ANNOUNCEMENT

First International Symposium on Thermal Stresses and Related Topics

Hamamatsu, JAPAN
June 5-7, 1995
Act City

THERMAL STRESSES '95

The objective of this Symposium is to provide a forum for engineers and scientists in the field of thermal stresses, for industrial applications and basic research, in order to exchange ideas and to effect further cooperation among the participants. The Symposium will enable researchers and engineers to meet at one place, where they will present their papers and conduct discussions.

The Symposium will be comprised of invited lectures, and presentation and discussion of contributed papers. Sessions are planned on stresses, deformations, shock, fracture, fatigue, cracking and ratcheting in thermal environments; thermoelasticity and plasticity; mechanical behaviors of materials and structures at high and low temperatures; dynamic problems; computational and experimental methods; and ceramic, composite and advanced materials.

The official language will be English

The Symposium will be held from Monday, June 5, to Wednesday, June 7, 1995, at the Act City in Hamamatsu, Japan. Hamamatsu City, located halfway between Tokyo and Osaka, is blessed with a mild climate and with surroundings of abundant natural beauty, such as Mt. Fuji and Lake Hamana.

Call for Papers

Participants who wish to contribute a paper are requested to submit two copies of an abstract (about 500 words) by June 30, 1994, to one of the following:

Dr. R.B. Hetnarski
James E. Gleason, Prof of Mech Eng
Rochester Institute of Tech
PO Box 9887
Rochester, NY 14623-0887, USA
Telephone: 716-475-2157
Telefax: 716-475-6879
Bitnet: 632HETNA@RITVAX

Professor N. Noda
Department of Mech Eng
Shizuoka University 5-1
Johoku 3 chome,
Hamamatsu, 432, JAPAN
Telephone: 81/53-471-1171, Ext. 267, 268
Telefax: 81/53-475-4794
E-Mail:tmnnoda@mm.shizuoka.ac.jp

The abstract should include the title, full name, address of the authors, telephone and fax numbers.

Schedule

• Submission of abstract:	June	30, 1994
• Notification of acceptance:	September	30, 1994
• Submission of paper:	December	31, 1994

Vibrations of planar curved beams, rings, and arches

P. Chidamparam and A.W. Leissa
Department of Engineering Mechanics, The Ohio State University, Columbus OH 43210

This work attempts to organize and summarize the extensive published literature on the vibrations of curved bars, beams, rings and arches of arbitrary shape which lie in a plane. In-plane, out-of-plane and coupled vibrations are considered. Various theories that have been developed to model curved beam vibration problems are examined. An overview is presented of the types of problems which are addressed in the literature. Particular attention is given to the effects of initial static loading, nonlinear vibrations and the application of finite element techniques. The significantly different frequencies arising from curved beam theories which either allow or prevent extension of the centerline during vibratory motion are shown. An extensive bibliography of 407 relevant references is included.

CONTENTS

INTRODUCTION

The study of free vibrations of curved bars (or beams) and rings (closed curved bars) assumes great importance in a wide variety of technical applications like spring design, turbomachinery blades, automotive tire dynamics, aircraft structures, design of bridges for dynamic loads and circumferential stiffeners for shells. Real life engineering applications may also be found in interdisciplinary areas such as bioengineering and vibration control. While the dynamics of straight beams is well established, the same cannot be said about curved beams. The initial curvature has been a source of difficulty in developing governing relations between stress resultants and deformations. Thus, many theories have evolved in attempts at refining already existing ones. A similar scenario is seen in the theory of shells. Whereas this hierarchy is well documented in the case of shells [1], the situation is quite different with curved beams.

Interest in this area can be traced back to the nineteenth century. During the past few years there has been a steady growth of publications and at least two survey articles devoted solely to the dynamics of arches and curved bars [2,3] and a book [4] have appeared. The report by Royster [5] and certain review articles on beam vibrations [6-8] also contain some useful information.

The theory of curved bars is an extremely complicated one in the context of the three dimensional theory of nonlinear elasticity. As in the technical theories of straight beams, simplifying assumptions are made in describing the deformation so as to reduce the problem to a one dimensional form. The Euler-Bernoulli hypothesis of plane cross sections remaining plane after deformation is a case in point. It is known that the shear stress distribution across the cross section is nonuniform. Theories that do not account for a nonuniform variation of the through-thickness shear stress use a shear correction factor depending on the cross section in order to compensate for the errors introduced. One drawback of all the theories involving torsion lies in the twisting moment-twist relation which is based on the torsional stiffness obtained from a study of the static torsion problem of a straight cylindrical rod of identical cross section as the bar under consideration. In spite of all these limitations, it has been found that reasonably accurate results can be obtained from the theories developed in the aforementioned fashion.

The most general problem in free vibration of plane curved beams involves in-plane, out-of-plane, coupled motions consisting of extension, flexure, shear and twist. However, if the plane containing the centerline of the undeformed beam axis is a principal plane of the cross section at every point along the bar and also a plane of material symmetry, the in-plane and out-of-plane motions uncouple. In the case of a beam made of laminated composite material, for example, this uncoupling may or may not occur depending on the orientation of the

laminates. The in-plane motion consists primarily of bending-extensional modes, while the out-of-plane motion is essentially bending-twisting dynamics.

Although the spatial motion of planar curved beams involves all the free vibration modes in varying proportions, the lowest natural frequency is predominantly flexural. Thus, many of the early investigators have used the inextensionality condition, wherein the length of the centerline of the beam is assumed to be invariant during deformation. Such a constraint condition typically simplifies the analysis and is acceptable in many practical problems wherein the extensional modes correspond to much higher frequencies. The classical theory ignores the effects of shear deformation and rotary inertia, both of which tend to decrease the natural frequencies. Classical boundary conditions refer to either hinged (simply supported), clamped or free ends.

Because the topic of this compilation is pursued by people with diverse backgrounds, the literature is replete with technical information from allied fields such as wave propagation, thin walled beams, shells, computational methods, mathematical theory of rods and other related areas. It was therefore necessary to present a somewhat restricted view of the field in sufficient detail for the survey to be reasonably comprehensive without being unduly lengthy. Consequently, the scope of this review has been to a large extent influenced by the technical interests of the authors.

IN-PLANE VIBRATIONS

The in-plane vibrations have been studied with theories for thin curved bars as well as ones for thick curved bars. Invariably, the majority of the existing theories are based on the Euler-Bernoulli hypothesis of plane cross-sections remaining plane during deformation, which applies to thin curved bars. It is rather difficult to have a sharp demarcation between thin and thick bars purely on the basis of physical dimensions. It is accepted practice, though, to refer to a ring as thin when the ratio of the radius of curvature to the in-plane thickness is greater than about 10. The thin curved bar approximation has as its essential ingredient the carry over of the moment-curvature relationship used in the technical theory of straight beams. Further, the centroidal axis and the neutral axis are assumed to coincide.

Consider the curved bar shown in Fig 1. The x and z axes are principal axes of the cross section at the centroid, with the z axis lying in the plane of initial curvature. The normal component of the displacement of the centroidal axis is w, while the tangential component is v. Both v and w are functions of s, the arc length measured along the centroidal axis from a fixed reference point as shown in Fig 1. Due to in-plane vibrations, the stress resultants at any cross section consist of a normal force N arising out of the normal stresses at the section, a shearing force Q_z that is the resultant of the distributed shear stresses across the section, and a bending moment M_x that is the moment resultant with respect to the centroidal axis of the normal stresses. The positive senses for all the quantities are as indicated in the figure. The radius of curvature ρ is assumed to be a function of s, i.e., $\rho = \rho(s)$. Further, the area of cross section is denoted by $A=A(s)$, the mass density (mass per unit volume) by $m=m(s)$, and the second moment of the area of cross section about the x axis by $I_x = I_x(s)$. The material of the bar is assumed to be linearly elastic with Young's modulus E and shear modulus G. As in Timoshenko beam theory, the total rotation of the centroidal axis (denoted by ω) is assumed to be composed of a part due to bending (denoted by ψ) and a part due to transverse shear effects.

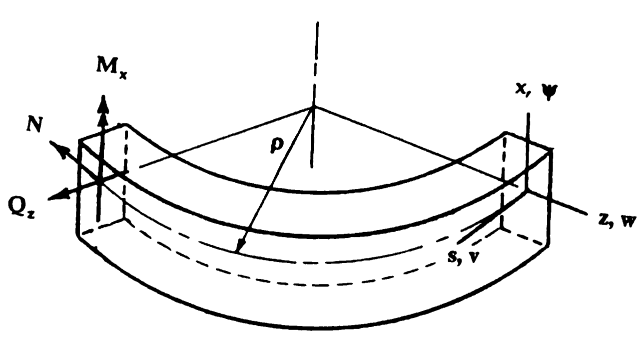

FIG 1. Curved beam coordinates and stress resultants for in-plane vibration.

Application of Newton's second law yields the following three differential equations, with primes denoting derivatives with respect to the arc length s and dots denoting time derivatives:

$$N' + \frac{Q_z}{\rho} = mA\ddot{v}, \tag{1a}$$

$$Q_z' - \frac{N}{\rho} = mA\ddot{w}, \tag{1b}$$

$$M_x' + Q_z = mI_x\ddot{\psi}. \tag{1c}$$

For small motions, the extensional strain (ε) and the rotation (ω) of the centroidal axis are given by:

$$\varepsilon = v' + \frac{w}{\rho}, \quad \omega = w' - \frac{v}{\rho}. \tag{2a, 2b}$$

Assuming a linearly elastic material, the normal force N is linearly related to ε, while the bending moment is proportional to the change in curvature as in the technical theory of beams. The shear force-shear strain relation is the familiar one from Timoshenko beam theory, with κ being the shear coefficient of the cross-section. Thus,

$$N = EA\varepsilon = EA\left(v' + \frac{w}{\rho}\right), \tag{3a}$$

$$Q_z = \kappa AG(\omega - \psi) = \kappa AG\left(w' - \frac{v}{\rho} - \psi\right), \tag{3b}$$

$$M_x = EI_x\psi'. \tag{3c}$$

Bresse [9] derived essentially the same equations as the ones presented above more than a century ago. Most of the work on purely in-plane motions of thin rings and curved beams are based on these equations, and sometimes under more restrictive conditions. Thus, by letting $G \to \infty$ in (3b) (no shear deformation) and $mI_x \to 0$ in (1c) (no rotary inertia), one gets the classical theory of extensional deformations with the equations of motion:

$$N' - \frac{M_x{}'}{\rho} = mA\ddot{v} \tag{4a}$$

$$-M_x{}'' - \frac{N}{\rho} = mA\ddot{w} \tag{4b}$$

where N is related to the displacement components v and w as in (3a), and M_x is given by

$$M_x = EI_x\left(w' - \frac{v}{\rho}\right)' \tag{5}$$

Although $\omega \to \psi$, because $G \to \infty$ in (3b) the shear force Q_z is finite. Waltking [10], obtained the above equations for the symmetric and antisymmetric extensional modes of hinged uniform circular arches. Adding the constraint of inextensionality, viz.,

$$\varepsilon = v' + \frac{w}{\rho} = 0, \tag{6}$$

one gets a sixth order equation in the tangential displacement v identical to the one developed by Hoppe [11], Federhofer [12] and Love [13]:

$$\frac{\partial^6 v}{\partial\theta^6} + 2\frac{\partial^4 v}{\partial\theta^4} + \frac{\partial^2 v}{\partial\theta^2} = \frac{mAR^4}{EI_x}\left(\frac{\partial^2 v}{\partial t^2} - \frac{\partial^4 v}{\partial\theta^2\partial t^2}\right) \tag{7}$$

where $\rho = R$ is the constant circular radius and $s = R\theta$. For a closed ring, displacements must be periodic in θ. Thus, one may assume a solution to (7) as:

$$v = C\cos n\theta \sin(\omega t + \gamma) \tag{8}$$

where n is an integer, ω is the free vibration frequency, C is an amplitude coefficient and γ is an arbitrary phase angle, with C and γ being determined by initial conditions. Substituting (8) into (7), one obtains the frequency equation derived by Hoppe [11],

$$\lambda^2 = \frac{n^2(n^2-1)^2}{n^2+1}, \tag{9}$$

where λ is a nondimensional frequency parameter defined by

$$\lambda = \omega R^2\sqrt{\frac{mA}{EI_x}} \tag{10}$$

Some of the other early works that treat thin rings are those of Rayleigh [14], Love [15] and Lamb [16]. Carver [17] considered bending-extensional coupling and found no significant variation in his results between thin and thick rings. Morley [18] presented the free vibration frequencies of the first ten symmetric and antisymmetric modes of a thin ring neglecting centerline extension. Archer [19] and Clayton and Royster [20] studied the damped inextensional vibrations of thin circular rings and outlined a solution procedure for time dependent displacement end conditions based on the Mindlin Goodman technique [21].

The equations of motion of rings and arches have also been obtained from plate and shell theory [22-28]. Ambati et al [29] analyzed the in-plane vibrations of an annulus of which the thin ring is a special case. Liu and Langhaar [30] examined the dilatationless circumferential ring vibration modes wherein the deformations of all cross sections are identical. Experimental data on circular rings can be found in [31-33]. Based on the eigenvalue problem for rectangular cross section thick rings, Lecoanet and Piranda [34] investigated the frequencies and modes of thick rings whose cross sections can be broken up into rectangles. Support motion problems have also received some attention in the literature [35-38]. A number of other authors have also analyzed thin rings [39-65].

For curved bars which are not complete rings, the inextensional theory is not adequate for determining in-plane vibrational behavior. Consider a circular arch subtended by an angle 2α, having appropriate boundary conditions at the ends $\theta = \pm\alpha$. Using the inextensional theory, one assumes

$$v(\theta, t) = V(\theta)\sin(\omega t + \gamma), \tag{11}$$

obtains a general solution to the ordinary differential equation in V resulting from (7), and applies the boundary conditions to obtain the frequency determinant. The extensional theory is obtained by not assuming $\varepsilon = 0$ in (6), but by substituting (5) into (4) to yield a set of coupled equations of motion in v and w. For circular curvature $\left(\rho = R, \frac{d}{ds} = \frac{1}{R}\frac{d}{d\theta}\right)$, they are [66]:

$$\left(1+k^2\right)\frac{\partial^2 v}{\partial\theta^2} + \left(-k^2\frac{\partial^3}{\partial\theta^3} + \frac{\partial}{\partial\theta}\right)w = \frac{mR^2}{E}\frac{\partial^2 v}{\partial t^2} \tag{12a}$$

$$\left(-k^2\frac{\partial^3}{\partial\theta^3} + \frac{\partial}{\partial\theta}\right)v + \left(k^2\frac{\partial^4}{\partial\theta^4} + 1\right)w = -\frac{mR^2}{E}\frac{\partial^2 w}{\partial t^2} \tag{12b}$$

where $k^2 = I_x/AR^2$. An exact solution of (12) may be obtained, and boundary conditions applied, to yield a proper frequency determinant.

Figure 2 shows nondimensional frequency parameters λ for circular arches of rectangular cross-section having both ends clamped ($v = w = \frac{\partial w}{\partial\theta} = 0$ at $\theta = \pm\alpha$), with varying arc segment half-angle, α. The thickness-to-mean radius ratio (h/R) is 0.1. The first four frequencies are given for both the inextensional and extensional theories described above. This corresponds to two symmetric and two antisymmetric modes for each theory. For the antisymmetric modes, it is seen that the inextensional and extensional results agree closely (but not exactly). Thus, the axial deformation required by the antisymmetric modes is small. However, the frequencies predicted by the two theories are observed to be greatly different for the symmetric modes, for $\alpha < 60°$ in the case of the first

modes 1-4 (inextensional)

FIG 2. Nondimensional frequency versus arc segment half-angle for clamped circular arches (h/R=0.1).

mode, and $\alpha < 90°$ (the semicircular arch) for the second mode. As expected, the frequencies from the extensional theory are less than the inextensional ones, for the constraint of no axial deformation is relaxed. However, for $\alpha = 25°$, Fig 2 shows the fundamental (lowest frequency) value of λ for the inextensional theory to be approximately twice that of the more accurate, extensional theory. For shallower arches, and for higher modes, the disparity becomes even greater. For $\alpha > 90°$, frequencies of the two theories approach each other, becoming equal at $\alpha = 180°$ (the full circle).

Figure 3 shows similar results for arches having both ends pinned ($v = w = M_x = 0$ at $\theta = \pm\alpha$). The frequencies are all considerably less than those of the previous clamped arches. Again, the antisymmetric mode frequencies from the two theories agree closely, but the symmetric mode frequencies may differ greatly. The differences are seen to be greater for the pin supported ends than for the clamped ends.

For thinner arches, agreement between the two theories is closer, as may be seen for the data shown in Fig 4 for pinned arches having h/R=0.01. Nevertheless, as the arches become shallower, the symmetric mode frequencies disagree considerably.

It is well known that the effects of shear deformation and rotary inertia are to decrease the natural frequencies and that these effects are very important with a short and stubby bar. Federhofer [67] considered the influence of centerline stretching, she[...]rmation and rotary inertia on the natural freq[...]ing vibrations of circular rings. Philipson [...]e inextensibility assumption for the flexur[...]hin rings by extending Love's [13] ana[...]ne effect of rotary inertia and centerli[...]ound the extensibility effects to be negl[...]] derived the equations of motion for a circular bar considering shear deformation, rotary inertia and stretching of the neutral axis. Austin and Veletsos [70] and others [71-75] examined the influence of shear deformation and rotary inertia on the free vibration characteristics of arches. Based on the numerical results in [70], it was concluded that the free vibration modes can be classified as mainly inextensional with flexural-shearing coupling, mainly extensional with rotary inertia and shear deformation having insignificant participation, and a

combination of these two types of behavior.

The thick ring theories differ from one another with regard to the through-thickness strain distribution. The description of the strain variation across the cross section has in fact been a difficult task even with straight rods [76]. Buckens [77] studied the influence of radial thickness on the natural frequencies of a ring considering the effect of shear and extension and concluded shear to be a significant factor affecting free vibration frequencies compared to rotary inertia and curvature, with extensibility playing a negligible role. Seidel and Erdelyi [78] derived the characteristic equation for the free vibration frequencies of thick rings considering transverse shear, rotary inertia and extensibility effects by formulating the Lagrangian. The normal strain variation across the cross section was assumed to be nonlinear and an average shear angle was used. It was shown that consideration of extensibility effects could lead to certain computational difficulties. Their frequency equation for inextensional deformation reads:

$$k^6\lambda^4 - k^2\left(\frac{e}{R}n^2 + \kappa\frac{G}{E} + \kappa\frac{G}{E}\frac{\left(n^2-1\right)^2}{\left(n^2+1\right)}k^2\right)\lambda^2 + \kappa\frac{G}{E}\frac{n^2\left(n^2-1\right)^2}{\left(n^2+1\right)}\frac{e}{R} = 0 \qquad (13a)$$

$$\text{where}\quad \frac{e}{R} = 1 - \frac{h/R}{\ln\left(2+\frac{h}{R}\right) - \ln\left(2+\frac{h}{R}\right)}, \qquad \frac{h}{R} < 2, \qquad (13b)$$

$$k^2 = \frac{I_x}{AR^2} = \frac{1}{12}\left(\frac{h}{R}\right)^2. \qquad (13c)$$

where h is the radial thickness of the ring, κ is the shear correction factor and λ is as given in (10).

Kirkhope [79] obtained an approximate frequency expression for thick circular rings using the Rayleigh method and assessed its accuracy with the experimental results of Kuhl [80] and Lincoln and Volterra [81]. This simple expression reads:

$$\lambda^2 = \frac{n^2\left(n^2-1\right)^2}{\left(n^2+1\right)}\frac{1}{1+n^2\alpha}, \qquad (14a)$$

$$\text{where}\quad \alpha = \frac{I_y}{AR^2}\frac{E}{G}\frac{1}{\kappa}. \qquad (14b)$$

Kirkhope [82] also derived a cubic frequency equation for the in-plane motion of a thick circular ring, the three roots corresponding to flexural, extensional and shear modes. The computed frequencies were again compared with the experimental results in [80] and [81]. Rao and Sundararajan [83] developed inextensional equations of motion for circular rings considering shear deformation and rotary inertia. Their frequency equation was:

$$\left(n^2+1\right)\frac{E}{\kappa G}k^4\lambda^4 - \left(k^2\left(n^2-1\right)^2 + \frac{E}{\kappa G}k^2n^2\left(n^2+1\right) + \left(n^2+1\right)\right)\lambda^2 + n^2\left(n^2-1\right)^2 = 0 \qquad (15)$$

A comparison of some of the various theories described above for a complete circular ring of rectangular cross section is presented in Fig 5 for the lowest frequency (n=2). The abscissa represents the ratio of thickness to radius of curvature (h/R). Representative values of the shear correction factor $\kappa = 5/6$ and the Poisson ratio $\nu = 0.29$ were used in plotting.

Gardner and Bert [84] proposed another theory for shear deformable rings and curved beams. The through thickness shear strain distribution was chosen to satisfy the zero shear conditions on the inner and outer boundaries of the ring. Natural frequencies predicted by this theory were compared with their own experimental results and also with other analytical and experimental results reported in the literature. Suzuki [85], in an attempt to improve the accuracy of existing solutions, considered the effect of cross section warping on in-plane vibrations. According to his conclusion, it is possible to improve solution accuracy by considering section warping.

A number of studies aimed at computing the natural frequencies of arcs (or ring segments) based on the Rayleigh-Ritz and related methods have been reported [86-96]. Takahashi [97] obtained the equations of motion governing the radial and tangential displacements of a thin circular arc bar by minimizing the Lagrangian of the system. With his coworkers [98] he conducted an analytical and experimental investigation of the in-plane vibration of curved bars of elliptic and sinusoidal

o Kirkhope [79] • Rao & Sundararajan [83]

FIG 5. Fundamental vibration frequency of a full circular ring.

centerlines, considering the effects of bending and extension. Suzuki et al [99] studied the free vibration of curved beams neglecting the effect of shear deformation and rotary inertia. Results were presented for clamped symmetric arcs with sinusoidal, catenary, hyperbolic, parabolic and cycloidal centerlines and for an asymmetric elliptic arc bar with both ends clamped. Suzuki and Takahashi [100] in a subsequent publication, used the Timoshenko theory to compute the natural frequencies and modes of clamped and hinged elliptic arc bars. A comparison was made with the classical theory to assess the relative importance of the shear and rotary inertia terms. Lee and Wilson [101] derived governing equations for the in-plane motions of arches of arbitrary centerline accounting for bending, extension and rotary inertia. Shear deformation was neglected. The lowest three natural frequencies of parabolic, sinusoidal and elliptic arcs under hinged and clamped end conditions were presented. The effect of rotary inertia on the frequencies was examined. Experimental data were reported to support the numerically generated results.

Discretization procedures [102-104] have been used to study the in-plane motions of a thin curved rod. Rings on multiple supports are considered in [105-110]. Vibrations of continuous and multisupported curved beams [111-122] have been pursued by some researchers. Finite difference schemes have been employed in the study of in-plane vibrations [123-126]. The vibrations of slightly curved (very shallow) beams were studied [127-132]. Nagaya [133] studied the in-plane vibration of thick-walled pipes and rings of arbitrary shape by solving the equation of motion of elastic solids under plane strain conditions.

The free vibrations of rings and arches with varying cross section has been the subject of numerous investigations [134-148]. Suzuki and Takahashi [134] derived the equations of motion based on classical theory for the in-plane vibrations of a curved bar with varying cross section using the Lagrangian approach. They presented extensive results for the natural frequencies and mode shapes of clamped and hinged symmetric elliptic arc bars, with thickness varying quadratically as $h = h_o(1 + ks^2)$. Lecoanet and Piranda [136] examined the in-plane vibrations of circular rings of radially variable thickness using the Galerkin method. They used the eigenfunctions of a constant thickness ring as trial functions and noticed good agreement with experimental data. Rutledge and Royster [137,138] developed mathematical models for the free vibrations of arcs of arbitrary shape and varying cross section. Royster [139] presented the fundamental extensional frequency of a clamped circular arc with a linear taper normal to the plane of the arc. Suzuki et al [140] deduced the equations of motion of inhomogeneous curved bars with varying cross sections and curvatures from the Lagrangian. Natural frequencies and modes for circular and elliptic arc bars with clamped and clamped-free ends were presented. Extensive studies have been made by Laura and his colleagues [141-155]. A number of these [141-145] use approximate methods to analyze the in-plane vibrations of variable cross section rings and arcs. Others [149-156] deal with the in-plane vibrations of curved beams and arcs with attached concentrated masses. Research has also been conducted on the vibrations of rings with irregularities and deviations [157-161] from perfect axisymmetry. Spline interpolation [162] and transfer matrix techniques [163-166] have been used. Forced vibration problems have also been attempted [167-178]. Vibrations of beams on foundations, and viscoelastic and composite curved beams [180-198] are also studied in the literature.

OUT-OF-PLANE VIBRATIONS

As shown in Fig 6, the out-of-plane motion is described by the displacement u, the bending rotation ς and the twist angle ϕ. Q_x and M_z are the out-of-plane shear force and bending moment, respectively, and M_t is the twisting moment. I_z is the second moment of the cross sectional area about the z axis and J is the polar moment. Newton's Laws give

$$Q_x' = mA\ddot{u}, \tag{16a}$$

$$-M_z' + \frac{M_t}{\rho} - Q_x = mI_z\ddot{\varsigma}, \tag{16b}$$

$$M_t' + \frac{M_z}{\rho} = mJ\ddot{\phi}. \tag{16c}$$

The stress resultants and displacements are related as follows:

$$Q_x = \kappa GA(u' - \varsigma), \tag{17a}$$

$$M_z = -EI_z\left(\varsigma' + \frac{\phi}{\rho}\right), \tag{17b}$$

$$M_t = C\left(\phi' - \frac{\varsigma}{\rho}\right). \tag{17c}$$

where C is the torsional stiffness coefficient.

Michell [199] developed the frequency equation for out-of-plane ring vibrations using classical theory. Love [15] gave frequency formulas for thin rings neglecting rotary inertia and shear deformation. Volterra [200,201] used the method of internal constraints to develop equations of motion of curved bars and discussed a solution methodology [202] for these equations based on that of a straight bar. Federhofer [203] derived an exact frequency equation for the lowest natural frequency of clamped arches. Brown [204] used the Rayleigh method for a clamped arch. Nelson [205] employed the Rayleigh-Ritz method for doubly symmetric thin circular ring segments, neglecting rotary inertia and shear deformation. Ojalvo [206] considered the out-of-plane twisting-bending dynamics of

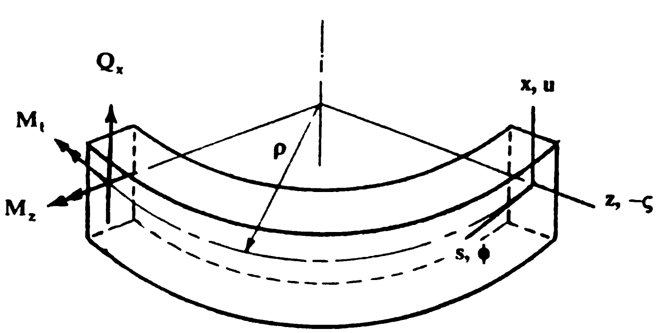

FIG 6. Curved beam coordinates and stress resultants for out-of-plane vibration.

clamped circular ring segments based on classical theory. Takahashi [207] obtained frequency equations for a circular arc with clamped and free ends considering rotary inertia, but not shear deformation. Kirkhope [208] and Rao [209] included shear deformation to develop equations of motion for thick circular rings. Irie et al [210] computed the natural frequencies of circular arcs vibrating out of the plane of curvature, for all combinations of classical boundary conditions, including shear deformation effects. Endo and Taniguchi [211] analyzed the in-plane flexural and out-of-plane twist bending vibrations of rings with cross sections having a single axis of symmetry. All these investigations neglected cross sectional warping and the variation of curvature through the thickness ($\rho^* = \rho + z$). Bickford and Maganty [212] developed equations of motion for symmetric cross section thick rings, accounting for curvature variation through the thickness and supported their frequency predictions with the experimental data of Kuhl [80].

Curved plates and plate-like theories for curved beams have also come under scrutiny [213-215]. Shell theories have been used to model ring vibrations [216,217]. Chang and Volterra [218,219] employed differential operator theory to assess the upper and lower bounds for the first four natural frequencies of elastic clamped and simply supported arcs. They considered centerlines in the form of circles, cycloids, catenaries and parabolas. Takahashi and Suzuki [220] studied the vibrations of elliptic arc bars. Suzuki and coworkers [221,222] obtained governing equations for the out-of-plane vibrations of plane curved bars of arbitrary centerline profile, based on both the classical and the shear deformation theory. Frequencies and mode shapes were given for clamped bars with centerlines in the form of ellipses, sines, catenaries, hyperbolas, parabolas and cycloids. Silva and Urgueira [223] developed tip dynamic stiffness matrices for a free-free curved beam, incorporating shear deformation and rotary inertia in their analysis. Model validation based on experimental results was also discussed. Curved beams with nonuniform cross section [224-226] have been studied. Reddy [227] used a lumped mass approach for out-of-plane vibrations. Free and forced vibration problems have been attempted using the transfer matrix approach [228-232]. Suzuki et al [233] investigated the out-of-plane, steady-state response of curved bars. Impulse response due to dynamic loads on bars and rings have been studied [234-236]. Joseph and Wilson [237] investigated the dynamic response of curved beams with moving loads. Elastically supported curved beams [238-240] and continuous curved beams [241-245] have also received some attention. More information is available in [246-253].

COUPLED VIBRATIONS

The coupled motion between in-plane and out-of-plane displacements gives rise to a twelfth order set of equations of motion and six boundary conditions at each end of the beam. Thus, in general, the free vibration problem yields a twelfth order frequency determinant, whose solution corresponds to two bending modes, a twisting mode, an extensional mode and two shearing modes if the displacements were to uncouple. However, in general, the motion is completely coupled. A derivation of the governing equations for the coupled motions of a thin curved bar are outlined in this section. The coordinate axes along with the displacement and stress resultant components are as indicated in Figs 1 and 6, except that x and z are now principal axes of inertia of the cross section. In general, the z-axis will not lie in the initial plane of curvature. Let the angle between the inward principal normal to the centerline and the z-axis be $\chi = \chi(s)$. Rotation angles about the x, s and z coordinates are ψ, ϕ and $-\varsigma$, respectively, as used in the previous two sections dealing with uncoupled motions. The displacement components u, v and w describe the motion of a point on the centerline (locus of centroids). Displacement and rotation components u, v, w, ψ, ϕ, and ς are functions of s. It is assumed that the displacements are small, and that plane cross sections remain plane during deformation. Thus cross sectional warping due to torsional motions is ignored.

The equations for the coupled motions of a curved and pretwisted bar were obtained by Washizu [254]. In the following, these results are presented for the case of no pretwist. The displacement components of any point in the bar denoted by U, V and W satisfying these requirements are given by:

$$U(s,t) = u(s,t) + z\phi(s,t), \tag{18a}$$
$$V(s,t) = v(s,t) - x\varsigma(s,t) - z\psi(s,t), \tag{18b}$$
$$W(s,t) = w(s,t) - x\phi(s,t). \tag{18c}$$

Based on this, it can be shown that the strain components for small motions are given by:

$$\varepsilon_y = 0,\ \varepsilon_z = 0,\ \varepsilon_{yz} = 0, \tag{19a-19c}$$

$$\varepsilon_s = \left(v' - \frac{\cos\chi}{\rho}w + \frac{\sin\chi}{\rho}u\right) + x\left(-\theta' - \chi'\psi + \frac{\cos\chi}{\rho}\phi\right) - z\left(\psi' - \frac{\sin\chi}{\rho}\phi - \chi'\theta\right) \tag{19d}$$

$$\varepsilon_{xs} = \frac{1}{2}\left[\left(u' - \frac{\sin\chi}{\rho}v + \chi'w - \theta\right) + z\left(\phi' + \frac{\cos\chi}{\rho}\theta + \frac{\sin\chi}{\rho}\psi\right)\right] \tag{19e}$$

$$\varepsilon_{zs} = \frac{1}{2}\left[\left(w' + \frac{\cos\chi}{\rho}v - \chi'u - \psi\right) - x\left(\phi' + \frac{\cos\chi}{\rho}\theta + \frac{\sin\chi}{\rho}\psi\right)\right] \tag{19f}$$

The only nonzero stress components in the case of a linearly elastic material with no Poisson effect are σ_s, σ_{xs} and σ_{zs}. The stress resultants are seen in Figs.1 and 6, and are given in terms of the stresses as:

$$Q_x = \int_A \sigma_{xs}dA, \qquad Q_z = \int_A \sigma_{zs}dA, \tag{20a,20b}$$

$$N = \int_A \sigma_s dA, \qquad M_x = -\int_A z\sigma_s dA, \tag{20c,20d}$$

$$M_z = \int_A x\sigma_s dA, \qquad M_t = \int_A (z\sigma_{xs} - x\sigma_{zs})\, dA. \quad (20e,20f)$$

In order to account for the variation of the shear strain across the cross section, a constant shear correction factor κ is introduced in the shear stress resultants. Evaluating the integrals given by (20a)-(20c) and incorporating the shear correction factor leads to:

$$Q_x = \kappa G A\left(u' + \chi' w - \frac{\sin\chi}{\rho} v - \varsigma\right), \quad (21a)$$

$$Q_z = \kappa G A\left(w' - \chi' u + \frac{\cos\chi}{\rho} v - \psi\right), \quad (21b)$$

$$N = EA\left(v' - \frac{\cos\chi}{\rho} w + \frac{\sin\chi}{\rho} u\right), \quad (21c)$$

The twisting moment-twist relationship, with C denoting the torsional stiffness of the section, and the bending moment-curvature change relations are:

$$M_t = C\left[\phi' + \frac{\cos\chi}{\rho}\varsigma + \frac{\sin\chi}{\rho}\psi\right], \quad (21d)$$

$$M_x = EI_x\left[\psi' - \chi'\varsigma - \frac{\sin\chi}{\rho}\phi\right], \quad (21e)$$

$$M_z = EI_z\left[-\varsigma' - \chi'\psi + \frac{\cos\chi}{\rho}\phi\right]. \quad (21f)$$

The equations of motion can be shown to be:

$$Q_x{}' + \chi' Q_z - \frac{\sin\chi}{\rho} N = mA\ddot{u}, \quad (22a)$$

$$N' + \frac{\sin\chi}{\rho} Q_x - \frac{\cos\chi}{\rho} Q_z = mA\ddot{v}, \quad (22b)$$

$$Q_z{}' - \chi' Q_x + \frac{\cos\chi}{\rho} N = mA\ddot{w}, \quad (22c)$$

$$-M_z{}' + \chi' M_x - \frac{\cos\chi}{\rho} M_t + Q_x = mI_z\ddot{\varsigma}, \quad (22d)$$

$$M_x{}' + \chi' M_z - \frac{\sin\chi}{\rho} M_t + Q_z = mI_x\ddot{\psi}, \quad (22e)$$

$$M_t{}' + \frac{\sin\chi}{\rho} M_x - \frac{\cos\chi}{\rho} M_z = mJ\ddot{\phi}. \quad (22f)$$

Substituting Eqs (21) into (22) yields a twelfth order system of differential equations in terms of the displacement components u, v, w and the rotation components ψ, ϕ and ς. It can be shown that Eqs (22a)-(22f) uncouple when $\chi = 180^\circ$ and the equations of motion for in-plane and out-of-plane vibrations presented previously may be recovered.

Endo [255], Hawking[illegible]6], Kirkhope et al [257] and Hammoud and Arch[illegible] analyzed unsymmetrical cross section ring[illegible] [illegible]lane and out-of-plane motions coupled. [illegible] 259,260] developed a generalized shear [illegible]y valid for thick and thin rings of circular centerline; with the classical thin ring theory and the shear deformation theory as special cases. Williams [261], in a well written paper, deduced the equations of motion for small motions of a circular ring of thin open cross section including the effects of warping deformations. Natural frequencies and mode shapes of both complete and incomplete rings were presented.

VIBRATIONS UNDER INITIAL STRESSES

Figure 7 shows a curved beam or arch subjected to components of normal (q) and tangential (p) static loading distributed along its length. In general, the magnitudes of the loads vary along the length; i.e., q=q(s) and p=p(s). These loads cause a static axial force $N_o = N_o(s)$, which affects the free vibration frequencies and mode shapes. Generally, if N_o is tensile, the frequencies are increased. If it is compressive, they are decreased. At a limiting (critical) value of N_o the fundamental frequency is reduced to zero. This corresponds to bifurcation buckling. Thus, it is possible to predict the fundamental buckling load based on a linearized free vibration analysis about a prestressed equilibrium state, and this procedure forms a convenient means of experimentally determining the buckling load by extrapolating the load-frequency curve.

Although a literature search has uncovered well over 100 published references dealing with the buckling of rings and arches [66], little research has taken place on the vibrations of loaded rings and arches. The theory is more intricate than that for unloaded configurations, for one must derive equations of motion based upon small displacements (to obtain a linear eigenvalue problem) away from an initial, loaded equilibrium state.

For an arch that is free to execute both in-plane and out-of-plane motions, the free vibration frequency and critical load associated with the out-of-plane motions may be considerably lower than those for in-plane motions [262], depending upon the aspect ratio of the cross section and the boundary conditions. Wasserman [263] examined the effect of hydrostatic loads, dead loads and centrally directed pressure loads on the frequencies of in-plane and out-of-plane vibrations of circular rings. Centerline extensibility was not considered. Exact and approximate expressions for the frequencies and critical loads of arches, considering end support flexibility have been obtained [264]. The effect of an elastic foundation on the free vibration frequency of a shallow arch subjected to a thrust load was analyzed by Plaut and Johnson [265]. Perkins [266] used a model for the in-plane behavior that accounts for geometric

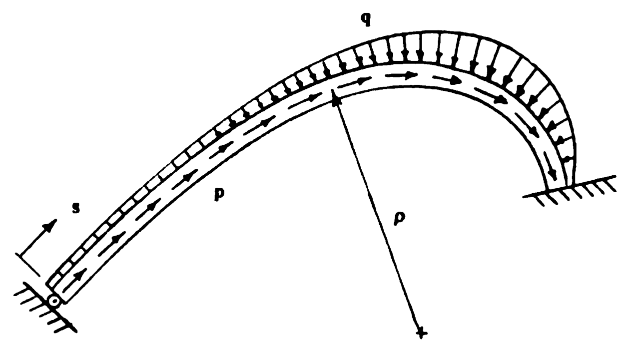

FIG 7. Curved beam under initial stresses.

nonlinearity in the extension and bending terms. The linear vibration problem about the equilibrium configuration was solved numerically for the free vibration frequencies and modes. Comparison of experimental data with theoretical results showed fairly good agreement. Lin and Soedel [267] developed the equations of motion for the general in-plane motion of rotating thick and thin rings on elastic foundations and subjected to initial stresses. They used the nonlinear strain displacement relations to form the energy terms. The simplified ring theories were recovered by imposing constraint conditions and eliminating the Lagrange multiplier. It was also shown that extensional coupling effects could be as significant as shear effects in the case of thick rings.

The effect of extensibility and initial equilibrium rotations on the in-plane stability and free vibrations under static preload, of thin curved beams of arbitrary centerline profile, have recently been analyzed [66]. Normally directed dead loads and gravity loading were considered. The rest of this section takes a closer look at the in-plane free vibration frequencies of loaded circular arches.

Extending the previously described inextensional and extensional theories for curved bars or arches to the loaded situation, it is possible again to obtain exact solutions for the free vibration frequencies and mode shapes of circular arches in the case of uniform normal loading. Fig 8 shows the variation in $\omega R^2\sqrt{mA/EI_x}$ with the nondimensional loading parameter $q_o R^3/EI_x$, where q_o is the uniform normal pressure (force/length) acting constantly in the radial direction, for an arch with both ends clamped, an arc segment $2\alpha = 80^o$ and a rectangular cross-section with a thickness ratio (h/R) of 0.1. The first four vibration frequencies are shown according to both the inextensional and extensional theories. As expected, positive (compressive) loadings cause decreases in the frequencies, and negative (tensile) loadings, which may be caused by uniform pressure on the underside of the arch, cause increases in the frequencies. The great differences previously seen in Fig 2 between the results from inextensional and extensional theories for the unloaded arch, are seen in Fig 8 to be magnified further by the loading.

The problem of the in-plane vibrations of rotating curved beams and rings [268-282] and the out-of plane motions of rotating curved beams [283-288] have also been studied. Additional information on the vibrations of loaded rings and arches can be found in [289-303].

NONLINEAR VIBRATIONS

Nonlinear vibration problems arise when the amplitude of motion cannot be considered to be small, or when the material behavior is nonlinear, or if nonlinear damping is present. Closed form solutions for nonlinear problems of continuous systems are extremely rare. A number of semianalytical techniques are in use that are capable of producing solutions of varied accuracy. One such approach is the assumed modes method that utilizes deflection shapes selected apriori. Alternatively, perturbation based methods are also employed.

Nonlinear free flexural vibrations of circular rings were examined by Federhofer [304]. Attempts have been made to characterize the nonlinear behavior of curved structural elements as having soft or hard spring responses. Many of these investigations were based on approximate solution techniques such as the assumed modes method. These methods can lead to an incomplete description of the frequency-amplitude relationship depending on the nature of the assumed solution. An interesting discussion can be found in [305]. A number of authors have addressed the free vibration of arches and rings [306-317]. Singh and Ali [310] discussed softening and hardening behavior in beams and curved members and also the transition between arches and curved beams. Simmonds [315] developed nonlinear equations for a ring and examined the frequency-amplitude dependence. The effects of extensibility, transverse shear and rotary inertia were found to be negligible and the nonlinearity was identified as a softening one. Maganty and Bickford [316] analyzed the nonlinear motions of thin circular rings by the method of multiple scales, neglecting shear deformation, rotary inertia and centerline stretching. The results for the nonresonant case demonstrated that the frequency of an out-of-plane bending mode is significantly reduced by the presence of a nonzero in-plane bending amplitude, whereas the results for the resonant case indicated the presence of unsteady oscillations with an exchange of energy between the in-plane and the out-of plane modes.

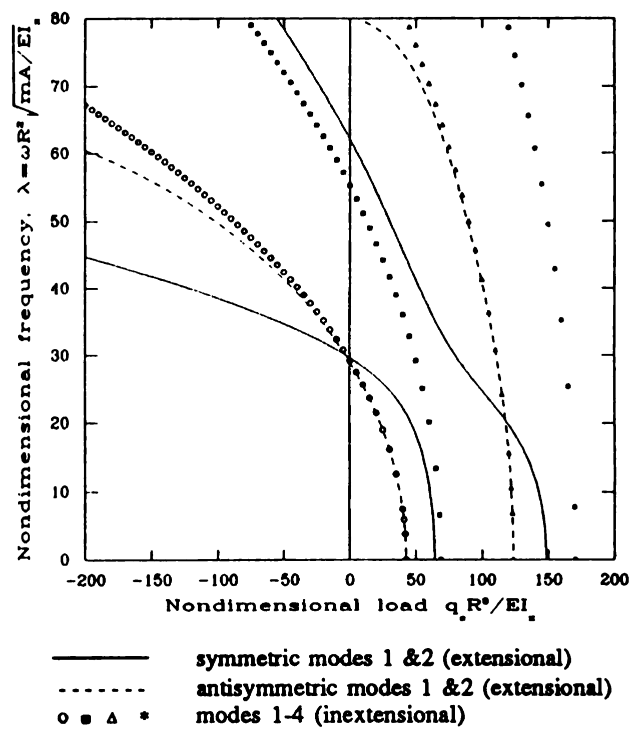

FIG 8. Load-frequency spectrum of a clamped circular arch under normal loading (h/R=0.1, $\alpha=40^o$).

Evensen [318-320] considered the in-plane response of thin circular rings with a nonlinear strain displacement relation to a harmonic excitation, both theoretically and experimentally. The inextensibility condition was used, which was later relaxed by Dowell [321] who found essentially identical results. Further information on nonlinear analysis and response evaluation can be found in [322-342].

FINITE ELEMENTS

The finite element method has been extensively used in the study of curved structures. Interest in developing curved beam elements was increased during the course of synthesizing shell elements. The curved beam element, being a one dimensional counterpart of the more complicated, two dimensional shell element offered simplicity and insight. Most of the investigations were limited to the in-plane motion of arches. It is not intended to describe the various stages in element synthesis that are usually associated with the solution of static problems. Rather, a very brief outline of the various elements that are being used, with particular attention to vibration problems will be presented.

The initial attempts at developing curved beam elements using low order independent interpolations for the in-plane displacements proved unsuccessful. Surprisingly, straight elements which do not account for flexural extensional coupling turned out to be more accurate than the curved elements in certain problems. The failure of these elements were incorrectly attributed to the inability of the assumed displacement fields to represent rigid body modes and constant strain states. Noor and Peters [343] found that the performance of displacement models based on independent low order interpolations (cubic or less) for displacement and rotation components deteriorated as the element became thin, and also in the limit of inextensional deformation. Later studies, however have shown that a spurious mechanism called shear locking was responsible for many such failures. Furthermore, selective integration procedures have been found to alleviate the difficulties. When an element cannot bend without being stretched, undesirable stiffness is added during bending, with subsequent loss of accuracy.

Dawe [344] conducted a numerical evaluation of various curved beam elements for the in-plane static problem. A wide variety of interpolation functions was used, based on both assumed strain distributions and independently interpolated displacement components of up to quintic order polynomials. Based on a study of both shallow and deep arches, it was concluded that the assumed strain models and the quintic-quintic displacement model performed well, while the performance of the low order independently interpolated displacement models degenerated as the arch became thin. Later, Prathap [345] used selective integration to rectify the poor performance of low order displacement models. Nonlinear finite elements, mixed, hybrid and penalty methods and the Timoshenko arch element have also received some attention.

There have been far more articles dealing with the application of finite element analysis for the in-plane vibration of arches [346-358] than with out-of-plane vibration [359,360]. Petyt and Fleischer [346] studied the radial vibrations of curved beams using three different elements. They obtained the most accurate results when both the normal and tangential displacements were approximated using polynomials of the same degree (cubic in their case). In a follow-up study [347], they presented finite element results and supported their findings on the basis of experimentation on multisupported curved beams. Sabir and Ashwell [348] conducted a convergence study on the frequency of free vibrations of thin and thick rings using four different elements. Davis et al [349] included the effects of transverse shear rotary inertia and centerline stretching in their element. An interesting feature of their formulation was that the displacement interpolations were obtained from the governing equations of static equilibrium, instead of assuming them outright. They used a similar technique for analyzing coupled twist bending vibrations [359]. Thomas and Wilson [360] utilized straight beam elements with six degrees of freedom per node to investigate the vibrational behavior of curved beams. Several previously cited research publications also use the finite element method for the vibration analysis of planar curved beams, rings and arches [187, 269, 270, 306, 314]. References [361-365] contain additional useful information.

OTHER RESEARCH ISSUES

During the course of this compilation, pertinent information on certain related topics including vibrations of thin walled curved beams [366-389], optimization problems [390-392], and vibrations of curved beams subjected to a temperature field [393,394] were also gathered. It is felt that this would constitute relevant information worth including for researchers in this field.

CONCLUDING REMARKS

Although the subject of curved beam vibrations had its beginnings in the nineteenth century, it was during the last two decades that the most progress, both in terms of theoretical developments as well as availability of engineering data, has been achieved. In spite of the purely academic motive behind some of the earlier publications, potential areas of engineering applicability do exist as described in the Introduction. Another incentive for such extensive research in this area stems from the interest in furthering the knowledge of the behavior of doubly curved structural elements like shells. The study of curved beams has in fact been thought to be an important first step in developing shell elements for finite element shell analysis as well as for an understanding of their nonlinear behavior.

The in-plane vibration problem has received considerably more attention than the out-of-plane and coupled problems. Most of the studies, have however been directed towards an understanding of the response of circularly curved beams, often under restrictive assumptions and classical boundary conditions. Experimental data is definitely lacking. Less has been accomplished for the vibrations of a general curved bar subjected to static loading, although curved bars with circular centerline have come under scrutiny. No studies have been found on the behavior of curved beams and rings subjected to acoustic excitation, although such studies do exist for shells. Thus, it is felt that research in this area will continue unabated for the near future.

One-dimensional (1-D) analysis of curved beams, rings and arches, upon which the foregoing review is based, requires kinematical assumptions about the behavior of cross-sections. These assumptions will be inaccurate for some situations, such as thick configurations. Further kinematic complications arise when coupling between in-plane and out-of-plane motions occurs. The accuracy of the one-dimensional theories may be tested in certain cases against more accurate 2-D models, such as shells. However, these models also require kinematic assumptions.

More accurate tests are potentially possible using 3-D, continuous system models, such as comparing frequencies with 3-D results for hollow cylinders [395-407]. However, accurate 3-D results are typically difficult to achieve with current numerical computation capabilities. Nonetheless, additional studies comparing numerical results obtained using 3-D elasticity with 1-D and 2-D models are needed to ascertain their ranges of validity.

P. Chidamparam received his B. Tech. in Mechanical Engineering from the Indian Institute of Technology Madras, India, in 1987 and his M.S. in Mechanical Engineering from the Ohio State University, in 1989. He was awarded the Alcan Scholarship in 1989 to pursue doctoral studies at the Ohio State University, where he is currently a doctoral candidate in Engineering Mechanics. He has been an active participant in the development and instruction of undergraduate courses in Mechanical Engineering and Engineering Mechanics at Ohio State. His research interests are in the general areas of structural vibrations, machinery dynamics and acoustics. He is a member of the Phi Kappa Phi Honor Society and the American Society of Mechanical Engineers.

After earning two degrees in Mechanical Engineering, Arthur W Leissa received his PhD degree in Engineering Mechanics in 1958 from Ohio State University, and remained there as Assistant Professor. He became Professor of Engineering Mechanics at Ohio State in 1964, and currently holds that position. The academic year 1972-73 was spent as Visiting Professor at the Federal Institute of Technology in Zurich, Switzerland, teaching graduate courses and doing research. Subsequently, 1985-86 was given to a Visiting Professorship at the Air Force Academy in Colorado Springs. He is the author of two books, Vibration of Plates and Vibration of Shells, which summarize the literature in these fields, as well as approximately 180 other publications dealing primarily with elasticity, plates, shells, vibrations and buckling of continuous systems, composite materials, and approximate methods of solving boundary value problems. A former Associate Editor for Applied Mechanics Reviews, *he recently was appointed Editor-in-Chief. He is on the editorial advisory boards of* Composite Structures, *the* Journal of Sound and Vibration, *and the* International Journal of Mechanical Sciences. *He is a Fellow of ASME and of the American Academy of Mechanics, and is a past President of the American Academy of Mechanics. The Pan American Congress of Applied Mechanics (PACAM) was conceived by him, and he was the general chairman of the first one, in 1989. His technical expertise includes employment by Sperry Gyroscope, Boeing Airplane, North American Aviation, Battelle Memorial Institute, and Kaman Nuclear as an engineer or consultant. In his spare time, he climbs mounta*

BOOK REVIEWS

Items with a reviewer byline (coded R) are by AMR's corps of dedicated outside volunteer reviewers. AMR will attempt to get critical reviews of all relevant textbooks, professional books, reference works, and handbooks. Items without a reviewer byline (coded N) are prepared by AMR in-house staff and are largely based on material such as a book's table of contents and editor's preface or foreword. In the interest of timeliness most conference proceedings and multi-author contributed volumes will receive descriptive notes in this fashion. Books deemed to be somewhat peripheral to AMR's basic scope may simply be listed by title (no code; not included in annual index). Also listed by title when first received are books under review.

I. FOUNDATIONS & BASIC METHODS

9R3. Numerical Recipes in Fortran; (Second Edition). The Art of Scientific Computing. - William H Press *(Harvard-Smithsonian Center for Astrophys)*, Saul A Teukolsky *(Dept of Phys, Cornell)*, William T Vetterling *(Polaroid)*, Brian P Flannery *(Exxon Res and Eng)*. Cambridge UP, New York. 1992. 963 pp. ISBN 0-521-43064-X.

Reviewed by Ben H Thacker (Struct Eng, PO Drawer 28510, SWRI).

This book will be appreciated by anyone involved in the numerical solution of engineering problems. Continuing in the tradition of their first edition, the authors have successfully blended tutorial discussion, fundamental mathematics, explanation of algorithms, and working computer programs into neatly packaged chapters covering all of the basic topics in numerical methods. What sets this book apart, in the reviewer's opinion, is the versatility of the book. It can be used as a textbook in a classroom environment, as an engineer or scientist's "toolkit" for development of a numerical application, or even as a *black-box* in which the computer programs are used as is without an understanding of the inner-workings of the methods. Simply using the programs as black-boxes, however, short-circuits this book's main strength, which is to demystify the traditional algorithms used in numeric computations.

Because Fortran coding is included in the manuscript, chapter 1 is devoted to preliminaries such as programming style, conventions, and machine accuracy. With the exception of chapter 20, which deals with "less-numerical algorithms," the remaining 18 chapters are divided into the traditional topics on numerical methods: solution of linear algebraic equations; interpolation and extrapolation; integration of functions; evaluation of functions; special functions; random numbers; sorting; root finding and nonlinear sets of equations; minimization or maximization of functions; eigensystems; fast Fourier transform; Fourier and spectral applications; statistical description of data; modeling of data; integration of ordinary differential equations; two point boundary value problems; integral equations and inverse theory; and partical differential equations.

Although the second edition is about 50% larger than the first edition, with over 300 included programs, the size is still quite manageable. The authors have (wisely) chosen to expand the book in breadth, not depth, so all of the topics are presented at the same accessible level used in the first edition. A partical list of some of the new topics covered are: integral equations, elliptic partial differential equations, linear algebra on sparse and banded matrices, Cholesky and QR decomposition, numerical derivatives, adaptive and recursive Monte Carlo integration, globally convergent methods for nonlinear equations simulated annealing minimization, FFT's, wavelet transforms, smoothing filters, statistical bootstrap method, and several new methods for solving differential equations. Thus, current owners of the first edition should seriously consider adding this second edition to their library.

Finding information in the book is very easy. The table of contents is well organized, extensive, but not cluttered. The index spans 30 pages, so the reader should have no trouble finding a quick route to the needed section. The reference list is complete, and even includes a "nucleus" of the author's recommended personal references. Finally, an index of programs and program dependencies is listed.

Numerical Recipes is also available in C, for those more familiar with the C programming language (Basic and Pascal versions of the programs are available only in the first edition). An example book and diskette containing the programs are also available in both programming languages. The reviewer highly recommends at least purchasing the diskette - hours of tedious keyboarding will be saved. Moreover, the example driver routines and several handy utilities are supplied with the disk, which are also quite helpful.

In short, *Numerical Recipes in Fortran* is indispensable. Having used the first edition for several years and this second edition for several months, the reviewer can recommend from experience that this book be kept within reach by anyone doing scientific computing.

Correction: The preceeding review appeared with inaccurate reviewer information in the July issue. Our apologies to Dr. Thacker.

9N1. BETA Mathematics Handbook, 2nd ed. - Lennart Rade and Bertil Westergren. CRC Press, Boca Raton FL. 1992. 494 pp. ISBN 0-8493-7758-7. $39.95. Outside US, $49.95.

BETA Mathematics Handbook is a comprehensive, accessible reference compilation of basic facts and information for pure and applied mathematics, probability and statistics, and numerical analysis and basic applications. It offers a blend of classical areas of mathematics such as algebra, geometry, and analysis with new, modern topics. As a result, the book is up to date with the latest math information frequently used in science and engineering.

Contents include: fundamentals; algebra; geometry and trigonometry; linear algebra; the elementary functions; differential calculus (one variable); integral calculus; sequences and series; ordinary differential equations (ODE); multidimensional calculus; vector analysis; orthogonal series and special functions; transforms; complex analysis; optimization; numerical analysis and programming; probability theory; and statistics.

9N2. Pocket Book of Integrals and Mathematical Formulas, 2nd ed. - RJ Tallarida *(Temple Univ, Philadelphia PA)*. CRC Press, Boca Raton FL. 1992. 240 pp. ISBN 0-8493-0142-4. $14.95. Outside US, $17.95.

This book is a handy, compact reference work containing concise discussions of mathematical concepts and formulas frequently needed by students and professionals in engineering, science, applied math and statistics. One of the book's special features is its comprehensive table of integrals arranged and formatted to facilitate the rapid location of the right form. Tables of derivitives; calculus applications; graphs of important Cartesian and polar curves; and formulas from algebra, geometry, trigonometry, calculus and statistics have also been arranged with convenience in mind. The book also lists infinite series and includes discussions and formula listings in differential equations and in advanced topics such as Fourier series, Laplace and z-transforms, vector analysis, and orthogonal polynomials. Important physical constants and numerical tables of probability distributions such as normal, Poisson, t, chi square, and F are provided.

Contents include: elementary algebra and geometry; determinants, matrices and systems of equations; trigonometry; analytical geometry; differential calculus; integral calculus; vector analysis; special functions; differential equations; statistics; table of derivatives and table of integrals.

II. DYNAMICS & VIBRATION

9R5. Detonation of Condensed Explosives. - Roger Cheret *(Commissariat a l'Energie Atomique, Paris, France).* Springer, New York. 1993. 425 pp. ISBN 0-387-97898-4.

Reviewed by Alfred Carmichael Buckingham (Comput Phys Div; Phys Dept, LLNL, Mail Code L-321, PO Box 808, Livermore CA 94551).

This is a well written, amply cross-referenced monograph on the physics and dynamics governing the initiation, evolution, and propagation of explosive detonation fronts, and the underlying detonation process itself. It provides a clear exposition of the fundamentally important current theoretical findings and remaining questions on detonation processes. The book is a comprehensive, theoretically well-grounded reference work for specialists working in a broad range of explosive technology topics such as: energetic propellant chemical composition, ignition and detonation onset criticality, analysis of detonation instabilities, their evolution and possible consequences, transient, multidimensional detonation wave growth and propagation influences on building structures, explosive vulnerability, and hazards related to outside shock stimuli. It provides a basis for evaluating and predicting potential biological hazards and safety requirements.

In introducing the subject, the author leads the reader from the origins of understanding detonation processes and applications in early Chinese innovations with black power, to the important thermodynamic state and fluidynamic discontinuous interface concepts developed and studied in the late 19th and early 20th centuries. The author next extends the description to the more recent progress in theoretical and experimental analysis and characterization of the macroscopic connection between the kinetic influences of the detonation process and the fluid motions that advect and mix the reactants and products. He completes his survey with descriptions on the dynamic and kinetic structure of the detonation process extended down to digital computer-aided simulation of microscopic molecular and electronic configuration scale interaction dynamics.

The author supports his development of the physical concepts by providing a compact but usefully comprehensive mathematical foundation based on integral relations, function theory, and singular perturbation methods. These provide both insight and guidance for the reader in developing an understanding of the interaction between thermodynamic and thermokinetic fields, fluid stress force and acceleration fields, and fluid motion fields. The frequent use of illustrations and diagrams complements the text and mathematical constructions. The reader is provided with timely reminders and guidance on physical concepts and mathematical constructions through a number of brief, but quite useful, appendices at the end of the book. These supply helpful notes on operator theory, singular matrix operations, treatments of critical phenomena, integral methods, asymptotic theory and, conveniently, a summary of the notation used and applied consistently. References are provided on most of the major background literature, including seminal work extending over almost two centuries. References are conveniently placed at the end of individual chapters in which they appear, or at the end of each of the four major sections into which the author divides the book.

Within this division, the first three chapters make up Part I. It consists of a review and fundamental theoretical framework for the discussion of the mechanical and thermodynamic concepts defining the development and propagation of detonation waves. It begins with a review of the relations governing basic fluid motion, arbitrary equation of state constructions valid at very high pressures, discontinuities of continuum motion, discontinuities leading to molecular constituent changes and ends with an examination of the detailed structure of the detonation process in the neighborhood of the reaction front aided by asymptotic singular perturbation analysis.

Part II (chapters four through six), moves from the macroscopic to the microscopic descriptive framework. Initially, the reader is provided with background information developed from atomic/molecular group interaction dynamics techniques followed by an extension to analysis of the influence of electron energetic distributions and configurations. Subsequently, the reader is provided with a discussion of reaction mechanism on an atomic/molecular scale, including explosive molecular/atomic decomposition.

Part III, consisting of chapters seven, eight, and nine, contains discussions on the macroscopic mechanisms generating detonation. These give the reader detailed insight on reaction mechanisms, explosive decomposition, cooperative mechanisms, propagation of chemical reactions, compositional changes, connections to (advective) fluid motion, and plane shock initiated detonations.

The final part, exclusive of the appendices and index mentioned previously, is devoted to the dynamic characterization of explosives. In chapters ten through twelve most of the emphasis is placed on experimental techniques, experimental diagnostics and specialized numerical methods for prediction and simulation of process evolution. It includes discussions of the basic principles of prompt measurement (μ-second time scale realizations), numerical "forecasting" simulations, and the computation of state surface detonation processes.

Generally, the book places emphasis on thermodynamical and thermo kinetic-reaction kinetic processes with considerable and very suitable attention to microscopic structure, microscopic scale interactions, and high pressure quantum mechanical dynamic interactions, with less emphasis on the continuum fluid motion influences. For example, background material is supplied on the important role of both reactive and inert discontinuous wave front propagation and interaction with reactive media, but little emphasis is given to the generally well recognized (but imperfectly understood) role of statistically chaotic (turbulent) transport and reactant mixing in the initiation and evolution of the detonation process. This and somewhat abbreviated attention given to more recent advances and applications of numerical simulation methods to isolate and test the influence of sub resolution (temporal and spatial) scale mechanisms are the only (minor) weaknesses I find in the author's otherwise interesting and comprehensive presentation. the author's careful step-by-step development of the subject, supported by systematic buildup of the mathematical foundation, makes necessary the reading of the book from beginning to end in order to develop a proper appreciation of the material. Fortunately, the book is well-written and eminently readable so that this cover-to-cover inspection becomes an interesting, rewarding, and enjoyable exercise.

In summary, *Detonation of Condensed Explosives* is a very good reference work which should be of particular interest and use to chemists, physicists, applied mathematicians, and engineers involved in many aspects of explosive tehcnology. It is also sufficiently self contained and possesses a systematically developed theoretical foundation and substantial references adequate to provide background material for preparation of either formal academic course work or less formal instructional material for industrial laboratory usage. It is recommended for personal acquisition and retention, as well as for more general library purchase.

9R6. Elastiche Mehrkorpersysteme. (Elastic Multibody Systems). (German). - Hartmut Bremer and Friedrich Pfeiffer *(Tech Univ Munchen).* B G Teubner, FRG. 1992. 283 pp. Paper. ISBN 3-519-02374-1.

Reviewed by Frederick V Pohle (61 Kilburn Rd, Garden City NY 11530).

This text of less than 300 pages, moderately priced, is a remarkably complete and comprehensive coverage of elastic multibody systems. Both authors have been active in many areas of this wide field, and this is evident in the detailed coverage which pays attention to the theoretical fundamentals, as well as to numerical and approximate methods, through the fullest use of computers. Their presentation is compact and not a word is wasted.

After a brief introduction on the nature of model building and its relation to engineering practice, the 2nd chapter presents the broad theory of elastic bodies, all in modern vector-matrix formulation. This material is then generalized in the 3rd chapter to multi-body systems and their decompositions, and then, in the 4th chapter, methods of solution (for example, to beams, plates, shells, finite elements, and related topics). Specific applications of current interest are treated in chapter 5 (dynamics of satellites), and in chapter 7 (the dynamics of robotics). In all, there are approximately 200 selected references to the literature, particularly to modern applications, but also to the classical literature as well.

Although some remarks are made on specific applications, there are not detailed discussions of problems and no exercises of any kind; this has made it possible to cover a vast amount of material comprehensively and fully. *Elastische Mehrkorpersysteme*, written in German, is suitable at the senior-graduate level for general and specific applications (particularly to satellites and robotics), and is an important addition not only to research libraries but also to individual libraries, since so much of the material is simply not readily available in one volume.

9R7. Mechanical Measurements, 3rd ed. - RS Sirohi and HC Radha Krishna *(Eng Des Center, Indian IT, Madras, India)*. Wiley, New York. 1991. 285 pp. ISBN 0-470-21953-X. $34.95.

Reviewed by Larry Zavodney (Dept of Engineering, Cedarville Col, Cedarville OH 45314-0601).

The authors advertise this book as a "text for both graduate and post-graduate classes and as a constant reference to a researcher." The book is 290 pages long, including a one-page appendix, 19 references, and a four-page index. There are 10 chapters - three devoted to generalized topics related to measurement and seven devoted to the specific measurement of some physical quantity or methodology. The title of the book accurately reflects the contents of the book. It is a brief summary of some current methods used to make measurements of physical quantities. Since it is so brief, it is an incomplete reference.

Chapter 1 is devoted to the concepts of measurements and uses a few transducer systems for illustration. Chapter 2 discusses performance characteristics of measuring instruments and static and dynamic systems. The discussion of the transfer function and frequency response function is at the undergraduate level as found in a discrete vibration or feedback control course; however, the nature of the exercises has little correlation with the chapter. Chapter 3 has a good but brief discussion on measurement inaccuracy, probability, and statistics; the eight exercises are good.

Chapter 4 summarizes some direct and indirect methods of measuring force and torque by measuring deformation of elastic members such as springs, bars, and rings, and discusses the load cell and dynamometer; there are five exercises at the end of the chapter. Chapter 5 discusses the measurement of strain and the subsequent calculation of stress from appropriate equations. Strain is measured by mechanical methods, opto-mechanical methods, and electrical methods that include capacitive, inductive, and resistive gauges. Basic equations and circuits for the most common applications are given. Grid techniques and Moire fringes and interferometric methods are mentioned.

Chapter 6 is devoted to the measurement of pressure and discusses manometers, the McLeod gauge, and the dead-weight tester. Deformation of elastic members as measured by mechanical devices (such as strain gages, piezoelectric crystals, and the Knudsen gauge) is used to measure pressure. Chapter 7 summarizes methods to measure flow and visualize flow fields. Popular flow meters that include obstruction meters and velocity probes, and specialized methods that include turbine, magnetic, and sonic flow meters, are discussed. Schlieren and interferometric techniques are mentioned. Chapter 8 discusses temperature measurement using the basic types of mechanical and electrical thermometers. Compensation methods for temperature-induced errors in leadwires for Wheatstone bridges are introduced here (instead of earlier when strain gauges and bridges are first mentioned). Radiation methods using optical pyrometers concludes the chapter.

Chapter 9 discusses optical methods, how the laser is used to measure displacement and velocity, and how the diffraction strain gauge and laser doppler anemometer work. The chapter includes a discussion on holography. Chapter 10 introduces fiber optics and discusses basic properties, emitters, detectors, methods of modulation and demodulation, incoherent and coherent sensors, and polarization modulation.

Because the book is brief and quite broad in its topics, it lacks depth in any one topic; hence, this book might be suitable for someone offering a low-budget survey course in mechanical measurements; equations are given--not derived. The book is basically a collection of how selected transducers work and focuses on the physics. There are no worked examples in the text. It is not suitable for undergraduate classes in instrumentation because it does not include some of the more popular transducers, such as dynamic load cells using piezoelectric crystals, LVDT's, or accelerometers (the only mention of an accelerometer is in reference to a method of measuring force). There is no discussion of computers, data acquisition techniques, analogue-to-digital conversion and vice-versa, or processing of analogue or digital signals. The book is organized around particular physical quantities rather than principles; eg, the description of how a piezoelectric crystal works is contained entirely within a discussion of pressure transducers. The book has a British flavor as evidenced in word spellings; noise is that which occurs at 50 Hz (instead of 60 Hz), and there are many articles missing. One would have expected that by the third edition the authors would have corrected the grammar. It is not well written. The qulity of the printing and figures is poor and appears related to the low cost of the book (which was printed in India). Given the availability of better texts suitable for both graduate and undergraduate classes and for reference, I would not recommend *Mechanical Measurements*.

9N8. Seismic Applications of Acoustic Reciprocity. - JT Fokkema *(Pet Eng and Tech Geophys, Univ of Tech, Delft, Netherlands)* and PM van den Berg *(Lab for Electromagnetic Res, Univ of Tech, Delft, Netherlands)*. Elsevier, UK. 1993. 350 pp. ISBN 0-444-89044-0. $156.50.

Progress in seismic data processing requires the knowledge of all the theoretical aspects of the acoustic wave theory. The reciprocity theorum was chosen as the central theme of this book as it constitutes the fundamentals of the seismic wave theory.

Contents of the book include: integral transformations; iterative solution of integral equations; basic equations in acoustics; radiation in an unbounded, homogeneous medium; reciprocity theorums; field reciprocity between transmitter and receiver; radiation in an unbounded, homogeneous medium; scattering by a bounded contrasting domain; scattering by disk; wavefield decomposition; deghosting; removal of surface related wave phenomena; boundary imaging; domain imaging, and seismic inversion.

III. AUTOMATIC CONTROL

9N9. Identification and Control in Systems Governed by Partial Differential Equations. Proceedings in Applied Mathematics 68. - Edited by HT Banks, RH Fabiano, K Ito. SIAM. 1993. 272 pp. ISBN 0-89871-317-X. $48.50.

Written on a graduate research level, this collection of invited papers presented at the 1992 AMS-IMS-SIAM Joint Summer Research Conference focuses on issues related to modeling (including design), parameter estimation and system identification, and feedback control problems described by partial differential equations. It includes applications of flow control (in high pressure vapor transport reactors, airfoil design, and noise suppression), as well as control of structures (beams, plates, robot arms and smart material structures).

Contents include: Modeling of flow dynamics and its impact on the optimal reactor design prob-

lem by HT Tran, JF Scroggs, and KJ Bachmann; Sensitivity calculations for a 2D, inviscid, supersonic forebody problem by J Borggaard, J Burns, E Cliff and M Gunzberger; Models for control in smart structures by HT Banks and RC Smith; Bootstrap methods for inference in least squares identification problems by BG Fitzpatrick and G Yin; MATLAB-software for parameter estimation in two-point boundary value problems by M Kroller and K Kunisch; Some stability estimates for the identification of conductivity in the one-dimensional heat equation by G Crosta; Estimation of material parameters in a dynamic nonlinear plate model with norm constraints by L White; Global stabilization of a von Karman plate without geometric conditions by ME Bradley and I Lasiecka; The standard problem of H∞ optimal control for infinite dimensional systems by A Bensoussan and P Bernhard; Perturbation of well-posed systems by state feedback by KA Morris; Point observation in linear-quadratic elliptic distributed control systems by L Ji and G Chen; Boundary control for a viscous Burgers' equation by CI Byrnes, DS Gilliam and VI Shubov; Feedback control of singular integro-differential systems: An input-output approach by H Ozbay and J Turi; Stable and unstable zero dynamics of infinite dimensional systems by TJ Tarn, AK Bejczy and C Guo; Covariance based control of linear hereditary systems by JA Reneke.

Measurement Errors: Theory and Practice. - Semyon Rabinovich. AIP. 1993. 270 pp. ISBN 0-88318-866-X. $100.00. (Under review)

IV. MECHANICS OF SOLIDS

9R10. Applied Elasticity. - Zhilun Xu *(Hohai Univ, PRC)*. Wiley, New York. 1992. 373 pp. ISBN 0-470-21868-1. $34.95.

Reviewed by Dimitris Lagoudas (Dept of Aerospace Eng, Texas A&M Univ, College Station TX 77843-3141).

This book is intended as a textbook on the theory and solution techniques of linear elasticity. The first chapter briefly introduces the concept of stress, emphasizing operational details rather than fundamental physical understanding. Chapters 2, 3, and 4 cover plane (2D) elasticity problems in rectangular and polar coordinates. Most of the material covered in these chapters can be found in classical texts in elasticity, eg, Timoshenko and Goodier. Unconventional terminology, like geometrical equations and physical equations, used in these chapters and repeated in later chapters renders the book somewhat difficult to follow, especially for a student without a global view of the subject. The inclusion of the complex variable method in chapter 5 (for the solution of plane problems in elasticity and the demonstration of the method to the elliptic hole and crack problems) is a positive step. Plane thermal stress problems are discussed in chapter 6, and the finite difference method for plane problems is introduced in chapter 7. Three-dimensional deformations are first introduced in chapter 8, with displacement potentials used for solving some fundamental problems in 3D elasticity. The theory of torsion of prismatic bars is discussed in chapter 8, where the finite difference method is again used as a numerical tool. Variational methods are introduced in chapter 11, while classical theory of plates and numerical applications using the finite difference scheme are covered in chapters 12 and 13, respectively. The last three chapters of the book are devoted to the general theory of shells, cylindrical shells, and shells of revolution.

Xu's book is a compilation of special topics in elasticity as presented by classical books on the subject, without a personal style other than a detailed account of the finite difference method. The author exclusively uses the finite difference method to obtain numerical solutions, even though the current trend in engineering education and industrial practice is to use the FE and/or the BEMs. Another key omission is the absence of any discussion on constitutive equations beyond the linearly elastic isotropic solid, especially the concept of material symmetries and applications to composites. The author also did not attempt to connect elasticity with continuum mechanics by excluding references to conservation principles, kinematics of deformations, and measures of strain. The book does not introduce tensorial notation, even as an additional alternative formulation, missing the opportunity to prepare students for advanced theoretical or numerical courses in solid mechanics. Treatment of elastodynamics is completely left out of the book.

Based on the above observations, the reviewer concludes that *Applied Elasticity* is out of touch with the current curriculum demands in the area of solid mechanics in the USA and does not recommend it as a textbook for an applied elasticity course. It might be of some use, however, as a reference book to the practicing engineer who does not have access to a FE code.

9R11. Metallurgical Failures in Fossil Fired Boilers; (2nd ed). - David N French *(David N French, Inc, Northborough MA)*. Wiley, New York. 1993. 560 pp. ISBN 0-471-55839-7. $69.95.

Reviewed by William J D Shaw (Mech Eng Dept, Univ of Calgary, 2500 Univ Dr NW, Calgary, T2N 1N4, AB, Canada).

This book is targeted toward those working with boilers and covers an extremely broad range of failures occurring under very diverse circumstances. It is a good documentation of microstructures and failures with excellent illustrative photographs. The book tackles this subject from an integrated approach, bringing in areas as far-reaching as statistics of boiler failures. It provides a general but limited basis of the various design considerations, such as stress analysis (ASME Codes), mass and heat transfer, specific fuel types, and material selections.

Coverage also extends through the metallurgical area, looking at the fundamentals of materials science with respect to atomic structure, phase diagrams, and time temperature transformation diagrams. Also covered is the mechanical behavior of materials; more specifically, the creep and fatigue areas. The metallurgy evolves from ferritic steels through stainless steels. However, what is missing in general is that of welding behavior and microstructure-property relationships and how these are affected by high temperature operation. Additionally, the stainless steel coverage is very weak and does not look at the broader range of stainless materials, which would give a more complete picture for designers using this book as a reference.

Other aspects that are looked at are failures that occur due to material-environment interaction, eg, failures taking place on both the stream side and the fire side of the heat exchanger. Similarly, corrosion is also explored, but due to the complex nature of this subject, it is somewhat weak in presentation. Weld failures are presented in fairly good detail, with the prevention of failures based primarily upon furnace design and creep relationships. Some aspects of remaining life assessment are also covered.

The main strength of the book is that many case studies are presented throughout which offer practical information and guidance to boiler designers. The book is well-referenced, with useful appendices and a fairly comprehensive index. It is definitely a major and important reference book for designers involved in the boiler industry. Years of invaluable information and failure feedback are contained within *Metallurgical Failures in Fossil Fired Boilers*. This, combined with the integrated approach, far exceeds any shortcomings that were mentioned above.

9R12. Stability Design of Steel Frames. - W F Chen *(Sch of Civ Eng, Purdue)* and E M Lui *(Dept of Civ and Env Eng, Syracuse Univ, Syracuse NY)*. CRC Press, Boca Raton FL. 1991. 392 pp. ISBN 0-8493-8606-3. $75.00. $90.00 outside US.

Reviewed by AN Sherbourne (Dept Civil Eng, Univ of Waterloo, Waterloo, ON, N2L 3G1, Canada).

A structural frame is an assembly of beam-column elements, and its stability analysis requires an investigation of overall as well as individual member behavior. Accurate methods for the stability analysis of beam-columns and frames are readily available; however, analytical and computational complexities do not permit easy implementation in day to day design practice. This has led to the development of numerous and simple approximate methods for stability analysis. This book is written with the objective of reviewing these analytical procedures and presenting a number of useful approximate design methods, which were mainly developed by the authors over the years. The authors suggest that the major issues of practical relevance in stability design are inelastic effects, moment-gradient, second order P-delta effects, and joint flexibility. The subject matter is thus centred around these topics

The book is divided into seven chapters. In the first chapter, the inelastic analysis of beam-columns is presented in detail, using the Newmark method and its more refined extension, the Cranston method. In the second chapter, design issues related to P-delta effects, moment-gradient, effective length factors, and interaction equations are addressed, and various design rules are summarized. In chapter 3, standard methods of elastic, nonlinear analysis, eg, finite element and beam-column approaches, are outlined. A method proposed by Lui, referred to as the pseudo-load method, is an interesting way of accommodating nonlinear effects in the load vector thus avoiding the need for updating the stiffness matrix in each cycle of computation.

For approximate second order inelastic analysis, gradual stiffness loss with progressive yielding is modeled by rotational springs attached to the member ends as discussed in chapter 4. In chapter 5, the characteristics of the more common types of beam-column connections are described and various empirical moment-rotation equations are reviewed. Chapter 6 describes the elastic and inelastic analysis of frames, including the effects of joint flexibility. The design of semi-rigid frames is intrinsically more complex than rigid frames because of the difficulty of predicting the moment-rotation behavior of connections. In chapter 7, however, a simple design approach, based on empirical moment-rotation curves, is developed.

A major feature of the book is to summarize a number of approximate methods for simplified stability analysis of frames, mainly derived from the authors research work. In some ways this limits the scope of the monograph. These approximate methods are essentially systematic attempts to amplify loads or deliberately weaken the structure to take into account second-order and inelastic effects. In this respect, *Stability Design of Steel Frames* should prove more useful to structural designers than university research workers.

9N13. Adhesive Bonding of Aluminum Alloys. - Edited by Edward W Thrall *(Aeronaut Struct Consult, Point Arena CA)* and Raymond W Shannon *(Aeronaut Struct Consult, Ray Shannon & Assoc, Santa Ana CA)*. Marcel Dekker, New York. 1993. 520 pp. ISBN 0-8247-7405-1. $140.00.

Contents of the book include: chromic acid anodize process as used in Europe; sealed chromic acid anodize; phosphoric acid anodize; surface analysis; adhesive selection from the user's viewpoint; epoxy adhesives; elevated-temperature-resistant adhesives; mechanical properties of adhesives; environmental-durability testing; chemical analysis for control; coatings; structural analysis of adhesive-bonded joints; basic principles for tooling design and inspection; nondestructive inspection; and adhesive-bonded aluminum structure repair.

9N14. Atlas of Fatigue Curves. - Edited by Howard E Boyer. ASM Int, Materials Park OH. 1986. 518 pp. ISBN 087170-214-2. $172.00.

This book contains more than 500 fatigue curves for industrial ferrous and nonferrous alloys. It also includes a thorough explanation of fatigue testing and interpretation of test results. Each curve is presented independently and includes an explanation of its particular importance. The curves are titled by standard industrial designations (AISI, CDA, AA, etc.) of the metals, and a complete reference is given to the original source to facilitate further research. The correction includes standard S-N curves, curves showing effect of surface hardening on fatigue strength, crack growth-rate curves, curves comparing the fatigue strengths of various alloys, effect of variables (ie temperature, humidity, frequency, aging, environment, etc.), and much more. This one volume consolidates important and hard-to-find fatigue data in a single comprehensive source.

9N15. Atlas of Stress-Strain Curves. - Edited by HE Boyer. ASM Int, Materials Park OH. 1986. 640 pp. ISBN 087170-240-1. $172.00.

This book contains more than 600 stress-strain curves for ferrous and nonferrous alloys. Curves show monotonic versus cyclic behavior, effect of strain rate, alloying elements, product forms, deformation mode, grain size, work hardening, temperature, and much more. Each curve is titled by standard industrial designations (AISA, CDA, AA, etc.) and thoroughly referenced to the original source to facilitate further research. Compiled from an exhaustive survey of the published literature and consolidated into this single comprehensive source.

9N16. Handbook of Aluminum Bonding Technology and Data. - J Dean Minford *(Consultant, Hilton Head SC)*. Marcel Dekker, New York. 1993. 744 pp. ISBN 0-8247-8817-6. $195.00.

This reference offers comprehensive discussions on important aspects of aluminum bonding for each level of manufacturing--from mill finished to deoxidized, conversion coated, anodized, and painted surfaces--and provides an extensive up-to-date review of adhesion science, covering all significant developments of the past century. It features a chronologically arranged numbering system for more than 4600 literature citations and more than 200 tables of data.

Contents include: factors affecting adhesion; surface characteristics of aluminum; surface treatment of aluminum adherends; selection of an adhesive; design of aluminum-bonded joints; mechanisms of bond joint failure; water in the service environment; test evaluation standards; durability of permanence of aluminum-bonded joints; and applications of adhesives in bonding aluminum structures.

9N17. Hardness Testing. - ASM Int, Materials Park OH. 1987. 188 pp. ISBN 087170-244-4. $87.00.

This technical manual is a practical handbook dealing with all aspects of hardness testing. Coverage includes specific hardness testing methods; Brinell, Rockwell, Vickers, and microhardness testing, and other hardness testing methods, such as scleroscope ultrasonic, scratch and file testing, and hardness evaluation by eddy current testing. One chapter examines how to select the correct hardness testing method. Another chapter deals with hardness testing applications. Use of hardness testing to measure case depth and evaluate hardenability is also examined. The last chapter looks at the factors that determine the optimum hardness testing method for a specific application. A directory of manufacturers, distributors and suppliers of hardness testing equipment and supplies in the United States and Canada is also included.

9N18. STP 1156 Composite Materials: Fatigue and Fracture, 4th vol. - Edited by Wayne W Stinchcomb *(VPI)*. ASTM. 1993. 664 pp. ISBN 0-8031-1498-2. $134.00.

Fatigue and fracture are topics of primary importance to the development of damage-tolerant composite materials, to the design of high-performance composite components and structures, and to the certification of composite products. STP 1156 addresses current issues related to fatigue and fracture of composites.

The technical results contained in this STP provide practical insights on new developments in areas of continuing interest, such as damage and failure analysis and test methods. They also provide new directions for emerging technology areas, such as micromechanics and interfacial analysis, which are applicable to fatigue and fracture of composites. The materials addressed are thermosetting and thermoplastic polymer matrix composites, metal matrix composites, and ceramic matrix composites, as well as specialty laminates. Results were obtained for several configurations of composites ranging from laboratory specimens to subcomponents to structural elements.

In all, 34 peer-reviewed papers are presented in sections on: Strength and failure modes; Damage: Measurement, analysis and modeling; Intralaminar and interlaminar fracture; Micromechanics and interfaces; Fatigue of polymer matrix composites; Fatigue of ceramic matrix, metal matrix, and specialty composites.

9N19. STP 1174 High Temperature and Environmental Effects on Polymeric Composites. - Edited by Charles E Harris and Thomas S Gates *(NASA Langley Res Center)*. ASTM. 1993. 222 pp. ISBN 0-8031-1491-5. $67.00.

Contents of the publication include: Part 1 Damage Mechanisms and Failure: measurement of stress corrosion crack growth in sheet molding compounds; mode I delamination of carbon fiber reinforced thermoplastic polymer under static and cyclic creep at elevated temperatures; delamination onset and accumulation in polymeric composite laminates under thermal and mechanical loads; high temperature behaviors of an innovtive polymeric matrix composite; Part 2 Materials Behavior Under Combined Effects: the effect of seawater environment on the galvanic corrosion behavior of graphite-epoxy composites coupled to metals; the simulation and detection of electrochemical damage in BMI-graphite fiber composites using electrochemical impedance spectroscopy; the effect of the interphase-interface region on creep and creep rupture of thermoplastic composites; determination of a load, heat, time-to failure surface of polymeric composites; property improvements of polymer composites after loading at high temperatures; Part 3 Constitutive Models: the effects of physical aging on the creep response of a thermoplastic composite; the effects of moisture sorption on the creep behavior of fibers; and the effects of elevated temperature on the viscoplastic modeling of graphite\polymeric composites.

9N20. STP 1210 Slow Strain Rate Testing for the Evaluation of Environmentally Induced Cracking: Research and Engineering Applications. - Edited by Russell D Kane *(Cortest Labs)*. ASTM. 1993. 304 pp. ISBN 0-8031-1870-8. $73.00.

Due to concerns for environmentally induced cracking, corrosion and material specialists have worked consistently for the development of better and more predictive laboratory tests for this phenomenon. STP 1210 highlights some of the new directions in testing for environmentally induced cracking using a variety of slow strain rate techniques.

Nineteen papers written by researchers from industry, government agencies, and universities from the United States, England, Germany, Spain and Japan, address: Development and application of slow strain rate testing techniques; Uses of slow strain rate SCC testing to control or monitor industrial processes: Applications in nuclear power; Research applications and developments in slow strain rate testing techniques; Industrial applications of slow strain rate testing to evaluate environmentally induced cracking; and Use of slow strain rate testing for qualification of SCC resistance of corrosion resistant alloys: Case histories in petroleum production.

Papers describe both fundamental research studies and more practical engineering applications.

Electrodeposition. The Materials Science of Coatings and Substrates. - JW Dini *(LLNL)*. Noyes, Park Ridge NJ. 1993. 367 pp. ISBN 0-8155-1320-8. $78.00. (Under review)

Soldering Processes and Equipment. - Michael G Pecht *(CALCE Electron Packaging Res Center, Univ of Maryland, College Park MD)*. Wiley, New York. 1993. 304 pp. ISBN 0-471-59167-X. $64.95. (Under review)

V. MECHANICS OF FLUIDS

9R21. Hydrostatic Lubrication, Theory and Practice. Tribology Series, 22. - R Bassani *(Eng, Univ di Pisa, Pisa, Italy)* and B Piccigallo *(Gruppo Construzioni e Tecnologie, Accad Navale, Livorno, Italy)*. Elsevier, New York. 1992. 542 pp. ISBN 0-444-88498-X. $180.00. Dfl 315.00.

Reviewed by William E VanArsdale (Mech Eng Dept, Univ of Houston, 4800 Calhoun Rd, Houston TX 77204-4792).

Hydrostatic lubrication uses an external pressurization system to maintain a fluid film between bearing surfaces. This type of lubrication provides low friction and negligible wear, but requires a more complex supply system than other techniques. Hydrostatic bearings have been in use since the middle of the last century. They have found application in everything from large telescopes down to smaller equipment, such as vibration attenuators and dynamometers. These applications involve a wide variety of thrust and radial bearing configurations subject to both static and dynamic loading as well as thermal effects.

Bassani and Piccigallo summarize progress in this field during the past 25 years. The authors approach is: "...the study of externally pressurized lubrication, both from the theoretical and the technical point of view." They provide useful background material on compensating devices and lubricants. Their review of basic equations suffers from minor inconsistencies, though, such as an unusual notation for divergence and confusing tensors with their components. However, the authors provide a thorough analysis of various pad and rotational bearings, as well as sections describing dynamics, optimization, and temperature effects. They conclude with chapters on experimental tests and applications. Throughout the book, the authors also provide "...design suggestions for the most common types of hydrostatic bearing..." to their intended audience of researchers, students, and technical designers.

Hydrostatic Lubrication is a technical reference for graduate students and specialists in bearing design. This book includes a useful listing of cited authors as well as a subject index. Illustrations are consistently good, with many drawings of different bearing designs. There are 46 examples used to illustrate applications in various chapters. The authors also cite a substantial number of references, but very few within five years of the copyright date (1992). The high list price and lack of exercises are a deterrent to classroom use. However, I recommend purchase by libraries and individuals with an interest in the design and analysis of hydrostatic bearings and lubrication systems.

9N22. Engineering Turbulence Modelling and Experiments -2. - Edited by W Rodi *(Karlsruhe, Germany)* and Martelli *(Florence, Italy)*. Elsevier, UK. 1993. 994 pp. ISBN 0-444-89802-6. $371.50.

The 89 papers, including 5 invited papers, in this volume present and discuss new developments in the area of turbulence modelling and measurements, with particular emphasis on engineering-related problems. Contents include: turbulence modelling; applications of turbulence models; direct and large-eddy simulations; experimental techniques; experimental studies; transition; turbulence control; aerodynamic flows; turbomachinery flows; combustion systems; and two-phase flows.

9N23. Fluid Transients in Pipe Networks. Computational Engineering Series. - Edited by AB de Almeida *(Dept of Civil Eng, Lisbon, Portugal)* and E Koelle *(Dept of Mech Eng, Sao Paulo, Brazil)*. Comput Mech, Billerica MA. 1992. 590 pp. ISBN 1-56252-096-2. $216.00.

This book presents modeling and computational techniques for fluid transients in pipe networks, including open channel flow.

Contents include: Pressure transient modeling and analysis network operational control; Pipe network systems and mathematical modeling; Pipe element modeling: Basic assumptions; Unified basic equations; Special dynamic effects; Global computer model and operational control: Network safety assessment; Control of pressure surges and case studies: Accident causes and pressure control tactics; Rapid flow disturbances; Surge control or protection; Flow control and valve maneuvers; Free surface transient flow: Basic equations; Uniform channels; Non-uniform channels; Free surface pipe elements; Dry bed; Node equation; Non-channel elements: Upstream Reservoir; Fast transients modeling: Secondary waves; and Open channel network simulation.

