. In dimensionless form, the pressure drop through randomly packed, nonconsolidated porous media can be characterized by means of the resistance coefficient, defined by

$$\Lambda = \frac{\Delta P}{L}\,\frac{d^2\phi^3}{\eta_s u\,(1-\phi)^2} \qquad (1)$$

where $\Delta P/L$ is the pressure drop per unit length of porous medium, including gravitational potential contributions, d is the particle diameter, ϕ is the porosity of the medium, η_s is the viscosity of the fluid, and u is a characteristic superficial velocity.

For the case of uniform one-dimensional flow of a Newtonian fluid with superficial velocity u, the resistance coefficient is only a function of the Reynolds number, defined by

$$Re = \frac{\rho_s\, u\, d}{\eta_s\,(1-\phi)} \qquad (2)$$

where ρ_s is the fluid density. When polymer solution data are analyzed, it is customary to use the viscosity and density of the solvent in the calculation of resistance coefficient and Reynolds number. In this case, as it will be discussed, the resistance depends on Reynolds number, and polymer concentration and molecular weight.

For Newtonian fluids, the relation between Λ and Re is empirically expressed through the Ergun equation,

ASME Reprint No AMR134

$$\Lambda = A + B\,Re \qquad (3)$$

where A and B are constants.

At low Reynolds numbers, Eq (3) indicates that the resistance coefficient is a constant, which means that the pressure drop is directly proportional to the superficial velocity. This behavior is commonly known as the Darcian regime. At high Reynolds numbers, the pressure drop is proportional to u^2. In this regime, inertial effects in the pores dominate over viscous effects.

The constants A and B vary slightly from one packing to another, depending on shape and roughness of the particles, and packing procedure.

One of the most important aspects of the flow of solutions of high molecular weight polymers through porous media is the sizable increase in pressure drop with increasing flow rate that is commonly observed for polymers with flexible molecular conformations. This increase in pressure drop is much more pronounced than the one observed for Newtonian fluids, and it leads to a departure of the resistance coefficient from the Newtonian behavior.

Figure 1 shows a typical curve of resistance coefficient vs Reynolds number, comparing Newtonian with polymer solution behavior. The Newtonian fluid is in this case pure water and the polymer solution is a dilute solution of poly(ethylene oxide) (PEO) in water. The Newtonian fluid follows the behavior represented by Eq 3. Three characteristic regions can be distinguished in the polymer solution case. In region 1, the polymer solution behaves as a Newtonian fluid, yielding practically constant values of the resistance coefficient. In region 2, the departure from the Newtonian behavior occurs. This is characterized by a sudden increase in flow resistance. In region 3, the value of Λ reaches a plateau. Some investigators have reported the existence of a fourth region, at still higher values of the Reynolds number, in which the resistance coefficient drops from the plateau value (e.g. Kulicke and Haas, 1984). It has been argued that this fourth region is a consequence of the mechanical degradation of the polymer molecules in the medium.

The increase in flow resistance for polymer solutions was first analyzed by Marshall and Metzner (1967), and Dauben and Menzie (1967). These investigators quantified this effect in the flow of PEO and polyacrylamide (PAA) solutions through packed beds of spheres. They proposed that the thickening behavior was due to the elongational nature of the flow, caused by the frequent contractions and expansions experienced by the fluid as it passes through the pore space in the medium.

James and McLaren (1975) performed experimental studies of the flow of PEO through packed beds. They suggested that the increase in flow resistance with flow rate was a result of the increase in the ... nal viscosity of the solution due to the extension ... molecules in the pores. More recently, Hoag... mme (1989) have confirmed the stretch ... of flexible polymers in porous media t... he technique termed hydrodynamic chromatography, which is based upon the injection of a pulse of a dilute polymer solution into a porous medium conformed by small particle packing. This technique allows to measure the effective lateral size (in a direction perpendicular to the mean direction of flow) of the polymer molecules as they pass through the pores. Hoagland and Prud'homme found that this effective size decreases as the flow rate through the medium increases, indicating the existence of a stretched molecular conformation.

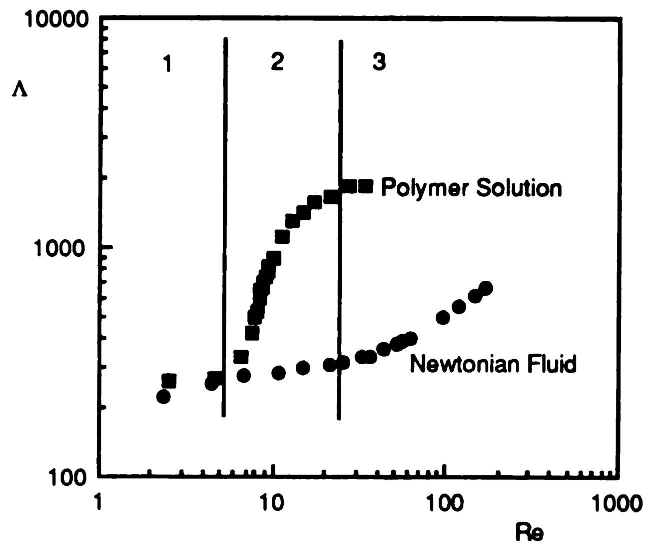

FIG 1. Typical behavior of flow resistance for Newtonian fluids and polymer solutions.

The hypothesis that molecular coil-stretch transition is the only mechanism responsible for the increase in flow resistance was challenged by Odell et al (1988) on the basis that the observed criticality of the phenomenon, in terms of the narrow range of Reynolds number through which it occurs, is not consistent with the wide molecular weight distributions of the polymers used. Odell et al proposed that the creation of transient networks of molecules was more consistent with the observations found in the literature. Recently, Rodríguez et al (1993) have provided more experimental evidence that suggests that in addition to coil-stretch transition, transient entanglement network formation seems to explain the sudden increase in flow resistance.

In the last two decades, a series of published works have assessed various aspects related to the flow of polymer solutions through porous media. Hill et al (1974) performed experiments with partially hydrolyzed PAA and xanthan polysaccharides, which are the polymers most commonly used in tertiary oil recovery. The PAA exhibited the increase in flow resistance discussed above, whereas the xanthan polymer showed shear thinning. They concluded that the xanthan polymers are less susceptible to mechanical degradation in the porous medium than the polyacrylamides. They also observed that degradation was evident only at flow rates that were higher than those corresponding to the onset of non-Newtonian behavior for PAA. Degradation of PAAs was also studied by Maerker (1976) and, more recently, by Farinato and Yen (1987). Maerker quantified the degradation in flow through consolidated and nonconsolidated porous media. Farinato and Yen analyzed the effect that polymer concentration has on molecular weight loss, defined as the ratio between the apparent molecular weight of the polymer after it passed through the medium and the original molecular weight. They concluded that the molecular weight loss is larger for solutions of lower concentrations.

James and McLaren (1975) reported that the non-Newtonian behavior and the mechanical degradation of the polymer were enhanced by a decrease in particle diameter. A lower particle diameter implies a locally higher stretching rate; i.e., a stronger elongational flow in the pores, which induces the changes in molecular conformation that produce the non-Newtonian effects and favor the break up of the polymer molecules. Since the increase in flow resistance is directly related to the elongational flow in the pores, one would expect the onset of this behavior to be controlled by the value of the average stretching rate (defined, for example, as the local fluid velocity divided by the particle diameter). Chauveteau (1986), through the analysis of experimental information, has confirmed that the onset stretching rate is independent of particle diameter.

The effect of solvent quality, solvent viscosity and solution temperature on the non-Newtonian effects was studied by Durst et al (1981), and Kulicke and Haas (1984). Invariably, any effect that leads to a decrease in the shear viscosity of the solution results in a decrease in the flow rate at which the onset of non-Newtonian effects is observed. In fact, this onset flow rate is inversely proportional to the shear viscosity of the solution, a fact that is consistent with the behavior observed in elongational flows through simple geometries, in which the relaxation time of the polymer molecules is known to be directly proportional to the viscosity of the solvent with which the molecules interact.

Kulicke and Haas (1984), Farinato and Yen (1987), and Rodríguez et al (1993) analyzed the effect of polymer concentration. Kulicke and Haas stated that the onset Reynolds number was independent of concentration in the dilute regime. However, Farinato and Yen, and Rodríguez et al found a definite decrease of onset Reynolds number with an increase in polymer concentration. The latter observation is consistent with the transient network hypothesis.