9N24. Plant Engineering's Fluid Power Handbooks, Vols 1 and 2. - Anton H Hehn *(Hehn & Assoc)*. Gulf Publ, Houston. 1993. 608 pp. ISBN 0-88415-089-5; 0-88415-072-0. $98.00. Info is for 2-vol set.

Fluid power equipment is used in nearly every branch of industry, including plastics processing, packaging, pharmaceuticals, petrochemicals, and others. This ever-increasing use of fluid power has resulted in a growing need for engineers, managers, technicians, and mechanics who are familiar with the operation, use, and care of this equipment. This two-volume set provides operating personnel with a ready resource in this field. Focusing on the design, application, maintenance, and troubleshooting aspects of fluid power systems, these guides--from the pages of *Plant Engineering* magazine--show how to avoid extended repairs and costly downtime.

Volume 1: *System Design, Maintenance, and Troubleshooting* provides an overview of the basic principles of hydraulic and pneumatic systems. This volume explains how the components are used, how they function, and how to maintain and troubleshoot fluid power systems. Volume 2: *System Applications and Components* deals with the design and application aspects of these same systems. Chapters cover component sizing and selection procedures, hydraulic circuit design, and applications of hydraulic and pneumatic systems. In each volume, the emphasis is on the cause-effect-cure relationships of systems, helping to readily identify faulty components.

9N25. Tribology in Metalworking: Friction, Lubrication and Wear. - John A Schey. ASM Int, Materials Park OH. 1983. 736 pp. ISBN 087170-155-3. $144.00.

This book acquaints you with plastic deformation and cutting; friction, wear and lubrication, lubricant classes, formulations, application, treatment and removal; measurement and evaluation techniques; and individual processes such as: rolling, drawing, extrusion, forging, sheet metalworking, and metal removal.

9N26. Vortex Flows and Related Numerical Methods. Proceedings of the NATO Advanced Research Workshop, Grenoble, France, June 15-19, 1992. - Edited by JT Beale *(Math, Duke Univ, Durham NC)*, GH Cottet *(Lab de Modelisation et Calcul, Univ Joseph Fourier, Grenoble, France)*, S Huberson *(Lab de Modelisation et Calcul, Univ du Havre, Grenoble, France)*. Kluwer, Norwell MA. 1993. 396 pp. ISBN 0-7923-2250-9. $165.00. £109.

Many important phenomena in fluid motion are evident in vortex flows, eg, flows in which vortical structures are significant in determining the whole flow. This book, which consists of lectures given at a NATO ARW held in Grenoble, France in June, 1992, provides an up-to-date account of current research in the study of these phenomena by means of numerical methods and mathematical modeling.

Such methods include Eulerian methods (finite difference, spectral and wavelet methods) as well as Lagrangian methods (contour dynamics, vortex methods) and are used to study such topics as 2- or 3D turbulence, vorticity generation by solid bodies, shear layers and vortex sheets, and vortex reconnection.

Intended for researchers and graduate students in computational fluid dynamics, numerical analysis, and applied mathematics.

VI. HEAT TRANSFER

9R27. Applied Thermodynamics for Engineering Technologists. - TD Eastop *(Univ of Exeter)* and A McConkey *(Mech and Indus Eng, Dundee Col of Tech)*. Wiley, New York. 1993. 695 pp. ISBN 0-582-09193-4.

Reviewed by John Rumierz (Chemistry, SKF Bearing Indust, 1100 First Ave, King of Prussia PA 19406).

The fifth edition of this standard text is aimed at undergraduate engineering students involved in programs which cover thermodynamics or design of thermal plants and equipment. This is a softcover book with an attractive format and many useful figures and diagrams. The topics are presented in a uncluttered fashion which provides easy access to the subject matter. A good subject index is provided.

The text follows the usual exposition of the material, with Chapters 1-4 covering the First and Second Law with parallel development of the necessary working fluid and process definitions. Specifically, the First Law is discussed and the concepts of reversibility and conservation of energy explained. Equations for the non-flow and the steady flow cases are derived. The concept of the working fluid leads to an introduction to the use of steam tables. Derivation of the perfect gas law is followed by a detailed discussion of reversible and irreversible processes. The development of the notion of the Second Law includes the concept of entropy and the consequences of irreversibility. The notion of exergy is introduced. All concepts covered are supported with examples of computations and problems for the student to solve.

Chapters 5, 6, and 7 start with the heat engine cycle and develop the necessary concepts and definitions to lead the student to practical combustion computations. Discussion of heat engine cycles is followed by absolute temperature scale and perfect gas cycles. The Carnot, Otto, and Diesel are among the cycles covered in detail. Dalton's Law and the Gibbs-Dalton Law for perfect gases and their mixtures are explained. Air and water vapor mixtures are discussed and appropriate definitions covered. The final chapter of this group extensively analyzes combustion processes from a practical perspective. Basic chemistry, combustion equations, and product analysis are discussed. Enthalpy of formation, enthalpy of reaction, and related quantities are defined. Finally, the calorific values of fuels and power plant efficiency are covered. Again, all topic discussions are supported by diagrams, examples, and problems.

Gas turbines, nozzles, and propulsion are covered in chapters 8-10. Steam cycles are again taken up, focusing on the Rankine cycle. Enthalpy-entropy charts are developed and used to discuss the reheat and regenitive cycles with practical topics, such as plant efficiencies and process steam considerations.

Nozzle and jet propulsion topics are developed in detail with critical discussions on pressure ratio, nozzle efficiency, and stagnation conditions following.

Chapters 11 and 12 discuss rotodynamic and positive displacement machines. Steam and gas turbine units are detailed, specifically impulse steam, radial flow, and axial flow turbines. Efficiency and reheat factors are discussed. Thermodynamic treatment of reciprocating compressors, vacuum pumps, and air motors are included in the units modelled.

Chapter 13 is devoted to reciprocating internal-combustion engines. A standard discussion of two-stroke and four-stroke cycle engines is followed by a treatment of new developments and alternate forms in this area.

Chapter 14 discusses refrigeration and heat pumps with an emphasis on the heat pump and the vapor-absorption plant. A section on refrigerants discusses the loss of atmospheric ozone and ozone-depleting substances. Analysis of exhaust gases, emission control of internal combustion engines, and the greenhouse effect are also included.

Chapter 15 covers psychrometry and air conditioning. The water vapor air mixture is now developed for the specific case of moist ambient air. The concepts of humidity, enthalpy, and specific heat capacity are defined and used in practical examples relevent to this area.

Chapter 16 is a long (102 pages) exposition of heat transfer. Aspects of Fourier's Law and Newton's Law buttress the discussion. Topics include: heat flow through ideal solids, steady and transient conduction, forced and natural convection, heat exchangers, black-body radiation, and the Stefan-Boltzmann Law. Extensive study problems and further topics for study are included.

Finally, chapter 17 addresses energy sources and related use and management. Included are sections on cogeneration, nuclear power and alternate energy sources. There are also discussions on combined heat and power, energy recovery, and a mention of pinch technology.

Applied Thermodynamics for Engineering Technologists approaches the topic of thermodynamics in a straightforward manner suitable for the freshman or sophomore engineering student. The mathematics involved are minimal, and the treatment of the subjects is readily comprehensible to all with a good background in high school mathematics. The English origin of the text will have little impact on the topical relevence or material accessibility to the American student. A two semester course may be needed to cover all the topics presented, although certain programs, such as chemical engineering, may allow only one for the subject at this level.

9R28. Benard Cells and Taylor Vortices. - E L Koschmieder *(Univ of Texas at Austin).* Cambridge UP, New York. 1993. 288 pp. ISBN 0-521-40204-2. $64.95.

Reviewed by Turgut Sarpkaya (Mech Eng Dept, Naval Postgraduate Sch, Code ME-SL, Monterey CA 93943-5000).

I do not know any teacher or researcher in fluid dynamics and heat transfer that would not want to have his name associated with an instability! Aside from being instruments of immortality to man (in name only), instabilities are windows to the soul of nature and temples of our knowledge. Thus, a book dealing with one or two of them that updates contributions (as well as papers) of a new generation of theoreticians and experimentalists (without demanding two PhDs in applied mathematics), presents critical accounts of historical facts, difficulties and continuing efforts, sorts out the essential facts, demands verification, and holds the interest of the reader from the beginning to the end with intriguing hints is indeed a welcome contribution. One cannot help but be impressed by the effort, sophistication and ingenuity that Koschmieder has exercised in writing this book. He deserves our congratulations.

The book may be used either as a reference or as a text for an advanced course. However, it should not be read because of a need, it should be read by all workers in heat transfer and fluid mechanics because it is there. About 340 pages long with an index and a large number of references (even after intentionally leaving out some papers), the book has two parts, as the title suggests. The first part, "Benard Convection and Rayleigh-Benard Convection," describes, in eight sections, all that is known and some of what "remains to be done in the future." I, for one, having taught fluid mechanics for nearly 40 years without ever contributing anything to either the Benard cells or Taylor vortices, enjoyed the clarity of the explanations and gained new insights. The second part, "Taylor Vortex Flow," is just as exciting and covers practically everything from the humble beginnings of the circular Couette flow, to Rayleigh's stability criterion, to GI Taylor's incomparable and immortal contribution in 1923 (as Koschmieder noted, "This paper is unique among the nearly 500 papers discussed in this book, in that it is the only one in which the basic theoretical and experimental results are combined in the same paper"), and the tremendous progress that has been made since then. The author raises the question: "One may ask whether it is worth the effort to pursue these obviously very difficult nonlinear aspects of the Taylor vortex problem:" *(irregular or chaotic flow, turbulent Taylor vortices)*, and notes that, "The answer to this question seems to be yes, because in the case of Taylor vortex flow we can pursue the formation of turbulence from laminar flow to full turbulence with great precision in all detail through a number of very characteristic stages." We certainly agree. What better place to look for the Holy Grail of turbulence?

I would enthusiastically recommend *Benard Cells and Taylor Vortices* to all researchers and graduate students interested in fluid dynamics, heat transfer, and scientific research. Cambridge University Press should be complimented for a superb production and publication.

9R29. HVAC Controls and Systems. - John I Levenhagen *(Johnson Controls)* and Donald Spethmann *(Honeywell Commercial Build Group)*. McGraw-Hill, New York. 1993. 334 pp. ISBN 0-07-037509-7.

Reviewed by Harry J Sauer Jr (Mech and Aerospace Eng, Univ of Missouri, Rolla MO 65401).

The authors have written an excellent introductory text on the basics of automatic control systems as related to air-conditioning [alias HVAC (heating, ventilating, and air-conditioning)] systems. For engineers entering the HVAC field, the book should provide a good background on how commerical HVAC systems are intended to function and the role that control systems play toward obtaining proper operation. However, the book does not get into the "technical" details of control theory, nor the design of such HVAC control systems.

The first few chapters of the book present the operation of some of the HVAC system components necessary for the control function: thermostats, dampers, and valves. Chapters 5 through 9 provide descriptive material on the controls, and direct digital control systems are covered. Chapters 10 through 14 delve deeper into the various types of air-conditioning systems and the means for providing the desired heating and cooling. Chapter 14 also integrates the typical control techniques with descriptions of the equipment used for providing hot and cold fluids.

Supervisory control, the total system monitoring and overall control of all subsystems, (also referred to as the building automation system), is the topic of chapter 15. In this significant chapter, the authors discuss such topics as system configurations and communications, proprietary versus open systems, energy management functions, and operator interface functions. Chapter 16 goes into the operations and maintenance of all types of HVAC systems, including the system as well as the associated controls. Chapter 17 provides a brief coverage of control selection, examined from the perspective of the type of organization that will be occupying and running the facility.

The book often presents a historical perspective and helps the reader to develop an appreciation for the improvements which have occurred with time and experience. The text does an excellent job of bringing the reader up-to-date on current practices in the HVAC field.

In summary *HVAC Controls and Systems* will be worthwhile reading for all system design engineers entering the HVAC field.

9N30. Combustion Efficiency Tables. - Harry Taplin, PE. ASM Int, Materials Park OH. 1992. 228 pp. ISBN 0-88173-143-9. $44.00.

Ninety-three combustion efficiency tables are contained in this reference. The tables are based on the ASME-ANSI Power Test Code 4.1, and are designed to systematically illustrate how different variables impact the combustion process.

9N31. Innovative Energy Design for the '90s. - Milton Meckler, PE. ASM Int, Materials Park OH. 1993. 403 pp. ISBN 0-88173-123-4. $64.00.

Contents include: Building HVAC system optimization; Multi-source hydronic heat pump systems; Advanced thermoelectric heat pumps; Cost-effective evaporative chilling; Integrated fire sprinkler and thermal energy storage systems; Geothermal power development; Introduction to daylighting; Evaluating daylight availability; Use of daylighting sky model; Use of light shelves; Use of geometric daylighting models; Applying daylighting computer models; Hybrid daylighting and space heating systems; Integrated desiccant cold air distribution system; New developments in desiccant cooling; Hybrid solar thermal systems; Hybrid photovoltaic systems for space power generation; and Hybrid heat pipe applications.

9N32. Manual on the Use of Thermocouples in Temperature Measurement, 4th ed. - ASTM. 1993. 311 pp. ISBN 0-8031-1466-4. $49.00. ASTM members, $44.

This new edition from ASTM (formerly STP 470B) includes principles, circuits, standard electromotive force (EMF) tables, stability and compatibility data, installation techniques, and other information that will aid users of thermocouples.

Completely revised in accordance with the International Temperature Scale of 1990 (ITS-90), the contents include: principles of thermoelectric thermometry; thermocouple materials; typical thermocouple designs; sheathed, compacted, ceramic-insulated thermocouples; thermocouple output measurements; reference junctions; calibration of thermocouples; application considerations; reference tables for thermocouples; cryogenics; temperature measurement uncertainty; terminology; list of ASTM standards pertaining to thermocouples; and the international temperature scale of 1990 (ITS-90).

Chemical Change in Deforming Materials. - Brian Bayly *(Dept of Geol, RPI)*. Oxford UP, New York. 1993. 225 pp. ISBN 0-19-506764-9. $75.00. (Under review)

Heat Exchange Engineering, vols 1 and 2. vol 1; design of heat exchangers; vol 2; compact heat exchangers; techniques of size reduction. - EA Foumeny *(Chem Eng, Univ of Leeds, UK)* and PJ Heggs *(Chem Eng, Bradford Univ, UK)*. Ellis Horwood, Chichester UK. 1991. 600 pp. ISBN 0-13-382409-8; 0-13-382391-1. (Under review)

Numerical Modeling in Combustion. - TJ Chung *(Univ of Alabama, Huntsville AL)*. Taylor & Francis, Washington DC. 1993. 632 pp. ISBN 0-89116-822-2. $199.50. (Under review)

Reduced Kinetic Systems for Application in Combustion Systems. - N Peters *(Inst fur Tech Mech, Templergraben, Germany)* and B Rogg *(Univ of Cambridge, Templergraben, UK)*. Springer, New York. 1993. 360 pp. ISBN 0-387-56372-5. $55.00. (Under review)

VIII. ENERGY & ENVIRONMENT

9N33. Alternative Energy Handbook. - Paul Rosenberg. ASM Int, Materials Park OH. 1993. 259 pp. ISBN 0-88173-140-4. $74.00.

This book is a guide to cost-effective alternative energy applications. A full range of alternative methods for generating power are examined, including innovative solar electric power systems, hydropower technologies, wind power, cogeneration, and independent electric power generators using a variety of fuel types. The latest developments in biomass and wood fuels are also examined. You'll get the facts on cost-effective heating strategies using solar, geothermal, and wood-burning technologies. An update on the latest developments in storage batteries for electric vehicles is also included.

IX. BIOENGINEERING

9N34. STP 1178 Composite Materials for Implant Applications in the Human Body: Characterization and Testing. - Edited by Russel D Jamison *(Smith and Nephew Richards)* and Leslie N Gilbertson *(Zimmer)*. ASTM. 1993. ISBN 0-8031-1852-X. $45.00.

Contents include: comparative study of carbon polymer composite and titanium femoral stems in dogs using computed tomography by EJ Char, AE Grierson, DT Reilly, CB Sledge and M Spector; environmental effect on a thermoplastic elastometer (TPE) for use in a composite intervertebral disc spacer by M Vuono Hawkins, MC Zimmerman, JR Parsons, NA Langrana and CK Lee; fatigue testing of femoral hip prostheses with a two-beam simulated femoral bone support fixture by SM Humphrey and LN Gilbertson; in vitro studies on the electrochemical behavior of carbon fiber composites by P Kovacs; the effect of interfacial bonding upon compressive strength and fracture energy of carbon fiber reinforced polymer (CFRP) composite: a theoretical investigation by RA Latour and G Zhang; a life prediction model for fatigue loaded composite femoral prosthesis by K Liao and KL Reifsnider; creep testing of a composite material human hip prosthesis by GR Maharaj and RD Jamison; intraoperative impact: characterization and laboratory simulation on composite hip prostheses by GR Maharaj and RD Jamison; stability of polysulfone composite materials in a lipid environment by RA Salzstein and JM Moran; characterization and optimization of small particle dental composites by TK Vaidyanathan, J Vaidyanathan and S Waknine; and a mechanical and historical analysis of the bonding of bone to hydroxylapatite-polymer composite coatings by MC Zimmerman, PS Boone, H Scalzo and JR Parsons.

Biomechanics. Mechanical Properties of Living Tissues. - YC Fung *(UCSD)*. Springer, New York. 1990. 433 pp. ISBN 0-387-90472-7. $49.50. (Under review)

REVIEW OF THE JOURNAL LITERATURE

for core list of journals scanned see Index Issue, published as Part 2 of the Dec issue of last year

I. FOUNDATIONS & BASIC METHODS

100. Continuum mechanics

9A1. Study of constitutive relations for pseudo-elasticity and shape memory behavior. - Zhigang Wang and Keh-chih Hwang *(Dept of Eng Mech, Tsinghua Univ, Beijing 100084, China).* Acta Mech Sinica 9(1) 44-52 (1993).

Constitutive relations are given for the description of the deformation behavior of shape memory materials. The deformation is the superposition of the elastic, the thermal, and the phase transformation deformation caused by the transformation from one to the other among the high temperature phase, the low temperature phase, and the stress induced phase. The phase transformation is controlled by the driving force, ie, the Gibbs energy difference between the phases.

9A2. FE analysis of vibration and damping of laminated composites. - R Rikards *(Riga Tech Univ, Kalku str 1, Riga 226047, Latvia).* Composite Struct 24(3) 193-204 (1993).

A sandwich composite beam and plate finite superelements with viscoelastic layers for vibration and damping analysis are presented. Each layer is considered as simple Timoshenko's beam or Mindlin-Reissner plate FE. The energy dissipation in the viscoelastic layers is taken into account with complex modulus of elasticity theory. Two methods for damping analysis of laminated composite beams or plates is considered: the method of complex eigenvalues and the energy method. The first one is an "exact method", in which the modal loss factors of structure for each frequency are determined as the ratio of imaginary and real parts of complex eigenvalues. The second method is approximate, in which the modal loss factors of structure for each frequency are calculated as the ratio of dissipated and elastic strain energy for one cycle of steady state-vibrations. For sandwich beams and plates with a viscoelastic middle layer, the vibration and damping analysis for a wide range of materials and geometric parameters was carried out. Comparison of the results obtained by the two methods gives good agreement with the results of other authors.

102E. OTHER SOLID MECHANICS APPLICATIONS

9A3. Deforming FEM for analysis of alloy solidification problems. - Yimin Ruan, Joshua C Liu, O Richmond *(Alcoa Tech Center, Aluminum Co of Amer, 100 Technical Dr, Alcoa Center PA 15069).* Finite Elements Anal Des 13(1) 49-63 (Apr 1993).

A better understanding of the heat transfer associated with any alloy solidification process may lead to precise control of the solidification process and improvement of the quality of castings. This requires accurate modeling of heat flux discontinuities and the multiple phases (solid, liquid, and mush) inside solidifying bodies. To deal with the complexity of the problem and improve the accuracy of numerical results, a deforming FEM for alloy solidification is developed in this paper. In this method, the velocities of the solid-mush and mush-liquid interfaces are primary variables. In the example problems of solidification of binary alloys, Scheil's equation and the lever rule are used to calculate the solid fraction in the mushy region. This method is accurate and can be easily implemented.

102J. OTHER APPLICATIONS

9A4. Local force calculation in 3D FEM with edge elements. - Akihisa Kameari *(Mitsubishi Atomic Power Industries, 4-1 Shibakouen 2-chome, Minato-ku Tokyo 105, Japan).* Int J Appl Electromagnetics Mat 3(4) 231-240 (Apr 1993).

A nodal force method has been proposed to calculate the local magnetic force in conductors and magnetic materials using the 3D FEM. It is formulated by volume integrations of the Maxwell's magnetic stress tensor with the virtual nodal displacement. The method can be easily implemented into the FEM programs. Numerical test calculations show that the calculated results agree well with analytic solutions and an experiment.

9A571. Finite element analysis of synchronous belt tooth failure

102L. SOLUTION ALGORITHMS

9A5. Analysis of element-by-element preconditioners for nonsymmetric problems. - MB van Gijzen *(Delft Univ of Tech, Delft, Netherlands).* Comput Methods Appl Mech Eng 105(1) 23-40 (May 1993).

A group of preconditioners for systems of linear equations arising from FE discretization, which is of increasing interest, is the class of element-by-element preconditioners. These preconditioners allow the solution of a system without the need to assemble the global stiffness matrix. The success of a preconditioner depends on how much it reduces the condition number of the global stiffness matrix. In this paper a bound on the condition number of the preconditioned stiffness matrix is derived in terms of norms of the element stiffness matrices, the element preconditioning matrices and the flexibility matrix.

9A6. Construction of stiffness matrices to maintain the convergence rate of distorted FEs. - MS Ingber and HL Schreyer *(Dept of Mech Eng, Univ of New Mexico, Albuquerque NM 87131).* Int J Numer Methods Eng 36(11) 1927-1944 (15 Jun 1993).

High-order elements are an option for providing an enhanced rate of convergence. However, it is not widely known that if a high-order element based on a mapping from a master-element space is distorted by displacing one of the side nodes slightly from the traditional midside position then the rate of convergence drops one order. The proof for a three-node element in 1D has been given previously. Here, a numerical demonstration is presented to show how quickly the rate is lost as the second node is moved from the midpoint. The numerical investigation shows that convergence appears to be retained but that the error associated with the incompatibility is greater than the error obtained with the use of distorted isoparametric elements. The results of this study are particularly appropriate for domains with curved boundaries and for nonlinear problems in which node positions are updated according to the deformation history.

9A7. Development of FE analysis post processing program. - R Karpurapu and RJ Bathurst *(Dept of Civil Eng, R Military Col of Canada, Kingston, ON, K7K 5L0, Canada).* Adv Eng Software 16(1) 15-22 (1993).

FE analyses may produce large amounts of response output that can obscure an understanding of model behavior by simply looking at the numbers produced by the numerical simulation. It is desirable to utilize a post processing program that can display selected aspects of model response in graphical form in order to properly interpret the results produced by FE analyses. This paper discusses some methods for efficient data management and principles for the development of post processing programs to analyse the response data produced by FE programs.

9A8. Virtual bubbles and Galerkin-least-squares type methods: GaLS. - C Baiocchi, F Brezzi *(Dipartimento Matematica dell'Univ Pavia, IAN-CNR, Corso Carlo Alberto 5, 27100 Pavia, Italy),* LP Franca *(Lab Nacional Computacao Cientifica, LNCC-CNPq, Rua Lauro Muller 455, 22290 Rio de Janeiro, Brazil).* Comput Methods Appl Mech Eng 105(1) 125-141 (May 1993).

The equivalence between stabilized FEMs (or Galerkin-least-squares type methods, GaLs) and the standard Galerkin method with bubble functions is established in an abstract framework. The results are applicable to various FE spaces, including high order elements, and applications to the advective diffusive model and to the Stokes problem are presented, illustrating the potential of the abstract theory introduced here.

102N. ELEMENT DEVELOPMENT

9A9. Consistent FE formulation of nonlinear membrane shell theory with particular reference to elastic rubberlike material. - A Ibrahimbegovic *(Ecole Polytech Fed Lausanne DGC LSC, CH-1015 Lausanne, Switzerland)* and F Gruttmann *(Inst Baumech, Numer Mech, Appelstr 9A, D-3000 Hannover 1, Germany).* Finite Elements Anal Des 13(1) 75-86 (Apr 1993).

In this paper we present a nonlinear membrane theory for rubberlike shells accounting for large elastic strains. We discuss the material model given as a general coaxial form of stress and strain measures. It includes, as a special case, the hypereleastic model in terms of principal stretches which is often used to characterize rubberlike materials. The displacement-based FEs are used. Cartesian coordinate systems are constructed locally at each numerical integration point in order to simplify computations.

9A10. Diagonal mass and associated stiffness matrices for isoparametric 5-node quadrilateral and 9-node hexahedron elements. - G Sauer *(Technischer Uberwachungsverein, Bayern, Munchen, Germany).* Finite Elements Anal Des 13(1) 37-47 (Apr 1993).

Expanded displacement interpolation functions that generate diagonal mass matrices are presented for the isoparametric 5-node quadrilateral and 9-node hexahedron. By applying 2×2 or $2 \times 2 \times 2$ Gauss integration, respectively, the modified interpolation functions contract the mass in the central node. The corner nodes are freed from masses. It is shown that the elements defined by the modified interpolation functions and the corresponding integration order are suited to satisfactorily reflect the dynamic structural properties.

9A11. Parallel FEM algorithms based on recursive spatial decomposition II. Automatic analysis via hierarchical substructuring. - M Saxena *(Solid Mech Lab, GE Corporate R&D, Schenectady NY 12301)* and R Perucchio *(Dept of Mech Eng, Univ of Rochester, Rochester NY 14267).* Comput Struct 47(1) 143-154 (3 Apr 1993).

In the companion paper, we discussed the applicability of a recursive spatial decomposition (RSD) based automatic meshing procedure for concurrent implementation. This paper describes an automatic substructuring scheme based on RSD of the domain, that can be closely integrated with the RSD-based automatic meshing procedure. The hierarchical data structures used to represent RSD-based automatically derived meshes also provide a one-to-one mapping between spatially decomposed subdomains and analytical substructures. Such a hierarchical organization of the substructures and the inherent parallelism of RSD are exploited to design the substructuring scheme suitable for parallel processing.

9A12. Verification of a general-purpose laminated composite shell implementation: Comparisons with analytical and experimental results. - YD Murray *(APTEK, San Jose CA 95129)* and LE Schwer *(SE&CS, 1070 Leslie Dr, San Jose CA 95117).* Finite Elements Anal Des 13(1) 1-16 (Apr 1993).

The constitutive behavior of a laminated shell element, implemented in a nonlinear FE code, is verified by analyzing a series of analytical and experimental results. Comparisons between the laminated shell model and analytical results available in the literature verify the implementation of the model for the membrane response, bending response with and without transverse shear, and the coupled response between the membrane and bending modes. The theoretical basis of the laminated shell model is verified by analyzing an impulsively loaded ring test.

9A13. An *a priori* geometry check for a single isoparametric FE. - DG Roddeman and LF Jansen *(TNO Build and Construct Res, PO Box 49, 2600 AA Delft, Netherlands).* Comput Struct 47(1) 69-72 (3 Apr 1993).

In order to check initial element geometry, the error in the displacement field is *a priori* bounded. The distorted element displacement field is determined by requiring a least squares difference with respect to a non-distorted (ie, reference) element solution. The least squares residual qualifies the element's approximation capabilities. An extra check on high aspect ratio is proposed. Several examples of geometry checks are included.

See also the following:

9A366. Comparison of two quarter-point element extrapolation equations for 3D mixed-mode problems

104. Finite difference methods

9A14. Evaluation of various high-order-accuracy schemes with and without flux limiters. - P Tamamidis and DN Assanis *(Dept of Mech and Indust Eng, Univ of Illinois, 1206 W Green St, Urbana IL 61801).* Int J Numer Methods Fluids 16(10) 931-948 (30 May 1993).

Conventional high-order schemes with reduced levels of numerical diffusion produce results with spurious oscillations in areas where steep velocity gradients exist. To prevent the development of non-physical oscillations in the solution, several monotonic schemes have been proposed. In this work, three monotonic schemes, namely Van Leer's scheme, Roe's flux limiter and the third-order SHARP scheme, are compared and evaluated against schemes without flux limiters. The latter schemes include the standard first-order upwind scheme, the second-order upwind scheme and the QUICK scheme. All the above schemes are applied to four 2D problems: (i) rotation of a scalar "cone" field, (ii) transport of a scalar "square" field, (iii) mixing of a cold with a hot front and (iv) deformation of a scalar "cone" field. These problems test the ability of the selected schemes to produce oscillation-free and accurate results in critical convective situations. The evaluation of the schemes is based on several aspects, such as accuracy, economy and complexity. The tests performed in this work reveal the merits and demerits of each scheme. It is concluded that high-order schemes with flux limiters can significantly improve the accuracy of the results.

9A15. Completed Richardson extrapolation. - PJ Roache and PM Knupp *(Ecodyn Res Assoc, PO Box 8172, Albuquerque NM 87198).* Commun Numer Methods Eng 9(5) 365-374 (May 1993).

The Richardson extrapolation method, which produces a 4th-order-accurate solution on a subgrid by combining 2nd-order solutions on the fine grid and the subgrid, is "completed" – in the sense that a higher-order-accurate solution is produced on all the fine grid points.

9A16. Fourier analysis of multigrid methods for general systems of PDEs. - P Lotstedt and B Gustafsson *(Dept of Sci Comput, Uppsala Univ, Uppsala, Sweden).* Math Comput 60(202) 473-493 (Apr 1993).

Most iteration methods for solving boundary value problems can be viewed as approximations of a time-dependent differential equation. In this paper we show that the multigrid method has the effect of increasing the time-step for the smooth part of the solution leading back to an increase of the convergence rate. For the nonsmooth part the convergence is an effect of damping. Fourier analysis is used to find the relation between the convergence rate for multigrid methods and singlegrid methods. The theoretical results are confirmed in simple numerical experiments.

9A17. Generation of unstructured tetrahedral meshes by advancing front technique. - H Jin *(Orbital Engine, 1 Whipple St, Balcatta WA 6021, Australia)* and RI Tanner *(Dept of Mech Eng, Univ of Sydney, NSW 2006, Australia).* Int J Numer Methods Eng 36(11) 1805-1823 (15 Jun 1993).

An algorithm for generating unstructured tetrahedral meshes by the advancing front technique is presented. Emphasis is placed on the construction of tetrahedral elements. Several measures are employed to prevent difficult situations. A control line-surface scheme is used to specify element size. Numerical examples are provided to show the performance of the algorithm.

9A18. New estimates for multilevel algorithms including the V-cycle. - JH Bramble *(Dept of Math, Cornell)* and JE Pasciak *(Dept of Appl Sci, BNL).* Math Comput 60(202) 447-471 (Apr 1993).

The purpose of this paper is to provide new estimates for certain multilevel algorithms. In particular, we are concerned with the simple additive multilevel algorithm discussed recently together with J Xu and the standard V-cycle algorithm with one smoothing step per grid. We shall prove that these algorithms have a uniform reduction per iteration independent of the mesh sizes and number of levels, even on nonconvex domains which do not provide full elliptic regularity. We also prove uniform convergence rates for the multigrid V-cycle for problems with nonuniformly refined meshes.

9A19. Runge-Kutta methods and local uniform grid refinement. - RA Trompert and JG Verwer *(Center for Math and Comput Sci, PO Box 4079, 1009 AB Amsterdam, Netherlands).* Math Comput 60(202) 591-616 (Apr 1993).

Local uniform grid refinement (LUGR) is an adaptive grid technique for computing solutions of partial differential equations possessing sharp spatial transitions. Using nested, finer-and-finer uniform subgrids, the LUGR technique refines the space grid locally around these transitions, so as to avoid discretization on a very fine grid covering the entire physical domain. This paper examines the LUGR technique for time-dependent problems when combined with static regridding. The present paper considers the general class of Runge-Kutta methods for the numerical time integration.

9A20. Some necessary conditions for convergence of the GBDF methods. - M Bin Suleiman *(Dept of Math Fac of Sci and Env Stud, Univ Pertanian Malaysia, 43400 UPM, Serdang)*. Math Comput 60(202) 635-649 (Apr 1993).

The Generalized Backward Differentiation methods for solving stiff higher-order ordinary differential equations are described. The convergence, zero stability and consistency of these methods are defined. Next, the zero stability and consistency conditions necessary for convergence are proven. The order for which the methods are zero stable is also determined.

106. Other methods in computational mechanics

9A21. Boundary element analysis of thermal stress intensity factors for cusp crack in transient state. - Kang Yong Lee *(Dept of Mech Eng, Yonsei Univ, Seoul 120-749, Korea)* and Jeong Kyun Hong *(Dept of Welding Eng, Ohio State Univ, Columbus OH 43210)*. Eng Fracture Mech 45(3) 309-320 (Jun 1993).

The BEM is applied to determine thermal stress intensity factors for a cusp crack in a transient state. In the steady temperature field, numerical values of thermal stress intensity factors for a Griffith crack and a symmetric lip cusp crack in a finite body are in good agreement within ±5% when compared with the previous solutions. In a transient state, the numerical values of thermal stress intensity factors for the Griffith crack are also in good agreement when compared with the previous solutions. In both steady and transient states, those for the symmetric lip cusp crack with the crack surface insulated or fixed to a constant temperature are calculated with various effective crack lengths, configuration parameters and uniform heat flow angles. The variations of the thermal boundary conditions of the crack surface have a great effect on stress intensity factors. The signs on the values of thermal stress intensity factors can be changed with time variation.

9A22. Simulating the non-isothermal mixing of polymer blends using the BEM. - PJ Gramann, JC Matzig, TA Osswald *(Dept of Mech Eng, Polymer Processing Res Group, Univ of Wisconsin, Madison WI 53706-1572)*. J Reinforced Plastics Composites 12(7) 787-799 (Jul 1993).

In most polymer processes the quality of the final part stems back in great part to the mixing of the compound and the viscous heating that occurs during the process. To date, these processes have been simulated using the finite difference or FEMs which rely on cumbersome remeshing techniques, restricting the analysis to simple geometries. However, mathematical manipulations of the governing equations results in boundary integrals, allowing the solution of complicated moving boundary problems without domain meshing. The resulting BEM and simulation results of the flow and heat transfer effects during mixing of polymer blends is presented in this article.

9A23. Orthogonal spline collocation Laplace-modified and alternating-direction methods for parabolic problems on rectangles. - B Bialecki and RI Fernandes *(Dept of Math, Univ of Kentucky, Lexington KY 40506)*. Math Comput 60(202) 545-573 (Apr 1993).

A complete stability ad convergence analysis is given for two- and three-level, piecewise Hermite bicubic orthogonal spline collocation, Laplace-modified and alternating-direction schemes for the approximate solution of linear parabolic problems of rectangles. It is shown that the schemes are unconditionally stable and of optimal-order accuracy in space and time.

9A24. Polynomial collocation using a domain decomposition solution to parabolic PDE's via the penalty method and explicit-implicit time marching. - K Black *(Center for Res in Sci Computation, N Carolina State Univ, Box 8205, Raleigh NC 27695-8205)*. J Sci Comput 7(4) 313-338 (Dec 1992).

A domain decomposition method is examined to solve a time-dependent parabolic equation. The method employs an orthogonal polynomial collocation technique on multiple subdomains. The subdomain interfaces are approximated with the aid of a penalty method. The time discretization is implemented in an explicit-implicit finite difference method. The subdomain interface is approximated using an explicit Dufort-Frankel method, while the interior of each subdomain is approximated using an implicit backwards Euler's method. The principal advantage to the method is the direct implementation on a distributed computing system with a minimum of interprocessor communication. Theoretical results are given for Legendre polynomials, while computational results are given for Chebyshev polynomials. Results are given for both a single processor computer and a distributed computing system.

9A25. Rate of convergence of the nonlinear Galerkin methods. - C DeVulder, M Marion *(Dept Math-Info-Syst, Ecole Centrale de Lyon, BP 163, 69131 Ecully, France)*, ES Titi *(Dept of Math, UC, Irvine CA 92717)*. Math Comput 60(202) 495-514 (Apr 1993).

In this paper we provide estimates to the rate of convergence of the nonlinear Galerkin approximation method. In particular, and by means of an illustrative example, we show that the nonlinear Galerkin method converges faster than the usual Galerkin method.

9A26. Neural networks in material processing and manufacturing: A Review. - JP Coulter *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*, LI Burke *(Dept of Indust Eng, Lehigh Univ, Bethlehem PA 18015)*, HH Demirci *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*. J Mat Processing Manuf Sci 1(4) 431-443 (Apr 1993).

Artificial neural systems have been proposed as advanced generic computer based tools that can lead to a wide variety of scientific, technological, and business improvements if properly utilized. In this article, a brief discussion of the background related to neural networks is provided, along with a summary of the application areas for which these biological intelligence based tools have been traditionally considered. Following this, a review of material processing and manufacturing studies during which artificial neural system technology has been investigated is presented. Processes such as welding, material removal, and tool wear monitoring, which served as the focus of a number of studies, are covered in detail. Additional manufacturing processes, such as injection molding and thermoplastic composite material tape consolidation, are also discussed. It is concluded that in all instances the proper implementation of neural networks in material processing and manufacturing applications has led to beneficial results, and that artificial neural system technology should be considered for an increased variety of manufacturing related applications in the years to come.

9A27. Comparison of coarse and fine grain parallelization strategies for the simple pressure correction algorithm. - AJ Lewis and AD Brent *(Newcastle Lab, BHP Res, PO Box 188, Wallsend NSW 2287, Australia)*. Int J Numer Methods Fluids 16(10) 891-914 (30 May 1993).

The primary aim of this work was to determine the simplest and most effective parallelization strategy for control-volume-based codes solving industrial problems. It has been found that for certain classes of problems, the coarse-grain functional decomposition strategy, largely ignored due to its limiting scaling capability, offers the potential for significant execution speed-ups while maintaining the inherent structure of traditional serial algorithms. Functional decomposition requires only minor modification of the existing serial code to implement and, hence, code portability across both concurrent and serial computers is maintained. Fine-grain parallelization strategies at the "DO loop" level are also easy to implement and largely preserve code portability. Both coarse-grain functional decomposition and fine-grain loop-level parallelization strategies for the SIMPLE pressure correction algorithm are demonstrated on a Silicon Graphics 4D280S eight CPU shared memory computer system for a highly coupled, transient 2D simulation involving melting of a metal in the presence for thermal-buoyancy-driven laminar convection. Problems requiring the solution of a larger number of transport equations were simulated by including further scalar variables in the calculation. While resulting in slight degradation of the convergence rate, the functional decomposition strategy exhibited higher parallel efficiencies and yielded greater speed-ups relative to the original serial code.

150. Kinematics and dynamics

9A28. Bounds on the friction-dominated motion of a pushed object. - JC Alexander and JH Maddocks *(Dept of Math and Inst for Phys Sci and Tech, Univ of Maryland, College Park MD 20742)*. Int J Robotics Res 12(3) 231-248 (Jun 1993).

We consider the friction-dominated, or quasistatic, motion of a rigid body being pushed over a horizontal plane in situations where the precise frictional interaction cannot be determined. Consequently, the complete set of motions corresponding to all possible friction distributions must be found. We demonstrate that if the contact region between the body and the supporting plane has one or two components, the set of all possible motions coincides with the set of motions arising for friction distributions restricted to two-point contact in the boundary in the contact region. Various examples are presented, and an effective numerical scheme based on a dissipation function is implemented.

9A29. Rotation angles. - WC Hassenpflug *(Dept of Mech Eng, Univ of Stellenbosch, Stellenbosch, S Africa)*. Comput Methods Appl Mech Eng 105(1) 111-124 (May 1993).

Problems of rigid body motion can be classified into three different types. For each one, different parameters may be the most suitable or natural coordinates to describe rotational position in space. As a common basis for comparison of different methods, we assume that the equations of motion are integrated numerically. For hinged bodies the three hinge angles are the most suitable, which for orthogonal hinges in different coordinates become the familiar different versions of the Euler angles. In this paper, we show that for free body motion, it may be preferable to use the nine elements of the rotation tensor directly. For elastically attached bodies, the most natural are the three elements of the rotation angle vector, for which we propose the name *Argyris* angles.

9A30. Stability of Ziegler's pendulum with eccentric load and load-dependent stiffness. - A Guran *(Dept of Civil and Env Eng, RPI)* and RH Plaut *(Dept of Civil Eng, VPI)*. Arch Appl Mech 63(3) 170-175 (Apr 1993).

The stability of Ziegler's pendulum with eccentric load and load-dependent stiffens is considered. It is shown that the flutter load is affected by a support that stiffness as it is compressed, and by eccentricity of the tangential load.

9A31. Study of stick-slip motion and its influence on the cutting process. - Jih-Hua Chin and Chun-Chien Chen *(Dept of Mech Eng, Natl Chiao Tung Univ, Hsinchu, Taiwan, ROC)*. Int J Mech Sci 35(5) 353-370 (May 1993).

The stick-slip motion of a machine tool has been investigated on the basis of a complete kinematic and kinetic model. The model is a generalized description of stick-slip motion of the machine tool which governs the whole cyclic process of this phenomenon and not just its slipping mode. Using this method some dynamic characteristics of this motion have been clarified. Further, an extended theory for chip-formation dynamics has been suggested to include the variation of feed.

9A32. Dynamic coupling between the joint and elastic coordinates in flexible mechanism systems. - AA Shabana and YL Hwang *(Dept of Mech Eng, Univ of Illinois, Chicago IL 60680)*. Int J Robotics Res 12(3) 299-306 (Jun 1993).

The aim of this investigation is to develop an efficient procedure for decoupling the joint and elastic accelerations while maintaining the nonlinear inertia coupling between the rigid body motion and the elastic deformation. The inertia projection schemes used in most existing *recursive methods* for the dynamic analysis of flexible robotics and mechanism systems lead to dense coefficient matrices in the acceleration equations, and consequently there is a strong dynamic coupling between the joint and elastic coordinates. This investigation discusses the problems associated with the inertia projection schemes used in the existing recursive methods, and it is shown that decoupling the joint and elastic accelerations using these methods requires the factorization of nonlinear matrices whose dimensions depend on the number of elastic dof of the system. The use of the procedure developed in this article is demonstrated using a four-bar flexible mechanism.

9A33. Analysis of a civil aircraft main gear shimmey failure. - R Van der Valk *(Fokker Aircraft BV, EDBS-BOO, 1117 ZJ Schiphol, Netherlands)* and HB Pacejka *(Vehicle Res Lab, Delft Univ of Tech, 2628 CD Delft, Netherlands)*. Vehicle Syst Dyn 21(2) 99-121 (1993).

A dynamic model is presented to analyze the stability of motion of the two-wheeled "Fokker F28-like" landing gear including tyres. The model is equally applicable to similar landing gears. The influence of the introduction of a specially designed torsional damper on the dynamical behavior of the landing gear-tyre combination is investigated. Results of the stability calculations are supported by test results.

9A34. Studies in spatial motion of a gyro on an elastic foundation. - A Guran *(Dept of Civil Eng, RPI)*, V Schlegel *(Arbeitsbereich Meerestechnik II Strukturmech, Tech Univ Hamburg-Harburg, Hamburg, Germany)*, K Ossia, FPJ Rimrott *(Atomic Energy of Canada, Sheridan Park Res Community, Mississauga, ON, Canada)*. Mech Struct Machines 21(2) 185-199 (1993).

To investigate the spatial motion of an axisymmetric gyro on an elastic foundation, a simplified model is proposed. The model is as simple as possible, yet designed to have all characteristics required to study its nonlinear behavior. Using Euler's law, the full nonlinear equations of motion are derived and then written in nondimensional form. Following analysis, numerical examples are investigated, and the evolution of nutation, precession, and spin angles is plotted.

9A35. Chaotic motion of a Kelvin type gyrostat in a circular orbit. - A Guran *(Dept of Civil and Env Eng, RPI)*. Acta Mech 98(1-4) 51-61 (1993).

The present paper deals with the following question: How does the inclusion of a symmetrical rotor affect the stability of an orbiting rigid axisymmetric body? To answer this question, the full nonlinear equations of motion of a rigid gyrostat in a gravitational field are obtained in a Hamiltonian formalism. Various dynamic behaviors of the spinning gyrostat satellite, eg, periodic, quasiperiodic, and chaotic, are studied via the Poincare map technique. The results show that some beneficial effects can be produced easily, eg, by increasing the rotor speed, chaotic motion of the satellite will become regular.

9A36. Fast recursive algorithm for molecular dynamics simulation. - A Jain *(JPL)*, N Vaidehi *(AA Noyes Lab of Chem Phys, CA IT, Pasadena CA 91125)*, G Rodriguez *(JPL)*. J Comput Phys 106(2) 258-268 (Jun 1993).

In this paper, we develop a recursive algorithm for solving the dynamical equations of motion for molecular systems. We make use of internal variable models which have been shown to reduce the computation times of molecular dynamic simulations by an order of magnitude when compared with Cartesian models. The O(N) algorithm described in this paper for solving the equations of motion provides additional significant improvements in computational speed. We make extensive use of the spatial operator methods which have been developed recently for the analysis and simulation of the dynamics of multibody systems. An alternative square factorization of the mass matrix leads to a closed form expression for its inverse. From this follows the recursive algorithm for computing the generalized accelerations. The computational cost of this algorithm grows only linearly with the number of dof.

9A37. General stochastic oscillatory systems. - EF Abdel Gawad and MA El Tawil *(Eng Math Dept, Fac of Eng, Cairo Univ, Giza, Egypt)*. Appl Math Model 17(6) 329-335 (Jun 1993).

We present a general stochastic nonlinear oscillatory system with a single dof. Square and cubic nonlinearities are considered. The excitation function is a nonstationary Gaussian process with zero mean. The solution moments are obtained using the small-parameter perturbation method with the Wiener-Hermite expansion approach. Computer results along with graphs are presented.

9A38. Response amplitude probability functions of a hardening Duffing oscillator subjected to filtered white noise. - PK Koliopulos, SR Bishop *(Dept of Civil Eng, Univ Col London, Gower St, London WC1E 6BT, UK)*, GD Stefanou *(Dept of Civil Eng, Univ of Patras, GR-26110 Patras, Greece)*. Comput Methods Appl Mech Eng 105(1) 143-150 (May 1993).

The problem of estimating the probability distribution of the response amplitude of a hardening Duffing oscillator subjected to narrow band excitation is addressed. A method is presented which is based on a quasi-static approximation of system behavior and is capable of reproducing the resulting concave shape of probability functions when a jump phenomenon occurs. Predictions are compared with those obtained via stochastic averaging techniques and with digital simulations.

9A39. Comparison of Mandelshtam's conditions with convergence conditions for iterative procedures in the analysis of complex dynamic systems by means of partial models. - TL Stanczyk *(Tech Univ, Kielce, Poland)*. Eng Trans 40(4) 457-467 (1992).

The convergence conditions for iterative procedures in the analysis of dynamic systems with the use of partial models are compared with Mandelshtam's conditions (uncoupling of vibrations of partial models). Both basic iteration procedures are discussed. The conditions for iterative procedures are found to be much weaker than those formulated by Mandelshtam. A simplified criterion for the selection of the type of procedure (a manner in which a system is to be decomposed) is presented.

9A40. Sturm sequence recurrence formula for eigensolution of locally modified systems. - M Kashiwagi *(Fac of Eng, Kyushu Tokai Univ, 9-1-1 Toroku, Kumamoto-shi 862, Japan)*, I Hirai *(Fac Eng, Kumamoto Univ, 2-39-1 Kurokami, Kumamoto-shi 862, Japan)*, T Katayama *(Sasebo Heavy Indust Co, 1 Tategami, Sasebo-shi 857, Japan)*, WD Pilkey *(Dept of Mech and Aerospace Eng, Univ of Virginia, Charlottesville VA 22901)*. Finite Elements Anal Des 13(1) 31-36 (Apr 1993).

This paper proposes a recurrence formula for the fundamental equation derived on the basis of the Sturm sequence property for the eigensolution of locally modified systems. The fundamental equation expressed using a condensed matrix, of order equal to the order of the modified part of the system, requires the multiple calculation of a determinant. The number of calculations is equal to the order of the original system. The recurrence formula set forth in this paper avoids multiple evaluations of the determinant.

154B. BEAMS, COLUMNS, RODS, AND BARS

9A41. Nonlinear vibrations of spatial viscoelastic beams. - S Wojciech *(Tech Univ, ul Majakowskiego 11/12, 80-952 Gdansk-Wrzeszcz, Poland)* and I Adamiec-Wojcik *(Branch of Lodz Tech Univ, ul Willowa 2, 43-309 Bielsko-Biala, Poland)*. Acta Mech **98**(1-4) 15-25 (1993).

This paper describes the solution of high amplitude cantilever spatial beam vibration problems. The standard linear damping model has been taken into consideration. In order to allow the large displacement analysis the rigid FEM has been introduced to discretize the beam. Denavit-Hartenberg's matrices and Lagrange's equations have been used to formulate the equations of motion. Both, numerical calculations and conclusions on the accuracy of the above mentioned method are shown.

9A42. Stability of a column with a follower load and a load-dependent elastic support. - A Guran *(Dept of Mech Eng, Univ of Toronto, 5 King's College Rd, Toronto, ON, M5S 1A4, Canada)* and RH Plaut *(Charles E Via, Jr Dept of Civil Eng, VPI)*. Acta Mech **97**(3-4) 205-214 (1993).

The influence of an elastic support on the stability of an elastic column under a follower load is investigated. The support is pinned and has a rotational spring whose stiffness is either constant or increases as the load is applied. Linear and quadratic stiffening functions are treated. An adjoint variational principle and a generalized Rayleigh-Ritz method are developed for this system. Characteristic curves are examined and the critical load, which is associated with flutter instability, is determined. The effects of the initial spring stiffness and the stiffening rate on the critical load are studied. It is found that an increase in either one of these parameters may lower the critical load, which is unexpected, and that support stiffening may have a significant influence on the vibrations and stability of a nonconservative system.

9A43. Torsional vibration of pretwisted thin-walled cantilevered I-beams. - OG McGee *(Sch of Civil Eng, Georgia Tech)*, MI Owings *(Am Precast Concrete, 3400 Jackson Pike, Grove City OH 43235)*, JW Harris *(Marathon Oil, 439 S Main St, Findlay OH 45840)*. Comput Struct **47**(1) 47-56 (3 Apr 1993).

Analytical natural frequencies and mode shapes are derived for the torsional vibration of pretwisted thin-walled cantilever I-beams. A multifilament model of a pretwisted thin-walled I-beam undergoing warp deformation and a moderately large twist about the axis of shear centers is used to derive the nonlinear boundary-value equations. Exact torsional vibration solutions are derived from the linear terms of the nonlinear boundary-value equations.

9A44. Vibration of bent tubes and rods in fluid flow. - S Devnin *(Krylov Res Inst, Russia)*. Heat Transfer Res **24**(5) 663-669 (1992).

Methods for prediction vibrations of bent pipes and rods in flowing fluids are derived. It is shown that the calculations involved in these predictions can be simplified by making use of the experimentally established fact of synchronicity of vortex shedding from bent rods in flows whose velocity changes along the tube axis. More experiments are needed to prove our computational technique.

9A45. Elastodynamics of thin plates with internal dissipative processes Part II. Computational aspects. - PA Fotiu *(Dept of Appl Mech and Eng Sci, UCSD)*. Acta Mech **98**(1-4) 187-212 (1993).

In part one of this paper an integral solution of the dynamic behavior of viscoplastic isotropic thin plates with ductile damage is derived. The main topic of the second part is the numerical solution of these integral equations. Green's functions due to external and internal excitation are split into quasistatic part and a purely dynamic part. Often the quasistatic part can be computed in a more convenient way than the complete dynamic fundamental solution. This paper develops an implicit time integration algorithm where the resulting system of equations is solved by an accelerated Newton-Raphson method.

9A46. Inhomogeneous annular plates with exactly beam-like radial spectra. - HPW Gottlieb *(Div of Sci and Tech, Griffith Univ, Nathan Brisbane, Queensland 4111, Australia)*. IMA J Appl Math **50**(2) 107-112 (1993).

There are seven classes of inhomogeneous beams which are isospectral with each other and with the homogeneous beams in the clamped-clamped configuration. By a logarithmic coordinate transformation, eight classes of inhomogeneous clamped annular plates may thereby be obtained which have different radial distributions for densities and flexural rigidities but which all have the same radial vibration spectrum characteristics of a clamped homogeneous beam.

9A47. Large amplitude vibration of antisymmetric imperfect cross-ply laminated plates. - Jenq-Yiing Yang and Lien-Wen Chen *(Dept of Mech Eng, Natl Cheng Kung Univ, Tainan, Taiwan, ROC)*. Composite Struct **24**(2) 149-159 (1993).

In this paper the large amplitude vibration of an initially stressed, imperfect, cross-ply plate is studied. The nonlinear equations of motion for an imperfect cross-ply plate in a general state of non-uniform initial stress are derived. The effects of both the transverse shear deformation and rotatory inertia are included. A multi-mode solution is formulated for a simply supported imperfect cross-ply plate. The modal equations are obtained by performing the Galerkin procedure and then solved by the Runge-Kutta method. It is found that the existence of geometric imperfections may result in a drastic change on the large amplitude vibration behavior. The effects of various parameters on the nonlinear vibration frequencies are investigated.

154H. SHELLS

9A48. Vibration and damping analysis of conical shells with constrained damping treatment. - TC Ramesh and N Ganesan *(Machine Dyn Lab, Dept of Appl Mech, Indian IT, Madras 600 036, India)*. Finite Elements Anal Des **13**(1) 17-29 (Apr 1993).

This paper presents an analysis of conical shells with a constrained viscoelastic damping treatment. A FE based on a discrete layer theory is developed for the purpose. The effects of core-to-facing thickness ratio, slant length and semi vertex angle of the cone on the frequencies and loss factors of conical shells with isotropic facings are investigated for three boundary conditions: clamped at both ends, simply supported at both ends and clamped at the small end.

154K. ROTATING SHAFTS (CRITICAL SPEED, BALANCING)

9A49. Steady-state analysis of a rotor mounted on nonlinear bearings by the transfer matrix method. - An-Chen Lee *(Dept of Mech Eng, Natl Chiao Tung Univ, Hsinchu 30049, Taiwan, ROC)*, Yuan Kang *(Dept of Mech Eng, Chung Yuan Christian Univ, Chung Li 32023, Taiwan, ROC)*, Shin-Li Lu *(Dept of Mech Eng, Natl Chiao Tung Univ, Hsinchu 30049, Taiwan, ROC)*. Int J Mech Sci **35**(6) 479-490 (Jun 1993).

The steady-state response of subharmonic, superharmonic and synchronous vibrations of a flexible rotor supported by bearings of power nonlinearity (ie, the bearing force satisfies a power law of the deflection) are studied. The transfer matrix method is applied to formulate the transfer matrices of nonlinear rotor-bearing systems with MDOF (multi dof) and in conjunction with the harmonic balance method to obtain the steady-state responses. Two examples of rotor-bearing systems with cubic nonlinearity spring characteristics are given to investigate the effects of nonlinearity on frequency response and the whirling orbits.

154L. FRAMES, TRUSSES, AND ARCHES

9A50. Dynamic reliability of large frames. - S Mahadevan and S Mehta *(Vanderbilt Univ, Nashville TN 37235)*. Comput Struct **47**(1) 57-67 (3 Apr 1993).

This paper presents a stochastic FEM (SFEM) for the reliability analysis of dynamically loaded large frames. This is facilitated by the computation of the sensitivity of dynamic response of the randomness in the dynamic excitation as well as in structural properties, by applying the chain rule of differentiation to the deterministic analysis. Since such computation requires large amounts of memory and computational time, matrix condensation is incorporated in SFEM for structures with a large number of dof. The computation of response sensitivity and variability is formulated in the context of stiffness and mass matrix condensation. A numerical example with a six-story frame is used to illustrate the proposed model.

154O. STRUCTURAL ELEMENTS ON FOUNDATIONS

9A51. General solution to vibrations of beams on variable Winkler elastic foundation. - Zhou Ding *(Dept of Mech Eng, E China IT,* *Nanjing, Jiangsu 210014, Peoples Rep of China).* Comput Struct 47(1) 83-90 (3 Apr 1993).

A general solution to vibrations of beams on variable Winkler elastic foundation is presented. The exact solution of the dynamic response of the beam is obtained by considering the reaction force of the foundation on the beam as the external force acting on the beam, which is an integral equation including the displacement of the beam. The four unknown constants in the solution are decided by the boundary conditions of the beam. The integrals in the solution are approximately and numerically calculated by means of the trapezoidal rules. The analysis and programming are very simple. It is possible to find the natural frequencies and mode shapes of vibrations by using a small number of the discrete nodes in the trapezoidal quadrature and it is concluded that the use of the method yields better convergence at lower computation costs.

9A52. **Hammer foundation analysis by the wave equation.** - YK Chow and DM Yong *(Dept of Civil Eng, Natl Univ of Singapore, 10 Kent Ridge Crescent, Singapore 0511).* Comput Struct 47(1) 107-110 (3 Apr 1993).

The vibration amplitudes of hammer foundations must be kept within acceptable limits during operation. A 1D wave equation model based on the FEM is proposed for the analysis of these foundations. The results of the wave equation model are shown to compare favorably with some reported solutions and with experimental measurements. The versatility of the model allows the various components of the hammer-foundation system to be readily simulated.

9A53. **Dynamics of fluidelastic vibrations of tube bundles in heat exchangers.** - S Kaplunov and N Makhutov *(Blagonravov Mech Eng Inst, Russian Acad of Sci, Russia).* Heat Transfer Res 24(5) 641-662 (1992).

The principal relationships governing the flow-induced vibrations of heat exchanges tube bundles, the knowledge of which is needed in the design stage in order to prevent destructive vibrations with runaway amplitudes, are derived by the general dynamic analysis of the fluidelastic behavior of the bundle, as well as its mechanical. The method employs probabilistic estimates of the possibility of actual attainment of the necessary frequency detuning to prevent resonance and generalized data on damping of the characteristic tube vibrations.

154Y. COMPUTATIONAL TECHNIQUES

9A54. **Adaptive time integration of nonlinear structural dynamic problems.** - BP Jacob and NFF Ebecken *(Civil Eng Dept, COPPE-Fed Univ Rio de Janeiro, PO Box 68506, 21945 Rio de Janeiro RJ, Brasil).* Eur J Mech A 12(2) 277-298 (1993).

This work presents the development of an adaptive computational strategy for the efficient nonlinear dynamic analysis of large-scale structural systems, particularly oriented towards the analysis of compliant structures for deepwater oil exploration and production. This strategy is devised having in mind the following requirements: (a) Superior computational efficiency when compared with conventional nonlinear dynamic analysis tools; (b) User-friendliness, reflected in savings in the time spent by the engineer for the preparation and submis[illegible] the computer jobs necessary to obtain [illegible]ponse; and (c) Improved charact[illegible] and robustness, reflected b[illegible]sults and the ability to complete an analysis without abnormal terminations. Applications on the nonlinear dynamic analysis of deepwater compliant structures are presented, to evaluate the aforementioned characteristics of the computational system.

9A55. **Perturbation analysis of vibration modes with close frequencies.** - Su-Huan Chen, Ahong-Sheng Liu, Chun-Sheng Shao, You-Qun Zhao *(Dept of Mech, Jilin Univ of Tech, Changchun 130022, Peoples Rep of China).* Commun Numer Methods Eng 9(5) 427-438 (May 1993).

This paper focuses on how parameter changes in a vibration system expressed by a discrete eigenvalue problem affect vibration modes in the special case of closely spaced eigenvalues, ie "eigenvalue clusters". For this class of problems, a perturbation analysis is developed that can be used to compute changes in eigenvalues and eigenvectors in response to small parameter changes. The analysis is applied to a 6-dof spring-mass system containing a single pair of closely spaced eigenvalues.

9A56. **Prediction of gear dynamics using fast Fourier transform of static transmission error.** - Hsiang Hsi Lin *(Dept of Mech Eng, Memphis State Univ, Memphis TN),* DP Townsend, FP Oswald *(Mech Syst Tech Branch, NASA Lewis Res Center, Cleveland OH).* Mech Struct Machines 21(2) 237-260 (1993).

An analytical computer simulation procedure for dynamic modeling of low-contact-ratio spur gear systems is presented. The procedure computes the gear static transmission error and uses a Fast Fourier Transform to generate its frequency spectrum at various tooth profile modifications. The dynamic loading response of an unmodified (perfect involute) gear pair is compared with that of gears with profile modifications. Correlations are found between several profile modifications and the resulting dynamic loads. Optimum profile modifications can be determined from the design curves, to yield a minimum dynamic effect for a gear system. This provides an essential tool for improved gear design.

9A57. **Statistical analysis of the dynamic cutting coefficients and machine tool stability.** - MA El Baradie *(Sch of Mech and Manuf Eng, Dublin City Univ, Dublin 9, Ireland).* J Eng Indust 115(2) 205-215 (May 1993).

Machine tool chatter is a statistical phenomenon since it is dependent on the interaction of two statistical quantities, these being the dynamic characteristics of the machine tool structure and the transfer function of the cutting process. In this paper, a generalized statistical theory of machine tool chatter has been developed. This takes into consideration the scatter of the dynamic data of the machine structure and/or that of the cutting process. The dynamics of the cutting process have been represented by a mathematical model which derives the cutting coefficients from steady state cutting data, based on a nondimensional analysis of the cutting process. The dynamics of the machine tool structure and the cutting process, being the input data to the theory, were determined experimentally. The predicted stability charts were plotted to take into consideration the scatter in the machine structure dynamics and/or the cutting process.

9A58. **Unified transfer function (UTF) approach for the modeling and stability analysis of long slender bars in 3D turning operations.** - IN Tansel *(Dept of Mech Eng, Florida Int Univ, Miami FL 33199).* J Eng Indust 115(2) 193-204 (May 1993).

A new approach is introduced to model 3D turning operations that are used for the stability analysis of long slender bars. This approach utilizes the unique relationship between externally created feed direction tool displacements (input) and the resultant thrust direction workpiece vibrations (output) to estimate stability limits in 3D turning operations from the data of a single dynamic cutting test. In this paper, this unique relationship is referred to as the "Unified Transfer Function" and its expressions are derived from conventional cutting and structural dynamics transfer functions. The proposed approach considers in-process structural and cutting dynamics and can be automatically implemented without any input from the operator for the traverse turning of a long slender bar.

9A59. **Semi-active damping with an electromagnetic force generator.** - D Ryba *(Fac of Mech Eng and Marine Tech, Univ of Tech, Delft, Netherlands).* Vehicle Syst Dyn 21(2) 79-95 (1993).

The main shortcoming of vehicle suspension systems is the amplification of input vibrations at the resonant frequency. A non-amplifying suspension system with a semi-active damping is being developed. The use of an electronically controlled rotational damper has been studied theoretically. A new spring seat is being designed for the improvement of the working conditions for drivers of road and terrain vehicles.

9A60. **Six-dof active vibration isolation using a Stewart platform mechanism.** - Z Geng and LS Haynes *(Intelligent Autom, 1370 Piccard Dr, Rockville MD 20850).* J Robotic Syst 10(5) 725-744 (Jul 1993).

Intelligent Automation has performed a study of a six-dof active vibration isolation system based on a Stewart platform mechanism to be used for precision control of a wide range of space-based structures as well as earth-based systems. This article presents part of the study results, which includes a new Terfenol-D actuator design and analysis, a design of a Stewart platform as a vibration isolation device and robust adaptive filter algorithms for active vibration control. Prototype hardware of a six-dof active vibration isolation system has been implemented and tested. About 30 dB of vibration attenuation is achieved in real-time experiments.

9A61. **Discrete modelling of wave propagation in bars with piecewise-linear characteristics.** - Z Szczesniak *(Military Tech Acad, Warszawa, Poland).* Eng Trans 40(4) 483-500 (1992).

A method is proposed to model 1D wave propagation problems in a discrete manner as applied to the material with piecewise-linear stress-strain relationship in loading and rigid-elastic behavior in unloading. The method consists in a simple combination of basic models, ie, an elastic model and a plastic model with rigid unloading to obtain a combined model. It turns out to be accurate and effective. Numerical algorithm is described. Errors are discussed and an example of unloading stress wave is given.

9A62. Torsional mode coupling and filtering in a composite waveguide with multiperiodic interface corrugations. - OR Asfar *(Dept of Elec Eng, Univ of Sci and Tech, Irbid, Jordan)* and MA Hawwa *(Dept of Eng Sci and Mech, VPI)*. J Acoust Soc Am 93(5) 2468-2473 (May 1993).

This study is concerned with the interaction of six torsional modes in a composite axisymmetric waveguide whose interfaces are sinusoidally corrugated in the axial direction. The modes are interacting when two resonant conditions on the codirectional modes and a Bragg condition occur simultaneously. In light of the weakness of the interface corrugations, the perturbation method of multiple scales is used to derive the mode coupling equations. A novel numerical scheme for two-point boundary-value problems is used to solve the coupled amplitude equations. The power reflection coefficient of a filter section is then calculated for the cases of uniform, tapered, and chirped corrugations. An optimal filter is realized by combining both taper and chirp thus producing a nearly ideal characteristics.

9A63. Traveling waves on a wire. - DS Jones *(Dept of Math and Comput Sci, The University, Dundee DD1 4HN, UK)*. Arab J Sci Eng 17(4B) 541-563 (Oct 1992).

The problem of the initiation and reflection of traveling waves on a long thin wire of finite length when it is simulated by a plane wave is investigated. By modeling the wire as a narrow tube it is shown that all the traveling waves, except the one supported by a longitudinal symmetrical current, decay exponentially at a rapid rate. The form of the longitudinal current is determined as well as its launching coefficient. The reflection coefficient when such a traveling wave encounters an end is also found. Expressions for the field scattering by the wire and the back scattering are derived in addition.

9A64. Point force excitation of an elastic infinite circular cylinder with an embedded spherical cavity. - S Olsson *(Div of Mech, Chalmers Univ of Tech, S-41296 Goteborg, Sweden)*. J Acoust Soc Am 93(5) 2479-2488 (May 1993).

In this paper the scattering of elastic waves in an infinite circular cylinder is considered. The elastic medium of the cylinder is assumed to be homogeneous, isotropic, and linear except for a finite inhomogeneity which, for simplicity, is chosen as a spherical cavity. By applying the null field approach (or T matrix method), the scattered field is obtained as a complicated expression containing the transition matrix of the cavity, the reflection matrix of the cylinder, and the transformation function between the spherical and cylindrical vector wave functions. Numerical results, both in the frequency and time domain, are presented.

158F. SURFACE WAVES

9A65. Surface stress waves in a transversely isotropic nonhomogeneous elastic semispace Part I. Equations of motion and equations of a Rayleigh-type surface wave. - T Roznowski *(Dept of Civil Eng and Operations Res, Princeton)*. Arch Mech 44(4) 417-435 (1992).

Plane state of strain of a transversely isotropic medium, nonhomogeneous in the plane of isotropy is considered; equations of motion expressed in terms of stresses are used to formulate the problem of propagation of Rayleigh-type surface stress waves. It is proved that in the case of a harmonic wave, the problem may be reduced to a solution of a fourth-order, ordinarily differential equation, with variable coefficients, for the "stress function" $\beta(z)$, ie, the normal stress σ_{zz} amplitude distribution in the semispace along the vertical direction; the remaining amplitudes are expressed in terms of $\beta(z)$. The form makes it possible to formulate and discuss several particular cases of the media under consideration. Equations are proved to be identical with those derived by J Ignaczak. The methods of solution of the equations of motion are presented. Conclusions are drawn.

9A66. Surface stress waves in a transversely isotropic nonhomogeneous elastic semispace Part II. Surface stress wave in a "weakly anisotropic" semi-space with "small nonhomogeneity". - T Roznowski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(4) 437-451 (1992).

A Rayleigh-type surface stress propagation is considered in a "weakly anisotropic" semispace of "small nonhomogeneity"; two elastic shear moduli are assumed to be monotone functions of depth, the ratio of Young's moduli is limited to the first two terms of a power series expansion. Waves of such type are described by the solution of an ordinary, fourth order differential equation with variable coefficients satisfying the corresponding boundary conditions. In this particular case of variability of the elastic moduli, the problem has a closed-form solution expressed in terms of Bessel functions. Analysis of the dispersion equation proves the Rayleigh wave speed C_R to depend on the wave-length and on the anisotropy and nonhomogeneity parameters. Using the asymptotic expansions of Bessel functions, the dispersion equation is written in an approximate form enabling a numerical analysis of the influence of the anisotropy and nonhomogeneity parameters upon the surface wave speed.

158H. PLASTIC, VISCOPLASTIC WAVES

9A67. Riemann solver and a second-order Godunov method for elastic-plastic wave propagation in solids. - X Lin and J Ballmann *(Lehr und Forschungsgebiet Mechanik, RWTH Aachen, Templergraben 64, 5100 Aachen, Germany)*. Int J Impact Eng 13(3) 463-478 (Aug 1993).

By use of three basic paths of elastic-plastic loading, a Riemann solver is established for the 1D combined longitudinal and torsional stress wave problem of the thin-walled elastic-plastic tube. Based on this, a second-order Godunov method is developed for the numerical computation of elastic-plastic waves. Finally, the numerical method is applied to some basic problems with known exact solutions and the comparison of results is made.

158I. VISCOELASTIC WAVES

9A68. Theory and computation of the steady state harmonic response of viscoelastic rubber parts. - AB Zdunek *(Dept of Struct, Aeronaut Res Inst of Sweden, Box 11021, S-161 11 Bromma, Sweden)*. Comput Methods Appl Mech Eng 105(1) 63-92 (May 1993).

A robust FEM for the determination of the static response due to small harmonic excitations superposed on a prestrained equilibrium state presented for rubber engineering applications. The method presented here is based on a Key-type variational formulation, for a nearly incompressible rubber-elasticity problem. The problems originating from the difficulty in approximating the accumulated pressure, common to several popular nonlinear single field strain projection methods, are removed. Use of a local elementwise pressure approximation allows elimination of pressure increments at the element level. Incrementally, the method is therefore reduced to a single field but distinct from pure displacement based formulations. Applications are provided as a verification of the computer implementation and as a support of the approach.

9A69. Self-consistent analysis of waves in a polycrystalline medium. - FJ Sabina *(Inst Investigaciones Matematicas Appl Sistemas, Univ Nacional Autonoma, Apdo PO Box 20-726 Admon No 20, Delegacion Alvaro Obregon 01000 Mexico DF, Mexico)* and JR Willis *(Sch of Math Sci, Univ of Bath, Claverton, Down BA2 7AY, UK)*. Eur J Mech A 12(2) 265-275 (1993).

A simple method, of self-consistent type, which was developed recently for a matrix-inclusion composite, is placed in a form suitable for application to composites in which no clearly-defined matrix phase exists, as in a polycrystal. Information on grain size and shape is incorporated through the solution of relevant single scattering problems; approximate account of multiple scattering is taken through "self-consistent" choice of a background, "effective", medium. Finding the properties to assign to the effective medium is facilitated by the adoption of simple approximate solutions of the single scattering problems; when the scatterers can be modelled as spheres, this approximation becomes exact in the static limit.

9A70. Boundary integral equation approach to elastodynamic inequality problems and applications. - E Mitsopoulou-Papasoglou *(Dept of Civil Eng, Aristotle Univ, GR-54006 Thessaloniki, Greece)*, PD Panagiotopoulos *(Inst for Tech Mech, RWTH, D-5100 Aachen, Germany)*, PA Zervas *(Dept of Civil Eng, Aristotle Univ, GR-54006 Thessaloniki, Greece)*. Eng Anal Boundary Elements 11(2) 145-155 (1993).

In the present paper the method of boundary integral equations (BIE) is extended to dynamic inequality problems involving convex energy superpotentials, ie, to problems involving monotone, possibly multivalued, relations between reactions and displacements, stress and strains, etc. Using semidiscretization with respect to time the authors obtain, within each time step, a minimum potential energy formulation, the equivalent variational inequality formulation and some equivalent saddle point formulations using appropriate Lagrangian functions. An elimination technique gives rise to minimum principles, on the boundary with respect to the unknown displacements or stresses of the time step under consideration; parameters are the velocities, etc, of the previous time step.

9A71. Choice of interpolation schemes for the BEM in elastodynamics. - TW Wu and L Lee *(Dept of Mech Eng, Univ Kentucky, Lexington KY 40506)*. Commun Numer Methods Eng 9(5) 375-385 (May 1993).

It is known that the BE coefficient matrices in steady-state elastodynamics are frequency-dependent. For a multifrequency run, the coefficient matrices have to be reformed at each different frequency. This procedure usually involves heavy numerical integration, and hence is very time consuming. In this paper, two interpolation schemes are initially introduced to accelerate the process of matrix reformation without sacrificing the solution accuracy. In the first scheme, the coefficient matrices are first slightly transformed and then interpolated in the frequency domain. In the second scheme, the Green function is interpolated in the spatial domain. Comparison between these two schemes both in terms of accuracy and efficiency is presented. Finally, a hybrid scheme that takes advantage of the best of both interpolation schemes is proposed. Numerical examples are given to demonstrate the three different interpolation schemes.

160. Impact on solids

9A72. Local loading of simply-supported steel-grout sandwich plates. - GG Corbett *(Dept of Eng, Kings College, Aberdeen Univ, Fraser Noble Build, Aberdeen AB9 2UE, UK)* and SR Reid *(Dept of Mech Eng, UMIST, PO Box 88 Sackville St, Manchester M60 1QD, UK)*. Int J Impact Eng 13(3) 443-461 (Aug 1993).

The results of tests are described in which simply-supported plates having steel skins and a grout filler were subjected to local penetration under both quasi-static and dynamic conditions. The influence of the grout thickness was examined in detail and the dominant deformation and failure mechanisms were identified. The results show that, in contrast to tubes of a similar construction, the energy absorbing performance of these plates is inferior to that of monolithic steel plates. The reasons for this are discussed. It is shown that despite this, the behavior of the sandwich plates is noticeably less sensitive to projectile nose shape than monolithic steel plates, and therefore this type of plate construction may be useful, in a modified form, in situations where monolithic steel plates are vulnerable to unfavorable impact conditions. Under impact loading conditions the lower skin of the sandwich plate is shown to behave similarly to a free standing quasi-statically loaded skin and to be the dominant energy absorbing component. The grout filler under impact loading absorbs energy in proportion to its thickness.

9A73. Quasi-static and dynamic local loading of monolithic simply-supported steel plate. - GG Corbett *(Dept of Eng, Kings Col, Aberdeen Univ, Fraser Noble Bldg, Aberdeen AB9 2UE, UK)* and SR Reid *(Dept of Mech Eng, UMIST, PO Box 88 Sackville St, Manchester M60 1QD, UK)*. Int J Impact Eng 13(3) 423-441 (Aug 1993).

The results of a series of experimental tests on the local loading of circular plates resting on a ring support are presented. Both quasi-static and impact loading tests were performed using hemispherically-tipped and flat-ended cylindrical indenters. The contrasts between the quasi-static and dynamic responses are examined as are the differences produced by the different indenters. The maximum energy absorbing capacity of the plates when subjected to impact from hemispherically-tipped and flat-faced projectiles are determined experimentally and compared with the available empirical formula. Two empirical formulae for the prediction of the energy required to perforate a steel plate with a hemispherically-tipped projectile, adapted from the well-known SRI and Neilson formulae for flat-faced projectiles, are proposed.

9A74. Numerical computation of 2D unsteady detonation waves in high energy solids. - JK Clarke *(Col of Aeronaut, Cranfield IT, Bedford MK43 0AL, UK)*, S Karni *(Dept of Math, Univ of Michigan, Ann Arbor MI 48109)*, JJ Quirk *(Inst for Comput Appl in Sci and Eng, NASA Langley Res Center, Hampton VA 23665)*, PL Roe *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109)*, LG Simmonds, EF Toro *(Col of Aeronaut, Cranfield IT, Bedford MK32 0AL, UK)*. J Comput Phys 106(2) 215-233 (Jun 1993).

We are concerned with theoretical modelling of unsteady, 2D detonation waves in high energy solids. A mathematical model and a numerical model to solve the associated hyperbolic system of equations are presented. The model consists of the Euler equations augmented by extra conservation laws and source terms to account for chemical reaction and tracking of materials. Both the thermodynamics and the chemistry are treated in a simple way. The numerical method selected for the full model is an extension of the conservative, shock capturing technique of Roe, together with an adaptive mesh refinement procedure that allows the resolution of the fine features such as reaction zones. Results for some typical tests problems are presented.

9A75. Experimental investigation of the scaling laws for metal plates struck by large masses. - He Ming Wen and N Jones *(Impact Res Centre, Dept of Mech Eng, Univ of Liverpool, PO Box 147, Liverpool L69 3BX, UK)*. Int J Impact Eng 13(3) 485-505 (Aug 1993).

An experimental investigation is presented into the geometrically similar scaling laws for circular plates impacted by cylindrical strikers with blunt ends travelling at velocities up to 5 m s^{-1} which produce permanent transverse displacements and perforation in some cases. The experimental results obey the geometrically similar scaling laws within the accuracy expected for such tests. It is observed that the impossibility of geometrically similar scaling of the material strain rate sensitive effects appears not to influence the plate perforation energies, at least within the range of experimental parameters studied in the present investigation.

9A76. Cylindrical wave solutions to the Korteweg-de Vries equation. - Yunkai Chen *(Dept of Math and Comput Sci, Fayetteville State Univ, Fayetteville NC)* and Shih-Liang Wen *(Dept of Math, Ohio Univ, Athens OH)*. Arch Mech 44(4) 479-483 (1992).

Cylindrical wave solutions for the Korteweg-de Vries equation are obtained within a reasonable approximation. They are shown to be representable as infinite sums of cylindrical solitons.

9A77. Experimental and numerical study of nonlinear internal waves. - DP Renouard *(IMG-LEGI, (UJF-CNRS-INPG), BP 53 X, 38041 Grenoble Cedex, France)*, GG Tomasson *(RMS, Parsons Lab, MIT)*, WK Melville *(Scripps Insts of Oceanog, USCD)*. Phys Fluids A 5(5) 1401-1411 (Jun 1993).

Nonlinear internal waves were measured on the large rotating platform at the Inst de Mecanique de Grenoble. The experimental data complement the results presented in Renouard *et al* and support the assumption that the solitary Kelvin wave is accompanied by Poincare waves. Based on the assumption of weak nonlinear, dispersive, and rotational effects, governing equations of the Boussinesq type are derived to model the evolution of an initial disturbance in a two-layer rotating fluid. The numerical study is based on these equations which are analogous to the Boussinesq equations of shallow-water theory and are not constrained to almost unidirectional propagation. Comparison of numerical solutions of the equations and experimental results are very good for moderately nonlinear conditions. These results provide supporting evidence for the resonant interaction of nonlinear Kelvin waves and linear Poincare waves, as described by Melville *et al.*

9A78. Nonlinear, dispersive, shallow-water waves developed by a moving bed. - M Villeneuve *(LaSalle Consult Group, Montreal, PQ Canada)* and SB Savage *(Dept of Civil Eng and Appl Mech, McGill Univ, Montreal, PQ Canada)*. J Hydraul Res 31(2) 249-266 (1993).

Landslides and avalanches plunging into lakes or reservoirs located in mountainous regions can generate large waves which can result in loss of life and significant property damage. As in the case with tsunamis generated in the ocean by underwater seismic activity, landslide induced water waves result from the motion of a solid boundary of the fluid. The present study deals with the mathematical modeling of water waves developed in a channel by a moving bed. A set of depth-averaged governing equations is derived to predict the evolution of the free surface resulting from a predetermined bed motion. These equations, which constitute a generalization of the Boussinesq system for waves over a flat bed, include both nonlinear and dispersive effects. Numerical solutions are obtained by using the finite difference method coupled with a Flux Corrected Transport (FCT) algorithm. The resulting model is used to predict the waves resulting from simple bed motions.

9A79. Transmission of an obliquely incident surface wave train through a submerged horizontal slot in a vertical wall. - PK Kundu *(Dept of Appl Math, Vidyasagar Univ, Midnapore 721 102, India)*. Acta Mech 98(1-4) 177-186 (1993).

Linear water wave theory is used for surface waves obliquely incident on a thin vertical wall in which there is an infinitely long submerged horizontal slot in deep water. The problem is reduced to an integral equation (IE) of the first kind over the slot. Assuming that the depth of submergence of the midsection of the slot is large compared to its breadth, a simple approximate solution to the IE is found, leading to an approximation for the transmission coefficient. A particular limiting case for the transmission coefficient is shown to produce the known result.

9A80. BEM for diffraction of oblique waves by an infinite cylinder. - M Rahman and M Chen *(Dept of Appl Math, Tech Univ of Nova Scotia, Halifax, NS, B3J 2X4, Canada).* Eng Anal Boundary Elements 11(1) 17-24 (1993).

This paper presents the solutions of the BEM for the potential flow problem associated with the diffraction of oblique waves by a horizontal cylinder of infinite length on a free surface. This physical model usually has its direct applications in engineering, such as in strip theory. The mathematical model for this problem is a 2D Helmholtz equation, whose BEM formulation involves kernels in the form of modified Bessel function. The application to this problem is among the first for this method. The diffraction forces and moment for a fixed rectangular cylinder have been calculated and compared with the existing results of KJ Bai, as an illustration of the effectiveness of the developed BEM code. The paper also compares results obtained using constant and linear elements.

9A81. Overhauser BE solution for periodic water waves in the physical plane. - JC Ortiz and SL Douglass *(Univ of S Alabama, Mobile AL 36688).* Eng Anal Boundary Elements 11(1) 47-54 (1993).

An Overhauser BEM for the modeling of nonlinear periodic waves in the physical plane is described. The Overhauser element, used to eliminate dicontinuities of the slope on the free surface of the wave, is described in detail. Examples for nonlinear steady and breaking waves are shown. The Overhauser element is compared to Lagrangian linear and cubic elements. It is noted that the Overhauser element system is very stable. Neither "smoothing" nor any other manipulation of the BEM results are necessary within the time-stepping algorithm to achieve a stable solution.

164. Waves in compressible fluids

9A82. Calculating the effects of variations in composition on wave propagation in gases. - RJ Pearson and DE Winterbone *(Dept of Mech Eng, UMIST, PO Box 88, Sackville St, Manchester M60 1QD, UK).* Int J Mech Sci 35(6) 517-537 (Jun 1993).

The equations of gas dynamics in one space dimension are solved whilst considering variations in gas composition and properties. A species continuity equation is derived and coupled in a single vector equation with the three usual conservation equations; the resulting system is solved directly in conservation law form using the two-step Lax-Wendroff technique. The effects of variable gas properties and composition on wave propagation are illustrated via the shock tube, or Riemann, problem. Significant errors are introduced, in the cases investigated, by assuming that the fluid is a perfect gas of constant composition. Flux-corrected transport (FCT) and nonupwind total variation diminishing (TVD) approaches are evaluated as a means of mitigating the spurious oscillations produced at discontinuities by the classical Lax-Wendroff scheme; these oscillations can give rise to mass fraction values from the species equation which are greater than unity or less than zero. It is found that the FCT algorithm does not suppress completely the oscillations at discontinuities and this corrupts the species transport calculations. The TVD algorithm eliminates the oscillations at shock waves and contact surfaces in the cases tested, thus maintaining the integrity of the species calculations. This is achieved at the expense of a 65% increase in computational effort over the constant gas property, constant composition case. The resolution of both the shock wave and contact surface can be improved significantly by the use of the artificial compression technique, but at an additional computational cost.

9A83. Shock wave reflection close to the leading edge of a wedge. - B Schmidt and J Fuchs *(Inst Stromungslehre und Stromungsmaschinen, Univ Karlsruhe, Karlsruhe, Germany).* Arch Mech 44(4) 453-462 (1992).

The aim of the present investigation is to show the development of the shock reflection process as soon as a shock wave hits a wedge. To resolve the structure of the shock waves, the experiments were performed under rarefied gas conditions. Because no field method is sufficiently sensitive, a laser differential interferometer was used. Varying the wedge angle, the development of the different types of reflection (regular reflection, Mach reflection) could be observed.

9A84. Variation of the specific heat ratio and the speed of sound in air with temperature, pressure, humidity, and CO_2 concentration. - O Cramer *(11588 Waresley St, Maple Ridge BC, V2X 9Z2, Canada).* J Acoust Soc Am 93(5) 2510-2516 (May 1993).

This paper describes a precise numerical calculation of the specific heat ratio and speed of sound in air as a function of temperature, presure, humidity, and Co_2 concentration. The above parameters are calculated using classical thermodynamic relationships and a real gas equation of state over the temperature range 0°C - 30°C. The shortcomings of previous determinations are also discussed. For both parameters, the coefficients of an interpolating equation are given, which are suitable for use in applications requiring high precision. The overall uncertainty in the specific heat ratio is estimated to be less than 320 ppm and the uncertainty in the speed of sound is similarly estimated to be less than 300 ppm.

166. Solid fluid interactions

9A85. Liquid-structure-foundation interaction of slender water towers. - HA Dieterman *(Fac of Civil Eng, Tech Univ, Stevinweg 1, 2628 CN Delft, Netherlands).* Arch Appl Mech 63(3) 176-188 (Apr 1993).

The dynamic behavior of a slender water tower based on a (deep) foundation is studied by a lumped model in which the parameters have been derived analytically from continuous models. The effects of the liquid and foundation on the structural dynamics can be studied analytically using this model, sensitivity analyses are easily performed. Ring baffles in the liquid tank and the local yielding of the pile-soil interaction along the shaft of the foundation piles may reduce the dynamic response.

172A. GENERAL THEORY

9A86. Finite amplitude standing waves in harmonic and anharmonic tubes. - DF Gaitan and AA Atchley *(Physics Dept, Naval Postgrad Sch, Monterey CA 93943).* J Acoust Soc Am 93(5) 2489-2495 (May 1993).

Finite amplitude standing waves have been studied in closed tubes filled with air and driven by a piston at frequencies near 200 Hz. The tubes were driven at resonance generating standing waves with amplitudes of up to 160dB re: 20 \mPa. The main objective was to measure the dissipation of the energy by the fundamental frequency and the higher harmonics, as well as by other nonacoustic mechanisms. A formulation developed by Coppens and Sanders using a single nonlinear equation to describe standing waves in cavities of arbitrary resonance frequencies and quality factors was used successfully to predict the higher harmonics. In addition, the effect of detuning the tubes on the energy dissipation was measured in tubes with variable cross sections. It was found that the detuned tubes effectively suppress the energy transfer into (and energy dissipation by) the higher harmonics. It was also found that expanding rather than contracting the cross section of the tubes minimized the dissipation of energy through nonacoustic mechanisms.

9A87. Resonance frequencies and structures of sound fields in the enclosures of acoustical systems. - IA Aldoshina and MV Olyushin *(AS Popov, All-Union Sci Res Inst, Russia).* Sov Phys Acoust 38(6) 529-534 (Nov-Dec 1992).

Methods based on perturbation theory are proposed for calculating resonance frequencies in the enclosures of acoustical systems having a complex geometry. Computational methods using the BE approach and eigenfunction expansions of the structure of the internal sound fields are investigated.

172B. SOUND GENERATION BY MOVING SURFACES

See the following:

9A621. Particle force and heat transfer in a dusty gas sustaining an acoustic wave

172D. SOUND WAVES IN GASES

9A88. Analysis of ultrasonic velocities in hydrocarbon mixtures. - JG Berryman *(LLNL).* J Acoust Soc Am 93(5) 2666-2668 (May 1993).

Ultrasonic velocity data on hydrocarbon mixtures were shown by Wang and Nur to agree quite well with the predictions of a simple mixing rule. The same data were reanalyzed using Wood's formula and the time-average approximation. Wood's formula for acoustic velocity is shown to be always less than the time-average formula, which is itself always less than the simple mixing rule result. Although the volume average rule agrees best with the data on binary mixtures of 1-decene and 1-octadecene, all these formulas agree with the data to within 1% and, therefore, it is not possible to distinguish among the formulas using this data set. Similar results are also found for six multicomponent hydrocarbon mixtures.

172E. SOUND WAVES IN LIQUIDS (UNDERWATER ACOUSTICS)

9A89. Application of ray theory with beam displacement to 3D sound propagation in a wedge shaped ocean. - KV Avudainayagam and GV Anand *(Dept of Elec Commun Eng, Indian Inst of Sci, Bangalore, 560 012, India)*. J Acoust Soc Am 93(5) 2581-2591 (May 1993).

Ray theory with beam displacement (RTBD) has been developed to evaluate the acoustic field in 3D in a wedge-shaped ocean with a lossy fluid bottom. An algorithm for tracing eigenrays in 3D is described. A procedure for determining the location of caustics in 3D is also presented. It is shown that the density of caustics reduces with increasing bottom attenuation. Sharp spurious peaks appear in the acoustic field in the vicinity of caustics. These caustic-related peaks can be readily identified and smoothed out, and no further corrections would be necessary in most situations of practical interest. Agreement between the smoothed RTBD solution and the "exact" two-way coupled mode solution is quite good for the 2D problem of up-slope propagation in the ASA benchmark wedge with a penetrable lossy bottom. Numerical results for the 3D problem are presented for several bottom slopes and directions of propagation.

9A90. Correlation of deep ocean noise (0.4 - 30 Hz) with wind, and the Holu Spectrum: A worldwide constant. - CS McCreery, FK Duennebier *(Sch of Ocean and Earth Sci and Tech, Univ of Hawaii, 2525 Correa Rd, Honolulu HI 96822)*, GH Sutton *(Woods Hole Oceanog Inst, RD2 Box 167C, Stone Ridge NY 12484)*. J Acoust Soc Am 93(5) 2639-2648 (May 1993).

One year of ambient ocean noise data, 0.4 to 30 Hz, from the Wake Island hydrophone array in the NW Pacific are compared to surface wind speeds, 0-14 m-s (0 - 28 kn). Between 0.4 and 6 Hz, noise levels increase with wind speed at rates of up to 2dB per m/s until a saturation is reached having a slope of about -23 dB-octave and a level of 75 dB relative to $1\mu Pa/\sqrt{Hz}$ at 4 Hz. This noise saturation, called the "Holu Spectrum", likely corresponds to saturation of short-wavelength ocean wind waves. It is probably a worldwide constant. Between 4 and 30 Hz, noise also increases with wind speed at rates of up to 2 dB per m-s, but no saturation level is observed and the slope increases to about 4 dB-octave. This may be acoustic noise from whitecaps. On a hydrophone less than 3 km from Wake, noise between 0.5 and 10 Hz increases with wind speed at a rate up to 2 dB per m-s, but absolute noise levels are significantly higher than levels on the other hydrophones more distant from Wake, and no saturation is apparent. Surf breaking against the shore of the island is the probable source of this noise.

9A91. Evolution of local spectra in smoothly varying nonhomogeneous environments: Local canonization and marching algorithms. - BZ Steinberg *(Dept of Interdisciplinary Stud, Fac of Eng, Tel-Aviv Univ, Tel Aviv 69978, Israel)*. J Acoust Soc Am 93(5) 2566-2580 (May 1993).

By applying the windowed Fourier transform directly to the Helmholtz wave equation a new formulation that governs the evolution of the local spectra of wave fields in a general nonhomogeneous environment is derived. By further invoking the so-called locally homogeneous approximation, a simplified evolution equation, termed as the locally homogeneous wave equation is developed, together with an upper bound on the error associated with the approximation. It is shown how simple analytical solutions of the new wave equation in a general smoothly varying nonhomogeneous environment can be obtained using well-known analytical techniques, and how the marching methodology connects these new solutions to the original problem described by the Helmholtz equation.

9A92. Experimental demonstration of sound-speed inversion with matched-field processing. - CC Karangelen *(Dept of Mech Eng, Catholic Univ of Am, Washington DC 22064)* and O Diachok *(Acoust Div, Code 5120, Naval Res Lab, Washington DC 20375-5000)*. J Acoust Soc Am 93(5) 2649-2655 (May 1993).

Matched-field processing is shown to be effective for estimating sound speed in a deep, range-independent ocean environment. The amplitude and phase of signals from a distant source measured on a large aperture vertical array are sensitive to changes in sound speed. This measured on a large aperture vertical array are sensitive to changes in sound speed. This sensitivity is exploited to infer the environment's sound-speed profile by matching predicted and measured amplitude and phase. Simulations and an initial experimental demonstration of the power of the technique are based on a modified version of Munk's canonical sound field model. This model is used in a simulated environment with a 15 Hz source where source and receiver locations are known. The simulation demonstrates that changes in the depth and strength of the modeled sound channel axis directly result in trackable errors in range and depth as well as in reduction of the received power level. The same model is used to determine sound-speed profile using a 15 Hz signal from a 244-m explosive source detected on a 675-m vertical array at a range of 53 km in a deep water Pacific environment, characterized by a classical range-independent sound channel at 700-m. The search for the best estimated profile is conducted by varying the sound channel axis strength and depth in the modified Munk equation, while maintaining a constant sound-speed profile at great depths. For the single test case, resultant differences between the matched-field estimated and measured profiles are less than ±2 m-s; the sound channel axis depth is determined within 20 m of the measured axis depth.

9A93. Form factor of a cylinder sonic source and application in borehole acoustics. - Shoumian Yu *(Dept of Phys, Shandong Univ, Jinan, Shandong 250100, Peoples Rep of China)* and Yinbin Liu *(Inst of Geophys, Chinese Acad of Sci, Beiging 100101, Peoples Rep of China)*. J Acoust Soc Am 93(5) 2592-2598 (May 1993).

By introducing the concept of a form factor for a cylindrical sonic source, a new method is constructed for solving boundary value problems of the wave field produced by such sources when the solutions for a simple source is known, provided the boundary conditions are axisymmetrical and are linear and homogeneous in the potentials. The form factor is defined in cylindrical coordinates as a function F(k) of the wave number k. The analytic properties of F(k) are described. It is proved that F(k) can be obtained from the farfield approximation and is related to the directional factor through a simple transformation. The form factors of several simple-shaped sources are derived. The theory is applied to the case of a borehole to shoe that the effect of the form factor on the profile of the full wavetrain is prominent in certain cases.

9A94. High frequency bistatic reverberation from a smooth ocean bottom. - S Stanic, E Kennedy, RI Ray *(Naval Ocean and Atmos Res Lab, Ocean Acoust Div, Stennis Space Center MS 39529-5004)*. J Acoust Soc Am 93(5) 2633-2638 (May 1993).

High-frequency bistatic reverberation was measured from a smooth, sandy featureless bottom located 19 miles south of Panama City, FL. Bistatic scattering variability is presented as a function of frequency (20 - 180 kHz), grazing angles (9.5° - 30°), and small horizontal and vertical bistatic scattering angles. Results show that bistatic variabilities tend to decrease with decreasing grazing angles and decreasing source beamwidths. Possible explanations for these decreasing variations are also presented.

9A95. Low frequency Arctic reverberation Part II. Modeling of long- range reverberation and comparison with data. - TC Yang and TJ Hayward *(Naval Res Lab, Washington DC 20375-5350)*. J Acoust Soc Am 93(5) 2524-2534 (May 1993).

In this paper a normal-mode model of scattering from surface and bottom protuberances is applied to model long-range reverberation data collected during the CEAREX 89 experiment in the Norwegian-Greenland Seas. Modeled reverberation spectrum levels at 23 Hz are compared with data to investigate the relative contributions of the ice and bottom to the measured reverberation. The normal-mode model of boundary scattering is based on a generalization of recent work of Ingenito treating scattering from a rigid sphere in a stratified waveguide. Adiabatic normal mode theory is used to model the propagation to and back from the scatterer in a range-dependent waveguide. Using the small ka approximation for the scattering functions, where k is the wave number and a is the dimension of the boundary protuberance, the normal-mode calculations of the long range reverberation levels are found to agree rather well with the CEAREX data for four different measurements involving different bottom bathymetries and source depths. For a source at 91 m depth in the 3000 m deep basin, it is found that the reverberation level for a receiver at 60 m is dominated by scattering from the ice except for reverberation associated with certain identifiable bottom features. For the same environment but a deeper source (244-m), reverberation levels from the ice and bottom are more comparable. For a strongly range dependent environment, returns from bottom features are clearly identifiable in the data.

9A96. Low frequency volume reverberation measurements. - T Akal *(SACLANT Undersea Res Center, La Spezia, Italy)*, RK Dullea *(Naval Underwater Syst Center, New London CT 06320)*, G Guido *(SACLANT Undersea Res Center, La Spezia, Italy)*, JH Stockhausen *(Defence Res Est Atlantic, Dartmouth, NS, Canada)*. J Acoust Soc Am 93(5) 2535-2548 (May 1993).

An experimental technique has been developed to measure broadband low-frequency volume reverberation. Experiments were performed in the North Atlantic with broadband explosive sources in conjunction with the end-fire beam of a vertical line array to provide scattering strength contours from measurements sampled in both frequency (~ 12 Hz) and depth (~ 4 m). The experimental and analysis techniques are described along with representative examples that compare high and low scattering levels observed during the experiment.

9A97. Low-frequency Arctic reverberation I. Measurement of under ice backscattering strengths from short-range direct-path returns. - TJ Hayward and TC Yang *(Naval Res Lab, Washington DC 20375-5350)*. J Acoust Soc Am 93(5) 2517-2523 (May 1993).

Under ice scattering strengths in the backward direction were measured in April 1989 during the CEAREX 89 field experiment in the Norwegian-Greenland Sea using a large-aperture vertical hydrophone array and 1.8 lb SUS explosive sources. Scattering strength estimates for frequencies of 24-105 Hz are presented as a function of scattering angle (2.5° - 40° grazing), averaged over incident angles in the range 10° - 15° grazing. The corresponding (monostatic) backscattering strength is found to be approximately 10dB below that reported by Milne for data collected at approximately the same time of year in 1962 near the Canadian Archipelago. The results are compared with scattering functions derived by Burke-Twesky model, which represents the ice ridges as rigid elliptical half-cylinders. The variations of the measured scattering strength with both scattering angle and frequency are well fitted by this model for scattering angles below 20° grazing.

9A98. Measurements of bottom-lined ocean impulse responses and comparisons with the time-domain parabolic equation. - RL Field and JH Leclere *(Naval Res Lab Detachment, Stennis Space Center MS 39529-5004)*. J Acoust Soc Am 93(5) 2599-2616 (May 1993).

Ocean impulse response functions computed with the time-domain parabolic equation model are shown to be consistent with response functions measured in a bottom-limited ocean located off the east coast of the US. The geoacoustics used in the model are developed from Deep Sea Drilling Project sites near the experimental area. Measured impulse responses are obtained by correlating the measured source signature of a 25 to 150 Hz linear, frequency-modulated signal with the signals received on a 15-element vertical line array. Correlation coefficients computed as a function of depth are used as a measure of comparison between measured and modeled responses. The capability of the time-domain parabolic equation to model wide-angle (68° - 75\edg) multipaths and subbottom layers with high impedance contrasts is shown. Correlation loss between response functions measured from different transmissions at the same range is shown to be attributable to the degree to which spatial invariance of the ocean can be assumed.

9A99. Modeling 3D propagation in an oceanic wedge using parabolic equation methods. - JA Fawcett *(Defence Res Est Pacific, FMO Victoria BC, V0S 1B0, Canada)*. J Acoust Soc Am 93(5) 2627-2632 (May 1993).

In this paper the predictions of aximuthally uncoupled and azimuthally coupled parabolic equation (PE) methods for 3D acoustic propagation in a penetrable oceanic wedge are compared. The individual modes of the waveguide at the source position are used as the initial field for the PE methods and the resulting PE fields are compared to the ray diagrams of 3D adiabatic mode theory.

9A100. Monostatic and bistatic reverberation results using linear frequency-modulated pulses. - JR Preston *(SACLANTCEN, CMR 426, APO, AE 09613)* and WA Kinney *(NRL, Stennis Space Center MS 39529)*. J Acoust Soc Am 93(5) 2549-2565 (May 1993).

Estimates of reverberant scattering strength are presented as a function of range and bearing for selected monostatic and bistatic geometries of a reverberation experiment. Diffuse scattering strengths were found to be comparable (within ~ 3 dB) for both monostatic and bistatic geometries. This experiment was performed off the west coast of Sardinia in approximately 2800 m of water during February of 1990. The receiver was a horizontal array of approximately 20 wavelengths. Source and receiver depths ranged from 50 to 120 m. The signals used consisted of linear frequency-modulated pulses centered near 1 kHz with durations ranging from 8 to 16 s and bandwidths ranging from 32 to 64 Hz. Monostatic and bistatic scattering strength values are estimated using uncorrelated (ie, not matched-filtered) pulses. The scattering strengths presented vary from -29 to -48 dB for ranges up to 40 km (but not data near fathometer returns). A method is described that shows different correlator gains against noise and reverberation. Comparisons of measured and modeled reverberation are presented using the generic sonar model (GSM) and curve fits with the decay in monostatic diffuse backscatter show good agreement with Lambert's rule using a -32 dB constant. Finally, GSM is used to estimate grazing angles from which plots of measured scattering strength versus grazing angle in the 10° - 26° interval are presented. Using this method, a Lambert's rule constant of ~ 30 dB was a better fit to the data.

9A101. Neural network feature vectors for sonar targets classifications. - A Svardstrom *(Circuits and Syst Group, Dept of Tech, Uppsala Univ, Box 534, S-751 21 Uppsala, Sweden)*. J Acoust Soc Am 93(5) 2656-2665 (May 1993).

This paper deals with classification of objects using active sonar and neural network classifiers. Various methods of feature extraction, ie, transformations of the recorded data to a form better suited as inputs to the classifier, have been applied to recorded active sonar data. The well-known multilayer perceptron architecture has been used. To reduce the computational effort and the number of parameters to estimate, the number of input nodes were limited, and it has been shown that feature vectors using Walsh transform coefficients are superior to feature vectors using Fourier transform coefficients under this constraint. Particularly with low SNR, the feature vectors based on Walsh transform coefficients outperform the Fourier based vectors. Some minor effort has been expended on optimizing the neural network implementation.

9A102. Performance stability of high-resolution matched-field processors to sound-speed mismatch in a shallow-water environment. - GB Smith, HA Chandler, C Feuillade *(Naval Res Lab, Stennis Space Center MS 39529-5004)*. J Acoust Soc Am 93(5) 2617-2626 (May 1993).

The effects of variations in water sound-speed parameters on the performance of four matched-field processing algorithms (Bartlett, maximum-likelihood, sector-focusing, and multiple constraint) have been investigated. The SNAP propagation model was used to generated the replica acoustic pressure field for a shallow water channel with a depth variable sound-speed profile typical of a midlatitude summer environment. It was also used to simulate a "detected" field due to an acoustic source. These were then correlated using the four algorithms for selected degrees of mismatch of the water sound-speed profile. The maximum likelihood and multiple constraint estimators achieved good peak resolution and high accuracy for small degrees of mismatch. The maximum likelihood estimator deteriorated quickly as the mismatch increased. The multiple constraint estimator performed significantly better, but both failed to give correct location estimates at the higher mismatch values. In contrast, the sector focusing estimator continued to give accurate location estimates over the whole range of sound-speed mismatch, with slightly less peak resolution at small mismatch values. It also performed significantly better overall than the Bartlett estimator, which was found to give accurate location estimates over the whole range of mismatch values used, but with poor peak resolution against a background containing many high sidelobes.

9A103. Microstructural characteristics of wave propagation in a saturated porous medium. - VP Bandov and VS Khalilov *(Bashkir State Univ, Russia)*. Sov Phys Acoust 38(6) 534-538 (Nov-Dec 1992).

The mechanisms of dynamic interaction of the phases in a model of a saturated porous medium is investigated. An idealized matrix deformation model in the form of close-packed identical spheres immersed in a compressible liquid is used to establish several deformation characteristics of the investigated medium, in particular, the influence of the geometrical structure of the phase interface and the elastic properties of the interstitial liquid on the compressibility of the medium. A hydrodynamic model in the form of a planar pore channel filled with a viscous liquid and bounded by movable walls is used to calculate the structure of the interstitial flows associated with wave propagation. The dependence of the filtration return flows on the properties of the medium and the wave parameters is determined. It is shown that these flows influence the wave propagation velocity and attenuation.

9A104. Propagation in an anisotropic periodically multilayered medium. - C Potel and JF de Belleval *(LG2MS, URA CNRS 1505, Univ de Tech, BP 649, 60206 Compiegne Cedex, France)*. J Acoust Soc Am 93(5) 2669-2677 (May 1993).

An anisotropic multilayered medium is studied using the method of transfer matrices, developed by Thomson and Haskell. The propagation equations in each layer of the multilayered medium use the form developed by Rokhlin et al. Physical explanations are given, notably when a layer is made up of a monoclinic crystal system medium. The displacement amplitudes of the waves in one layer may be expressed as a function of those in another layer using a propagation matrix form, which is equivalent to relating the displacement stresses of a layer to those in another layer. An anisotropic periodically multilayered medium is then studied by using a propagation matrix that has particular properties: a determinant equal to one and eigenvalues corresponding to the propagation of the Floquet waves. An example of such a medium with the axis of symmetry of each layer perpendicular to the interfaces is then presented together with the associated reflection coefficients as a function of the frequency or of the incident angle.

172H. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

9A105. Acoustic and elastic wave scattering from elliptic cylindrical shells. - RP Radlinski *(Naval Undersea Warfare Center Detachment, New London CT 06320)* and MM Simon *(Alliant Telesyst, Everett WA 98204)*. J Acoust Soc Am 93(5) 2443-2453 (May 1993).

An acoustic scattering formulation has been derived from a modification of the extended boundary integral method (null-field approach) developed for elastic wave scattering from infinite cylindrical shells of arbitrary shape. Thin shell theory is assumed to describe the motion of the scatterer. Acoustic and elastic p-p wave scattering calculations are presented for elliptic-cylindrical shells of different materials and eccentricities. At low frequencies, the scattering by an elliptical shell in a fluid is dominated by the bending resonances. At higher frequencies, the acoustic scattering is strongly dependent on the angle of incidence, material characteristics, and the predominately extensional structural resonances. In an elastic material, resonant modal responses of the shell were found to increase mode conversion of dilatational waves into shear waves. By comparison with elasticity theory for shells and by extrapolations from thick and thin plate theories, the limitations of the thin shell theory are shown to be material dependent. The present method is used to re-examine examples of backscatter from elliptic-cylindrical shells reported in other studies.

9A106. Backscattering of chirped bursts by a thin spherical shell near the coincidence frequency. - G Kaduchak and PL Marston *(Dept of Phys, Washington State Univ, Pullman WA*

99164-2814). J Acoust Soc Am 93(5) 2700-2706 (May 1993).

Previous ray calculations and observations have shown that tone bursts with a carrier frequency ka close to the coincidence frequency of a thin spherical shell in water exhibit a backscattering enhancement. A distinct feature associated with the a_{0-} guided wave was enhanced relative to the specular reflection by a factor close to 3.1. In the present research, a Fourier synthesis from the partial wave series is used to investigate how chirping the frequency of the incident burst influences the enhancement. An enhancement is still evident even when the incident burst is swept through the entire ka range of interest sufficiently rapidly for the specular and guided wave echoes to remain distinct. The enhancement is larger when ka is swept from high-to-low than from low-to-high. This is a consequence of a decrease in the group velocity with ka resulting in a localization of the echo for the high-to-low sweep. The enhancement can now exceed the aforementioned value of 3.1 and should increase the signal-to-noise ratio. Experimental records confirm the effect on a real shell.

9A107. Inverse problem of the scattering of ultrasound by a boundary inhomogeneity in an isotropic solid. - VA Burov, IP Prudnikova, NS Sirotkina *(MV Lomonosov State Univ, Moscow, Russia).* Sov Phys Acoust 38(6) 555-558 (Nov-Dec 1992).

The 2D problem of the scattering of ultrasound by an unknown void in a solid is investigated. A nonlinear functional is formulated, and the minimum conditions for it are used to derive a system of nonlinear equations for determining the characteristic function of the object. The number of positions from which to irradiate the object in order to guarantee a unique solution of the problem is discussed.

9A108. Quantitative reconstruction of internal density distributions from laser ultrasonic data. - Yichi Lu, JA Goldman, HNG Wadley *(Intelligent Processing of Mat Lab, Sch of Eng and Appl Sci, Univ of Virginia, Charlottesville VA 22903).* J Acoust Soc Am 93(5) 2678-2687 (May 1993).

An ultrasonic method has been investigated for the quantitative recovery of density distributions of porous bodies similar to those produced by pressure-assisted sintering of powders. It relies upon the strong relationship between the ultrasonic velocity and the density of a porous body. Noncontact laser generated -nterferometrically detected ultrasound has been propagated along ray paths in a planar cross section of model samples and ultrasonic time-of-flight projections obtained. Two approaches have been explored for reconstructing the internal velocity (and thus density) distribution from the projection data. The first approach was a standard convolution backprojection algorithm used frequently in computerized tomographic reconstruction. A combination of ray bending (due to refraction by the velocity gradient within the sample), noise in the projections, and practical limits upon the number of projections that can be obtained have all adversely affected the reconstruction quality of this method. The second approach explored a (nontomographic) nonlinear least-squares approach. It utilized *a priori* information about the general functional form of the velocity (density) distribution (which is available from predictive models of the densification process) and gave significantly better results for samples with simple geometry even when projection data were sparse.

9A109. Sound scattering by thin-walled elastic cylinders of finite length. - AV Lebedev and AI Khil'ko *(Inst of Appl Phys, Russian Acad of Sci, Russia).* Sov Phys Acoust 38(6) 578-582 (Nov-Dec 1992).

The scattering of acoustic fields by thin-walled elastic cylinders of finite length is investigated. An approximate scattering model based on the method of successive reflections is used for the calculations and estimations. The range of geometrical parameters of the shell for the observation of clearly pronounced forward scattering is determined.

9A110. Ultrasonic nondestructive evaluation of thin (sub-wavelength) coatings. - VK Kinra and C Zhu *(Center for Mech of Composites, Dept of Aerospace Eng, Texas A&M Univ, College Station TX 77843).* J Acoust Soc Am 93(5) 2454-2467 (May 1993).

This paper describes a technique for ultrasonic nondestructive evaluation (NDE) of a thin coating on a thick substrate; here thin means the thickness of the coating is less than the wavelength of the ultrasonic wave used to interrogate it. A plane longitudinal wave that is normally incident upon the coating is considered. Transfer functions have been derived for both the coating-side and the substrate-side insonification. A systematic analysis of the sensitivity of the transfer functions to the thickness and wave speed has been carried out. An inverse algorithm, which utilizes the well-known Newton-Raphson method, has been developed to reconstruct the thickness and the phase velocity through a comparison of the theoretical and the measured transfer functions; fortunately, this algorithm is independent of substrate thickness. Using this technique both the thickness and the wave speed of the coating can be extracted from the same measurement without knowing either. The technique is fully automated and computer-controlled and can be easily used for in-situ NDE applications. The technique was used to measure the thickness and wave speed of epoxy and Plexiglas coatings (50-100 \umm) on an aluminum substrate using low-frequency (10- and 20-MHz) transducers; the ratio of thickness-wavelength was about 1/3. The precision in the measurement of the thickness and the wave speed was found to be $\pm\mu m$ and $\pm 3\%$, respectively.

172I. ACOUSTIC PROPERTIES OF MATERIALS

9A111. Characteristic dimensions and prediction at high frequencies of the surface impedance of porous layers. - D Lafarge, JF Allard, B Brouard *(Lab d'Acoustique, CNRS URA No 1101, Fac de Sci du Mans, BP 535, Ave Olivier Messiaen, F-72017 Le Mans Cedex, France),* C Verhaegen, W Lauriks *(Lab voor Akoestiek, Katholieke Univ Leuven, Celestijnenlaan 200 D, B-3001 Heverlee, Belgium).* J Acoust Soc Am 93(5) 2474-2478 (May 1993).

The surface acoustic impedance of a glass wool and a reticulated foam is measured in a free field up to 20 000 Hz. The characteristic dimensions Λ and Λ` can be calculated for the glass wool, and the surface impedance can be predicted with no adjustable parameters. The motion of the frame is not taken into account. The agreement between measurement and prediction is good. For the foam, the characteristic dimensions cannot be calculated, because the geometry of the frame is not simple. A correct choice of Λ and Λ` allows a precise prediction of the surface impedance for a large range of frequencies and different thicknesses.

172J. NOISE CONTROL AND REDUCTION (INCL ACTIVE CONTROL)

9A112. Acoustic control by wave field synthesis. - AJ Berkhout, D de Vries, P Vogel *(Lab of Seismics and Acoust, Delft Univ of Tech, PO Box 5046, 2600 GA Delft, Netherlands).* J Acoust Soc Am 93(5) 2764-2778 (May 1993).

The acoustics in auditoria are determined by the properties of both the direct sound and the later arriving reflections. If electroacoustics means are used to repair disturbing deficiencies in the acoustics, one has to cope with unfavorable side effects such as localization problems and artificial impressions of the reverberant field (electronic flavor). To avoid those side effects, the concept of electroacoustic wave front synthesis is introduced. The underlying theory is based on the Kirchhoff-Helmholtz integral. In this new concept the wave fields of the sound sources on stage are measured by directive microphones; next they are electronically extrapolated away from the stage, and finally they are re-emitted in the hall by one or more loudspeaker arrays. The proposed system aims at emitting wave fronts that are as close as possible to the real wave fields. Theoretically, there need not be any differences between the electronically generated wave fields and the real wave fields. By using the image source concept, reflections can be generated in the same way as direct sound.

9A113. Active control of point acoustic sources in a half-space. - KA Cunefare and S Shepard *(George W Woodruff Sch of Mech Eng, Georgia Tech).* J Acoust Soc Am 93(5) 2732-2739 (May 1993).

Analysis of active noise control applications generally neglect the presence of nearby reflective surfaces, such as a ground plane. The research presented in this paper examines the impact of the presence of a nearby reflective plane on the active control of sound radiated by a number of point sources. It is shown that when the sources to be controlled are within one wavelength of the reflective plane, be it rigid or pressure release, that the plane can significantly impact the control versus control under free-field conditions with the same source separations. The orientation of the noise sources and the control sources with respect to each other and to the plane also significantly influences the control. For sources more than one wavelength away from the reflective plane, the use of the simpler free-space analysis yields acceptable results as compared to using the more complex half-space analysis.

9A114. Active control of sound power using acoustic basis functions as surface velocity filters. - K Naghshineh *(Acoust and Radar Tech Lab, SRI Int, 333 Ravenswood Ave, Menlo Park CA 94025)* and GH Koopmann *(Center for Acoust and Vib, 157 Hammond Build, Penn State).* J Acoust Soc Am 93(5) 2740-2752 (May 1993).

An improved method of active structural acoustics control is presented that is based on the minimizations of the total power radiated from any structure expressed in terms of a truncated series sum. Each term of this sum is related to the coupling between the orthogonal eigenvectors of the radiation impedance matrix (referred to as "basis functions" in this paper) and the structural surface velocity vector. The basis functions act as surface velocity filters. These acoustic basis functions are found to be weak functions of frequency but their corresponding weighting coefficients increase monotonically with frequency. The minimization of the radiated power is shown to result in a structural surface velocity vector that couples poorly to those acoustic basis functions that account for high-efficiency sound radiation. This strategy is demonstrated numerically for a clamped-clamped baffled beam in air. Point force primary and control actuators (shakers) are used to explore the control mechanisms. As expected, the minimization of the radiated power results in a controlled beam response that contains much lower supersonic wave-number content than that of the uncontrolled beam response. Finally, an unexpected benefit of the control strategy described is that it provides a rational procedure for selecting the number and placement of actuators and sensors on a structure for effective control. This development is significant since this procedure does not require *a priori* knowledge of the dynamics of the structure.

9A115. Active control of sound radiation from a simply supported beam: Influence of bending near field waves. - C Guigou and CR Fuller *(Vib and Acoust Labs, Mech Eng Dept, VPI)*. J Acoust Soc Am 93(5) 2716-2725 (May 1993).

Active control of sound radiation from a baffled simply supported finite beam is analytically studied. The beam is subjected to a harmonic input force and the resulting acoustic field is minimized by applying a control point force. For a single frequency, the flexural response of the beam subject to the input and control forces is expressed in terms of flexural waves of both propagating and near-field types. The optimal control force complex amplitude is derived by minimizing the acoustic radiated pressure at one point located in the far-field. The far-field radiated pressure, the displacement of the vibrating beam, and the 1D wave-number spectrum of the beam velocity are extensively studied. In order to further understand control mechanisms, the radiated pressure due to the flexural propagating wave and the flexural near-field wave, respectively, is investigated at the minimization point before and after the control is involved. The analysis shows that, when the control is applied, the combination of the radiated pressure due to the two different types of waves (as their associated radiation is out-of-phase) at the minimization point causes the large pressure attenuation. These results demonstrate that structural near-fields are important in terms of predicting performance in active control of structurally radiated sound.

9A116. In situ estimation of an acoustic source in an enclosure and prediction of interior noise by using the principle of vibroacoustic reciprocity. - Bong-Ki Kim and Jeong-Guon Ih *(Dept of Mech Eng, Korea Adv Inst of Sci and Tech, 373-1 Kusung-dong, Yusung-ku Taejon 305-701, Korea)*. J Acoust Soc Am 93(5) 2726-2731 (May 1993).

The volume velocity of an acoustic source can be widely used in determining the vibroacoustic transfer functions, in measuring the acoustic transfer impedances, and in finding the generated power of an acoustic source. Several techniques utilizing special experimental devices have been proposed for this purpose, including the laser velocimetry, the internal pressure measurement, and the face-to-face electroacoustic measurement. However, for a source in an enclosure with flexible walls the vibroacoustic coupling should be considered, especially in the case of a loudspeaker source that has low internal mechanical impedance. The present method, which uses the principle of vibroacoustic reciprocity, can give a reasonable estimation of the transfer functions and can be used in determining the volume velocity of a source *in situ*. Because the present method does not require a special facility or the information of the source surface vibration, the method can be applied to any irregularly shaped source in a flexible enclosure. With the obtained vibroacoustic transfer functions, the interior noise field in an enclosure can be predicted by vectorial summation when the boundary points are excited by uncorrelated dynamic forces. The predicted internal pressure in an enclosure is in good agreement with the measured internal pressure, even in the presence of sound absorbers inside the enclosure.

9A117. Numerical method for noise optimization of engine structures. - MG Milsted *(nCode Int, Sheffield, UK)*, T Zhang *(MG Bennett and Assoc, Rotherham, UK)*, RA Hall *(Ricardo Consult Eng, Shoreham-by-Sea, UK)*. Proc Inst Mech Eng D 207(D2) 135-143 (1993).

A numerical procedure is described for optimizing FE models of engine structures for minimum noise radiation. A statistical technique is used to select sample points in a multi-dimensional design variable space from which an approximating response surface is derived. Optimization of this analytic model is then carried out interactively with variable bounds and constraints are required to meet design objectives. The underlying noise analysis calculation uses a modal analysis algorithm to determine the surface vibration velocity and hence the radiated sound power.

9A118. Optimization of location and amount of viscous damping to minimize random vibration. - VH Neubert *(Dept of Eng Sci and Mech, Penn State)*. J Acoust Soc Am 93(5) 2707-2715 (May 1993).

A novel procedure is presented for minimizing random vibrations of a linear, elastic structure by optimizing the size and location of viscous damping devices, with a constraint on the total amount of damping available. Viscous damping, represented symbolically by dashpots between structural nodes, can be achieved practically by using fluid devices or magnetic eddy-current devices. The problem is developed as a nonlinear optimization problem. Nonproportional damping is considered. Since the mean-square response depends on the modal damping ratios, first, the sensitivities, or partial derivatives, of the modal damping ratios with respect to the system damping parameters are discussed. The sensitivities are sometimes negative, which means that simply increasing the size of some dashpots could increase response. Second, the sensitivities of the mean-square amplitudes to the system damping parameters are determined and used to minimize the response. A two-parameter example is presented for a ten-bar truss for which the optimum parameters are found by a modification of the method of steepest descent. The problem was solved using the program TPSENS, developed as part of this study. A ten-parameter optimization is also described, which was accomplished by coupling TPSENS with CONMIN, an available NASA FORTRAN program for constrained function minimization.

9A119. Simulating transfer functions in a reverberant room including source directivity and head-shadow effects. - M Kompis and N Dillier *(ENT Dept, Univ Hospital, CH-8091 Zurich, Switzerland)*. J Acoust Soc Am 93(5) 2779-2787 (May 1993).

A new procedure for simulating the acoustical response of a receiver to a source in a reverberant room is proposed. Convolving such an impulse response with an input signal, eg, speech, is useful in applications where an acoustical environment must be highly reproducible, easily controllable, or is unavailable for an actual recording. The proposed procedure is an extension of the image method by Allen and Berkley. The new features include the possibility to simulate simple source and microphone directivity, as well as head-shadow effects, which can be considerable for subjects with microphones mounted close to the head. A rigid sphere diffracting a plane wave provides a good approximation for the effects of speaker as well as listener head shadow and allows simple yet realistic simulations of many relevant situations. Implementational issues are discussed and the method is verified by comparing simulation results with recordings in actual rooms. It was found that by including source directivity and head shadow, transfer functions become significantly more realistic.

9A120. Influence of frequency and width of an ultrasonic bounded beam in the investigation of materials: Study in terms of heterogeneous plane waves. - K Van Den Abeele *(Belgian Natl Found for Sci Res)* and O Leroy *(Interdisciplinary Res Center, KUL Campus Kortrijk, B-8500 Kortrijk, Belgium)*. J Acoust Soc Am 93(5) 2688-2699 (May 1993).

Theoretically obtained 3D plots showing the behavior of the reflection coefficient for heterogeneous plane waves upon arbitrary layered media as function of incidence angle and heterogeneity, supply valuable information for the investigation of the reflector when using bounded ultrasonic beams. The presence of leaky interface modes and their angular positions for a specific sample are determined by the fd products (frequency times thickness) of the constituent layers. Deformations of the reflected and transmitted bounded beam profiles and the contribution of surface wave radiation at vibrational mode angles are governed by the fW product (frequency times beamwidth). For a given layered medium, optimum conditions for observing particular mode vibrations and large deformations of reflected ultrasonic profiles can be predicted theoretically.

9A121. Recovery of perturbations in an acoustic medium with attenuation from several plane wave responses. - BJ Chaderjian *(Dept of Math, California State Univ, Long Beach CA 90840)* and KP Bube *(Dept of Math, Univ of Washington, GN-50, Seattle WA 98195)*. SIAM J Appl Math 53(3) 829-846 (Jun 1993).

A linearized inverse problem is studied for recovering a stratified acoustic medium with attenuation from reflection data known at the medium's surface. The inverse problem is based on a plane wave decomposition of the medium's response to a point-source input. This paper shows that the inverse problem for recovering perturbation in density, wave speed, and the coefficient of attenuation from known perturbations in three plane wave responses is well posed in the appropriate function spaces. The question of whether the medium itself can be recovered from the point-source response is discussed.

9A122. Strong localized perturbations of eigenvalue problems. - MJ Ward *(Dept of Math, Stanford)* and JB Keller *(Dept of Math and Mech Eng, Stanford)*. SIAM J Appl Math 53(3) 770-798 (Jun 1993).

This paper considers the effect of three types of perturbations of large magnitude but small extent on a class of linear eigenvalue problems for elliptic partial differential equations in bounded or unbounded domains. The perturbations are the addition of a function of small support and large magnitude to the differential operator, the removal of a small subdomain from the domain of a problem with the imposition of a boundary condition on the boundary of the resulting hole, and a large alteration of the boundary condition on a small region of the boundary of the domain. For each of these perturbations, the eigenvalues and eigenfunctions for the perturbed problem are constructed by the method of matched asymptotic expansions for $\in$ small, where $\in$ is a measure of the extent of the perturbation.

9A123. Determination of the acoustic far field of a radiating body in an acoustic fluid from boundary measurements. - GV Borgiotti *(Dept of Elec Eng and Comput Sci, George*

Washington Univ, Washington DC 20052) and KE Jones *(David Taylor Res Center, Bethesda MD 20084)*. J Acoust Soc Am 93(5) 2788-2797 (May 1993).

The far field (FF) of a radiating or scattering object immersed in an acoustic fluid can be represented in the frequency domain as a finite dimension linear combination of basis functions, which are determined by the shape and the size of the object in acoustic wavelengths. The coefficients of the linear combination are obtained as the outputs of a bank of spatial filters whose inputs are either the boundary normal velocity – or the radiation problem – or the boundary pressure and the normal velocity – for the scattering problem – measured by a dense set of sensors. The filter outputs provide the information sufficient to reconstruct the radiated or scattered far field, amplitude and phase. The structure of the filters is identified from the singular valve decomposition of the appropriate radiation or scattering operator, mapping the boundary normal velocity, or the combination of normal velocity and pressure, into the FF. Also, from the filter outputs, the efficiently radiating component of the boundary field can be extracted. For example the boundary total normal velocity may have a localized high peak, which however may be completely or almost completely absent in the radiating component. Selected results of an extensive simulation are presented illustrating the accuracy of the reconstruction of the FF from the spatial filtering of the boundary field.

200. Systems theory and design

9A124. Sensitivity analysis of multiple eigenvalues. - AP Seyranian *(Inst of Problems in Mech, Acad of Sci, Moscow, Russia)*. Mech Struct Machines 21(2) 261-284 (1993).

This paper is devoted to sensitivity analysis of eigenvalues of nonsymmetric operators that depend on parameters. Special attention is given to the case of multiple eigenvalues. Due to the non-differentiability (in the common sense) of multiple roots, directional derivatives of eigenvalues and eigenvectors in parametric space are obtained. Sensitivity analysis is based on the perturbation method of eigenvalues and eigenvectors. The generalized eigenvalue problem and vibrational systems are also investigated. The results obtained are important for qualitative and quantitative study of mechanical systems subjected to static and dynamic instability phenomena.

9A125. Space structures and the crossing number of their graphs. - A Kaveh *(Inst Allgemeine Mech, Tech Univ, Vienna, Austria)*. Mech Struct Machines 21(2) 151-166 (1993).

In this paper, theorems are proved that relate the degree of statical indeterminancy of space structures to their planar topological properties. An algorithm is developed for suboptimal layout of an arbitrary space structure in a plane, and a lower bound is established to the crossing number of its graph model.

202. Control systems

9A126. Numeri[illegible] of H^∞ optimal performar[illegible] [illegible] *(Appl and Comput Math, Princeton)* and JM Orszag *(Dept of Economics, Univ of Michigan, Ann Arbor MI 48109)*. J Sci Comput 7(4) 289-311 (Dec 1992).

We present new algorithms for computing the H^∞ optimal performance for a class of single-input and single-output infinite-dimensional systems. The algorithms here only require use of one or two fast Fourier transforms and Cholesky decompositions; hence the algorithms are particularly simple and easy to implement. Numerical examples show that the algorithms are stable and efficient and converge rapidly. The method has wide applications including to the H^∞ optimal control of distributed parameter systems. We illustrate the technique with applications to some delay problems and a partial differential equation model. The algorithms we present are also an attractive approach to the solution of high-order finite-dimensional models for which use of state space methods would present computational difficulties.

9A127. New tool for solving industrial continuous optimization problems. - R Ouellet and RT Bui *(Dept Sci Appl, Univ Quebec, Chicoutimi, PQ, Canada)*. Appl Math Model 17(6) 298-310 (Jun 1993).

A numerical method is proposed to tackle the continuous optimal control problems involving industrial thermal processes. The latter are characterized by their complex mathematical models. Formulated through various calculus using the Pontryagin maximum principle, the resulting two-point boundary value problem is discretized with a Euler central differentiation scheme. Solution is obtained by the Newton-Raphson method, and Richardson extrapolation is used to increase accuracy and refine the grid automatically as needed. The Jacobian matrix is evaluated numerically. This new method promises to open new possibilities for applications in an important class of engineering problems.

9A128. Engineering functional analysis. Part I. - MR von Spakovsky. *(Dept Mec, Lab Energetique Indust, Ecole Polytech Fed, Lausanne, Switzerland)* and RB Evans *(Woodruff Sch of Mech Eng, Georgia Tech)*. J Energy Resources Tech 115(2) 86-92 (Jun 1993).

In this paper, a new formalism called *Engineering Functional Analysis* is presented. This formalism results in higher degrees of decentralization for engineering systems optimization than is otherwise possible. By *decentralization*, it is meant that the improvement or optimization of individual components by *themselves* (ie, components which are *isolated economically* from the rest of the overall system), serves to improve or optimize the system as a whole (with some degree of error, which defines the *degree of decentralization*).

9A129. Engineering functional analysis. Part II. - RB Evans *(Woodruff Sch of Mech Eng, Georgia Tech)* and MR von Spakovsky *(Dept Mec, Lab Energetique Indust, Ecole Polytech Fed, Lausanne, Switzerland)*. J Energy Resources Tech 115(2) 93-99 (Jun 1993).

In this paper, a new formalism called *Engineering Functional Analysis* is presented. This formalism results in higher degrees of decentralization for engineering system optimization than is otherwise possible. By *decentralization*, it is meant that the improvement or optimization of individual components by *themselves* (ie, components which are *isolated economically* from the rest of the overall system) serves to improve or optimize the system as a whole (with some degree of error, which defines the *degree of decentralization*). Higher degrees of decentralization are important in that they provide a more stable economic environment for individual components, thus permitting more rapid synthesis and greater system improvement than could otherwise be obtained.

206B. END EFFECTORS

9A130. Computing two-finger force-closure grasps of curved 2D objects. - J Ponce, D Stam *(Beckman Inst, Dept of Comput Sci, Univ of Illinois, Urbana IL 61801)*, B Faverjon *(ALEPH Tech, Batiment Heliopolis, 38400 Saint Martin d'Heres, France)*. Int J Robotics Res 12(3) 263-273 (Jun 1993).

This article presents an algorithm for computing force-closure grasps of piecewise-smooth, curved, 2D objects. We consider the case of a gripper equipped with two hard fingers and assume point contact with friction. Object boundaries are represented by collections of polynomial parametric curves, and force-closure grasps are characterized by systems of polynomial constraints in the parameters of these curves. The algorithm has been implemented on a distributed architecture, and experiments using a PUMA robot equipped with pneumatic two-finger gripper and a vision system are presented.

9A131. Family of Stewart platforms with optimal dexterity. - KH Pittens and RP Podhorodeski *(Adaptive Robotic Telesyst Lab (ARTLAB), Dept of Mech Eng, Univ of Victoria, Victoria, BC, V8W 3PG, Canada)*. J Robotic Syst 10(4) 463-479 (Jun 1993).

Stewart platform configurations (architectures and poses) optimizing local dexterity are investigated. The condition number of the Jacobian matrix is used to quantify the dexterity of the manipulator. For a platform-centered Jacobian reference location and a given characteristic length for scaling purposes, a two-parameter family of optimal configurations is shown to exist. Two suitable architectural parameters defining the family are identified and properties of the optimal configurations are discussed. The optimization results are shown to be easily extended for other Jacobian reference locations and for other singular value-based local dexterity measures.

206E. KINEMATICS, DYNAMICS

9A132. Dynamic analysis and control of a Stewart platform manipulator. - G Lebret, K Liu, FL Lewis *(Autom and Robotics Res Inst, Univ of Texas, 7300 Jack Newell Blvd, S Ft Worth TX 76118)*. J Robotic Syst 10(5) 629-655 (Jul 1993).

In this article, we study the dynamic equations of the Stewart platform manipulator. Our derivation is closed to that of Nguyen and Pooran because the dynamics are not explicitly given but are in a step-by-step algorithm. However, we give some insight into the structure and properties of these equations. We obtain compact expressions of some coefficients. These expressions should be interesting from a control point of view. A stiffness control scheme is designed for milling application. Some path-planning notions are discussed that take into account singularity positions and the required task. The objective is to make the milling station into a semiautonomous robotic tool needing some operator interaction but having some intelligence of its own. It should interface naturally with part delivery and other higher level tasks.

9A133. Efficient method for inverse dynamics of manipulators based on the virtual work principle. - Chang-De Zhang and Shin-Min Song *(Dept of Mech Eng, Univ of Illinois, PO Box 4348, Chicago IL 60680)*. J Robotic Syst 10(5) 605-627 (Jul 1993).

The computational efficiency of inverse dynamics of a manipulator is important to the real-time control of the system. For serial manipulators, the recursive Newton-Euler method has been proven to be the most efficient. However, for more general manipulators, such as serial manipulators with closed kinematic loops or parallel manipulators, it must be modified accordingly and the resultant computational efficiency is degraded. This article presents a computationally efficient scheme based on the virtual work principle for inverse dynamics of general manipulators. The present method uses a forward recursive scheme to compute velocities and accelerations, the Newton-Euler equation to calculate inertia forces-torque, and the virtual work principal to formulate the dynamic equations of motion. This method is equally effective for serial and parallel manipulators. For serial manipulators, its computational efficiency is comparable to the recursive Newton-Euler method. For parallel manipulators or serial manipulators with closed kinematic loops, it is more efficient than the existing methods. As an example, the computations of inverse dynamics (including inverse kinematics) of a general Stewart platform require only 842 multiplications, 511 additions, and 12 square roots.

9A134. Exact methods for determining the kinematics of a Stewart platform using additional displacement sensors. - KC Cheok, JL Overholt, RR Beck *(Syst Simulation and Tech Div, US Army Tank-Automotive Command, Warren MI 48397-5000)*. J Robotic Syst 10(5) 689-707 (Jul 1993).

This article describes two new direct and exact methods for computing the translational and rotational displacements of an Stewart platform (SP) by employing extra translational displacement sensors (TDSs), in addition to the existing TDSs for the six links of the SP. The key for the approach lies in knowing where to employ the TDSs for determining positional vectors of strategic platform locations. By taking advantage of a tetrahedral geometry, *closed form* solutions for the forward kinematic transformation can then be derived and directly evaluated. The new methods produce accurate solutions with only minimal computation necessary. The advantages and disadvantages of the proposed methods are discussed and compared to an existing method. The exact methods are being investigated for an on-line implementation of a nonlinear adaptive control system and redundancy scheme for a 25-ton Stewart platform based Crew Station-Turret Motion Base Simulator at the US Army Tank Automotive Command.

9A135. Geometric analysis of antagonistic stiffness in redundantly actuated parallel mechanisms. - Byung-Ju Yi *(Dept of Mech Eng, Korea IT and Educ, 37-1 San, Gajeon Ri, Byungcheon Myun Cheonan Kun Chungnam, Korea)* and RA Freeman *(Dept of Mech Eng, Univ of Texas, Austin TX 78712)*. J Robotic Syst 10(5) 581-603 (Jul 1993).

Parallel closed-chain mechanical architectures allow for redundant actuation in the force domain. Antagonistic actuation, afforded by this input force redundancy, in conjunction with nonlinear linkage geometry creates an effective stiffness directly analogous to that of a wound metal spring. A general stiffness model for such systems is derived and it is shown that the constitutive relationship between actuation effort and active stiffness is the second-order kinematic constraint set relating the actuation sites. The extent of stiffness modulation possible is then evaluated and necessary conditions for full stiffness modulation are obtained. Configuration-dependent, second-order, geometric singularities affecting stiffness generation are illustrated in terms of a 3-dof parallel spherical mechanism example and discussed in relation to their more commonly investigated-first order counterparts that affect force and velocity transmission. Finally, a load distribution methodology for simultaneous motion and stiffness generation is introduced, and it is shown that with hyperredundant actuation the internal load state of the mechanism can be controlled independent of its motion and effective stiffness.

9A136. Inverse kinematics and inverse dynamics for control of a biped walking machine. - Ching-Long Shih *(Dept of Elec Eng, Natl Taiwan IT, Taipei, Taiwan, ROC)*, WA Gruver *(Sch of Eng Sci, Simon Fraser Univ, Burnaby, BC, V5A 1S6, Canada)*, Tsu-Tian Lee *(Dept of Elec Eng, Natl Taiwan IT, Taipei, Taiwan, ROC)*. J Robotic Syst 10(4) 530-555 (Jun 1993).

Analytical techniques are presented for the motion planning and control of a 12 dof biped walking machine. From the Newton-Euler equations, joint torques are obtained in terms of joint trajectories, and the inverse dynamics are developed for both the single-support and double-support cases. Physical admissibility of the biped trajectory is characterized in terms of the equivalent force-moment and zero-moment point. A simulation example illustrates the application of the techniques to plan the forward-walking trajectory of the biped robot. The implementation of a prototype mechanism and controller is also described.

9A137. Kinematic decoupling in mechanisms and application to a passive hand controller design. - V Hayward, C Nemri, Xianze Chen, B Duplat *(Res Center for Intelligent Machines, McGill Univ, 3480 University St, Montreal, PQ H3A 2A7, Canada)*. J Robotic Syst 10(5) 767-790 (Jul 1993).

Observations regarding the kinematics of mechanisms are applied to the synthesis of a passive hand controller. It is argued that stiffness (and damping) properties are central to the effectiveness of such devices and in particular that the simplicity of these properties is crucial. What simple means is analyzed and it is shown that only certain types of manipulators can appropriately be used. In effect, decoupling is shown to be architecture and configuration dependent. The properties of parallel mechanisms are reviewed and found appropriate for restricted-workspace hand controllers. A particular kinematic design is then derived and a practical implementation described.

9A138. Kinematic design of serial link manipulators from task specifications. - CJJ Paredis and PK Khosla *(Dept of Elec and Comput Eng, Robotics Inst, Carngie Mellon Univ, Pittsburgh PA 15213-3890)*. Int J Robotics Res 12(3) 274-287 (Jun 1993).

The Reconfigurable Modular Manipulator System (RMMS) consists of modular links and joints that can be assembled into many manipulator configurations. This capability allows the RMMS to be rapidly reconfigured to custom tailor it to specific tasks. An important issue related to the RMMS is the determination of the optimal manipulator configuration for a specific task. This article addresses the problem of mapping *kinematic* task specifications into a *kinematic* manipulator configuration. For the design of 2-dof planar manipulators, an *analytical* solution is derived. The numerical procedure determines the Denavit-Hartenberg parameters of a nonredundant manipulator with joint limits that can reach a set of specified positions-orientations in an environment that may include parallelepiped-shaped obstacles.

9A139. Kinematics and control of a fully parallel force-reflecting hand controller for manipulator teleoperation. - MD Bryfogle *(Sci Appl Intl, McLean VA 22102)*, CC Nguyen, SS Antrazi, PC Chiou *(Robotics and Control Lab, Dept Elec Eng, Catholic Univ of Am, Washington DC 20064)*. J Robotic Syst 10(5) 745-766 (Jul 1993).

Force feedback can enhance the efficiency of a teleoperation system by providing the operator with a sense of *feel* forces and torques arising from the interaction of the slave manipulator with the remote environment. This article addresses the kinematic analysis and control of a Parallel Force-Reflecting Hand Controller (PFORHC) whose design and implementation are based on a fully parallel mechanism. Kinematic analysis on the PFORHC is performed and results in a closed-form solution for the inverse kinematics. The forward kinematics is solved by Newton-Raphson's method. A fixed-gain PD control scheme is developed for force feedback control. Experiments are conducted to study the performance of the force-reflecting capability of the PFORHC. Experimental results show that the force control scheme utilizing a handgrip force sensor provides smaller steady-state errors as compared to the case utilizing no handgrip force sensor.

9A140. Kinematics of an infinitely flexible robot arm. - PJ Choi, JA Rice, JC Cesarone *(Dept of Mech Eng, Univ of Mech Eng, Chicago IL 60680)*. J Robotic Syst 10(4) 407-425 (Jun 1993).

This article describes a research effort to develop a command and control algorithm for a proposed flexible arm. This robot arm, unlike previous arms, is assumed to be extremely flexible, possessing a large number of dof and functioning as a "tentacle". Algorithms for commanding smooth motion of this arm in the presence of obstacles are developed, including both forward and inverse kinematics. This approach is based on the use of Catmull-Rom splines and local radius of curvature commands to discrete actuators along the arm's length. Several example trajectories are presented and explained.

9A141. Periodic motions of a hopping robot with vertical and forward motion. - RT M'Closkey and JW Burdick *(Dept of Mech Eng, California IT, Pasadena CA 91125)*. Int J Robotics Res 12(3) 197-218 (Jun 1993).

This article analyzes the global dynamic behavior of simplified hopping robot models that are analogous to Raibert's experimental machines. We first review a 1D vertical hopping model that captures both the vertical hopping dynamics and nonlinear control algorithm. Second, we present a more complicated 2D model that includes both forward and vertical hopping dynamics and a foot placement algorithm. These systems are analyzed using a Poincare return map. The approximate return map is shown to closely predict the behavior of the exact map for small forward running velocities. In addition, the approximate return map can be used to quantitatively explore the coupling of vertical and lateral dynamics and to determine the effect of the foot placement algorithm on dynamical behavior.

9A142. Synthesis and analysis of a new class of six-dof parallel minimanipulators. - Lung-Wen Tsai *(Mech Eng Dept and Syst Res Center, Univ of Maryland, College Park MD 20742)* and F Tahmasebi *(Robotics Branch, NASA, Goddard Space Flight Center, Greenbelt MD 20771)*. J Robotic Syst 10(5) 561-580 (Jul 1993).

A new class of 6-dof parallel minimanipulators is introduced. The minimanipulators are designed to provide high resolution and high stiffness for fine position and force control in a hybrid serial-parallel manipulator system. 2-dof planar linkages and inextensible limbs are used to improve positional resolution and stiffness of the minimanipulators. The 2-dof linkages serve as drivers for the minimanipulators. The minimanipulators require only three inextensible limbs and, unlike most of the six-limbed parallel manipulators, their direct kinematics can be reduced to solving a polynomial in a single variable. In addition, by using three limbs instead of six other benefits such as lower possibility of mechanical interference between limbs can be realized. All of the minimanipulators actuators are base-mounted. As a result, higher payload capacity, smaller actuator sizes, and lower power dissipation can be obtained. In addition to the design discussion, kinematic analysis of the minimanipulators is also presented.

9A143. **Adaptive control of a Stewart platform-based manipulator.** - CC Nguyen, SS Antrazi, Zhen-Lei Zhou *(Robotics and Control Lab, Dept of Elec Eng, Catholic Univ of Am, Washington DC 20064)*, CE Campbell Jr *(NASA, Goddard Space Flight Center, Greenbelt MD 20771)*. J Robotic Syst 10(5) 657-687 (Jul 1993).

This article presents the implementation of a joint-space adaptive control scheme used to control noncompliant motion of a Stewart platform-based manipulator (SPBM) that is used in a facility called the Hardware Real-Time Emulator developed at Goddard to emulate space operations. The SPBM is comprised of two platforms and six linear actuators driven by dc motors, and possesses 6 dof. The article briefly reviews the development of the adaptive control scheme, which is composed of proportional-derivative controllers whose gains are adjusted by an adaptation law driven by the errors between the desired and actual trajectories of the SPBM actuator lengths. The derivation of the adaptation law is based on the concept of model reference adaptive control and Lyapunov direct method under the assumption that SPBM motion is slow as compared to the controller adaptation rate. An experimental study is conducted to evaluate the performance of the adaptive control scheme implemented to control the SPBM to track a vertical and circular path under step changes in payload. Experimental results show that the adaptive control scheme provides superior tracking capability as compared to fixed-gain controllers.

9A144. **Analysis and design of a robotic distance sensor.** - O Partaatmadja, B Benhabib, AA Goldenberg *(Comput Integrated Manuf Lab, Dept of Mech Eng, Univ of Toronto, Toronto, ON, M5S 1A4, Canada)*. J Robotic Syst 10(4) 427-445 (Jun 1993).

Analysis and design of a robotic electrooptical distance sensor, based on the phase-shift measurement of a modulated light intensity, is addressed in this article. The transducer of this sensor employs two light sources (light-emitting diodes), whose intensities are modulated by different-phase sine-wave signals, and one photodiode receiver. The distance of an object's surface with respect to the sensor is measured by investigating the received phase shift. Experiments undertaken show that these parameters indeed affect the performance of the sensor. The exemplary optimization analysis carried out considered only two performance aspects of the sensor, namely, sensitivity and operational range, and yielded corresponding optimal design parameters.

9A145. **Contact sensing from force measurements.** - A Bicchi *(Dept of Elec Syst and Autom DSEA Centro "E Piaggio", Univ Pisa, via Diotisalvi 2, 56125 Pisa, Italia)*, JK Salisbury, DL Brock *(Artificial Intelligence Lab, MIT)*. Int J Robotics Res 12(3) 249-262 (Jun 1993).

This article addresses contact sensing (ie, the problem of resolving the location of a contact, the force at the interface, and the moment about the contact normals). Called "intrinsic" contact sensing for the use of internal force and torque measurements, this method allows for practical devices that provide simple, relevant contact information in practical robotic applications. Such sensors have been used in conjunction with robot hands to identify objects, determine surface friction, detect slip, augment grasp stability, measure object mass, probe surfaces, and control collision and for a variety of other useful tasks. This article describes the theoretical basis for their operation and provides a framework for future device design.

9A146. **Coordinated dynamic hybrid position-force control for multiple robot manipulators handling one constrained object.** - Tsuneo Yoshikawa and Xin-Zhi Zheng *(Dept of Mech Eng, Kyoto Univ, Kyoto 606, Japan)*. Int J Robotics Res 12(3) 219-230 (Jun 1993).

In coordinated manipulation of a single object using multiple robot arms or a multifingered robot hand, simultaneous control of the object motion and of the internal force exerted by arms or fingers on the object is required. Furthermore, in the case where the motion of the object is constrained in some directions because of contact with its environment, control of the constraint force also becomes necessary. In this article, we propose a coordinated dynamic hybrid control method for multiple robotic mechanisms. Several experimental results that show the validity of the proposed approach are presented. The results of this article will be useful for the fine manipulation tasks using multiple robotic mechanisms, where the individual specifications of the object motion, the interaction force between the object and its environment, and the grasping force of the object are given.

9A147. **Design of robust PD-type control laws for robotic manipulators with parametric uncertainties.** - SM Shahruz *(Berkeley Eng Res Inst, Berkeley CA 94709)*, G Langari *(Dept of Mech Eng, Texas A&M Univ, College Sta TX 77843)*, M Tomizuka *(Dept of Mech Eng, UCB)*. J Robotic Syst 10(4) 447-462 (Jun 1993).

In this article, design of a simple robust control law that achieves desired positions and orientations for robotic manipulators with parametric uncertainties is studied. A discontinuous control law is proposed, which consists of a high-gain linear proportional plus derivative (PD) term and additional terms that compensate for the effect of gravitation. The stability of the robotic system under the proposed control law is proved by LaSalle's stability theorem. Furthermore, by the theory of singularly perturbed systems, it is shown that if the proportional and derivative gain matrices are diagonal with large positive elements then the system is decoupled into a set of first-order linear systems. Simulation results are presented to illustrate the application of the proposed control law to a two-link robotic manipulator.

9A148. **Nonlinear control with end-point acceleration feedback for a two-link flexible manipulator: Experimental Results.** - F Khorrami and S Jain *(Control-Robotics Res Lab, Sch of Elec Eng and Comput Sci, Polytech Univ, Brooklyn NY 11201)*. J Robotic Syst 10(4) 505-530 (Jun 1993).

Experimental results for end-point positioning of multi-link flexible manipulators through end-point acceleration feedback are presented in this article. The advanced controllers are implemented on a two-link flexible arm developed at the Control-Robotics Research Laboratory at Polytechnic University. The advocated approach in this article is based on a two-stage control design. The first stage is a nonlinear O(1) feedback linearizing controller corresponding to the rigid body motion of the manipulator. Because this scheme does not utilize any feedback from the end-point motion, significant vibrations are induced at the end effector. Experimental and simulation results validate the fact that the end-effector performance is significantly better with the proposed O(1) feedback linearizing control as compared with the linear independent joint PD control. In addition, the nonlinear control offers other advantages in terms of smaller and smoother actuator torques and reducing the effects of nonlinearities.

9A149. **Review and unification of reduced-order force control methods.** - MT Grabbe *(BDM Eng Services, Huntsville AL 35806)*, JJ Carroll, DM Dawson *(Dept of Elec and Comput Eng, Clemson Univ, Clemson SC 29634-0915)*, Z Qu *(Dept of Elec Eng, Univ of Central Florida, Orlando FL 32816-0450)*. J Robotic Syst 10(4) 481-504 (Jun 1993).

In this article, we compare some of the recent methods developed for simultaneous position and force control of a single n-link constrained robot manipulator. Mathematical models of the constrained manipulator are introduced and the advantages and disadvantages of the associated control formulations are discussed. The similarities between each of the proposed formulations are also highlighted.

206I. MISCELLANEOUS APPLICATIONS

9A150. **The NIST Robocrane.** - J Albus, R Bostelman, N Dagalakis *(Robot Syst Div, NIST)*. J Robotic Syst 10(5) 709-724 (Jul 1993).

The Robot Systems Division of the National Institute of Standards and Technology (NIST) has been experimenting for several years with new concepts for robot cranes. These concepts utilize the basic idea of the Stewart platform parallel link manipulator. The unique feature of the NIST approach is to use cables as the parallel links and to use winches as the actuators. As long as the cables are all in tension, the load is kinematically constrained and the cables resist perturbing forces and moments with equal stiffness to both positive and negative loads. The result is that the suspended load is constrained with a mechanical stiffness determined by the elasticity of the cables, the suspended weight, and the geometry of the mechanism. Based on these concepts, a revolutionary new type of robot crane, NIST ROBOCRANE, has been developed that can control the position, velocity, and force of tools and heavy machinery in all 6 dof (x, y, z, roll, pitch, and yaw). Depending on what is suspended from its work platform, the ROBOCRANE can perform a variety of tasks. Examples are: cutting, excavating, and grading, shaping and finishing, lifting, and positioning. A 6-m version of the ROBOCRANE has been built and critical performance characteristics analyzed.

206Y. COMPUTATIONAL TECHNIQUES

9A151. **Identification of position-independent robot parameter errors using special Jacobian matrices.** - CR Mirman *(Eng Dept, Wilkes Univ, Wilkes-Barre PA 18766)* and KC Gupta *(Dept of Mech Eng, Univ of Illinois, Chicago IL 60680)*. Int J Robotics Res 12(3) 288-298 (Jun 1993).

Common production manipulators are designed to be controlled through the use of a closed-form kinematic solution algorithm. This closed-form solution uses manufacturer-specified nominal parameter values to model the given manipulator. These position-independent parameters, link lengths, twists, and offsets are geometrical and do not change as the manipulator is driven. However, manufacturing tolerances or usage may cause the actual parameters to deviate from the nominal robot parameters. The iterative regression algorithm for parameter identification uses the end-effector information at several arbitrary manipulator positions, as well as nominal parameter and joint variable information to compute the parameter error values. The use of the special Jacobian matrices allows for easy determination of mathematical singularity conditions. Through several examples, it will be shown that the use of this parameter identification algorithm produces accurate results. This article will discuss the possibilities of deterministic as well as probabilistic parameter errors.

208. Manufacturing

9A152. **Knowledge-based expert system for ballscrew grinding.** - SS Billatos *(Dept of Mech Eng, Univ of Connecticut, Storrs CT 06269-3139)* and JA Webster *(Grinding Center, Univ of Connecticut, Storrs CT 06269-3237)*. J Eng Indust 115(2) 230-235 (May 1993).

This paper discusses the ballscrew grinding process and provides a newly structured knowledge-based expert system (KBES) developed to automate the process based on fuzzy pattern recognition techniques for shape control with recommendations for further optimization considering practical machining constraints. The KBES offers several advantages including the use of semiskilled operators who can monitor several machines simultaneously, the consistent production of high quality parts, and the significant reduction in cycle time due to automatic adjustment of steadies.

IV. MECHANICS OF SOLIDS

250. Elasticity

250A. GENERAL THEORY

9A153. **Application of the Green and the Rayleigh-Green reciprocal identities to path-independent integrals in 2D and 3D elasticity.** - NI Ioakimidis *(Div of Appl Math and Mech, Sch of Eng, Univ of Patras, PO Box 1120, GR-261 10 Patras, Greece)* and EG Anastasselou *(Div of Mech, Natl Tech Univ, PO Box 61-28, GR-151 10, Greece)*. Acta Mech 98(1-4) 99-106 (1993).

An elementary but quite general method for the construction of path-independent integrals in plane and 3D elasticity is suggested. This approach consists simply in using the classical Green formula in its reciprocal form for harmonic functions and, further, the more general Rayleigh-Green formula also in its reciprocal form, but for biharmonic functions. A large number of harmonic and biharmonic functions appears in a natural way in the theory of elasticity. An application to the determination of stress intensity factors at crack tips is considered in detail and only the sum of the principal stress components is used in the path-independent integral.

9A154. **Elastic analysis of the half plane inhomogeneity problem.** - DA Kouris and JP Nuxoll *(Dept of Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287-6106)*. Acta Mech 97(3-4) 169-184 (1993).

The paper presents an analytical solution for the elastic field in the vicinity of a semi-circular inhomogeneity, embedded at the free surface of an elastic half-plane. This bi-material system is loaded by uniform remote tension or a constant eigenstrain sustained by the inhomogeneity.

250C. NONLINEAR AND FINITE DEFORMATION PROBLEMS

9A155. **Bifurcation of a solid circular elastic cylinder under finite extension and torsion.** - ED Duka *(Phys and Mech Div, Sch of Tech, Aristotle Univ, 54006 Thessaloniki, Greece)*, AH England *(Dept of Theor Mech, The University, University Park, Nottingham N97 2RD, UK)*, AJM Spencer *(Dept of Theor Math, The University, University Park, Nottingham N97 2RD, UK)*. Acta Mech 98(1-4) 107-121 (1993).

The problem of bifurcation of a solid circular cylinder subjected to finite extension and torsion is investigated using the theory of small deformations superposed on large elastic deformations. The material of the cylinder is assumed to be isotropic, elastic, homogeneous and incompressible. A numerical scheme is adopted to solve the system of partial differential equations and the associated boundary conditions governing the problem for a class of strain-energy functions. The numerical results obtained determined the critical twist corresponding to a given extension of the cylinder.

9A156. **Cylindrical and spherical inflation in compressible finite elasticity.** - JM Hill *(Dept of Math, Univ of Wollongong, NSW 2500, Australia)*. IMA J Appl Math 50(2) 195-201 (1993).

Murphy (1992) examined cylindrical and spherical inflation of compressible perfectly elastic materials having three spherical forms of the strain-energy function. In this paper a general procedure for handling such problems for any strain-energy function is proposed. This procedure is used to confirm some of the results by Murphy as well as to deduce new solutions. One solution obtained by that author for cylindrical infiltration is found to be incorrect.

9A157. **Expansion of a cavity in a rubber block under unequal stresses.** - Y-W Chang, AN Gent, JP Padovan *(Inst of Polymer Eng, Univ of Akron, Akron OH 44325-0301)*. Int J Fracture 60(3) 283-291 (1 Apr 1993).

Elastic expansion of a small spherical void in the interior of a rubber block has been investigated by FE analysis (FEA). The block was subjected to a far-field tensile or compressive stress while an internal pressure was applied to the cavity. The rubber was assumed to be virtually incompressible in volume and neo-Hookean in elastic behavior. Critical stress states were determined at which the void would become indefinitely large - a form of elastic instability. An applied tensile stress was found to lower the critical inflation pressure for instability, in agreement with experimental observations whereas a compressive stress increased it. The critical mean stress was lowest for an isotropic stress system (when the applied tension was zero). It was higher when either compressive or tensile stresses were applied, ie, under non-isotropic stresses, in agreement with the analysis of Hou and Abeyaratne. However, the present results show a considerably smaller effect of tensile stress than predicted by Hou and Abeyaratne.

9A158. **Stress rate measure for finite elastic plastic deformations.** - Z Xia and F Ellyin *(Dept of Mech Eng, Univ of Alberta, Edmonton T6G 2G8, Canada)*. Acta Mech 98(1-4) 1-14 (1993).

A new stress rate, based on the spin of a material triad that coincides momentarily with the principal axes, is applied to the analysis of constrained and unconstrained shear with and without superposed normal stresses of hypoelastic and rigid plastic, kinematically hardening solids. A comparative study of various alternative stress rates that have been proposed, including the Jaumann rate, favors the new formulation from the viewpoint of qualitative behavior, general applicability and ease of implementation.

250E. STRESS CONCENTRATIONS AND SINGULARITIES

9A159. **Stress concentration around holes in composite laminates with variable fiber spacing.** - Le Chung Shiau and GC Lee *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan, ROC)*. Composite Struct 24(2) 107-115 (1993).

An 18 dof higher-order triangular plane stress element is developed to investigate the effect of variable fiber spacing on the stress concentration around a hole in a composite laminated plate subjected to in-plane boundary loading. This element accounts for the irregular in-plane elastic properties across the element domain, thus, the nonuniformly spaced fibers in the laminate can be easily incorporated into the element stiffness matrix through the fiber content calculated at each Gaussian integration point. Results show that reducing the fiber volume ratio near the hole edges can significantly reduce the stress concentration in that region.

9A160. **Stress concentration in the bending of sandwich beams with transversely flexible core.** - Y Frostig *(Fac Civil Eng, Technion Israel IT, Haifa 32000, Israel)*. Composite Struct 24(2) 161-169 (1993).

Stress concentrations in sandwich beams with a soft core subjected to bending loading are investigated and the level of stresses is analytically determined. The cases discussed include stress concentration effects (i) in the vicinity of concentrated loads and supporting zones; (ii) at the edges of debonding regions edge and inner delamination types at the interface layer between the skins and the core; and in the vicinity of vertical cut-off connections; and (iii) at the location of diaphragms that are bonded and unbonded with adjacent core and embedded in it. The results are determined with the aid of a variational rigorous analytical systematic elastic high-order theory that uses closed form solutions. This theory is applicable to any type of sandwich construction with and without discrete diaphragms (i) to any type of loading, concentrated or distributed; and (ii) to any type of boundary conditions including cases in which at the same section the conditions at the upper skin are different from those at the lower skin. The stress concentration effects are presented in terms of deflections, internal forces, and normal stresses (peeling) in the interface layers between the skin and core. A parametric study is conducted and investigates the level of stresses as a result of (i) the vertical modulus of elasticity of the core; (ii) the delamination length; (iii) the reinforcing diaphragm in a typical connection; and (iv) the presence of diaphragms, either bonded or unbonded with the adjacent core, at specific locations.

250H. CONTACT PROBLEMS AND INCLUSIONS

9A161. **About multi-Hertzian-contact hypothesis and equivalent conicity in the case of S1002 and UIC60 analytical wheel-rail profiles.** - J-P Pascal *(Lab Tech Nouvelles, Inst Rech sur les Transports leur Securite, BP 34, 94114 Arcueil, France).* Vehicle Syst Dyn 21(2) 57-78 (1993).

In a previous paper, a new method using "multi-Hertzian" elasticity for identifying equivalent parameters of railway wheelsets rolling on defined tracks was presented. Another method also using Hertzian elasticity has produced different results. Without knowing the origin of these discrepancies, the question was asked, whether any of these methods could adequately describe actual non-Hertzian contacts. This paper, using as a basis Kalker's "Contact" software which solves the non-Hertzian case for normal and tangential forces, answers this question, demonstrating that the assumption of summing Hertzian contacts is realistic provided that enough ellipses are considered.

9A162. **Almost constant contact stress distributions by shape optimization.** - A Klarbring *(Dept of Mech Eng, Linkoping IT, S-581 83 Linkoping, Sweden)* and J Haslinger *(KFK MFF UK, Charles Univ, Ke Karlovu 5, 120 00 Praha, Czechoslovakia).* Struct Optim 5(4) 213-216 (Apr 1993).

This paper addresses the problem of finding shapes of contacting bodies avoiding undesirable stress concentrations. It has previously been shown that designing the shape of a rigid body in contact with a fixed linear elastic body by minimizing the equilibrium potential energy under an isoparametric constraint results in a uniform contact pressure distribution. As an extension of this result, it is shown here that when the shape of an elastic body in contact with a flat rigid foundation is chosen on the same premises, the uniform pressure distribution is found only if displacement gradients can be considered small. From the point of view of applications, an important conclusion is that this smallness holds in a case when linear elasticity is physically valid.

9A163. **Numerical treatment of the nonmonotone (zig-zag) friction and adhesive contact problems with debonding.** Approximation by monotone subproblems. - ES Mistakidis *(Dept of Civil Eng, Aristotle Univ, GR-54006 Thessaloniki, Greece)* and PD Panagiotopoulos *(Fac of Math and Phys, RWTH, D-5100 Aachen, Germany).* Comput Struct 47(1) 33-46 (3 Apr 1993).

Nonmonotone friction problems or adhesive contact friction problems introduce zig-zag-type laws which cannot be effectively treated by the classical numerical methods for nonlinear stress-strain laws. In order to calculate accuracy the arising free boundaries we propose a new approximation method of the nonmonotone problem by monotone ones. The proposed method finds its justification in the approximation of a hemivariational inequality by a sequence of variational inequalities.

250K. RESIDUAL STRESSES

9A164. **Residual stresses in welded jumbo box columns.** - Sheng-Jin Chen and SC Chang *(Dept of Construct Eng, Natl Taiwan IT, Taipei, Taiwan).* J Construct Steel Res 25(3) 201-209 (1993).

Eight full-scale welded jumbo box columns fabricated with different details are selected to examine the distribution and magnitude of residual stresses. It is found that the maximum tensile residual stresses can be as high as 1.1 F_y and the maximum compressive residual stress is 0.43 F_y, where F_y, is the yield stress.

250Y. COMPUTATIONAL TECHNIQUES

9A165. **Completed double layer BEM in elasticity.** - N Phan-Thien and D Tullock *(Dept of Mech Eng, Univ of Sydney, NSW 2006, Australia).* J Mech Phys Solids 41(6) 1067-1086 (Jun 1993).

This paper reports on indirect BEM in elasticity that is most suitable to deal with particular solids. The method involves a distribution of a double layer potential and, after a suitable completion and deflation, is amenable to iterative solution techniques. It can therefore accommodate a large number of particles with complex geometries. Convergence of the method is significantly improved by the introduction of a simple domain decomposition to solve the system of equations. The method is illustrated by the translating sphere problem, the load transfer problem between two spheres at near contact, and the shear deformation of a cluster of 125 spheres initially in a simple cubic array.

9A166. **Complex method for the elliptical hole in an unsymmetric laminate.** - W Becker *(Dornier GmbH Deutsche Aerospace, Abteilung RST 111, Postfach 1420, W-7990 Friedrichshafen 1, Germany).* Arch Appl Mech 63(3) 159-169 (Apr 1993).

Within the framework of linear-elastic classical laminated plate theory, the problem of an elliptical hole in an infinitely extended unsymmetric laminate is treated. For the underlying non-symmetric layup arbitrary bending extension coupling is admitted and is taken into account by means of a new complex potential approach. The derived solution describes all essential plate quantities in any vicinity of the elliptical hole and it reveals interesting features of the considered bending extension coupling.

9A167. **Convex multilevel decomposition algorithms for non-monotone problems.** - GE Stavroulakis and PD Panagiotopoulos *(Sch of Tech, Aristotle Univ, GR-54006 Thessaloniki, Greece).* Int J Numer Methods Eng 36(11) 1945-1966 (15 Jun 1993).

A convex, multilevel decomposition algorithm is proposed in this paper for the solution of static analysis problems involving non-monotone, possibly multivalued laws. The theory is developed here for a model structure with non-monotone interface or boundary conditions. First the nonmonotone laws are written in the form of a difference of two monotone functions. Under this decomposition, the nonlinear elastostatic analysis problem is equivalent to a system of convex variational inequalities and to non-convex minmin problems for appropriately defined Lagrangian functions. Numerical results concerning the calculation of elastic and rigid stamp problems and of material inclusion problems with delamination and non-monotone stick-slip frictional effects illustrate the theory.

9A168. **Fast algorithm to solve the Beltrami equation with applications to quasiconformal mappings.** - P Daripa *(Dept of Math, Texas A&M Univ, College Station TX 77843).* J Comput Phys 106(2) 355-365 (Jun 1993).

Two algorithms are provided for the fast and accurate computation of the solution of Beltrami equations in the complex plane in the interior of a unit disk. There are two integral operators which are fundamental in the construction of this solution. A fast algorithm to evaluate one of these integrals is given by Daripa. An algorithm for fast evaluation of the second integral is provided here. These algorithms are based on representation of the solution in terms of a double integral, some recursive relations in Fourier space, and fast Fourier transforms. A numerical method is provided and explored numerically for the construction of quasiconformal mappings using the Beltrami equation.

9A169. **Fundamental solutions of the I-st plane problem of micropolar elasticity with a harmonically varying distortion field.** - J Dyszlewicz and J Wytrazek *(Inst of Math, Wroclaw Univ of Tech, Wroclaw, Poland).* Eng Trans 40(4) 419-434 (1992).

The paper deals with the I-st plane problem of microelasticity in the case of a distortion field varying harmonically in time. Differential equations of the problem, expressed in terms of displacements and rotations, are solved by direct integration with the help of the Fourier integral transforms. Fundamental solutions are obtained for the displacements and rotations induced by concentrated distortions acting in an infinite plane. All limit cases of the fundamental solutions are given which are relevant to derived theories.

9A170. **New description of the tensors of elasticity based upon irreducible representations.** - Y Surrel *(Dept of Mech and Mat Eng, Ecole Nationale Superieure Mines de Saint-Etienne, 158 Cours Fauriel, 42023 Saint-Etienne Cedex 2, France).* Eur J Mech A 12(2) 219-235 (1993).

This paper gives the irreducible decomposition of the representations of the spatial group of rotations realized by the tensors of elasticity. From the tensor components are defined some complex quantities spanning the irreducible subspaces. The law of transformation of those quantities under spatial rotations is explicitly given, as well as the law of elasticity with this formalism, in the most important material symmetry cases.

9A171. **Three dimensional anisotropic elasticity with BEM using the isotropic fundamental solution.** - NA Schclar and PW Partridge *(Wessex IT, Univ of Portsmouth, Ashurst Lodge, Southampton SO4 2AA, UK).* Eng Anal Boundary Elements 11(2) 137-144 (1993).

The anisotropic fundamental solution for BEM analysis of elasticity problems cannot be expressed in a closed form in such a way that numerical integration and interpolation must usually be employed in its evaluation with a resulting increase in computer run times. An alternative is to express the anisotropic constants as a sum of average isotropic values and residuals, thus permitting the use of an isotropic fundamental solution. In this paper the dual reciprocity method is used to approximate the residuals and take the relevant domain integral to the boundary.

252. Viscoelasticity

9A172. Effects of stress rates on the strength and deformation of concrete at ambient and elevated temperatures. - GD Stefanou *(Sch of Eng, Univ of Patras, GR-261 10 Patras, Greece)*, P Koliopoulos *(Sch of Eng, Univ College, Gower St, London WC1, UK)*, E Nichol *(Sch of Eng, Univ College London, Gower St, London WC1, UK)*. Eng Fracture Mech 45(2) 265-276 (May 1993).

Experimental data relating to standard rates of loading are studied on concrete control specimens 28 days after casting. Normal concrete with an oven-dry density in the range of 2000 - 2800 kg/m^3 is used for the specimens. The rates of compression are about 0.3 $N/mm^2/sec$, or a strain rate of about $30 \times 30^{-6}/sec$ and the corresponding rates of tension are 0.03 N/mm^2 sec or $3 \times 10^{-6}/sec$. Examples of stress-strain relationships are given. The effects of stress and strain rates are discussed.

9A173. Interpretation of impression creep data using a reference stress approach. - TH Hyde, KA Yehia, AA Becker *(Dept of Mech Eng, Univ of Nottingham, University Park, Nottingham NG7 2RD, UK)*. Int J Mech Sci 35(6) 451-462 (Jun 1993).

A sound, mechanics-based approach has been developed to allow conventional creep data to be obtained from impression creep test data; the reference stress method was used, to analyze the results of axisymmetric finite calculations, for this purpose. The equivalent stress was found to be 0.296 times the mean indenter pressure and the effective gauge length was found to be about 0.755 times the indenter diameter. These values correspond closely with those which have been obtained by fitting indenter creep data to conventional uniaxial creep data.

9A174. Viscoelastic effects on intralaminar fracture toughness of epoxy-carbon-fibre laminates. - R Frassine, M Rink, A Pavan *(Dept Chimica Industriale Ingegneria Chimica, Politec Milano, P Leonardo da Vinci, 32-20133 Milano, Italy)*. J Composite Mat 27(9) 921-933 (1993).

The Double Torsion technique has been applied to characterize the fracture resistance of a unidirectional and a woven epoxy and carbon-fibre composite material. The crack speed has been varied by about four orders of magnitude for testing temperatures ranging from below the glass transition of the rubber modifier of the epoxy matrix to the glass transition of the matrix itself. A noteworthy variation was found in the fracture toughness and surface morphology of the unidirectional composite. Decreasing fracture toughness values were observed by increasing crack speed at 23°C, which is somewhat unusual for viscoelastic materials. Results have been discussed in the framework of viscoelastic fracture mechanics, and the fracture behavior at different rates and temperatures has been shown to be related to different viscoelastic mechanisms.

9A175. FE analysis of viscoelastic fracture. - JR Masuero and GJ Creus *(Dept of Civil Eng, Univ Federal Rio Grande do Sul, 90210 Porto Alegre RS, Brazil)*. Int J Fracture 60(3) 267-282 (1 Apr 1993).

A numerical procedure based on the FEM and Schapery's formulation is proposed to determine the critical condition of cracks in viscoelastic structures. Some initial results trying to couple fracture mechanics with continuum damage mechanics also are presented.

9A176. Analysis of identification methods for the viscoelastic properties of materials. - L Dietrich and K Turski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 40(4) 501-523 (1992).

A complete solution of the constitutive equations for the viscoelastic material described by Burgers model is presented under various initial conditions. Possibilities to determine the viscoelastic properties of materials for various loading patterns of a specimen are pointed out. Test results on asphalt mixture obtained under various loads and strain rates are discussed. Creep, cyclic deformations and constant strain rate loading are found to enable the viscoelastic properties to be determined in different ranges of strain rates. The obtained results of these types of tests provide a consistent spectrum of these properties as functions of the initial strain rates.

254A. GENERAL THEORY

9A177. Plasticity model for punching shear of laterally restrained slabs with compressive membrane action. - JS Kuang and CT Morley *(Dept of Eng, Univ of Cambridge, Trumpington St, Cambridge CB2 1PZ, UK)*. Int J Mech Sci 35(5) 371-385 (May 1993).

A plastic theoretical model is presented for the punching shear failure of laterally restrained concrete slabs, in which a parabolic Mohr failure criterion for concrete is adopted. The proposed method allows for the effect of compressive membrane action and a membrane-modified flexural theory of elasto-plasticity is used to calculate the compressive membrane forces. The predictions by the proposed analysis shows good agreement with a wide range of experimental test results.

254C. NONLINEAR AND FINITE DEFORMATION PROBLEMS

9A178. Effect of frictional force on the steady state axisymmetric deformations of a viscoplastic target. - X Chen and RC Batra *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401-0249)*. Acta Mech 97(3-4) 153-168 (1993).

We study steady state axisymmetric deformations of a thick viscoplastic target being penetrated by a fast-moving long rigid cylindrical rod with a hemispherical nose. The deformations of the target appear steady to an observer situated on the penetrator nose tip and moving with it. The objective of this work is to investigate the effect of the frictional force acting on the target-penetrator interface upon the deformations of the target. It is postulated that the frictional force at a point on the target-penetrator interface is proportional to the normal traction there and depends upon the speed of the target particle relative to the penetrator. It is found that the frictional force affects significantly the variation of the tangential speed and the second invariant of the strain-rate tensor on the penetrator nose surface, but minimally the distribution of the normal stress there, since the dominant component of the normal stress is the hydrostatic pressure which is affected little by the consideration of friction forces.

9A179. Loss of hyperbolicity in elastic-plastic material at finite strains. - Lianjun An *(Dept of Math and Stat, McMaster Univ, Hamilton L8S 4K1, ON, Canada)*. SIAM J Appl Math 53(3) 621-654 (Jun 1993).

In this paper, a linear analysis is carried out for partial differential equations (PDEs) describing granular flow. Regarding constitutive effects, elasticity and shear hardening with a nonassociative flow rule are included. The paper shows that flutter illposedness is an essential feature of many such constitutive models. In the paper, a readily applicable criterion for the occurrence of flutter illposedness is developed. The paper demonstrates this material with a deviatorically associative flow rule at small strains; although flutter illposedness does not occur, a generic small perturbation will cause flutter illposedness.

9A180. Model of internal stress superplasticity based on continuum micromechanics. - E Sato and K Kuribayashi *(Inst of Space and Astron Sci, 3-1-1 Yoshinodai Sagamihara, Kanagawa 229, Japan)*. Acta Metall Mat 41(6) 1759-1767 (Jun 1993).

A new theoretical model is proposed to explain internal stress superplasticity under a simultaneous applied stress during thermal cycling. The analyzed material is an elastically uniform body containing an elastic spherical inclusion, surrounded by a plastic matrix obeying a power law creep. It is assumed that only relaxation by interface diffusion is significant. At first it is shown that an inclusion dilatation can be counterbalanced by a certain matrix plastic flow. Assuming a certain stress distribution for this condition, a stationary flow on heating or cooling results. Typical behavior of this stationary flow is analyzed for the specific cases of high or low applied stresses.

254E. CONTACT PROBLEMS AND INCLUSIONS

9A181. Elasto-plasticity of slackened systems. - A Gawecki *(Poznan Univ of Tech, Poznan, Poland)*. Arch Mech 44(4) 363-390 (1992).

The paper concerns the so-called "slackened" systems, ie, systems with gaps (clearances) at the joints between FEs. Fundamental theoretical problems of mechanics of such systems made of the elastic-plastic materials have been presented. Only quasi-static processes, within the framework of the geometrically linear theory, are considered, and all friction effects are neglected. Several theorems concerning the problems of analysis and synthesis have been derived. Particular attention has been paid to the problems of uniqueness of solutions. A mathematical problem proposed in the work can describe the behavior of locking elastic-plastic systems. This model covers a considerably wide class of time-independent materials. The theory allows us to describe the frictionless cases of unilateral constraints in the frame of small deformations. Results obtained in the paper can be applied in structural and solid mechanics.

254I. VISCO- AND ELASTO-PLASTIC MEDIA

9A182. Identification and validation of viscoplastic and damage constitutive equations. - G Amar and J Dufailly *(Lab Mec Tech ENS Cachan-CNRS, Univ Paris-VI, 61 Ave President Wilson, 94235 Cachan Cedex, France)*. Eur J Mech A 12(2) 197-218 (1993).

This paper is devoted to the lifetime prediction of structures to very severe thermomechanical loadings leading to very small numbers of cycles to rupture (10 to 100). An isothermal elasto-viscoplastic model coupled to the damage constitutive relation is considered. Its complete identification under isothermal conditions is developed and the corresponding experimental program is described.

9A183. Inadaptation analysis with hardening and damage. - A Siemaszko *(Inst of Fund Tech Res, Swietokrzyska 21, PL-00 049 Warsaw, Poland)*. Eur J Mech A 12(2) 237-248 (1993).

The paper presents a method of inadaptation (non-shakedown) analysis of elastic-plastic discrete structures subjected to variable repeated loading. The method accounts for nonlinear geometrical effects, nonlinear isotropic or kinematic hardening and progressive damage of the material. The problem is formulated as a sequence of linear programming tasks and is solved by a step-by-step procedure. The method provides the most stringent plastic deformation path of the structure (so called inadaptation curve) constituting an envelope of all the possible inadaptation processes. The inadaptation analysis method, presented here, is applied to the example of elastic-plastic frame structures subjected to variable loads.

9A184. Pareto solution of an inverse problem in elastoplasticity. - LMC Simoes *(Dept Eng Civil, Fac Ciencias Tec, Univ Coimbra, 3049 Coimbra, Portugal)*. Adv Eng Software 16(2) 103-110 (1993).

An elastic-perfectly plastic discretized structure subjected to given proportional loads, undergoes displacements, some of which are measured. On the basis of this experimental data the yield limits and the hardening coefficients are sought, whereas the elastic properties are known. A number of possible ways of tackling this inverse problem are outlined and discussed. The present paper contains results on the sensitivity analysis for elastoplastic problems in the case of discrete structures modeled by the FEs.

9A185. Ratchetting behavior in viscoplasticity, a technical note. - AD Freed *(NASA Lewis Res Center, Cleveland OH 44135)* and KP Walker *(Eng Sci Software, Smithfield RI 02917)*. Eur J Mech A 12(2) 191-196 (1993).

Viscoplastic models that use the [Armstrong & Frederick, 1966] kinematic hardening relationship are known to generally overpredict the observed accumulation of ratchet strains [Inoue *et al*, 1991]. The reason for this behavior is a consequence of the mathematics used to describe Hooke's law and the evolution equations for plastic strain and back stress. Conditions for ratchetting exist whenever there is a cycle-averaged mean stress present over a cyclic loading path. Overcoming the possible adverse trends in predicted ratchetting behavior is a difficult task, and how one ought to go about doing this is not yet completely clear. We therefore choose to discuss the mathematical cause of ratchetting and how it has been dealt with to date in the literature, but we make no attempt to correct this flaw.

9A186. Fundamental issues in FE analyses of localization of deformation. - R DeBorst *(Dept of Civil Eng, TNO Build and Construct Res, Univ of Tech, PO Box 5048, Delft, Netherlands)*, LJ Sluys *(Dept of Civil Eng,Univ of Tech, PO Box 5048, Delft, Netherlands)*, H-B Muhlhaus *(Div of Geomech, CSIRO, PO Box 54 Mt Waverley, Vic, Australia)*, J Pamin *(Dept of Civil Eng, Univ of Tech, PO Box 5048, Delft, Netherlands)*. Eng Comput 10(2) 99-121 (Apr 1993).

Classical continuum models, ie, continuum models that do not incorporate an internal length scale, suffer from excessive mesh dependence when strain-softening models are used in numerical analyses and cannot reproduce the size effect commonly observed in quasi-brittle failure. In this contribution three different approaches will be scrutinized which may be used to remedy these two intimately related deficiencies of the classical theory, namely (i) the addition of higher-order deformation gradients, (ii) the use of micropolar continuum models, and (iii) the addition of rate dependence. By means of a number of numerical simulations it will be investigated under which conditions these enriched continuum theories permit localization of deformation without losing ellipticity for static problems and hyperbolicity for dynamic problems.

9A187. HyperQ/Plastics: An intelligent design aid for plastic material selection. - K Beiter, S Krizan, K Ishii *(Dept of Mech Eng, Ohio State Univ, Columbus OH)*, L Hornberger *(Apple Computer)*. Adv Eng Software 16(1) 53-60 (1993).

The selection of material and processing techniques for plastic parts is a challenging task for design engineers. This paper describes the development of an intelligent program that helps engineers perform this task. An extensive survey of practicing engineers, product designers and material specialists revealed that these experts used both qualitative and quantitative selection methodologies. The program described, HyperQ/Plastics, is a HyperCard program that uses PROLOG to combine these two types of selection methodologies. The current version of this program is undergoing tests at several industrial sites.

9A188. Non-unique numerical solutions in visco-plasticity. - HJ Antunez *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 40(4) 525-536 (1992).

We present the numerical analysis of a series of cutting problems for a visco-plastic material. The model is implemented in a FE program written in the flow formulation framework. Almost ideal plasticity is achieved as the limit case of a visco-plastic material. Solution dependence on the chosen initial configuration (the final one being not known) suggests non-uniqueness inherent to the visco-plastic material with free surfaces, since a residual rate dependence is conserved in the model.