The parameter that has the greatest influence over the increase in flow resistance is the molecular weight of the polymer. Durst et al (1981) reported that an increase in molecular weight leads to a decrease in onset Reynolds number. The fact that the molecular weight can be considered the controlling factor of the non-Newtonian effects in flow through porous media has led several investigators to propose that a porous medium can be used as a rheometer in which resistance coefficient curves can be used for an approximate determination of the molecular weight of a polymer sample (Haas and Kulicke, 1984, Farinato and Yen, 1987).

To our knowledge, the increase in flow resistance with Reynolds numbers has not been reported in the literature for xanthan polysaccharides, which are polymers with semi-rigid (worm-like) molecular conformations. These polymers exhibit shear-thinning behavior in the porous medium. Sorbie and Huang (1991) have recently characterized this behavior. They observed the fact that the shear-thinning behavior was more drastic under shear flow conditions than in the porous medium. They attributed this observation to the existence, and change with the flow rate, of a layer close to the solid phase that exhibits lower concentration of polymer molecules due to topological restrictions caused by the worm-like structure of the xanthan.

In this work we address three aspects of the flow of polymer solutions through porous media. First, we study the nonuniform flow of such fluids, in order to establish the impact of the presence of polymer on the flow distribution, and the effect that the flow nonuniformities have on the macroscopic non-Newtonian pressure drops. Second, we analyze the degradation of the polymer in the porous medium, emphasizing the differences in degree of degradation encountered in the three different regions of behavior of the resistance coefficient (see Fig 1). Finally, we presents results regarding the effect of the molecular weight of the polymer of the non-Newtonian behavior.

EXPERIMENTAL

A detailed description of the experimental set up used can be found in a previous work (Rodríguez et al, 1993). The apparatus allows the fluid to pass through a bed packed with spheres of diameter 1 mm, and average porosity of 0.4. Two different beds were used. One of them was designed to ensure a one-dimensional (uniform) flow of the fluid through the packing. This bed was a cylinder with an internal diameter of 1.9 cm and a packing length of 30 cm. Nonuniform flow experiments were performed in a different bed, which was also cylindrical, but it had a diameter of 6 cm and a length of 27.5 cm. The flow pattern was completely three-dimensional since the entrance and exit of the fluid to the bed were located on the surface of the cylinder at a distance of 4.7 cm from the ends. Both entrance and exit were circular orifices with diameter equal to 3 mm.

The experiments were carried out at 20°C, and atmospheric pressure conditions at the exit of the set up. Pressure drops and fluid flow rates were measured at steady state. The fluids used were distilled water, and aqueous solutions of two polydisperse PEOs provided by Polysciences Inc. The viscometric average molecular weights of the polymers were 3E06 and 4E06. Measurements of shear viscosity of the solutions were performed by means of a Ubbelohde viscometer submerged in a temperature-controlled bath. These measurements were used to quantify polymer degradation by determining the viscometric molecular weight of the polymer.

RESULTS AND DISCUSSION

Flow distribution

The influence of the flow distribution on the resistance coefficient is presented in Fig 2, for PEO solutions with a viscometric molecular weight (M_v) equal to 4E06. For the uniform flow case, the water curve exhibits the expected behavior for Newtonian fluids, for which Λ is nearly constant at low Reynolds numbers, and increases for Re>10, a point at which inertial effects become important. When the PEO solutions flow through the uniform porous medium, they exhibit a sudden increase in Λ beyond a critical Reynolds number, which we denote as the onset Reynolds number (Re_0), where deviations from the Newtonian behavior occur. Notice that the onset Reynolds number undoubtedly decreases as the polymer concentration increases. It is also interesting to point out that the curves reach the expected plateau. The plateau value of the resistance coefficient increases with increasing concentration. Another aspect of interest is the fact that, for small Reynolds numbers, the results corresponding to high polymer concentrations (e.g. C=1000 ppm for the uniform flow case) do not reach the water value of Λ, but a higher value. This is due to the fact that the viscosity used in the calculation of the resistance coefficient is the viscosity of the solvent and not the shear viscosity of the solution. If this latter parameter were used, one would expect all the curves to reach the viscous limit of the water curves as the Reynolds number becomes small.