9A189. Strength analysis of axially symmetric elements with a series of rectangular notches. - L Dietrich, J Miastkowski, R Szczebiot *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 40(4) 435-456 (1992).

Complete solutions for axially-symmetric tensile rods with rectangular notches of arbitrary spacing are presented. On the basis of the obtained solutions both limit values of a diameter of the rod outside notch and appropriate spacings of a series of notches have been determined. Strength analysis of such elements within entire range of their geometrical parameters has also been made. The obtained results are compared with experimental tests on specimens made of aluminium alloy.

9A190. On the yield surface behavior in the case of proportional cyclic loading histories. - W Trampczynski and E Sender *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Arch Mech 44(4) 391-408 (1992).

Experimental results concerning the yield surface evolution in the case of proportional cyclic loading histories are reported. They were obtained for 18G2A steel, at room temperature, using one specimen technique, where the "offset" yield definition was assumed to be n = 0.0005. The experiments were carried out on thin-walled tubes under cyclic tension-compression and opposite torsion with constant strain rate $\dot{\varepsilon}_e$ = 3.4×10^{-4} s^{-1}. The influence of former plastic strain history on the yield surface shape and magnitude in steady cyclic state is shown. It was found that yield surface in the σ_x, $\sqrt{3}\tau_{xy}$ space can be described by an ellipse, + 8%; - 6% accuracy, independently on the former plastic strain history.

256A. GENERAL THEORY

9A191. Antiplane shear problems of perfect and partially damaged matrix-inclusion systems. - Xiangzhou Zhang *(Dept of Aircraft Eng, NW Polytech Univ, Xian 710072, China)* and Norio Hasebe *(Dept of Civil Eng, Nagoya IT, Nagoya 466, Japan)*. Arch Appl Mech 63(3) 195-209 (Apr 1993).

Antiplane shear problem of an infinite medium containing a circular inclusion of different material is investigated in this article. Perfectly bonding between the matrix and the inclusion, as well as partial debonding in the form of a circumferential crack occurring at the interface of these two constituents, are considered. Using the complex variable method in conjunction with a semi-inversed technique, exact expressions for the stress, displacement and stress intensity factor in the problem are obtained for various external loading conditions, including that brought about by stress singularities.

9A192. **Beneficial influence of matrix anisotropy in fiber composites.** - PS Theocaris *(Acad of Athens, PO Box 77230, 17510 Athens, Greece)*. Acta Mech 97(3-4) 127-139 (1993).

It has recently been shown that the stress concentrations in anisotropic materials with distinct complex or imaginary roots of the respective characteristic function are much higher than in materials with equal roots. It was further shown that anisotropic materials with equal roots behave like quasi-isotropic materials. Modern carbon-carbon and metal-ceramic composites are intuitively using these facts to create much stronger materials by reinforcing the matrix properties. A theory is presented in this paper where the coupling of strongly anisotropic fibers along their axis with strongly anisotropic matrices along either the fiber direction or the transverse plane to the direction of the fibers, either deteriorates, or improves perceptibly the mechanical behavior of the composites. It was shown that anisotropy of the matrix, increasing its mechanical properties on the transverse isotropic plane of the composite, increased the transverse Poisson's ratio, whereas decreased the longitudinal shear modulus G_{LC}. This resulted in values of the eigenangle ω_c receding from the corresponding value ω_{ic} for the respective isotropic case. This resulted in deterioration of the mechanical performance for the composite since the material now has the tendency to develop higher stress concentrations for equivalent loadings. On the contrary, a strong anisotropic matrix along the direction of the fibers yielded the inverse results for the various moduli of the anisotropic composite. The most important results is the increase of the longitudinal shear modulus G_L, so that ratio $E_L/2G_L$ is consistently decreasing, thus yielding values of the eigenangle ω_c tending to approach the critical value ω_i for the isotropic material. This decrease of ω_c indicates the improvement of the quality of the composite, which develops relatively lower stress concentration factors approaching their respective isotropic values. This fact makes the anisotropic composite material to approach an equivalent state of quasi-isotropy and thus to improve the strength of the material by reducing considerably the eventual anisotropic stress concentration factors of the respective structural elements. Examples with T300-N5208 Graphite-Epoxy composites and Borsic-1100 Aluminum metal-metal composites indicate clearly the beneficial effect of the anisotropy of their matrices.

9A193. **Bounds and estimates of overall moduli of composites with periodic microstructure.** - S Nemat-Nasser *(Center for Excellence for Adv Mat, Dept of Appl Mech and Eng Sci, UCSD)*, N Yu *(Dept of Eng Sci and Mech, Univ of Tennessee, Knoxville TN 37996)*, M Hori *(Dept of Civil Eng, Univ of Tokyo, Bunkyo-ku, Tokyo 113, Japan)*. Mech Mat 15(3) 163-181 (May 1993).

Bounds on the overall moduli of a broad class of composites with periodic microstructure are obtained by generalized Hashin-Shtrikman variational principles. Piecewise constant eigenstrains and eigenstresses are used, and exact, computable bounds are developed. The formulation is valid for composites comprised of an anisotropic (or isotropic) matrix with an arbitrary number of periodically distributed anisotropic (or isotropic) inhomogeneities. Examples of two-phase particulate whisker, and fiber-reinforced composites are considered for illustration. Finally, an estimate of the overall moduli, based on the selection of the effective medium as the reference material, is proposed for periodic microstructure.

256B. PARTICULATE MEDIA, INCL CEMENTS

9A194. **Behavior of high-strength concrete under confined stresses.** - K Lahlou, P-C Aitcin, O Chaallal *(Dept of Civil Eng, Fac of Appl Sci, Univ de Sherbrooke, Sherbrooke, PQ J1K 2R1, Canada)*. Cement & Concrete Composites 14(3) 185-193 (1992).

This paper presents the preliminary results of an experimental investigation on confined high-strength concrete, which is ongoing in the Civil Engineering Department of the University of Sherbrooke. The results of the present preliminary study limited to concentrically loaded short circular columns show that confining high strength concrete in a steel tube greatly increases its strength and results in outstanding new ultrahigh-strength concrete; confining high-strength concrete in a steel tube improves its ductility; and the confinement efficiency slightly increases with concrete compressive strength.

9A195. **Computational modeling of impact tests on steel fiber reinforced concrete beams.** - LJ Sluys and R De Borst *(Dept of Civil Eng, TNO Build and Construct Res, Univ of Tech, Delft, Netherlands)*. Heron 37(4) 3-69 (1992).

Concrete fracture under impact loading is modeled using rate-independent and rate dependent smeared crack representations. Both models have been used to simulate the behavior of concrete beams with both conventional and steel-fiber reinforcement. The rate-dependent crack model turns out to be superior in the sense that it properly captures the experimentally observed distributed crack pattern, but the differences in the prediction of the global structural response are hardly noticeable.

9A196. **Effect of field and lab curing on the durability characteristics of plain and Pozzolan concretes.** - H Saricimen, M Maslehuddin, AI Al-Mana, O Eid *(Res Inst, King Fahd Univ of Pet and Minerals, PO Box 1686, Dhahran 31261, Saudi Arabia)*. Cement & Concrete Composites 14(3) 169-177 (1992).

The environmental conditions in the Arabian Gulf countries are classified as aggressive and severely corrosive. Field and lab studies have shown that concrete in this region should be designed not only for strength but also for durability. Utmost emphasis should be given to produce dense and impermeable concrete, to extend the service life of structures. In this study, concrete samples were prepared using various types of cements and fly ashes at various mix designs. The samples were cured in the field and in lab conditions. The permeability was determined by volume of permeable voids and absorption tests. The results showed that continuous water curing is necessary to obtain the least permeable concrete for both plain and pozzolan concretes. Irrespective of curing procedure followed, the fly ash concrete exhibited lower permeability than plain concrete for an initial test period of 7 days during curing. The fly ash concrete samples cured in the lab exhibited lower initial surface absorption than control concretes after 90 days of curing for all fly ash additions (10-40%) and cement factors (275-450 kg-m^3) used.

9A197. **Energy principle of the indentation-induced inelastic surface deformation and hardness of brittle materials.** - M Sakai *(Dept of Mat Sci, Toyohashi Univ of Tech, Tempaku-cho, Toyohashi 441, Japan)*. Acta Metall Mat 41(6) 1751-1758 (Jun 1993).

Energy-based considerations on the inelastic surface deformation of brittle materials are conducted. The hysteresis loop energy U_r which is dissipated during the indentation loading-unloading cycle is related to the true hardness H, apparent hardness H, and the work-of-indentation Γ_I. The true hardness has its energy-derived meaning of the irreversible energy consumption to create a unit volume of the indentation impression of ideally plastic materials. The relationships between U_r and the three-half power of indentation load $P^{3/2}$, and between U_r and the volume of the indentation impression V_I are used to separate the plastic contribution from the complicated plastic-elastic surface deformation processes in indentation hardness tests. The mechanical and physical meanings of the conventional Vickers indentation hardness of brittle materials are also addressed in relation to H, H and Γ_I.

9A198. **Influence of curing methods on the strength and permeability of GGBFS concrete in a simulated arid climate.** - SA Austin, PJ Robins, A Issaad *(Struct Mat Res Group, Dept of Civil Eng, Univ of Tech, Loughborough LE11 3TU, Leics, UK)*. Cement & Concrete Composites 14(3) 157-167 (1992).

Problems are frequently encountered in producing good-quality concrete in hot climates. Inadequate curing results in early cracking or porous and permeable concrete, or both; these effects, in turn, make structures prone to reinforcement corrosion and other processes of degradation. This research compares the development of strength and permeability of ordinary Portland cement (OPC) and ground granulated blast furnace slag (GGBFS)-modified concretes which were cured in a simulated arid climate. This was achieved with an environmental room in which temperature and humidity were cycled to imitate a typical Algerian Sahara climate. Four curing regimes were investigated to encompass the range of practical methods encountered on site. Specimens were placed in the hot environment immediately after casting and conditioned for up to 28 days. The strength of the GGBFS concretes was higher than that of the OPC control concrete at all test ages (7, 14, and 28 days) when good curing was provided. Partial cement replacement with GGBFS therefore offers the potential to produce stronger and more durable concrete in hot climates. The disadvantage of GGBFS concretes is that they proved to be more sensitive to poor curing than OPC concrete. In this case, both their strength and permeability, and hence their durability, were seriously impaired. Therefore, special care must be taken when using this type of concrete, especially on site, where the working conditions and the application of curing are not as easy to control as in the lab.

9A199. **Microstructure of the interfacial zone around aggregate particles in concrete.** - JA Larbi *(TNO Build and Construct Res, Dept of Build Tech, Rijswijk, Netherlands)*. Heron 38(1) 3-69 (1993).

The study is aimed at examining the microstructural characteristics of the interfacial region around aggregate particles in concrete and exploring the influence of this interfacial zone on some of the properties of concrete such as, the compressive strength, the water transport capacity, and the diffusion of ions into concretes prepared with and without mineral additives.

9A200. **Mutual compatibility of mortar and concrete in composite members.** - N Ignatiev *(Dept of Civil Eng, Univ of Architect and Civil Eng, Sofia, Bulgaria)* and S Chatterji *(Danish Tech Inst, Copenhagen, Denmark)*. Cement & Concrete Composites 14(3) 179-183 (1992).

In many countries, a layer of cement-sand mortar is applied to concrete structures, either for decoration or protective purposes. Often this mortar layer develops a crack pattern soon after it application. Reasons for this crack formation have been investigated. A physicochemical and a mathematical analysis show that this is due to an incompatibility between the properties of the mortar layer and the underlying concrete, and that this crack formation will occur even when both the components are individually made with the best materials. This crack formation could be avoided only by adjusting the properties of the mortar layer. A few typical examples have been worked out to show the effect of this incompatibility on the age of crack formation.

256D. CARBON FIBER REINFORCED MEDIA

9A201. **Effect of fiber concentration on the thermal conductivity of a polycarbonate-pitch-based carbon fiber composite.** - A Demain and J-P Issi *(Unite Physico-Chimie Phys Mat, Univ Catholique Louvain, Place Croix du Sud 1, B-1348 Louvain-la-Neuve, Belgium)*. J Composite Mat 27(7) 668-683 (1993).

Results of measurements of the thermal and electrical conductivities of polycarbonate samples as a function of chopped pitch-based carbon fiber concentration are reported. The fibers, roughly 500 μm long, were found to be strongly oriented in the composite leading to a highly anisotropic thermal conductivity. We proposed a new model which is a derivation of equations used for continuous fibers composites. This model is quite well in accordance with the linear dependence of the longitudinal thermal conductivity on the fiber concentration of our data.

9A202. **Increasing the limit of usability of CFRP tubes by built in stresses.** - RG Cuntze *(MAN Tech AG, Bauschingerstr 20, D 8000 Munchen 50, Germany)* and R Heibel *(URENCO, Oxford Rd, Marlow SL7 2NL, UK)*. Composite Struct 24(3) 251-264 (1993).

The limit of usability of a CFRP structure is often determined by first ply failure (FPF) indicated by interfiber-matrix cracking. It will be shown how for certain types of CFRP structures this crack initiation threshold can be delayed. The process used here is prestraining in analogy to that of prestressed concrete. It is so-called thermo-mechanical after treatment, inducing advantageous compression built-in stresses, ie, negative strains transverse to the fibers. Cylindrical tube specimens were wound, prestrained and submitted to hydraulic pressurization or spin load testing. Acoustic emission monitoring and crack counting following sectioning confirmed and an increase in crack threshold level for this specimen type from $\epsilon_{hoop} \approx 0.8\%$ to 1.3%, which is higher than the operational strain, normally defined as tensile failure strain $e^{\parallel}$ of the fiber divided by the usual design factor $j_u = 1.5$. Theoretical investigations were done in support of the design of the prestraining device and of the tube specimen, as well as an evaluation of experimental data.

256F. OTHER FIBER REINFORCED MEDIA

9A203. **Anelastic deformation of a thermoplastic-matrix fiber composite at elevated temperature Part I.** Neat resin structure characterization. - AW-L Chen *(Eastman Kodak, Rochester NY)*, A Miyase *(Univ of Houston, Houston TX 77204)*, PH Geil *(Natl Center for Composite Mat Res, Col of Eng, Univ of Houston, 1304 W Green St, Urbana IL 61801)*, SS Wang *(Univ of Houston, Houston TX 77204)*. J Composite Mat 27(9) 862-885 (1993).

This is part of a series of articles on the properties of thermoplastic polyamide matrix [PACM-12, DuPont, poly(bis-4-4'-dicyclohexylmethane) n-dodecane-diamide]/graphite fiber (AS4, Hercules) composite. The structural characterization of the neat resin by differential scanning calorimetry (DSC) and X-ray diffraction as a function of processing history is described here. PACM-12, considered a representative thermoplastic matrix polymer for advanced composites, as well as an engineering plastic, is partially crystalline (ca 20%) under normal composite processing conditions, but can be quenched to a completely amorphous state. The complex DSC results are shown to result, at least in part, from the presence of a different crystal structure in slow cooled PACM-12 than in quenched, annealed or fiber samples, to a melting-re-crystallization-melting process during heating and to the effect of heating rate.

9A204. **Anelastic deformation of a thermoplastic-matrix fiber composite at elevated temperature Part II.** Time-temperature dependent matrix behavior. - A Miyase *(Dept of Mech Eng, Univ of Houston, Houston TX 77204)*, AW-L Chen *(Eastman Kodak, Rochester NY)*, PH Geil *(Natl Center for Composite Mat Res, Col of Eng, Univ of Illinois, Urbana IL 61801)*, SS Wang *(Dept of Mech Eng, Univ of Houston, Houston TX 77204)*. J Composite Mat 27(9) 886-907 (1993).

The tensile deformation and failure behavior, dynamic mechanical properties and creep behavior of PACM-12 (DuPont, poly(bis 4-4' dicyclohexylmethane n-dodecanediamide), a representative thermoplastic polymer for use as a matrix in advanced composites and as an engineering plastic, as a function of processing history are described. Although injection molded PACM-12 fails in a brittle fashion at room temperature, completely amorphous PACM-12 is ductile; the difference is attributed to variations in cooling in the interior of the samples due to sample thickness effects. Partially crystalline samples are brittle at room temperature, with all samples being ductile near and above T_g. A master creep curve for the partially crystalline samples can be obtained by horizontal shift alone.

9A205. **Anelastic deformation of a thermoplastic-matrix fiber composite at elevated temperature Part III.** Structure and thermomechanical properties of AS4-PACM-12 composite. - A Miyase, SS Wang *(Dept of Mech Eng, Univ of Houston, Houston TX 77204)*, AW-L Chen *(Eastman Kodak, Build 35 Kodak Park, Rochester NY 14650)*, PH Geil *(Dept of Mat Sci and Eng, Univ of Illinois, Urbana IL 61801)*. J Composite Mat 27(9) 908-920 (1993).

Structural characterization of AS4-graphite fiber-PACM-12 matrix composites was conducted using Differential Scanning Calorimetry (DSC) and Wide-Angle X-Ray Diffraction (WAXD) analyses. The DSC results indicate the significant effect of processing variables on the morphology, microstructure and crystallinity of the fiber reinforced semicrystalline thermoplastic matrix prepreg and unidirectional laminates. From WAXD results the crystallinity was determined. Time-temperature dependent thermomechanical properties of the laminates were evaluated using dynamic mechanical spectroscopy and creep compliance measurements. Dynamic mechanical spectra revealed the matrix-dominated time-temperature dependent behavior of the laminate under torsional loading. Elevated temperature creep compliance in the longitudinal direction showed time-temperature independent behavior whereas transverse creep deformation was found to be significantly time-temperature-stress dependent.

9A206. **Application of the statistical strength model of fiber-reinforced composites.** - YT Zhu and Guisheng Zong *(Center for Mat Sci and Eng, Univ of Texas, Austin TX 78712-1063)*. J Composite Mat 27(9) 944-959 (1993).

Further research was done on the previously reported unidirectional fiber-reinforced composite tensile strength model so as to overcome the mathematical difficulties in its applications. A computer program was developed to calculate the composite strength based on the composite strength model. With this computer program, the composite tensile strength can be directly calculated once certain basic fiber and matrix properties are known. Comparisons with several other composite strength models showed that this model has the best agreement with experimental data and is relatively easy to use. Applications of this model to the composite strength design were also discussed.

9A207. **Cavity formation during tensile straining of particulate and short fibre metal matrix composites.** - AF Whitehouse and TW Clyne *(Dept of Mat Sci and Metall, Univ of Cambridge, Pembroke St, Cambridge CB2 3QZ, UK)*. Acta Metall Mat 41(6) 1701-1711 (Jun 1993).

The formation of cavities in commercially pure aluminium composites, made by both powder and casting routes and reinforced with alumina (short fibres, angular particles and spherical particles), has been monitored using periodic density measurements during tensile testing and microstructural examinations. Stable cavities always form well before final failure, usually adjacent to the reinforcement, particularly when it is elongated in the loading direction and has a relatively flat surface normal to the stress axis. A simple geometrical model is proposed, allowing prediction of the failure strain as a function of the reinforcement content, aspect ratio and strain to failure of the unreinforced matrix. The data presented are in good agreement with predictions from this model.

9A208. **Dimensioning and numerical modeling of metal fiber reinforced concrete (MFRC) structures.** - P Rossi and X Wu *(Lab Central des Ponts et Chaussees, 58 Blvd Lefebvre, 75732 Paris Cedex 15, France)*. Cement & Concrete Composites 14(3) 195-198 (1992).

This paper discusses points related to the inclusion of MFRCs in French design rules and to numerical modeling (FEM) of these fibrous composite materials. It is shown that as the use of these design rules for dimensioning of fiber reinforced concrete structures leads to an inoperative result, it is necessary to develop numerical modeling to justify, mechanically, the interest in this type of application. In this framework, a numerical modeling method is proposed.

9A209. **Effects of material properties and crush conditions on the crush energy absorption of fiber composite rods.** - WH Tao, RE Robertson *(Dept of Mat Sci and Eng, Univ of Michigan, Ann Arbor MI 48109-2136)*, PH Thornton *(Ford Motor, Dearborn MI 48121-2053)*. Composites Sci Tech 47(4) 405-418 (1993).

Crushing along the fiber axis of unidirectional E-glass fiber composite rods was examined to determine the effects of fiber volume fraction, fiber diameter, matrix compressive yield strength, crush rate, fiber surface treatment, and crush plate geometry. The volume specific energy absorption was found to increase with fiber content, fiber diameter, matrix yield strength, and crush rate. The crush load stability was found to be independent of fiber content and fiber diameter but not of matrix yield strength. The crush load became less stable as the yield strength increased. The crush behavior of specimens containing clean fibers was about the same as with sized fibers, but specimens with a release agent on the fiber surface crushed with less energy absorption that decreased even as the fiber content increased, but the crush load was more stable than with sized or clean fibers. The volume specific energy absorption was greater when the rod specimens were crushed against concave surfaces than against a flat plate. A relatively simple model was able to account for the dependence of the energy absorption on fiber volume fraction and matrix yield strength.

9A210. **FE simulation of the micromechanics of interlayered polymer-fiber composites: A study of the interactions between the reinforcing phases.** - V Nassehi, J Dhillon, L Mascia *(Loughborough Univ of Tech, Loughborough, Leicestershire LE11 3TU, UK)*. Composites Sci Tech 47(4) 349-358 (1993).

FE analysis has been applied to study the mechanical behavior of composites with ductile thermoplastic and rubbery interlayers between fibers and matrix. The stress distribution in the transverse direction and the interactions between fibers was investigated with particular emphasis on the effect of varying the modulus and thickness of the interlayers. The results of the analysis show that the use of interlayers is more beneficial at higher fiber volume fractions in enhancing the energy absorbing capabilities of a polymer-fiber composite. In particular, ductile interlayers are clearly shown to have a less detrimental effect than rubbery interlayers on the modulus of coated fiber composites.

9A211. **Interlaminar shear test for fibre-reinforced plastics.** - E Sideridis *(Eng Sci Dept, Tech Univ, Athens, Greece)*, JN Ashton, R Kitching *(Dept of Mech Eng, Univ of Manchester, Inst of Sci and Tech, Manchester, UK)*. Proc Inst Mech Eng E 207(E1) 61-74 (1993).

The measurement of the interlaminar shear strength of glass-reinforced plastic laminates is proposed using an offset four-point bend test on a beam where two (P) of the four forces differ from the other two (Q) and the ratio $\lambda = P/Q$ depends upon the relative positions along the beam. The paper describes the development of this test which appears simpler, more economic and more realistic in many aspects than other test methods. It is demonstrated theoretically and experimentally that the span length (L), thickness (t) and the ratio λ are important test parameters in determining whether the failure is by shear or by flexure.

9A212. **Plastic strain distribution and texture development in fiber composites.** - RE Bolmaro, FM Guerra, UF Kocks, RV Browning *(Center for Mat Sci, LLNL)*, PR Dawson *(Dept of Mech and Aerospace Eng, Cornell)*, JD Embury, WJ Poole *(McMaster Univ, Hamilton, ON, Canada)*. Acta Metall Mat 41(6) 1893-1905 (Jun 1993).

A model situation – plane-strain deformation of a composite with many infinitely long, regularly arranged, undeformable fibers perpendicular to the plane of straining – has been analyzed by FE simulation of an isotropic continuum and subsequent polycrystal simulation of texture development for the strain and rotation paths of some characteristic material points. The principal effect of the inclusions is a change in flow pattern in the area far away from them; by comparison, "dead-zone" or "cluster" effects in the immediate vicinity of the inclusions are quite small in extent. The changed flow pattern in about half the matrix material consists of shears and rotations that change both with progressing deformation and with location.

9A213. **Prediction of the overall moduli of a cylindrical short-fiber reinforced composite.** - Shanyi Du and Linzhi Wu *(Harbin IT, Harbin 150006, China)*. Acta Mech Sinica 9(1) 53-60 (1993).

With respect to the effective elastic moduli of the composite, the present theory differs from both Eshelby's equivalent inclusion method and Hill's self-consistent one, both of which only consider the mechanical properties of the matrix and the inclusion (fibers). In fact, the inclusion-inclusion interaction is more pronounced when the volume fraction of inclusions of the composite increases. Hence, in this paper the effective elastic moduli of the composite are derived by taking into account the shapes, sizes, and distribution of inclusions, and the interactions between inclusions.

9A214. **Temperature resistant glass fiber-epoxy composites.** - W Eichberger *(Isovolta, Osterreichische Isolierstaffwerke AG, A-2355 Wiener Neudorf, Austria)*. Composite Struct 24(3) 205-212 (1993).

This paper deals with a new group of epoxy-resin based composites developed by Isovolta which exhibit properties close to those of expensive advanced composites but with price levels closer to those of conventional thermosetting composites. Efforts in the field of epoxy resin chemistry led to the development of a special resin-hardener system, the so-called Isoval system, which is used to produce laminates that have served the electrical industry for many years. Continuing improvements of this resin system and in-depth studies of the properties of those laminates showed that they possess vastly superior temperature and chemical resistance in comparison to standard epoxy resin composites. Laminates and prepregs based on this resin system (Isoval and Isopreg) offer composites which are economical, have long-term temperature endurance between 180 and 200°C and can be heated to temperatures up to 300°C for short periods of time.

9A215. **Unit cell geometry of 3D braided structures.** - Guang-Wu Du and Frank K Ko *(Fibrous Mat Res Lab, Drexel Univ, Philadelphia PA 19104)*. J Reinforced Plastics Composites 12(7) 752-768 (Jul 1993).

The traditional approach used in modeling of composites reinforced by 3D braids is to assume a simple unit cell geometry of a 3D braided structure with known fiber volume fraction and orientation. In this article, we first examine 3D braiding methods in the light of braid structures, followed by the development of geometric models for 3D braids using a unit cell approach. The limiting geometry has been computed by establishing the point at which yarns jam against each other. Using this factor makes it possible to identify the complete range of allowable geometric arrangements for 3D braided preforms.

9A216. **Compression of laminated composite beams with initial damage.** - NL Breivik, Z Gurdal, OH Griffin JR *(Dept of Eng Sci and Mech, VPI)*. J Reinforced Plastics Composites 12(7) 813-824 (Jul 1993).

Compression testing is conducted for specimens with well-documented initial damage states obtained from three-point bending testing. Strengths and failure modes are determined for specimens with four quasi-isotropic stacking sequences and two thicknesses. Initial damage prior to compression testings is divided into three classifications based on the extent and location of the damage. It was found that specimens with short multiple delaminations experienced the greatest reduction in compression strength compared to the undamaged specimens. All of the sublaminates formed by the delamination failed at the same time with no indication of sublaminate buckling.

9A217. **Design of composite laminates by a Monte Carlo method.** - Chin Fang and GS Springer *(Dept of Aeronaut and Astronaut, Stanford)*. J Composite Mat 27(7) 721-753 (1993).

A Monte Carlo procedure was developed for optimizing symmetric fiber reinforced composite laminates such that the weight is minimum and the Tsai-Wu strength failure criterion is satisfied in each ply. The laminate may consist of several materials including an idealized core, and may be subjected to several sets of combined in-plane and bending loads. The procedure yields the number of plies, the fiber orientation, and the material of each ply and the material and thickness of the core. A user friendly computer code was written for performing the numerical calculations. Laminates optimized by the code were compared to laminates resulting from existing optimization methods.

9A218. **Finite-rotation theories for composite laminates.** - Y Basar *(Inst Konstruktiven Ingenieurbau, Ruhr-Univ Bochum, Lehrstuhl Statik und Dynamik, D-W 9630 Bochum, Germany)*. Acta Mech 98(1-4) 159-176 (1993).

For the FE analysis of arbitrary composite laminates various finite-rotation theories are presented in a single formulation. First a refined theory is derived which allows a quadratic shear deformation distribution across the thickness. The so-called difference vector appearing in the kinematic relations is expressed in terms of rotational dof permitting a clear determination of the deformed normal vector in every nonlinear range. The constitutive relations derived are applicable to orthotropic material properties varying arbitrarily across the thickness and to curvilinear laminate coordinates as well. This refined theory is then transformed into simplified theories of Kirchhoff-Love and Mindlin-Reissner types.

9A219. Mechanical properties for CFRP-damping-material laminates. - Jun Fujimoto, Tetsuya Tamura *(Resources and Env Protection Res Lab, NEC, 1-1 Miyazaki 4-chome Miyamae-ku Kawasaki, Kanagawa 216, Japan)*, Kazuhide Todome *(Space Dev Div, NEC, 4035 Ikebe-cho Midori-ku Yokohama, Kanagawa 227, Japan)*, Toshio Tanimoto *(Dept of Mat Sci and Ceramic Tech, Shonan IT, 1-1-25 Tsujido-nishikaigan Fujisawa, Kanagawa 251, Japan)*. J Reinforced Plastics Composites 12(7) 738-751 (Jul 1993).

New materials that possess high damping capabilities and have high strength properties have been studied in carbon fiber reinforced plastics (CRFP). These materials are referred to in this article as CFRP-damping-material laminates. The CFRP-damping-material laminates investigated here are composed of a unidirectional carbon-epoxy prepreg sheet and a polyethylene-based damping material sheet used as an interleaf. Cantilever beam tests revealed the high damping properties of these laminates. Tensile test results for quasi-isotropic laminated based composites indicated that the damping material interleaf is effective for suppressing delamination and multiple splitting in the 0° angle layer.

9A220. Probabilistic methods for the calculation of laminate properties. - HL McManus *(Rm 33-311, MIT)*. J Reinforced Plastics Composites 12(6) 712-722 (Jun 1993).

A method for calculating the properties of advanced composite laminates, including their variations due to known variations in the properties of the individual plies and the laminate geometry, is presented. The method is useful for understanding scatter in the measured properties of composite laminates. The scatter is particularly important in the design of ultra-low coefficient of thermal expansion (CTE) laminates. Such laminates are designed with a theoretically zero CTE, but in practice have a distribution of non-zero CTEs. Information useful for designing ultra-low expansion laminates is discussed.

256J. MICROMECHANICS

9A221. From micro to macroproperties of polymer based composite systems by integration of the characteristics of the interphase regions. - AH Cardon *(Composite Syst and Adhesion Res Group of the Free Univ Brussels, VUB TW-KB, Pleinlaan 2, B-1050 Brussels, Belgium)*. Composite Struct 24(3) 213-217 (1993).

After an overview and discussion about the amount of information on the interphase region given by classical "single number" characterization methods such as ILST, pull-out and fragmentation tests, different models of the interphase region considered as classical continuum are analyzed. A model is proposed, based on an interphase region with varying properties. By integration of those varying properties over the thickness of the interphase region, from the bulk properties of one phase to those of the other phase, assuming the transverse dimensions as very small, the control parameters, or integrated moduli, of the interphase region are obtained. This model indicates the importance of the gradients of the properties of the interphase region on the stress transfers between the original phases. The application of this model under specific stress states used for the classical mechanical "single number" tests can give insight in the physical meaning of the results of those tests and can give a rational way to compare the scales for the results of those tests.

9A222. Micromechanical behavior of Kevlar-149 and S-glass hybrid seven-fiber microcomposites I. Tensile strength of the hybrid composite. - Yiping Qiu *(Dept of Mech Eng, MIT)* and P Schwartz *(Fiber Sci Program, Cornell)*. Composites Sci Tech 47(3) 289-301 (1993).

To understand the mechanism of the hybrid effect on the tensile properties of "hybrid" composites, single fiber type and hybrid microcomposites were fabricated by using Kevlar-149 as the low elongation fiber and S glass fibers as the high elongation fiber, in a DER 331-DER 732 epoxy mixture (70/30, w/w). Kevlar-149 fiber showed a significantly higher tensile strength in the microcomposite than as a single filament. For the hybrid, Kevlar-149 fibers usually broke one by one. A positive hybrid effect for the failure strain but a negative hybrid effect for the strength of the hybrid were observed. Tensil strength of the microcomposites predicted by Monte Carlo simulation agreed with the experimental results reasonably well. The tensile modulus of the hybrid followed the rule of mixtures.

9A223. Micromechanical behavior of Kevlar-149 and S-glass hybrid seven-fiber microcomposites II. Stochastic modeling of stress-rupture of hybrid composites. - Yiping Qiu *(Dept of Mech Eng, MIT)* and P Schwartz *(Fiber Sci Program, Cornell)*. Composites Sci Tech 47(3) 303-315 (1993).

To understand the stress-rupture behavior of hybrid composites, single-fiber type (SFT) and hybrid microcomposites were fabricated with Kevlar 149 as the low-elongation fiber and S-glass as the high-elongation fiber in a DER 331-DER 732 epoxy mixture (70/30, w/w). The microcomposites were stress-rupture tested at 80, 85, and 90% of their Weibull scale parameters for tensile strength. Both the model and the stress-rupture tests of the hybrid and Kevlar 149 SFT microcomposites indicated that there is a negative hybrid effect for lifetime at high stress ratio while a positive hybrid effect exists at low stress ratio. The higher fraction of the total load for each LE fiber was responsible for the negative hybrid effect at high stress ratio, while smaller static and dynamic overstress was beneficial to the positive hybrid effect at low stress ratio.

9A224. Microstructure and mechanical properties of mullite-zirconia reaction-sintered composites. - R Torrecillas *(Inst Tec Mat, 33428 Llanera, Asturias, Spain)*, JS Moya, S De Aza *(Inst Ceramica, Vidrio CSIC, Arganda del Rey, 28500 Madrid, Spain)*, H Gros, G Fantozzi *(GEMPPM INSA de Lyon, 69621 Villeurbanne, Cedex, France)*. Acta Metall Mat 41(6) 1647-1652 (Jun 1993).

The flexural strength, fracture toughness (K_{IC}), creep behavior and thermal shock of mullite-zirconia and mullite-zirconia-alumina composites obtained by reaction-sintering of zircon + alumina mixtures have been studied in the temperature interval ranging from room temperature to 1400° C. The results are discussed in terms of the microstructural features of the reaction-sintered composites.

256N. DYNAMIC BEHAVIOR

9A226. Aspects of dynamic mechanical analysis in polymeric composites. - M Akay *(Dept of Mech and Indust Eng, Univ of Ulster, Newtownabbey Co Antrim, N Ireland BT37 0QB, UK)*. Composites Sci Tech 47(4) 419-423 (1993).

Patterns of behavior of dynamic and mechanical properties in the glass transition region have been considered and it is shown that the tan δ peak always occurs at a higher temperature than the E" peak. The temperature interval between the peaks varies significantly in unidirectional carbon-fiber-epoxy laminates, depending on the fiber orientation with respect to the applied load. The E" peak is shown to be a more consistent indicator of the behavior of the composites. Fiber incorporation reduces viscoelastic damping beyond that possible by matrix volume reduction alone. This was observed in various fiber reinforced polymers and is explained in terms of fiber matrix interactions.

9A227. Experimental study on the use of static effective modulus theories in dynamic problems. - JJ Ditri and JL Rose *(Dept of Eng*

Sci and Mech, 114 Hallowell Bldg, Penn State). J Composite Mat 27(9) 934-943 (1993).

In a recent paper the effective elastic constants of a $[0, \pm45, 0]_{34}$ graphite epoxy laminated composite were determined by ultrasonic wave velocity information, and the Young's moduli calculated from these constants were compared to those obtained using a quasi-static loading technique for six different directions. In this article, the previously obtained results are compared to those predicted using a 3D static effective modulus theory. It is shown that, if low frequency ultrasonic waves are used, the calculated Young's moduli compare favorably with both the static measurements and those predicted by the effective modulus theory. Comments on the applicability of the various measurement techniques for different purposes are also discussed.

9A228. **Impact characterization of graphite fiber reinforced thermoplastic laminates.** - J Chaudhuri, GH Choe *(Dept of Mech Eng, Natl Inst for Aviation Res, Wichita State Univ, Wichita KS 67208)*, JR Vinson *(Dept of Mech Eng, Univ of Delaware, Newark DE 19716)*. J Reinforced Plastics Composites 12(6) 677-685 (Jun 1993).

Instrumented drop-weight impact testings were conducted in conjunction with the ultrasonic C-scan and scanning electron microscopy to characterize the impact response at low velocities. Thermoplastic composite materials in the simply supported case showed dramatic improvements in impact damage resistance compared to the thermoset composite materials as reported. Scanning electron microscopy examination of the fracture surface revealed fiber-matrix-debonding, fiber pull-out, and few delaminations. Matrix behavior can be characterized by a hackly appearance.

256Q. STRUCTURAL APPLICATIONS

9A229. **Composites with multiple cutouts.** - TJ Walsh and OO Ochoa *(Center for Mech of Composites, Dept of Mech Eng, Texas A&M Univ, College Station TX 77843-3123)*. Composite Struct 24(2) 117-124 (1993).

An experimental and analytical study of composite coupons and panels with multiple cutouts are presented. Coupons with circular and rectangular cutouts with aligned and staggered hole configurations were examined under tensile loads. 2D and 3D FE analysis is utilized to predict in-plane and interlaminar stress response, respectively. A stiffened hat panel is selected as the structural component to illustrate the effects of cutouts in actual composite parts. Throughout testing, C-scans and X-ray photographs were utilized to document the damage formation. Both numerical and experimental results highlighted the presence of reduced stress fields in the vicinity of the rectangular cutout versus the circular.

9A230. **Construction and analysis of high performance composites.** - B Knauer *(Inst fur Luftfahrttechnik und Leichtbau EV, Elsasser str 7/204, 0-8019, Dresden, Germany)*. Composite Struct 24(3) 181-191 (1993).

High performance composites are defined here, and they are classified in a general survey of polymer composites. The memory and computer aided design will be promoted and generalized. For calculations, refer to norm-standards and software. The proof of reliability has been calculated by the method of marginal maintains. The designing of, and the designing with high performance composites will be based on the static, dynamic, and tribologic load.

9A231. **Experimental and analytical investigation of composite drive shafts with noncircular end cross-sections.** - RS Gross *(Aerospace Eng Dept, Auburn Univ, 211 AE Bld, Auburn AL 36849)* and JG Goree *(Dept of Mech Eng, Clemson Univ, Clemson SC 29634)*. J Composite Mat 27(7) 702-720 (1993).

An optimization methodology is presented for the selection of the end cross-sectional shape of composite torque tubes (drive shafts) with noncircular end geometries. In a typical application, metal inserts are adhesively bonded in the ends of the tubes to allow for torque transmission. The worst case scenario of bond failure with subsequent torque transmission via insert-tube contact is considered. Optimization of the tube end cross-sectional shape under this worst case situation is the goal of this study. This methodology is verified through comparison with experimental data. Results obtained from the analytical and experimental studies indicate a spline-like cross-sectional shape as the optimal design.

9A232. **Analysis of thin-walled composite beams by energy method.** - KB Subrahmanyam *(Dept of Mech Eng, NBKR Inst of Sci and Tech, Vidyanagar 524 413 Nellore District, Andhra Pradesh, India)*. J Reinforced Plastics Composites 12(6) 642-669 (Jun 1993).

Utilization of fiber reinforced plastics in the aerospace structures has become commonplace recently. However, considerable amount of research work is needed to understand the various coupling phenomena that arise from the use of the FRP materials, and in efficiently modeling the coupling behavior in analytical formulations. The present effort describes the formulation and solution of FRP box beam type of structures through the use of the total potential energy functional in conjunction with the Ritz method. Results obtained from the present effort are compared to those obtained from a FE formulation and also to those from experimental results available in the literature.

9A233. **Overall potentials and extremal surfaces of power law or ideally plastic composites.** - PM Suquet *(Lab Mec Acoustique, CNRS, 31 Chemin Joseph Aiguier, 13402 Marseille Cedex, 20, France)*. J Mech Phys Solids 41(6) 981-1002 (Jun 1993).

A method is proposed for bounding the overall properties of a class of composite materials in terms of the properties of the individual phases and of their arrangements. It applies to power law materials and, as a special case, to rigid ideally plastic materials. A link between the overall potential of a nonlinear composite and the overall energy of a fictitious linear composite is presented with no assumptions on the arrangement of the phases. With this method, any upper bound available for linear materials can easily be transposed to nonlinear materials. A new characterizing of the extremal surface of ideally plastic composites is given.

9A234. **Analysis of a mini-sandwich compression test specimen.** - Seng C Tan *(Wright Mat Res, PO Box 31667, Dayton OH 45431)*. Composites Sci Tech 47(4) 369-382 (1993).

Mini-sandwich compression specimens have been analyzed by using a rule-of-mixtures approach and a FEM which takes into account the mechanical and nonmechanical loadings. The results of stress analysis are illustrated for an $[(AS4/3501\text{-}6)/3501\text{-}6]_s$ specimen and an $[(AS4/APC\text{-}2)/APC\text{-}2]_s$ specimen as examples. Both specimen configurations contain face sheets consisting of two plies of 0° orientation. The compressive strengths of these two unidirectional composites were computed from the experimentally measured strengths of the minisandwich specimen and the stress state predicted by the present analysis. The present result shows that a rule-of-mixtures approach can cause considerable error in the interpretation of the compressive strength of unidirectional face sheets. Procedures for the accurate determination of the compressive strength of the face sheets for mini-sandwich specimens are presented. A simplified nonlinear approach reveals that it is important to consider the final tangent or secant material properties rather than the initial material properties to obtain accurate stress distributions of the specimen prior to failure.

9A235. **Four-point bending tests on off-axis composites.** - M Grediac *(Dept Mec and Mat, Ecole Natl Superieure des Mines de Saint-Etienne, 158, cours Fauriel, 42023 Saint-Etienne Cedex 2, France)*. Composite Struct 24(2) 89-98 (1993).

This paper deals with the accurate measurement of longitudinal off-axis bending compliances of composites using four-point bending tests. The effect of supports that induce additional twisting moments is examined analytically, numerically, and experimentally. A new testing device allowing the rotation of the tested sample about its principal axis is described and used to assess longitudinal bending compliances of several specimens. It is shown that usual four-point bending devices provide apparent compliances that are lower than actual ones.

9A236. **Measurement of residual stresses in sapphire fiber composites using optical fluorescence.** - Qing Ma and DR Clarke *(Mat Dept, UC, Santa Barbara CA 93106)*. Acta Metall Mat 41(6) 1817-1823 (Jun 1993).

The residual stresses in c-axis sapphire fibers in a γ-TiAl matrix and in a polycrystalline Al_2O_3 matrix as a function of distance below a surface are determined. They are obtained from the shift in frequency of the characteristic R_2 fluorescence line of chromium in sapphire obtained by focusing an optical probe at different depths in a sapphire fiber intersecting the surface of the composite. The method is described together with its calibration. Both the axial and radial components of the residual stress in the fiber are observed to vary over a depth of approximately the fiber diameter and are then almost independent of depth.

9A237. Whole-field strain analysis of the Iosipescu specimen and evaluation of experimental errors. - YM Xing, CY Poon, C Ruiz *(Dept of Eng Sci, Univ of Oxford, OX1 3PJ, UK)*. Composites Sci Tech 47(3) 251-259 (1993).

A whole-field strain analysis is performed on the Iosipescu specimen by both moire interferometry and the FEM. The strain distribution outside and within the test section is examined for a graphite-epoxy woven (0°, 90°) laminate specimen. The effect of factors such as twist, bending moment and loading points, which cause the experimental errors, is studied.

9A238. Strength and stiffness of a flexible high-pressure spiral hose. - PC Bregman *(Trelleborg BV, PO Box 33, NL-9600 AA Hoogezand, Netherlands)*, M Kuipers *(Fac of Math and Phys Sci, Dept of Math, Univ of Groningen, PO Box 800, NL-9700 AV Groningen, Netherlands)*, HLJ Teerling *(Trelleborg BV, PO Box 33, NL-9600 AA Hoogezand, Netherlands)*, WA van der Veen *(Fac of Math and Phys Sci, Dept of Math, Univ of Groningen, PO Box 800, NL-9700 AV Groningen, Netherlands)*. Acta Mech 97(3-4) 185-204 (1993).

We consider a flexible high-pressure rubber hose with separate reinforcing cylinders which each consist of one family of spiralized fibres. The straight tube is radially and axially loaded by an internal pressure. This paper gives an approximate analysis of the stresses and strains occurring in the rubber and the filaments. Some numerical values could be compared with experimental findings obtained by Trelleborg BV, Hoogezand. It appeared possible to estimate some unknown parameters, introduced in the approximate calculation model beforehand, so that a reasonable agreement between the theoretical and empirical findings could be attained.

9A239. Effect of axial restraints on the deflection of strain hardening beams. - AN Sherbourne and F Lu *(Dept of Civil Eng, Univ of Waterloo, ON, N2L 3G1, Canada)*. Int J Mech Sci 35(5) 397-423 (May 1993).

Centrally loaded, rigid-linear strain hardening rectangular beams with variable axial restraints are investigated. Load-deflection solutions are presented for beams with four common types of end conditions. It was found that the effect of strain hardening cannot be neglected, especially for beams of larger depth to length ratios. By considering strain hardening, the influence of such beam depth to length ratio on the load-deflection curve can be quantified and the length of the plastic zone estimated.

9A240. Minimizing deflection and bending moment in a beam with end supports. - SV Amiouny, JJ Bartholdi III, JH Vande Vate *(Sch of Indust and Syst Eng, Georgia Tech)*. Mech Struct Machines 21(2) 167-184 (1993).

In this paper, heuristics are given to sequence blocks on a beam, like books on a bookshelf, to simultaneously minimize the maximum deflection and maximum bending moment of the beam. For a beam with simple supports at the ends, one heuristic places the blocks so that the maximum deflection is no more than $16/9\sqrt{3} \approx 1.027$ times the theoretical minimum and the maximum bending moment is within four times the minimum. Similar results hold for beams with fixed supports at the ends.

9A241. Detachment of an elastic beam from a viscoelastic support: A variational approach. - A Drozdov and I Gertsbakh *(Dept of Math and Comput Sci, Ben Gurion Univ of the Negev, Beer-Sheva, Israel)*. Int J Mech Sci 35(6) 463-478 (Jun 1993).

The paper is devoted to the analysis of failure in multi-layer composite materials. For the experimental study of the failure mechanisms, the peel tests are used. The peel test is modeled as the detachment of an elastic beam attached to a rigid adherend by a viscoelastic adhesive layer. For solving this problem, we use the principle of minimum free energy and derive a new energy criterion for the detachment. We propose a model of aging viscoelastic material describing the viscoelastic behavior in terms of elastic objects. Using this model we propose an expression for the specific potential energy of an aging viscoelastic medium and derive a new formulation of the principle of minimum free energy for a viscoelastic system. A numerical method for solving nonlinear integro-differential equations describing the detachment process is developed, and its convergence is established. We analyze numerically the dependence of the detachment on the construction and material parameters, and on the loading history. We demonstrate the existence of a limited training effect, which allows considerable reduction of the detachment zone by a special preliminary loading program ("training").

9A242. Mechanics of thin-walled laminated composite beams. - EJ Barbero *(Dept of Mech and Aerospace Eng, W Virginia Univ, Morgantown WV 26506-6101)*, R Lopez-Anido, JF Davalos *(Dept of Civil Eng, W Virginia Univ, Morgantown WV 26506-6101)*. J Composite Mat 27(8) 806-829 (1993).

A formal engineering approach of the mechanics of thin-walled laminated beams based on kinematic assumptions consistent with Timoshenko beam theory is presented. Thin-walled composite beams with open or closed cross sections subjected to bending and axial load are considered. A variational formulation is employed to obtain a comprehensive description of the structural response. An explicit expression for the static shear correction factor of thin-walled composite beams is derived from energy equivalence. A numerical example involving a laminated I-beam is used to demonstrate the capability of the model for predicting displacements and ply stresses.

9A243. Linear and geometrically nonlinear analysis of composite beams under transverse loading. - K Chandrashekhara *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)* and KM Bangera *(EGS Inc, Oak Park MI 48237)*. Composites Sci Tech 47(4) 339-347 (1993).

The flexural analysis of fiber-reinforced composite beams based on a higher-order shear deformation theory is studied. The geometric nonlinearity is incorporated in the formulation by considering the von Karman strains. The FEM is used to solve the nonlinear governing equations by direct iteration. Unlike conventional beam models, the present beam model accounts for y direction strains. It is observed that the solution obtained from the two approaches differ slightly in the case of cross-ply laminates, but there exists a considerable difference in the case of angle-ply laminates. The influence of boundary conditions, beam geometries, and ply orientations on the deflections and stresses of laminated beams is shown both in tabular and graphical form.

9A244. NDT and structural condition monitoring of mechanical cables. - PAA Laura *(Inst of Appl Mech (CONICET-SENID-ACCE) and Dept of Eng, Univ Nacional del Sur, 8000 Bahia Blanca, Argentina)*. Appl Mech Rev 46(4) 133-138 (Apr 1993).

This article concerns the problem of evaluating the structural health of cables or ropes by means of non-destructive testing methods. Special emphasis is placed upon electromagnetic techniques and the acoustic emission method.

9A245. Cracked plates subjected to out-of-plane tearing loads. - MJ Young and CT Sun *(Sch of Aeronaut and Astronaut, Purdue)*. Int J Fracture 60(1) 1-18 (1 Mar 1993).

Cracked plates subjected to out-of-plane tearing loads were investigated using both classical plate theory and Reissner-Mindlin plate theory. It was shown that the total strain energy release rate according to Reissner-Mindlin plate theory converges to that of classical plate theory as the thickness to crack length ratio approaches zero. It was demonstrated that it is not meaningful to separate mode II and mode III strain energy release rates using classical plate theory.

9A246. Family of shear deformation theories for shallow shells. - Z Rychter *(Dept of Arhictec, Tech Univ of Bialystok, Krakowska 9, 15-875 Bialystok, Poland)*. Acta Mech 98(1-4) 221-232 (1993).

Two-dimensional shear deformation type theories for shallow elastic shells are presented as a one-parameter family embedded in a family of 3D displacement and stress fields of uniform order of accuracy throughout the range of the parameter. Families of admissible physical interpretations for the generalized displacement of shell theory are provided, allowing diverse models of geometric boundary conditions to choose from. The relationship between the parameter (shear factor) and the generalized displacements is established. As a special, degenerate case, results for Kirchhoff-Love type shell theories are derived.

9A247. Suitable microcomputer method for the bending analysis of arbitrary quadrilateral plates with general boundary conditions. - Chen Jun *(Changsha Eng Military Acad, Peoples Rep of China)*, Lanfen Li, Sjiuap Long *(Hunan Univ, Peoples Rep of China)*, Y Zhan *(Central South Univ Tech, Peoples Rep of China)*. Adv Eng Software 16(1) 7-13 (1993).

In this paper, a spline Kantorovich method on a cubic B-spline function is presented to obtain an approximate solution for the bending problem of quadrilateral plates with various boundary conditions by the variational principle and bilinear coordinate transformation. The spline Kantorovich method is a typical numerical Kantorovich method, which can, not only, transform 2D problems into 1D problems, but also has the advantages of the spline method, such as high precision and rapid convergence. A computational scheme is derived which is well suited to microcomputers. The numerical values of the deflection for arbitrary quadrilateral plates are compared with those from other investigators' methods and the FEM. The solutions to bending problems of trapezoidal, parallelogram and rectangular plates are given as particular examples.

9A248. Upper bound on the collapse load of plate bending by using a quasi-conforming element and the Monte-Carlo method. - Hexiang Lu, Limin Tang, Xiaoling Wang *(Dept of Mech, Dalian Univ of Tech, Dalian 116024, China).* Finite Elements Anal Des 13(1) 65-73 (Apr 1993).

A new method to obtain the upper bound of collapse loads for plates is given by a quasi-conforming element technique and the Monte-Carlo method in this paper. A universal velocity pattern of the collapse for arbitrarily shaped plates is given without need of experimental reference. The advantage of this method is that whenever the collapse load of the plate is calculated, the collapse velocity pattern is obtained as well.

9A249. Dynamic carrying capacity of elasto-visco-plastic cylindrical shells. - A Baltov, O Minchev, J Ivanova *(Dept of Solid Mech, Inst of Mech and Biomech, "Acad G Bonchev", Str Block 4, 1113 Sofia, Bulgaria).* Arch Appl Mech 63(3) 189-194 (Apr 1993).

We consider axially-compressed thin cylindrical shells, which deform elasto-visco-plastically under high intensity external impulsive loading and in which volume damage can occur. The shell carrying capacity is determined in accordance with deformation, stability and strength criteria. Our propose is, introducing special dimensionless parameters, to obtain the relation between the geometrical sizes and the material characteristics of the shell – on one hand and the dynamic impulse parameters (amplitude and duration) on the other, when the shells lose their carrying capacity.

9A250. Bending analysis of laminated plates using a refined shear deformation theory. - Ji-Fan He, Mon Chou, Xiang Zhang *(Dept of Eng Mech, Tsinghua Univ, Beijing, Peoples Rep of China).* Composite Struct 24(2) 125-138 (1993).

In this paper the refinement of a previously published discrete-layer shear deformation laminated plate theory by the assumption that the transverse shear strains across any two layers are linearly dependent on each other is briefly described. The theory contains the same dependent variables as first-order shear deformation theory, but the set of governing differential equations is of the twelfth order. No shear correction factors are required. Solutions for simply-supported symmetric and antisymmetric cross-ply plates are discussed. The numerical results are compared with 3D elasticity solutions and first-order shear deformation theory solutions. The present theory gives a better estimate of the deflections and stresses even for fairly thick laminates. For laminates of the same thickness, it is shown that the solution accuracy improves as the number of layers increases.

9A251. Pseudo-transient large-deflection elastic analysis of fibre reinforced composite plates. - T Kant and JR Kommineni *(Dept of Civil Eng, Indian IT, Powai, Bombay 400 076, India).* Eng Comput 10(2) 159-173 (Apr 1993).

A unified approach is presented for the pseudo-transient (static) linear and geometrically nonlinear analysis of composite laminates. A FE idealization with a four-noded linear and a nine-noded quadrilateral isoparametric elements, both belonging to the Lagrangian family are used in space discretization. An explicit time marching scheme is employed for time integration of the resulting discrete ordinary differential equations with the special forms of diagonal fictitious mass and/or damping matrices. The usefulness and effectiveness of this approach is established by comparing computational time required by this approach and Newton-Raphson's approach.

9A252. Semi-infinite plate on a Winkler base, free along the edge, and subjected to a vertical force. - AD Kerr *(Dept of Civil Eng, Univ of Delaware, Dupont Hall, Newark DE 19716)* and Soon Seop Kwak *(Dept of Architec Eng, Chung Buk Natl Univ, Cheong Ju, Chung-Buk 360-763, Korea).* Arch Appl Mech 63(3) 210-218 (Apr 1993).

At first, a brief review of published data analyzed for related problems is presented. Then a new solution is derived for the case when plate is subjected to a concentrated force at any point on the plate. As in the reviewed papers, the analysis is based on the linear bending theory of thin plates. The solution procedure utilizes the closed-form Green's function for the infinite plate, in conjunction with the Fourier integral method. The advantage of the present approach is that the characteristic response of the plate near the load is represented by the closed-form Green's function which contains the proper singularity, whereas the other terms represent the correction due to the free edge.

9A253. Elastic and inelastic analysis of variable thickness plates, using equivalent systems. - DG Fertis and Chin T Lee *(Univ of Akron, Akron OH).* Mech Struct Machines 21(2) 201-236 (1993).

This paper develops a closed-form solution that can be used for both elastic and inelastic analysis of thin rectangular and circular plates with variable thickness in 1D. The solution is given in the form of an equivalent system of flat plates that replaces the original variable thickness plate. At a given point, the sum of the deflections, rotations, bending moments, or bending stresses of the flat plates is equal to that of the corresponding elements of the original variable thickness plates. A simplified equivalent system of constant rigidity is also obtained, in order to reduce the mathematical complexity of the variable thickness problem. Conclusions are derived by observing the changes in the load-deflection curves and the rigidity variation along one or two dimensions of the plate.

260Y. COMPUTATIONAL TECHNIQUES

9A254. BE for plate bending analysis. - WS Venturini and JB de Paiva *(Sao Carlos Sch of Eng, Univ of Sao Paulo, Av Dr Carlos Botelho 1465, Sao Carlos, SP 13 560, Brazil).* Eng Anal Boundary Elements 11(1) 1-8 (1993).

This paper is related to the applications of BEM to practical plate bending problems in engineering. Some aspects of the boundary formulations are shown, describing particular characteristics that can be considered to improve numerical solutions. Several different ways of defining the BE system of equations are proposed. Comparisons among them are also shown emphasizing some interesting behaviors.

9A255. BE analysis of the paradox circle-polygon in plate bending. - JB de Paiva *(Eng Sch of Sao Carlos, Univ Sao Paulo, 13 560 Sao Carlos, SP, Brazil).* Eng Anal Boundary Elements 11(2) 157-163 (1993).

A BE analysis of the so-called circle polygon paradox is presented and the results show that a polygon simply-supported plate does not converge to a circular supported plate, as the number of sides increase to infinity due to the boundary condition at the corners of the polygon plate. It shows too that a polygonal plate supported only at its corners does converge to a circular supported one as the number of sides increase to infinity.

9A256. General quadrilateral multilayered plate element with continuous interlaminar stresses. - M Di Sciuva *(Dept of Aerospace Eng, Politec Torino, Corso Duca delgi Abruzzi 24, 10129 Turin, Italy).* Comput Struct 47(1) 91-105 (3 Apr 1993).

The purpose of this work is the formulation of a general quadrilateral multilayered anisotropic plate element. The plate element is formulated on the basis of a refined third-order shear deformation plate theory recently proposed by the author. The plate model makes use of a displacement field that fulfills *a priori* the geometric and stress continuity conditions at the interfaces between the layers, and requires only five generalized displacements to describe the kinematics of the laminate deformation. To test the performance of the developed plate element, both closed-form and FE-based solutions are given and compared with results from 3D elasticity and other approximate 2D plate models.

9A257. Generalized conforming quadrilateral plate element by using semi-loof constraints. - Long Zhifei *(Dept of Civil Eng, N Jiaotong Univ, Beijing 100044, China).* Commun Numer Methods Eng 9(5) 417-426 (May 1993).

A 12-DOF quadrilateral element for plate bending is formulated based on the concept of generalized compatibility and semi-Loof constraints. The element DOFs are defined with the conventional displacements at corner nodes and the semi-Loof constraints are used in the formulation. This element is a generalized conforming one which passes Irons' patch test and can be used to solve problems with complicated boundaries. When overall considerations of simplicity, accuracy and reliability are taken into account, this new element is one of the best 12-DOF quadrilateral plate-bending elements currently available.

9A258. New discrete Kirchhoff-Mindlin element based on Mindlin-Reissner plate theory and assumed shear strain fields Part I. An extended DKT element for thick-plate bending analysis. - I Katili *(Dept of Civil Eng, Univ Indonesia, Kampus UI, Depok 16 424, Indonesia)*. Int J Numer Methods Eng 36(11) 1859-1883 (15 Jun 1993).

This is the first of a two-part paper on plate bending elements with shear effects included. This paper presents a new three-node, nine-dof triangular plate bending element valid for the analysis of thick to thin plates. The element, called DKMT, has a proper rank (contains no spurious zero-energy modes), passes the patch test for thin and thick plates in an arbitrary mesh and is free of shear locking. Very good results have been obtained for thin and thick plates by the element. An extended DKQ element for thick-plate bending analysis is evaluated in Part II.

9A259. New discrete Kirchhoff-Mindlin element based on Mindlin-Reissner plate theory and assumed shear strain fields Part II. An extended DKQ element for thick-plate bending analysis. - I Katili *(Dept of Civil Eng, Univ Indonesia, Kampus UI, Depok 16 424, Indonesia)*. Int J Numer Methods Eng 36(11) 1885-1908 (15 Jun 1993).

This is the second of a two-part paper on plate bending elements with shear effects included. This paper presents a new four-node, 12-dof quadrilateral plate bending element valid for the analysis of thick to thin plates. The element called DKMQ, has a proper rank (contains no spurious zero-energy modes), passes the patch test for thin and thick plates in an arbitrary mesh and is free of shear locking. Very good results have been obtained for thin and thick plates by the element. An extended DKT element for thick-plate bending analysis is evaluated in Part I.

9A260. Performance of a reformulated four-node plate bending element in moderately thick to very thin plate applications. - D Briassoulis *(Dept of Agri Eng, Agri Univ, Athens, Greece)*. Comput Struct 47(1) 125-141 (3 Apr 1993).

This paper analyzes the behavior of a reformulated four-node Mindlin plate bending element in thin to very thin and in moderately thick element applications. The shear locking mechanism is rejected with the proposed formulation whereas machine-related locking remains the only problem potentially developed in thin element applications of the reformulated element. The solution to the machine locking problem may be achieved with the implementation of a simple technique rendering the element completely locking-free. In moderately thick element applications, the reformulated four-node plate bending element is shown to exhibit an excellent performance in accordance with Mindlin-Reissner theory.

9A261. Design of transversely stiffened webs of I-beams. - MA Bradford *(Dept of Struct Eng, Sch of Civil Eng, Univ of New S Wales, Kensington, NSW 2033, Australia)*. J Construct Steel Res 25(3) 229-240 (1993).

The design rules for webs in shear given in the limit states British and Australian steel standards are reviewed. The semi-analytical complex finite strip method of buckling analysis is then used to obtain the elastic local buckling coefficients of the webs of I-beams subjected to shear when the restraint provided by the flanges is included. It is shown quantitatively how the flange restraint increases the local buckling coefficient above the value for a web with simply supported edges, the latter forming the basis of the strength rules in the present standards.

9A262. Euler buckling of pultruted composite columns. - EJ Barbero and IG Raftoyiannis *(Mech and Aerospace Eng, W Virginia Univ WV 26506-6101)*. Composite Struct 24(2) 139-147 (1993).

Pultruted composite structural members with open or closed thin-walled sections are being used as columns for structural applications where buckling is the main consideration in the design. An analytical model for Euler buckling is developed herein. Failure envelopes for some commercially available structural shapes are presented. The analytical model presented can be used to predict the behavior of any new material.

9A263. Large plane dynamic postcritical deformations of elastic beam. - Z Wesolowski and J Widlaszewski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland)*. Eng Trans 40(4) 469-481 (1992).

Large elastic deformations of a prismatic beam with inextensible axis are analysed. The beam at rest is an elastic arch formed by buckling from an initially straight beam and fixing its ends. The beam is modelled as a system of rigid elements connected by means of elastic hinges. The resulting equations are integrated numerically. The initial-boundary problem is solved with the use of Lagrange multipliers at each time step. Static characteristics are obtained with the use of the dynamic relaxation method.

9A264. Lateral post-buckling analysis of beams. - G Ioannidis *(Struct Anal and Steel Bridges, Natl Tech Univ, 42 Patission St, Athens 147, Greece)*, O Mahrenholtz *(Arbeitsbereich Meerestech II, Tech Univ Hamburg-Harburg, Postfach 90 10 52, W-2100 Hamburg 90, Germany)*, AN Kounadis *(Struct Anal and Steel Bridges, Natl Tech Univ, 42 Patission St, Athens 147, Greece)*. Arch Appl Mech 63(3) 151-158 (Apr 1993).

The nonlinear lateral buckling response of prefect stocky beams in the vicinitiy of the critical bifurcational state is discussed. Attention is focused on the initial post-buckling response. This depends on the nature of the critical branching point which is explored by using a nonlinear (lateral) bending-curvature relationship. It is found that the plane of loading (associated with the major moment of inertia) looses its stability through a stable symmetric bifurcation point. Hence, the above beams are not sensitive to imperfections, exhibiting post-buckling strength.

9A265. Effect of varying the support conditions on the buckling of laminated composite plates. - Gin Boay Chai and Poh Wah Khong *(Nanyang Tech Univ, Nanyang Ave, Singapore 2263, Singapore)*. Composite Struct 24(2) 99-106 (1993).

The buckling analysis of laminated composite plates using a semi-numerical approach called the finite strip method is presented. The composite plates are subjected to in-plane compression and their boundary conditions on the unloaded edges are simulated to vary from the free condition to clamp condition using a quintic polynomial function. Along the loaded edges three different support conditions are simulated using single term trigonometric functions. The coupling influence in these laminated plates on the buckling behavior is accounted for in the analysis through the use of the reduced bending stiffness concept. The validity of the results obtained are verified by comparison with published results and experimental results. Some parametric studies towards the end of this paper give an interesting insight into the effect of changing the support conditions on the buckling behavior of laminated composite plates. The limitations using the finite strip method found in the present study are also discussed.

9A266. Thermal post buckling behavior of rectangular antisymmetric cross-ply composite plates. - G Singh, G Venkateswara Rao *(Struct Des and Anal Div, Struct Eng Group, Vikram Sarabhai Space Centre, Trivandrum 695 022, India)*, NGR Iyengar *(Dept of Aerospace Eng, Indian IT, Kanpur 108 016, India)*. Acta Mech 98(1-4) 39-50 (1993).

The thermal post buckling behavior of simply-supported, antisymmetric cross-ply plates with immovable edges is investigated in this paper. For this purpose, a one term approximation for the in-plane and transverse displacements is assumed and Rayleigh-Ritz method is used to obtain the equations of equilibrium. It is shown that nonlinear bending stiffness for such plates is direction dependent, because of an extra quadratic nonlinear term in addition to the usual cubic nonlinear term in the governing equilibrium equation. Results are presented for various plate configurations.

9A267. Shear capacity of large fabricated steel cylinders: A truss model. - KH Obaia *(Syncrude Canada, Ft MacMurray, AB, Canada)*, AE Elwi, GL Kulak *(Dept of Civil Eng, Univ of Alberta, Edmonton, AB, T6G 2G7, Canada)*. J Construct Steel Res 25(3) 211-227 (1993).

Failure of large diameter steel cylinders fabricated from hot rolled sheet steel plates and subjected to transverse beam shear occurs when large diagonal buckles develop in the panels formed by the circumferential stiffeners. The load-carrying capacity then drops to a slightly lower level than the ultimate strength level. Whereas the ultimate strength has been shown to be significantly reduced in the presence of fabrication residual stresses, the postbuckling load level is not affected. Further, this load level is stable. It is advocated, therefore, that the postbuckling load can be used as a conservative design base for calculation of shear capacity.

9A268. Elastic stability of skew laminated composite plates subjected to biaxial follower forces. - C-L Liao and Z-Y Lee *(Dept of Mech Eng, Natl Taiwan IT, Taipei, Taiwan, ROC)*. Int J Numer Methods Eng 36(11) 1825-1847 (15 Jun 1993).

The present study investigates the elastic stability of skew laminated composite plates subjected to biaxial inplane follower forces by the FEM. The plate is assumed to follow first-order shear deformation plate theory. The kinetic and strain energies of skew laminated composite plate and the work done by the biaxial inplane follower forces are derived by using tensor theory. Then, by Hamilton's principle, the dynamic mathematical model to describe the free vibration of this problem is formed. Numerical results are presented to demonstrate the effects of those parameters, such as various inplane force combinations, skew angle and lamination scheme, on the elastic stability of skew laminated composite plates subjected to biaxial inplane follower force.

9A269. Dynamic contact instability of spherical caps. - Long-Yuan Li and TCK Molyneaux *(Dept of Civil Eng, Univ of Liverpool, Liverpool L69 3BX, UK)*. Int J Impact Eng 13(3) 479-484 (Aug 1993).

This paper presents a numerical study of the dynamic contact instability of shallow spherical shells. The problem considered is that of a spherical shell loaded through a massless rigid circular plate by a sudden step load acting in the direction normal to the loading plate and along the axis of symmetry of the shell. The numerical analysis demonstrates that the system may be dynamically stable even if local snap-through buckling occurs in the central area of the spherical shell. Dynamic instability occurs only in the case where the spherical shell exhibits an overall snap-through buckling.

264. Electromagneto solid mechanics

9A270. A new method for magnetic field computation on anisotropic permanent magnets. - Fumihito Mohri *(Electron Mat Res Lab, Kaneka, 1-1 2-chome Hieitsuji Ohtsu, Shiga 520-01, Japan)*. Int J Appl Electromagnetics Mat 3(4) 241-248 (Apr 1993).

A new magnetic field computation method has been developed for simulation of magnetizing anisotropic permanent magnets. The absolute value of the magnetization and its rotational angle are chosen as the unknown variables. All material data are obtained from only two curves; the curve for the axis for easy magnetization and the curve for the axis for hard magnetization. To treat the imperfection of particle orientation simply, a new quantity, "the residual angle", and a new model, "the representative particle model" have been introduced. Two-dimensional magnetization measurement has been used to examine the method.

9A271. Large strain ferroelectrics for micromechatronics. - KR Udayakumar *(Mat Res Lab, Penn State)*, AM Flynn *(MIT Artificial Intelligence Lab, Cambridge MA 02139)*, J Chen, LE Cross *(Mat Res Lab, Penn State)*. Int J Appl Electromagnetics Mat 3(4) 307-311 (Apr 1993).

The overall intent of this work has been done to develop batch-fabricatable micromotors that can couple power to a load. Ferroelectric thin films of lead zirconate titanate (PZT) fabricated for application as flexure-wave piezoelectric micromotors are generally characterized by low speed and high torque, eliminating complex gearing. In this paper, alternate thin film material systems that engender higher strain levels through new mechanisms as active elements of an actuator are examined.

9A272. Phase change of electromagnetic wave induced by static strain. - Chau-Shioung Yeh and Chun-Bo Lin *(Inst of Appl Mech, Natl Taiwan Univ, Taipei, Taiwan, ROC)*. Int J Appl Electromagnetics Mat 3(4) 269-288 (Apr 1993).

The electromagnetic wave in a deformable body such as optical fibers will be affected by applying mechanical disturbance. Some previous investigators have focused on the phase change of the electromagnetic wave caused by strain and then applied the photoelastic theory to explain the experimental results. In this paper, we develop another approach based on coupled electromagnetic and mechanical equations for deformable electrodynamics to study the same phenomena. Constitutive equations which are derived from rational mechanics rather than measured by experiments are used to fit the coupled equations mentioned above. The relationships between electrostriction constants and elasto-optical coefficients, which are very important and valuable to make the result derived from deformable electrodynamics comparable to that from the photoelastic theory, are developed and discussed.

9A273. Effective properties of piezoelectric composites with spheroidal inclusions. - Biao Wang and Shanyi Du *(Sch of Astronaut, Harbin IT, Harbin 150006, China)*. Int J Appl Electromagnetics Mat 3(4) 289-295 (Apr 1993).

In this paper, general relations between the overall properties of piezoelectric composites and the properties of their constituents are derived. Based on the solution for an ellipsoidal inclusion in a piezoelectric material developed by Wang, it is found that the coupled elastic and electric field inside a spheroid inclusion in a transversely isotropic, piezoelectric matrix can be expressed in terms of a system of the linear algebraic equations which contains only some simple integrals. These internal fields are then used to obtain the effective constants of a piezoelectric composite.

9A274. A few properties of the resonant frequencies of a piezoelectric body. - JS Yang *(Dept of Math and Comput Sci, Fayetteville State Univ, Fayetteville NC)*. Arch Mech 44(4) 475-477 (1992).

This paper presents a constraint variational formulation for the resonant frequencies of a piezoelectric body. The formulation is in a nonnegative form which is then used to prove a few properties of the lowest resonant frequency.

9A275. Preliminary determination of measurement device position in biomagnetic research. Using a reference source. - MA Primin *(Inst of Cybernetics, Ukrainian Acad of Sci, Akademik Glushkov St 40, 252207 Kiev, Ukraine)*. Int J Appl Electromagnetics Mat 3(4) 263-268 (Apr 1993).

Analytical methods of data processing and algorithms of measurement of a reference magnetic source field are proposed and allow one to determine the measurement device position in a coordinate system associated with this source in biomagnetic investigations. Possible effects of magnetic noise, reference source dimensions, etc, to the accuracy of the inverse problem are numerically simulated.

9A276. Reevaluation of the adhesive relationship between the tire and the soil. - G Komandi *(Univ of Agri Sci, Godollo, Hungary)*. J Terramech 30(2) 77-83 (Mar 1993).

The author proved in an earlier article that the shear diagram is not in accord with its mechanical definition. The shear stress cannot be zero at the beginning of the initial rising portion of the curve. Shearing is not an increasing loading process, rather it is a limiting case to which a finite shear stress belongs. On the other hand the sheared surface varies under the tire. There are kinematic reasons for this. Points on the tire surface describe a looped cycloid and they slip in a backward direction (opposite to the direction of travel) while contacting the soil. Thus the driving force, which points in the direction of travel, is the product of the shear stress of finite magnitude and the sheared area. The latter increases proportionally with slip. The author describes his equation which is based on the principles discussed above. He supports his theory with a numerical example.

9A278. Effects of cap thickness and pile inclination on the response of a pile group foundation by a 3D nonlinear FE analysis. - MM Zaman *(Sch of Civil Eng and Env Sci, Univ of Oklahoma, Norman OK 73019)*, YM Najjar *(Dept of Civl Mech and Env Eng, George Washington Univ, Washington DC 20052)*, A Muqtadir *(Dept of Civil Eng, Univ of Eng and Tech, Dhaka, Bangladesh)*. Comput Geotech 15(2) 65-86 (1993).

Effects of pile-cap and pile inclination on the distribution of displacements, stresses, axial forces, shear forces and bending moments in different piles in a group are investigated using a nonlinear 3D FE technique. An algorithm based on the interpolation of nodal displacements and finite difference approximation of the displacement field is developed to evaluate the bending moments and the shear forces in the piles and pile cap. Emphasis is given to identify the manner in which loads are shared by individual piles in the group.

9T279. Internal waves in a large offshore storage tank. - SK Chakrabarti *(Chicago Bridge and Iron Tech Services, Plainfield IL 60544-8929)*. J Energy Resources Tech 115(2) 133-141 (Jun 1993).

9A280. Long-term allowable tensile stresses for polyethylene geomembranes. - RR Berg *(2190 Leyland Alcove, Woodbury MN 55125)* and R Bonaparte *(GeoSyntec Consult, 5775 Peachtree Dunwood Rd, Ste 200F, Atlanta GA 30342)*. Geotextiles Geomembranes 12(4) 287-306 (1993).

The objective of this paper is to present a rational methodology for establishing long-term allowable tensile stresses for polyethylene geomembranes used in waste-containment applications. Procedures currently used in the USA do not account for all of the factors that may significantly affect this parameter. The proposed procedure is intended to address this limitation by providing a framework to account for time, temperature, exposure environment, seam response, and boundary-stress and deformation conditions. The proposed procedure is conceptually similar to procedures used to establish the long-term allowable tension for geosynthetic reinforcement.

9A281. Study of soil-geotextile interaction by an X-ray method. - M Kharchafi and M Dysli *(Inst of Soils, Rocks and Found, Fed IT, Lausanne, Switzerland)*. Geotextiles Geomembranes 12(4) 307-325 (1993).

The study presented in this paper consists of an aspect of geotextile utilization in the reinforcement of embankments and retaining walls. Emphasis was placed on the behavior of the anchorage zone. For this purpose, several pullout tests were carried out with a nonwoven geotextile and two kinds of soil: a dry sand and a damp silt. The effects of several parameters, such as the stiffness of geotextile, its anchorage length, the normal stress applied, the type of soil, and their consequences on the entire reinforced mass, such as deformability and the tension in the geotextile were studied. Some recommendations for practical design were established concerning the friction angle to take into account for the soil-inclusion, the tensile distribution in the geotextile, and the size of the soil zone influenced by the movement of the reinforcement.

9A282. **Deformation of brittle rocks under compression - with particular reference to microcracks.** - Chunlin Li and E Nordlund *(Div of Rock Mech, Lulea Univ, S-951 87 Lulea, Sweden)*. Mech Mat 15(3) 223-239 (May 1993).

A constitutive model for brittle rocks has been developed based on the analysis of microcracks. The macroscopic deformation of a rock is decomposed into three components: response of the rock matrix, closure of open cracks and deformation due to the fracture of microcracks. The main contribution of this approach is the prediction of macroscopic deformation induced by microcracking. The basic model units are sliding cracks. Wing cracks are initiated at tips of sliding cracks and propagated in the major loading direction. The relationships between the compressive stress, the length of the growing crack and deformation due to the fracture of cracks are established. A deformation solution to an elliptic crack is employed to describe the closure effect of an open crack under compression. The total deformation caused by the closure and fracture of cracks is obtained by the sum of the components of individual cracks. In this model, the nonlinear behavior of deformation results either from the closure of open cracks at low stress levels, or from the fracture of microcracks at high stress levels. Hysteresis is captured under cyclic loading. Comparisons of the model simulations with experimental data are presented and show good agreement in the prefailure stage.

9A283. **Fracture of rock: Effect of loading rate.** - ZP Bazant, Shang-Ping Bai, R Gettu *(Center for Adv Cement-Based Mat, NWU)*. Eng Fracture Mech 45(3) 393-398 (Jun 1993).

Fracture parameters of limestone at loading rates ranging over four orders of magnitude in the static regime are determined using the size effect method. Three sizes of three-point bend notched specimens were tested under crack-mouth opening displacement control. The fracture toughness and nominal strength decrease slightly with a decrease in rate, but the fracture process zone length and the brittleness of failure are practically unaffected. The effect of material creep on the fracture of limestone is negligible in the time range studied here. However, the methodology developed for characterizing rate effects in static fracture can be easily applied to other brittle-heterogeneous materials. The decrease of fracture toughness as a function of the crack propagation velocity is described with a power law. A formula for the size- and rate-dependence of the nominal strength is also presented.

9A284. **Factors related to propellant-driven anchoring in rock.** - Ghang Zhou *(Dept of Aeronaut, Imperial Col, London SW7 2BY, UK)* and W Goldsmith *(Dept of Mech Eng, UCB)*. Int J Impact Eng 13(3) 403-421 (Aug 1993).

The penetration into rocks comprising the ocean floor by propellant-driven model projectiles and their resistance to extraction at oblique angles were investigated both experimentally and numerically. The required static and dynamic friction coefficients between steel and rock were also measured. Targets were examined subsequent to impact by sectioning and by means of X-rays. The projectile penetration into soft sandstone target was simulated using DYNA2D. The scaling law for the oblique pull-out case has been established by using a similarity analysis.

9A285. **Thermal aspect in design of rotary drill bit supports.** - AK Dzhanakhmedov, TG Faradzhev, RA Rasulov *(M Azizbekov Azerbaigan Indus Inst, Baku, Russia)*. Sov J Friction Wear 13(6) 41-46 (1992).

Main causes of decreasing rotary bit wear resistance are considered. The rotary bit is taken as a hollow sphere with an internal source of heat. The sphere is cooled by a circulating drilling fluid from outside. While solving heat equation for the given case the temperature and thermal stress distributions are determined. With decreasing rotation velocity thermal stresses in support are shown to decrease under other conditions being equal. Thus, with the rotation velocity decreases from 400 to 25 rpm radial thermal stresses decrease more than 18 times and the tangential stresses - more than 20 times. The stress increases with duration of continuous drilling. A cooling (drilling fluid) affects significantly the heating depth of the surface layers.

272B. APPLICATIONS OF PLASTICITY THEORY

9A286. **Analysis of 3D deep drawing by the energy method.** - HS Lee *(Dept of Precision Eng and Mechatronics, Korea Adv Inst of Sci and Tech, Taejon, Korea)* and DY Yang *(R&D Dept, Prod Eng, Kia Motors, Kwang-Myung, Korea)*. Int J Mech Sci 35(6) 491-516 (Jun 1993).

A systematic approach of the energy method is proposed for analysis of 3D sheet metal forming of noncircular cups with complicated shape. In the proposed method, the whole deforming region is divided into several zones by considering the geometric characteristics and contact boundary condition. The geometric shape is expressed by sweeping the section curves defined on the boundary of each zone. Velocity fields are expressed in a similar manner by sweeping the boundary velocity functions. The solution is found through optimization of the total energy dissipation with respect to some parameters assumed in the kinematically admissible velocity field defined over each zone. In order to check the effectiveness of the present method, 3D deep drawing by the elliptic punch and the clover-type punch are analyzed and compared with the corresponding experiments. In analyzing the deep drawing process by the elliptic and clover-type punches, the total deforming region has been divided into five zones. The computed results are shown to be in good agreement with the experiment in punch load, deformed edge contour and distribution of thickness strain.

272D. EXTRUSION

9A287. **Model for predicting slip velocity during extrusion with fluoropolymer processing additives.** - CW Stewart, RS McMinn, KM Stika *(EI du Pont de Nemours, Exp Sta, PO Box 80323, Wilmington DE 19880-0323)*. J Reinforced Plastics Composites 12(6) 633-641 (Jun 1993).

A molecular model, based on the concept of the activation rate theory, is developed for slip of a polymer as it flows through a die. The model correctly predicts the dependence of the apparent slip velocity of high molecular weight, linear polyethylene resins on wall shear stress, up to the onset of gross melt fracture.

272E. ROLLING

9A288. **Comparison of asymptotic and numerical rolling models for quasi-3D problems.** - ME Karabin *(Alcoa Tech Center, Pittsburgh PA 15069)* and RE Johnson *(Univ of Illinois, Urbana IL 61801)*. Int J Mech Sci 35(5) 425-439 (May 1993).

This study compares two quasi-3D steady-state rolling models. The validity of both models assumes that the ratio of strip half-thickness to contact length is small. Thickness to length ratios less than 0.3 are acceptable, and sometimes the models work well beyond this limit. One model is a FE calculation which uses one layer of elements through the strip half-thickness. The other is an asymptotic approach which includes both first- and second-order terms. An important feature of the solution is that it is very sensitive to the spread. Small changes in spread often lead to significant changes in stresses. The predicted spreads are always found small and their magnitudes are typical of those found in practice.

272F. DRAWING

9A289. **Production of tapered cups by sequential deep drawing of sheet metals using drawn cups as a part of punch.** - K Yamaguchi *(Dept of Mech and Syst Eng, Kyoto IT, Matsugasaki Sakyo-ku, Kyoto 606, Japan)*, K Kanayama *(Government Indust Res, Inst of Nagoya, Hirate-machi Kita-ku, Nagoya 462, Japan)*, MH Parsa, N Takakura *(Dept of Mech and Syst Eng, Kyoto IT, Matsugasaki Sakyo-ku, Kyoto 606, Japan)*. J Eng Indust 115(2) 224-229 (May 1993).

A new deep drawing process of sheet metals is developed to facilitate small-lot production of deep cups with large drawing ratio. In this process, unlike the conventional deep drawing method, a few drawn cups are always stacked on the punch and used as a part of punch for the subsequent deep drawing of a given blank. Before drawing a new blank, a drawn cup which is in contact with the punch is stripped off. In this paper, this new deep drawing process is applied to the production of tapered cups and the main feature of the process is shown.

272G. SHEET METAL FORMING AND STAMPING

9A290. **Rigid plastic implicit scheme for non and 3D analysis of metal forming by FEM.** - G De Saxce *(Lab de Mec des Mat et des Struct, Faculte Polytech de Mons, 9 rue de Houdain, B-7000 Mons, Belgium)*, ZQ Feng *(Dept de Genie Mech, Univ de Tech de Compiegne, BP 649, F-60206 Compiegne, France)*, G Touzot *(Dept Genie Mech, Univ Tech de Compiegne, BP 649, F-60206 Compiegne, France)*. Eng Comput 10(1) 49-60 (Feb 1993).

This paper is devoted to the analysis of metal forming with assumption of rigid-plastic behavior with strain hardening. As opposed to the classical rate problem formulation based on Markov's principle and the explicit scheme, a more satisfactory incremental approach is deduced from Moreau's catching up algorithm. This implicit scheme, although more complicated, gives better results concerning convergence and numerical stability. Using an internal variable representing the strain hardening, an incremental strain energy density is defined which leads to a principle of minimum of the total incremental strain energy. In the numerical approximation using FE, the nonlinear equilibrium equations are solved by classical Newton's method. An approximation of Coulomb's criterion is used in order to represent friction with a rigid foundation. The simple compression test is simulated and shows that the implicit scheme is faster than the explicit one.

272H. MACHINING (INCL NM)

9A291. Computer simulation and experimental analysis of chip monitoring for deep hole drilling. - Jih-Hua Chin, Jang-Shyong Wu, Rouh-Song Young *(Dept of Mech Eng, Natl Chiao Tung Univ, Hsinchu, Taiwan, ROC)*. J Eng Indust 115(2) 184-192 (May 1993).

Chip congestion is a long time bottleneck in deep hole drilling. This paper addresses the problem of chip state monitoring in single-edge deep hole drilling by computer simulation and experimental analysis. Two phenomenological models were proposed to interpret the physics of chip discharging in normal and congested states, respectively. Length and diameter of the chip are chosen to represent the geometric features of the chip, and the formation of a chip signal is discussed. Computer simulation shows that the normal chip discharging in a real drilling process can be interpreted by the proposed slug flow model.

9A292. Modeling complex force systems Part 2. A decomposition of the pad forces in deep drilling. - BJ Griffiths and RJ Grieve *(Dept of Manuf and Eng Syst, Brunel Univ, UK)*. J Eng Indust 115(2) 177-183 (May 1993).

This paper is a continuation of the earlier Part I paper in which it was shown that the force system existing during a deep hole drilling operation was complex and indeterminate using a single dynamometer approach. However, by using complementary dynamometers in conjunction with a force relationship to model the radial and tangential pad forces the system could be analyzed.

9A293. Modeling complex force systems, Part I. The cutting and pad forces in deep drilling. - BJ Griffiths *(Dept of Manuf and Eng Syst, Brunel Univ, UK)*. J Eng Indust 115(2) 169-176 (May 1993).

This paper is the first part of a two-part series which analyzes the complex force system existing within a deep hole drilling operation where cutting forces exist at a single cutting edge and burnishing and friction forces exist at two pads. In this first paper the forces at the pads and cutting edges are determined by (1) assuming that the pad forces are related by coefficients and (2) by the use of complimentary dynamometers.

9A294. Monitoring and control of electrochemical machining (ECM). - KP Rajurkar, B Wei *(Indust and Man Syst, Eng Dept, Univ of Nebraska, Lincoln NE 68588-0518)*, CL Schnacker *(Hewlett Packard, Cupertino CA 95014)*. J Eng Indust 115(2) 216-223 (May 1993).

The main advantages of the electrochemical machining (ECM) process, such as high material removal rates and smooth, damage-free machined surface, are often offset by the poor dimensional control and process stability resulting from the complex and stochastic nature of the interelectrode gap (IEG) states. Full economic utilization of ECM will be realized only when reliable dimensional and process control systems are developed. This paper presents an ECM control model based on the basic ECM dynamics that accounts for the dynamic nature of the ECM process. The signals are digitized and analyzed with an IBM PC. The frequency analysis of the signal leads to a better insight of the physical mechanism of the ECM process. A comprehensive review of the state-of-the-art ECM research and development efforts in the areas of spark and short circuit detection and IEG control is also included in the paper.

272J. CASTING

9A295. Numerical simulation of continuous casting solidification by BEM. - E Majchrzak *(Inst of Mech Theory, Silesian Tech Univ, Ul Pstrowskiego 16, 44-100 Gliwice, Poland)*. Eng Anal Boundary Elements 11(2) 95-99 (1993).

The problem of casting solidification modelling on the basis of the BEM is a rather difficult one. Yet, essential advantages of the BEM suggests that the use of this method for numerical simulation of Stefan's problem should be the subject of numerous scientific investigations in the range of effective algorithms construction. This paper presents a different algorithm. The BEM and the alternating phase truncation method APTM are used in order to identify the solidification front and temperature field in the volume of rectangular copper continuous casting.

272M. WRAPPING AND LAYING-UP (COMPOSITE MATERIALS)

9A296. Direct processing of continuous fibers onto injection molding machines. - FM Truckenmuller *(Inst Kunststofftech, Univ Stuttgart, Boblingerstr 70, 7000 Stuttgart 1, Germany)*. J Reinforced Plastics Composites 12(6) 624-632 (Jun 1993).

A new injection molding process "DIF" (Direct Incorporation of Continuous Fibers) is proposed whereby roving strands are directly incorporated into the polymer melt by using a reciprocating-screw-plasticating unit. The DIF-technology offers the possibility to substitute the relatively expensive pultrusion process which is used to produce long fiber pellets. Furthermore it can be used as a fast and flexible R&D tool. The results of fundamental mechanical and physical property investigations are presented including dispersion of fiber clusters and bundles, fiber length distribution, and fiber orientation.

9A297. Effect of mandrel material on the processing-induced residual stresses in thick filament wound composite cylinders. - SR White and Z Zhang *(Dept of Aeronaut and Astronaut Eng and Dept of Theor and Appl Mech, Univ of Illinois, Urbana IL 61801)*. J Reinforced Plastics Composites 12(6) 698-711 (Jun 1993).

Residual stresses are known to be detrimental to a number of mechanical properties in composite materials. The mechanisms by which they develop in the filament winding of composite cylinders and tubes is not fully understood. In this work a process model is presented to predict the residual stresses induced during the processing of two-layer composite cylinders. Chemical shrinkage, thermal expansion-contraction, and cure-dependent properties are accounted for in the model. The influence of mandrel stiffness and thermal expansion coefficient is examined and a case study of an aluminum and a steel mandrel is compared.

9A298. Simultaneous process of filament winding and curing for polymer composites. - VN Korotkov, YA Chekanov, BA Rozenberg *(Dept of Polymer and Composite Mat, Inst of Chem Phys, Russian Acad of Sci, Chernogolovka Moscow Region 142432, Russia)*. Composites Sci Tech 47(4) 383-388 (1993).

The simultaneous process of filament winding and curing a composite cylindrical shell is considered. From the macrokinetic point of view it is characterized by the small thickness of the relative effective reaction zone. The thermochemical conditions in manufacturing are governed by the following process variables: speed of winding, initial conversion and temperature of the filament bundle wound, and the heating applied. A thermochemical model is developed for simulation of the temperature and conversion distributions during the process. An approximate solution of the thermochemical model in the form of the constant traveling wave is derived for constant values of process variables and a thermally isolated mandrel. A non-uniform cure stress model of the process is developed for the case of using elastic orthotropic constitutive relations for a composite material. It is found that the thickness of the relative effective reaction zone drastically influences the cure stresses. The dependence of the stress level on the process variables is analyzed.

272P. RAPID SOLIDIFICATION

9A299. Variational algorithms and pattern formation in dendritic solidification. - R Almgren *(Dept of Math, Univ of Chicago, Chicago IL 60637)*. J Comput Phys 106(2) 337-354 (Jun 1993).

We present a completely new variational algorithm for computing dendritic solidification. This algorithm reproduces the Gibbs-Thomson relation as a balance between bulk and surface energy and is able to operate in the infinity-mobility limit with no unphysical time-step restriction. It may be used with arbitrary non-smooth surface energy functions and may include finite kinetic mobility. We perform computations with isotropic and anisotropic surface energy; from a small irregular seed we generate radial tip-splitting structures for isotropic energy and parabolic dendrites with side-branching for anisotropic energy.

272R. MICROPROCESSING (EG BY LASER AND ION BEAMS)

9A300. Microwave heating of dispersive media. - GA Kriegsmann *(Dept of Math, Center for Appl Math and Stat, NJIT, University Heights, Newark NJ 07102)*. SIAM J Appl Math 53(3) 655-669 (Jun 1993).

The heating of a compact dispersive target by a pulsed, plane microwave is modeled and studied herein. The dispersive character of the medium is described by a Debye model, and the conductive nature is modeled by an ionic conductivity. The electrical and thermal parameters are allowed to depend upon temperature, which gives rise to a highly nonlinear initial boundary value problem. A two-step algorithm is proposed for the numerical solution of these equations. When convection is weak, the algorithm converges very slowly. Specifically, the temperature is spatially uniform in the target and evolves in time according to a first-order ordinary differential equation. The nonlinearity in this equation is a functional of the electric field within the target. The equation is solved for a number of specific examples, and physical conclusions are drawn about certain heating processes.

272T. CERAMICS, REFRACTORIES, GLASSES

9A301. Role of rheology in colloidal processing of ZrO_2. - YK Leong, N Katiforis, DBO'C Harding, TW Healy, DV Boger *(Adv Mineral Prod Res Center, Univ of Melbourne, Parkville 3052, Australia)*. J Mat Processing Manuf Sci 1(4) 445-453 (Apr 1993).

Wet colloidal processing techniques such as milling, spray drying, slip casting, pressure filtration and centrifuge casting are employed to produce ceramics of improved reliability. Each of these processes requires a specific rheological behavior or type of particle interaction which can be achieved by surface chemistry control. Results showing the effects of pH, ionic strength and the addition of adsorbing anionic polyacrylate and cationic polyallylamine hydrochloride on the rheological properties of ZrO_2 suspensions are presented. ZrO_2 suspensions exhibit a maximum in viscosity or yield stress at the isoelectric point (IEP) of pH 7.0. The suspensions deflocculate at a pH of about 5.0 and 10.0. The pH of maximum yield stress and the deflocculation pH were lowered significantly by the adsorbed polyacrylate, while these same pHs were increased by the addition of polyallylamine hydrochloride. More significantly, at relatively high additive concentrations (0.5% dwb or g/100 g ZrO_2), the maximum yield stress at the isoelectric point is greatly reduced. This reduction can be explained by the adsorbed polymer keeping the interacting particles further apart as a result of steric mechanisms and possibly the reduction of the effective Hamaker constant, as the polymer Hamaker constant is 2.5 times less than that of ZrO_2. At low concentrations of polyallylamine hydrochloride, a slight increase in the maximum yield stress was observed. This increase may be due to bridging flocculation and hydrophobic interaction of the adsorbed polymer. Surface property measurements showed excellent agreement between the isoelectric point and the pH of maximum yield stress for a wide range of polymer additive concentrations.

9A302. Crystallization and its effect on the processing of polypropylene. - Tay-Yuan Chen, VW Wang *(AC Tech, 31 Dutch Mill Rd, Ithaca NY 14850)*, MJ Bozarth *(Himont USA, 800 Greenbank Rd, Wilmington DE 19808)*. J Reinforced Plastics Composites 12(6) 686-697 (Jun 1993).

In this article, the kinetics of crystallization for semi-crystalline polymers has been successfully incorporated into a cavity flow simulation. The flow resistance, in terms of filling pressure, can be significantly underestimated if crystallization is neglected during the calculation. In addition, the filling behavior for nucleated semi-crystalline materials is quite different from that of its virgin counterpart.

9A303. Shrinkage and warpage prediction for injection molded components. - SF Walsh *(Moldflow Pty, 259-261 Colchester Rd, Kilsyth, Vic 3137, Australia)*. J Reinforced Plastics Composites 12(7) 769-777 (Jul 1993).

Shrinkage and warpage analysis is now and important part of Computer Aided Engineering for injection molded components. The theory behind this analysis (including effects of crystallinity, orientation and cooling stress relaxation) is presented, along with a number of case studies showing the successful application of this technology.

274. Fracture and damage processes

274B. CRACK INITIATION

9A304. New approach to the determination of the macrocrack nucleation period near a stress concentrator. - VV Panasyuk, GS Ivanitska, OP Ostash *(GV Karpenko Physico-Mech Inst, Ukrainian Acad of Sci, 5 Naukova St, Lviv, Ukraine)*. Fatigue Fracture Eng Mat Struct 16(4) 453-464 (Apr 1993).

The stress-strain state of a rectangular plate with a central circular hole and a disc with an edge notch is analyzed both for elastic and elastic-plastic behavior when cracks emanate from the contours of these concentrators. Stress intensity factors are determined as well as the value of the inelastic deformation at stress concentration zones. The parameters describing the process of crack nucleation are established.

274C. SUBCRITICAL CRACK PROPAGATION

9A305. Experimental and FE study on stable crack growth in three point bending. - SK Maiti and AS Keshbat *(Dept of Mech Eng, Indian IT, Bombay 400 076, India)*. Int J Fracture 60(2) 179-194 (15 Mar 1993).

Experimental and FE results are presented on mode I and mixed mode (involving I and II only) stable crack growth under static loading through an aircraft grade aluminium alloy (D16AT) in three point bending. The results include load-displacement diagrams, J-integrals, plastic zones, tunneling (or crack front curving), etc. During experiment a substantial amount of tunneling is observed, the extent of which increases as the extension progresses in both mode I and mixed mode. The tunneling reduces as a_0/w increases. The crack extends initially almost along a straight line at an angle with the initial crack in a mixed mode. The maximum load is observed to be as high as 1.6 times the initiation load in the whole range examined. From the FE study it is seen that, in a mixed mode, the J-integral at the onset of extension is the lowest compared with the values at the later stages. The plastic zone size grows as the stable extension progresses; the growth is approximately the maximum along the crack extension line. The direction of initial crack extension in a mixed mode can be predicted through an elastic FE analysis and using the criterion of maximum tangential principal stress. The study also indicates that the load-displacement diagram associated with a mixed mode stable crack growth can be predicted reasonably accurately using the criterion of crack opening angle.

9A306. Fatigue crack growth under biaxial loading. - YC Lam *(Dept of Mech Eng, Monash Univ, Clayton, Vic 3168, Australia)*. Fatigue Fracture Eng Mat Struct 16(4) 429-440 (Apr 1993).

Fatigue crack growth under biaxial loading for long cracks subjected to low cyclic stress levels was investigated. The biaxial stress ratio λ ranging from - 0.5 to + 1.0 was considered. The strain energy density factor range was used as the criterion for predicting the crack growth rates and crack path. The agreement between prediction and experimental results was reasonable for crack growth rates and marginal for crack paths.

9A307. Influence of strength and stress ratio on short-crack thresholds and non-propagating fatigue cracks. - DN Lal *(Dept of Metall Eng, IT, Banaras Hindu Univ, Varanasi 221 005, India)*. Fatigue Fracture Eng Mat Struct 16(4) 419-428 (Apr 1993).

Quantitative predictions of the influence of yield strength and stress ratio, R, on the physically small crack fatigue threshold stress intensity, $\Delta K_{0(S)}$, are presented. It is shown that at R = 0 to - 1, although the threshold stress $\Delta\sigma_0$ increases, the threshold stress intensity, $\Delta K_{0(s)}$, decreases with increasing yield strength. Moreover, a lower bound value, $\Delta K_{0(s)(min)}$, is shown to have a constant value, irrespective of the strength and stress ratio. The formation and length of non-propagating fatigue cracks, a_{np}, are also discussed. The methods suggested for estimating $\Delta K_{0(s)}$ and a_{np} may be found useful in design procedures.

9A308. Mechanisms and behavior of overload retardation in AISI 304 stainless steel. - CS Shin and SH Hsu *(Dept of Mech Eng, Natl Taiwan Univ, Taipei, ROC)*. Int J Fatigue 15(3) 181-192 (May 1993).

The overload retardation phenomenon has been investigated in AISI 304 stainless steel under different baseline ΔKs, overload ratio and R ratios. Both the crack growth and crack closure behavior were carefully monitored. It was found that the extent and degree of retardation increase with overload ratio, decrease with R ratio, but are not correlated in a simple manner with the baseline ΔK. For R $\leq$ 0.6, momentary acceleration followed by well-defined delayed retardation were observed. The crack growth behavior before maximum retardation can be correctly predicted by Paris' law taking into account the experimentally measured crack closure value. Such a correlation failed beyond the maximum retardation point because of the occurrence of a discontinuous closure mechanism. Artificial introduction of crack closure by vacuum-infiltrating epoxy resin into the crack flanks also produced a similar retardation phenomenon. On the other hand, for R ratio $\geq$ 0.65, immediate retardation was observed. Mechanisms that have been proposed to explain the overload retardation phenomenon are reviewed and examined against the current experimental observations. It is concluded that the major mechanism causing overload retardation is plasticity-induced crack closure. Secondary mechanisms, such as crack-tip blunting and residual compressive stress ahead of the crack tip are significant only at high R ratios when crack closure is suppressed.

274D. DYNAMIC PROCESSES

9A309. Three coplanar moving Griffith cracks in an infinite elastic strip. - AN Das *(Dept of Math, N Bengal Univ, W Bengal, Darjeeling, India)*. Arch Mech 44(4) 463-474 (1992).

The dynamic anti-plane problem of determining stress and displacement due to three coplanar Griffith cracks moving steadily at a subsonic speed in an infinite elastic strip has been considered. Employing Fourier integral transform, the problem when the lateral boundaries are subjected to shearing stress, has been reduced to solving a set of four integral equations. These integral equations have been solved using finite Hilbert transform technique and Cook's result to obtain the exact form of crack opening displacement and stress intensity factors. Numerical results for stress intensity factors have been presented in the form of graphs.

274E. FATIGUE CHARACTERISTICS OF MATERIALS

9A310. Creep-fatigue interaction behavior of type 308 stainless steel weld metal and type 304 stainless steel base metal. - K Bhanu, S Rao, R Sandhya, SL Mannan *(Mat Dev Div, Indira Ghandhi Centre for Atomic Res, Kalpakkam 603 102, India)*. Int J Fatigue **15**(3) 221-229 (May 1993).

The effects of hold condition (tension-only, compression-only and tension-plus-compression holds of 1 min duration) and hold time (up to 10 min in tension) on the low-cycle fatigue behavior of type 304 stainless steel base metal and type 308 stainless steel all-weld metal were investigated at 923 K. All the tests were performed in total axis strain control in air, employing a strain range of 1.0%. The welds were prepared by a submerged metal arc welding process. The microstructure of the base metal and the weld consisted of gamma phase and duplex gamma-delta ferrite respectively. The results clearly indicated a reduction in continuous cycling as well as creep-fatigue interaction life of type 308 SS weld metal compared with type 304 SS base metal under identical testing conditions. Hold times displayed an effect on life that was dependent not only on material condition but also on the position of the hold in cycle. Fatigue lives recorded for type 308 SS weld in the 1 min hold-time tests were in the order: compression hold → continuous cycling → tension-plus-compression hold → tension hold. Fatigue lives of 304 SS were in the order: continuous cycling → compression hold → tension-plus-compression hold → tension hold. A significant reduction in the life of the weld metal was noted on increasing the duration of tension hold time to 10 min. 308 SS weld metal exhibited cyclic softening whereas 304 SS base metal showed rapid initial hardening followed by a saturation stage. The observed variations in life are explained on the basis of crack initiation and propagation modes and microstructural changes that occurred during low-cycle fatigue and creep-fatigue interaction testing.

9A311. Cyclic deformation and fatigue behavior of the low carbon steel SAE 1045 in the temperature regime of dynamic strain aging. - M Weisse, CK Wamukwamba, H-J Christ, H Mughrabi *(Inst fur Werkstoffwissenschaften, Lehrstuhl 1, Friedrich-Alexander-Univ Erlangen Nurnberg, Martenstr 5 DW-8520 Erlangen, Germany)*. Acta Metall Mat **41**(7) 2227-2233 (Jul 1993).

The cyclic deformation behavior of normalized SAE 1045 steel (german steel grade Ck 45) has been investigated over a range of temperatures between 20 and 375°C. Special attention has been paid to the effects of dynamic strain aging, which are most pronounced around 300°C. Different types of deformation tests (tension tests, incremental step tests, and constant amplitude cyclic deformation tests under stress control with a stress amplitude of 400 MPa as well as under plastic strain control with a plastic strain amplitude of 0.5%) were carried out to observe the influence of temperature on the macroscopic mechanical behavior. These tests were followed by TEM studies on microstructural features. In the temperature range of maximum dynamic strain aging, the material was found to show maximum strength in unidirectional as well as in cyclic deformation tests. While the fatigue life is maximum at the temperature of maximum dynamic strain aging in stress controlled tests, it is minimum in plastic strain controlled tests. At the temperature of maximum dynamic strain aging around 300°C, the dislocations are arranged in dense dislocation tangles and parallel dislocation walls, whereas at room and at higher temperatures (375°C) mainly dislocation cell structures are observed.

9A312. Cyclic strain resistance and cyclic fracture behavior of 2124 aluminium alloy. - TS Srivatsan *(Dept of Mech Eng, Univ of Akron, Akron OH)*, D Lanning Jr *(Dept of Aerospace Eng, Ohio State Univ, Columbus OH 43201)*, KK Soni *(Dept of Mat Sci and Eng, Lehigh Univ, Bethlehem PA)*. Int J Fatigue **15**(3) 231-242 (May 1993).

In this paper, the cyclic strain resistance and cyclic fracture behavior of aluminium alloy 2124 are examined. Test specimens of the alloy were cycled using tension-compression loading, under total strain control, over a range of plastic strains giving less than 10^4 cycles to failure. The alloy displayed hardening in both the longitudinal and transverse directions of the wrought plate. The observed hardening behavior is ascribed to contributions from synergistic influences of dislocation multiplication and dislocation-disclocation interactions. The alloy followed the Coffin-Manson relation and exhibited a single slope for the variation of cyclic plastic strain amplitude with reversals to failure. Fracture of the alloy samples was predominantly transgranular for both orientations, with microscopic crack propagation along the grain boundaries. The low-cycle fatigue characteristics and fracture behavior of the alloy are discussed in terms of competing and synergistic influences of cyclic plastic strain amplitude, response stress, intrinsic microstructural effects and dislocation-microstructure interactions during cyclic straining.

9A313. Effect of surface texture on fatigue life in a squeeze-cast 6082 aluminium alloy. - S Gungor and L Edwards *(Fracture Res Group, Mat Discipline, Fac of Tech, Open Univ, Milton, Keynes MK7 6AA, UK)*. Fatigue Fracture Eng Mat Struct **16**(4) 391-403 (Apr 1993).

The effect of surface texture on fatigue life in a squeeze-cast Al-Mg-Si alloy has been investigated in terms of initiation and subsequent propagation of small fatigue cracks. Small cracks nucleated from defects on both as-cast and polished surfaces. However, the large (~90 μm in diameter) surface defects found on as-cast surfaces caused an approximate 20% reduction in fatigue life when compared to polished surfaces where cracks initiated from smaller (~12 μm in diameter) microporosity. Integration of averaged and small fatigue crack growth data enables the fatigue lives of both types of specimen to be predicted at stresses above the fatigue limit, showing that the difference in fatigue behavior is principally due to the extra period of crack growth in the polished surfaces.

9A314. Effects of temperature and frequency on fatigue crack growth in 18% Cr ferritic stainless steel. - K Makhlouf and JW Jones *(Dept of Mat Sci and Eng, Univ of Michigan, Ann Arbor MI 48109)*. Int J Fatigue **15**(3) 163-171 (May 1993).

The fatigue crack growth behavior of a ferritic stainless steel has been investigated as a function of test temperature, thermal exposure and frequency at intermediate growth rates. In general, fatigue crack growth rates increased with increasing temperature and in the temperature range 500-700 °C growth rates were described by a kinetic process with an activation energy of 48 kJ/mole. Higher than normal growth rates at 475 °C were observed and attributed to an embrittlement process which is known to occur in this temperature regime in high-chromium ferritic stainless steels. The influence of frequency on fatigue crack growth rates was examined at 500 and 655 °C for a load ratio of 0.1 and over four decades of frequency. A transition from time-independent to time-dependent behavior was observed at each temperature as frequency was lowered. The frequency at which this transition occurred was dependent on temperature. For all temperatures investigated, near threshold crack propagation occurred by a crystallographic or faceted propagation mechanism. At high crack growth rates, crack-tip plasticity was significant and propagation proceeded by a ductile striation formation process. At intermediate growth rates a mixed-mode fatigue crack growth mechanism was observed where some intergranular fracture occurred.

9A315. Evaluation of composites under dynamic load. - F Orth, L Hoffmann, H Zilch-Bremer, GW Ehrenstein *(Lehrstuhl fur Kunststofftech der Friedrich-Alexander-Univ Erlangen-Nurnberg, Demonstrationszentrum fur Faserverbundwerkstoffe, D-8520 Erlangen-Tennenlohe, Am Weichselgarten 9, Germany)*. Composite Struct **24**(3) 265-272 (1993).

During the dynamic fatigue test it is desirable not only to determine the fatigue strength, but also to characterize the damage in the material. The observation of characteristic quantities provides information on the dynamic fatigue performance. Hysteresis measurements allow measurement of four kinds of quantities: stresses, extensions, stiffnesses and mechanical energies. By means of the stored energy and the energy loss the damping factor is calculated. It is also possible to distinguish between the material behavior in the tensile loading phase and the compression loading phase. The experimental equipment and procedure for hysteresis measurements are presented here. The application of this test method is demonstrated by two investigations. The first one deals with the dynamic fatigue behavior of glass fiber reinforced laminates for rotor blades of wind turbines and the second one is the evaluation of a valve spring retainer of carbon fiber reinforced plastic.

9A316. Fatigue behavior of a commercial aluminium alloy in sea water at different temperatures. - MR Bayoumi *(Dept of Prod Eng and Mech Syst Des, King Abdulaziz Univ, PO Box 9027, Jeddah 21413, Saudi Arabia)*. Eng Fracture Mech **45**(3) 297-307 (Jun 1993).

Fatigue tests of a commercial aluminium alloy are conducted in sea water at different temperatures using a specially designed experimental environmental chamber installed on a standard rotating bending fatigue testing machine. The tests are carried out in air at 20°C to establish the σ-N curve for this alloy as a reference curve, while tests in sea water are at 20, 30, 50 and 80°C to investigate the role of temperature on the fatigue behavior. Changing the medium from air to sea water during fatigue results in a significant decrease in the fatigue endurance limit. Increasing the temperature from 20 to 80°C reduces the endurance limit from 0.58 to 0.3 σ_y. In a generalized empirical estimation formula, the present study suggests an incorporation of an environmental factor (C_E) which depends on both the working medium and the temperature. Fracture surface examination on the scanning electron microscope indicates a great dependence of the pitting and/or intergranular corrosion fatigue cracks on the testing temperature and the applied cyclic stress levels.

9A317. Mode I fatigue cracking in a fiber reinforced metal matrix composite. - DP Walls *(United Tech, Pratt and Whitney, W Palm Beach FL 33410-9600)*, G Bao *(Dept of Mech Eng,* *Johns Hopkins Univ, Baltimore MD 21218)*, FW Zok *(Mat Dept, UC, Santa Barbara CA 93106-5050)*. Acta Metall Mat 41(7) 2061-2071 (Jul 1993).

The mode I fatigue crack growth behavior of a fiber reinforced metal matrix composite with weak interfaces is examined. In the longitudinal orientation, matrix cracks initially grow with minimal fiber failure. The tractions exerted by the intact fibers shield the crack tip from the applied stress and reduce the rate of crack growth relative to that in the unreinforced matrix alloy. In some instances, further growth is accompanied by fiber failure and a concomitant loss in crack tip shielding. The measurements are compared with model predictions, incorporating the intrinsic fatigue properties of the matrix and the shielding contributions derived from the intact fibers. The magnitude of the interface sliding stress inferred from the comparisons between experiment and theory is found to be in broad agreement with values measured using alternate techniques. The results also indicate that the interface sliding stress degrades with cyclic sliding, an effect yet to be incorporated in the model. In contrast, the transverse fatigue properties are found to be inferior to those of the monolithic matrix alloy, a consequence of the poor fatigue resistance of the fiber-matrix interface.

274F. STRESS OR STRAIN LIFE ANALYSIS OF FATIGUE

9A318. Analytical master curve for Goodman diagram data. - A Berkovits and D Fang *(Fac of Aerospace Eng, Technion Israel IT, Haifa 32000, Israel)*. Int J Fatigue 15(3) 173-180 (May 1993).

Estimation of the remaining safe life of structural parts which are not easily inspectable continues to be a problem. Even when load histories are available, laborious interpolation of Goodman diagram data is required in order to determine the remaining fatigue life of such parts. An analytical formulation of Goodman diagram data would expedite the life check. It is shown in this paper that, for many engineering materials at room temperature, the entire range of Goodman diagram data collapses on to a single master curve when presented as the ratio of lifetime with mean stress to lifetime at R = -1 for a given stress amplitude, as a function of a non-dimensional load parameter consisting of stress amplitude, mean stress, and material strength. The master curve is conveniently expressed in terms of two easily determined Weibull constants. Stress-concentration factor influences the value of the constants, as does the strain-rate sensitivity of some materials. By use of the master curve formula in an algorithm together with the Manson-Coffin life relation and Miner cumulative damage rule, computed fatigue lives lay within a factor of 2 of results obtained in tests under aircraft spectrum loads.

9A319. Improved technique for the prediction of axial fatigue life from tensile data. - JH Ong *(Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*. Int J Fatigue 15(3) 213-219 (May 1993).

This paper introduces an improved technique over existing methods for the prediction of axial fatigue life from uniaxial tensile data. The method uses multilinear regression analysis for initial prediction of the elastic and plastic strain amplitudes at 10^6 and 10^4 reversals to failure respectively from uniaxial tensile data. The fatigue strength coefficient is assumed to be equal to the true fracture stress of the material. The fatigue ductility coefficient is approximated to be equal to the logarithmic ductility of the material. The fatigue strength exponent and fatigue ductility exponent are then located on the strain-life curve by making use of the estimated elastic-plastic strain amplitudes, logarithmic ductility and the true fracture stress of the material. The validity of the method was investigated by examining 49 steels whose material properties cover a wide range of variables that might affect fatigue behavior.

9A320. Stress field intensity approach for predicting fatigue life. - Weixing Yao *(Dept of Aircraft, Nanjing Aeronaut Inst, Nanjing 210016, Peoples Rep of China)*. Int J Fatigue 15(3) 243-245 (May 1993).

In this paper a new design approach for predicting fatigue life – the stress field intensity approach – is presented from the point of view of macromechanics on the basis of the mechanism of fatigue damage of metals. In this new approach the stress field intensity over the local region of damage, instead of the stress peak values as in the local stress-strain approach, was taken as the parameter with which to measure the fatigue strength of structures. Many fatigue phenomena, which the nominal stress approach and the local stress-strain approach could not explain, can be explained reasonably in this new approach.

9A321. Textures induced by tension and deep drawing in low carbon and extra low carbon steel sheets. - D Daniel *(Pechiney - Centre Rech Voreppe, BP 27, 38340 Voreppe, France)*, J Savoie, JJ Jonas *(Dept of Metall Eng, McGill Univ, 3450 Univ St, Montreal, H3A 2A7, PQ Canada)*. Acta Metall Mat 41(6) 1907-1920 (Jun 1993).

The texture evolution induced by tensile deformation and by deep drawing was investigated. For this purpose, the textures of 3 types of steel (rimmed, Al-killed drawing quality, and interstitial free) were measured and analyzed using the series expansion method. The results indicate that the initial texture changes drastically after a few percent of plastic strain and evolves towards a single orientation for which the <110> direction is aligned with the tensile or drawing axis.

274G. OTHER ASPECTS OF FATIGUE

9A322. Anisotropic damage mechanics model for fatigue failure. - June Wang *(Dept of Mech, Huazhong Univ of Sci and Tech, Wuhan, Hubei 430074, Peoples Rep of China)*. Eng Fracture Mech 45(3) 349-355 (Jun 1993).

The development of an anisotropic theory of continuum damage mechanics for fatigue failure is described. The fatigue damage evolution model is based on earlier publications of the author on the anisotropic ductile damage and uniaxial fatigue damage theories. A more general damage characteristic tensor capable of characterizing micro-crack growth on the maximum shear plane as well as on the plane normal to the maximum tensile stress is formulated. The validity of the damage model proposed is verified by comparing the predicted and measured number of cycles to failure for RS50 steel and excellent agreement has been achieved.

9A323. Durability evaluation for components by simulating fatigue test and extreme value analysis. - Chuan-Yao Chen and Da-Xing Gao *(Dept of Mech Eng, Huazhong Univ of Sci and Tech, Wuhan 430074, Peoples Rep of China)*. Eng Fracture Mech 45(1) 25-29 (May 1993).

A simulating fatigue testing method and requirements are explored to evaluate quantitatively the durability of components which cannot be conveniently and economically tested. Three requirements for analogies are necessary, ie, the geometry and manufacturing quality of critical detail, stress and stress gradient at the expected cracking plane, and the crack initiation position and crack propagation path. The initial fatigue quality of components may be described by using the simulation test results and the extreme value theory. The distribution of time to reach any given crack size and the probability of crack exceedance, which is the measurement of component damage in service, are then obtained.

9A324. Effect of stress ratio on the fatigue threshold condition of physically small cracks. - DN Lal *(Dept of Metall Eng, IT, Banaras Hindu Univ, Varanasi 221 005, India)*. Fatigue Fracture Eng Mat Struct 16(4) 405-418 (Apr 1993).

An approach is proposed to predict the intrinsic threshold of physically small cracks without invoking crack closure considerations. The basic assumption invoked is that a ΔK representation is valid for short cracks, hence the lower-bound threshold value, $\Delta K_{0(s)(min)}$ for short cracks can be numerically equated with the lower-bound threshold value of long cracks, $\Delta K_{x0(1)(min),s}$ of the same material. Several experimental observations provide a basis for this rationalization.

9A325. Formation of slip bands in aluminium foil subject to variable stress loading and the application of this technique to stress measurement. - Y Nagase, Y Sawaki, H Yoshida *(Dept of Mech Eng, Shizuoka Univ, 3-5-1 Johoku, Hamamatu 432, Japan)*. Int J Fatigue 15(3) 205-211 (May 1993).

In this paper, the fundamental characteristics of fatigue slip bands formed in an aluminium foil are investigated under both constant and variable stresses, and this phenomenon is utilized to monitor the stress amplitude with the use of the foil. It is found that variation of stress amplitude hardly affects the increase of slip bands, and the fraction of slip bands under variable stress is correlated with the equivalent stress defined by $(\Sigma\sigma^{\alpha}_i N_i/\Sigma N_i)^{1/\alpha}$, where σ_i, N_i and α are stress amplitude, the number of cycles and the material factor which is peculiar to the foil used, respectively. It is concluded that the fraction of slip bands can be a measure of stress evaluation for both constant and variable stresses.

9A326. Possible effects of magnetic fields in fatigue. - IK Bhat *(Dept of Mech Eng, Inst of Eng Tech, Lucknow, India)*, MK Muju *(Dept of Mech Eng, Indian IT, Kanpur, India)*, PK Mazumdar *(General Eng Dept, Univ of Puerto Rico, Mayaguez 00680, Puerto Rico)*. Int J Fatigue 15(3) 193-197 (May 1993).

The fatigue life of mild steel (a ferromagnetic metal) in a magnetic field seems interesting: at a given stress level, after decreasing initially with increasing applied magnetic field (ie, current), the life approaches a limiting value as magnetic inductance (or magnetization) of the metal assumes its saturated (maximum limiting) value, which occurs when the applied magnetic field exceeds a critical value. This possibility is examined here through a life model that includes the effects of an applied field on dislocation flow as well as the strain which domains experience along their magnetization direction (called magnetostriction). The magnetic field apparently reduces life by affecting strain to a greater extent. Other possibilities that could contribute to life reduction by affecting both crack nucleation and propagation are also indicated. These include large-scale crack-tip plasticity due to easier dislocation flow, reduced crack closure during stage II cracking, and the stress concentration effects arising from possible diffusion of carbon atoms to the surface as impurities.

274H. CORROSION AND EMBRITTLEMENT

9A327. Chloride corrosion of steel rebars in mortars with fly ash admixtures. - N Kouloumbi and G Batis *(Section of Mat Sci and Eng, Natl Tech Univ, Heroon Polytechniou 9, Zografou 15773, Athens, Greece)*. Cement & Concrete Composites 14(3) 199-207 (1992).

This paper presents the results of an experimental investigation of the corrosion of steel rebars in different types of mortars immersed in 3.5% sodium chloride solution. The corrosion rate of the steel bars was determined in relation to the curing time and to the addition of Greek fly ash at 15 wt% and 30 wt%. The corrosion activity was evaluated by measuring (a) the gravimetric weight loss of the reinforcing steel bars; (b) their corrosion rate using the linear polarization resistance technique; and (c) the total and free chloride content of the various mortars used, by a selective chloride electrode. Additionally some X-ray diffraction measurements were made in order to identify the complex substances formed. The results indicate that the addition of Greek fly ash, at both percentages, improves the corrosion behavior of the reinforcing steel bars by lowering the free chloride content. Also, the 28-days of curing time increases the corrosion resistance of the specimens, especially those without additive. In all cases the 28 days cured specimens show a lower content of total and free chloride and a reduced corrosion rate with respect to the 1- and 7-days cured specimens.

9A328. Influence of additives in a H_2SO_4 environment on the stress corrosion cracking of type 304 stainless steel. - M Asawa *(Col of Educ, Shinshu Univ, Nishi-nagano, Nagano 380, Japan)*. Arab J Sci Eng **17**(4A) 445-452 (Oct 1992).

This study evaluates the resistance of type 304 stainless steel to stress corrosion cracking in sulfuric acid solutions with after addition of potassium cyanate, potassium selenocyanate, decomposition products of cyanate (NH_4OH, $NaHCO_3$, or $(NH_4)_2CO_3$), and NaOH. Cracking or localized attacks occurred at sulfate ion concentrations of 1.5-4 M and at pH values less than 0.35. The results show that addition of KOCN, NH_4OH, $NaHCO_3$ and $(NH_4)_2CO_3$ cause cracking to predominate by inhibiting general corrosion both by neutralization of some of the aggressive H^+ ions and, by adsorption of these species on the metal surface. KSeCN induces localized attack but inhibits general corrosion, through adsorption. NaOH induces SCC by its inhibitive effect decreasing the H^+ ion concentration.

9A329. Influence of loading profile and superimposed flutter load frequency on the fracture behavior of a submarine hull steel in seawater. - MZ Shah Khan *(Mat Res Lab, Ship Struct and Mat Div, Defence Sci and Tech Org, PO Box 50, Ascot Vale, Vic 3032, Australia)*. Int J Fatigue **15**(3) 199-203 (May 1993).

Fracture surface examination is a useful approach in gaining an understanding of the fracture behavior of materials. In this study, the fracture surfaces of submarine hull steel specimens, which failed by corrosion fatigue in seawater, were examined in order to determine the micromechanics of the fracture process. Results show that the early stage of crack advance, corresponding to an approximate zone of 0.5 mm from crack initiation, was environment-controlled and independent of the loading profile and superimposed flutter load frequencies. Beyond this zone the influence of loading profile and superimposed flutter frequency on the fracture morphology was clearly in evidence. The changes in the fracture morphology are described. The combinations of loading profile and superimposed flutter load frequency which influenced the cracking behavior are identified. The influence of cracking modes on the overall fatigue life is also discussed.

9A330. Investigation of corrosion prevention method for determination of steel structure condition. - LD Dukic *(Fac of Civil Eng, Univ of Zagreb, Rakuse 1 PO Box 165, Zagreb 41001, Croatia)* and I Stern *(Fac of Chem Eng and Tech, Univ of Zagreb, Pierottijeva 6 PO Box 177, Zagreb 41001, Croatia)*. J Construct Steel Res **25**(3) 167-183 (1993).

Corrosion influences the service life of building materials and accordingly the service life of whole structures. In order to avoid corrosion activity, it is necessary to separate the structures from the aggressive environment. The investigation has been made to develop a comprehensive expert system corrosion prevention method (ESCPM), to establish the condition of corrosion protection on structures during their service life. New types of assessment have been proposed to create a uniform assessment of corrosion protection on structures, and an optimum procedure has been developed for its maintenance.

274I. FRETTING, WEAR, AND EROSION

9A331. The differential effect of the hardness of metallic materials on their erosion and abrasion resistance. - G Sundararajan *(Defence Metall Res Lab, Kanchanbagh, Hyderabad 500258, India)*. Wear **162-164**(PART B) 773-781 (13 Apr 1993).

The resistances of annealed pure metals to solid particle erosion and two-body abrasion increases linearly with increasing hardness and thus are similar. However, alloyed metal shows a contrasting behavior. For example, a substantial increase in the hardness of steels achieved by quenching and tempering does not alter the erosion resistance. The abrasion resistance, however, does increase, although not as dramatically as in the case of pure metals. The objective of this paper is to understand the reasons behind such contrasting erosion and abrasion in conjunctions with the estimates of the average strain rates at which the plastic deformation occurs within the plastic zone, leads to the conclusion that deformation occurs under fully adiabatic conditions only during erosion and not under abrasion conditions. This conclusion, when incorporated in the localization models for erosion and abrasion proposed earlier by the present author, results in theoretical expressions for erosion and abrasion resistance which have different dependences on hardness. Thus the differential effects of hardness on erosion and abrasion are explained.

9A332. Effect of fretting on electroplated Pd-Ni contacts. - Hideaki Murata *(Yazaki, 1500 Misyuku Susono, Shizuoka 410-11, Japan)*, Yasuo Imada, Fumihiro Honda, Koichi Nakajima *(Toyota Tech Inst, 2 Hisakata Tempaku, Nagoya 468, Japan)*. Wear **162-164**(PART A) 339-346 (13 Apr 1993).

Surface observations of the composition and chemical state were carried out to understand the fretting behavior of an electroplated of Pd-20wt%Ni contact compared with that of an electroplated Pd contact. The experiments were conducted in ambient room air and in the relevant organic vapor. By fretting in ambient room air, the Pd-Ni contact acquired a high contact resistance because of oxidation, but with an Au-flash plating 0.1 μm thick on it, it remained stable and with a low contact resistance. This is attributed to the solid lubricant effect because of the soft, thin layer of gold on the much harder Pd-Ni. By fretting in the environmental containing toluene vapor, organic deposits (frictional polymers) were found on the Pd-Ni contact surface as well as on the Pd contact. Investigation of a possible correlation between the quantities of C and O on the contact surface detected by electron probe microanalysis revealed the existence of a small amount of organic deposits. At a low toluene concentration, some metal oxides were produced during the formation of organic products, and the correlation coefficient of C and O were reduced. By Fourier transform IR spectroscopy, the organic products were observed to include aryl or unsaturated esters. Organic deposits on the Pd-Ni contact functioned as a lubricant and inhibited the oxidation of the metal surface. This inhibitory effect was confirmed by characterizing X-ray spectrum analysis. In contrast, the deposits on the Pd contact did not act sufficiently as a lubricant, resulting in an increased contact resistance. Therefore, the Pd-Ni contact has some advantages over the Pd contact in the environment containing toluene vapor.

9A333. Effects of erodent recycling in solid particle erosion testing. - AJ Sparks and IM Hutchings *(Dept of Mat Sci and Metall, Univ of Cambridge, Pembroke St, Cambridge CB2 3QZ, UK)*. Wear **162-164**(PART A) 139-147 (13 Apr 1993).

In solid particle erosion tests, recycling of the erodent can lead to rounding, or in some cases significant fracture, of the particles, and thus to a progressive change in the test conditions. This work examines changes in particle size and shape resulting from impact, for a typical silica sand and for glass spheres. The target material was a glass-ceramic, and experiments were performed with an air-blast erosion rig. Erodent particles classified by sieving contained a significant proportion outside the nominal size range. Particle size distributions determined by sieving and optical methods showed disparities, due to particle shape effects. Both types of particles showed extensive fragmentation on striking glass-ceramic targets at 89 - 98 m s^{-1} at normal incidence. Repeated impact led to further fragmentation and a progressive reduction in the average particle size in the erodent sample, although some particles remained unbroken after more than ten impacts. The fragmentation of the particles led to changes in the measured erosion rate as they were recycled. At least three factors were responsible: the intrinsic size effect, aerodynamic effects in the gas-blast erosion rig, and changes in particle angularity due to fracture.

9A334. Erosive wear behavior of chemical vapor deposited multilayer tungsten carbide coating. - D Garg and PN Dyer *(Air Prod and Chem, 7201 Hamilton Blvd, Allentown PA 18195)*. Wear **162-164**(PART A) 552-557 (13 Apr 1993).

Erosive wear of components by solid particle impingement is a problem faced by many industries. A variety of protective coatings deposited by thermal spray, physical vapor deposition, and chemical vapor deposition techniques have been developed over the years to reduce erosive wear of components and increase their useful life. These coatings generally provide adequate protection in a mild, low-impingement angle environment, but they fare poorly in a harsh, high-impingement angle environment. This paper describes a new multilayer tungsten carbide-based coating, which has been developed to protect components both in low and high impingement angle environments. The multilayer coating is deposited by the chemical vapor deposition technique and consists of an outer tungsten carbide layer with a fine-grained, layered morphology at the top of a columnar tungsten inner layer. It can be deposited on several metals and alloys used by the aerospace industry at low temperatures without degrading their mechanical properties. The erosive wear behavior of the multilayer coating is compared with titanium nitride coatings deposited by the physical vapor deposition technique.

9A335. Gross slip criteria in fretting. - O Vingsbo and J Schon *(Dept of Mech Eng, Univ of Houston, Houston TX)*. Wear **162-164**(PART A) 347-356 (13 Apr 1993).

One of the most important characteristics in fretting is the transition from mixed stick-slip conditions to gross slip, as given by the corresponding regime boundary in fretting maps. The regime boundary is determined by the critical values of frequency, normal force, tangential force amplitude and displacement amplitude. Three sets of criteria for incipient gross slip have been studied in the present investigation: fretting scar morphology tangential force and displacement amplitude interrelations, and fretting energy dissipation. A fully computerized fretting tester has been used, in which the relative displacement between the specimens can be very accurately controlled and measured. Tangential force and relative displacement measurements can be made with resolutions of 2 nm and 5 mN respectively. Pure copper (UNS C11) specimens were studied. Post-test studies of fretting scars were performed by SEM. With some practice, it is possible to identify scar morphologies characteristics of the different regimes. The last two criteria were compared by plotting tangential force amplitude and energy dissipation together as functions of displacement amplitude in so-called FED (force energy displacement) diagrams. Some FED diagrams display force curves without a well-defined critical force amplitude, rendering the force criterion difficult to apply. The energy curves, however, always have a sharp bend, corresponding to a change in energy dissipation characteristics at the gross slip transition. The energy criterion occurs for a lower critical displacement amplitude than the force criterion (when applicable). A possible explanation of this observation is discussed.

9A336. **Influence of nozzle roughness on conditions in a gas-blast erosion rig.** - PH Shipway and IM Hutchings *(Dept of Mat Sci and Metall, Univ of Cambridge, Pembroke St, Cambridge CB2 3QZ, UK)*. Wear **162-164**(PART A) 148-158 (13 Apr 1993).

Although the gas-blast method of erosion testing is widely used, little is known about the distribution of particle velocities and trajectories in the plume of erodent particles leaving the nozzle. In this work, experimental methods have been developed to study and describe these, and in particular the influence of the internal roughness of the nozzle has been examined. An analytical function has been derived which describes the angular distribution of particle trajectories in the plume; this distribution is uniquely described by a single dimensionless "focus coefficient", β, which depends, among other factors, on the nozzle bore roughness and on the nature of the erodent particles. The nozzle roughness also significantly affects the velocity of the erodent particles; a rough nozzle bore is associated with lower erodent velocity, a greater spread of velocities and a more widely spread plume. The results are relevant to erosion testing by the gas-blast method, and suggestions are made for improvements in the control and standardization of the erosion conditions in such tests.

9A337. **Modeling of abrasive particle trajectories during erosion by a slurry jet.** - S Turenne *(Indust Mat Inst, NRC, Boucherville, Canada)* and M Fiset *(Dept of Mines and Metall, Laval Univ, PQ, Canada)*. Wear **162-164**(PART B) 679-687 (13 Apr 1993).

The aim of this study was to investigate the effect of fluid flow on the trajectories of abrasive particles near a specimen surface subjected to slurry erosion. In order to identify the different erosion mechanisms, it is necessary to know the impact parameters, such as the impact angle and the local velocity of the abrasive particles. An analysis based on potential and stream functions led to the determination of the velocity components of the fluid in the axisymmetrical jet (normal incidence). The boundary conditions corresponding to the free surface of the jet were included in the numerical resolution of the differential equations given by the inverse formulation of the fluid flow. From the velocity components of the fluid, it was possible to evaluate the viscous drag force on a particle and consequently the particle trajectories. The theoretical predictions show that the particle trajectories are, in some conditions, strongly deviated near the test surface. The observation of the eroded surfaces of the aluminum specimens was useful to verify the predictions that could be made from these particle trajectories. The observation pointed out the influence on particle trajectories of the abrasive particle size and the abrasive concentration in the slurry.

9A338. **Performance of aluminium alloys and particulate reinforced aluminium metal matrix composites in erosive-corrosive slurry environments.** - JA Bester and A Ball *(Dept of Mat Eng, Univ of Cape Town, Private Bag, Rondebosch 7700, S Africa)*. Wear **162-164**(PART A) 57-63 (13 Apr 1993).

A range of aluminium alloys and particulate reinforced aluminium metal matrix composites has been tested in an apparatus which simulates the erosive-corrosive action of a slurry. The slurry used in the investigation is composed of synthetic mine water and silica sand. The corrosion component of the mass loss was found to be an important synergistic factor. The addition of ceramic reinforcement particles to the matrix alloys has a detrimental effect on the slurry erosion resistance.

9A339. **Relationship between surface hardness and erosion damage caused by solid particle impact.** - YI Oka, M Matsumura, T Kawabata *(Dept of Chem Eng, Fac of Eng, Hiroshima Univ, Higashi-Hiroshima 724, Japan)*. Wear **162-164**(PART B) 688-695 (13 Apr 1993).

A model for erosion caused by solid particles was studied and an equation based upon the relationship between dynamic indentation and the hardness of the material was proposed. This equation was established by the relationship between the surface hardness and the erosion damage to the materials. Erosion tests using a gas gun unit were conducted on five materials over a wide range of hardness values (Hv number 9 - 1100) up to an impact velocity of 150 m s^{-1}. An increase in the hardness was seen on the fully eroded surfaces obtained in the case of iron and aluminium, but a decrease was seen in the case of quenched carbon tool steel. No change in the hardness was seen in the cases of the acrylic resin and nylon. The hardness of the eroded surfaces, as opposed to that of the non-eroded surfaces, slightly improved the correlation with erosion damage, but it was not necessarily sound. The softening observed on the eroded surface of the quenched carbon tool specimen suggested that heat was generated during the impact of the particles and also that the surface hardness during the course of erosion was different from that both before and after erosion. The temperature increase of an iron leaf sample owing to the impact of a 3.18 mm steel ball or silica sand particles pointed to a transiently high temperature on the impacted surfaces and the possibility of softening during the course of the erosion process. As a result, the surface hardness of each material estimated with respect to work hardening and softening reasonably correlated with the erosion damage. Also, numerical formulation and the soundness of this equation were discussed through many erosion tests under various conditions.

9A340. **SEM studies of material damage in alumina ceramics by angular single and multiple particle impacts.** - Jianren Zhou *(Dept of Mech Eng, Prairie View A&M Univ, Prairie View TX 77446)* and S Bahadur *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*. Wear **162-164**(PART A) 285-295 (13 Apr 1993).

The mechanisms of erosion in alumina ceramics have been investigated by scanning electron microscopy. The five commercial aluminas tested ranged from pure alumina to those containing different proportions of silicate glassy phase and zirconia. In single particle impact tests, the targets were impacted with 1035 μm angular SiC particles and in multiple particle tests with 151 μm SiC particles. The particles were always impacted under normal impact condition with an impingement velocity of 50 m s^{-1}. It was found that whereas brittle failure was the basic erosion mechanism, the morphological features of eroded surfaces were quite different for different materials and depended upon their compositions. The presence of secondary phases improved the bonding between alumina grains and also increased toughness by absorbing part of the impact energy. Therefore, the erosion resistance was enhanced by the presence of secondary phases in alumina. The erosion rates of these materials are analyzed briefly in terms of the erosion mechanisms. It was found that the classical lateral cracks which are typical of brittle indentation fracture was not present on the eroded surfaces of aluminas.

9A341. **Solid-particle erosion of *in situ* reinforced Si_3N_4.** - M Marrero, J Routbort *(Mat Sci Div, ANL)*, P Whalen, Chien-Wei Li *(Allied-Signal, Morristown NJ 07962-1021)*, KR Karasek *(Allied-Signal, Des Plaines IL 60017-5016)*. Wear **162-164**(PART A) 280-284 (13 Apr 1993).

Steady-state solid-particle erosion has been investigated on *in situ* reinforced Si_3N_4 and the "equivalent" fine-grained hot-isostatically-pressed Si_3N_4 whose R-curve beahviors are quite different, having K_{IC} values in the long-crack limit of 8.3 and 5.6 MPa $m^{1/2}$ respectively. Experiments were carried out at 20 °C, using SiC abrasives, whose diameters ranged from 42 to 1035 μm, varying the angle of impact from 15 to 90° and the velocity from 50 to 100 to 150 m s^{-1}. The erosion rates of the two materials were, within a factor of two, the same, indicating that the long-crack-length-limit toughness is not an indication of erosion resistance, for the range of particle size and velocities studied.

9A342. **Specimen diameter, impact velocity, erosion rate and particle density in a slurry pot erosion tester.** - HM Clark *(Dept of Mech Eng, Univ of Kansas, Lawrence KS 66045-2234)*. Wear **162-164**(PART B) 669-678 (13 Apr 1993).

Using the technique of measuring impact crater size, stagnation line impact velocities of glass spheres (mean diameter 666 μm) suspended in diesel oil at 40° C on cylindrical copper erosion test specimens ranging in diameter from 3.2 mm to 9.5 mm tested at normal speed of 18.7 m s^{-1} in a slurry pot tester have been measured. Similarly, the variation in normal impact velocity of the same glass spheres as a function of angular location about the specimen has been measured for a 4.7 mm diameter specimen. Erosion rates for 1020HR steel specimens in the diameter range 3.2 mm to 9.1 mm were determined using a 1.2 wt% suspension in diesel oil of silicon carbide particles, mean size 136 μm. Stagnation line impact velocities have been measured for spherical particles ranging in density between 2420 kg m^{-3} and 7830 kg m^{-3} suspended in diesel oil. The changes in impact conditions and erosion rates were analyzed using a model of suspension flow about, and particle impact on, a cylindrical target. It is shown that changes in erosion rate can be well accounted for by the changes in mean kinetic energy dissipated in collision and the frequency of particle impact, themselves controlled by the conditions of two-phase flow. It was also found that while the dispersion of solid particles in a slurry pot tester is very fast, the test method is subject to uncertainty in the value of the free-stream velocity. This effect is thought to be caused by rotation of the suspension in the test apparatus. A method of estimating its magnitude is given.

9A343. **A study of the fundamental mechanisms of erosion using Hertzian fracture tests.**

- Jyh-Woei Lu *(Supertech Consult, Chandler AZ 85224)*, GA Sargent *(Univ of Dayton, Dayton OH 45469)*, H Conrad *(N Carolina State Univ, Raleigh NC 27695)*. Wear 162-164(PART B) 856-863 (13 Apr 1993).

Hertzian fracture tests were conducted at room temperature on Pyrex glass under static and dynamic loading conditions to study the fundamental mechanisms of erosion. The effects of specimen surface roughness, a grease coating, loading rate and indenter materials, size and roughness on the fracture load and ring crack radius were considered. It was found that the ratio of the ring crack radius to contact radius decreased with increasing load, indenter size and loading rate. Also, the above ratio and fracture load increased with increase in elastic modulus mismatch between indenter and specimen and with abrasion of the indenter and/or specimen. The effects of abrasion and indenter material on Hertzian fracture behavior were in quantitative accord with predictions of friction and roughness effects proposed by Johnson *et al.* The increase in critical load to fracture observed in the dynamic tests compared with the static tests, and the increase in critical load due to the grease coating were concluded to be due to kinetic effects associated with the presence of water vapor at the crack tip.

9A344. Study on mechanism of combined action of abrasion and cavitation erosion on some engineering steels. - Zhao Kang, Gu Chenqing, Shen Fusan, Lou Bingzhe *(Dept of Mat Sci, Shaanxi Mech Eng Inst, Xi'an, Shaanxi 710048, China)*. Wear 162-164(PART B) 811-819 (13 Apr 1993).

The abrasion and cavitation erosion properties as well as the relevant failure mechanisms of several steels to be used for hydraulic turbine parts were investigated. The tests were carried out using rotating disc equipment under simulated working conditions, instead of the conventionally used venturi tube or vibration apparatus. Different weight loss curves were obtained. The experimental results obtained from our scanning electron microscopy, transmission electron microscopy, light microscopic observations, X-ray analysis and other test methods proved that it is more reasonable to consider the cavitation erosion as a failure of low cycle (plastic strain) fatigue. Hence, it was derived from the Manson-Coffin relation that the resistance to cavitation erosion depends on the square of the product of the hardness and that the true fracture strain ε_f of the steel. Sand-water abrasion is actually a microcutting of the surface layer of the steels and, here, the hardness of the steels is proved to be the main resistance factor. The failure of steels in muddy and sand-carrying water is due to the combined action of abrasion and cavitation erosion, and the consequent weight loss rate is the weighted sum of the individual rates of abrasion and cavitation erosion. Equations that relate the weight loss rate of abrasion and also of cavitation erosion to the mechanical properties of the steels were developed. The calculated values and the experimental data agree well. Conclusions drawn give useful reference principles for the microstructural design of steels to be selected and also for the improvement of their heat treatment.

9A345. Surface temperatures and fretting corrosion of steel under conditions of fretting contact. - HM Ghasemi, MJ Furey, C Kajdas *(Dept of Mech Eng, VPI)*. Wear 162-164(PART A) 357-369 (13 Apr 1993).

One of the fundamental questions in tribology is the magnitude of surface temperatures generated in the fretting of steel and if this is a factor in the formation of metallic oxides. An infrared microscope was used as a means of direct measurement of surface temperatures generated under low frictional heat rates (lower than 1.5 J s^{-1}) encountered in fretting experiments. A photo-video technique was developed to view the fretting contact interface in "real time" and to observe the process of oxide formation. In addition, wear scars on the steel were examined using both photomacrography and scanning electron microscopy. Spherical 52100 steel specimens, 1.25 cm in diameter, were studied under various loads (4 N-20 N), amplitudes (20 μm and 100 μm), and at a constant frequency of 150 Hz. Studies in air showed that even with surface temperatures as low as 25-30 °C, significant quantities of oxides quickly formed on the steel ball in contact with sapphire during fretting. The observed formation of iron oxides in low surface temperature tribological experiments is explained in terms of exoelectron emission is suggested by Kajdas. The measured surface temperature rises were also compared with Archard's theoretical model. The wear rates of steel under these fretting conditions depended on load, vibration amplitude, and environment - the latter two effects being greatest. For example, in air, increasing the amplitude from 20 to 100 μm resulted in a 20 fold increase in wear for a given sliding distance. Fretting experiments in nitrogen, under high load and high amplitude conditions, resulted in a 100 fold decrease in wear compared with that observed in air. However, the magnitudes of surface temperature rise in air and in nitrogen were not significantly different.

274J. CREEP

9A346. Application of double cantilever beam model to the analysis of creep crack growth under neutron irradiation. - S Murakami, K Hayakawa *(Dept of Mech Eng, Nagoya Univ, Furo-cho Chikusa-ku, Nagoya 464-01, Japan)*, M Mizuno *(Dept of Mech Eng, Kyoto Univ, Yoshida-honmachi Sakyo-ku, Kyoto 606-01, Japan)*. Eur J Mech A 12(2) 249-263 (1993).

The effect of neutron irradiation on creep crack growth in an infinite plate is analyzed by use of a double cantilever shear beam model. The model is assumed to consist of a stripe of creep damage zone which includes the crack plane and is in a state of uniaxial tension perpendicular to the crack plane, combined with the shear dominant elastic zone outside the creep damage zone. The creep crack growth in the creep damage zone is modeled by the constitutive equations of irradiation creep and irradiation creep damage proposed by the present authors.

9A347. Creep and creep damage of glass fiber reinforced polypropylene. - J Hugo, M Sova, J Cizinsky *(Natl Res Inst for Mat, Opletalova 25, 113 12 Prague 1, Czech Republic)*. Composite Struct 24(3) 233-244 (1993).

Composites based on isotactic polypropylene matrix and short glass fibers were tested for creep, creep damage and creep rupture at different temperatures and stress levels. Four composites of 5-30 wt% of glass fiber content having standard fiber-matrix adhesion were used, while two materials with 20 and 30 wt% of fibers were prepared as elevated adhesion composites. Unreinforced polypropylene was tested as a reference material. The rate of steady-state creep (which was determined by an arbitrary method) was used as a criterion for the examination of glass fiber content and fiber-matrix adhesion effects on creep. Secondary criteria, type and extent of damage and time to rupture were applied. Up to 40°C the steady state creep and creep damage of all tested polypropylene composites are retarded by glass fibers according to the fiber content. At 60°C and above, there is a distinct difference between composites of standard and elevated fiber-matrix adhesion. At higher temperatures the creep and creep damage are more or less accelerated by higher content of standard adhesion fibers; these fibers induce crazing (as a typical creep damage) at relatively low stress. Fibers of elevated adhesion shift the processes of nonrecoverable creep and crazing to the higher stress range, even if their craze inducing activity remains. It was found that the creep, creep damage and creep rupture are controlled by the steady state creep mechanism of polypropylene, a conclusion which was deduced from the stress and temperature dependence of the creep rate, as well as from the morphological analysis of damaged and ruptured specimens.

9A348. Effects of grain boundary diffusion and power law creep on cylindrical cavity deformation. - YS Lee *(Dept of Mech Eng, Chung BUK Natl Univ, Cheong JU, Chung-BUK 360-763, S Korea)*, TA Kozlosky, TJ Batt *(Westinghouse Elec, PO Box 2728, Pittsburgh PA 15230-2728)*. Acta Metall Mat 41(6) 1841-1854 (Jun 1993).

Volume growth rate, rupture time and the phenomenological creep damage parameter are investigated using both grain boundary diffusion and power law creep. Voids are assumed to be cylindrically shaped with a dihedral angle of $\pi/2$, and are arrayed in the grain boundary at constant spacing and radius. The grain boundary separation velocity is obtained from a modification of the stress analysis result obtained from a previous analysis. The results obtained in the analysis are compared with the results obtained using the spherical cap (dihedral angle, $\psi = 70°$) of Needleman and Rice. The results show that if L/a is large, cavity deformation is controlled by the grain boundary diffusion mechanism while power law creep controls the deformation in the range of small L/a. These results are consistent with the results obtained by Needleman and Rice.

9A349. Experimental study of behavior of low alloy steels in the initial growth stage of creep cracks. - Akio Fuji, Masaki Kitagawa *(Res Inst, Ishikawajima-Harima Heavy Indust, Toyosu Kotu-ku, Tokyo 135, Japan)*, A Toshimitsu Yokobori *(Dept of Mechatronics and Precision Eng, Tohoku Univ, Aoba, Sendai 980, Japan)*. Eng Fracture Mech 45(1) 39-50 (May 1993).

In the early stage of creep crack growth, low alloy steels exhibit a transitory behavior of which the expression for the crack growth rate (da/dt or a) as a function of the Cx integral or of the load line displacement rate (δ) becomes anomalous: the data deviate from the linearity describing a nose, thereby forming a part called the tail. In empirically analyzing the phenomenon, which has been taken to indicate the extent of degradation of the material, the following observations are made for its formation mechanism and chronological progress for 1CrMoV steel and 2.25 Cr-1Mo steel. The electrical potential method overestimates the crack length while it is small.

9T350. Life extension of high temperature components. - BF Dyson *(Div of Mat Appl, Natl Phys Lab, Teddington, Middlesex TW11 0LW, UK)* and FA Leckie *(Dept of Mech and Env Eng, UC, Santa Barbara CA 93106)*. Appl Mech Rev 46(5) 229-231 (May 1993).

9A351. Physical aging in the creep behavior of thermosetting and thermoplastic composites. - JL Sullivan, EJ Blais, D Houston *(Ford Motor, PO Box 2053, Dearborn MI 48121)*. Composites Sci Tech 47(4) 389-403 (1993).

The creep behavior of a series of fiber-reinforced plastics (FRP) and corresponding resins has been studied, with emphasis on elucidating the role of physical aging effects on FRP viscoelastic behavior. Thermosetting and thermoplastic composites were studied, representing semicrystalline, amorphous, adn highly filled amorphous polymer matrix FRPs. It was found that physical aging effects are operative for all FRPs including the semicrystalline systems. Time-aging-time and time-temperature superposition are found to be valid procedures for short-term creep behavior; they cannot be applied to long-term creep behavior. However, long-term creep can be satisfactorily predicted from momentary creep by using an effective time theory. Evidence of a universal, temperature shift factor temperature dependence is presented.

274K. ABLATION, SPALLATION, DELAMINATION

9A352. **Description of 2D spallation in pure copper.** - Ze Ping Wang *(Inst of Appl Mech, SW Jiaotong Univ, Chengdu, Sichuan 610031, Peoples Rep of China)*, Feng Lei Huang, Min Hou, Shou Rong Yun, Jing Ding *(Mech Eng Dept, Beijing IT, PO Box 327, Beijing 100081, Peoples Rep of China)*. Int J Fracture 60(3) 195-208 (1 Apr 1993).

A new ductile dynamic failure model, based on a porous element consisting of a single spherical void of radius a in a sphere of radius b subject to internal pressure P_g and external stress $\sigma_r = -\alpha P + (\alpha - 1)P_g$, is developed in the present work. Work-hardening behavior, rate-dependent contribution and inertial effects are taken into account in the model. Stress controlling mechanism is adopted while considering the contribution of void nucleation to rate of porosity Φ. The mathematical model presented here is incorporated in a hydrodynamic 2D finite-difference computer code, to simulate 2D spallation of pure copper. Comparison of numerical calculation with experimental results show that the model described the process of spall experiment successfully. The future improvements of the model are discussed.

9A353. **Role of indentation fracture in free abrasive machining of ceramics.** - R Chauhan, Y Ahn, S Chandrasekar, TN Farris *(Sch of Indust Eng and Aeronaut and Astronaut, Purdue)*. Wear 162-164(PART A) 246-257 (13 Apr 1993).

Free abrasive machining (FAM) is widely used for stock removal and surface finishing of ceramics. In FAM, material removal results from mechanical action between the abrasive slurry, which is trapped between the workpiece and a rotating lapping block, and the workpiece. Microscopic observations of the machined surface show that lateral cracking due to indentation by the abrasive particles contributes substantially to material removal. A simple model of FAM is developed which is based on indentation fracture and takes into account the abrasive particle distribution in the slurry. The model is used to predict the number of particles actually involved in the machining process, the distribution of load among these particles, and the depth of the plastically deformed layer on the workpiece surface. Many of the predictions of the model are well supported by experimental observations from the FAM of aluminum oxide, Ni-Zn ferrite, and glass using a silicon carbide slurry.

274M. MICROMECHANISMS

9A354. **Ductile fracture by the growth and coalescence of microvoids of nonuniform size and spacing.** - PF Thomason *(Dept of Aeronaut and Mech Eng, Univ of Salford, Salford M5 4WT, UK)*. Acta Metall Mat 41(7) 2127-2134 (Jul 1993).

A 2D plane strain model of void growth and coalescence in a rigid-plastic solid, containing void sizes and spacings which can be highly non-uniform, is developed to investigate the effects of non-uniform distributions of void-nucleating particles on the ductility of a metal. The theoretical void-growth strains to ductile fracture for a wide variation in void diameters and spacings show that, for a given volume fraction of voids, the minimum ductile fracture strain occurs when the voids are of uniform size and spacing. For the same volume fraction voids, greatly increased ductility is likely to be achieved when the void sizes and spacings are highly non-uniform and the sub-cell volume fractions are also non-uniform.

274X. STOCHASTIC ASPECTS

9A355. **Comparison of analytical counting methods for Gaussian processes.** - V Bouyssy *(Tech Univ, Munchen, Germany)*, SM Naboishikov *(Tech Univ, Vinniza, Ukraine)*, R Rackwitz *(Tech Univ, Lehrstuhl Massivbau, Arcisstr 21, D-8000 Munchen 2, Germany)*. Struct Safety 12(1) 35-57 (Apr 1993).

For structural components under random loading, realistic fatigue life predictions require a damage accumulation law together with a cycle counting method. If the classical, linear and memory-less summation rule according to Palmgren-Miner is adopted and the underlying stress process is ergodic substantial simplifications can be reached. From experiments and certain theoretical considerations, so-called rainflow range or local range counting appears most appropriate. Even if the underlying is a Gaussian process, easy analytical solutions are at most available for special types of processes. Therefore, counting usually must be done numerically at observed or artificial stress histories which is extremely time consuming.

9A356. **Mechanistically based approach to probability modeling for corrosion fatigue crack growth.** - DG Harlow and RP Wei *(Dept of Mech Eng and Mech, Lehigh Univ, Bethlehem PA 18015)*. Eng Fracture Mech 45(1) 79-88 (May 1993).

An approach and methodology for developing a probability model for life prediction and its utility are demonstrated. The goal of this probabilistic approach is to make stochastically tight estimates of life for conditions that are beyond the range used in typical supporting data. Probability models, versus statistically based modes, are used to describe the influences of fundamental variables through mechanistically based models of the failure processes. The approach and methodology is illustrated through the use of a simplified model for reaction controlled corrosion fatigue and crack growth for ferrous alloys in aqueous environments.

9A357. **Note on cycle counts in irregular loads.** - I Rychlik *(Dept of Math, Univ of Lund, Box 118, S-22100 Lund, Sweden)*. Fatigue Fracture Eng Mat Struct 16(4) 377-390 (Apr 1993).

In this paper we discuss cycle counting methods, such as rainflow-, crest-to-trough-, positive peak-count and different damage accumulation rules, for irregular random loads, which have an infinite number of local extremes in finite intervals, eg, the fourth spectral moment is infinite. We present conservative bounds for the expected damage for such loads from the upcrossing intensity. These results are illustrated by examples of Gaussian x^2-, and Morison-loads.

9A358. **Statistical analysis of material damage with changing internal structure.** - CW Woo and DL Li *(Dept of Mech Eng, Univ of Hong Kong, Hong Kong)*. Eng Fracture Mech 45(2) 245-254 (May 1993).

An investigation on the mechanical properties of material with changing internal structure or damage induced by large deformation is carried out. A new experimental procedure has been established for the ductile damage test with a large number of specimens for the purpose of the statistical analysis. The experimental results show that the macroscopic mechanical properties of material both prior to and during the process of the mechanical damage vary in a random manner. The statistical analysis reveals that the scatter of the material properties during the process of damage evolution is larger then that of the original material properties. When the original material properties are treated separately as deterministic and random ones, the obvious statistical discrepancy during the process of the damage evolution is exposed. The results obtained provide much useful information for the prediction of material damage based on the probabilistic formulation.

276. Fracture and damage mechanics

276A. GENERAL THEORY

9A359. **Fracture mechanics-based failure analysis.** - AR Rosenfield and CW Marschall *(Battelle, Columbus OH 43210)*. Eng Fracture Mech 45(3) 333-338 (Jun 1993).

Twenty case studies, involving the application of fracture mechanics to structural integrity, have been reviewed and compared to a similar report published in 1978. Sixteen of the new cases discussed failures, while four were fitness-for-purpose analysis (ie, evaluation of safe operating conditions of defect-containing structures). In reviewing the case studies, it was found that the calculated value of stress intensity at failure was usually only approximately equal to the reported value of fracture toughness. Furthermore, in a number of cases, the calculated stress intensity was significantly less than the reported fracture toughness, thereby indicating a non-conservative fracture mechanics analysis. The probable cause for this relatively poor correlation was that the inputs into the analyses, particularly fracture toughness were often approximations. Both reviews suggest that the likelihood of failure is particularly large when there is a defect greater than 25 mm (1.0 in) in size and when the fracture toughness: yield strength ratio is less than $0.16\sqrt{m}$ ($1.0\sqrt{in}$). No significant improvement in accuracy of failure analysis was detected compared to the earlier paper.

9A360. **Screw dislocation dipoles near an internal crack.** - KM Lin *(Dept of Mat Sci, Feng Chia Univ, Taichung, Taiwan, ROC)*, CT Hu, Sanboh Lee *(Dept of Mat Sci and Eng, Natl Tsing Hua Univ, Hsinchu, Taiwan, ROC)*. Eng Fracture Mech 45(3) 321-331 (Jun 1993).

Based upon the results of previous work the system of the screw dislocation dipole interacting with an internal crack is studied. The analytic formulae of the physical variables, such as stress field, strain energy and flipping energy, image force and image torque, and stress intensity factor, are obtained. Both dipole emission from the crack and the effect of the dipole on crack shielding are discussed in detail. If a dipole near an internal crack is originated from the crack, it must be at an orientation angle α_{max} corresponding to a state of maximum energy when emission occurs, and then rotates to lower its strain energy to an orientation angle α_{min} in the range of $(90° + \lambda/2)$ and $(270° + \lambda/2)$ due to the image torque, where λ denotes the angle between emission and crack planes. A dipole orienting at an angle α_{min} shields both crack tips simultaneously. In addition, the behavior of a dipole coplanar with the crack is also investigated. It is found that (1) under the action of a mode III applied stress, a zero-force point exists in front of the crack tip when the dipole orients at $\alpha = 180°$; and (2) a maximum shielding (for $\alpha = 180°$) or antishielding (for $\alpha = 0°$) on the left-hand crack tip occurs when the ratio of the half crack length to the distance from the right-hand tip to the dipole center (l/p) is equal to 0.25.

9A361. Strain energy release rate for a cracked plate subjected to out-of-plane bending moment. - MJ Young and CT Sun *(Sch of Aeronaut and Astronaut, Purdue)*. Int J Fracture 60(3) 227-247 (1 Apr 1993).

For a through-the-thickness crack in an infinite plate subjected to out-of-plane uniform bending moment, the strain energy release rate is determined using the virtual crack extension and the variation of potential energy. It is shown that the strain energy release rate for the Reissner's plate approaches the classical plate solution as the ratio of plate thickness to crack size becomes infinitesimally small. By using this result, the limiting expression of the stress intensity factor can be explicitly obtained. For general problems, the modified crack closure method is shown to be an efficient tool for evaluating the strain energy release rates from which the stress intensity factor can be calculated. Both the classical plate element and the Mindlin plate element are investigated, and the applicability of the classical plate element is evaluated. Because the stress-free conditions along the crack face lead to inter-penetration of the plate, a line contact model is assumed to investigate the closure effect using Reissner plate theory. Closure at the compressive side is shown to reduce crack opening displacement and consequently the stress intensity factors. When closure is considered, the strain energy rate based on the Reissner plate theory converges to the classical plate solution. This is similar to the nonclosure case.

276B. LINEAR ELASTIC FRACTURE MECHANICS

9A362. Fracture criterion for the axisymmetric disking process. - S Santhanam *(Dept of Mech Eng, Villanova Univ, Villanova PA 19085)*. Int J Fracture 60(1) 65-77 (1 Mar 1993).

Disking is a process designed to cut brittle plates and rods. In axisymmetric disking, a pre-cracked cylindrical rod is placed in an elastic, annular sheath and the composite is subjected to biaxial fluid pressure. At a critical pressure the crack runs across the circular section of the rod producing a clean cut. A linear elastic fracture mechanics analysis is used to develop a fracture criterion for the process. The problem is formulated as a singular integral equation of the first kind with a Cauchy type kernel. The stress intensity factors are determined as a function of crack size and shear moduli.

9A363. Stress intensity factors and interaction of three cracks on both edges of finite width sheet. - MJ Shu *(Dept of Mech Eng, Univ of Pet, Shandong, Dongying 257062, Peoples Rep of China)*, J Petit, ZD Jiang, G Bezine *(Lab Mec Phys Mat, URA CNRS 863, ENSMA 86034 Poitiers, Cedex, France)*. Eng Fracture Mech 45(3) 407-414 (Jun 1993).

Two equal parallel cracks on one edge and one unequal parallel crack on the other edge of a finite width sheet are studied. Formulae for calculating the stress intensity factors (SIF) of this crack configuration are obtained from the results of FE analysis. The differences between the formula and the FE results is less than 3%. On this basis, the influence of crack interactions on SIF is discussed.

276D. STRESS INTENSITY FACTOR CALCULATIONS

9A364. Applications of the weight function method. - TPJ Mikkola *(Tech Res Centr, VTT, Ship Lab, Vuorimiehentie 5, SF-02150 Espoo, Finland)*. Eng Fracture Mech 45(2) 209-231 (May 1993).

New solutions were developed for the stress intensity factor and the crack opening displacement at the crack center for the semi-elliptical surface crack in a wide plate under remote tension and bending loads. The solutions were based on results of FE analyses made by an automated program system and the accuracy of the results were carefully studied. The new solutions were used for developing weight functions for the structure. The accuracy of the present weight function method is sufficient for practical applications.

9A365. Boundary element crack closure calculation of 3D stress intensity factors. - TN Farris and M Liu *(Sch of Aeronaut and Astronaut, Purdue)*. Int J Fracture 60(1) 33-47 (1 Mar 1993).

A general method for BE-crack closure integral calculation of 3D stress intensity factors is presented. An equation for the strain energy release rate in terms of products of nodal values of tractions and displacements is obtained. Embedded and surface cracks of modes I, II, and III are analyzed using the proposed methods. The multidomain BE technique is introduced so that the crack surface geometry is correctly modeled and the unsymmetrical boundary conditions for mode's II and III crack analysis are handled conveniently. For all the examples demonstrated in this paper, 54 BEs are used, and the most suitable ratio of the width of crack front elements to the crack depth is 1/10 and the calculation error is kept within ± 1.5%.

9A366. Comparison of two quarter-point element extrapolation equations for 3D mixed-mode problems. - Li Sen Chen and Jao Hwa Kuang *(Dept of Mech Eng, Natl Sun Yat-Sen Univ, Kaohsiung 80424, Taiwan, ROC)*. Eng Fracture Mech 45(1) 21-23 (May 1993).

Two quarter-point extrapolation equations for the stress intensity factors in 3D mixed-mode problems are compared, one set of equations proposed by Rhee and the other derived from the Tracey-Barsoum equations. The nodal displacements of the collapsed quarter-point elements around the crack tip are employed by both methods to extrapolate the stress intensity factors. The analytical derivations indicate good agreement between the methods.

9A367. Generalized WF solution for mode I 2D part-elliptical cracks. - GS Wang *(Struct Div, Aeronaut Res Inst, S-161 11 Bromma, Sweden)*. Eng Fracture Mech 45(2) 177-208 (May 1993).

A generalized approximate weight function solution is achieved for the 2D mode I part-elliptical crack subjected to arbitrary crack surface pressure. This solution can be used to solve the general crack problem according to the superposition principle. The weight functions are derived from one or several stress intensity factor results and the corresponding crack surface pressures. A newly developed generalized approximate crack surface displacement solution for the arbitrary crack type and crack surface pressure, along with a criterion, is used in the solution so that good accuracy can be achieved for various problems. Examples are given to demonstrate this procedure.

9A368. Influence of crack closure on SIF for plates under bending: A mixed mode case. - KN Ramachandran Nambissan *(Dept of Civil Eng, REC, Calicut 673 601, India)* and M Sreekumar *(Dept of Civil Eng, MIT, Manipal 576 119, India)*. Eng Fracture Mech 45(2) 149-158 (May 1993).

Solutions to mixed mode problems for plates under bending, with inclined through-the-thickness cracks, are obtained taking the closure phenomenon on the compression zone into account. A 3D FEM using singular and transition elements to model the crack tip region is employed for the analysis. The closure region on the crack faces is determined by a trail and error procedure.

9A369. Mixed-mode stress intensity factors for interacting semi-elliptical surface cracks in a plate. - RB Stonesifer *(Comput Mech, Julian PA 16844)*, FW Brust and BN Leis *(Dept of Eng Mech, Battelle, Columbus OH 43201)*. Eng Fracture Mech 45(3) 357-380 (Jun 1993).

Mixed-mode stress intensity factor solutions are presented for two parallel, but not necessarily coplanar, interacting surface cracks in a plate. The plate is subjected to a remote uniaxial stress acting normal to the crack planes. The crack separation distances, measured normal and parallel to the crack planes, are varied to provide 24 crack geometries. The smallest separation distances is equal to a quarter of the plate thickness. The equal sized interacting cracks have fixed depth-to-thickness ratio of 0.5 and fixed half-width-to-depth ratio of 3. The FE alternating method is used to develop the solutions. The tendency for the cracks to grow apart or to coalesce is discussed.

9A370. Simple estimates of stress intensity factors by crack path approximation with application to fatigue reliability. - HH Harkness *(Dept of Theor and Appl Mech, NWU)* and T Belytschko *(Dept of Civil Eng, NWU)*. Eng Fracture Mech 45(2) 255-264 (May 1993).

Simple methods for estimating stress intensity factors are developed for non-rectilinear edge cracks in 2D. These methods are based on observations that the stress intensity factors depend primarily on only a few crack geometry characteristics; for edge cracks in a uniaxial stress field, the location of and tangent to the crack tip are critical. Examples demonstrate that the stress intensity factor estimates obtained by approximating the shape of edge cracks are highly accurate.

9A371. Stress intensity factors for a crack in planar disking. - S Santhanam *(Dept of Mech Eng, Villanova Univ, Villanova PA 19085)*. Int J Fracture 60(1) 19-32 (1 Mar 1993).

Disking is a relatively new manufacturing process for cutting-slicing brittle plates and rods. In the planar disking configuration, a pre-cracked plate is placed against plate and the two are squeezed together by fluid pressure. At a critical pressure the crack runs across the thickness of the brittle plate producing a clean cut. In this paper a fracture criterion is developed for the process using linear elastic fracture mechanics. The problem is formulated in terms of a singular integral equation with the derivative of the crack surface displacement (dislocation density) as the unknown function. Numerical quadrature is used to determine the stress intensity factors as a function of the parameters of the problem.

9A372. Weight functions for interface cracks. - L Banks-Sills *(Eda and Jaime David Dreszer Fracture Mech Lab, Dept of Solid Mech Mat and Struct, Fac of Eng, Tel-Aviv Univ, 69978 Ramat Aviv, Israel)*. Int J Fracture 60(1) 89-95 (1 Mar 1993).

Weight functions are developed for determining stress intensity factors of cracks along an interface between two linear, elastic materials. As a result of the interface, both mode I and II components will be present for all but very special loading cases. The weight functions are employed to produce exactly the known stress intensity factors of a crack along an interface loaded by tensile and shear point forces.

276E. VISCOELASTIC PROBLEMS

9A373. **Effect of grain-size on the stress and velocity fields ahead of a crack in a material which deforms by Coble creep.** - J Pan and ACF Cocks *(Dept of Eng, Cambridge Univ, Trumpington St, Cambridge CB2 1PZ, UK)*. Int J Fracture 60(2) 121-134 (15 Mar 1993).

The stress and velocity fields ahead of a grain-boundary crack in a material which deforms by Coble creep are investigated for a series of grain sizes using the numerical analysis technique established by Cocks. The numerical results are compared with the linear viscous fields obtained by the BEM and the FEM. It is demonstrated that a detailed knowledge of the micromechanical processes of material transport and deformation are required to determine the stress and displacement fields for the grains which immediately surround the crack tip. But the response of the surrounding material can be adequately described from a conventional linear viscous analysis of the problem.

9A374. **Void growth ahead of a dominant crack in a material which deforms by coble creep.** - ACF Cocks and J Pan *(Dept of Eng, Cambridge Univ, Trumpington St, Cambridge CB2 1PZ, UK)*. Int J Fracture 60(3) 249-265 (1 Apr 1993).

This paper examines the process of void growth ahead of a dominant crack in a material which deforms by grain-boundary diffusion. A numerical technique recently developed by the authors is used to analyze the full interaction between void growth and deformation ahead of the crack tip. For the situation where voids only grow within a narrow zone directly ahead of the crack tip, it is possible to develop a range of simple analytical models. It is demonstrated that for this class of problem of suitable utilization of the dislocation model suggested by Thouless provides a good estimation of the void growth rate.

276F. CRACK TIP PLASTICITY PROBLEMS

9A375. **Best fit curve through crack growth fracture resistance data.** - BK Neale *(Nucl Elec, Berkeley Tech Centre, Berkeley, Glos GL13 9PB, UK)*. Fatigue Fracture Eng Mat Struct 16(4) 465-472 (Apr 1993).

The ESIS recommendations for determining the fracture resistance of ductile materials make use of an offset power law to evaluate the best fit curve to crack growth fracture resistance data. Evaluation of the offset power requires the use of nonlinear regression analysis, although an iterative linear regression analysis can be used if the data are transformed by taking logarithms. The two analyses are compared with a proposed alternative formulation for the offset power law which can be evaluated using an iterative linear regression analysis without the need to transform the data.

9A376. **Complete theoretical analysis for higher order asymptotic terms and the HRR zone at a crack tip for mode I and mode II loading of a hardening material.** - S Yang, YJ Chao, MA Sutton *(Dept of Mech Eng, Univ of S Carolina, Columbia SC 29208)*. Acta Mech 98(1-4) 79-98 (1993).

A complete development for the first two terms of the crack tip fields for both Mode I and Mode II loading of a hardening material in either plane stress or plane strain is performed, including the elastic deformation in the analysis. It is shown that the determination of the order of the second term depends on both n and whether plane stress or plane strain is considered. In addition, regions of HRR dominance at a crack tip for the field variables are estimated.

9A377. **Computational procedure for the simulation of ductile fracture with large plastic deformation.** - S Roy, RJ Dexter, AF Fossum *(Eng and Mat Sci Div, SWRI)*. Eng Fracture Mech 45(2) 277-293 (May 1993).

It is now well-known that the applicability of the single-parameter J-approach is restricted only to high constraint crack geometries and materials of low ductility. Consequently, there is a need to develop a ductile fracture criterion that does not suffer from the geometry dependence exhibited by the J-integral. The purpose of this paper is to describe the formulation and implementation of an efficient finite deformation algorithm that can be used for the prediction of elasto-plastic fracture in ductile materials where J-dominance is violated. The application of continuum damage models as potential ductile fracture criteria is discussed. The overall efficiency of the code is enhanced by means of the BFGS (Broyden, Fletcher, Goldfarb and Shanno) solution algorithm. The effectiveness of including material damage in the constitutive behavior to predict ductile failure in a notched tensile specimen is addressed.

9A378. **Dependence of acoustic emission for low strength steels upon the embrittlement and the plastic zone reduction at the crack tip during corrosion fatigue crack propagation.** - ZF Wang, J Li, W Ke *(Corrosion Sci Lab, Inst of Corrosion and Protection of Metals, Acad Sinica, Shenyang, China)*, Z Zhu *(State Key Lab for Fatigue and Fracture of Mat, Inst of Metal Res, Acad Sinica, Shenyang, China)*. Fatigue Fracture Eng Mat Struct 16(4) 441-451 (Apr 1993).

Acoustic emission signals were continuously monitored during fatigue crack propagation for two kinds of low strength steel placed in either laboratory air or 3.5% NaCl solution. The plastic deformation of the materials at the crack tips were compared by determining the changes in specimen geometry at the fracture surface in the thickness direction while the hydrogen distribution from the crack tip material was analyzed by SIMS. The results showed that acoustic emission was less active in an aqueous solution than in air and that the plastic zone size was reduced in a corrosive medium.

9A379. **Determination of the asymptotic fields for steady crack growth through the application of path independent integrals.** - FJ Barth *(Lehrstuhl Tech Mech, Univ Kaiserslautern, Erwin Schrodinger Str, 6750 Kaiserslautern, Germany)*. Int J Fracture 60(1) 79-87 (1 Mar 1993).

An asymptotic analysis of the near tip fields is given for a steadily propagating crack. The power hardening material is characterized by J_2 flow theory as well as deformation theory. A further condition for steady state crack growth is obtained. By using a new path independent integral, explicit results are given for the order of the crack tip singularity. It was found that the singularities calculated by using the different material models are not the same.

9A380. **Failure analysis of a cracked plate based on endochronic plastic theory coupled with damage.** - CL Chow *(Dept of Mech Eng, Univ of Michigan, Dearborn MI 48128-1491)* and XF Chen *(Dept of Mech Eng, Univ of Hong Kong, Pokfulam Rd, Hong Kong)*. Int J Fracture 60(1) 49-63 (1 Mar 1993).

An anisotropic model of damage mechanics for ductile fracture incorporating the endochronic theory of plasticity is presented in order to take into account material deterioration during plastic deformation. An alternative form of endochronic (internal time) theory which is actually an elasto-plastic damage theory with isotropic-nonlinear kinematic hardening is developed for ease of numerical computation. Based on this new damage model, a FE algorithm is formulated and then employed to characterize the fracture of thin aluminum plate containing a center crack. A new criterion termed as Y_R-Criterion is proposed to define both the crack initiation angle and load.

9A381. **Higher order asymptotic crack fields in a power-law hardening material.** - S Yang, YJ Chao, MA Sutton *(Dept of Mech Eng, Univ of S Carolina, Columbia SC 29208)*. Eng Fracture Mech 45(1) 1-20 (May 1993).

The asymptotic stress and deformation fields for plane problems are developed for a crack tip embedded in a power-law elastic-power material. Using an asymptotic expansion and separation of variables for the stress function, a series solution is obtained for the stress and deformation at a crack tip. The most singular term in the series solution is the HRR solution, after Hutchinson and Rice and Rosengren. Good agreement with the FE results confirm the analytical findings. It is further demonstrated that in the plane strain, Mode I case the first three terms, controlled by two parameters, can be used to characterize the crack tip stress fields for a variety of specimen geometries and materials with various hardening exponents.

9A382. **Influence of plasticity on mixed mode interface toughness.** - V Tvergaard *(Solid Mech Dept, Tech Univ, Lyngby, Denmark)* and JW Hutchinson *(Div of Appl Sci, Harvard Univ, Cambridge MA)*. J Mech Phys Solids 41(6) 1119-1135 (Jun 1993).

Calculation are reported for the mixed mode toughness of an interface joining an elastic-plastic solid to a solid which does not yield plastically. A potential function of the components of the crack face displacements is used to generate the tractions along the interface where the fracture processes causing separation occur. The two main parameters characterizing this potential are the work of separation per unit area and a peak normal stress. This description of the interface process is embedded within the continuum description as a boundary condition on the interface linking the adjoining solids. Particular emphasis is placed on the ratio of the steady-state interface toughness to the "intrinsic" work of separation as it depends on plastic yielding and on the combinations of modes 1 and 2. Plasticity enhances the interface toughness for all modes of loading, but substantially more so in the presence of a significant mode 2 component of loading than in near-mode 1 conditions.

9A383. **J-integral computations in the incremental and deformation plasticity analysis of small-scale yielding.** - DM Stump *(Idaho Natl Eng Lab, PO Box 1625 MS 2218, Idaho Falls ID 83415-2218)* and E Zywicz *(UC PO Box 808 L-122, LLNL)*. Eng Fracture Mech 45(1) 61-77 (May 1993).

Detailed numerical studies of small-scale yielding in elastic power-law plastic materials under Mode I loading reveal a path dependence of the J-integral in small-strain incremental-theory plasticity calculations, while corresponding studies employing deformation-theory plasticity show no such behavior. The path dependence of the incremental-theory calculations is sensitive to the pressure of T-stresses and deviates substantially from the remote elastic J-value at radial distances, r, on the order r ≤ CTOD (crack-tip opening displacement). A comparison of the fields predicted by the two different plasticity implementations reveals that deep within the plastic zones, stresses are in reasonable agreement over the angular interval 10° < θ < 160° with moderate disagreement in the regions near the crack faces.

9A384. On a mixed-mode Dugdale model. - DW Nicholson *(Mech and Aerospace Eng, Univ of Central Florida, Orlando FL 32816)*. Acta Mech 98(1-4) 213-219 (1993).

A model attributed to Dugdale provides a correction for plasticity effects at crack tips in Mode I, under the assumption of small-scale yielding. Similar models have been proposed for Modes II and III, the former fairly recently. In the present study, the Dugdale model is extended to cases combining Modes I, II, and III, based on the von Mises yield criterion. The combined model provides an a posteriori estimate for plasticity effects, based only on the stress intensity factors from the elasticity solution.

9A385. Two-dimensional model for numerical investigations of stable crack growth in thick smooth fracture mechanics specimens. - GX Shan, O Kolednik *(Erich-Schmid-Inst Festkorperphys, Osterreichischen Akad, Wissenschaften 8700, Leoben, Austria)*, FD Fischer *(Inst Mech, Montanuniv Leoben, Christian-Doppler-Lab Mikromech Werkstoffe 8700, Leoben, Austria)*, HP Stuwe *(Erich-Schmid-Inst Festkorperphys, Osterreichischen Akad, Wissenschaften 8700, Leoben, Austria)*. Eng Fracture Mech 45(1) 99-106 (May 1993).

A numerical simulation for the stable crack growth in a thick smooth compact tension specimen with 2D elastic-plastic FE analyses is presented. The different fracture behaviors in the center and near the side surfaces of the specimen were accounted for by using plane strain analysis for the center part and plane stress analysis for the surface part. The input data to control the fracture initiation and crack growth, ie, $CTOD_i$ and $CTOA_c$, were directly measured from the center and the side surfaces of specimens. The calculated results were compared with the experimental ones.

9A386. Actual contribution of crack deflection in toughening platelet-reinforced brittle-matrix composites. - G Pezzotti *(Inst of Sci and Indust Res, ISIR Osaka Univ, Ibaraki 567, Osaka, Japan)*. Acta Metall Mat 41(6) 1825-1839 (Jun 1993).

The effectiveness of crack deflection as a single toughening mechanism is evaluated in the case of brittle-matrix reinforced by high aspect-ratio platelets. Microstructural parameters characterizing size, morphology, orientation and distribution of the second phase including aspect ratio, volume fraction and interparticle distance, were experimentally obtained by means of image analysis techniques on a model composite. It is concluded that crack deflection processes may play an important role only as precursors for other operative mechanisms, being, in the general case, the deflection of the crack path only phenomenologically related to toughening.

9A387. Combined experimental and FE study to predict the failure mechanisms in SiC coated carbon-carbon composites at room and elevated temperatures under flexural loading. - H Mahfuz, PS Das, Dongwei Xue, J Krishnagopalan, S Jeelani *(Mat Res Lab, Tsukegee Univ, Tsukegee AL 36088)*. J Reinforced Plastics Composites 12(7) 825-842 (Jul 1993).

Response of quasi-isotropic laminates of SiC coated Carbon-Carbon (C-C) composites have been investigated under flexural loading at various temperatures. Variation of load-deflection behavior with temperatures are studied. Increase in flexural strength and stiffness are observed with the rise in temperature. Extensive analyses through Optical Microscope and Non-Destructive Evaluation have been performed to understand the failure mechanisms. Data generated using FE analysis are presented to corroborate the experimental findings, and a comparison in respect of displacement and stress-strain behavior are given to check the accuracy of the FE analysis. Reasonable correlation between the experimental and FE results have been established.

9A388. Damage development in a short fiber reinforced composite. - Kai-Youarn Hour *(B&W Nucl Env Services, Lynchburg Tech Center, PO Box 11165, Lynchburg VA 24506)* and Huseyin Sehitoglu *(Dept Mech and Mat, Natl Sci Found, 1800 G St NW, Washington DC 20550)*. J Composite Mat 27(8) 782-805 (1993).

The important issue of finding a relationship between a macroscopic damage variable and the process of damage accumulation within a material is addressed in this article. Monotonic and cyclic deformation behavior has been studied in a randomly distributed glass reinforced polyester matrix composite. The composite material is called sheet molding compound, abbreviated as SMC, with a short glass fiber weight of 30%. Based on these measurements, the damage volumetric strain was calculated that increased continuously with cycles in load-controlled experiments. Microscopic observations revealed that cracks grew along the matrix-fiber interfaces as well as the matrix-filler interfaces. Many of these cracks are normal to the specimen thickness direction.

9A389. Delamination growth in composite plates subjected to transverse loads. - LE Doxsee, P Rubbrecht, L Li, I Verpoest *(Dept of Metall and Mat Eng, Katholieke Univ, Leuven, Belgium)*, M Scholle *(DSM-Res, Geleen, Netherlands)*. J Composite Mat 27(8) 764-781 (1993).

Experiments were performed to study the growth of damage in fiber reinforced cross-ply carbon-epoxy composite plates subjected to transverse loads. The plates were repeatedly loaded and unloaded, with the maximum displacements of each loading cycle greater than or equal to the previous cycle. After certain loading cycles, the extent of damage was measured by a combination of C-scanning, optical microscopy, and radiography. The critical strain energy release rate for delamination growth was determined by relating the delamination area to the amount of energy dissipated by the formation of that delamination.

9A390. Delamination, fiber bridging and toughness of ceramic matrix composites. - DAW Kaute, HR Shercliff, MF Ashby *(Eng Dept, Cambridge Univ, Mat Group Trumpington St, Cambridge CB2 1PZ, UK)*. Acta Metall Mat 41(7) 1959-1970 (Jul 1993).

Delamination cracks in long-fiber reinforced ceramic matrix composites are found to be bridged by fibers which span the crack wake at a shallow angle. The *in situ* observation of bridging fibers reveals that these are subject to considerable tensile forces, giving rise to a substantial crack closure force. The overall crack closure force is determined by the number of bridging fibers, steadily reduced by fiber failure caused by high bending moments at the root of each fiber. This leads to a model for crack closing forces combining simple mechanics and Weibull statistics. The model relates these forces to the properties of fibers, matrix and their interface.

9A391. Effects of fabric weave and surface texture on the interlaminar fracture toughness of aramid-epoxy laminates. - BJ Briscoe, RS Court, DR Williams *(Dept of Chem Eng and Chem Tech, Imperial Col of Sci Tech and Med, Kensington, London SW7 2BY, UK)*. Composites Sci Tech 47(3) 261-270 (1993).

The mode I interlaminar fracture toughness of woven aramid-fibre and epoxy resin laminates has been investigated as a function of the fabric weave and the fabric surface texture used in the construction of the laminates. The experimental values of G_{IC} were found to increase significantly with increasing crack length for all the materials investigated. This behavior is ascribed to the presence of fibre bridging during crack propagation. The presence of fibre bridging in the cracks has been observed directly. The maximum values of G_{IC} determined were in the range of 0.5 - 3.0 kJ/m^2, depending upon both the fabric weave and the surface texture. An optical comparison of sections of these laminates confirmed an enhanced concentration of fibre ends in the resin-rich interply zones for the fabrics with the most obvious concentration of fibre ends in their surface. This type of fabric surface texture provided a more homogeneous fibre distribution in the composite which resulted in enhanced levels of fibre bridging and, as a consequence, enhanced fracture toughness.

9A392. Evaluation of the stress intensity factor of brittle polymers based on the crack arrest concept. - K Idonije, M Motuku, I Shehata, H Aglan *(Dept of Mech Eng, Tuskegee Univ, Tuskegee AL 36088)*. J Reinforced Plastics Composites 12(7) 778-786 (Jul 1993).

One of the commonly used criteria for characterizing the fracture resistance of brittle glassy polymers or their composites is the critical stress intensity factor or crack resistance. Specimen geometries such as single edge notch, compact tension, and three-point bend etc, are conventionally used for this purpose. On this basis, the critical stress intensity factor is evaluated at the onset of crack propagation by using the length of the initial notch. Plastics in general experience a slow crack growth regime before the avalanche-like fracture, which is not taken into consideration in the calculation of the critical stress intensity factor. Hence, serious errors are encountered in the evaluation of the resistance of plastics to crack propagation based on the critical stress intensity factor concept, when standard test geometries are employed. In the present work, a crack arrest experiment employing a double cleavage drilled compression specimen is proposed to evaluate the resistance of brittle polymers to fracture.

9A393. Fracture analysis of dental composites. - RMV Pidaparti, WA Boehmer *(Dept of Mech Eng, Purdue Univ, Indianapolis IN 46402)*, MW Beatty *(Section of Dental Mat, Dept of Adult Restorative Dentistry, Univ of Nebraska, Lincoln NE 68583)*. Eng Fracture Mech 45(1) 51-59 (May 1993).

Three dental composite materials were tested in three-point bending to determine fracture toughness using the stress intensity factor approach. Finite element analysis was used to model the specimens and the fracture toughness was calculated using the J integral and crack closure methods. The effects of tension, compression, and tension-compression moduli on the fracture toughness are presented and discussed. The results from J integral and crack closure methods were in good agreement with experimental data for the three dental composites considered.

9A394. Fracture strength testing of δ-alumina fibers with variable diameters and lengths. - AS Kim *(Div of Eng, Brown Univ, Providence RI 02912)*, S Bengtsson *(Studsvik AB, Hot Cell Lab, S-611 82 Nykoping, Sweden)*, R Warren *(Dept of Mat Sci and Prod Tech, Lulea*

Univ, S-951 87 Lulea, Sweden). Composites Sci Tech 47(4) 331-337 (1993).

Tensile tests were performed on individual δ-alumina fibers (Safil, RF grade). The results revealed a large scatter in strengths and a clear dependence of the fracture strength on the specimen volume. The tests were evaluated on the basis of the Weibull probability function, a special modification of the Weibull analysis being developed that successfully copes with the problem of testing fibers with various diameters and test lengths. For the sample studied the Weibull modulus, m, was found to be 2.2, with a scaling constant σ_0=6.0MPa (units of volume mm^3; ie, $V_0=1mm^3$).

9A395. Fracture surface of hybrid fibre composites. - MA French *(British Aerospace, Stevenage, UK)* and G Pritchard *(Sch of Appl Chem, Kingston Univ, Penrhyn Rd, Kingston upon Thames Surrey KT1 2EE, UK)*. Composites Sci Tech 47(3) 217-223 (1993).

A study has been made of the fracture surfaces of unidirectional hybrid glass-carbon-epoxy laminates after environmental stress corrosion (ESC) by dilute sulphuric acid. Labelled isotope studies showed that the acid does not diffuse through the uncracked epoxy resin matrix, and must therefore travel through microcracks. Photomicrographs show how the carbon fibre plies can act as primary crack stoppers. Secondary cracks continue into the glass plies, often at a short distance along the carbon fibres from the primary crack. The sequence of events by which ESC cracks fracture the glass fibres and propagate through glass plies is discussed. It is proposed that some of the damage observed in glass fibres occurs after fibre fracture rather than before.

9A396. Matrix cracking and modulus reduction during the fatigue of an injection-moulded glass-nylon composite. - SA Hitchen and SL Ogin *(Dept of Mat Sci and Eng, Univ of Surrey, Guildford, Surrey GU2 5XH, UK)*. Composites Sci Tech 47(3) 239-244 (1993).

Damage accumulation in the core layer of a 50% by weight discontinuous glass fibre reinforced Nylon composite has been studied. Damage in the core, in the form of transverse cracks, has been quantified by means of a dye penetrant-sectioning technique and related to a modulus reduction measured during fatigue cycling. The experimental data are compared with the predictions of a shear lag model developed for continuous fibre cross-ply laminates relating modulus reduction to the average crack spacing.

9A397. Micromechanical elastic cracktip stresses in a fibrous composite. - J Fish *(Dept of Civil Eng and Sci Comput Res, RPI)*, N Fares *(Dept of Civil Eng, Polytech Univ, Brooklyn NY 11201)*, A Nath *(Dept of Civil and Sci Comput Res Center, RPI)*. Int J Fracture 60(2) 135-146 (15 Mar 1993).

This paper presents elastic stress distributions near a cracktip in a continuous fiber composite. The material heterogeneity is explicitly accounted for by using the FEM and a new Mesh Superposition Technique. This new technique superposes a fine mesh with heterogeneous material properties over a coarse mesh with homogeneous ones. The results indicate that the load transferred by fibers near a cracktip may be well described by the homogeneous orthotropic elastic K_I field. A technique to postprocess the K_I field to accurately obtain the detailed stress distributions within the fiber and matrix is also presented.

9A398. Mixed-mode delamination of fibre composite materials. - AJ Kinloch, Y Wang, JG Williams, P Yayla *(Dept of Mech Eng, Imperial Col of Sci Tech and Med, Exhibition Rd, London SW7 2BX, UK)*. Composites Sci Tech 47(3) 225-237 (1993).

The present paper is concerned with an investigation of the mixed-mode delamination of polymeric fibre composite materials. Various test geometries have been used to measure the interlaminar fracture energy, G_c, of both thermoplastic and thermosetting carbon fibre composites when subjected to various ratios of mode I to mode II loadings. In particular, the mixed-mode bending delamination test has been studied in detail and the results from this test method compared to those obtained from the fixed-ratio mixed-mode (FRMM) test method. Further, for the FRMM results, two methods of partitioning the measured interlaminar fracture energy G_c, have been employed; namely, by way of a local single-field approach and by a global method based on a consideration of the applied energy release rates.

9A399. Modeling of anisotropic damage at a crack tip in composite laminates. - WF Li and SY Du *(Sch of Astronaut, Harbin IT, Harbin 150006, Peoples Rep of China)*. Eng Fracture Mech 45(3) 381-385 (Jun 1993).

Anisotropic continuum damage mechanics was applied to analyze the damage at a crack tip in composite laminates. An initial attempt was made to connect continuum damage mechanics with fracture mechanics. Some quantitative relations such as those between stress, energy release rate and damage variables were established by means of the model described in this paper. It was shown that the formula $G_I = K^2_I/E$ is not applicable when the damage at a crack tip is taken into account. Also, the relation between the critical crack length and the critical damage variables was estimated and it was proved that damage variables can describe the fracture condition of composite laminates.

9A400. Modelling of 90° ply cracking in crossply laminates, including 3D effects. - FJ Guild, SL Ogin, PA Smith *(Dept of Mat Sci and Eng, Univ of Surrey, Guildford GU2 5XH, Surrey, UK)*. J Composite Mat 27(7) 646-667 (1993).

The mechanics of transverse ply cracking in crossply composite laminates is examined in detail. A 3D FE model has been developed. This has been used to calculate fracture mechanics parameters associated with transverse ply crack growth across the width of a glass fiber reinforced epoxy laminate. The predictions of the model are shown to be in good agreement with existing shear-lag analyses and experimental results from the literature.

9A401. Near-tip fields for a crack along an interface between an elastic-ideally plastic crystal and a rigid substrate. - V Gupta *(Thayer Sch of Eng, Dartmouth Col, Hanover NH 03755)*. J Mech Phys Solids 41(6) 1035-1066 (Jun 1993).

Asymptotic, plane strain stress and deformation fields are derived near the tip of stationary and a quasi-statically growing crack at an interface idealized as being rigid on one side, and single crystal on the other side. The crystalline substrate is assumed to have a limited set of possible slip systems and to have a critical resolved shear stress for plastic flow to occur on each. Two crack orientations with some previous experimental background are considered. One orientation considered is such that the interface crack is parallel to the (001) plane with its tip along [110] and growing along the perpendicular face direction, [110]. The second orientation considers the crack parallel to the prism plane (0110) of an hcp crystal, with its tip along [2110] and growing in the [0001] direction. For both these orientations, the near-tip stress state is shown to be locally constant within the angular sectors that are stressed to yield levels at a stationary crack tip, and to change discontinuously from sector to sector. Families of solutions with both compressive and tensile normal stresses in the wake region are also found. For both the growing and the stationary crack cases, solutions are obtained for a very limited range of the possible crack line near-tip shear-normal stress ratios.

9A402. Phenomenon of curved microcracks in $[(S)/90_n]_s$ laminates: Their shapes, initiation angles and locations. - Shoufeng Hu, JS Bark, JA Nairn *(Mat Sci and Eng, Univ of Utah, Salt Lake City UT 84112)*. Composites Sci Tech 47(4) 321-329 (1993).

A variational analysis of the stress state in microcracked cross ply laminates has been used to investigate the phenomenon of curved microcracking in $[(S)/90_n]_s$ laminates. Previous investigators proposed that the initiation and orientation of curved microcracks are controlled by local maxima and stress trajectories of the principal stresses. We have implemented a principal stress model using a variational mechanics stress analysis and were able to make predictions about curved microcracks. The predictions agree well with experimental observations and therefore support the assertion that the variational analysis gives an accurate stress state that is useful for modeling the microcracking properties of cross ply-laminates. An important prediction about curved microcracks is that they are a late stage of microcracking damage. They occur only when the crack density of straight microcracks exceeds some critical value-the critical crack density for curved microcracking. The predicted critical crack density for curved microcracking agrees well with experimental observations.

9A403. Prediction of delamination in composite laminates subjected to low velocity impact. - CJ Jih and CT Sun *(Sch of Aeronaut and Astronaut, 1282 Grissom Hall, Purdue)*. J Composite Mat 27(7) 684-701 (1993).

A method for predicting impact-induced delamination in composite laminates was proposed. This method is suitable for low velocity impact with heavy impactors. Static delamination fracture toughness was used to predict delamination crack growth under impact conditions. Curing stresses were also considered and found to play a significant role in evaluating the fracture toughness of some laminates such as $[90_5/0_5/90_5]$. The prediction of delamination size using static fracture toughness was found to agree very well with the experimental results.

9A404. Pull-out of fibres with a branched structure and the interference of strength and fracture toughness of composites. - Shaoyun Fu, Benlian Zhou, Chiwei Lung *(Inst of Metal Res, Acad Sinica, Shenyang 110015, Peoples Rep of China)*. Composites Sci Tech 47(3) 245-250 (1993).

In an experimental investigation of the pull-out of synthetic fibres with a branched structure, it was generally observed that the force and energy of fibre pull-out are greater than those for plain fibres, and increase with the branching angle. An approximate theory of pull-out of fibres with branched structure from a matrix is developed with the aim of quantifying the effects of the branched structure of the fibre. This theory agrees well with the experimental results by adjusting the snubbing friction coefficient between fibre and matrix and neglecting the bending of the fibre at the fibre branching point.

9A405. Role of coatings in axial tensile strength of long fiber reinforced metal-matrix composites. - Zhenhai Xia *(Dept of Metallic Mat Sci and Eng, Hebei IT, Tianjin 300130, Peoples Rep of China)*. Acta Metall Mat 41(7) 2097-2104 (Jul 1993).

A model that includes effects of coatings, interfacial behavior, plastic deformation of matrix and reaction zone has been developed for analysis of the behavior of metal-matrix composites reinforced by coated fibers. The stress concentration caused by the cracks in the reaction zone was calculated from the model and the results show that it can be relaxed by choosing coatings of low modulus and controlling interfacial strength to a relatively low value. The predictions of the model in composite strength are consistent with that from the Griffith relationship with strong interfacial bonding and the experimental results for SiC-coated C/Al composites. Both the theory and the experiment show that high strength of the composites can be maintained by SiC coating even when there is a serious reaction at the coating-matrix interface.

9A406. Analysis of finite anisotropic media containing multiple cracks using superposition. - MS Wu *(Dept of Eng Mech, Univ of Nebraska, 212 Bancroft Hall, Lincoln NE 68588-0347)*. Eng Fracture Mech 45(2) 159-175 (May 1993).

A method is presented for estimating the stress intensity factors of interacting cracks in a finite anisotropic medium. The method is based on the simultaneous application of two superposition schemes. In the first scheme, concentrated forces and couples acting at various locations along an imaginary curve within an infinite medium are superposed using the framework of the boundary force method. In the second scheme, approximating tractions acting on crack lines are superposed to compute the stress fields required for determining stress intensity factors. It is shown that the computed stress intensity factors of a single crack or several cracks in rectangular specimens agree closely with published data for isotropic specimens.

9A407. Correlation between crack tortuosity and fracture toughness in cementitious material. - MA Issa, AM Hammad, A Chudnovsky *(Dept of Civil Eng, Mech and Metall, Univ of Illinois, Chicago IL 60680)*. Int J Fracture 60(2) 97-105 (15 Mar 1993).

This paper proposes a new technique for the evaluation of fractal dimension (D) of fracture surface and a quantitative correlation between D and fracture toughness of cementitious materials. The experimental program has been performed on compact tension (CT) specimens (600 × 525 × 125 mm) with three different aggregate sizes (d_{max} = 4.7mm, 18.8mm and 37.5mm). The fractal geometry concept is utilized in the evaluation of fracture surface roughness. To avoid indirect or destructive experimental procedures that are prohibitively laborious and time consuming, a new non-destructive technique is presented. Results of the analysis indicate that the concept of fractal geometry provides a useful tool in the fracture surface characterization. The results also suggest that the fracture toughness can be correlated with the fractal dimension of fracture surface.

9A408. Fracture parameters for the orthotropic bimaterial interface cracks. - Chyanbin Hwu *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan 70101, Taiwan, ROC)*. Eng Fracture Mech 45(1) 89-97 (May 1993).

In order to define a proper bimaterial stress intensity factor, a general solution for the collinear interface cracks between dissimilar anisotropic media is applied to the near tip of an interface crack. Through the operation of normalization, scaling, nondimensionalization and transformation, a comparable definition which can be reduced to the classical stress intensity factors for a crack tip in homogeneous media has been obtained.

9A409. Stress analysis around a partially bonded rigid cylinder in an elastic medium with process zones. - K Fujii, Y Kato *(Dept of Civil Eng, Gifu Univ, Yanagido, Gifu 501 11, Japan)*, S Duan *(Dept of Civil Eng, N China Inst of Water Conservancy and Hydroelec Power, Handan, Hebei 05621, Peoples Rep of China)*, K Nakagawa *(Dept of Civil Eng, Gifu Univ, Yanagido, Gifu 501 11, Japan)*. Eng Fracture Mech 45(1) 31-38 (May 1993).

The stress and displacement field around a circular-arc interface crack between a rigid cylinder and an infinite elastic medium is analyzed. Two process zones at the crack tips along the interface are formed, and a concentrated force P is applied at the center of the cylinder along the x-axis. The solution is given by the Fourier series. It is shown that both tensile and shear stresses exist along the interface but no oscillation appears.

9A410. Stresses near the edge of bonded dissimilar materials described by two stress intensity factors. - D Munz and YY Yang *(Univ of Karlsruhe and Nucl Res Center, Karlsruhe, Germany)*. Int J Fracture 60(2) 169-177 (15 Mar 1993).

Stresses near the free edges of the interface of bonded dissimilar materials can be described by the sum of a regular stress term and one or two stress singularity terms. A method for the calculation of the corresponding stress intensity factors from FE results is presented which is useful to determine two stress intensity factors together. Results for some geometries show that all three terms may contribute significantly to the stress distribution near the free edge of the interface for thermal stress.

9A411. Smeared crack analysis for reinforced concrete structures under blast-type loading. - FBA Beshara *(Dept of Civil Eng, Fac of Eng, Zagazig Univ, Shoubra, Egypt)*. Eng Fracture Mech 45(1) 119-140 (May 1993).

A smeared crack analysis is presented for the nonlinear FE analysis of plane and axisymmetric reinforced concrete structures under blast and impulsive loading conditions. Based on the fixed crack approach, a rate dependent strain criterion is proposed to serve as a crack initiation condition. The crack propagation is governed by nonlinear reversible formulations to model concrete tension softening as a function of concrete fracture energy, tensile strength, cracking strain and crack characteristic length. Shear transfer due to aggregate interlock and dowel bars is simulated by a nonlinear model dependent on the strain across the crack. A new crack monitoring algorithm, as part of a comprehensive computer program FEABRS, is developed which follows the cracking behavior with the time stepping scheme. The results of some dynamic applications are presented and compared with those from other numerical and experimental sources.

9A412. Crack-interfaces of fractal type with friction. - PS Theocaris *(Natl Acad, PO Box 77230, GR-17510 Athens, Greece)* and PD Panagiotopoulos *(Dept of Civil Eng, Aristotle Univ, GR-54006 Thessaloniki, Greece)*. Acta Mech 98(1-4) 63-78 (1993).

Here a theory is presented for the study of frictional effects on crack interfaces which have given geometry of fractal type. The arising problems are of non-classical nature, not only due to the fact that the interface conditions are expressed in terms of the non-differentiable friction superpotential, but also because of the fractal interface geometry and the singularities introduced by the crack. The fractal interface is analyzed by means of a sequence of classical-geometry interface problems. They result from the mathematical description of the fractal interface: it is the "fixed point" or the "deterministic attractor" of a given transformation. The theory is illustrated by a numerical application.

9A413. High frequency scattering of plane horizontal shear waves by a Griffith crack propagating along the bimaterial interface. - SC Pal *(Comput Centre, Univ of N Bengal, Darjeeling District, W Bengal 734 430, India)* and ML Ghosh *(Dept of Math, Univ of N Bengal, Darjeeling District, W Bengal 734 430, India)*. Eng Fracture Mech 45(1) 107-118 (May 1993).

The problem of diffraction of horizontally polarized shear waves by a finite crack moving on a bimaterial interface is studied. In order to obtain a high frequency solution, the problem is formulated as an extended Wiener-Hopf problem. The expressions for the dynamic stress intensity factor at the crack tip and the crack opening displacement are derived for the case of wave lengths which are short compared to the length of the crack.

9A414. Principle of maximum energy dissipation rate in crack dynamics. - LI Slepyan *(Fac of Eng, Tel-Aviv Univ, POB 39040 Ramat Aviv, 69978 Tel Aviv, Israel)*. J Mech Phys Solids 41(6) 1019-1033 (Jun 1993).

The principle of maximum energy dissipation rate is introduced as an energy criterion for crack dynamics. That allows us to explain observed limiting crack speeds in brittle materials, and to complete the crack dynamics formulation. The upper limits of the crack speed is perfectly elastic and elastic-plastic bodies are obtained. It is found that the theoretical maximum crack speed in an isotropic elastic body (in the first mode of crack propagation) is approximately equal to half the shear wave speed. The self-similar problem for the fracture mode III is solved (assuming the plastic zone to be narrow) and the crack speed limit is found as a function of the ratio of loading to yield limit: the plasticity decreases the crack speed limit and the latter tends to zero with the yield limit.

9A415. *Global-Local* approach to lengthwise cracked beams: Dynamic analysis. - TN Farris and JF Doyle *(Sch of Aeronaut and Astronaut, Purdue)*. Int J Fracture 60(2) 147-156 (15 Mar 1993).

A simple model is developed for the calculation of dynamic stress intensity factors for lengthwise cracked beams subjected to impact or transient loading. The model is based on a *Global-Local* approach that separates the *Global* structural dynamics from the *Local* crack tip zone dominated by singular stresses. The *Global* model is that of connected waveguides while the *Local* model is based on a novel application of the J-integral that converts dynamic structural resultants directly into strain energy release rate. The accuracy of this approach is assessed by comparing it to a fully 2D FE analysis in which the modified crack closure integral is used to calculate the dynamic strain energy release rate. Both mode I and mode II examples are given, and situations with multiple wave reflections are emphasized.

276W. MICROMECHANISMS

9A416. Effective elastic properties of a solid with crazes. - S Wu and A Chudnovsky *(Dept of Civil Eng Mech and Metall, Univ of Illinois, Chicago IL 60680)*. Eng Fracture Mech 45(2) 233-243 (May 1993).

The effective elastic properties of an elastic solid with a craze array are discussed. The effective elastic properties of a crazed material with a low density craze array are obtained by nonlinear analysis of a craze. For the high density craze array case, the effective elastic properties are obtained by a simple beam model. Results of effective elastic properties for all cases depend on a dimensionless parameter which represents the rigidity of fibrils inside the craze.

9A417. Near-tip field of anti-plane crack in a micro-cracked power-law solid. - Ch Zhang and D Gross *(Inst of Mech, TH Darmstadt, W-6100 Darmstadt, Germany)*. Int J Fracture 60(2) 107-120 (15 Mar 1993).

Asymptotic near-tip field is investigated for an anti-plane (mode III) crack in a power-law solid permeated by a distribution of micro-cracks. The micro-crack location is assumed to be random, while the micro-crack orientation is taken to be non-random. The anisotropic nature of this kind of damage gives rise to anistropic constitutive equations for the overall macroscopic strains and stresses. The structure of the asymptotic field at a macro-crack tip is analyzed by solving a nonlinear eigenvalue problem. It is shown that under the assumptions made in this analysis the asymptotic crack tip field of the damaged solid has the same structure as the mode III HRR-field of the undamaged solid. Numerical results are presented for the angular functions, the contours of constant effective shear stress, the normalization constant arising in the near-tip field, and the crack opening displacement. By means of these results, the effects of the micro-crack density and orientation on the crack-tip field will be explored.

9A418. Significance and role of deformation micromechanisms in life-predictive modeling of aging structures. - KL Murty *(Dept of Nucl Energy, N Carolina State Univ, Raleigh NC 27695-7909)*. Appl Mech Rev 46(5) 194-200 (May 1993).

Transitional creep mechanisms are exhibited by materials used in power systems and a thorough knowledge of these is a prerequisite in reliable extrapolations of short-term data to service conditions mainly due to the dominance of viscous creep mechanisms such as Nabarro-Herring, Coble and more importantly Harper-Dorn creep at low stresses. The paper summarizes the deformation mechanisms pertinent to various classes of materials.

9A419. Stable damage evolution in a brittle continuous medium. - GA Francfort *(Lab Central des Ponts Chaussees, 58 Blvd Lefebvre, 75732 Paris Cedex 15, France)* and J-J Marigo *(Lab Proprietes Mec Thermodyn Mat, Inst Galilee Univ Paris XIII, Ave JB Clement, 93430 Villetaneuse, France)*. Eur J Mech A 12(2) 149-189 (1993).

A model of partial brutal damage is investigated for a class of brittle solids. A global stability criterion is proposed. It is shown to prohibit the existence of a undamaged-damaged type solution and to promote fine mixtures of the undamaged and damaged phases. Thus microstructures appear as a byproduct of the criterion and not as the constitutive element of the model, in striking contrast with the micromechanical approach to damage. The resulting model is studied, especially in the 2D problems and for the problem of cylindrical torsion.

276Y. COMPUTATIONAL TECHNIQUES

9A420. Analysis of surface cracks using the line-spring BEM and the virtual crack extension technique. - Zhao-Jing Zeng, Shu-Ho Dai, Yi-Min Yang *(Dept of Mech Eng, Nanjing Inst of Chem Tech, 5 New Model Rd, Nanjing 210009, Peoples Rep of China)*. Int J Fracture 60(2) 157-167 (15 Mar 1993).

The authors have developed a new line-spring BEM which couples the line-spring model with the BEM to deal with the problem of a surface cracked plate. However, the drawback of the line-spring model is that a reliable stress intensity factor could not be directly obtained near the free surface intersection. Therefore, the virtual crack extension technique is employed in a post-processor of the line-spring BEM to obtain the stress intensity factor at the crack front-free surface intersection. Theoretical analysis is described. Stress intensity factors for surface cracks are calculated to verify the proposed method. The interaction of two surface cracks is also investigated. The solutions obtained by the line-spring BEM show that the method proposed is efficient and reasonably accurate.

9A421. Analytical stress intensity solution for the stable Poisson loaded specimen. - LJ Ghosn *(Sverdrup Tech, Lewis Res Center Group, Brook Park OH 44142)*, AM Calomino *(NASA, Lewis Res Center, Cleveland OH 44135)*, DN Brewer *(US Army Res Lab, Lewis Res Center, Cleveland OH 44135)*. Int J Fracture 60(3) 209-220 (1 Apr 1993).

An analytical calibration of the Stable Poisson Loaded (SPL) specimen is presented. The specimen configuration is similar to the ASTM E-561 compact-tension specimen with displacement controlled wedge loading used for R-curve determination. The crack mouth opening displacement (CMOD) are produced by the diametral expansion of an axially compressed cylindrical pin located in the wake of a machined notch. Due to the unusual loading configuration, a 3D FE analysis was performed with gap elements simulating the contact between the pin and specimen. In this report, stress intensity factors, CMOD's and crack displacement profiles, are reported for different crack lengths and different contracting conditions. It was concluded that the computed stress intensity factor decreases sharply with increasing crack length thus making the SPL specimen configuration attractive for fracture testing of brittle, high modulus materials.

9A422. Applications of the BE and dislocation density methods in plane crack problems. - A Sturt, D Nowell, DA Hills *(Dept of Eng Sci, Univ of Oxford, Parks Rd, Oxford OX1 3PJ, UK)*. Eng Anal Boundary Elements 11(2) 129-135 (1993).

Crack modeling using the dislocation density method has become an increasingly popular technique for plane crack problems and allows the fast, efficient determination of stress intensity factors. The range of geometries which may be solved by the basic technique is, however, somewhat limited and this paper outlines a hybrid formulation combining the dislocation density technique with constant displacement discontinuity BEs to satisfy a range of far boundary conditions. The method described can analyze configurations with an arbitrary number of buried or surface breaking cracks and can be implemented on a personal computer to provide an efficient tool for crack analysis.

9A423. Comparison of accurate with approximate expressions of stresses for the interface crack problem. - CP Spyropoulos *(Sec of Mech, Dept of Eng Sci, Natl Tech Univ, Athens GR-157 73, Greece)*. Eng Fracture Mech 45(3) 339-348 (Jun 1993).

The plane problem of two bonded dissimilar materials with a central crack along the common interface and subjected to biaxial load at infinity is examined by comparing the accurate expression for stresses, equally valid everywhere, both near and far from the crack tip regions, with the approximate expressions for the stresses used up to now which have a limited accuracy and area of validity. To illustrate the advantages of the closed form expressions for the stresses over the approximate ones based on the singular solution, improved by taking into account the non-singular term due to the biaxial loading parameter, selective stress distributions for both expressions are presented. On these charts, for reasons of better comparison, the relative errors between the closed form expressions and the best approximate expressions for each of the stress components are presented. The existing significant differences urge one to make use of the proposed expressions in any problem related to the subject of this article.

9A424. Damage simulation in heterogeneous materials from geodesic propagations. - D Jeulin *(Center de Geostat, Ecole des Mines de Paris, 77305 Fontainebleau, France)*. Eng Comput 10(1) 81-91 (Feb 1993).

We propose a simplified method to simulate damage evolution in hetergeneous media from geodesi propagation calculations. The method introduced for the case of porous media (polycrystalline graphite), was generalized to multiphase media, and then to a continuous variation of local fracture energy. It is based on a minimization of the fracture energy criterion, ignoring the local variations of the stored strain energy. Our approach is illustrated from 2D simulations corresponding to various types of microstructure involving the following microgeometrical distributions of the local fracture energy: isotropic and anisotropic two-phase media, polycrystal with cleavage and intergranular fracture, material with a continuous distribution of surface energy.

9A425. Eigenstrain methods in 3D crack problems: An alternative integration procedure. - DN Dai, D Nowell, DA Hills *(Dept of Eng Sci, Univ of Oxford, Parks Rd, Oxford OX1 3PJ, UK)*. J Mech Phys Solids 41(6) 1003-1017 (Jun 1993).

In this paper 3D crack problems are analyzed using the eigenstrain method (body force method). The formulation leads to set of hypersingular integral equations which is solved numerically using a discretization technique. An analytical expression is derived for the evaluation of the singular integrals, ie, the 2D singular integrals are reduced to regular integrals along the contour of the domain, thus avoiding the direct calculation of cumbersome singular integrals and minimizing the numerical effort. The analytical expression is independent of the size and shape of the domain, allowing the use of high order elements in numerical solutions.

9A426. Hypersingular-boundary integral equation method for the solution of an elastic multiple interacting crack problem. - WT Ang *(R&D Section, Hong Leong Eng Pte, 117 Jalan Tun HS Lee 50000, Kuala Lumpur, Malaysia)* and G Noone *(Electron Res Lab, PO Box 1600, Salisbury, S Australia)*. Eng Anal Boundary Elements 11(1) 33-37 (1993).

The authors formulate the antiplane problem concerning a finite elastic body with an arbitrary number of coplanar cracks in its interior in terms of a system of boundary integral equations coupled with Hadamard finite-part singular integral equations. These integral equations are readily amenable to numerical treatment and, for the purpose of illustrations, they are employed to obtain numerical values of the stress intensity factors for certain specific problems.

9A427. Incompatible numerical simulation of the axisymmetric cracked body made of ideally elastic-plastic material. - YK Cheung *(Dept of Civil and Struct Eng, Univ of Hong Kong, Hong Kong)* and Chang-Chun Wu *(Dept of Modern Mech, Univ of Sci and Tech, Hefei, China)*. Eng Fracture Mech **45**(3) 399-405 (Jun 1993).

It is well known that isoparametric axisymmetric elements always encounter various numerical difficulties in computational plasticity. An incompatible axisymmetric element which can avoid the above-mentioned difficulties is presented and then used to solve axisymmetric ductile fracture problems. As an example a stretched cylinder with a circumferential crack is investigated, and elastic, elastic-plastic solutions, and plastic limit loads of the cracked cylinders are given and examined. In addition, the path-independence of the J integral is inspected, and the limits for use of the axisymmetric J integral are suggested.

9A428. Using a symbolic manipulator to solve fracture problems in composite materials. - AK Kaw, KS Gadi, D Jadhav *(Dept of Mech Eng, Univ of S Florida, Eng 118, Tampa FL 33620-5350)*. Adv Eng Software **16**(1) 31-36 (1993).

A symbolic manipulator is used to understand the mechanics of a crack problem in fiber reinforced composite materials. Stress intensity factors in the front of crack tips are found directly in terms of the stiffness properties of the constituents, for constant crack lengths. The results are compared with the numerical solutions available in the literature.

276Z. EXPERIMENTAL TECHNIQUES

9A429. New method for measurement of fracture toughness K_{IC} by three point bend specimen. - Zhe-ming Zhu *(Dept of Basic Sci, Fuxin Mining Inst, Fuxin 123000, Peoples Rep of China)*. Eng Fracture Mech **45**(2) 141-147 (May 1993).

The relationship between the three-point bend (TPB) specimen size and the measured fracture toughness K_{IC} value is analyzed by the theory of crack opening displacement. According to the concept of plane strain fracture toughness K_{IC}, a new formula for K_{IC} is presented. For small-scale or large-scale TPB specimens, the K_{IC} values of material can all be obtained for the new formula and the corresponding curve of load versus crack mouth opening displacement. For large-scale specimens, the new formula is compatible with the ASTM standard.

280. Materials testing and stress analysis

9A430. Investigation of the nonlinear elastic properties of metals by a vibration method. - LA Rozenblyum *(Inst of Appl Phys, Russian Acad of Sci, Russia)*. Sov Phys Acoust **38**(6) 587-591 (Nov-Dec 1992).

A method is proposed for determining the nonlinearity parameters of the stress-strain curve of metals in the microplasticity region, based on the dependence of the resonance shift, the variation of the reciprocal quality factor Q^{-1}, and the second- and third-harmonic amplitudes on the vibration amplitude of the mechanical oscillatory circuit formed by a metal rod sample loaded with weights at both ends. A phenomenological model of the stress-strain curve of a metal is proposed for interpreting the observed nonlinear effects.

9A431. Two-function method for the prediction of concrete creep under decreasing stress. - LL Yue and L Taerwe *(Magnel Lab for Reinforced Concrete, Univ of Ghent, Technologiepark Zwijnaarde 9, B9052 Ghent, Belgium)*. Mat Struct **26**(159) 268-273 (Jun 1993).

It is well known that the application of the principle of superposition in the service stress range yields an inaccurate prediction of concrete creep when unloading takes place. It appears that after a period of compression creep, the experimental creep recovery is significantly less than predicted by the principle of superposition. In the present study, this nonlinear behavior, attributed to the sustained compressive preload, is modeled by a two-function method. In this approach, a creep function is used for modeling the time-dependent deformations due to increasing stress and a separate creep recovery function represents the behavior under decreasing stress. Good agreement with test data is achieved.

9A432. Abrasive wear study of selected white cast irons as liner materials for the mining industry. - Xu Liqun, C Vose, D StJohn *(CRA, Adv Tech Dev, Perth PO Box 347, Cannington WA 6107, Australia)*. Wear **162-164**(PART B) 820-832 (13 Apr 1993).

The abrasive wear behavior of three white cast irons, designed as 10Cr-3.5Ni, 15Cr-3Mo and 16.5Cr-1.5Mo irons (where the compositions are in weight per cent), was studied in a field test as liners installed in a transfer of an iron ore operation and in three laboratory wear tests (pin-on-drum, dry-sand-rubber-wheel (DSRW) and paddle testers) to determine the relevance of the laboratory wear tests to the field liner test. The results from the wear tests and wear mechanism study showed that under the test conditions, the DSRW test most closely predicts the relative wear rate of the white irons in the field liner test. However, a perfect match of both the wear mechanism and the rank of the wear rate for the iron from the laboratory wear test to the field liner test was not achieved, owing to the complexity of the field liner wear condition. The wear mechanisms were elucidated by microscopic examination of the worn surfaces for both field-tested liners and laboratory-tested specimens, and by subsurface examination of paddle-tested specimens, together with the microstructural study of the irons. The predominant wear mechanisms depend upon both the wear conditions and the microstructural properties of the irons. It was found that the wear resistance of the white irons for the low stress abrasion is controlled by the matrix, and that for the high stress abrasion and impact abrasion is mainly determined by the bulk hardness of the irons.

9A433. Repeated impact-abrasion testing of alloy white cast irons. - IR Sare, BK Arnold *(CSIRO Div of Manuf Tech, Adelaide Lab, PO Box 4, Woodville SA 5011, Australia)*, GA Dunlop *(AMDEL, PO Box 338, Torrensville SA 5031, Australia)*, PG Lloyd *(CSIRO Div of Manuf Tech, Adelaide Lab, PO Box 4, Woodville SA 5011, Australia)*. Wear **162-164**(PART B) 790-801 (13 Apr 1993).

A small Hazemag rotary impact crusher has been adapted for the assessment of the repeated impact-abrasion properties of alloy white cast irons. The test specimens were cast as blow bars for use in the crusher, and each test involved the comminution of 2000 kg of quarry stone. A series of six alloy white cast irons has been tested in the crusher in order to assess the influences of chemical composition, hardness, eutectic carbide volume fraction and retained austenite content on combined repeated impact-abrasion performance. The results showed that hardening by heat treatment, and hence variations in retained austenite content, has no influence on weight loss, but that weight loss increased significantly with increasing eutectic carbide volume fraction. Post-wear examination of worn blow bars revealed significant gouging and impact damage on the surface, and on a finer scale, extensive fracture of eutectic fracture of eutectic carbides, decohesion at carbide-matrix interfaces, matrix fracture, and microscope spall formation.

9A434. Current trends in obtaining deformation data from grids. - PJ Sevenhuijsen *(Struct and Mat Div, Natl Aerospace Lab, Amsterdam, Netherlands)*, JS Sirkis *(Dept of Mech Eng, Univ of Maryland, College Park MD)*, F Bremand *(Lab Mech des Solides, Univ Poitiers, Cedex, France)*. Exp Tech 17(3) 22-26 (May-Jun 1993).

Grid methods offer a means of measuring the deformation of structural components. Grids are made to conform to structures so that grid motion monitored through a loading history is indicative of structural deformation. Grid characteristics such as location of points, pitches of points, pitches of lines, and the directions of lines can all be measured and compared to a prescribed state for different load conditions. These comparisons provide such useful quantities as displacement, curvatures and strains. Current trends in extracting useful information from these comparisons is presented here. Emphasis is on using digital-image processing and digital-pattern recognition as a tool in the extraction of data from structural in-plane grid methods. The term, structured grid, refers to some regular array of lines or dots. The purpose of this paper is to familiarize the reader with some of the current trends in the grid methods and to provide the basis for comparison to the more traditional grid methods.

9A435. Impact-echo response of concrete plates containing delaminations: Numerical, experimental, and field studies. - C Cheng and M Sansalone *(Dept of Struct Eng, Cornell)*. Mat Struct **26**(159) 274-285 (Jun 1993).

This paper describes the use of the impact-echo technique - a non-destructive testing technique based on the use of transient stress waves - for detecting delaminations in concrete plate-like structures such as bridge decks, slabs, and walls. Results obtained from numerical (FE) analysis and controlled-flaw laboratory studies are presented and used to explain the elastic impact response of delaminated plates. Current impact-echo instrumentation is described, and results obtained from concrete bridge decks containing delaminations caused by corrosion of reinforcing steel are presented. These results provide a better understanding of the impact response of delaminated plates.

9A436. Basic study for predicting the disaster in rock engineering with an acoustic emission technique. - Yin Fei *(Res Div, Reconnaissance Planning and Des Inst, Yellow River Conservance, Zhengzhou, Peoples Rep of China)*. Eng Fracture Mech **45**(3) 387-391 (Jun 1993).

This paper deals with the prediction of disaster in rock engineering with an acoustic emission technique. Variations of acoustic emission signals have been detected on the specimens from two dam areas in the process of rock fracture, and the relationship between these variations has been investigated. The results show that it is possible to detect and predict the unstable tendency of surrounding rocks, slide and collapse on the bases of their roles of acoustic emission in the process of rock deformation and damage. Though there are some difficulties in using this method *in situ*, no doubt, this method is one of hopeful means to predict the occurrence of disaster, and is worth researching further.

9A437. Inverse problems in electromagnetic nondestructive evaluation. - HA Sabbagh *(Sabbagh Assoc, 4639 Morningside Dr, Bloomington IN 47407)* and RG Lautzenheiser *(Rose-Hulman IT, Terre Haute IN 47803)*. Int J

Appl Electromagnetics Mat 3(4) 253-261 (Apr 1993).

We present a rigorous model for electromagnetic (eddy-current) nondestructive evaluation. It consists of a pair of coupled integral equations, in which the unknowns, the electric field and conductivity of the flaw, appear multiplied together. This nonlinear (bilinear) inverse problem is solved using gradient techniques. Conclusions concerning the use of alternative algorithms, such as simulated annealing and statistical decision theory, to start and finish the inversion process are made.

282C. STRUCTURAL OPTIMIZATION

9A439. **Exposition of the material derivative approach for structural shape sensitivity analysis.** - JS Arora *(Optimal Des Lab, Col of Eng, Dept of Civil and Env Eng and Mech Eng, Univ of Iowa, Iowa City IA 52242).* Comput Methods Appl Mech Eng 105(1) 41-62 (May 1993).

The material derivative approach for structural shape design sensitivity analysis is described in a unified manner using the continuum formulation. Both the direct differentiation and adjoint methods are derived and computer implementation aspects are discussed. The basic purpose of the paper is to present the shape design sensitivity analysis as an application of the material derivative concept of continuum mechanics, and the calculus of variation procedures for taking variations of integrals over the variable domains. It is also shown that the use of a recently developed variational principle for design sensitivity analysis greatly simplifies derivation of the adjoint method.

9A440. **Finding the optimal distribution of material properties.** - UT Ringertz *(Dept of Lightweight Struct, Royal IT, S-100 44 Stockholm, Sweden).* Struct Optim 5(4) 265-267 (Apr 1993).

The compliance of 2D structures is minimized using the elements of the costitutive matrix as design variables. The amount of materials to be used is required to be less than a prescribed amount and further constraints on the constitutive matrix are imposed as matrix inequalities. The apparent nonsmoothness of the matrix inequalities is removed by use of a barrier transformation.

9A441. **General related variational approach to shape optimum design.** - A Longo, J Unzueta, E Schaeidt, A Alvarez, JJ Anza *(Anal and Des Dept, LABEIN Cuesta de Olabeaga 16, 48013 Bilbao, Spain).* Adv Eng Software 16(2) 135-142 (1993).

A general variational approach to shape optimum design is presented. The paper is concerned mainly with two fundamental subjects involved within shape optimization methodologies: the Geometric Representation or Design Model definition and the evaluation of shape sensitivities. Within this context, the term variational is related, on one hand, to the use of variational geometry concepts at the level of Design Model and, on the other hand, to the evaluation of sensitivities by means of the material derivative concept of generalized calculus of variations. At the end of the paper, an industrial application, called SIDOMAT, is described.

9A442. **Method for structural optimization which combines second-order approximations and dual techniques.** - T Larsson and M Ronnqvist *(Dept of Math, Linkoping IT, S-581 83 Linkoping, Sweden).* Struct Optim 5(4) 225-232 (Apr 1993).

A structural optimization problem is usually solved iteratively as a sequence of approximate design problems. Traditionally, a variety of approximation concepts are used, but lately second-order approximation strategies have received most interest since high quality approximations can be obtained in this way. Furthermore, difficulties in choosing tuning parameters such as step-size restrictions may be avoided in these approaches. Methods that utilize second-order approximations can be divided into two groups; the first, a Quadratic Programming (QP) subproblem including all available second-order information is stated, after which it is solved with a standard QP method, whereas the second approach uses only an approximate QP subproblem whose underlying structure can be efficiently exploited. The numerical results show that the proposed solution is a valid approach to solve the QP subproblems arising in second-order approximation schemes.

9A443. **Optimal topology of trusses or perforated deep beams with rotational restraints at both ends.** - GIN Rozvany, T Lewinski, O Sigmund, D Gerdes, T Birker *(FB 10, Essen Univ, Postfach 103764, D-4300 Essen, Germany).* Struct Optim 5(4) 268-270 (Apr 1993).

This note discusses the least-weight layout of a truss having support conditions similar to those for a clamped deep beam. Numerical solutions are presented and confirmed by analytical considerations based on Michell's optimality criteria.

9A444. **Optimality criteria design method for tall steel buildings.** - DE Gierson and C-M Chan *(Dept of Civil Eng, Univ of Waterloo, N2L 3E5 ON, Canada).* Adv Eng Software 16(2) 119-125 (1993).

An efficient computer-based method is developed for the optimum design of tall steel building frameworks. Specifically, an optimality criteria method is applied to minimize the weight of a lateral load-resisting structural system of fixed topology subject to constraints on overall and interstorey drift. By exploiting the fact for building frameworks that member forces are relatively insensitive to changes in member sizes, rigorously-derived optimality criteria are shown to be readily satisfied through an iterative redesign procedure that converges in but a few cycles.

9A445. **Optimality criterion for maximum fundamental frequency of free vibrations of frames including axial and bending effects.** - W Szyszkowski and JM King *(Dept of Mech Eng, Univ of Saskatchewan, Saskatoon, SK, S7N 0W0, Canada).* Struct Optim 5(4) 250-255 (Apr 1993).

An optimality criterion for maximum multiple fundamental frequency of free vibrations for structures of prescribed weights is presented. The criterion includes both axial and bending effects and can be used for analysis of truss, beam and frame structures. The error norm based on the criterion is proposed and used to verify trial designs against the optimum. The accompanying iterative procedure reduces this error norm to zero and drives a trial design to the optimum. The modality of the design at the optimum and the corresponding set of Lagrange multipliers are determined automatically.

9A446. **Optimization applications for aircraft engine design and manufacture.** - TK Pratt, LH Seitelman, RR Zampano, CE Murphy *(Man Info Syst, Pratt & Whitney, United Tech, E Hartford CT 06108),* F Landis *(Dept of Mech Eng, Univ of Wisconsin, Milwaukee WI 53201).* Adv Eng Software 16(2) 111-117 (1993).

Numerical optimization is an important tool in many aspects of jet engine design, development, and test. Early optimization work centered on structural optimization projects, while more recent applications are multidisciplinary in nature. A variety of constrained and unconstrained minimization techniques have been applied to the solution of these problems. Some projects have resulted in substantial cost savings relative to previously used methods; others have provided automated solutions not previously attainable when an engineer was part of the iteration process. An interesting hybrid solution process combines the penalty function and constrained optimization techniques. An acoustic data reduction project has provided an automated procedure to match analytical models to engine data.

9A447. **Optimum design of rectangular panels with a hole.** - CS Han *(Dept of Mech and Mat Eng, Wright State Univ, Dayton OH 45435)* and BP Wang *(Dept of Mech Eng, Univ of Texas, Arlington TX 76019).* Adv Eng Software 16(2) 127-134 (1993).

The optimum design of composite panels with a circular or an elliptical hole is considered in this paper. The objective is to find the best hole location, size and orientation so as to minimize the maximum tangential strain along the circumference of the hole. The problem is treated as a shape optimization problem, and the hole boundary parameterization method is developed in order to maintain the required hole shape. The parameterized relation is further utilized to transform the sensitivity data. The optimization problem is solved iteratively using p-method FE analysis and linear programming.

9A448. **Optimum design of thin wall structures under variable amplitude fatigue loading.** - MEM El-Sayed and EH Lund *(Dept of Mech Eng, Florida Int Univ, Miami FL 33199).* Adv Eng Software 16(2) 97-101 (1993).

This paper presents a method for considering fatigue life requirements in the optimal design of thin wall structures under variable amplitude load histories. The basic concept is to use the load histories combined with the stresses of the structure and the material fatigue properties to calculate the fatigue life during the optimization process. The life requirement is considered as a side constraint and the structure weight as the objective function.

9A449. **Shape optimal design of an engine exhaust manifold.** - RJ Yang and SC Poe *(Ford Motor, Village Plaza, Ste 1100, 23400 Michigan Ave, Dearborn MI 48124).* Struct Optim 5(4) 233-239 (Apr 1993).

An engine exhaust manifold made of cast iron cracks during thermal shock testing. The test process is simulated by FE analysis. The manifold is formulated as a linear heat transfer and thermo-elasticity problem in a variational form. Analytical expressions for shape design sensitivities of general 3D problems are presented, using the material derivative approach. A hybrid approach is described and used during the optimization process. This approach takes advantage of the direct and the adjoint variable methods and is the most efficient in calculating the sensitivity of the structural responses. After the FE model is verified by comparing the results with those from testing, the engine exhaust manifold is optimized with respect to its geometry.

9A450. Shape optimization of axisymmetric structures with adaptive FE procedures. - M Ozakca, E Hinton, NVR Rao *(Dept of Civil Eng, Univ Col, Singleton Park, Swansea SA2 8PP, UK)*. Struct Optim 5(4) 256-264 (Apr 1993).

A robust and versatile algorithm for shape optimization with adaptive FE procedures is developed for the design of axisymmetric structures. The algorithm is based on the use of boundary parameterization with cubic splines for describing shape changes and takes advantage of the utilities available in an advancing front type mesh generator. Six-noded triangular elements are adopted. Shape optimization examples involving solid axisymmetric structures are presented to illustrate the various features of the integrated approach.

9A451. Structural optimization based on relaxed compatability and overlapping decomposition. - G Thierauf and F Spengemann *(Univ of Essen, Essen, Germany)*. Adv Eng Software 16(2) 89-95 (1993).

A two stage sequential technique for the solution of a wide class of structural optimization problems is proposed. It is based on an overlapping decomposition of the structural domain, which is assumed to be discretized by FEs. The optimal overlapping decomposition is derived from the nullspace of the equilibrium equations which is computed by a turn-back LU-decomposition minimizing the overlap of the subdomains. The iterative solution of the structural optimization problem is performed by a two level approach where the nodal displacements are the coordination variables.

9A452. Structural optimization of multiple attributes. - DL Thurston and R Sun *(Decision Syst Lab, Dept of General Eng, Univ of Illinois, Urbana IL 61801)*. Struct Optim 5(4) 240-249 (Apr 1993).

This paper presents a methodology for structural design optimization of multiple objectives, or attributes. The method represents an improvement over Pareto optimization-based methods by quantitatively representing trade-offs between conflicting objectives in a single multi-attribute objective function. Classical utility analysis is first used to determine a multi-attribute evaluation function for a particular structure from the designer's viewpoint. A one-bay, three storey steel frame building example demonstrates the methodology for determining the design configuration with the best combination of cost and drift index.

9A453. Structural shape optimization of vibrating shells and folded plates using two-noded finite strips. - E Hinton, M Ozakca, NVR Rao *(Dept of Civil Eng, Univ Col, Swansea SA2 8PP, UK)*. Eng Comput 10(2) 139-157 (Apr 1993).

This paper deals with the structural shape optimization of vibrating prismatic shells and folded plates. The finite strip method is used to determine the natural frequencies and modal shapes based on Mindlin-Reissner shell theory which allows for transverse shear deformation and rotatory inertia effects. An automated optimization procedure is adopted which integrates finite strip analysis, parametric cubic spline geometry definition, automatic mesh generation, sensitivity analysis and mathematical programming methods. The objective is to maximize the fundamental frequency by changing thickness and shape design variables defining the cross-section of the structure, with a constraint that the total volume of the structure remains constant.

9A454. Thirty years of modern structural optimization. - GN Vanderplaats *(VMA Eng, 5960 Mandarin Ave, Ste F, Goleta CA 93117)*. Adv Eng Software 16(2) 81-88 (1993).

Modern structural optimization began in earnest in 1960 when Schmidt first combined FE analysis with nonlinear numerical optimization methods to created what he called "Structural Synthesis". Since that time, the methods have been continually developed and improved, so that today we can say that this technology has matured to become a practical design tool. The purpose here is to review the history of structural optimization and to identify the present state of the art.

9A455. Active control of composite plates using piezoelectric stiffeners. - V Birman *(Eng Educ Center, Univ of Missouri-Rolla, 8001 Natural Bridge Rd, St Louis MO 63121)*. Int J Mech Sci 35(5) 387-396 (May 1993).

The governing equations for geometrically nonlinear, arbitrarily laminated rectangular plates reinforced by stiffeners which include piezoelectric and composite layers are presented. General equations obtained in the paper are reduced to a single equation of motion for piezoelectrically reinforced, geometrically linear, specially orthotropic plates. A criterion for an effective control of forced vibrations of such plates using piezoelectric stiffeners and a static electric field is illustrated. Numerous active control problems can be addressed using the theory outlined in the paper.

A method for evaluating time-dependent reliability of a structural system subjected to stochastic loads is presented. Structural deterioration due to environmental stressors is also taken into account. An adaptive Monte Carlo simulation procedure combined with conditional expectation is proposed. The optimum common ratio of the standard deviation of an importance sampling variables to that of the corresponding valuables is estimated iteratively as well as their mean values. Unlike systems evaluated by simple Monte Carlo simulations, the accuracy of the failure probability evaluated by adaptive importance sampling is relatively insensitive to the magnitude of the probability.

282H. CONCRETE (REINFORCED)

9A461. Effect of hot weather on strength of reinforced concrete beams. - A-GF Abbasi, A-HJ Al-Tayyib, MB Al-Ali *(Dept of Civil Eng, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)*. Cement & Concrete Composites 14(3) 209-221 (1992).

Many development projects being executed in hot-climate countries involve construction of reinforced concrete structures in hot weather. Three basic concepts for which these structures are designed are moment, shear, and bond-development length. This paper presents results of tests conducted on 52 reinforced concrete beams of various dimensions containing reinforcing bars of various sizes and yield strengths. The beams were prepared and cured in hot-weather environments at various concrete mix temperatures. The results of the tests show that, even if proper precautions are taken to obtain the required compressive strength of the concrete, the strength of the reinforced concrete beams prepared and cured in hot weather could be reduced by as much as 25% when the concrete mix temperature reaches 45 °C (126.00°C).

9A462. Sensitivity study of criteria governing collapse of centrally loaded R-C slabs. - MSA Abbasi, MH Baluch, AK Azad *(Dept of Civil Eng, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)*, HH Abdel-Rahman *(Dept of Civil Eng, King Abdulaziz Univ, Jeddah 21413, Saudi Arabia)*. Eng Comput 10(2) 175-187 (Apr 1993).

This paper presents the full range sensitivity study of various components of material model on the response of reinforced concrete slabs subjected to central patch loads using nonlinear FE analysis. A layered degenerate quadratic plate element with five dof was employed. Smeared crack model was used with orthogonal cracking. The components considered in this work are: perfectly plastic models *versus* hardening models, role of crushing condition on collapse load, influence of dowel effect on punching capacity, parametric variation of tension stiffening parameter, parametric variation of degraded shear modulus and the role of yield criterion.

9A463. Stress resultant FE analysis of reinforced concrete plates. - A Ibrahimbegovic and F Frey *(Dept of Civil Eng, Swiss Fed IT, EPFL, GC, LSC, CH-1015, Lausanne, Switzerland)*. Eng Comput 10(1) 15-30 (Feb 1993).

An efficient implementation of a constitutive model for reinforced concrete plates is discussed in this work. The constitutive model is set directly in terms of stress resultants and their energy conjugate strain measures, relating their total values. The latter simplification is justified by our primary goal being an evaluation of the limit load of a reinforced concrete plate. A concept of the "rotating crack model" is utilized in proposing the constitutive model to relate the principal values of bending moments and the corresponding values of curvatures. Efficient implementation is provided by a very robust, but inexpensive plate element. The element is based on an assumed shear strain field and a set of incompatible bending modes, which provides that the nonlinear computations, pertinent to constitutive model, can be carried out locally, ie, independently at each numerical integration point. Set of numerical examples is presented to demonstrate a very satisfying performance of the proposed model.

This paper discusses the effects of aging of petrochemical facilities with regard to the impact on seismic performance. Examples of typical construction and serious concerns are presented. Requirements in evaluation and retrofits are discussed. A comparison is made with the current state-of-practice in offshore platforms and nuclear power plants.

282P. DESIGN CODES

9T466. **Current progress toward natural phenomena hazards mitigation for aging DOE structures, systems, and components.** - RC Murray *(LLNL)*. Appl Mech Rev 46(5) 250-255 (May 1993).

9A467. **Structures and geriatrics from a failure analysis experience viewpoint.** - DH Hopper *(Hopper & Assoc Eng, 300 Vista Del Mar, Redondo Beach CA 90277)*. Appl Mech Rev 46(5) 213-216 (May 1993).

In a failure analysis consulting engineering practice one sees a variety of structural failures from which observations may be made concerning geriatric structures. Representative experience with power plants, refineries, offshore structures, and forensic investigations is summarized and generic observations are made regarding the maintenance of fitness for purpose of structures.

282Y. COMPUTATIONAL TECHNIQUES

9A468. **Matroids in structural mechanics.** - A Kaveh *(Inst Allgemeine Mech, TU-Wien, A-1040 Vienna, Austria)*. Comput Struct 47(1) 169-174 (3 Apr 1993).

Matroids encountered in various branches of structural mechanics are presented. It is shown that minimal bases for matroids involved in the force method of structural analysis can theoretically be obtained using the Greedy algorithm for the combinatorial optimization. The problems encountered in the practical use of this algorithm are discussed and methods are suggested for their solution.

9A469. **Nth-order stiffness sensitivities in structural analysis.** - MB Fuchs *(Dept of Solid Mech Mat and Struct, Fac of Eng, Tel Aviv Univ, 69978 Ramat Aviv, Israel)*. Struct Optim 5(4) 207-212 (Apr 1993).

This paper presents a general expression for the Nth-order stiffness sensitivities in linear elastic frames. It is based on modeling the structure as being composed of unimodal elements. It is shown that the sensitivity of the structural response to the variation of the stiffness of an arbitrary component depends only on the corresponding elemental displacements. These are the nodal displacements due to nodal element loads applied to the structure at the end nodes of the considered element. Partial derivatives with respect to several element stiffnesses are obtained from the elemental displacements of the considered elements. The method is equally applicable to more general FE models. It requires, however, the preliminary decomposition of the FE into their unimodal components.

9A470. **Initial shape of cable-stayed bridges.** - PH Wang, TC Tseng, CG Yang *(Dept of Civil Eng, Chung-Yuan Christian Univ, Chung-Li, Taiwan, ROC)*. Comput Struct 47(1) 111-123 (3 Apr 1993).

A FE computation procedure for determining the initial shape of cable-stayed bridges under the action of dead load of girders and pretension in inclined cables is presented. The system equation of cable-stayed bridges including the nonlinearities due to large displacement, beam-column, and cable sag effects is first set up and then solved using the Newton-Raphson method on increment-iterationwise. Based on a reference configuration and an assumed cable pretension force, the equilibrium configuration under dead load is found. Further, by adjusting cable forces, a shape iteration is carried out and a new equilibrium configuration, ie, a more reasonable initial shape, can be determined.

9A472. **Minimizing distortion in truss structures: A comparison of simulated annealing and tabu search.** - RK Kincaid *(Dept of Math, Col of William and Mary, Williamsburg VA 23185)*. Struct Optim 5(4) 217-224 (Apr 1993).

Inaccuracies in the length of members and the diameters of joints of large space structures may produce unacceptable levels of surface distortion. Based on the influence matrices generated by a small deformation linear analysis, we formulate a combinatorial optimization problem to maximize surface distortion (DRMS). A deterministic heuristic, tabu search, is presented for DRMS. A comparison of the computational performance of tabu search is made with a randomized heuristic, simulated annealing.

9A473. **Modified elastic-plastic analysis including graphical processing of plane framed structures.** - SC Patodi and JS Patel *(Appl Mech Dept, Fac of Tech and Eng MS, Univ of Baroda, Baroda-390 001, India)*. Comput Struct 47(1) 155-161 (3 Apr 1993).

A stiffness-based modified approach is developed for the elastic-plastic analysis of rigid jointed plane frames by tracing the response of the frame under increasing loads from the beginning to collapse by a stepwise electric analysis. An important feature of the suggested approach is that it involves treating each span, which may or may not have plastic hinges and which may be subjected to concentrated and or uniform loads, as an undivided member with six dof. Each aspect of the analysis is translated into a C language instruction with emphasis on the development of graphics processors.

9A478. **Analysis of the multi-link independent suspension system.** - DMA Lee *(Dept of Mech Eng, Univ of W Ontario, London N6J 4A4, ON, Canada)*, DM Pascoe *(Universe Eng, Markham L3R 8E4, ON, Canada)*, WH ElMaraghy *(Dept of Mech Eng, Univ of W Ontario, London N6J 4A4, ON, Canada)*. Int J Vehicle Des 14(1) 44-58 (1993).

The most prevalent type of suspension found in most high performance vehicles has been the double wishbone suspension. Expanding upon the idea of the wishbone types, this paper deals with the analysis of the multi-link (five-link) independent suspension system which is adopted by the automotive industry in some high performance vehicles. The multi-link suspension is similar in construction to the double wishbone; however, the upper (and lower) control arms are divided into four distinct links. This allows variations to be made in the suspension parameters so that certain stability criteria can be satisfied. A brief introduction to the multi-link suspension is provided and a discussion of the effectiveness of the suspension design is presented at the conclusion. The theoretical development presented has been implemented as a PC-based CAD software package.

9A479. Simplified FE representation of fuselage frames with flexible castellations. - ME Heerschap *(Fac of Aerospace Eng, Univ of Tech, PO Box 5058, 2600 GB Delft, Netherlands).* Comput Struct 47(1) 19-32 (3 Apr 1993).

The frames in an aircraft fuselage are commonly attached to the skin by flexible castellations to reduce the stresses in the frames when the fuselage is pressurized. This results in a complex deformation of the frames and castellations. Nevertheless it is impractical to model these in detail in a FE model of the fuselage as a whole, because of the number of frames and castellations present in the fuselage and the many elements which would be needed to model a single frame and castellation. A suitable, highly simplified representation of the frame with castellations is developed here. It is shown that the errors, with regard to stresses in the skin, can be reduced to an acceptable level.

9A480. Identification of support conditions of buried pipes using a vibrating pig. - UG Kopke *(Vipac Engs and Scientists, Woodville, Australia)* and HEM Hunt *(Dept of Eng, Univ of Cambridge, UK).* Proc Inst Mech Eng E 207(E1) 29-40 (1993).

This paper describes a method for monitoring the variation in support condition of pipelines using a vibration technique. The method is useful for detecting poor support of buried pipelines and for detecting spanning and depth of cover in subsea lines. Variation in the pipe support condition leads to increased likelihood of pipe damage. A vibrating "pig" has been developed and tested on buried pipelines. Certain features of pipe support, such as voids and hard spots, display characteristic responses to vibration, and these are measured by the vibrating pig. Post-processing of the measured vibration data is used to produce a graphical representation of the pipeline support and certain "feature characteristics" are identified.

9A481. Transverse vibration of buried pipelines due to internal excitation at a point. - UG Kopke *(Vipac Engs and Scientists, Woodville, Australia).* Proc Inst Mech Eng E 207(E1) 41-59 (1993).

This paper is concerned with the dynamic response of buried pipelines due to excitation located inside the pipe. This work is important for application to techniques that employ vibration to investigate pipeline support conditions using a vibrating pipe inspection device. Three different theoretical models are developed and investigated. Good agreement between these modes is demonstrated. The beam-on-elastic Pasternak foundation model is successfully used to predict "signatures" of the pipe-soil response that characterize soil support features, such as hard and soft supports.

9A482. Stress evaluation along the sidewalls of a box-shaped spillway structure. - EC Kalkani *(Dept of Civil Eng, Natl Tech Univ, Patission 42, Athens 10682, Greece).* Comput Struct 47(1) 163-167 (3 Apr 1993).

The stress distribution along the walls of a box-shaped spillway-chute is investigated to locate the destressed areas on the structure. The deformed shape of the structure is also examined. The analysis is performed considering gravity loads, hydrostatic loads, equipment loads and uplift pressures. The distribution of maximum principal stresses indicate that the box-shaped structure is subject mainly to compression due to the cumulative effect of all external forces. The maximum principal stresses developed are checked against the allowable stresses in the concrete.

292. Friction and wear

292A. GENERAL THEORY

9A483. Modelization of damage by abrasion. - A Magnee *(Dept of Appl Sci, Metall and Mat Sci, Centre Rech Metal and Univ of Liege, rue E Solvay, 11-B-4000 Liege, Belgium).* Wear 162-164(PART B) 848-855 (13 Apr 1993).

This paper takes step to determine the non-negligible parameters governing the wear process. Modelization leads to the generalization of the Archard law. A new nondimensional law is proposed in which the sharpness of the abrasive, its mineralogical hardness and the microstructural characteristics (elasto-plasticity and toughness) of the abraded material are taken into account. The mathematical expression constituents the theoretical formulation of numerical experimental results, including those achieved several years ago by a well-known worker in the field, MM Khrushchov.

9A484. Self-organization and concepts of wear resistance of tribosystems. - LI Bershadskii *(Inst of Prob in Mat Sci, Ukrainian Acad of Sci, Kiev).* Sov J Friction Wear 13(6) 101-114 (1992).

A number of experimental facts of basic cognitive significance in tribology are discussed in terms of systematized features of self-organization (synergetics). Some ideas and models related to self-organization of tribosystems are analyzed, mainly those published in the Soviet Journal of Friction and Wear. Concepts of wear resistance of tribosystems and materials and some unsolved problems of tribosynergetics are discussed.

292B. FRICTION

9A485. Effects of surfactants on the tribological properties of a Cr_2O_3 coating. - Jianjun Wei and Qunji Xue *(Lab of Solid Lubrication, Lanzhou Inst of Chem Phys, Chinese Acad of Sci, Lanzhou, China).* Wear 162-164(PART A) 229-233 (13 Apr 1993).

A block-on-ring tester was used to investigate the effects of surfactants on the tribological properties of a Cr_2O_3 coating at ambient conditions. The results show that the critical micelle concentration (CMC) of surfactants have significant effects on the friction and wear properties of Cr_2O_3 coating. The friction and wear decrease rapidly up to the CMC but become stable above the CMC. Compared with water, the surfactants (above the CMC) can markedly reduce the friction; sodium dodecyl benzyl sulphanate and sorbitan monooleate have effective wear-reducing functions. X-ray photoelectron spectroscopy analyzes show that the lubricity of surfactants is due to their physical adsorption on rubbing surfaces.

9A486. Friction and wear of self-lubricating composites at temperatures to 450 °C in vacuum. - Mineo Suzuki *(Natl Aerospace Lab, Chofu, Tokyo, Japan)*, Minoru Moriyama *(Pure Mat Lab, Kokubunji, Tokyo, Japan)*, Makoto Nishimura *(Natl Aerospace Lab, Chofu, Tokyo, Japan)*, Masaji Hasegawa *(Pure Mat Lab, Kokubunji, Tokyo, Japan).* Wear 162-164(PART A) 471-479 (13 Apr 1993).

The tribological characteristics of hot-pressed self-lubricating composites, consisting of molybdenum disulfide, refractory metal oxides and refractory metals, were evaluated at temperatures up to 450 °C in vacuum. Sliding bearings made from the composites were run against 304 stainless steel shafts at a rotational speed of 120 rev min^{-1} under an applied load of 1.7 N for (6-10) × 10^6 revolutions. Wear was negligible at temperatures under 100 °C. However, wear of the composite bearings, at a specific wear rate of (2-5) × 10^{-8} mm^3 N^{-1} mm^{-1}, occurred at 300 °C. At 450 °C, a weight loss of about 10-30 mg of the shaft and a weight gain of almost the same amount of the bearings were observed. X-ray photoelectron spectroscopy analysis revealed iron and traces of iron sulfide on the bearing surface, indicating that a chemical reaction had occurred between the composite bearing and the steel shaft. To examine the effect of counterpart materials, pin-on-disk friction tests using a composite pin and an Si_3N_4 disk were performed at temperatures up to 450 °C. In contrast to the 304 steel counterpart, an excellent tribological response was found with the Si_3N_4 disk. The specific wear rate of the composite pin at 450 °C was 2.2 × 10^{-10} mm^3 N^{-1} mm^{-1} and the wear of the Si_3N_4 disk was negligible. An attempt was made to improve the strength of the composite. By adding 304 stainless steel in a fraction of 5% to the composition, an improvement in strength of the composite of about 30% was obtained. Furthermore, this had a good effect on the tribological performance of the composite at high temperature.

9A487. Friction behavior of ceramic fiber-reinforced aluminum metal-matrix composites against a 440C steel counterface. - SV Prasad and KR Mecklenburg *(Mat Directorate, Wright Lab, WL/MLBT, WPAFB).* Wear 162-164(PART A) 47-56 (13 Apr 1993).

This paper describes the friction behavior of kaowool (Al_2O_3•SiO_2) and saffil (Al_2O_3) fiber-reinforced aluminum metal-matrix composites (MMCs) prepared by the squeeze infiltration technique. A hypoeutectic Al-Si alloy was used as the matrix. Friction measurements were made using a ball-on-disc configuration, in which a 440C stainless steel ball was held against a rotating MMC disc. Wear tracks on MMC discs and material transfer to the steel counterface were examined using a scanning electron microscope equipped with an energy dispersive X-ray spectroscope. There were also no significant differences in the friction behavior of the three MMCs and the unreinforced alloy when metallographically polished samples were used as test specimens. In all four cases, the friction trace was rough with large fluctuations in friction force; the coefficients of friction varied between 0.4 and 0.6. When the surface of the MMC was etched, the friction coefficient dropped to a low value of 0.18 and the stick-slip type behavior disappeared. With increase in normal load (and sliding distance), the stick-slip behavior type, characteristic of polished surfaces, reappeared. The transition from smooth to stick-slip behavior is correlated to the microstructure and surface topography of the MMC. Factors influencing the transfer of aluminum (from the MMC disc) to steel are discussed.

9A488. Friction microprobe investigation of particle layer effects on sliding friction. - PJ Blau *(Metals and Ceramics Div, ORNL).* Wear 162-164(PART A) 102-109 (13 Apr 1993).

Interfacial particles (third bodies), resulting from wear or external contamination, can alter and even dominate the frictional behavior of solid-solid sliding in the absence of effective particle removal processes (eg, lubricant flow). A unique friction microprobe, developed at ORNL, was used to conduct fine-scale friction studies using 1.0 mm diameter stainless steel spheres sliding on several sizes of loose layers of fine aluminum oxide powders on both aluminum and alumina surfaces. Conventional, pin-on-disk experiments were conducted to compare behavior with the friction microprobe results. The behavior of the relatively thick particle layers was found to be independent of the nature of the underlying substrate, substantiating previous work by other investigators. The time-dependent behavior of friction, for a spherical macrocontact starting from rest, could generally be represented by a series of five rather distinct phases involving static compression, slider breakaway, transition to steady state, and dynamic layer instability. A friction model for the steady state condition, which incorporates lamellar powder layer behavior, is described.

9A489. Frictional behavior of extremely smooth and hard solids. - DE Kim *(Ohio State Univ, 206 W 18th Ave, Columbus OH 43210)* and NP Suh *(Dept of Mech Eng, MIT)*. Wear **162-164**(PART B) 873-879 (13 Apr 1993).

Frictional behavior of extremely smooth (average roughness ~ 1 nm) and hard (approximately 800 - 2200 kg mm^{-2}) solids in air has been investigated. The present study was conducted to obtain the minimum friction under dry sliding conditions by eliminating the friction components due to mechanical interactions such as plowing and asperity deformation. By using extremely smooth and hard materials (silicon, sapphire, SiC, quartz and glass), static friction coefficients as low as 0.06 and steady state friction coefficients between 0.09 and 0.17 could be obtained with an undetectable amount of wear. The low friction and wear behavior of smooth and hard solids in air has attributed to the low probability of asperity interaction wear particle generation as well as to surface films. Even for such low frictional interaction, plastic deformation is still the major cause of friction in crystalline systems, as suggested by the existence of dislocation etch pits on silicon surfaces along the sliding track.

9A490. Further investigation on the tribological behavior of Cu-20% Nb *in situ* composite. - P Liu *(Sch of Tech, E Illinois Univ, Charleston IL 61920)*, S Bahadur *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*, JD Verhoeven *(Ames Lab, USDOE, Dept of Mat Sci and Eng, Iowa State Univ, Ames IA 50011)*. Wear **162-164**(PART A) 211-219 (13 Apr 1993).

Sliding friction and wear behavior of Cu-20 vol% Nb *in situ* composite sliding against a tool steel disk was studied under dry ambient conditions. Studies were directed towards the understanding of the roles of the filament and the matrix materials during sliding. It was found that Nb filaments underwent reorientation, shearing and refinement. Irrespective of their prior orientation, Nb filaments close to the contact surface were oriented along the sliding direction. These processes resulted from the friction-induced surface deformation and led to the strengthening of the subsurface layer of the composite. There was no separation of Nb filaments from Cu matrix observed in the sliding process. The effects of annealing, sliding speed and filament orientation on the friction and wear behavior of the composite were also investigated. The micromechanisms of wear were studied by scanning electron microscopy. Surface deformation, filament reorientation and refinement, and oxidation seemed to play important roles in the friction and wear processes.

9A491. Hardness, friction and wear of multiplated electrical contacts. - PA Engel *(Mech and Indust Eng Dept, Binghamton Univ, Binghamton NY 13902-6000)*, EY Hsue *(IBM Dev Lab, Endicott NY 13760)*, RG Bayer *(Consult, Vestal NY 13850)*. Wear **162-164**(PART A) 538-551 (13 Apr 1993).

Full interpretation of the composite (eg, Vickers) microhardness is given for typical multilayer platings used for electrical contacts. For relatively thick layers plated on a Cu substrate, an effective highly stressed region (delimited by the "plastic boundary") is identified, which introduces a significant modification in the prior interpretive theory of thin platings. An approximate computation for the internal plastic work is devised. The work done on the underlying substrate is shown to correlate well with findings of the subsurface deformation theory of multiplated contacts. In particular, wear and friction are shown to be, respectively, proportional and inversely proportional, to the plastic work done on the substrate during multiple passes of a slider.

9A492. Role of dielectric properties in the tribological behavior of insulators. - S Fayeulle, H Berroug, B Hamzaoui, D Treheux *(Lab Mat-Mec Phys, URA CNRS 447, Ecole Centrale de Lyon, 69131 Ecully, France)*, CL Gressus *(CEA-DAM, Bruyeres, Le Chatel, France)*. Wear **162-164**(PART B) 906-912 (13 Apr 1993).

The friction properties of single-crystal alumina were investigated under dry conditions. The relative humidity was kept to less than 1% and the contact pressure was chosen to be very small to prevent the formation of wear debris at the interface. The tangential force and acoustic emission were recorded continuously during tests. The dielectric properties of samples were characterized before and after tribological tests using scanning electron microscopy. The effect of X-ray irradiation on the dielectric and friction properties was investigated. Sapphire samples annealed at 1500° C did not charge, but after X-ray irradiation the charging capacity was highly increased, as was the friction coefficient (by a factor of 4). After the friction tests, the charging capacity of sapphire was observed both inside and outside the wear track. X-ray irradiation of the samples outside the wear track also modified the friction behavior. Based on the results, others from the literature and on the increasingly understood correlation between the mechanical and electrical properties of dielectrics, an energetic explanation of the friction and wear behavior of insulator materials is proposed. Friction and wear are shown to be related to the mechanisms of storage and dissipation of energy. Because of the dielectric properties of insulators, this energy results from electrostatic interactions: polarization of the material and displacements of electrical charges. Polarizaton is quickly achieved and increases during friction because of the build-up of a space charge in the material owing to the trapping of charge carriers. This trapping of defects already present in materials before testing or created during friction allows the storage in the lattice of very high amounts of energy (5 eV or more per charge) which, when dissipated, can lead to catastrophic failure.

9A493. Sliding friction and wear of ceramics in neutral, acid, and basic aqueous solutions. - B Loffelbein, M Woydt, K-H Habig *(Fed Inst for Mat Res and Testing, BAM, Unter den Eichen 87, W-1000 Berlin 45, Germany)*. Wear **162-164**(PART A) 220-228 (13 Apr 1993).

Self-mated sliding couples of SSi_3N_4, $HIP-RBSi_3N_4$ SSiC, SiSiC, $MgO-ZrO_2$ and Al_2O_3 were tested in different aqueous solutions (H_2O, NaOH, KOH, NH_4OH, HNO_3, H_2SO_4, H_3PO_4, CH_3COOH, HCI, $HClO_4$) under conditions of boundary or mixed lubrication. The friction and wear behavior depended considerably on the composition of the ceramics, but the nature of the aqueous solutions was of minor importance. The best frictional behavior was observed with couples of SSiC, with steady state friction coefficients of 0.05. The lowest wear coefficients were measured for couples of the two types of Si_3N_4, SSiC and Al_2O_3 with values of approximately 10^{-7} mm^3 Nm^{-1}. If low friction and low wear are required, couples of SSiC seem to be the best choice in most aqueous solutions.

9A494. Sliding friction and wear up to 600° C of high speed steels and silicon nitrides for gas turbine bearings. - THC Childs *(Dept of Mech Eng, Univ of Leeds, Leeds LS2 9JT, UK)* and A Mimaroglu *(Dept of Mech Eng, Univ of Bradford, Bradford, UK)*. Wear **162-164**(PART B) 890-896 (13 Apr 1993).

The sliding friction coefficients and specific wear rates of a range of differently processed (sintered and wrought) high speed steels and (hot isostatically pressed, hot pressed and sintered) silicon nitrides have been measured in both dry and boundary lubricated conditions at temperatures from 20 to 600° C (dry) or 200° C (lubricated). In dry conditions, the wear of high speed steels and silicon nitrides on themselves was similar up to 400° C, rising from 5×10^{-9} mm^3 mm^{-1} N^{-1} at 20° C to 5×10^{-8} mm^3 mm^{-1} N^{-1}. However, in the range 400 - 600° C, the wear rates of the silicon nitrides continued to rise, while those of the tungsten high speed steels stayed constant and those of the molybdenum steels decreased. There was no effect of processing route. The boundary lubricated testing was carried out under a synthetic ester with and without a zinc dithiophosphate (ZDDP) additive. For all the materials, the specific wear rates were in the range 10^{-11} - 10^{-10} mm^3 mm^{-1} N^{-1} but these rates were near the measurement limit and running-in waves was still progessing over the 1 to 2 km sliding distance of the tests. A small amount of dry testing has been performed with silicon nitride sliding on high speed steel and on alumina and these results also are reported. A characteristic of all the dry testing was the formation of surface films from which the wear debris was formed. This perhaps explains the lack of any processing route effect.

9A495. Study of friction feed paper separation. - KD Stack and RC Benson *(Mech of Flexible Struct Project, Dept of Mech Eng, Univ of Rochester, Rochester NY 14267)*. J Eng Indust **115**(2) 236-241 (May 1993).

An understanding of the mechanics of paper separation is very important to the design of reliable photocopiers, and in this paper a model is developed to simulate friction feed paper separation. The importance of such system parameters as roller acceleration and compressive load is demonstrated. The variability of friction coefficients is shown to have a significant effect on feeding reliability. Experimental data are shown to be in good agreement with predicted results. Recommendations are made for the design of reliable friction feed paper separators.

9A496. Tribological behavior of a titanium-nickel alloy. - P Clayton *(Dept of Mat Sci and Eng, Oregon Graduate Inst of Sci and Tech, 19600 NW Von Neumann Dr, Beaverton OR 97006-1999)*. Wear **162-164**(PART A) 202-210 (13 Apr 1993).

Titanium-nickel alloys based on the unusual intermetallic compounds TiNi exhibit a ductility comparable with metallic alloys. The primary interest in these materials has focused on their shape memory alloy effects. The mechanical behavior of a titanium-nickel alloy in sliding and rolling-sliding contacts has been investigated. The purpose was to examine the potential of the material as a rim for a locomotive wheel. The possible benefits include an enhancement of the coefficient of friction between wheel and rail under the typical conditions of mild contamination. Wear tests were carried out under non-lubricated conditions to compare the material with conventional pearlitic steel. The titanium-nickel alloy exhibits a high resistance to wear under severe contact conditions. It also gives excellent resistance to water lubricated rolling contact fatigue when run against itself. In tests of titanium-nickel alloy on steel, some steel rollers failed at very short lives and others wore and did not experience fatigue. The wear and rolling contact fatigue results are discussed in the context of monotonic and cyclic stress-strain properties. The capacity of TiNi for cyclic strain hardening is considered to be very significant.

9A497. **Accelerated wear testing using the grit size effect.** - D Forrest *(Trib Res Program, Dept of Mech Eng, MIT)*, Kaoru Matsuoka *(Matsushita Elect Indust, Osaka, Japan)*, Ming-Kai Tse, E Rabinowicz *(Trib Res Program, Dept of Mech Eng, MIT)*. Wear 162-164(PART A) 126-131 (13 Apr 1993).

This paper describes a technique for wear prediction. It has been empirically established that the wear rate of an abraded workpiece is directly related to the grit size of the abrasive. Using this relationship, the wear rate of material subjected to very mild abrasion can be predicted from the measured wear rates of the same material under more severe conditions. This technique has been successfully applied to estimate the wear of magnetic recording head materials in a video tape system. Our results demonstrate that the wear rate of the head can be accelerated by as much as four orders of magnitude using abrasive lapping tapes of large grit size. The results also indicate that the wear rate of the recording head material decreases significantly with the magnetic or abrasive tape wear, which typically occurs during the first five to ten tape passes. Microscopic examination using scanning electron microscopy indicates that this reduction in wear rate is not due to clogging of the abrasive tape but rather to changes in abrasive particle shape. This means a recording head subjected to continuous sliding with fresh tape will wear considerably faster than a head which slides repeatedly against a loop of tape. Accordingly, in reporting the wear rates of head materials, it is important to describe the corresponding tape condition of usage history explicitly.

9A498. **Ball-on-flat reciprocating sliding wear of single-crystal, semiconductor silicon at room temperature.** - E Zanoria and S Danyluk *(Dept of Civil Eng, Mech and Metall, Univ of Illinois, PO Box 4348, Mail Code 246, Chicago IL 60680)*. Wear 162-164(PART A) 322-338 (13 Apr 1993).

This paper describes the reciprocating linear sliding fiction and wear experiments of a polycrystalline silicon ball in a single-crystal, silicon flat at room temperature in an argon environment. The normal loads used were 2.65, 3.59, 4.73, and 5.80 N, and the sliding velocity was 1.3 cm s^{-1}. The coefficient of friction at a normal load of 2.65 N initially decreased from 0.45 and stabilized at 0.23 after 400 cycles. At higher normal loads, the coefficients of friction were initially 0.45 but later fluctuated between 0.2 and 0.4. The degree of frictional fluctuation as well as the wear volume increased with load. The fluctuation of the coefficient of friction is related to the geometry of the wear debris which form into a cylindrical shape ("rolls"). A mechanism for roll formation is described.

9A499. **Ceramic tool wear when machining austempered ductile iron.** - IR Pashby, J Wallbank, F Boud *(Warwick Manuf Group, Dept of Eng, Univ of Warwick, Coventry CV4 7AL, UK)*. Wear 162-164(PART A) 22-33 (13 Apr 1993).

Four different types of commercially available ceramic tools - Al_2O_3, Al_2O_3:TiC, Al_2O_3:SiC_w and a sialon - have been used to turn heat treated SG iron at speeds between 150 and 450 m min^{-1}. The irons were either hardened by an austempering treatment giving a hardness of ~350 Hv, or softened to a hardness of ~180 Hv by an annealing treatment. Wear on the flank of the tools was the most common cause of tool rejection although tool fracture occurred when machining the austempered iron at the highest speed. Sialon tools suffered rapid wear and the Al_2O_3:SiC_w significantly underperformed the other alumina based tools under most conditions. Fracture damage on the tools' cutting edge and chemical interaction between tool and workpiece have been identified as important wear mechanisms in controlling tool life.

9A500. **Characterization of wear behavior of steel and ceramics in the VAMAS round robin tests.** - Yuji Enomoto and Kazuyuki Mizuhara *(Mech Eng Lab, Namiki 1-2, Tsukuba Ibaraki 305, Japan)*. Wear 162-164(PART A) 119-125 (13 Apr 1993).

The first and the second wear round robin tests within the framework of the Versailles Project on Advanced Materials and Standards (VAMAS) have been performed with materials combinations of α-Al_2O_3, Si_3N_4 and AISI 52100 steel under given sliding conditions of the ball-on-disk test system. The results, as reported elsewhere, showed a characteristic wear behavior depending on the material pairing. To obtain a deeper understanding of the wear behaviors of these materials, some additional observations and analyzes of the worn surfaces were conducted by means of various observations and analytical tools, such as topographic scanning electron microcopy, micro-Fourier transform IR, and so on. It was shown that the wear of the steel and Si_3N_4 was not a simple process, but had a complex manner in that both tribo-oxidation action and abrasive action of the steel and Si_3N_4 wear particles contributed to the higher wear of these materials.

9A501. **Combined effect of speed and humidity on the wear and friction of silicon nitride.** - MG Gee and D Butterfield *(Div of Mat Metrology, Natl Phys Lab, Queens Rd, Teddington, Middlesex TW11 0LW, UK)*. Wear 162-164(PART A) 234-245 (13 Apr 1993).

A series of ball-on-ring wear tests was performed on sintered silicon nitride. The experiments were carried out to investigate a discrepancy in the literature on the effect of humidity on the wear of silicon nitride. In the experiments reported here, a range of different testing speeds was used and the humidity of the tests held at less than 5% relative humidity (RH), 50% (RH), or 90% (RH). It was found that at the lowest speed that was used, the wear rate at low humidity was higher than that for higher humidity. As the speed increased there was a maximum in the wear rate for the high humidity tests, and a minimum for the low humidity tests, with wear rates for the low humidity tests much lower than those for the high humidity tests. At high speeds, the wear rate for the low humidity tests was much lower than that for the high humidity tests. The main mechanism of wear was the tribochemical oxidation of the silicon nitride to form silicon oxide.

9A502. **Effect of grain size on friction and sliding wear of oxide ceramics.** - K-H Zum Gahr, W Bundschuh, B Zimmerlin *(Inst of Mat Sci, Univ of Karlsruhe and Nucl Res Center of Karlsruhe Inst of Mat Res, PO Box 3640, W-7500 Karlsruhe, Germany)*. Wear 162-164(PART A) 269-279 (13 Apr 1993).

Microstructures of Al_2O_3 and 3mol%Y_2O_3-ZrO_2 (TZP) with symmetrically varying average grain sizes were produced by sintering. The hardness and fracture toughness of the ceramics as well as the amount of tetragonal, cubic and monoclinic phases of TZP-ZrO_2 were measured. Wear tests were carried out on the different self-mated microstructures in dry unidirectional and reciprocating sliding contact respectively, using block-on-ring geometries in air at ambient temperatures. The microstructures and worn surfaces were systematically analyzed using scanning electron microscopy and X-ray diffraction techniques. Experimental results showed that plastic deformation, intercrystalline microfracture, grain fragmentation, surface layers and delamination fracture contributed to the friction and wear processes. The theoretical analysis of wear as a function of time or length of wear path revealed a sharp transition from a high to a low level of wear intensity with decreasing apparent surface pressure for both oxide ceramics. A transition in the wear intensity occurred also as a function of the average grain sizes. These effects were attributed to a change in wear mechanisms.

9A503. **Effect of microstructure on the wear transition of zirconia-toughened alumina.** - C He, YS Wang, JS Wallace, SM Hsu *(Ceramics Div, NIST)*. Wear 162-164(PART A) 314-321 (13 Apr 1993).

The mechanical properties of alumina ceramics can be improved by the addition of pure or partially stabilized zirconia particles. In the present study, the wear characteristics of zirconia-toughened alumina (ZTA) composites under a non-reactive fluid (paraffin oil) lubricated condition were investigated. The wear transition load (ie, the load at which a rapid increase in wear occurs) increased with increasing zirconia content up to 20 vol%. The transition from mild to fracture-controlled wear of ZTA depends on the material properties (eg, hardness, elastic modules), the contact conditions (eg, Hertzian stress, coefficients of friction) and the microstructure of the material. The effect of the microstructure on wear was demonstrated and a Hall-Petch-type relationship between the microfracture stresses and the grain size was found. The effect of the grain size distribution on the wear transition load was also shown.

9A504. **Effect of sliding velocity on the wear-effect of time-temperature equivalence.** - J Song and GW Ehrenstein *(Dept of Polymer Eng, Univ of Erlangen-Nuremberg, Am Weichselgarten 9, DW-8520 Erlangen-Tennenlohe, Germany)*. Wear 162-164(PART B) 662-668 (13 Apr 1993).

The product from sliding velocity and normal load is usually used to calculate the working life of sliding elements. The fundamentals for this calculation and a wear factor which is independent of normal load and one which is independent of sliding velocity. Nevertheless, both increasing and decreasing wear factors with increasing sliding velocity were observed in tribological tests on polymeric materials. The reasons for this behavior seem to be two compensating effects of sliding velocity on the viscoelastic properties of polymeric materials, namely time-temperature equivalence and temperature dependence of the mechanical properties. The principle of time-temperature equivalence tells us that the change in the rate of strain (sliding velocity for tribology) has an effect equivalent to that of the change in the temperature. A high rate of strain leads to a high Young's modulus. In contrast, a high sliding velocity leads to a high temperature rise. The Young's modulus and strength of polymeric materials decrease with increasing temperature. The wear factor decreases with decreasing modulus. The effect of the sliding velocity is the sum of both effects. Therefore, a strongly marked dependence of the mechanical properties of polymeric materials on rate of strain leads to decreasing wear factor with increasing sliding velocity. In the case of a weaker time-temperature effect, the temperature dependence of the mechanical properties is dominant. Therefore, a slightly increasing wear factor with increasing sliding velocity can be observed.

9A505. **An evaluation of the penetration of ceramic femoral heads into polyethylene acetabular cups.** - D Dowson, B Jobbins, A Seyed-Harraf *(Dept of Mech Eng, Univ of Leeds, Leeds LS2 9JT, UK)*. Wear 162-164(PART B) 880-889 (13 Apr 1993).

It is desirable to evaluate the performance of new designs of total replacement hip joints and new materials in joint simulators prior to clinical trials, yet few satisfactory hip joint simulators are available. In a previous paper we have reported on the design and development of a versatile hip joint simulator and recorded an initial study of the performance of a standard 22 mm diameter Charnley prosthesis. There is now considerable interest in the use of ceramic femoral heads in total replacement hip joints and in the present paper we report the performance of larger diameters (32 mm) femoral heads made from high purity, fine grain alumina. A new procedure for the evaluation of penetration and wear volumes based upon the use of coordinate and roundness measuring machines is described. The results show a relatively rapid initial penetration of the femoral heads into the ultra-high molecular weight acetabular cups during the first 1.5×10^6 cycles of loading, followed by a very low penetration rate of about 27 μm per million cycles. This is shown to compare favorably with the previous findings for smaller, metallic Charnley prosthesis femoral heads of 22 mm diameter.

9A506. **Increasing wear resistance in polymer-based composites using radiation-modified polymeric additives.** - YM Pleskachevskii, VV Smirnov, VN Aderikha *(Metal-Polymer Res Inst, Belarus Acad of Sci, Gomel 246652, Belarus)*. Wear 162-164(PART A) 426-431 (13 Apr 1993).

The effect of radiation treatment of polymers and polymeric compositions on their structure and service properties is examined. The treatment of commercial dispersed polymers and their compositions is shown to be an efficient method for preparing friction modifiers that ensure increased wear resistance of plastics.

9A507. **Influence of carbon content of martensitic matrix and retained austenite on wear of martensitic ductile iron.** - Chuan-Gui Li, Qing-De Zhou *(Dept of Mech Eng, Xian Jiaotong Univ, Xian 710049, China)*, Guang-Shun Song, Zhen-Shu Fang *(Steel Foundry Shop, Hubei Plant of Cement Machinery, Huangshi, Hubei 435000, China)*. Wear 162-164(PART A) 75-82 (13 Apr 1993).

The influence of the carbon content of the martensitic matrix (at different austenizing temperatures) and the amount of retained austenite (AR) on the two-body abrasion and impact abrasion wear of martensitic ductile iron was studied. The results showed that: (1) the wear of martensitic ductile iron in two-body abrasion is a process of plastic deformation fatigue in the case of a soft abrasive, but a process of cutting in the case of a hard abrasive; (2) the carbon content in the martensitic matrix has an optimal value in impact wear testing; (3) the effect of AR on wear resistance depends on the loading condition. When the load is without impact such as in two-body abrasion, the retained austenite contributes to the wear resistance if the process is controlled by a fatigue mechanism; however, it has no significant effect on wear resistance if the process is controlled by the cutting mechanism. However, under impact load, retained austenite is harmful to the wear resistance.

9A508. **Influence of retained austenite on the wear resistance of high chromium cast iron under various impact loads.** - Jun-Tong Xi, Qing-De Zhou *(Dept of Mech Eng, Xian Jiaotong Univ, Xian 710049, China)*, Shi-Hui Liu, Guang-Shun Song *(Steel Foundry Shop, Hubei Plant of Cement Machinery, Huangshi, Hubei 435000, China)*. Wear 162-164(PART A) 83-88 (13 Apr 1993).

A high chromium cast iron was heated and maintained at 980 °C, and then cooled in five media of different temperatures to obtain various amounts of austenite (designated Ar). The specimens were subjected to impact wear tests under impact loads ranging from 1 to 6.2 J. The number of impacts was 6000 for each test. The results showed that (1) the influence of Ar on the impact wear resistance of high chromium cast iron depended on the magnitude of the impact load and wear mechanism. (2) Under a small impact load the mechanism was mainly cutting wear and Ar has no significant effect on impact wear resistance. (3) Under heavy impact load the mechanism was mainly impact fatigue wear and Ar exhibited a harmful effect on the impact wear resistance of the iron.

9A509. **Lubricated sliding and rolling wear of austempered ductile iron.** - Wu-Sheng Zhou, Qing-De Zhou *(Dept of Mech Eng, Xian Jiatong Univ, Xian 710049, Peoples Rep of China)*, Shou-Kang Meng *(Dept of Mech Eng, Yunnan IT, Kunming, Yunnan 650051, Peoples Rep of China)*. Wear 162-164(PART B) 696-702 (13 Apr 1993).

A series of austempered ductile iron samples were prepared by varying the austenizing temperature and austempering temperature. The lubricated sliding and rolling wear were studied and the wear mechanisms discussed. The results showed that in the case of lubricated sliding wear the wear resistance decreased with increasing austenizing temperature (850 - 950° C) and austempering temperature (300 - 400° C), and the mechanism was fatigue wear and in the case of lubricated rolling wear the wear resistance decreased initially with increasing austempering temperature (300 - 400° C) to a minimum and then increased considerably, and the mechanism was mainly fatigue spalling. It was supposed that a structure composed of lower bainite and low carbon content retained austenite is always beneficial to wear resistance. Hardness was an important property influencing the wear resistance. The hardening due to the phase transformation of retained austenite contributed to the rolling wear resistance.

9A510. **Macroscopic and microscopic wear mechanisms in ultra-high molecular weight polyethylene.** - JR Cooper, D Dowson, J Fisher *(Dept of Mech Eng, Univ of Leeds, Leeds LS2 9JT, UK)*. Wear 162-164(PART A) 378-384 (13 Apr 1993).

Studies of the wear of ultra-high molecular weight polyethylene sliding on relatively smooth metallic and ceramic counterfaces under a wide range of tribological conditions in pin-on-disc and pin-on-plate tests, hip joint simulators and components taken from patients, have demonstrated evidence for two separate types of wear processes. Microscopic wear processes were associated with the very small asperities or the smooth counterfaces (less than 0.2 μm). Macroscopic polymer asperity wear processes were associated with stress concentrations under the much larger peaks in the polymer surface (amplitude less than 10 μm). For constant load tests with rougher counterfaces, microscopic asperity wear dominated. However for smooth counterfaces ($R_a < 0.02$ μm) under constant load, the contribution of microscopic asperity wear was small, and incremental increase in wear rates were caused by removal of macroscopic polymer asperities due to high subsurface strains and failure. In artificial joints under dynamic loading, the macroscopic polymer asperity wear processes were accelerated by subsurface cracking and fracture producing high wear factors on smooth counterfaces.

9A511. **Mechanisms of hard alloy wear in frictional processes with polymers and composite materials.** - AL Zaitsev *(Metal-Polymer Res Inst, Acad of Sci, Gomel 246652, Belarus)*. Wear 162-164(PART A) 40-46 (13 Apr 1993).

Wear mechanisms have been analysed for a hard alloy prepared from cobalt and tungsten carbide when rubbed against polymers and their composites. The influence of the polymer chemical structure on hard alloy wear by the oxidation-fatigue mechanism was considered, as well as the effect of the hard alloy surface roughness and composite formulation on the running-in process. The relative area of layers transferred by friction onto the hard alloy surface during contact interaction was found to affect the mechanism by which the surface wears. The abrasive wear mechanism changes for the oxidation mechanism in the case of steady friction transfer layer formation owing to weaker friction hardening of the hard alloy surface layer, and to fatigue tear-out of carbide grains.

9A512. **Microstructure and wear resistance of pearlitic rail steels.** - AJ Perez-Unzueta and JH Beynon *(Dept of Eng, Univ of Leicester, University Rd, Leicester LE1 7RH, UK)*. Wear 162-164(PART A) 173-182 (13 Apr 1993).

Despite competition from bainitic and martensitic steels, pearlitic microstrctures remain dominant for railway track. Techniques developed over recent years have progressively refined the interlamellar spacing to produce harder, more wear-resistant pearlitic steels. This study aims to explain the mechanisms for the wear performance by observing how the microstructure adapts to the wear loading. Four pearlitic rail steels, with similar chemical compositions but with different interlamellar spacings, have been examined. Wear tests have been performed under both pure sliding and rolling-sliding conditions, the latter designed to simulate track conditions. The worn surfaces and the plastically deformed subsurface regions have been examined by optical metallography and scanning electron microscopy. It was observed that the plastic deformation produced considerable fracturing and realignment of the hard cementite lamellae. The softer ferrite matrix was severely deformed, allowing a reduction in the interlamellar spacing on approaching the worn surface. The effect of these realignments on the surface was to present an increased area fraction of hard cementite lamellae on planes parallel to the surface. Thinner cementite lamellae, associated with low interlamellar spacings, were easier to bend before fracturing. It is believed that shear ductility plays an important role in the period of time that any particular volume of material remains at the surface before becoming a loose particle.

9A513. **Movement patterns of abrasive particles in three-body abrasion.** - L Fang, XL Kong, JY Su, QD Zhou *(Dept of Mech Eng, Xian Jiaotong Univ, 710049 Xian, China)*. Wear 162-164(PART B) 782-7789 (13 Apr 1993).

The movement patterns of abrasive particles in three-body abrasion are very important to the wear of materials. In the present paper, the movement of a single abrasive particle could be observed in detail through new wear apparatus for three-body abrasion. The new apparatus was used to carry out short-travel wear testing for a single particle sandwiched between two metal surfaces and to measure the frictional force at the same time. A number of experiments showed that there were mainly two kinds of movement patterns of the particles, ie, sliding and rolling. Based on the experimental results, a criterion was proposed for the movement patterns of abrasive particles. The criterion matched with the experiments quite well.

9A514. **Reactions during preparation and sliding of sintered Fe-Mo-S wear-resistant materials.** - Zhang Guowei, Ouyang Jinlin, Meng Xiukun, Ma Li, Qi Shangkui, Zhang Fu *(Lab of Solid Lubrication, Lanzhou Inst of Chem Phys, Chinese Acad of Sci, Gansu, 730 000 Lanzhou, China)*. Wear 162-164(PART A) 450-457 (13 Apr 1993).

Using quick hot-press sintering, Fe-Mo-S materials were prepared with the properties of low wear rates (eg, as an 8S28Mo64Fe pin sliding against a 45 steel disk in air, the specific wear of the pin is 8.6×10^{-14} M^3 N^{-1} M^{-1}, while that of the disk is 1.21×10^{-14} M^3 N^{-1} M^{-1}). Using X-ray diffraction, X-ray photoelectron spectroscopy, Auger electron spectroscopy, and differential thermal analysis, the reactions related to Fe-Mo-S mateials were studied. Thermodynamic analysis of the reactions to form sulphides was performed. It was found that a non-stoichiometric Mo-S compared with a crystal structure similar to hexagonal MoS_2 and $Fe_{1.3}Mo_6S_8$ formed in the materials during preparation. Grey-black films formed on the wear tracks of the steel disks during sliding against Fe-Mo-S pins in air. Oxides are the major constituents and sulphides the minor constituents of the films. Comapring Fe-Mo-S materials and the alloys without sulphur (eg, 45 steel or Fe-Mo alloy) indicates that the low wear rates of the materials are attributed to the formation of the films, and a catalytic effect of sulphides of the oxidation is a necessary condition in forming the films. The mechanism of improving the tribological properties by catalytic reaction films has been used successfully to develop Ni-Mo-S high temperature, self-lubricating materials.

9A515. Selected thermoplastic bearing materials for use at elevated temperatures. - AM Hager, K Friedrich *(Inst Verbundwerkstoffe, Univ Kaiserslautern, 6750 Kaiserslautern, Germany)*, R Junghans *(Wissenschaftsbereich Tribstech, Tech Univ, O-9010 Chemnitz, Germany)*. Wear **162-164**(PART B) 649-655 (13 Apr 1993).

Various polyaryletherketone-based composites were investigated with regard to their high temperature dry-sliding behavior. In the range between room temperature and 220° C, all grade with a polytetrafluoroethylene (PTFE) content of 10 - 15 wt% exhibited a friction behavior that is very similar to that of neat PTFE. Studies of the wear-pv relationship of some of the grades showed that fibre content of 30 wt% are found to stabilize the specific wear, up to pv products of 16 MPa m s^{-1}.

9A516. Study of some active wear mechanisms in a titanium-based cermet when machining steels. - H Thoors, H Chandrasekaran, P Olund *(Swedish Inst for Metals Res, Drottning Kristinas Vag 48, S-11428 Stockholm, Sweden)*. Wear **162-164**(PART A) 1-11 (13 Apr 1993).

This paper discusses the results from a study devoted to the understanding of the wear behavior of a Ti(CN)-based cermet tool material. Variation in the qualitative and quantitative nature of wear of this tool material in longitudinal and turning was effected by the choice of a steel type and cutting conditions. The three work materials (two quenched and tempered steels and one ball-bearing steel) have different microstructures and inclusion contents. The study revealed that the presence of conventional flank wear, varying degrees of crater wear and negligible notch wear, while plastic deformation of the cutting edge appears to be the life-limiting factor. Detailed investigation of the active surfaces of the tool revealed abrasion from hard phases and adhesion (micro and macro) to be dominant in the case of the quenched and tempered steel machining, while with ball-bearing steel microchipping, plastic deformation and cracking ply play an important role. Metallurgical interaction was also observed between the constituents of the tool material and the chip material or reaction products of inclusions, resulting in the embrittlement of the tool material and facilitating rapid wear. The observerd differences in the micromechanisms of wear were also in conformity with the variations in the evaluated tool-chip contact stress.

9A517. Study on reduction in wear due to magnetization. - K Kumagai *(Akita Univ, 1-1 Tegata Gakuen-machi, Akita 010, Japan)*, Koshi Suzuki *(Tohoku Elec Power, 3-7-1 Ichiban-cho Aoba-ku, Sendai 980, Japan)*, Osamu Kamiya *(Akita Univ, 1-1 Tegata Gakuen-machi, Akita 010, Japan)*. Wear **162-164**(PART A) 196-201 (13 Apr 1993).

Operating the pin-rotor type wear test using the ferromagnetic materials, an Ni pin and steel rotor combination, even a weak magnetization of the pin decreased the wear. In order to probe that phenomenon, the grain size distributions of wear particles have been analyzed by means of the computer-aided image analyzer. The experimental results indicate the relationship that wear rate reduces with the fining down of the wear particles. It is concluded that magnetization accelerated the oxidation at rubbing surfaces and wear particles. Oxidation prevents the rubbing surfaces from mutual material transfer and the consequent pile up to form larger particles, therefore the wear particles remain fine. The cause of wear reduction was the fining down of wear particles by accelerated oxidation in magnetic effect, and those oxidized as fine-wear-particles existed between rubbing surfaces and were attracted by a magnetic force, which acted as a lubricant and reduced the wear. The observation that the magnetization accelerated oxidiation was verified by the fact that the oxidation reaction of a magnetized steel piece was more severe than one without magnetization. Moreover, the oxygen density at the surface of ferromagnetic materials in air was a little increased by magnetization, which also contributed to the acceleration of oxidation at a rubbing surface.

9A518. Transmission electron microscopy study of wear of magnesia partially stabilized zirconia. - WM Rainforth *(Dept of Eng Mat, Univ of Sheffield, PO Box 600 Sir Robert Hadfield Build, Mappin St, Sheffield S1 4DU, UK)* and R Stevens *(Sch of Mat, Univ of Leeds, Leeds LS2 9JT, UK)*. Wear **162-164**(PART A) 322-331 (13 Apr 1993).

The role which the stress assisted transformations of the tetragonal to monoclinic phase plays in the wear of zirconia ceramics remains unclear. This paper discusses the use of detailed transmission electron microscopy of the worn surface to assess the role of transformation in the sliding wear of magnesia partially stabilized zirconia against a steel counterface. Three mechanisms were identified for the wear of the ceramic. Firstly, transformation occurred cooperatively in bands along the [100] directions which led to extensive microcrack formation. Coalescence of the microcracks promoted preferential wear from the bands. Thus, transformation of the tetragonal to the monoclinic phase has led to an increased wear rate. Secondly, clear experimental evidence was found of a tribochemical wear mechanism of the zirconia. In such areas, the transformation of the tetragonal to monoclinic phase played a minor role and was only found to a depth of 200 nm. Finally, abrasive grooving was shown to cause extensive plastic deformation. Interestingly, no evidence of fracture or transformation was found at the abrasive grooves. Thus, this work has demonstrated that under these particular sliding conditions, transformation toughening can have a detrimental as well as a beneficial effect on the tribological properties of zirconia.

9A519. Tribological behavior of blends in polyether ether ketone and polyether imide. - Jong Hyun Yoo and NS Eiss Jr *(VPI)*. Wear **162-164**(PART A) 418-425 (13 Apr 1993).

In this study polyether ether ketone (PEEK) and polyether imide (PEI) were blended to raise the glass transition temperature (T_g) above that of PEEK while retaining the low-wear characteristics of PEEK. The friction and wear of injection-molded blends were measured in dry sliding by a stainless steel ball sliding on a polymer blend disk. The test variables were normal load, sliding speed and the percentage of crystallinity of the PEEK component of the blend. The wear mechanism of the pure PEEK was plowing with no net loss of material. This mechanism persisted for blends up to 70% PEEK-30% PEI (70/30) for which the T_g was raised to 15 °C above that of PEEK. For 50/50 and pure PEI the wear mechanism was changed to that of fatigue, as evidenced by the generation of small particles after a period of sliding with no wear. The wear rates were higher for the PEI-dominated blends: as much as 40 times larger at the highest load and sliding speed. As the percentage of PEEK in the blends was reduced, the crystallinity of the PEEK component was also reduced; for the 50/50 blend the crystallinity was zero. Annealing the injection-molded samples raised the crystallinity of the PEEK in the blends to that of the pure PEEK injection-molded sample. In general, the increase in crystallinity caused by annealing reduced the wear rate of the blends. The coefficient of friction for the blends with low wear was below 0.15, while it was 0.2 to 0.3 for the blends which had the higher wear rates. For these latter blends, the friction coefficient was low until the wear track formed, at which time it increased to the higher level.

9A520. Tribological stability of metallic materials at elevated temperatures. - H Berns *(Inst Werkstoffe, Lehrstuhl Werkstofftech, Ruhr Univ, Postfach 102148, Bochum 1, Germany)* and A Fischer *(NU-TECH, Ilsahl 5, 2350 Neumunster, Germany)*. Wear **162-164**(PART A) 441-449 (13 Apr 1993).

The sliding abrasion wear rates of metallic materials against flint, measured between 25 and 1050 °C under an argon atmosphere, are shown and discussed. Above 550 °C, wear is governed mainly by the properties of the metal matrix and can be correlated with its resistance to plastic deformation. Thus, the hot hardness and work hardening capability affect the wear rate under stationary conditions. Instabilities occur when dynamic recrystallization appears within the metal matrix, bringing about a total loss of its work hardening capability. Hard phases have only a small effect on the tribological behavior under stationary and non-stationary conditions.

9A521. Wear and film formation in the presence of methanol and formic acid. - L Mattsson, B Olsson *(Dept of Phys, Chalmers Univ of Tech, S-412 96 Goteborg, Sweden)*, PH Nilsson, G Wirmark *(Tech Dev, Dept 06170, AB Volvo, S-412 88 Goteborg, Sweden)*. Wear **165**(1) 75-83 (May 1993).

Increased wear in methanol fuelled engines has been observed, especially at low operating temperatures. Combustion intermediates, for instance, formic acid, are believed to promote wear in the piston ring-cylinder liner assembly. In this study, tribological effects of methanol and formic acid were investigated in a model system. The study was focused on the running-in process under normal conditions and how the running-in was affected by the presence of methanol and formic acid in oils with different lubricant additives. The study showed that a tribosystem with the anti-wear additive ZDDP (zinc dialkyldithiophosphate) had the ability to redistribute the surface layer. After an initial phase of large wear, this redistribution process resulted in a surface film with excellent wear resistance. Adding methanol and formic acid contaminants to this lubricant disturbed the film formation process and a higher steady state wear was observed. A more fully formulated lubricant, with detergent and dispersant, could better withstand these contaminants even though a rise in the steady state wear rate was found in experiments performed at room temperature.

9A522. Wear and scratch hardness of 304 stainless steel investigated with a single scratch test. - TA Adler and RP Walters *(US Dept of the Interior, Bureau of Mines, 1450 Queen Ave SW, Albany OR 97321-2198)*. Wear **162-164**(PART B) 713-720 (13 Apr 1993).

The wear and scratch hardness of 304 stainless steel was investigated with a scratch test developed by the US Bureau of Mines. The scratch was produced by a diamond indenter with a 0.2-mm spherical tip in air and in a corrosive environment. Scratch hardness was calculated from the width of the scratch and was correlated with Vickers hardness. Wear was measured by integrating the area between the profile of the scratch and the original surface. At low loads wear occurs in a rubbing mode. At higher loads wear debris was formed. The transition from rubbing wear to wear with a continuous formation of debris occurred at a critical value of the attack angle. A relationship between the attack angle, the radius of the tip of the scratcher, and the load on the scratcher, and the hardness of the material is presented. Stainless steel was scratched at an anodic potential (with a passive film on the surface) and at a cathodic potential (with no passive film on the surface). The presence or absence of the passive film had no effect on the scratch hardness or wear for either the rubbing mode or the mode of wear with debris. The interface shear strength was not affected by the change in potential.

9A523. **Wear deformation of ordered Fe-Al intermetallic alloys.** - HE Maupin, RD Wilson *(US Bureau of Mines, Albany Res Center, Albany OR 97321-2198)*, JA Hawk *(US Bureau of Mines, Albany Res Center, Albany OR 97321-2198)*. Wear 162-164(PART A) 432-440 (13 Apr 1993).

The Bureau of Mines conducted abrasive wear research in DO_3 ordered and disordered Fe_3Al intermetallics. The effect of abrasion on these alloys were studied through microscopy, X-ray diffraction and hardness measurements. The region near the wear surface undergoes dynamic recrystallization, ie, the original microstructural morphology of micron-size grains is replaced by one with nanosize grains. Abrasions of the Fe_3Al alloys also results in a loss of the DO_3 ordering in the wear surface region. The bulk temperature rise of the specimen during abrasion was approximately 28 °C which is insufficient to cause recrystallization in these alloys. Therefore, the flash temperature due to interface frictional heating is considered more important than the bulk temperature when considering dynamic recrystallization as the transformation mechanism in the near wear surface region.

9A524. **Wear mechanisms of ultrahard, nonmetallic cutting materials.** - W Konig and A Neises *(Lehrstuhl Tech Fertigungsverfahren, WZL RWTH, Steinbachstr 53 B, W-5100 Aachen, Germany)*. Wear 162-164(PART A) 12-21 (13 Apr 1993).

Basic wear mechanisms of polycrystalline diamond (PCD) and polycrystalline cubic boron nitride (PCBN) composite cutting materials were examined. The investigation included the planning and realization of model wear test systems closely connected to and including the main tribological parameters of the real cutting process during turning of metals. Considerable attention has been given to the chemical composition and the microstructure of the cutting tool materials. A series of diffusion and abrasion model tests were carried out to reveal the effect of the diffusion mechanism on the abrasion resistance of PCD and PCBN during cutting processes. The forms of wear which occurred during the model tests were compared with the wear state produced by means of real turning tests and found to be useful in explaining the wear behavior of PCB and PCBN during cutting operations. The diminution of the abrasion resistance of the cutting material owing to graphitization seems to be the dominant wear mechanism when turning a titanium alloy at elevated cutting speed with PCD composites. However, the wear rate obviously is dependent on the grain size of the diamond crystals. In the case of PCBN, the chemical composition of the binder and its percentage in the composite is important for thermal stability, as it is required for cutting tools. PCBN samples, exposed to the diffusion tests with steel as the workpiece material at elevated temperatures up to 950° C suffered significant changes in the structure of the binder. This seems to result in a reduction of the bulk material resistance to abrasive wear. Scanning electron microcopy and energy-dispersive spectroscopy investigation of inserts used in real cutting tests turning a bearing steel helped to ascertain the practical relevance of the results achieved with the model test series.

9A525. **Wear reduction systems for coal-fueled diesel engines I. The basics of powder lubrication.** - H Heshmat *(Mech Tech, 968 Albany-Shaker Rd, Latham NY 12110)*. Wear 162-164(PART A) 508-517 (13 Apr 1993).

The objective of this investigation is to resolve the problem of severe wear occurring in systems using coal-water particulates as fuels or as a process material. The approach discussed herein consists of replacing conventional oil lubrication with a powder lubrication system that uses the process particles, either alone or in combination with another powder. Unlike previous work in this field, this approach is based on the postulate of the quasi-hydrodynamic nature of powder lubrication. This postulate is deduced from past observation and present verification that there are a number of basic features of powder flow in narrow interfaces that have the characteristic behavior of fluid film lubrication. In addition to corroborating the basic mechanism of powder lubrication, the conceptual and experimental work performed in this investigation provide guidelines for selection of the proper geometries, materials, and powders suitable for this tribological process. The present investigation describes the fundamentals of quasi-hydrodynamic powder lubrication and defines the rationale underlying the design of the test facility. A follow-up paper dealing with the performance and the results of the experimental investigation presents conclusions reached regarding design requirements as well as the formulation of a proper model of quasi-hydrodynamic powder lubrication.

9A526. **Wear-corrosion-resistant materials for mechanical components in harsh environments.** - PL Ko *(Trib and Mech Lab, NRC, 3650 Wesbrook Mall, Vancouver BC, V6S 2L2, Canada)*, A Wozniewski *(Project and Tech Services, Esso Resources Canada, 237 4th Ave SW, Calgary Alta, T2P 0A6, Canada)*, PA Zhou *(Wear Res Group, CAAMS, 1 Beishatan Deshengmen Wai, Beijing, China)*. Wear 162-164(PART B) 721-732 (13 Apr 1993).

In pumping the deviated and slant oil wells, many commonly used materials are readily attacked by the combined effect of mechanical wear and the harsh environment at the bottom hole. Three groups of new materials that include ceramics, alloys and hard coatings were evaluated for the downhole application. Two sets of tests, which involved scaling and corrosion for the first, and wear for the second, were carried out in parallel. The wear tests were further divided into reciprocating sliding and impact-fretting, in dry and in 2% sand slurry conditions. The investigation identified the wear mechanism involved. The test results showed that a steel alloy with a titanium carbide composite in a martensitic matrix, and both nitrided and chrome-plated carbon steels could provide good wear resistance for both dry and slurry conditions.

9A527. **Load ratings of spherical plain bearings.** - Yang Xian Qi and Jiang Shao Feng *(Luoyang Bearing Res Inst, Jiling Rd, Luoyang 471039 Henan, China)*. Wear 165(1) 35-39 (May 1993).

Up to now, the load ratings of spherical plain bearings have been calculated using a nominal contact pressure and a projected bearing surface area. This type of method does not show real capacity of the bearings. In this paper, the steel-steel spherical plan bearings under load were studied by the FEM. The contact stress distribution in the bearing was determined. A relationship between maximum contact pressure and deformation was found. Based on these results, new definitions for the bearing load ratings are recommended, and general formulae to calculate the ratings are determined.

9A528. **Rolling-contact-fatigue wear characteristics of diamond-like hydrocarbon coatings on steels.** - Ronghua Wei, PJ Wilbur *(Colorado State Univ, Ft Collins CO 80523)*, MJ Liston *(NTN Tech Center, Ann Arbor MI 48108)*, G Lux *(Charles Evans and Assoc, Redwood City CA 94063)*. Wear 162-164(PART A) 558-568 (13 Apr 1993).

Adherent diamond-like hydrocarbon (DLHC) coatings were applied on AISI M-50, 52100, 4118 and 440C steel rods by using an approximately 0.2 μm amorphous-silicon-hydrocarbon (a-SiHC) bonding layer between the DLHC and the steel. Both the a-SiHC and DLHC coatings were applied using a single, broad-beam ion source. The rods were subjected to rolling-contact-fatigue (RCF) testing under high cyclic Hertzian stress (5.5 GPa), low lubricant-film-thickness parameter (lambda = 0.7) conditions. Order of magnitude increase in the fatigue lives of all four rod materials were observed. Systematic RCF tests coupled with microscopic examination after various test intervals show that micro-polishing by hard DLHC coating fragments may play an important role in prolonging fatigue lives. Raman spectroscopic measurements suggest that cyclic stressing of the DLHC layer causes it to transform from what was initially amorphous carbon into the more lubricous and stable graphite phase.

292F. THERMOMECHANICAL EFFECTS

9A529. **Effect of temperature on the wear of unfilled and filled liquid crystal polymers.** - Yoshitaka Uchiyama, Yutaka Uezi *(Fac of Tech, Kanazawa Univ, Ishikawa 920, Japan)*, Atsushi Kudo, Takeshi Kimura *(Starlite, Tsurumi-ku, Osaka 538, Japan)*. Wear 162-164(PART B) 656-661 (13 Apr 1993).

The friction and wear properties of unfilled and filled liquid crystal polymers (LCPs) (polyester derived from terephthalic acid, P-hydroxybenzoic acid and P,P-biphenol) were examined in the longitudinal (L), transverse (T) and normal (N) directions of the polymer molecules. When rubbed against an abrasive paper, the wear rate of the unfilled LCP depended on the sliding direction. The maximum wear rates were observed in the T direction, the minimum wear rates in the N direction and medium wear rates in the L direction. The wear rates steeply increased above 100° C. In the LCPs filled with graphite only, or graphite in combination with polytetrafluoroethylene (PTFE), the orientation was minimized but there was no minimizing effect of the wear rates. When rubbed against a chromium-plated disk at room temperature, the wear rates of the unfilled LCP were of the order of 10^{-7} mm^3 N^{-1} m^{-1}. The wear rates steeply increased, above room temperature and reached a figure of the order of 10^{-4} mm^3 N^{-1} at 100° C. The filled LCPs in the N direction showed very low rates of the order of 10^{-8} mm^3 N^{-1} m^{-1} at room temperature. However, the wear rates in the L and T directions were of the order of 10^{-7} mm^3 N^{-1} at room temperature. The wear rates for the graphite-filled LCP steeply increase beyond room temperature and maximum wear rates of the order of 10^{-5} mm^3 N^{-1} at room temperature. However, the wear rates in the L and T directions were of the order of 10^{-7} mm^3 N^{-1} m^{-1} occurred at 120° C in the temperature range examined. At 160° C, the wear rates were much lower than those at 120° C. The wear rates for the LCP filled with graphite in combination with PTFE also steeply increased above room temperature. However, the wear rates at temperatures from 60 to 160° C were lower than those of the graphite-filled LCP. The friction coefficients for the filled LCPs were relatively high at room temperature but tended to decrease above 60° C. The filled graphite with PTFE had obvious reducing effects on the wear rates at elevated temperaures.

292H. SURFACE EFFECTS, TOPOGRAPHY, COATINGS

9A530. **Abrasion, erosion and scuffing resistance of carbide and oxide ceramic thermal sprayed coatings for different applications.** - G Barbezat, AR Nicoll *(Plasma-Tech, Rigackerstr 16, 5610 Wohlen, Switzerland)*, A Sickinger *(Electro-Plasma, Irvine CA)*. Wear 162-164(PART A) 529-537 (13 Apr 1993).

In the area of antiwear coatings, carbide-containing coatings (Cr_3C_2-NiCr, WC-Co, WC-Ni etc). and oxide ceramic coatings (Al_2O_3, Cr_2O_3 etc) are applied using different thermal spray processes in the form of individual layers. In many industries these coatings have become technically significant on components where wear and friction can cause critical damage in the form of abrasion, erosion and scuffing together with corrosion. Carbide-containing and ceramic coatings have been produced with different thermal spray processes (atmospheric plasma spraying, vacuum plasma spraying, high velocity flame spraying and detonation gun spraying) for the determination of abrasive, adhesive and erosive wear resistance. Two types of abrasion tests, namely an adhesion wear test and an erosion test in water at a high velcoity (up to 170 m s^{-1}), were used for the characterization of wear resistance under different conditions. The coatings were also characterized with regard to microstrucutre, composition and fracture toughness. The influence of the thermal spraying process parameters on the microstructure is presented together with the influence of the microstructure on the behavior of the coatings under simulated service conditions.

9A531. **Calculation of flat surface wearing by spherical indenter under random contact.** - IA Soldatenkov *(Inst for Prob, Russian Acad of Sci, Moscow, Russia)*. Sov J Friction Wear 13(6) 8-14 (1992).

The analysis is presented for a flat surface wearing by a sliding spherical indenter. The indenter moves along the surface with random deviations of its center from the given trajectory. Load is varied randomly. A joint probability density of the center deviations from the trajectory and the load are assumed to to be given. Averaging the dependence of wear rate on the contact pressure by its parameters we derive an equation of wear kinetics in terms of averages. The case of low wear is considered and a solution of wear kinetics equation is obtained in explicit form. In general case, the equation is solved numerically.

9A532. **Experimental study of self-welding of materials in high temperature liquid sodium.** - S Chander, C Meikandamurthy, RD Kale *(Dept of Atomic Energy, Indira Gandhi Centre for Atomic Res, Kalpakkam, Tamil Nadu 603 102, India)*, R Krishnamurthy *(Indian IT, Madras, India)*. Wear 162-164(PART A) 458-465 (13 Apr 1993).

The study self-welding of materials in high temperature liquid sodium, an experimental set-up consisting of a sodium-circulating loop, a test vessel, a loading mechanism for material specimens and instrumentation were designed, installed, and operated at IGCAR, Kalpakkam. Combinations of austenitic stainless steel, hard chrome plating and Stellite-6 with the surface finish of the contact surfaces typical of that of components in fast breeder reactors were exposed to liquid sodium at 530 °C under load intensities of 10 and 40 MPa for 500 and 1000 h. The paper discusses the experimental set-up installed and the results of self-welding of these material combinations. The role of surface finish on self-welding tendency is also briefly discussed.

9A533. **Failure of poly (ether ether ketone) in high speed contacts.** - BJ Briscoe, BH Stuart, S Sebastian *(Dept of Chem Eng and Chem Tech, Imperial Col, London SW7 2BY, UK)*, PJ Tweedale *(Natl Centre for Trib, AEA Tech, Risley, Warrington WA3 6AT, UK)*. Wear 162-164(PART A) 407-417 (13 Apr 1993).

The paper describes an experimental study, with an associated analysis incorporating supplementary data, of the anti-boundary lubricating action of an alkane-aliphatic carboxylic acid lubricant system in a poly (ether ether ketone)-mild steel contact. The experiments involve progressively increasing the load in a contact formed between a polymer plate and a rotating steel shaft and estimating the frictional work dissipated. Scuffing is identified when a rapid increase in frictional work is noted at a characteristic normal load. It is shown that the additive induces premature scuffing. Subsidiary data is provided using Raman spectroscopy and hardness probes, and confirms that certain additives such as decanoic acid and dodecylamine will induce surface plasticization in poly (ether ether ketone). The trends in the frictional data have been interpreted using the adhesive model of friction in conjunction with temperature-dependent interfacial rheology and bulk mechanical property data. It is proposed that the scuffing is induced prematurely as a consequence of excessive additive-induced subsurface plasticization. Restricted surface plasticization in this system provides an enhanced self-lubricating capacity.

9A534. **Friction and wear of heterogeneous coating under boundary lubrication Part 2. Sliding parts with hard coatings.** - YP Serdobintsev and SI Sharavin *(Machine-Tool Inst, Moscow, Russia)*. Sov J Friction Wear 13(6) 25-30 (1992).

A mathematical model is developed which takes into account a nature of boundary lubrication of rough surfaces and physicochemical adsorption in tribocontact. A portion of load supported by a lubricant film adsorbed on asperities is determined. Analytical relationships for friction coefficient depending on roughness parameters and lubricant molecule size are derived, provided that low friction occurs in the situation of inadequate or irregular lubrication. The relationships may be used to develop technological principles of surface formation.

9A535. **A general model for sliding wear in electrical contacts.** - RG Bayer *(4609 Marshall Dr W, Vestal NY 13850)*. Wear 162-164(PART B) 913-918 (13 Apr 1993).

A variety of models, generally either based on abrasive, adhesive or surface fatigue wear concepts, have been used with some success in describing the sliding wear of electrical contacts. There are also empirical observations which support the individual or simultaneous occurrence of these various mechanisms in wear of such contacts. In addition to these mechanisms, which may be referred to as surface wear mechanisms, a subsurface mechanism has also been identified in recent studies of the wear of a card-edged connector system. This mechanism is associated with the plastic deformation of the substrate and can coexist with all, or any, of the surface mechanisms. In this paper, a model is developed for this subsurface mechanism and combined with models for the surface mechanism to provide a general model for the sliding wear of contact systems. The relationships, which result from these models, are shown to agree with observed behavior in the case of a card-edge contact system. It is suggested that the method of combining the effects of several simultaneous wear mechanisms may be applicable to more general wear situations.

9A536. **The generation of worn surfaces by the repeated interaction of parallel grooves.** - Y Xie and JA Williams *(Eng Dept, Cambridge Univ, Trumpington St, Cambridge CB2 1PZ, UK)*. Wear 162-164(PART B) 864-872 (13 Apr 1993).

Whenever loaded surfaces are in relative tangential motion, hard asperities on one of them, or perhaps hard particles entrained between them, may be dragged across the surface and give rise to the surface degradation and wear. Damage caused by individual asperity or particle interactions builds up and the profiles of the worn surface are the result of many superimposed wear events. The practical, quantitative prediction of wear rates, and thus of component lives, depends on having both a satisfactory understanding of individual interactions and a suitable procedure for combining these under circumstances when subsequent contacts are made on a surface whose topography and material properties may have been much changed from their initial states. Experiments have been carried out on a novel rig which provides very precise control over the position of a representative asperity and the worn surface it generates, and in this paper we describe a number of tests in which the wear arising from the repeated interaction of parallel wear tracks has been investigated. Three different regimes of wear debris production have been identified, namely micromachining, surface ductile fracture and subsurface fatigue, and the wear rates associated with each measured. An analytical model is being developed to produce a wear map appropriate to the abrasion of a metal surface. On the basis of such a map it is possible to identify the predominant wear mechanisms and predict the wear rates of real wearing surfaces.

9A537. **Grain size effect on abrasive wear mechanisms in alumina ceramics.** - AK Mukhopadhyay and Yiu-Wing Mai *(Center for Adv Mat Tech, Dept of Mech Eng, Univ of Sydney, Sydney, NSW 2006, Australia)*. Wear 162-164(PART A) 258-268 (13 Apr 1993).

Despite the wealth of literature on the friction and wear behavior of ceramics, their wear mechanisms are far from well understood. The need to develop a precise understanding of the wear mechanisms is imperative for the development of better wear-resistant ceramics. Particularly in alumina ceramics, grain coarsening has been found to improve the crack growth resistance characteristics. However, if the same would be beneficial for wear resistant applications has not been systematically investigated. To evaluate if there exists a strong grain size effect on abrasive wear mechanisms in ceramics, a series of tests were conducted under severe sliding contact conditions in an alumina ceramic. Unlubricated sliding wear tests were performed on alumina of three different grain sizes, 0.7, 5, and 25 μm, using a blunt conical diamond indenter of about 100-μm tip radius as the slider at room temperature under normal loads of 8-40 N and sliding distances up to 120 mm. The abrasive wear behavior was characterized by measuring the wear volume and wear rate as a function of normal load and sliding distance. In addition, the friction behavior was also studied simultaneously as a function of these two variables. The wear damage mechanisms were examined using both optical and electron microscopy as well as energy dispersive X-ray spectroscopy. For a given grain size and sliding distance, the width and depth of the worn track (hence wear volume) and the frictional force all increased with normal load. These observations were more markedly displayed in the coarse-grained than in the fine-grained alumina. In the 0.7-μm fine-grained alumina, the wear process appeared to be mainly controlled by plastic deformation especially at low loads (eg, < 10 N). At higher loads, however, both plastic deformation and grain boundary fracture processes seemed to be involved. In the 5-μm and 25-μm coarse-grained aluminas, the predominant material removal process was controlled by both intergranular and transgranular fractures.

9A538. High speed sliding of Al_2O_3 pins against an En-24 steel disc. - A Ravikiran and BN Pramila Bai *(Dept of Mech Eng, Indian Inst of Sci, Bangalore 560 012, India)*. Wear **162-164**(PART A) 296-304 (13 Apr 1993).

During the high speed sliding of an 87% Al_2O_3 pin against steel, surface chemical interactions lead to the formation of a surface layer. The coefficient of friction is affected by the surface layer and under certain conditions starts to oscillate between two levels, while under other conditions it has a steady single value. The factors which decide the nature of the friction appear to be not only the speed and pressure, but also the relative contact area (the ratio of the pin surface area to the disc track area). The following empirical relation has been suggested to identify the occurrence of oscillating friction: $N = S^2 P^{0.75} A^{0.5}$ where S is the speed (m s^{-1}), P the pressure (MPa) and A on the ratio of the contact area of the pin to the disc track area. For N < 19 the expected behavior is that of R3, for 19 < N < 21 the response can be of either regions and for N > 21 R4 behavior occurs.

9A539. In situ wear experiments in the scanning Auger spectrometer. - WA Glaeser *(Battelle Columbus Lab, 505 King Ave, Columbus OH 43201)*, D Baer, M Engelhardk *(Battelle Pacific NW Lab, Richard WA)*. Wear **162-164**(PART A) 132-138 (13 Apr 1993).

Sliding contact experiments have been conducted in the chamber of a high resolution Auger spectrometer. A pin-on-disk wear tester has been used. The Auger surface analysis capability has been used to characterize the disk surface before and after sliding in the chamber. The effect of surface chemistry on metal transfer during sliding contact and on boundary lubrication of zinc dialkyldithiophosphate (ZDDP) has been investigated. Hydrocarbon "contamination" from fabrication of the steel disk caused an induction period during sliding in which friction was low and no transfer occurred. The contaminant was eventually worn off but transfer did not take place until the native oxide film was substantially removed also. The oxide film on the steel surface plays an essential role in the boundary lubrication process of ZDDP. A resulting iron sulfide film effectively inhibits adhesive wear. This film was found only in the wear tracks, showing that the contact stress conditions trigger the boundary film reactions.

9A540. Material response to 2D scratching by wedges. - SV Kailas and SK Biswas *(Dept of Mech Eng, Indian Inst of Sci, Bangalore 560 012, India)*. Wear **162-164**(PART A) 110-118 (13 Apr 1993).

Flats of lead, aluminium copper and titanium were scratched by normally loaded wedges of attack angles varying from 15° to 45° under dry and lubricated conditions and sliding speeds of 1.66×10^{-5} m s^{-1} to 1.66×10^{-3} m s^{-1}. Scratching of lead showed a cutting mode at attack angles of more than 15°. As the scratched material was changed from lead to aluminium, copper and titanium, in that order, the propensity of cutting at these attack angles and the coefficient of friction decreased while the surface damage increased. On the basis of uniaxial compression data obtained at the strain rates which are of the same order as those experienced in scratching, it is inferred that the observed trends in scratching can be related qualitatively to the microstructural stability of these materials at these strains and strain rates.

9A541. Microscopic deformations in KCl single crystals by indentation and scratching with steel ball and pyramidal indenters. - S Kobayashi, T Okui *(Dept of Mech Eng, Doshisha Univ, Kyoto, Japan)*, S Miura *(Dept of Eng Sci, Kyoto Univ, Kyoto, Japan)*. Wear **162-164**(PART A) 92-101 (13 Apr 1993).

The subject of sliding friction is of great technological importance and has been studied extensively on an engineering basis. However, many of the underlying microscopic factors that control friction and wear remain obscure. The present study is part of an effort to relate sliding deformation to the crystal structures of the contacting surfaces. The methods used are to indent a steel ball or a diamond quadrangular pyramid and to scratch these indenters on the accurately finished {100} crystal face of KCl single crystals. Two scratch directions, <100> and <110>, were chosen in the scratch tests. The study was made to examine the appearance of the dislocation structure and the mechanism of microscopic deformation and to elucidate the topographical deformations and strain hardening due to indentations and scratches. The width of the scratched track, the distribution pattern of etch pits and the dislocation density around the indent or track were examined in detail. The width of the scratched track is wider in the <100> scratch than in the <110> scratch, whereas the plastic deformation range is greater in the <110> scratch. The plastic deformation produced by scratching is formed with a continuous series of deformations due to indentation. Dislocation motions with the slip system of $\{110\}_{90}\langle 110\rangle$ are mainly observed on the scratched surface, while $\{110\}_{45}\langle 110\rangle$ dislocations are observed on the cross-section perpendicular to the scratched surface.

9A542. Microstructures and tribological characteristics of electron-beam co-deposited Ag-Mo thin film coating. - SC Tung and YT Cheng *(Res Dept, General Motors Tech Center, 30500 Mound Rd, Warren MI 48090-9055)*. Wear **162-164**(PART B) 763-772 (13 Apr 1993).

The tribological characteristics of surface coatings on a metal substrate are affected by several factors including the microstructure of the coatings, the iterations between the coatings and metal substrate, and the mechanical properties of the substrate. Techniques are available to fabricate different types of metastable film structure to aid in unraveling their influences on tribological behavior. In this study, we investigated the friction and wear properties of thin film coatings consisting of Ag and Mo which were co-deposited by electron-beam evaporation in an ultra high vacuum. Ag and Mo were chosen because the metastable structures, such as extended solid solutions or nano-crystalline microstructures, can be formed by co-deposition, although alloys of the two metals cannot exist in thermodynamic equilibrium. Using a Cameron-Plint high frequency pin-on-plate friction machine, test results show that a co-deposited film having an optimum composite ratio of Ag:MO = 69:31 (denoted by $Ag_{69}Mo_{31}$, and having a thickness of 150 nm, has the lowest friction (20% - 25% reduction) and improved anti-wear properties compared with coatings of other compositions. A bare steel plate after dry sliding of 30 h against a steel sphere shows substantial wear and plastic deformation. In contrast, the same plate with a thin film coating of $Ag_{69}Mo_{31}$ shows a much smoother surface. The improved tribological characteristics may be attributed to the greater wear-resistant and shearing capabilities of nano-crystalline binary mixtures on iron surfaces.

9A543. Microwear processes of polymer surfaces. - R Kaneko *(NTT Interdisciplinary Res Lab, Midori-cho Musashino-shi, Tokyo 180, Japan)* and E Hamada *(Dev Section, Operation Headquarters 1, 1 Taiyo Yuden Co, Yawatabara-machi, Takasaki-shi, Gunma 370, Japan)*. Wear **162-164**(PART A) 370-377 (13 Apr 1993).

At atomic force microscope was used to scan-scratch polycarbonate (PC), polymethyl-methacrylate (PMMA), and epoxy (EP) surfaces. A diamond tip with a radius of 0.1 μm was used for scratching and for profile measurements. The sample surfaces were scan-scratched with a load of 500 nN and three different feeds (50, 25, and 12.5 nm). The surfaces were also scan-scratched repeatedly with a load of 200 nN and a feed of 10 nm. The microwear process of PC, PMMA, and EP were clarified from these experiments. (1) The microwear process of PC has three steps: the scan-scratched surface forms a plateau-like upheaval and no wear particles are produced (first step); the surface distorts to make projections and again no wear particles are produced (second step); and the surface is worn down and wear particles are produced (final step). (2) The microwear process of PMMA also has three steps, which are almost the same as those for PC. However, the deformation proceeds rapidly to destruction. (3) The microwear process of EP only has the final step. Wear particles are produced from the start. (4) The order of deformation is EP < PMMA < PC. However, the order of wear is EP < PC < PMMA. This suggests that the deformation of a material with a high elongation rate is large, but that the deformation rate is not related to the wear rate.

9A544. Plastic deformation and damage accumulation below the worn surfaces. - AT Alpas, H Hu, J Zhang *(Eng Mat Group, Univ of Windsor, ON, N9B 3P4, Canada)*. Wear **162-164**(PART A) 188-195 (13 Apr 1993).

Delamination of material layers adjacent to the worn surfaces is a commonly observed form of wear in unlubricated or poorly lubricated surfaces. In ductile materials, the delamination process usually involves large plastic deformation and subsurface damage. In this study, metallographic techniques have been used to determine the extent of plastic deformation and strain localization events during the sliding wear of annealed OFHC copper samples. Tests were performed using a block-on-ring type wear machine under constant load and constant velocity conditions. Subsurface displacement and microhardness gradients were measured as a function of sliding distance. It was observed that both the magnitude of plastic strain (and stress) gradients and the depth of highly deformed layers increased with the sliding distance. The flow stress and strains at the subsurface regions are shown to obey a Voce type constitutive equation. Wear proceeded mainly by a mechanism of delamination via subsurface crack growth. It is proposed that the competition between the plastic strain which enhances void growth and the hydrostatic pressure which suppresses it is responsible for the generation of a damage gradient so that the delamination takes place at a certain depth where the damage accumulation rate is maximum. A model based on the Rice and Tracey analysis of ductile void growth is developed and used to determine the location of subsurface crack propagation.

9A545. Reciprocating sliding wear evaluation of a polymeric-coating tribological system. - JF Braza and RE Furst *(Adv Tech Center, Torrington Co, 59 Field St, Torrington CT 06790)*. Wear 162-164(PART B) 748-756 (13 Apr 1993).

In a reciprocating tribotester, five polymeric materials were evaluated against viscous hard coatings deposited on a stainless steel substrate. The polymeric-coating systems were compared with the wear of a baseline phenolic impregnated polytetrafluoroethylene (PTFE)-polyester woven fabric composite against an uncoated stainless steel substrate. Water was used as the lubricant, which contained alumina (Al_2O_3) particulates to simulate a contaminated environment. The polymeric composites used were two polyimides, a polyamide-imide, a polybenzimidazole and an injection-moldable polyether ether ketone (PEEK). The processing techniques and the amounts of PTFE, carbon fiber, graphite and other additives to reduce friction and improve wear were the significant differences. The hard coatings were deposited on a precipitation hardened PH 13-8 Mo stainless steel by different techniques, such as electrospark alloying, thermal spraying, electroless chemical conversion and physical vapor deposition. The wear scar generated on the fabric was larger than the alternative polymeric materials. The polymeric composites that contained PTFE additives exhibited greater wear resistance than the composites that did not contain this additive. In general, the harder the coating, the more resistant it was to damage by the Al_2O_3 particulate contaminants, subsequently producing a smaller wear scar on the polymer specimen.

9A546. Review of multicomponent and multilayer coatings for tribological applications. - C Subramanian and KN Strafford *(Surface Eng Res Group, Dept of Metall, Gartrell Sch Mining, Metall and Appl Geol, Univ of S Australia, The Levels, SA 5095, Australia)*. Wear 165(1) 85-95 (May 1993).

Improvement in performance of engineering components is achieved through the proper choice of materials, design, or both. Materials perform more efficiently even under severe working conditions when they are surface-engineered, ie coated and/or surface treated. Physical and chemical vapor deposition techniques have found increasingly wider use in such applications in recent years. The so-called *first generation* coatings (eg TiN) are widely used in industrial applications, whereas adoption and implementation of *second generation* coatings (egt Ti(CN), (TiAl)N) are currently under serious consideration. The *third generation* of coatings – multicomponent and multilayer coating variants – are at the research stage. In this paper, the development of multicomponent and multilayer coatings for tribological applications are reviewed and the rationale behind the improved performance – established and anticipated – of such coatings is discussed.

9A547. Rolling-sliding behavior of rail steels. - M Sato *(Yawata R&D Lab, Nippon Steel, 1-1 Tobihata Tobata, Kitakyushu 804, Japan)*, PM Anderson, DA Rigney *(Mat Sci and Eng, Ohio State Univ, 116 W 19th Ave, Columbus OH 43210-1179)*. Wear 162-164(PART A) 159-172 (13 Apr 1993).

A twin disk-rolling-sliding contact machine has been used to investigate the deformation, wear, and cracking that occur during rolling-sliding of high-carbon rail and wheel steels. A martensitic wheel steel with initial hardness of 360 HV contacted pearlitic or martensitic rail steels of different initial hardness, 280 - 360 HV. Other variables included test time, test environment and slip ratio (0%, 5%, 10% and 26%). Tests were run in air, but with different lubrication conditions, eg, dry, with water, water with inhibitor, silicone oil, and various combinations. Wear was measured by weight loss. Wear surfaces, sample cross-sections and wear debris were observed by optical and scanning electron microscopy. Principal conclusions are as follows. The thickness of the highly deformed layer was very small for pure rolling compared with cases involving slip. Wear debris was generated from near-surface material in which the cementite phase had broken into small particles. Cracks initiated at the surface and propagated along lines of earlier plastic flow, rather than normal to the local direction of maximum tensile stress. The results of rolling-sliding in water or other liquids, after dry rolling-sliding indicate that extensive deformation from sliding during the dry stage prepares the material for extensive cracking during subsequent operation with a lubricant.

9A548. Study of antiwear adhesive coating under different erosion conditions. - Xiang-Dong Ma, Fu-Yan Lin, He-Sheng Shao *(Beijing Graduate Sch, China Univ of Mining and Tech, 100083 Beijing, China)*. Wear 162-164(PART A) 569-573 (13 Apr 1993).

The characteristics of antiwear adhesive coating in solid particle erosion and slurry erosion were investigated. The influence of the angle of impingement, the size of antiwear filler and the size of abrasive was studied. It was discovered that the erosion mechanisms of the coating under the two erosion conditions were similar. It was indicated that the filler (aluminium oxide) exhibited typical erosion behavior of brittle material and the binder exhibited semiductile behavior. These experiments also showed that the erosion resistance of the coating in slurry erosion was better than that in solid particle erosion.

9A549. Study of the comet-shaped carbides in the uppermost surface layer of bearings. - Fanju Meng *(Dept of Mech Eng, Muroran IT, 27-1 Mizumoto-cho, Muroran 050, Japan)*, Rujun Tang *(Shanghai Res Inst of Mat, Shanghai, China)*, Kohsuke Tagashira *(Dept of Mech Eng, Muroran IT, 27-1 Mizumoto-cho, Muroran 050, Japan)*. Wear 162-164(PART A) 466-470 (13 Apr 1993).

The structure of the uppermost surface layer for commercial bearings with poor grinding procedures has been studied by means of transmission electron microscopy, electron probe X-ray microanalysis, and Auger electron spectroscopy methods. It was found that a new etching-resistant phase with a comet shape appeared, which was identified by structure analysis as being $(Cr, Fe)_7C_3$ carbides. We supposed the formation of the new etching-resistant phase was due to the grinding heat and grinding force.

9A550. Transfer and wear of nylon and CuS-nylon composites: Filler proportion and counterface characteristics. - S Bahadur and Deli Gong *(Dept of Mech Eng, Iowa State Univ, Ames IA 50011)*. Wear 162-164(PART A) 397-406 (13 Apr 1993).

This work was done as a follow-up of an earlier study which showed that CuS as the filler in nylon was very effective in reducing the wear of nylon. The aspects investigated were the variation of wear with the filler proportion in CuS-nylon composite and the wear of nylon and its composite with counterface surface roughness and materials. It was found that 35 vol% CuS as the filler was most effective in reducing the wear of nylon. The wear rate of unfilled nylon increased with an increase in surface roughness R_a from 0.04 to 0.3 μm but that of the composite did not change with the increase in R_a from 0.04 to 0.11 μm. The wear rates of both the unfilled and filled nylons were considerably higher for sliding against glass counterfaces than against tool steel disks. The differences in wear rates with the counterface roughness and materials were examined in terms of the transfer film characteristics. X-ray photoelectron spectroscopy (XPS) studies revealed the presence of Cu in the transfer film of CuS-nylon composite, thereby indicating the decomposition of CuS during sliding conditions. The decomposition played a role in bonding between the composite transfer film and counterface materials.

9A551. Tribological behavior of unidirectional graphite-epoxy and carbon-PEEK composites. - BS Tripathy and MJ Furey *(Dept of Mech Eng, VPI)*. Wear 162-164(PART A) 385-396 (13 Apr 1993).

An infrared microscope system developed at VPI was used to study the tribological behavior as unidirectional graphite-epoxy and carbon-PEEK (PEEK = poly(ether ether ketone)) composites in sliding contact with sapphire. Effects of fiber orientation and sliding velocity on friction, surface temperature and wear were examined. The surface temperatures measured were on the order of 100-160 °C even at relatively low rates of frictional heat generation (up to 14 W). Surface temperatures were found to increase with an increase in velocity, but levelled off as the glass transition temperatures of the matrix materials were reached. The coefficients of friction were generally found to decrease with an increase in sliding velocity and were significantly influenced by fiber orientation. The influence of sliding velocity on wear was quite different for the two polymer composite systems. With graphite-epoxy, wear was found to decrease with increasing velocity and later increase - resulting in minimum wear at an intermediate velocity. However, with carbon-PEEK, the effect was just the opposite, leading to maximum in wear. From the scanning electron micrographs of the wear scars, we believe that wear is primarily due to a combination of adhesion and fatigue and that the difference in the wear behavior between the two composites is due to the difference in response of the respective matrices to fatigue loading. The relationship between surface temperature and wear is rather complex. An attempt is made here to explain this relationship through a proposed "two-velocity-regime" wear model. Estimation of the real area of contact was done using photomacro-video techniques. Comparison of experimental surface temperatures with temperatures predicted by Archard's and a new theory developed by VPI and SU was also made.

9A552. Wear mechanisms of silicon nitride, partially stabilized zirconia and alumina in unlubricated sliding against steel. - P Gautier and K Kato *(Dept of Mech Eng, Tohoku Univ, Sendai, Japan)*. Wear 162-164(PART A) 305-313 (13 Apr 1993).

The dry-sliding wear mechanisms of Si_3N_4, partially stabilized zirconia (PSZ) where Al_2O_3 were studied using a ball-on-disc wear apparatus. A wide range of sliding velocities and normal loads were tested in order to draw experimental load-velocity friction and wear maps through careful examination of wear morphologies. The three pairings behave differently, even if some wear mechanisms were common to the three systems. The PSZ-steel pair showed the least wear in mild load-velocity conditions, followed by the Si_3N_4-steel pair in harder sliding conditions. It is suggested that the wear of ceramics is mainly related to transgranular or intergranular fracture. Steel discs presented much more intricate wear patterns, including abrasion, oxidation, and delamination. Also, the wear rate ($mm^3 s^{-1}$) of each component is shown to be related to the "frictional power" provided to the tribological system. This important result led us to propose an alternative approach of the classical wear rate concept.

9A553. Wear of selected materials and composites sliding against MoS_2 films. - AW Ruff and MB Peterson *(Ceramics Div, Tech Admin, US Dept of Commerce, NIST)*. Wear **162-164**(PART A) 492-497 (13 Apr 1993).

Improved vacuum deposition methods are now available to produce dense, suitably oriented, durable films of molybdenum disulfide on substrates appropriate for tribological applications. It is of interest to examine materials in sliding contact with such films in order to identify optimum combinations, and to improve further tribological performance of the system. Results of wear and friction measurements are presented on a number of materials including self-lubricating composites sliding against four different types of vacuum-deposited MoS_2 films. The testing program utilized a controlled environment, pin-on-ring tribometer, with load and speed conditions appropriate to a possible application. Differences in wear over four orders of magnitude, and friction up to a factor of seven times, were measured among the materials. One application area of interest for these material combinations would be as ball retainers in rolling element bearings for space satellite systems.

9A554. Wear reduction by pyrolytic carbon tribosurfaces. - JL Lauer, BL Vlcek, BL Sargent *(Dept of Mech Eng, Aeronaut Eng and Mech, RPI)*. Wear **162-164**(PART A) 498-507 (13 Apr 1993).

Sliding tests with pin-on-disc tribometer and both sliding and rolling tests with a modified four-ball tester at bulk temperatures of about 500 °C and initial contact pressures of about 2.2 GPa have demonstrated up to 80% reductions of friction and wear with silicon nitride surface when a system of ethylene is directed into the conjunction region. The effects are even more pronounced when the ethylene is prenucleated by flow over a coil of nichrome wire electrically heated to about 800 °C and located about 30 cm upstream of the exit nozzle. Steel and Ni-plated steel are lubricated by this method even more efficiently at lower temperatures. The underlying mechanism is probably analogous to that of hydrocarbon pyrolysis by flash photolysis, which was studied by Porter in the 1950s, with the rapid heating to the "flash temperatures" and subsequent cooling occurring naturally in friction contacts. The observation that pyrolysis of hydrocarbons to solid carbon occurs in two stages, nucleation and particle growth, has allowed their physical separation, the former taking place in the ethylene stream and the latter in the frictional contact some distance away.

9A555. The wear resistance of diffusion treated surfaces. - KG Budinski *(Metall Group, Eastman Kodak, Bldg 23, 5th Fl, Kodak Park, Rochester NY)*. Wear **162-164**(PART B) 757-762 (13 Apr 1993).

For many years there has been a controversy over the relative abrasion and metal-to-metal wear resistance of wear resistant platings and diffusion coatings. Does chromium plating wear better than nitrided or carburized steel? Because these surface treatments can be as thin a 3 μm and as thick as 500 μm it is difficult to assess their relative wear resistance using the same tests. In this study, we used a modification of the ASTM dry sand abrasion test (G65) that is under study by the ASTM G2 Committee for coating evaluation and a newly developed tape abrasion test to rank the relative abrasion resistance of common diffusion treatments (carburizing, nitriding, boronizing, et) and compare their abrasion resistance with that of chromium, and electroless nickel platings. These same surface treatments were compared in a block-on-ring wear test (G77) self-mated and against a carburized counterface. The test results are intended to be a selection aid for use of these surface treatments.

292I. WEAR MONITORING

9A556. Dry sliding wear of TiN based ternary PVD coatings. - E Vancoille, JP Celis, JR Roos *(Dept of Metall and Mat Eng, Katholieke Univ Leuven, de Croylaan 2, B 3001 Heverlee, Belgium)*. Wear **165**(1) 41-49 (May 1993).

In order to understand the tribological characteristics of TiN, (Ti, Al)N, (Ti, Nb)N and Ti(C, N) coatings, ball-on-disc experiments were performed under dry sliding ambient conditions. The coefficient of friction and the wear resistance against a corundum counterbody were determined as a function of coating composition and sliding speed. The wear of the (Ti, Nb)N coatings was found to be comparable to that of the TiN coatings and this was related to the formation of a similar type of oxide in the tribo-contact. In the case of the (Ti, Al)N coatings, the wear volume increased markedly as the aluminium in the coating increased, and the tribo-oxide formed was found to be Al_2TiO_5. Ti(C, N) coatings exhibited an extremely low wear against corundum because of the low coefficient of friction. A mild-oxidational wear model was found to give a qualitative fit to the experiments. Measuring the coating wear as a function of sliding speed opens the possibility of calculating the activation energy for tribo-oxidation processes of thin coatings.

9A557. Investigation of the wear behavior of tyre steel cords using electrochemical methods. - A Reisenbauer, A Grunberger, P Federspiel, GE Nauer *(Inst for Phys Chem, Univ of Vienna, Wahringerstr 42, A-1090 Vienna, Austria)*. Wear **165**(1) 57-62 (May 1993).

The goal of our investigations was to characterize tyre steel cords of different constructions according to their wear behavior by measuring some corrosion parameters in dilute K_2SO_4 as electrolyte. The wear tests were performed using Hunter-type machines, where the probes with a length of 29.6 cm are fixed at one end by a guide hole and the other end is placed in a drilling jig. This drilling jig rotates with a definite velocity for different times (from 1 to 24 h). The effect of the fatigue on the corrosion behavior of the steel cords was measured on single filaments of the same cords. During the rotation the cord filaments show characteristic wear damage, which can be measured using electrochemical techniques, such as the determination of the time dependence of the corrosion potential and of the corrosion current densities (using modified Butler-Volmer techniques). It was possible to show that the wear damage of steel cords depends strongly on the surrounding atmosphere during the Hunter treatment and on the construction of the steel cords. In an air or oxygen-containing atmosphere the cathodic reaction of the overall corrosion process is oxygen reduction. According to the large area of exposed surface, where oxygen reduction can proceed, the total corrosion reaction rate is high and, in relatively short times, visible corrosion products appear on some parts of the steel cord with wear damage of single filaments. We found highly negative corrosion potentials in relation to the untreated reference materials. In an argon atmosphere the corrosion reaction proceeds more slowly and we found more positive corrosion potentials, only small corrosion current densities and no significant wear damage.

9A558. Measurements of wear and acoustic emission from fuel-wetted surfaces. - RJ Boness *(R Military Col of Canada, Kingston, ON, K7K 5LO, Canada)*. Wear **162-164**(PART B) 703-705 (13 Apr 1993).

This paper is concerned with the measurement and subsequent analysis of acoustic emission (AE) signals obtained during the wear testing of steel surfaces lubricated by Jet A-1 fuel. The results show that AE rms signals can detect different wear processes occurring in air and nitrogen atmospheres. Further wear studies of commercially available Jet A-1 fuel and clay-treated Jet A-1 fuel, in nitrogen, indicate that AE rms signals can identify the critical load at which gross failure, or scuffing of the test surfaces, occurs. Consequently, AE measurements are able to detect the presence of wear-reducing additives.

9A559. New look at carbide tool life. - D Mari *(Dept of Mat Sci and Eng, MIT)* and DR Gonseth *(UFEC SA, 1297 Founex, Switzerland)*. Wear **165**(1) 9-17 (May 1993).

The mechanical behavior of WC-Co composites can be divided into three temperature domains. WC-Co is brittle below 500°C, tough between 500 and 800°C and shows plastic deformation above 800°C. Once the tool temperature has been related to the cutting speed, the life of WC-Co cutting tools can be predicted based on the mechanical behavior of WC-Co as a bulk material. As a result, the plot of the tool life as a function of speed also shows three domains of behavior associated with the wear of the tool, due to brittle fracture, ductile fracture and plastic deformation. A model is presented to explain the observed behavior of the tool life versus speed for continuous cutting (Taylor curve). This curve is generally nonlinear on a log-log plot. The overall tool wear rate is generated by the superposition of a non-thermally activated process and two thermally activated ones. The interpretation of tool wear, based on three domains of temperature, also holds for interrupted cutting, such as milling. In this case, a qualitative model explains the brittle rupture observed below 500°C, and the occurrence of comb cracks above 500°C.

9A560. Quantitative analysis of cam follower wear in relation to various material properties. - Makoto Kano *(Nissan Res Centre, Mat Res Lab, Nissan Motor, 1 Natsushima-cho Yokosuka-shi, Kanagawa 237, Japan)* and Yoshitsugu Kimura *(Inst of Indust Sci, Univ of Tokyo, Tokyo, Japan)*. Wear **162-164**(PART B) 897-905 (13 Apr 1993).

Results of wear simulation motoring experiments are presented for various wear-resistant materials used to make automotive engine cam followers. A multiple regression analysis is conducted to find the relation between follower wear and typical material properties. A linear regression formula is derived which provides a high multiple correlation coefficient for a series of ferro-based powder metals which adhere to the regression formula. Close observation of worn cam follower surfaces reveals that a common wear mechanism is at work, ie, fatigue cracks propagate in the matrix around carbides to detach wear particles. This mechanism coincides with the implications of the formula.

9A561. Structure and dose effects on improved wear properties of ion-implanted polymers. - GR Rao, EH Lee, LK Mansur *(Metals and Ceramics Div, ORNL)*. Wear **162-164**(PART B) 739-747 (13 Apr 1993).

Polyethylene, polypropylene, polystyrene and polyethursulfone, representing an increasing complexity in molecular structure were implanted with 200 keV boron to three doses of 1.7, 5 and 17×10^{18} ions m^{-2}. Polystyrene was also implanted with 100 keV boron to the same three doses. The polymers were investigated for near-surface micromechanical property changes using a nanoindentation technique. Wear properties for the polymers were studied using a reciprocal tribometer with a nylon ball as the counterface. Tests were conducted for 10 000 sliding cylces using a 1 N normal load, a stroke length of 3 mm and an oscillation frequency of 100 cycles min^{-1}. The ion implantation increased the near-surface hardness of the four polymers and the increase was proportional to the dose and beam energy. A clear structure dependence was observed for the hardness changes that were related to cross-linking of molecular chains caused by the ion irradiation. In general, the implantation also significantly improved the wear properties of the four polymers. For each polymer, an optimum dose was identified that yielded the best wear improvement. With increasing dose, the dominant wear mechanism shifted from adhesive and abrasive wear to no observable wear to surface fatigue. Remarkable wear improvements were observed for polystyrene and polyethersulfone for which, at the optimum dose, no wear damage was visible even after 10 000 sliding cycles.

9A562. Study of the relationship between wear rate and nitrogen concentration profile and application to plasma source ion implanted Ti-6Al-4V alloy. - A Chen, J Blanchard, JR Conrad, P Fetherston, X Qiu *(Eng Res Center of Plasma-Aided Manuf, Univ of Wisconsin, 1500 Johnson Dr, Madison WI 53706)*. Wear 165(1) 97-101 (May 1993).

Nitrogen implantation by plasma source ion implantation was conducted on Ti-6Al-4V alloy. The wear performance was characterized using a pin-on-disk wear tester and an alpha-step profilometer. Nitrogen concentration depth profiles of implanted samples were studied using a scanning Auger microprobe. It is found that the lowest wear rate in the implanted zone corresponds to the nitrogen concentration peak. By varying the target temperature, the nitrogen concentration profile was engineered to achieve a better wear behavior. The pin-on-disk wear data agree with the expected result.

9A563. Three-body abrasive wear of 0.98% carbon steel. - S Das, BK Prasad, AK Jha, OP Modi, AH Yegneswaran *(Region Res Lab, Council of Sci and Indust Res, Hoshangabad Rd near Habibganj Naka, Bhopal 462026 MP, India)*. Wear 162-164(PART B) 802-810 (13 Apr 1993).

Low stress abrasion studies of hypereutectoid steel have been carried out using a rubber wheel abrasion test apparatus. Hardness of the steel was changed by subjecting the specimens to different heat treatment cycles. Abrasion tests were conducted at various loads and wheel speeds using crushed silica sand as the abrasive medium. Wear rates of the steel in all test conditions decreased significantly during the running-in period prior to attaining steady state values, which was considered to be due to the abrasion-induced work hardening of the regions close to the abraded surface. Results showed that the increase in bulk hardness of the steel specimen caused a linear increase in wear resistance. Furthermore, up to a bulk hardness of about 400 HV, the rate of increase was higher than that above 400 HV. Increase in the applied load caused lower wear resistance, while speed did not show any definite trend. One of the material removal mechanisms, in particular, was found to be microcutting as indicated by continuous grooves on the wear surface and generation of machining chips in the debris. Micropitting was found to be another wear mechanism as evidenced by the formation of craters on the wear surface and flake-shaped particles in the wear debris.

9A564. Tribological behavior of aluminium alloy composites: A comparative study with a copper-based alloy. - S Das and BK Prasad *(Regional Res Lab, CSIR, Hoshangabad Rd, near Habibganj Naka, Bhopal 462 026 MP, India)*. Wear 162-164(PART A) 64-74 (13 Apr 1993).

This paper describes the results of dry sliding wear tests of LM13 alloy and graphite-particle-reinforced LM13 alloy composite in cast and heat-treated conditions, and their comparison with a conventionally used copper-based bearing alloy. Sliding wear tests were conducted on a pin-on-disc wear test apparatus against a rotating steel (EN25) counterface at a sliding velocity of 2.68 m s^{-1}. Results of the present investigation showed that the wear rate of the composite was considerably less than that of the copper-based alloy at an applied pressure of less than 4.0 MPa. Above 4.0 MPa the composite samples seized. However, the seizure pressure of the composite was less than that of the copper-based alloy. Detailed studies of wear surfaces, wear debris and subsurface deformation have been carried out. The overall results indicate that the heat-treated aluminium alloy-graphite composite could be considered as an excellent substitute for a conventional bearing alloy, such as Cu-Sn-Pb, at relatively low applied pressures (below 4.0 MPa), while the copper-based alloy can withstand higher pressures (up to 10 MPa).

9A565. Tribological behavior of austempered spheroidal graphite aluminum cast iron. - SMA Boutorabi, JM Young, V Kondic *(Sch of Metall and Mat, Univ of Birmingham, Birmingham B15 2TT, UK)*, Dept of Mat Eng Salehi *(Isfahan Univ of Tech, Isfahan, Iran)*. Wear 165(1) 19-24 (May 1993).

The effects of austempering time and temperature on the microstructure and tribological behavior of austempered SG Al(2.2%) cast iron have been studied. An austenitizing temperature of 900°C, austempering temperatures of 250-400°C and austempering time of 5-240 min were used: lower and upper bainitic structures were obtained by austempering within this temperature range. The results show that the influence of aluminium (Al) on bainitic reaction is similar to silicon (Si) in conventional SG case irons: aluminium is a strong graphitizer and produces a bainitic structure with a high wear resistance. The transformation kinetics were investigated using X-ray diffraction and microstructural studies were undertaken using optical and scanning electron microscopy. Dry sliding wear tests were conducted on a modified Amsler-type machine from which it was found that the austempering fo SG Al iron significantly increases the wear resistance. The relationship between volume fraction of retained austenite and wear (weight loss) revealed that optimum tribological behavior can be obtained by varying the austempering temperature and time. The results show that the hardness and wear resistance decrease with an increase in austempering time and temperature. The observed changes in tribological behavior can be correlated with the kinetics and austempered microstructure of the irons.

9A566. Wear in Zn-Al-Si alloys. - Li Jian, EE Laufer *(Dept of Mining and Metall Eng, Tech Univ of Nova Scotia, PO Box 1000, Halifax NS, B3J 2X4, Canada)*, J Masounave *(Ecole de Tech Superieur, Montreal PQ, Canada)*. Wear 165(1) 51-56 (May 1993).

The zinc-aluminum based casting alloy ZA-27 is useful in bearing applications. Its tribological properties may be improved by replacing its small copper content with silicon. These are further improved if the silicon particle size is controlled by suitable additions of strontium. This effect is related to the observation that wear properties of the alloy are governed by the development of a thin surface film of the Al-rich α phase. The integrity of this surface film during wear is controlled by the interplay between the lubricant film thickness and particle size. Wear performance is optimum when the silicon particles are larger in diameter than the lubricant film thickness, but small enough that they may embed in the bearing surface and be covered by the surface film. It is suspected that a similar conclusion may hold for particles such as grit from a dirty operating environment.

9A567. Wear resistance of an Ni-Cu-P brush plating layer on different substrates. - Yan-Sheng Ma, Jia-Jun Liu, Bao-Liang Zhu, Guang-Jie Zhai, Lin-Qing Zheng *(Trib Res Inst, Tsinghua Univ, 100084 Beijing, China)*. Wear 165(1) 63-68 (May 1993).

In order to increase the bonding strength between plating layer and substrate and promote the formation of a transfer film, a new type of Ni-Cu-P brush plating layer with excellent wear resistance was developed on the basis of an Ni-P amorphous plating layer, although it showed different behavior when the substrate was changed. This paper systematically investigated its tribological behavior on a "ball-on-disc" testing machine under lubrication with paraffin oil, and analyzed in depth the effect of substrates (conventionally heat treated 1045 steel and nitrided 1045 steel) on its microstructure, hardness, wear resistance, and wear mechanism. The results showed that the load bearing capacity of an Ni-Cu-P brush plating layer on a nitrided 1045 steel substrate can be more than ten times that of a 1045 steel without a plating layer, and more than twice that of a 1045 steel substrate without a nitriding layer. The composite coating process can usually offer an immeasurable effect through the interaction between composite layers.

9A568. Wear resistance of C^+-implanted silicon investigated by scanning probe microscopy. - T Miyamoto *(NTT Interdisciplinary Res Lab, 3-9-11 Midori-cho Musashino-shi, Tokyo 180, Japan)*, S Miyake *(Nippon IT, 4-1 Gakuendai Miayshiro-machi, Minamisaitama-gun Saitama 345, Japan)*, R Kaneko *(NTT Interdisciplinary Res Lab, 3-9-11 Midori-cho Musashino-shi, Tokyo 180, Japan)*. Wear 162-164(PART B) 733-738 (13 Apr 1993).

A scanning probe microscope with a very sharp tip was used to investigate the wear resistance of single-crystal silicon and C^+-implanted silicon. The C^+ implantation conditions were 100 keV and 2×10^{17} ions cm^{-2}. The C^+ concentration was analysed using secondary ion mass spectrometry, while the chemical structures of C^+-implanted silicon and solid SiC were analysed using X-ray photoelectron spectroscopy. (1) The C^+ concentration in C^+-implanted silicon reached a maximum of 1.5×10^{22} atoms cm^{-3} at a depth of 290 nm. (2) Around this 290 nm depth the wear durability of C^+-implanted silicon was higher than that of single-crystal silicon. (3) The structure of the region in which the C^+ concentration was high was similar to that of solid SiC. This structure increases the hardness of the C^+-implanted layer and protects against plastic deformation, resulting in a high wear durability for C^+-implanted silicon.

9A569. BEM frictional contact analysis: Modeling considerations. - KW Man, MH Aliabadi *(Wessex IT, Univ of Portsmouth, Ashurst Lodge, Ashurst SO4 2AA, UK)*, DP Rooke *(Defense Res Agency, RAE Farnborough, Hants GU14 7TU, UK)*. Eng Anal Boundary Elements 11(1) 77-85 (1993).

In this paper, the use of linear and quadratic element for modeling frictional contact problems is studied. It is found that while linear elements are capable of modeling the frictional aspect of the problem accurately, the use of quadratic elements results in oscillations in the tangential tractions under certain contact conditions. Numerical studies of particular interest to these problems have been presented. The case of the oscillations in the quadratic results has been identified and eliminated by using linear elements locally, so that only those node-pairs nearest to the edges of contact can be brought into contact at any one load step. Outside the potential contact region, standard quadratic BE were used.

9A570. **Formulation and implementation of conditions for frictional contact.** - K Runesson *(Dept of Struct Mech, Chalmers Univ of Tech, S-41296 Goteborg, Sweden)*, M Klisinski, R Larsson *(Dept Struct Mech, Chalmers Univ Tech, S-41296 Goteborg, Sweden)*. Eng Comput 10(1) 3-14 (Feb 1993).

FE implementations of the classical (stick-slip) and regularized (elastic-slip) friction laws are compared for a class of nonlinear slip criteria. The fully implicit method is used for integrating the friction law. A novel implementation of the stick slip law, that involved transformation to a nonorthogonal coordinate system at each contact point, is assessed. A numerical comparison is carried out for a simple problem, that has previously been analyzed in the literature. The convergence of the elastic-slip law for increasing stiffness is evaluated in addition to convergence behavior of the adopted Newton iterations for a given law.

9A571. **Finite element analysis of synchronous belt tooth failure.** - KW Dalgarno, AJ Day *(Dept of Mech and Manuf Eng, Univ of Bradford, UK)*, THC Childs *(Dept of Mech Eng, Univ of Leeds, UK)*. Proc Inst Mech Eng D 207(D2) 145-153 (1993).

This paper describes a FE analysis of a synchronous belt tooth under operational loads and conditions with the objective of obtaining a greater understanding of belt failure by tooth root cracking through an examination of the strains within the facing fabric in the belt. The analysis used the ABAQUS FE program, and was based on a 2D FE model incorporating a hyperelastic material model for the elastomer compound. It is concluded that the critical strains in the facing fabric of the belt, and therefore the belt life, are largely determined by the tangential loading condition on the belt teeth.

9A572. **Design and analysis of an antilock brake control system with electric brake actuators.** - WC Lin *(Vehicle Syst Res Dept, General Motors NAO R&D Center, Warren MI 48090-9055)*, DJ Dobner *(Elec and Electron Eng Dept, General Motors NAO R&D Center, Warren MI 48090-9055)*, RD Fruechte *(Vehicle Syst Res Dept, General Motors NAO R&D Center, Warren MI 48090-9055)*. Int J Vehicle Des 14(1) 13-42 (1993).

This paper analyzes the feasibility of an antilock brake control system using an electric brake actuator. The analysis is focused on the closed-loop control of wheel slip. Wheel and vehicle dynamics during longitudinal braking on uniform surfaces are first analyzed to provide a model for performance evaluation using a linear feedback controller design with ideal feedback information from the vehicle, wheel and actuator sensors. The robustness of the linear controller is then analyzed by a parametric study of the system's root locus. Since the linear controller was found to have difficulty solving the sensitivity problem, a nonlinear feedback control was then analyzed.

9A573. **EHD analysis of a misaligned journal bearing.** - HB Sharda, HN Chandrawat, RC Bahl *(Dept of Mech and Indust Eng, Thapar Inst of Eng and Tech, Patiala 147 001, India)*. Int J Mech Sci 35(5) 415-423 (May 1993).

Elastohydrodynamic performance characteristics of a misaligned journal bearing are reported. It is observed that bush flexibility in a misaligned bearing, unlike that in an aligned bearing improves the bearing load capacity owing to an increase in minimum film thickness at higher values of load. The misalignment is found to improve the stability of the bearing, whereas the flexibility of the bush tends to reduce this improvement.

Several 3D numerical simulations of beam-to-column welded joints in steel skeletal structures have been earlier performed, leading to a deep understanding of the joint mechanical behavior up to failure. This in turn motivated the authors to develop a new concept of semi-rigid FEs. The new element family considers the real dimensions of the joint and incorporates its different flexibility characteristics. It can be implemented into any general FE code and assembled with any existing beam element.

9A575. **Thermomechanical generalization of pin joints in finite-plates.** - Ripudaman Singh and TS Ramamurthy *(Dept of Aerospace Eng, Indian Inst of Sci, Bangalore 560 012, India)*. Comput Struct 47(1) 73-81 (3 Apr 1993).

The understanding of thermoelastic behavior of joints is significant in order to ensure the integrity of large and complex structures exposed to a thermal environment, particularly in fields such as aerospace and nuclear engineering. Thermomechanical generalization of partial contact behavior of a pin joint under combined in-plane mechanical loading and on-axis unidirectional heat flow has already been established by the authors for the analytically simpler domains of large plates. This paper successfully extends the on-going investigation to a single pin in a finite rectangular isotropic plate as a 2D abstraction from a practical situation of a multipin fastener joint.

9A576. **Computation of GMAW welding heat transfer with BEM.** - M Hang *(Welding Inst, Gansu Univ of Tech, Lanzhou 730050, Peoples Rep of China)* and A Okada *(Natl Res Inst Metals, 2-3-12 Nakameguro, Meguro-ku, Tokyo 153, Japan)*. Adv Eng Software 16(1) 1-5 (1993).

Based on the computation model for quasi-steady heat transfer problems of welding with the BEM, a computer program is developed and used for the computation of thermal cycles at heat affected zones with gas shielded metal arc (GMAW), welding on medium thickness plates. The computed results are in good agreement with those from experiments, showing the capabilities and versatilities of the BEM to deal with the computerized simulation of welding thermal processes.

9A577. **Thermal analysis for resistance welding of large-scale thermoplastic composite joints.** - ST Holmes and JW Gillespie Jr *(Center for Composite Mat and Dept of Mech Eng, Univ of Delaware, Newark DE 19716)*. J Reinforced Plastics Composites 12(6) 723-736 (Jun 1993).

The need for effective and reliable joining methods continues to grow as the use of thermoplastic composites becomes widespread. It is now possible to join large-scale components with the development of an automated sequential resistance welding process. The thermal history generated by the heating element placed at the interface between adherends determines the quality and performance of the welded joint. This article presents a thermal analysis for the resistance welding of large-scale components that overcomes the limitations of previous models. Regions of localized overheating where potential current leakage may occur were identified as a function of process parameters. Insights on promoting more uniform heating for the resistance welding process are discussed.

The Godunov method, is adapted to computation of dambreak flood waves. Review of commonly used methods for discontinuous flows (flows with shocks) has shown the need for a new type of algorithm to cope efficiently with mixed flow regimes and strong shocks in non-prismatic channels. The 1D open-channel flow equations are solved with two variants of the Godunov method: one based on linear, the other on piecewise parabolic interpolation (PPM). The proposed methods agree well with the analytical solution (where available), and perform significantly better than the other compared methods for all examined cases.

9A582. Kinematics of the moving hydraulic jump. - JP Martin Vide, J Dolz, J Del Estal *(Dept of Hydraul Eng, Civil Eng Sch, Tech Univ of Catalunya, Barcelona, Spain)*. J Hydraul Res 31(2) 171-186 (1993).

The moving hydraulic jump, considered as an example of rapidly varied unsteady flow, is theoretically revised. Experimental work is conducted to study the kinematic characteristics of the jump propagation. The position, velocity and conjugate depths of the jump during its propagation either upstream or downstream are investigated and some semi-empirical equations are derived. From this work, some differences are observed between the moving hydraulic jump propagation upstream and downstream. A phenomenon called extinction of the moving hydraulic jump is reported in the latter case. This phenomenon is explained on the grounds of previous theoretical analysis.

A 3D nonlinear problem of supercavitating flow past an axisymmetric body at a small angle of attack is investigated by means of the perturbation method and the Fourier-cosine-expansion method. The first three order perturbation equations are derived in detail and solved numerically using the boundary integral equation method and iterative techniques. Computational results of the hydrodynamic characteristics and cavity shapes of each order are presented for nonaxisymmetric flow past cones with various apex-angles at different cavitation numbers. The numerical results are found to be in good agreement with experimental data.

9A587. Static anaysis of floating ice block stability. - BA Coutermarsh and WR McGilvary *(USA Cold Regions Res and Eng Lab, Hanover NH 03755)*. J Hydraul Res 31(2) 147-160 (1993).

A laboratory study was performed to measure the pressures caused by fluid acceleration beneath a floating parallel-piped block. Dynamic fluid pressure was measured at discrete points beneath the block for various fluid velocities, block angles of attack and block thickness-to-depth ratios. Some of these pressures tended to stabilize the block while others tended to underturn it. The measured pressures were used to calculate block underturning moments and a hydrostatic analysis was used to calculate a block righting moment. From this, a densimetric Froude underturning criteria is presented.

9A588. Efficient numerical method for subcritical and supercritical open channel flows. - P Glaister *(Dept of Math, Univ of Reading, PO Box 220, Whiteknights, Reading RG6 2AX, UK)*. Appl Numer Math 11(6) 497-508 (Apr 1993).

An efficient numerical method is developed for the 1D open channel flow equations. The scheme incorporates upwind differencing applied to a numerical characteristic decomposition, and produces satisfactory results to a problem of flow in a river whose geometry can induce a region of supercritical flow.

9A589. Explicit time-domain transmitting boundary for dam-reservoir interaction analysis. - R Yang, CS Tsai, GC Lee *(Dept of Civil Eng, Sch of Eng and Appl Sci, SUNY, Buffalo NY 14260)*. Int J Numer Methods Eng 36(11) 1789-1804 (15 Jun 1993).

An explicit time-domain transmitting boundary for the analysis of dam-reservoir interactions is presented. This transmitting boundary is a semi-analytical solution of the governing wave equation of the far field of the reservoir. By using this transmitting boundary, the radiation condition and water compressibility can readily be incorporated in the time-domain analysis of dam-reservoir systems. Numerical results have excellent agreement with the available analytical solution. Results also show that the proposed explicit transmitting boundary is more efficient computationally than the implicit transmitting boundary presented by Tsai and Lee.

354. Incompressible flow

354A. GENERAL THEORY

9A590. Laminar flow in an annulus between two concentric rotating porous spheres. - SD Gulwadi, AF Elkouh, T-C Jan *(Dept of Mech and Indust Eng, Marquette Univ, Milwaukee WI 53233)*. Acta Mech 97(3-4) 215-228 (1993).

An analysis is presented for the steady laminar flow of an incompressible Newtonian fluid in an annulus between two concentric porous spheres with injection-suction at their boundaries. The inner sphere rotates with constant angular velocity about its own fixed axis, while the outer sphere is stationary. A solution of the Navier-Stokes equations is obtained by employing a regular perturbation technique. The solution obtained is in the form of a power series expansion in terms of the rotational Reynolds number Re, and an injection-suction Reynolds number Re_w, and is valid for small values of these parameters. Results for the velocity distributions, streamlines, and viscous torques for various values of the flow parameters Re, Re_w and radius ratios λ are presented. Viscous torques at the inner and outer spheres are compared with those obtained from the numerical solution of the Navier-Stokes equations, in order to find the range of Re and Re_w for which this solution is accurate.

354B. IRROTATIONAL FLOW

354C. ROTATIONAL (NONVISCOUS) FLOW, VORTICES

9A591. Vortex drift I. Dynamic interpretation. - N Rott and B Cantwell *(Dept of Aeronaut and Astronaut, Stanford)*. Phys Fluids A 5(5) 1443-1450 (Jun 1993).

Vortical flow, restricted to a finite domain (in 3D) in an unbounded incompressible viscous fluid that is at rest at infinity, is investigated by the consideration of the dynamics in the potential flow region that surrounds the vortical domain. The evolution equations are considered for a flow that is given at an initial time t. The potential change in the far field is connected to the pressure, which in turn is expressed as the solution of a Poisson equation with sources distributed over the whole flow field. The leading term of the pressure at infinity is a quadrupole, which is caused by a drifting dipole field with a constant strength that is given by the impulse. This "dynamic" value of the drift is then identified with the classical "kinematic" definition as the speed of the impulse centroid. The main new result obtained by this method is the solution of the asymptotic drift problem in 3D, complementing the corresponding solution of Cantwell and Rott for plane flow. The connection to the solution of the classical drift problem for a vortex ring is also established.

9T592. Vortex drift II. The flow potential surrounding a drifting vortical region. - N Rott and B Cantwell *(Dept of Aeronaut and Astronaut, Stanford)*. Phys Fluids A 5(5) 1451-1455 (Jun 1993).

9A594. Levelling of paint films. - SK Wilson *(Dept of Math, Univ of Strathclyde, Livingstone Tower, 26 Richmond St, Glasgow G1 1XH, UK)*. IMA J Appl Math 50(2) 149-166 (1993).

Using a brush to apply paint to a flat surface almost inevitably means that the bristles of the brush level behind an uneven paint surface. As the paint dries out, these non-uniformities tend to flatten out to leave a protective and aesthetically pleasing even coating; however, experiments have shown that some solvent-based high-gloss alkyd paints can exhibit more unusual behavior as they dry. In this paper the author presents a mathematical model for the drying of a layer of solvent-based high-gloss alkyd paint and analyzes the linear stability of a uniform layer of paint subject to an initial perturbation representing the endks left by a paint brush. Investigating the model highlights the crucial role played by solvent evaporation and leads to a plausible physical explanation of the observed phenomena.

354Y. COMPUTATIONAL TECHNIQUES

9A595. Analytical approach to the Oseen drag on a sphere at infinite Reynolds number. - AJ Weisenborn and BIM Ten Bosch *(Koninklijke-Shell-Lab, Shell Res BV, Badhuisweg 3, 1031 CM Amsterdam, Netherlands)*. SIAM J Appl Math 53(3) 601-620 (Jun 1993).

This paper analytically evaluates the Oseen drag coefficient C_D of a sphere at infinite Reynolds number. For this purpose, the method of induced forces is used. This method enables the obtainment of a series of rationals converging to the desired values for C_D. The best value for C_D on the basis of this series truncated to its first 50 terms has only a three-decimal accuracy.

9A596. Convenient method to convert 2D CFD codes into axisymmetric ones. - Sheng-Tao Yu *(Aeromech Dept, Sverdrup Tech, NASA Lewis Res Center, Brook Park OH 44142)*. J Propulsion Power 9(3) 493-494 (May-Jun 1993).

Although 3D CFD calculations are commonplace, axisymmetric flow solvers are indispensible tools, especially for flowfields of propulsion systems. In axisymmetric solvers, one applies curvilinear grids in the axial and radial directions and no grid is used in the azimuthal direction. Thus, each control volume is a body of revolution with constant 2D cross-sectional areas in the azimuthal direction. For the time being, we will call these coordinates the axisymmetric coordinate system. In this note, we propose a convenient and systematic procedure to convert 2D CFD codes into axisymmetric ones. First, we organize the governing equations in a form suitable for CFD applications. Then we carefully examine the calculations of the volume and surface areas of the axisymmetric control-volume element. Through the conversion process, the procedures of modifying the 2D codes becomes self-evident. Although we concentrate on the finite-volume method in this note, similar procedure could be applied for finite difference codes.

9A597. Least squares Petrov-Galerkin FEM for the stationary Navier-Stokes equations. - Tian-Xiao Zhou *(Comput Tech Res Inst, Chinese Aeronaut Est, Xi'an 710068, China)* and Min-Fu Feng *(Dept of Math, Xi'an Jiaotong Univ, Xi'an, China)*. Math Comput 60(202) 531-543 (Apr 1993).

In this paper, a Galerkin and least-squares-type FEM is proposed and analyzed for the stationary Navier-Stokes equations. The method is consistent and stable for any combination of discrete velocity and pressure spaces (without requiring a Babuska-Brezzi stability condition). The existence, uniqueness and convergence (at optimal rate) of the discrete solution is proved in the case of sufficient viscosity (or small data).

9A598. Numerical algorithm for hydrodynamic free boundary problems. - WG Szymczak *(Info and Math Sci Branch-Code R44, Naval Surface Warfare Center, Silver Spring MD 20903-5000)*, JCW Rogers *(Dept of Math, Polytechnic Univ, Brooklyn NY 11201-2907)*, JM Solomon, AE Berger *(Info and Math Sci Branch-Code R44, Naval Surface Warfare Center, Silver Spring MD 20903-5000)*. J Comput Phys 106(2) 319-336 (Jun 1993).

A generalized formulation of inviscid incompressible hydrodynamics as a system of conservation laws subject to a one-sided density constraint is used as the basis of a numerical algorithm for a variety of hydrodynamic free surface problems. Benchmark calculations for colliding masses of fluid and for the motion of a spherically symmetric bubble are compared with theoretical predictions. Also shown are profiles calculated for an evolving underwater bubble near a wall. Energy dissipation is introduced as a measure of turbulence and is used in analyzing the numerical results. Convergence behavior of the numerical algorithm is discussed.

9A599. Solution of the 2D incompressible flow equations on unstructured triangular meshes. - M Williams *(Rocketdyne Div, Rockwell Int, PO Box 7922, 6633 Canoga Ave, MS IB31, Canoga Park CA 91309-7922)*. Numer Heat Transfer B 23(3) 309-325 (Apr-May 1993).

A numerical method for calculating 2D turbulent incompressible flow on unstructured triangular meshes is developed. A primitive variable formulation is used. The Helmholtz equation algorithm is used to enforce the velocity continuity relation for incompressible flow. A careful treatment of the pressure dissipation model is presented. A standard k - ε model with wall functions is used to provide closure for the governing equations. A backward-facing step turbulent flow is calculated using an unstructured triangular mesh and the results are compared to experimental and computational data.

9A600. Stream function vorticity solution using high-p element-by-element techniques. - E Barragy and GF Carey *(Univ of Texas, Austin TX 78712)*. Commun Numer Methods Eng 9(5) 387-395 (May 1993).

A p-type FE scheme is introduced for Navier-Stokes problems in a fully coupled stream function-vorticity formulation. The resulting coupled nonlinear system is solved using a Newton iteration with incremental continuation in the Reynold's number. A biconjugate gradient (BCG) scheme in an element-by-element setting is applied to solve the linearized system at each Newton iteration. Pseudo-element block preconditioners produce a practical PBCG method, even for ill-conditioned systems arising from high-p elements in the case of Stokes flow. The problem at higher Reynolds numbers further limits p.

9A601. Vorticity-velocity method for the numerical solution of 3D incompressible flows. - G Guj and F Stella *(Dept Mec Aeronaut, Via Eudossiana 18, 00184 Rome, Italy)*. J Comput Phys 106(2) 286-298 (Jun 1993).

A new method for the numerical solution of the 3D Navier-Stokes equations written in terms of vorticity-velocity is presented. The advantages of this formulation with respect to primitive variables and vorticity-vector-potential ones are discussed in view of physical as well as engineering applications. A suitable form of the continuum equations, the most appropriate discretization scheme, and variable location in order to guarantee the solenoidality of the velocity and vorticity fields are introduced and justified. A 3D lid driven cavity problem for $400 \leq Re \leq 3200$ is chosen as a test case for comparison and validation purposes.

356C. TRANSONIC FLOW

9A602. Study of integral equation methods for transonic flow calculations. - Hong Hu *(Dept of Math, Hampton Univ, Hampton VA 23668)*. Eng Anal Boundary Elements 11(2) 101-107 (1993).

An integral equation method based on the full-potential equation for transonic flow calculations is presented. The full-potential equation is written in the moving frame of reference, in the form of the Poisson's equation. The integral equation solution in terms of the velocity field is obtained by the Green's theorem. The numerical solutions are obtained by a time-marching (if unsteady flows), iterative procedure. Through studying the method and computational examples, the capabilities and limitations of the transonic integral equation method are discussed. Finally, the need for further research is addressed.

9A603. Variational principles and generalized variational principles for fully 3D transonic flow with shocks in a turbo-rotor Part II. Rotational flow. - G-L Liu *(Shanghai Univ of Tech and Shanghai Inst of Appl Math and Mech, 149 Yan-Chang Rd, Shanghai 200 072, People's Republic of China)*. Acta Mech 97(3-4) 229-238 (1993).

Two variational principle (VP) families for fully 3D transonic potential, Beltrami rotational flows with shocks in a rotor are put forth in terms of stream functions. By making use of functional variations with variable domain one succeeded in converting most of the boundary conditions and matching conditions across unknown discontinuities (such as shocks and free trailing vortex sheets), including the generalized Rankine-Hugoniot shock relations, into natural ones. This paper is intended to provide a rigorous theoretical foundation for constructing a novel computational method which incorporates a new FE with self-adapting embedded discontinuities (now under development) and the artificial density concept, could capture all unknown discontinuities automatically and clearly. The applicability of VPs for rotational flow, in contrast to those for Beltrami flow, is not limited to transonic flow with moderate Mach numbers.

356D. SUPERSONIC FLOW

9A604. Numerical study of wave propagation in a confined mixing layer by eigenfunction expansions. - Fang Q Hu *(Dept of Math and Stat, Old Dominion Univ, Norfolk VA 23529)*. Phys Fluids A 5(5) 1420-1426 (Jun 1993).

It is well known that the growth rate of instability waves of a 2D free shear layer is reduced greatly at supersonic convective Mach number. In previous works, it has been shown that new wave modes exist when the shear layers are bounded by a channel due to the coupling effect between the acoustic wave modes and the motion of the mixing layer. The present work studies the simultaneous propagation of multiple stability waves using numerical simulation.

356E. HYPERSONIC FLOW

9A605. Density measurements in an expanding flow using holographic interferometry. - SP Sharma, SM Ruffin *(NASA Ames Res Center, Moffett Field CA 94035)*, SA Meyer, WD Gillespie *(Stanford)*, LA Yates *(Eloret Inst, Palo Alto CA 94303)*. J Thermophys Heat Transfer 7(2) 261-268 (Apr-Jun 1993).

A nonequilibrium expansion of nitrogen through a 2D nozzle of a reflected shock tunnel is investigated with laser holography, time-resolved pressure measurements, and emission spectroscopy to characterize the flowfield for future vibrational relaxation measurements. A 2D computation is used to simulate the nozzle flowfield. Synthetic holograms are generated using the computed density profiles and are compared with the experimental holograms. Computational accuracy of both models is assessed against the experimental data.

9A606. Development of braided rope seals for hypersonic engine applications: Flow modeling. - R Mutharasan *(Chem Eng, Drexel Univ, Philadelphia PA 19104)*, BM Steinetz *(Struct Dyn Branch, NASA Lewis Res Center, Cleveland OH 44135)*, Xiaoming Tao, Guang-Wu Du *(Fibrous Mat Res Center, Drexel Univ, Philadelphia PA 19104)*, F Ko *(Mat Eng, Drexel Univ, Philadelphia PA 19104)*. J Propulsion Power 9(3) 456-461 (May-Jun 1993).

A new type of engine seal is being developed to meet the needs of advanced hypersonic engines. A seal braided of emerging high-temperature ceramic fibers comprised of a sheath-core construction has been selected for study based on its low leakage rates. Flexible, low-leakage, high-temperature seals are required to seal the movable engine panels of advanced ramjet-scramjet engines, either preventing potentially dangerous leakage into backside engine cavities or limiting the purge coolant flow rates through the seals. To predict the leakage through these flexible, porous seal structures, new analytical flow models are required. Two such models based on Kozeny-Carman equations are developed herein and are compared to experimental leakage measurements for simulated pressure and seal preload conditions, showing good agreement. The models developed allow prediction of the gas leakage rate as a function of fiber diameter, fiber packing density, gas properties, and pressure drop across the seal. The first model treats the seal as a homogeneous fiber bed. The second model divides the seal into two homogeneous fiber beds identified as the core and the sheath of the seal.

9A607. Hypersonic shock-tunnel testing at an equilibrium interface condition of 4100 K. - MAS Minucci *(Divisao Lasers, Inst Estudos Avancados-CTA, Sao Jose dos Campos, Sao Paulo 12231, Brazil)* and HT Nagamatsu *(Dept of Mech Eng, RPI)*. J Thermophys Heat Transfer 7(2) 251-260 (Apr-Jun 1993).

An investigation has been conducted on the operation of the RPI 0.61-m-diam hypersonic shock tunnel at an equilibrium interface condition of 5.8 MPa and 4100 K. The numerical analysis shows a strong dependence of the equilibrium interface pressure and temperature on the initial driver temperature and incident interface speed. A fairly good agreement was observed between the measured equilibrium pressure and the predicted value for the shock-tunnel conditions.

9A608. Monte Carlo simulation of entry in the Martian atmosphere. - DB Hash and HA Hassan *(Mech and Aerospace Eng, N Carolina State Univ, Raleigh NC 27695)*. J Thermophys Heat Transfer 7(2) 228-232 (Apr-Jun 1993).

The Direct Simulation Monte Carlo method of Bird is used to investigate the characteristics of low density hypersonic flowfields for typical aerobrakes during Martian atmosphieric entry. The method allows both thermal and chemical nonequilibrium. Results are presented for a 60-deg spherically blunt cone for various nose radii and altitudes.

9A609. Theory of radiation from low velocity shock heated air. - DA Levin, RT Loda *(Sci and Tech Div, Inst for Defense Anal, 1801 N Beaugregard St, Alexandria VA 22311)*, GV Candler *(Dept of Mech Aerospace Eng, N Carolina State Univ, Raleigh NC 27695)*, C Park *(NASA Ames Res Center, Moffett Field CA 94035)*. J Thermophys Heat Transfer 7(2) 269-276 (Apr-Jun 1993).

Application of hypersonic computational fluid dynamics models to low velocity vehicles is examined. Important modeling aspects such as chemical kinetics, electronics excitation and de-excitation mechanisms, and existence of equilibrium vs nonequilibrium conditions in the flow were examined. Flowfields properties and in-band radiances in the wavelength region of 0.25 μ in the vicinity of the stagnation streamline are given for a hemisphere with a radius of 0.0762 m. Comparison with recent shock tube data is also shown.

356K. NONEQUILIBRIUM AND CHEMICAL EFFECTS

9A610. Coupled implicit method for chemical non-equilibrium flows at all speeds. - Jian-Shun Shuen *(Sverdrup Tech, NASA Lewis Res Center, Cleveland OH 44135)*, Kuo-Huey Chen *(Univ of Toledo, NASA Lewis Res Center, Cleveland OH 44135)*, Yunho Choi *(Sverdrup Tech, NASA Lewis Res Center, Cleveland OH 44135)*. J Comput Phys 106(2) 306-318 (Jun 1993).

A time-accurate, coupled solution procedure is described for the chemical nonequilibrium Navier-Stokes equations over a wide range of Mach numbers. This method employs the strong conservation form of the governing equations, but uses primitive variables (p_g, u, v, h, Y_i) as unknowns. Real gas properties and nonequilibrium chemistry are considered. Numerical tests include steady convergent-divergent nozzle flows with air dissociation-recombination chemistry, dump combustor flows with n-pentane-air chemistry, and nonreacting unsteady driven cavity flows. Numerical results for both the steady and unsteady flows demonstrate the efficiency and robustness of the present algorithm for Mach numbers ranging from the incompressible limit to supersonic speeds.

9A609. Theory of radiation from low velocity shock heated air

356Y. COMPUTATIONAL TECHNIQUES

9A611. Application of the locally implicit method to upwind TVD schemes. - Yih Nen Jeng and Uon Jien Payne *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan,* *Taiwan, ROC).* J Sci Comput 7(4) 339-357 (Dec 1992).

The local implicit scheme of Reddy et al is extended to the minmod and third-order upwind TVD schemes. Numerical tests show that the proposed scheme is stable. In addition, it is found that if the flow field has a dominant direction, setting the iteration sweep to align with this direction can significantly improve the converging speed.

9A612. **Chebyshev collocation method and multi-domain decomposition for Navier-Stokes equations in complex curved geometries.** - CR Schneidesch and MO Deville *(Unite Mec Appl, Univ Catholique, Louvain-La-Neuve, Belgium).* J Comput Phys 106(2) 234-257 (Jun 1993).

A general multidomain decomposition is proposed for the numerical solution of the 2D incompressible stationary Navier-Stokes equations. The solution technique consists in a Chebyshev orthogonal collocation method preconditioned by a standard Galerkin FE technique. The preconditioned system is then solved through a Richardson procedure. The domain of interest is decomposed into quadrilaterals, curved when needed. A Gordon transfinite interpolation performs the curvilinear grid generation of the obtained simply-connected planar subdomains. The study of model Stokes problems demonstrates that the current method still behaves spectrally in distorted geometries. For curvilinear distortion, a loss of several orders of magnitude is observed in the solution accuracy even when the distortion is very limited.

9A613. **Multigrid technique for the compressible Euler and Navier-Stokes equations.** - AE Kanarachos and IP Vournas *(Dept of Mech Eng, Natl Tech Univ, PO Box 64078, 15710 Athens, Greece).* Eng Comput 10(2) 123-137 (Apr 1993).

An optimized multigrid method (NSFLEX-MG) for the NSFLEX-code (Navier-Stokes solver using characteristic flux extrapolation) of MBB (Messerschmitt Bolkow Blohm GmbH) is described. The method is based on a correction scheme and implicit relaxation procedures and is applied to 2D test cases. The principal feature of the flow solver is a Godunov-type averaging procedure based on the eigenvalues analysis of the Euler equations by means of the inviscid fluxes are evaluated at the finite volume faces. Viscous fluxes are centrally differenced at each cell face.

9A614. **Semi-implicit spectral method for the anelastic equations.** - SR Fulton *(Dept of Math and Comput Sci, Clarkson Univ, Potsdam NY 13699-5815).* J Comput Phys 106(2) 299-305 (Jun 1993).

This paper describes the efficient and accurate solution of the 2D anelastic equations by a Fourier-Chebyshev spectral method. A fourth-order Runge-Kutta method is used for the time integration, with the diffusion terms treated implicitly and all other terms (including the pressure gradient) treated explicitly. The model is free from aliasing and converges quickly once the solution is resolved. Numerical results are given for nonlinear flow generated by an atmospheric density current.

9A615. **Solution of the compressible Navier-Stokes equations using improved flux vector splitting methods.** - D Drikakis *(Dept of Fluid Mech, Univ of Erlangen-Nurnberg, Cauerstr 4 D-8520, Germany)* and S Tsangaris *(Dept of Mech Eng, Natl Tech Univ, Athens, Greece).* Appl Math Model 17(6) 282-297 (Jun 1993).

In this paper the accuracy of two flux vector splitting methods using upwind schemes up to the fourth order for the solution of the unsteady compressible Navier-Stokes equations is improved. Two of the most well-known methods for the solution of the inviscid gas dynamic equations, the flux vector splitting method by Steger an[illegible] Warming and the flux vector splitting method [illegible] van Leer are presented for the first time in combination with a five-point upwind scheme. Inaccuracies of flux vector splitting methods, which have been presented in the recent literature, can be eliminated using the present schemes in conjunction with proposed corrections for the flux splittings. The present techniques can be used in compressible viscous flows, predicting with accuracy viscous phenomena such as separation and shock boundary layer interaction.

9A616. **Three BEM schemes for the calculating of subsonic compressible plane cascade flow.** - AX Liao *(2nd Dept of Mech Eng, SW Jiaotong Univ, Chengdu, Sichuan 610031, Peoples Rep of China)* and CX Lin *(Dept of Thermal Eng, Chongqing Univ, Chongqing, Sichuan 630044, Peoples Rep of China).* Eng Anal Boundary Elements 11(1) 25-32 (1993).

This paper reports research work on the calculation of slightly perturbed 2D subsonic compressible potential flow through a cascade by direct BEMs. The work has been performed in three schemes: 1) orthotropic medium method; 2) equivalent cascade method; 3) compressibility correction method. Using the above three schemes, six slightly perturbed cases of 2D subsonic compressible potential flow through a cascade composed of K-7 compressor-blades has been calculated. The results obtained according to these three schemes are compared with each other, and with the results of experiments performed by the authors. Satisfactory coincidence has been obtained.

9A617. **Use of a rotated Riemann solver for the 2D Euler equations.** - DW Levy, KG Powell, Bram van Leer *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109).* J Comput Phys 106(2) 201-214 (Jun 1993).

A scheme for the 2D Euler equations that uses flow parameters to determine the direction for upwind-differencing is described. The approach respects the multidimensional nature of the equations and reduces the grid-dependence of conventional schemes. Several angles are tested as the dominant upwinding direction, including the local flow and velocity-magnitude-gradient angles. Roe's approximate Riemann solver is used to calculate fluxes in the upwind direction, as well as for the flux components normal to the upwinding directions. Solutions of the Euler equations are calculated for a variety of test cases. Substantial improvement in the resolution of shock and shear waves is realized.

358. Rarefied flow

9T618. **Kinetic theory analysis of steady evaporating flows from a spherical condensed phase into a vacuum.** - Yoshio Sone and Hiroshi Sugimoto *(Dept of Aeronaut Eng, Kyoto Univ, Kyoto 606-01, Japan).* Phys Fluids A 5(5) 1491-1511 (Jun 1993).

9A619. **Monte Carlo code describing the neutral gas transport in pipe configurations with attenuating media.** - A Nicolai *(Inst Plasmaphys Forschungszentrum Julich GmbH, Assoziation, EURATOM-KFA, Postfach 1913, D-5170 Julich, Germany).* J Comput Phys 106(2) 377-390 (Jun 1993).

A 3D Monte Carlo description of the neutral gas transport in pipe configurations with almost arbitrary torsion and curvature is presented. To avoid quadratic or even transcendental expression describing the pipe surfaces confining and guiding the neutral gas, a decomposition into plane geometrical elements is chosen. Furthermore, a [illegible] of the pseudo collision, "pseudo-[illegible] of the standard tracklength es[illegible]ced. The pseudo collision estimator or - mainly for comparison - the pseudo tracklength estimator are used in the plasma domain. This estimator combination allows us to treat the throat plasma similarly to a homogeneous absorbing medium (speeding up the geometrical and atomic physics related calculations) and to use the standard tracklength estimator if the tracklength is to be calculated during particle tracing anyway. To reduce the variances, important sampling is applied leading to an exponential 1D-importance function.

9A620. **Experimental investigations on two-phase flow past a sphere using digital particle-image-velocimetry.** - M Schmidt and F Loffler *(Inst Mech Vefahrenstech und Mech, Univ Karlsruhe (TH), D-7500 Karlsruhe, Germany).* Exp Fluids 14(5) 296-304 (Apr 1993).

Digital Particle-Image-Velocimetry was applied to investigate particle trajectories in a gas flow past a sphere. The particle displacement was determined by autocorrelation analysis of image sections. To enhance the signal-noise ratio a synthetic image with idealized particle pictures was generated from the real image. The autocorrelation function was calculated using the Fast Hartley Transformation. The desired secondary maximum of this function was detected by an algorithm with subpixel resolution. A data validation step testing the plausibility of the velocity vectors completes the image analysis. Particle trajectories are traced with help of the particles' velocity vectors. The particle deposition on a sphere can be deduced from the course of these trajectories.

9A621. **Particle force and heat transfer in a dusty gas sustaining an acoustic wave.** - S Temkin *(Dept of Mech and Aerospace Eng, Rutgers Univ, Piscataway NJ 08855-0909).* Phys Fluids A 5(5) 1296-1304 (Jun 1993).

This work considers the effects of finite mass concentrations on the force and the heat transfer rate for a small particle in a dusty gas. The particular flow studied is a plane, monochromatic sound wave, where the particle velocity and temperature slips are very small. Assuming that the fluid's temperature and velocity near a test particle are changed by amounts of which depend on the mass loading and on the respective slips, it is shown that the heat transfer rate to a sphere in the suspension changes from the pure condition limit q_{k0}), applicable to an isolated sphere to q_{k0($1 + C_m c_{pp}/c_{pf}$), where C_m is the mass loading, c_{pp} is the specific heat of the particle material, and c_{pf} is the constant pressure specific heat of the gas. Another but less significant effect is to change the corresponding viscous force from the Stokes values, F_{v0}, to $F_{v0}\gamma m/\gamma_f$, where γ_m and γ_f are the specific heat ratios for the suspension and for the dust-free gas, respectively.

9A622. **Numerical solutions for the deformation of a bubble rising in dilute polymeric fluids.** - DS Noh, IS Kang *(Dept of Chem Eng, Pohang Inst of Sci and Tech, PO Box 125, Pohang 790-600, Korea),* L Gary Leal *(Dept of Chem and Nucl Eng, UC, Santa Barbara CA 93106).* Phys Fluids A 5(5) 1315-1332 (Jun 1993).

The steady-state deformation of a bubble rising in polymeric liquid has been investigated using a general numerical technique for the solution of free-boundary problems in non-Newtonian fluid mechanics. The technique is based on a finite-difference solution of the governing equations on an orthogonal curvilinear coordinate system, which is constructed numerically and adjusted to fit the boundary shape exactly at any time. This problem was analyzed based on the constitutive equation proposed by Chilcott and Rallison, which models a dilute polymer solution as a suspension of dumbbells with finite extensibility. Computations were carried out to investigate the effect of conformation change of polymer chains on the bubble deformation for various values of the Deborah number, maximum chain extensibility, (ie, roughly proportional to molecular weight), capillary number, and the Reynolds number. Numerical results show good agreement with existing experimental findings reported elsewhere. Especially, the tendency of transition from a prolate shape to a cusped shape has been observed in the creeping flow limit.

9A623. Strong vortex-boundary layer interactions Part I. Vortices high. - AD Cutler *(George Washington Univ JIAFS, NASA Langley Res Center, Hampton VA 23681)* and P Bradshaw *(Dept of Mech Eng, Stanford)*. Exp Fluids 14(5) 321-332 (Apr 1993).

Detailed measurements with hot-wires and pressure probes are presented for the interaction between a turbulent longitudinal vortex pair with "common flow" down, and a turbulent boundary layer. The interaction has a larger value of the vortex circulation parameter, and therefore better represents many aircraft and vortex interactions, then those studied previously. The vortices move down towards the boundary layer, but only the outer parts of the vortices actually enter it. Beneath the vortices the boundary layer is thinned by lateral divergence to the extent that it almost ceases to grow. Outboard of the vortices the boundary layer is thickened by lateral convergence, The changes in turbulence structure parameters in the boundary layer appear to be due to the effects of "extra-rate-of-strain" produced by lateral divergence (or convergence) and by free-stream turbulence. The effect of interaction on the vortices (other than inviscid effect of the image vortices below the surface) is small. The flow constitutes a searching test case for prediction methods for 3D turbulent flows.

9A624. Effect of distributed roughness on laminar-turbulent transition in the boundary layer over a rotating cone. - T Watanabe *(Dept of Mech Eng, Iwate Univ, Morioka 020, Japan)*, HM Warui, N Fujisawa *(Dept of Mech Eng, Gunma Univ, Kiryu 376, Japan)*. Exp Fluids 14(5) 390-392 (Apr 1993).

Laminar-turbulent transition in the 3D boundary layer over a rotating body is of fundamental importance in fluid mechanics. This phenomenon has been investigated both experimentally and theoretically since the experiment by Smith (1947) for the flow over a rotating disk. The main feature of this transition process is the appearance of spiral vortices in the transition region, which are caused by the combined instability mechanism of Tollmien-Schlichting waves and 3D Taylor-Gortler vortices.

9A625. Computations and experiments for a multiple normal shock-boundary-layer interaction. - BF Carroll, PA Lopez-Fernandez *(Dept of Aerospace Eng Mech and Eng Sci, Univ Florida, Gainesville FL 32611)*, JC Dutton *(Dept of Mech and Indust Eng, Univ Illinois, Urbana IL 61801)*. J Propulsion Power 9(3) 405-411 (May-Jun 1993).

Results from a numerical investigation of a Mach 1.61 multiple normal shock wave-turbulent boundary-layer interaction are compared to wall static pressure and laser Doppler velocimeter measurements. The computations used the explicit, time-dependent, second-order accurate MacCormack scheme to solve the mass-averaged Navier-Stokes equations. Turbulence was modeled by means of the Baldwin-Lomax algebraic model and the Wilcox-Rubesin two-equation model. The computation with the Wilcox-Rubesin model was able to capture the major features of the normal shock train and accurately predicted the flow reacceleration mechanisms which occur between shocks. However, this computation failed to accurately predict the level of flow separation under the first shock. The Baldwin-Lomax computation displayed a more limited ability to capture the features of this shock train flow.

9A626. Unsteady 3D boundary layer flow due to a stretching surface. - V Rajeswari, M Kumari, G Nath *(Dept of Math, Indian IT, Bangalore 560 012, India)*. Acta Mech 98(1-4) 123-141 (1993).

In this numerical study, the unsteady laminar incompressible boundary-layer flow over a continuously stretching surface has been investigated when the velocity of the stretching surface varies arbitrarily with time. Both the nodal and the saddle point regions of flow have been considered for the analysis. Results have been obtained for the stretching velocities which are accelerating and decelerating with time. Results show that the skin friction, the heat transfer and the mass transfer parameters respond significantly to the time dependent stretching velocities. The Prandtl number and the Schmidt number strongly affect the heat and mass transfer of the diffusing species, respectively.

9A627. Boundary layer flow of power-law fluids past arbitrary profiles. - M Pakdemirli *(Dept of Eng Sci and Mech, VPI)*. IMA J Appl Math 50(2) 133-148 (1993).

Two-dimensional steady-state boundary layer equations of power-law fluids are derived using a special coordinate system which makes the equations independent of the body shape immersed in the flow. In deriving the boundary layer equations, the method of matched asymptotic expansions is used. It is shown that the similarity solutions for power-law fluids are much the same as those for Newtonian fluids.

9A628. Developments on an unsteady boundary-layer analysis: Internal and external flows. - TH Ramin and RH Pletcher *(Dept of Mech Eng and Comp Fluid Dyn Center, Iowa State Univ, Ames IA 50011)*. Numer Heat Transfer B 23(3) 289-307 (Apr-May 1993).

A boundary-layer solution for 2D, compressible unsteady flows has been developed for the non-Cartesian generalized grids consistent with first-order boundary-layer theory. The scheme is applicable to both internal and external unsteady flows. Example results demonstrate advantages of using a non-Cartesian grid for external flows. Boundary-layer solutions were reported for the first time for a number of flows that had been computed only by quite different approaches, including the numerical solutions to the Navier-Stokes equations. The results computed for several test cases were found to be in good agreement with data available in the literature.

364. Internal flow (pipe, channel, Couette)

9A629. Tracer dispersion in rough channels: A 2D numerical study. - J Koplik *(Benjamin Levich Inst and Dept of Phys, CCNY)*, I Ippolito *(Lab Phys Mec Milieux Heterogenes, ESPCI, 10 rue Vauquelin, 75321 Paris Cedex 05, France)*, JP Hulin *(Lab Phys Mec Milieux Heterogenes, ESPCI, 10 rue Vauquelin, 75321 Paris Cedex 05, France)*. Phys Fluids A 5(5) 1333-1343 (Jun 1993).

Numerical results are presented on the hydrodynamic dispersion of passive tracer in flow through a 2D channel boundary by parallel plates, one having substatial rugosities perpendicular to the flow. The simulation is based on the numerical solution of the microscopic Stokes and convention-diffusion equations, over a range of Peclet numbers and of degrees of rugosity of the channel. One observes a tenfold increase of the effective dispersion between the smooth plate case (classical Taylor dispersion) and the maximum rugosity case, attributable to the trapping of tracer inside deep rugosities. The results were analyzed in terms of tracer exchange models, involving a characteristic exchange time between the low- and high-velocity zones and their relative volume fractions, as a function of the Peclet number and the relative depth of the rugosities. The simulations were compared to "echo" dispersion experiments in which the tracer is first injected into the model and then, upon reversal of the fluid flow, drawn back through the inlet.

9A630. Drag of plane microslot ducts with rough walls. - YP Dyban, NM Zotov, AA Khoroshavin *(Eng Thermophys Inst, Ukrainian Acad of Sci, Volgograd Polytechnic Inst, Kiev, Ukrain)*. Heat Transfer Res 24(3) 398-407 (Apr 1992).

Experimental results on flow of air in plane microslot ducts are presented. The effect of the roughness of the duct walls on the drag coefficient in different flow modes is investigated. With increasing roughness, transition to turbulent flow occurs at even lower Reynolds number. A technique for determining the equivalent height of the roughness for purposes of analysis of laminar flows in such ducts is suggested.

9A631. Computer simulation of gradually varied flow profiles in circular sections. - NA Zaghloul and MM Shahin *(Dept of Civil Eng, Kuwait Univ, PO Box 5969, Kuwait)*. Adv Eng Software 16(1) 37-46 (1993).

Most wastewater flow and storm drainage transportation systems consist largely of circular pipes. Gradually varied flow (GVF) conditions predominate in such systems. This paper presents a software package based on Lotus 1-2-3 to solve for GVF problems in circular pipes using the direct step method. The results are presented in tabular form. In addition, the Lotus print graph capabilities are used to delineate the GVF profiles.

366. Internal flow (inlets, nozzles, diffusers, cascades)

9A632. Inlet turbulence distortion and viscous flow development in a controlled diffusion compressor cascade at very high incidence. - GV Hobson and RP Shreeve *(Turbopropulsion Lab, Naval Postgraduate Sch, Monterey CA 93943)*. J Propulsion Power 9(3) 397-404 (May-Jun 1993).

Detailed two-component laser Doppler velocimeter (LDV) measurements of the flow through a controlled diffusion compressor cascade at a Reynolds number of about 700,000 and at a low Mach number are reported in this article. A very high-incidence angle (8° above design) was considered throughout this investigation, which included the full experimental characterization of the turbulence field. The LDV measurements were fully automated and were all taken in coincidence mode, thus turbulent flow correlations could be determined. Most significant was the measurement of the distortion of the inlet freestream turbulence upstream of the blade leading edges. Such information is important in assessing viscous codes which incorporate transport equations to describe the turbulence within the flowfield. The laminar-leading edge separation bubble, which reattached turbulent, was enlarged on the suction surface of the blade. Consistent with measurements at lower incidence angles, the suction surface boundary layer remained attached over the rear part of the blade. The pressure side boundary layer initially showed little or no growth, however, it finally developed into a profile similar to a wall jet. The wake profiles showed significant asymmetry due to the high loading on the blades at the increased incidence angle.

9A633. Study on vortex generator flow control for the management of inlet distortion. - BH Anderson *(NASA Lewis Res Center, Cleveland OH 44135)* and J Gibb *(Defense Res Agency, Bedford, England, UK)*. J Propulsion Power 9(3) 422-430 (May-Jun 1993).

The present study demonstrates that the reduced Navier-Stokes RNS3D code can be used very effectively to develop a vortex generator installation to minimize the engine face circumferential distortion by controlling secondary flow. The computing times required are small enough that studies such as this are feasible within an analysis-design environment with all its constraints of time and costs. This research study also established the nature of the performance improvements that can be realized with vortex flow control, and suggests a set of aerodynamic properties (called observations) that can be used to arrive at a successful vortex generator installation design. This study also indicated that scaling between flight and typical wind-tunnel test conditions is possible only within a very narrow range of generator configurations close to an optimum installation. Lastly, this study indicated that vortex generator installation design for inlet ducts is more complex than simply satisfying the requirement of attached flow, it must satisfy the requirement of minimum engine face distortion.

9A634. Computational study of advanced exhaust system transition ducts with experimental validation. - C Wu *(United Tech, USBI, PO Box 1900, Huntsville AL 35807)*, S Farokhi *(Aerospace Eng and Flight Res Lab, Univ of Kansas, Lawrence KS 66045)*, R Taghavi *(Aerospace Eng, Univ of Kansas, Lawrence KS 66045)*. J Propulsion Power 9(3) 437-442 (May-Jun 1993).

A subsonic, 3D parabolized Navier-Stokes code is used to construct stall margin design charts for optimum length advanced exhaust systems' circular to rectangular transition ducts. Computer code validation has been conducted to examine the capability of wall static pressure predictions. The comparison of measured and computed wall static pressures indicates a reasonable accuracy of the PNS computer code results. Computations have also been conducted on 15 transition ducts, 3 area ratios, and 5 aspect ratios. The three area ratios investigated are constant area ratio of unity, moderate contracting area ratio of 0.8, and highly contracting area ratio of 0.5. The degree of mean flow acceleration – ie, the area ratio of the duct – is identified as a dominant parameter in establishing the minimum duct length requirements. The effect of increasing aspect ratio in the minimum length transition duct is due to increase the length requirement, as well as to increase the mass-averaged total pressure losses.

9A635. Nonreflecting boundary conditions of 3D Euler equations calculations for strut cascades. - K Imanari and H Kodama *(R&D Dept, Aeroengine and Space Operations, Ishikawajima-Harima Heavy Indust, Tokyo, Japan)*. J Propulsion Power 9(3) 443-448 (May-Jun 1993).

In this article, 3D nonreflecting boundary conditions regarding pressure waves and associated components in density and velocity waves have been formulated and applied to time-marching Euler equation calculations of steady flows around uncambered thick strut cascades. The linearized solutions including a Fourier-Bessel double expansion with an exponential variation in the axial direction have been developed for far-field perturbations from the uniform freestream with subsonic axial velocity in a cylindrical annular duct, and used to provide the information for the correction of boundary conditions. Numerical examples for the symmetric struts, and the nonuniform strut cascades comprising two types of vanes, have demonstrated the correctness and accuracy of the present method, allowing a considerable reduction of the computational domain.

368. Free shear layers (mixing layers, jets, wakes, cavities, plumes)

9A636. Flow regimes and frequency selection of a cylinder oscillating in an upstream cylinder wake. - J Sun *(LRC, Univ Provence, 13397 Marseille, Cedex 13, France)*, J Li, B Roux *(Inst de Mec des Fluides, 1 Rue Honnorat, 13003 Marseille, France)*. Int J Numer Methods Fluids 16(10) 915-929 (30 May 1993).

This paper describes flow around a pair of cylinders in tandem arrangement with a downstream cylinder being fixed or forced to oscillate transversely. A sinusoidal parietal velocity is applied to simulate cylinder oscillation. Time-dependent Navier-Stokes equations are solved using FEM. It is shown that there exist two distinct flow regimes: "vortex suppression regime" and "vortex formation regime". Averaged vortex lengths between the two cylinders, pressure variations at back and front stagnation points as well as circumferential pressure profiles of the downstream cylinder are found completely different in the two regimes and, thus, can be used to identify the flow regimes. It is shown that frequency selection in the wake of the oscillating cylinder is a result of nonlinear interaction among vortex wakes upstream and downstream of the second cylinder and its forced oscillation. Increasing cylinder spacing results in a stronger oscillatory incident flow upstream of the second cylinder and, thus, a smaller synchronization zone.

9A637. Numerical simulation of vortex shedding past triangular cylinders at high Reynolds number using a κ - ε turbulence model. - SH Johansson, L Davidson, E Olsson *(Dept of Thermo and Fluid Dyn, Chalmers Univ of Tech, S-412 96 Gothenburg, Sweden)*. Int J Numer Methods Fluids 16(10) 859-878 (30 May 1993).

Calculations of unsteady turbulent flow around and behind triangular-shaped flameholders using a finite volume code with a $\kappa - \varepsilon$ model of turbulence are presented. The flow behind the flameholders is found to be unsteady (a von Karman vortex street appears) with a well defined Strouhal frequency (predicted Sr = 0.27 compared with an experimental value of 0.25). The predicted profiles of velocity and fluctuating kinetic energy agree well with experiments. The periodic motions in the vortex street are shown to be far more important than the turbulent stochastic motions in exchanging momentum in the transversal direction. The pressure-velocity coupling is handled with the SIMPLEC pressure correction procedure. The discretization in time is fully implicit and 90 time steps are used to resolve one time cycle. It was found that to capture the vortex street it is very important that the grid spacing is sufficiently fine (180 × 100).

9A638. Plane wake of a cylinder: Measurements and inferences on turbulence modeling. - D Aronson and L Lofdahl *(Thermo and Fluid Dyn, Chalmers Univ of Tech, 412 96 Goteborg, Sweden)*. Phys Fluids A 5(5) 1433-1437 (Jun 1993).

Hot wire measurements in the far field region of the plane wake of a cylinder have been carried out. The data obtained indicated that transverse distributions of mean-velocity and Reynolds stresses were self-preserving for a downstream distance greater than 400 momentum thicknesses. Dissipation rate and triple velocity correlations were measured at a downstream position of 880 momentum thicknesses, these measured profiles were compared with the profiles obtained from closure models for the Reynolds stress equations. It was found that the dissipation rate anisotropy could essentially be accounted for by the employed model, larger deviations were observed between the measured and modeled profiles for the triple velocity correlations.

9A639. Optimal excitation of 3D perturbations in viscous constant shear flow. - BF Farrell *(Dept of Earth and Planet Sci, Harvard Univ, Cambridge MA 02138)* and PJ Ioannou *(Center for Meteorol and Phys Oceanog, MIT)*. Phys Fluids A 5(5) 1390-1400 (Jun 1993).

The 3D perturbation to viscous constant shear flow that increase maximally in energy over a chosen time interval are obtained by optimizing the complete set of analytic solutions. These optimal perturbations are intrinsically 3D of restricted morphology, and exhibit large energy growth on the advective time scale, despite the absence of exponential normal modal instability in constant shear flow. The optimal structures can be interpreted as combinations of two fundamental types of motion associated with two distinguishable growth mechanisms: streamwise vortices growing by advection of mean streamwise velocity to form streamwise streaks, and upstream tilting waves growing by the down gradient Reynolds stress mechanism of 2D shear instability. The optimal excitation over a chosen interval of time comprises a combination of these two mechanisms, characteristically giving rise to tilted roll vortices with generally amplified perturbation energy. It is suggested that these disturbances provide the initial growth leading to transition of turbulence, in addition to providing an explanation for coherent structures in a wide variety of turbulent shear flows.

9A640. Problems in the weakly nonlinear theory of hydrodynamic stability and its improvements. - Zhou Heng and Xueyi You *(Dept of Mech, Tianjin Univ, Tianjin 300072, China)*. Acta Mech Sinica 9(1) 1-12 (1993).

There are three main problems in the weakly nonlinear theory of hydrodynamic stability: 1) The radius of convergence with respect to the perturbation parameter is too small and there is no concrete estimation for it. 2) The solution has a special structure, thus in general, it can not satisfy the initial condition posed by many practical problems. 3) When the linear part of its solution does not correspond to a neutral case, there are more than one way in determining the Landau constants, and practically no one knows which is the best way. In this paper, problems (1) and (2) are solved theoretically, and ways for its improvement have been proposed. By comparing the theoretical results with those obtained by numerical simulation, problem (3) has also been clarified.

9T641. Singularities of the Euler equation and hydrodynamic stability. - S Tanveer *(Dept of Math, Ohio State Univ, Columbus OH 43210)* and CG Speziale *(Dept of Aerospace and Mech Eng, Boston Univ, Boston MA 02215)*. Phys Fluids A 5(5) 1456-1465 (Jun 1993).

9A642. Three-dimensional stability analysis of the periodic flow around a circular cylinder. - BR Noack *(Max-Plank-Inst fur Stromungsforschung, Bunsenstr 10, 3400 Gottingen, Germany)*. Phys Fluids A 5(5) 1279-1281 (Jun 1993).

The onset of 3D in the von Karman vortex street behind a circular cylinder is investigated by carrying out the first global, nonparallel, 3D stability analysis of the periodic flow. This flow is found to become unstable at a Reynolds number of 170 by a critical, 3D Floquet mode with a spanwise wavelength of 1.8 diam. The spatial structure of this mode indicates that the onset of 3D is due to a near-wake instability and not caused by a stagnation-line or a boundary-layer instability.

9A643. Pattern selection for the oscillatory onset in thermosolutal convection. - Yuriko Yamamuro Renardy *(Dept of Math and Interdisciplinary Center for Appl Math, VPI)*. Phys Fluids A 5(5) 1376-1389 (Jun 1993).

A layer of fluid lies between two parallel horizontal walls and the solute concentration and temperature are higher at the bottom wall. The onset of time-periodic instability in this double diffusion problem in 3D is analyzed. Periodicity with respect to the hexagonal lattice is assumed. The no-slip condition is imposed at the top and bottom boundaries. There are 11 bifurcating solutions, and their stability is presented. For relatively low solutal and thermal Rayleigh numbers, the solutions are found to be unstable. For the heating of salty water, situations are presented where the standing rolls, the standing patchwork quilt, and either the standing hexagons or the standing regular triangles, may be stable.

9A644. Kelvin-Helmholtz instability of Couette flow between vertical walls with a free surface. - JS Walker *(Dept of Mech and Indust Eng, Univ of Illinois, Urbana IL 61801)*, G Talmage *(Dept of Mech Eng, Penn State)*, SH Brown, NA Sondergaard *(Carderock Div, Naval Surface Warfare Center, Annopolis MD 21402-5067)*. Phys Fluids A 5(5) 1466-1471 (Jun 1993).

A novel type of Kelvin-Helmholtz instability model is developed from hydrodynamic theory. The classical Kelvin-Helmholtz instability involves a horizontal interface between two fluids with different parallel, uniform, horizontal velocities. If the upper fluid is a gas with a much smaller density than the lower fluid which is a liquid, then the phase velocity of the critical disturbance equals the liquid's velocity, so that the liquid sees a standing interfacial wave. The inertial force driving the interfacial instability involves only the gas, no matter how small its density is. In a much more realistic flow model, the liquid velocity at the free surface is not uniform, but varies across the free surface. The disturbance phase velocity can only equal the liquid velocity at one point, while liquid on either side of the point moves faster or slower than the wave. The inertial forces in the liquid then dominate and the gas plays a negligible role. The concept is developed from a Couette flow hydrodynamic model where the fluid flows between two parallel vertical walls with a free surface. The importance of a nonuniform liquid velocity is demonstrated. This modified theory will be applied in future work to study the ejection instability at the interface of the liquid metal and inert cover gas in sliding electrical contacts.

9A645. Meausrements on transition to turbulence in a Taylor-Couette cell with oscillatory inner cylinder. - KJ Maloy *(Fysisk Inst, Univ Oslo, Postboks 1048, Blindern N-0316 Oslo, Norway)* and W Goldburg *(Dept of Phys and Astron, Univ of Pittsburgh, Pittsburgh PA 15260)*. Phys Fluids A 5(5) 1438-1442 (Jun 1993).

The transition line at onset of instability and the distance between the vortex rolls in a Taylor-Couette with an oscillatory inner cylinder having zero mean velocity are measured. When the amplitude of the velocity oscillations increases slightly above the critical value, a transition to a turbulent "mixing regime" takes place. In this regime, homodyne correlation spectroscopy have been used to measure the characteristic velocity fluctuations $<\delta v_q(l)>$ between points separated by a distance l. Scaling of the correlation function $G(\tau,q,l)$ was found, ie, $G(\tau,q,l) = G(x)$, where $x=q\tau<\delta v_q(l)>$, with $<\delta v_q(l)>\sim l^{0.76}$.

9A646. Time-dependent instabilities in curved rotating channel flows. - OJE Matsson *(Dept of Mech and Fluid Phys, RIT, S-100 44 Stockholm, Sweden)*. Phys Fluids A 5(5) 1514-1516 (Jun 1993).

The *principle of exchange of instabilities* is not valid for certain regions of the parameter space of curved rotating channel flow and it is shown that for this situation the most unstable model is inclined traveling roll cells and hence this instability determines the critical Reynolds number.

9A647. Stability of liquid bridges between equal disks in an axial gravity field. - LA Slobozhanin *(Inst for Low Temp Phys and Eng, Ukrainian Acad of Sci, 47 Lenin Ave, 310164 Kharkov, Ukraine)* and JM Perales *(LamfIETSIA Lab Aerodin ETSI Aeronaut, Univ Politec, 28040 Madrid, Spain)*. Phys Fluids A 5(5) 1305-1314 (Jun 1993).

The stability of axisymmetric liquid bridges spanning two equal-diameter solid disks subjected to an axial gravity field of arbitrary intensity is analyzed for all possible liquid volumes. The boundary of the stability region for axisymmetric shapes (considering both axisymmetric and nonaxisymmetric perturbations) have been calculated. It is found that, for sufficiently small Bond numbers, three different unstable modes can appear. If the volume of liquid is decreased from that of an initially stable axisymmetric configuration the bridge either develops an axisymmetric instability (breaking in two drops as already known) or detaches its interface from the disk edges (if the length is smaller than a critical value depending on contact angle), whereas if the volume is increased the unstable mode consists of a nonaxisymmetric deformation. This kind of nonaxisymmetric deformation can also appear by decreasing the volume if the Bond number is large enough. A comparison with other previous partial theoretical analyses is presented, as well as with available experimental results.

372. Turbulence

9A648. Vortex-induced disturbance field in a compressible shear layer. - D Papamoschou *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717)* and SK Lele *(Dept of Mech Eng and Dept of Aeronaut and Astronaut, Stanford)*. Phys Fluids A 5(5) 1412-1419 (Jun 1993).

The disturbance field induced by a small isolated vortex in a compressible shear layer is studied using direct simulation in a convected frame. The convective Mach number, M_c, is varied from 0.1 to 1.25. The vorticity perturbation is rapidly sheared by the mean velocity gradient. The resulting disturbance pressure field is observed to decrease both in magnitude and extent with increasing M_c, becoming a narrow transverse zone for $M_c > 0.8$. A similar trend is seen for the perturbation velocity magnitude and for the Reynolds shear stress. By varying the vortex size, it was verified that the decrease in perturbation levels is due to the mean-flow Mach number and not the Mach number across the vortex. At high M_c, the vortex still communicates with the edges of the shear layer, although communication in the near-flow direction is strongly inhibited. The growth rate of perturbation kinetic energy declines with M_c primarily due to the reduction in shear stress. For $M_c \geq 0.6$, the pressure dilatation also contributes to the decrease of growth rates. Calculation of the perturbation field induced by a vortex doublet revealed the same trends as in the single-vortex case, illustrating the insensitivity of the Mach-number effect to the specific form of initial conditions.

9A649. Brownian particle deposition in a directly simulated turbulent channel flow. - H Ounis, G Ahmadi, JB McLaughlin *(Clarkson Univ, Potsdam NY 13699)*. Phys Fluids A 5(5) 1427-1432 (Jun 1993).

Diffusion of submicron particles in a simulated turbulent channel flow field is studied. The turbulent flow velocity field is generated by a direct numerical integration of the Navier-Stokes equation with the pseudospectral method. The equation of motion of particles including the Brownian effects is used and ensembles of particle trajectories are numerically evaluated and statistically analyzed. A uniform initial concentration of particles is used in the analysis. Effects of size on particle dispersion and wall deposition processes are studied. The results are compared with the existing models for the submicron particle deposition rate.

9A650. Large-eddy simulation scheme for turbulent reacting flows. - Feng Gao *(Center for Turbulence Res, Stanford)* and EE O'Brien *(Dept of Mech Eng, SUNY, Stony Brook NY 11794-2300)*. Phys Fluids A 5(5) 1282-1284 (Jun 1993).

A general methodology is developed for simulating complicated reacting flow problems. This method combines the large-eddy simulation technique with the existing probability density function approach for turbulent reacting flows and provides a closed form representation for all terms that are involved in the simulations. Some other issues related to this problem are also discussed.

9A651. Shock polar analysis and analytical expressions for vorticity deposition in shock-accelerated density-stratified interfaces. - R Samtaney and NJ Zabusky *(Dept of Mech and Aerospace Eng and CAIP Center, Rutgers Univ, Piscataway NJ 08855)*. Phys Fluids A 5(5) 1285-1287 (Jun 1993).

Vorticity is deposited due to baroclinic effects on the surface of a density-stratified interface accelerated by a shock. An analytical expression is presented, derived from shock polar analysis, for circulation per unit length on a fast-slow planar density interface inclined at an angle to the incident shock. The analytical expression is integrated to yield total circulation on nonplanar interfaces (sinusoidal and semicircular interfaces) accelerated by shocks. The analytical results agree well with diagnostics from numerical experiments using a second-order Godunov code for the Euler equations.

9A652. High Reynolds number calculations using the dynamic subgrid-scale stress model. - U Piomelli *(Dept of Mech Eng, Univ of Maryland, College Park MD 20742)*. Phys Fluids A 5(5) 1484-1490 (Jun 1993).

The dynamic subgrid-scale eddy viscosity model has been used in the large-eddy simulation of the turbulent flow in a plane channel for Reynolds numbers based on friction velocity and channel half-width ranging between 200 and 2000, a range including values significantly higher than in previous simulations. The computed wall stress, mean velocity, and Reynolds stress profiles compare very well with experimental and direct simulation data. Comparison of higher moments is also satisfactory.

9A653. Small-scale turbulence model. - TS Lundgren *(Dept of Aerospace Eng and Mech, Univ of Minnesota, Minneapolis MN 55455)*. Phys Fluids A 5(5) 1472-1483 (Jun 1993).

A previously derived analytical model for the small-scale structure of turbulence is reformulated in such a way that the energy spectrum may be computed. The model is an ensemble of 2D vortices with spiral structure, each stretched by an axially symmetric strain flow. Stretching and differential rotation produce an energy cascade to smaller scales in which the stretching represents the effect of instabilities and the spiral structure is the source of dissipation at the end of the cascade. The energy spectrum of the resulting flow may be expressed as a time integration involving only the enstrophy spectrum of the time evolving 2D cross-section flow, which may be obtained numerically. Examples are given in which a $\kappa^{-5/3}$ spectrum is obtained by this method. The $\kappa^{-5/3}$ inertial range spectrum is shown to be related to the existence of a self-similar enstrophy preserving range in the 2D enstrophy spectrum. The results are found to be insensitive to time dependence of the strain rate, including even intermittent on-or-off strains.

9A654. Measurement of the diffusion coefficient in a heated plane airstream. - E Pemha *(Lab de Mec, Fac Sci, BP 812, Yaounde, Cameroun)*, B Gay, A Taillard *(Lab de Mec des Fluides, Ecole Centrale de Lyon, 36 Ave Guy des Collongues, 69131 Ecully, France)*. Phys Fluids A 5(5) 1289-1295 (Jun 1993).

In order to measure the diffusion coefficient of a heated plane airstream, a single laser beam is passed through the jet, perpendicularly to the flow direction. The thermic turbulence in the airstream causes random fluctuations of the refractive index. Consequently, the beam direction undergoes, in the flow, random perturbations. After having traversed the jet, the beam produces a luminous trace on a photoelectric cell placed outside the jet. An experimental setup for measuring the probabilities of the beam impact positions in the cell is described. From the Markovian process model, applied along the whole random path of the beam, it has been possible to compute these probabilities by solving the Einstein-Fokker-Kolmogorov equation. The diffusion coefficient can be determined by adjusting the numerical solution to agree with the experimental results. In addition, the calculation procedure gives the order of magnitude of an integral scale, characterizing the dimension of the turbulent structures in which the propagation of light can be considered rectilinear. A good agreement between the results and the published data obtained by means of the cold-wire anemometer technique proves the validity of the method.

In this paper the plasma engineering aspects involved with the reliable and safe operation of present-day large tokamaks are described. First a brief review of the underlying empirical and theoretical knowledge of equilibrium and stability of tokamak plasmas is given. Then some of the recent experiments with disruption preventive actions are discussed. Finally the state of the art in feedback control systems, real-time protection circuits, and the application of pulse scenarios is reviewed.

9A656. Analysis of a power plant with an experimental thermonuclear reactor. - YV Smolkin *(Inst of Heat and Mass Transfer, Minsk, Russia)*. Heat Transfer Res 24(3) 366-373 (Apr 1992).

The structure and the parameters of a thermal diagram of a power plant with an experimental thermonuclear reactor have been analyzed. Recommendations concerning the types and parameters of turbine plants are given.

9A657. MHD flow in complex-geometry tubes. - VV Yakovlev *(Inst of Heat and Mass Transfer, Minsk, Russia)*. Heat Transfer Res 24(3) 310-317 (Apr 1992).

The problem of simulating electroconducting liquid flow with an inhomogeneous electromagnetic force distribution in complex-geometry tubes is considered. The development of specific MHD effects in such tubes is discussed. Special attention is paid to problems classified as local magnetohydrodynamic resistances (LMHDR). New experimental data concerning the resistance to motion in a number of LMHDRs are presented.

The paper presents the results of an experimental investigation into film MHD flows on models of liquid-metal contact devices (LMCD) with solid and porous sublayers. The effect of wettability and electroconductivity of the sublayer and side walls material as well as of the sublayer porosity and magnetic field direction on the film flow formation conditions is investigated. An estimation of the thermal characteristics of the LMCD with a porous sublayer and energy receiver channel is made.

9A659. Thermal instability of a nonlinear magnetic fluid under the influence of both non-vertical magnetic field and Coriolis forces. - AA Abdullah *(PO Box 6337, Makkah, Saudi Arabia)*. Arab J Sci Eng 17(4B) 625-633 (Oct 1992).

This work examines the convective instability of a horizontal layer of a magnetohydrodynamic fluid of variable permeability when subjected to both a non-vertical magnetic field and Coriolis forces. A model proposed by PH Roberts (1981) in the context of neutron stars is used. The results obtained are also relevant to ferromagnetic fluids. This nonlinear relationship has no effect on the development of instabilities through the mechanism of stationary convection which is the preferred process in terrestrial applications. However, in non-terrestrial applications the nonlinearity influences the onset of overstable convection and overstability is the preferred mechanism. In the context of ferromagnetic fluids, both stationary and overstable instability can be expected to be realizable possibilities.

9A660. Unsteady MHD flow of a dusty viscous liquid in a rotating channel with Hall currents. - HS Takhar *(Dept of Eng, Univ of Manchester, Manchester M13 9PL, UK)*, PC Ram, SS Singh *(Dept of Math, Kenyatta Univ, Nairobi, Kenya)*. Int J Energy Res 17(1) 69-74 (Jan 1993).

The unsteady magnetohydrodynamic flow of a dusty, viscous, incompressible liquid in a rotating channel, in the presence of a transverse magnetic field with Hall currents, is considered. Analytical expressions for the velocities of the liquid and the dust particles are obtained. The effects of Hall current m, and the rotation parameter K on the velocity are shown graphically, and are discussed.

9A661. Magnetic field effects on the computed flow over a Mars return aerobrake. - G Palmer *(Aerothermodyn Branch, NASA Ames Res Center, Moffett Field CA 94035)*. J Thermophys Heat Transfer 7(2) 294-301 (Apr-Jun 1993).

A numerical algorithm is developed to calculate the electromagnetic phenomena simultaneously with the fluid flow in the shock layer over an axisymmetric blunt body in a thermal equilibrium, chemical nonequilibrium environment. The flowfield is solved using an explicit time-marching, first-order spatially accurate scheme. The electromagnetic phenomena are coupled to the real-gas flow solver through an iterative procedure. The technique is applied in calculating the flow over a Mars return aerobrake vehicle entering the Earth's atmosphere. With the application of an external magnetic field of 0.05 to 0.1 T, the solution indicates an increase in stagnation line shock standoff distance, wall pressure, and radiative heat transfer and a decrease in convective heat transfer.

9A662. Multiconstrained variational problems in magnetohydrodynamics: Equilibrium and slow evolution. - B Turkington *(Dept of Math, Univ of Massachusetts, Amherst MA 01003)*, A Lifschitz *(Dept of Math, Univ of Illinois, Chicago IL 60680)*, A Eydeland, J Spruck *(Dept of Math, Univ of Massachusetts, Amherst*

MA 01003). J Comput Phys 106(2) 269-285 (Jun 1993).

A computational method is proposed for solving magnetohydrodynamical equilibrium problems with prescribed flux and mass within the magnetic surfaces that foliate the plasma. Such problems arise in tokamak modeling, for instance, where they determine either equilibria with given adiabatic profiles or slowly evolving quasi-equilibra governed by the Grad-Hogan equations. The classical variational principles of Kruskal and Kulsrud and Woltjer, which express these problems in terms of energy minimization subject to infinite families of nonlinear, nonlocal constraints, are taken as the basis for a direct method of solutions. A natural discretization of the classical constraint families is devised, and an iterative algorithm is developed to solve the resulting optimization problems.

9A663. Experimental study of a turbulent wing-body junction and wake flow. - JL Fleming, RL Simpson, JE Crowling, WJ Devenport *(Dept of Aerospace and Ocean Eng, VPI).* Exp Fluids 14(5) 366-378 (Apr 1993).

The primary goal of this research was to determine the effects of the approach boundary layer characteristics on the function flow. To accomplish this goal, the authors' results were compared to several other junction flow data sets obtained using the same body shape. The trailing vortex leg flow structure was found to scale on T. A parameter known as the momentum deficit factor (MDF = $(Re_T)^2(\theta/T)$) was found to correlate the observed trends in mean flow distortion magnitudes and vorticity distribution. Changes in δ/T were seen to affect the distribution of u', with lower ratios producing well defined local turbulence maxima. Increased thinning of the boundary layer near the appendage was also observed for small values of δ/T.

9A664. Three-dimensional vortex method for parachutes. - M Humi *(Dept of Math Sci, Worcester Polytech Inst, 100 Institute Rd, Worcester MA 01609-2280).* Int J Numer Methods Fluids 16(10) 879-889 (30 May 1993).

We describe the implementation of a new 3D vortex algorithm for the computation of the drag and flow field around parachutes. Among its novel features, the algorithm couples large eddy simulation methodology with the vortex method, away from the wall region. Furthermore, boundary conditions for a wall (no-slip) and compliant boundaries were implemented. The results of several simulations using this algorithm are analyzed and discussed. The spectral contents of the vortex method are also considered.

9A665. Simulation of range-resolved DIAL measurements on in-flight rocket plumes. - CT Christou, RT Loda, DA Levin *(Sci and Tech Div, Inst for Defense Anal, Alexandria VA 22311).* J Thermophys Heat Transfer 7(2) 233-240 (Apr-Jun 1993).

Feasibility studies were carried out for a ground-based experiment using the differential absorption LIDAR (DIAL) method, to measure spatially resolved rocket plume temperature profiles from solid-aluminized propellants. The core of this effort was a numerical simulation of the dynamics of the laser-plume interaction and the retrieval of average temperatures from the received signals using parameters appropriate to a low-altitude rocket plume. Signal-to-noise ratios were adequate for the assumed experimental conditions and for both a clear and moderately clear atmosphere, to ensure detectability of the returned signals over most of the plume.

9A666. Consequences of recent gas turbine developments for industrial CHP applications. - J Stromberg *(Dept of Heat and Power Tech, Chalmers Univ of Tech, S-412 95 Goteborg, Sweden)*, P-A Franck *(CIT Energy Tech Anal, Sweden)*, T Berntsson *(Dept of Heat and Power Tech, Chalmers Univ of Tech, S-412 96 Goteborg, Sweden).* Heat Recovery Syst CHP 13(3) 219-231 (May 1993).

Developments in gas turbine (GT) technology have been considerable during the last few yeas. In this paper, consequences regarding the technical performance for industrial combined heat and power applications are discussed and the most important design parameters are identified. Some GT types, which represent different stages of the developmental trend, are analysed in the simple and the combined cycle. Both the industrial and the aero-derivative GT classes are included. Conclusions are: (i) Generally, the developments have broadened the span of achievable power-to-heat ratios (α-values). (ii) The total efficiencies available depend strongly, and differently for different GT types, on the nature of the heat demands in industrial processes. (iii) When opportunities do not exist to cool the exhaust gases in an economizer, ie, when the stack temperature is directly given by process heat demands, the total efficiency is independent of the GT classes. (iv) When opportunities exist to cool the exhaust gases in an economizer (which is often the case for the simple cycle and always for the combined cycle), the industrial GT developments have given improved ability to reach a high total efficiency. (v) When supplementary firing is applied, however, the total efficiency is high and similar for all various units and conditions. The new aero-derivative units have, in that case, superior α-values - especially in the combined cycle.

9A667. Design of rotor blades of high-temperature gas turbines for a specified service life and minimum loss of output power on blade cooling. - GP Nagoga, VI Tseytlin, VP Balter *(Kuybyshev Aviation Inst, Trud Corp, Kiev).* Heat Transfer Res 24(4) 483-493 (Apr 1992).

The problems of minimizing fuel (and potential turbine output power) losses on air cooling of a gas-turbine rotor blade while providing for the desired blade service is stated. A solution for a turbine with two sets of operating modes is given. It is shown that fuel losses can be minimized by employing a turbine cooling system in which the cooling-air flowrates are controlled solely by the operating conditions.

9A668. Multipassage 3D Navier-Stokes simulation of turbine rotor-stator interaction. - NK Madavan *(NASA Ames Res Center, M-S 202A-2, Moffett Field CA 94035)*, MM Rai *(Fluid Dyn Div, NASA Ames Res Center, M-S 258-1, Moffett Field CA 94035)*, S Gavali *(Supercomput Group, Fujitsu Am, 3055 Orchard Dr, San Jose CA 95134).* J Propulsion Power 9(3) 389-396 (May-Jun 1993).

This article deals with the development and validation of a 3D multipasage, Navier-Stokes code for predicting the unsteady effects due to rotor-stator interaction in turbomachines. Prior work in 2D has demonstrated the necessity of including multiple rotor and stator passages in order to closely approximate the stator-to-rotor airfoil count ratio, and thus accurately predict the unsteady flowfield resulting from rotor-stator interaction. In this article, this multipassage capability is extended to 3D. Numerical results obtained from a multipassage calculation of an axial turbine stage are presented. The stator-to-rotor airfoil count ratio (3:4) used in the present calculations is a close approximation to that in the actual turbine configuration (22:28). The numerical results are compared with experimental data wherever possible and to earlier single-passage calculations. The present multipassage approach results in a more accurate computation of the unsteady flowfield than that possible from a single passage approach.

9A669. Results from a set of low speed blade-vortex interaction experiments. - MB Horner, E Saliveros, A Kokkalis, RA McD Galbraith *(Dept of Aerospace Eng, Univ of Glasgow, Glasgow G12 8QQ, UK).* Exp Fluids 14(5) 341-352 (Apr 1993).

The results of a Blade-Vortex Interaction (BVI) experiment are presented. The experiments were the second series to be carried out at Glasgow Univ (see Kokkalis and Galbraith 1986, 1987), and reflect improvement to the facility. These improvements have resulted in sufficient resolution to observe clear evidence of vortex passage and propagative disturbances caused by the BVI. Additionally the quality of the pressure data permitted a meaningful assessment of force and moment coefficients, and a clear correspondence between their detailed time histories was observed. The data obtained are also compared with the results of previous studies, and qualitative and quantitative similarities are discussed.

9A670. Efficient hybrid scheme for the analysis of counter-rotating propellers. - R Srivastava *(NASA Lewis Res Center, Cleveland OH 44135)* and LN Sankar *(Sch Aerospace Eng, Georgia Tech).* J Propulsion Power 9(3) 382-388 (May-Jun 1993).

An efficient solution procedure has been developed for analyzing inviscid unsteady flow past counter-rotation propellers. This scheme is first-order accurate in time and second-order accurate in space. The spatial accuracy can be extended to fourth-order in the axial direction. The solution procedure has been applied to a two-bladed SR-7 single-rotor propeller and to a GE F7-A7 counter-rotating propeller. The pressure coefficients and the global quantities, power, and thrust, show good correlation with experimental measurements.

9A671. Using a full potential solver for propulsion system exhaust simulation. - RG Melvin *(Appl Math and Stat, Boeing Comput Services, MS 7H-96 PO Box 3707, Seattle WA 98124)*, FT Johnson *(Aerodyn Res, Boeing Commercial Airplane Group, MS 7H-96 PO Box 3707, Seattle WA 98124)*, DP Young *(Appl Math and Stat, Boeing Comput Services, MS 7H-96 PO Box 3707, Seattle WA 98124)*, DW Foutch *(Propulsion Res, Boeing Commercial Airplane Group, MS 7H-96 PO Box 3707, Seattle WA 98124)*, JE Bussoletti *(Aerodyn Res, Boeing Commercial Airplane Group, MS 7H-96 PO Box 3707, Seattle WA 98124)*, MB Bieterman *(Appl Math and Stat, Boeing Comput Services, MS 7H-96 PO Box 3707, Seattle WA 98124).* J Propulsion Power 9(3) 412-421 (May-Jun 1993).

The need for accurate simulations of engine installations on modern commercial transport aircraft has led to consideration of several formulations capable of modeling engine exhausts. Since such exhausts often interact with wings, struts, and nacelles, a complex geometry computational fluid dynamics (CFD) capability is desirable. Engine exhausts often contain nonlinear effects such as weak shock waves. There are very few

CFD codes that can model these effects for complex geometries in a timely way. However, a full potential formulation has been implemented in the general geometry code TRANAIR. This model incorporates certain assumptions, the main one being that the flowfield can be divided into a finite number of regions in each of which the total pressure and total temperature are constant. The purposes of this article are to state the theoretical assumptions made by the full potential and Euler models and to validate the methods on an axisymmetric test case. In the situations considered (typical of modern turbofan engines) the full potential and Euler results agree very well.

9A672. Numerical solution of heavily loaded elastohydrodynamic contact. - EL Airapetov, II Kudish, MY Panovko *(AA Blagonravov Inst of Machines Sci, Russian Acad of Sci, Moscow, Russia)*. Sov J Friction Wear 13(6) 1-7 (1992).

A numerical method is presented for analysis of isothermal elastohydrodynamic (EHD) problem at heavy loads. The method is based on quasi-linearization of the equation system for EHD contact. Numerical scheme makes it possible to determine a lubricant film thickness, exit location and pressure distribution, as well as to regularize the solution procedure, and to provide for the constancy of lubricant flow through the clearance. A numerical solution for isothermal heavily loaded EHD line contact with Newtonian lubricant was performed by using the method. The pressure distribution, lubricant film thickness, slip and roll tractions on the contact were obtained. A comparison shows that the Grubin formula underestimates significantly the film thickness under high load. The method permits to solve the problem for conditions of light and moderate loading.

9A673. Lubrication of a cylindrical synovial joint considering rolling motion and elastic incompressible cartilage. - M Hlavacek and D Vokoun *(Inst of Theor and Appl Mech, Czechoslovak Acad of Sci, Vysehradska 49, 12849 Prague 2, Czech Republic)*. Wear 165(1) 1-7 (May 1993).

In the analysis of lubrication of rolling cylinders with low modulus coatings, attention is drawn to elastic incompressible layers. The constrained column model (a simplified model where layer compression is assumed proportional to fluid pressure) fails for the Poisson ratio v of the layers close to 0.5. An approximate lubrication model is proposed for v = 0.5 and highly deformed coatings, ie for the low ratio of elastic layer thickness to fluid film length. This model does not result in a rigid differential equation for high loading as is the case with the constrained column model. The model is applied to the rolling motion of the human ankle joint.

9A674. Development of fracture resistant, multilayer films for precision ball bearings. - GB Hopple *(Lockheed Missiles and Space, PO Box 3504, Sunnyvale CA 94089-3504)*, JE Keem *(Ovonics Synthetic Mat, 1788 Northwood Dr, Troy MI 48084)*, SH Loewenthal *(Lockheed Missiles and Space, O/77-30 B/551, PO Box 3504, Sunnyvale CA 94089-3504)*. Wear 162-164(PART B) 919-924 (13 Apr 1993).

High density, sputtered MoS_2 films are being investigated as lubricants for the next generation of spacecraft bearings. Low bearing torque signatures and long life are the primary requirements of these films. Although multilayer (alternating MoS_2 with metal interlayers) films have exhibited relatively low wear rates (long lives) during laboratory testing using pin on disc-type testers, similar results have not been duplicated in actual precision ball bearings. Moreover, examination of bearing ball wear tracks on a race indicates little film remains intact even after relatively short period of bearing testing. The reason for this early loss of film appears to be associated with substrate surface roughness. Although these films worked well when used with a polished substrate, the high hardness and poor fracture toughness typical of these wear resistant films resulted in film delamination when applied to ground bearing race surfaces. In order to develop films that resist fracture associated with film ductility and substrate roughness, a specialized test that involved cycling a ball on a flat substrate was developed. Using this test combined with a scanning electron microscopy examination, dramatic differences in film fracture and delamination were observed between lapped and ground surfaces. Moreover, film fracture and delamination could be virtually eliminated on the ground surface by increasing the thickness of the metal layer in the film.

9A675. Mechanistic study of the synergism between Sb_2O_3 and MoS_2 lubricant systems using Raman spectroscopy. - JS Zabinski, MS Donley *(WL/MLBT, Mat Directorate, Wright Lab, WPAFB)*, NT McDevitt *(RAMSPEC Res, 4399 East Mohave Dr, Dayton OH 45431)*. Wear 165(1) 103-108 (May 1993).

A number of materials have been added to MoS_2 to improve its lubricating properties. However, the mechanism underlying this improvement is not fully understood. Perhaps the most widely used and studied additive is Sb_2O_3. While not a lubricant itself, it acts synergistically with MoS_2 to improve friction and wear properties. This paper is directed towards developing a better fundamental understanding of the synergism between Sb_2O_3 and MoS_2 in adhesively bonded films. A commercial preparation was used to form the films and laser Raman spectroscopy was used to analyze them before and after rubbing. It is shown that films layer as a result of tribostress – MoS_2 preferentially coats film surfaces and Sb_2O_3 becomes enriched in the next deeper layer. The mechanism proposed to explain the synergistic behavior is that only the thin layer of MoS_2 residing on top is exposed to degradation from the environment. The Sb_2O_3 layer acts as thermal and oxygen diffusion barrier to retard oxidation deeper into the film. Sb_2O_3 also acts as a beneficial support for MoS_2 as was demonstrated earlier by Centers (*Tribol Trans*, 31/32 (1987)149). The proposed mechanism suggests that protection is provided against tribo-oxidation but not necessarily thermal oxidation. To validate this concept, wear oxidation is evaluated in situ using a Raman tribotester and the results are compared with thermal oxidation data. Films containing Sb_2O_3 are indeed more resistant to tribo-oxidation than MoS_2 films. It is also shown that the transfer film surface is enriched with MoS_2. This indicates that friction is primarily governed by MoS_2 rubbing against MoS_2 and that Sb_2O_3 plays a secondary role.

9A676. Micromechanics of MoS_2 lubrication. - Chao Gao, L Bredell, D Kuhlmann-Wilsdorf, DD Makel *(Dept of Mat Sci, Univ of Virginia, Charlottesville VA 22901)*. Wear 162-164(PART A) 480-491 (13 Apr 1993).

The micromechanical behavior of MoS_2 acting as a solid lubricant and the effects of humidity thereon have been studied in moist nitrogen through simultaneous measurements of momentary friction and electrical contact resistance in the so-called hoop apparatus. The sliding couple consisted of the gold-plated copper substrate (the circumferential track inside the hoop) lubricated with a burnished MoS_2 film, and a slider in the form of three bundles of 50 μm thick gold-plated copper fibers. This geometry permits indirect detailed studies of the film conditions at the contact spots, since both the friction and the contact resistance are exclusively determined by the film. All measurements were found to be reversible, with the friction coefficient and contact resistance depending in a somewhat complex manner on average sliding speed between 0.05 and 3.0 cm s^{-1}, load between 0.5 N and 8 N, and relative humidity between 20% and 90%. The data indicate that adsorbed moisture causes the MoS_2 film to mechanically soften and that the film is partly pushed ahead to the sides of moving contact spots. As a result, the film thickness between the contact spots, presumably with the basal plane preferentially parallel to the interface, decreases with humidity but increases slightly with sliding speed and contact spot size, ie, load. Accordingly, the major part of the coefficient friction, namely $\mu_o \approx 0.1$ through distributed shearing of the MoS_2 film parallel to the basal plane, is little affected by any of the variables, but the contribution due to film plowing rises with increasing humidity from zero up to $\mu_P \approx 0.1$. The contact resistance, by contrast, varies through almost two orders of magnitude. It increases much faster than proportional with the film thickness at the a-spots, due to a strong increase of the MoS_2 resistivity with film thickness, on account of a semiconductor effect.

9A677. Wear reduction systems for coal-fueled diesel engines II. Experimental results and hydrodynamic model of powder lubrication. - Hooshang Heshmat *(Mech Tech, 968 Albany-Shaker Rd, Latham NY 12110)*. Wear 162-164(PART A) 518-528 (13 Apr 1993).

This paper is the second part of an investigation of the mechanism and performance of powder lubrication. In the first part of the investigation, the basic features of the quasi-hydrodynamic nature of particulate lubricants were conceptualized and the experimental setup for testing was described. In the tests described herein, load capacity, friction levels, and, most importantly, rates of wear were recorded for a wide range of operating conditions and various surface geometries, materials, and powder lubricants. The test results demonstrate the viability of powder lubrication. The results also corroborate the postulated quasi-hydrodynamic nature of particulate films. In addition, features specific to powder lubrication were brought to light, such as the onset of starvation with time, and the phenomenon of film adhesion. Based on these findings, design requirements for the proper functioning of practical powder-lubricated systems are described. Finally, a hydrodynamic model consisting of a mating surface, intermediate films, and a particulate lubrication film is presented. With these tools developed, analytical or semi-empirical relations should become available for the design of full-scale powder-lubricated tribosystems.

9A678. Ferrofluid lubrication of cylindrical rollers with cavitation. - P Sinha, P Chandra *(Dept of Math, Indian IT, Kanpur 208 106, India)*, D Kumar *(Dept of Math, Narmada Col of Sci and Tech, Bharuch, Gujrat, India)*. Acta Mech 98(1-4) 27-38 (1993).

This paper analyzes the ferrofluid lubrication of cylindrical rolls under combined rolling and normal motion. The analysis, which takes into account the rotation of magnetic particles, has been made for general cases where the magnetization vectors need not be parallel to the applied magnetic field. A perturbation scheme in terms of non-dimensional Brownian time relaxation parameter has been used and the effects of various parameters on bearing characteristics have been studied.

9A679. **Experimental approach to the calibration and use of triple hot-wire-probes.** - TJ Gieseke and YG Guezennec *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210).* Exp Fluids 14(5) 305-315 (Apr 1993).

A method of calibrating and extracting velocities from arbitrary geometry triple hot-wire probes has been developed and tested. The three-step procedure involves experimental determination of an accurate cooling law for each wire in the array, use of these models to develop a set of tables relating anemometer output to flow velocity input, and a table look-up procedure to extract the velocities. The functional form for the cooling law can be arbitrarily chosen and these equations are never directly inverted. Solutions are tabulated making use of special variable transformations that separate the dependence on flow angle and velocity magnitude. Errors in the table look-up procedure are commensurate with those in exact inversion techniques. Most of the error arises from accurate determination of the cooling laws. An application to turbulent boundary layer measurements is presented as an example of the use of the method.

9A680. **Development and application of a fast-response DC-coupled flame ionization current sensor.** - Z Hu, JR Laker, E Mastorakos, C Vafidis, HM Xu *(Dept of Mech Eng, Thermofluids Section, Imperial Col of Sci Tech and Med, Exhibition Rd, London SW7 2BX, UK).* Exp Fluids 14(5) 316-320 (Apr 1993).

The principles of the design of a fast-response DC-coupled ionization probe and associated electronic circuit are described for the measurement of the mean and fluctuating components of the ion concentration in the reaction zones of stationary and transient flames. The performance of the ionization probe is evaluated by bench tests and with measurements of ion current mean and fluctuating levels in laminar and turbulent premixed flames and in the combustion chamber of a spark ignition engine. The results demonstrate the wide frequency bandwidth, good spatial resolution and electronic noise immunity of the ionization probe, making it suitable for a host of combustion applications.

9A681. **Backscatter phase-Doppler anemometry for transparent non-absorbing spheres.** - Y Hardalupas and CH Liu *(Thermofluids Section, Mech Eng Dept, Imperial Col of Sci Tech and Med, London SW7 2BX, UK).* Exp Fluids 14(5) 379-390 (Apr 1993).

The application of phase-Doppler anemometer for scattering angles between the main rainbow and direct backscatter, was examined by calculating the spatial intensity distribution and the phase of the light scattered by a particle crossing the measuring volume. Geometrical optics was assumed and contributions to the scattered light due to reflection on the external surface of the particle and first internal reflection were considered. The response curve of the technique was calculated for different particle refractive indices, beam intersection angles, collection angles and spacings between the collection apertures. Linear response curves were obtained after integration of the intensity of the scattered light over sufficiently large rectangular collection apertures, but they become non-monotonic after a critical value of phase shift, which varied with the optical arrangement between around 220° and 360°, did not scale with common scaling parameters used for forward scatter light, and limited the possible size range of the instrument for one optical arrangement. The particle refractive index determined the collection angle and limited sizing to particles with little uncertainty in refractive index, since 5% change in refractive index led to uncertainties in size of the order of 100%. An alternative sizing technique is suggested for the backscatter region.

9A682. **Analysis of regenerative gas-turbine cycles.** - VY Tikhoplav, II Kirillov, TS Tikhoplav *(Energomash TurboMachinery Works, Leningrad).* Heat Transfer Res 24(3) 424-432 (Apr 1992).

The results of an analysis designed to define the optimum cycle of a gas turbine with regeneration are presented. The independent variables that define the dof of the various thermodynamic cycles are identified. The theoretical possibilities for optimizing the cycle parameters and layouts of gas turbines are defined. It is shown that the gas-turbine efficiency can be greatly improved over a wide range of pressure gains in the compressor.

9A683. **Availability accumulation and destruction in a DI diesel engine with special reference to the limited cooled case.** - CD Rakopoulos, EC Andritsakis *(Thermal Eng Section, Mech Eng Dept, Natl Tech Univ, 42 Patission St, Athens 10682, Greece),* DK Kyritsis *(Princeton).* Heat Recovery Syst CHP 13(3) 261-276 (May 1993).

This work develops a method for the calculation of both the irreversibility produced during combustion and the work medium availability at the end of the expansion process in a high speed, direct injection (DI), naturally aspirated, four-stroke diesel engine, on which experiments were conducted at the author's laboratory. The experimental data were processed for the determination of fuel reaction rates; the combustion irreversibility production rate was then computed from the fuel reaction rates via an analytical mathematical expression which was developed by the present research groups, based on the combined resolution of the first and second laws of thermodynamics. These calculations are applied for a wide range of measured loads, injection timings and engine rotational speeds; they are also expanded in the direction of intensity of the rate of heat transfer loss (to the engine cooling medium) for every combination of the experimentally determined engine variables. Therefore, apart from investigating the effect of various operating parameters on the availability balance, it is possible to evaluate the effect of the engine heat transfer reduction (limited cooled engine), from the second law analysis point of view, on the potential for efficiency improvements made by using the increased exhaust in heat recovery devices (eg, the exhaust turbine or Rankine bottoming cycle compounding).

9A684. **Derived thermodynamic design data for refrigeration and heat pump systems operating on HCFC-123.** - S Devotta and S Gopichand *(Chem Eng Div, Natl Chem Lab, Pune 411 008, India).* Heat Recovery Syst CHP 13(3) 213-218 (May 1993).

The current status of HCFC-123 as the alternative to CFC-11 in air-conditioning refrigeration and heat pump systems is reviewed. The theoretical Rankine coefficient of performance (COP) and the present ratios have been presented for heat pumps operating on HCFC-123. Composite plots between pressure ratio, theoretical Rankine coefficient for performance and (T_{CO} - T_{EW}) for the appropriate temperature ranges of T_{EV} and T_{CO} are presented for HCFC-123 for refrigeration and heat pump systems, respectively.

9T685. **Power and refrigeration plants for minimum heat exchanger inventory.** - A Bejan *(Dept of Mech Eng and Mat Sci, Duke Univ, Durham NC 27706).* J Energy Resources Tech 115(2) 148 (Jun 1993).

9A686. **Sliding pressure analysis using the second law.** - GE Weber *(Fossil Tech Services, Commonwealth Edison, 125 S Clark St, Rm 227, Chicago IL 60603)* and WM Worek *(Dept of Mech Eng MC 251, Univ of Illinois, PO Box 4348, Chicago IL 60680).* Heat Recovery Syst CHP 13(3) 253-260 (May 1993).

Over the last 20 years many technical papers have been written by manufacturers on the concept of reducing or sliding the turbine inlet pressure at lower loads to reduce frictional losses. This paper takes a unique look at why sliding pressure is needed using both the first and second laws of thermodynamics. The derived equations are applied to the flow of steam across a single valve and then applied to a simplified turbine control valve system. The optimal control point at which to initiate sliding pressure is analyzed. It is also shown that the optimal operating point is not when the second-law efficiency is maximum, but when the first-law efficiency is maximized.

9A687. **Thermodynamic properties of molecular hydrogen plasma in thermal and chemical nonequilibrium.** - Kuan Chen *(Dept of Mech Eng, Univ of Utah, Salt Lake City UT 84112)* and TL Eddy *(Natl Eng Lab, EG&G Idaho, Idaho Falls ID 83415).* J Thermophys Heat Transfer 7(2) 277-284 (Apr-Jun 1993).

A nonequilibrium plasma model is developed for computing the thermodynamic properties of partially ionized molecular hydrogen in both non-local thermal equilibrium (non-LThE) and non-local chemical equilibrium (non-LChE). The model uses multitemperatures for thermal non-equilibrium. Nonzero chemical affinities are used as a measure of the deviation from chemical equilibrium. It is found that a positive affinity of the recombination reaction or a decrease in plasma pressure will cause ionization to occur at lower temperatures, resulting in higher plasma enthalpy, internal energy, and entropy. Increase of the temperature of a particular energy mode also increases the total energy and entropy of the plasma, but the translational temperature play a dominant role in the temperature range considered.

9A688. Conjugate problem of unsteady heat transfer in laminar flow over a plate, assuming temperature-dependent physical properties of the fluid. - YI Shvets, OI Didenko, OD Lipovetskaya *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev)*. Heat Transfer Res 24(4) 433-439 (Apr 1992).

An iterationless method for the numerical solution of the unsteady conjugate problem of heat transfer with correction for the temperature dependence of thermophysical properties of the fluid is presented. Transfer of heat in both the flow and in the body is described by a single generalized equation, whose numerical analog was obtained by the control-volume technique. It is shown that the effect of variability of the properties is significant. It depends on the type of fluid and on the ratio of the thermal conductivities of the fluid and the body.

9A689. Coupling of conduction and forced convection past an impulsively started infinite flat plate. - A Pozzi, E Bassano *(Fac Ing, Inst Gasdin, Univ Naples, Italy)*, L de Socio *(Dipartimento di Mec ed Aeronaut, Univ of Rome, Italy)*. Int J Heat Mass Transfer 36(7) 1799-1806 (May 1993).

In this paper the unsteady coupling of conduction and convection for a thin body in a high speed stream is considered. The body is modeled as a strip on one side of which the fluid is impulsively started in motion whereas on the other side two different thermal boundary conditions are given: constant temperature or vanishing heat flux. In the first part of the analysis an approximate solution of the energy equation in the solid enables us to obtain relations between the temperature and the heat flux at solid-fluid interface which are more accurate than those currently used in the literature. In the second part the exact solution of the two problems that arise from the coupling of the thermofluid-dynamic equations and the relations between the temperature and its derivatives at the interface are presented.

9A690. Heat transfer and flow past a backstep with the nonlinear k-ε turbulence model and the modified k-ε turbulence model. - S Dutta and S Acharya *(Dept of Mech Eng, Louisiana State Univ, Baton Rouge LA 70803)*. Numer Heat Transfer A 23(3) 281-301 (Apr-May 1993).

This paper presents a comparative study of the standard k - ε model, the nonlinear k - ε model, and the modified k - ε model utilizing the double-pass procedure. The three models are used to predict the flow and heat transfer past a backstep, and the predictions are compared with selected experimental data. The comparison indicates that the modified and nonlinear k - ε models agree better with measurements than the standard k - ε model predictions.

9A691. Heat transfer in a turbulent boundary layer disturbed by means of a manipulator for breaking up large eddies. - Kyoji Inaoka, Kenjiro Suzuki, Hiroshi Suzuki, Hiroshi Kigawa *(Dept of Mech Eng, Kyoto Univ, Kyoto 606, Japan)*. Heat Transfer Japan Res 21(7) 705-720 (1992).

An experimental study was performed on a turbulent boundary layer disturbed by insertion of a single large eddy breakup manipulator. The skin-friction coefficient, heat-transfer coefficient, and averaged and fluctuating components of streamwise and cross-stream velocities were measured. A quadrant analysis was applied to the measured fluctuating velocity signals. The dissimilarity between the momentum transfer and heat transfer in this boundary layer is discussed in comparison with that found previously in a turbulent boundary layer disturbed by a cylinder.

9A692. Heat-transfer augmentation in a turbulent boundary layer disturbed by means of a vortex generator. - Kyoji Inaoka, Kenjiro Suzuki, Yoshimichi Hagiwara, Kazuyuki Suzuki *(Dept of Mech Eng, Kyoto Univ, Kyoto, 606, Japan)*, Hiroshi Suzuki *(Dept of Mech Eng, Hiroshima Univ, Japan)*. Heat Transfer Japan Res 21(7) 721-735 (1992).

An experimental study was conducted to determine if the deterioration in heat transfer caused by an insertion of a large eddy breakup manipulator (LEBU plate) could be recovered by attaching a half-delta-wing type vortex generator to the LEBU plate. The vortex generator was found to work well to augment the wall heat transfer over a large streamwise distance, although the LEBU plate itself is expected to eliminate the large-scale eddy motion in the boundary layer. Some geometric parameters of the inserted LEBU plate with the vortex generator attached were varied in several steps.

9A693. Analytical-numerical prediction of the 3D temperature variation in tubes having streamwise internal fins. - A Campo *(Col of Eng, Idaho State Univ, Pocatello ID 83209)* and JC Morales *(Dept of Mech Eng, Univ of Texas, Austin TX 78712)*. Numer Heat Transfer A 23(3) 319-339 (Apr-May 1993).

An analytical-numerical analysis is made of the hydrodynamic and heat transfer characteristics of a fluid flow through internal, longitudinal finned tubes. Employing control volume discretization in the cross section of the tube only, the 2D momentum equation is solved numerically, whereas the 3D energy equation is solved analytically. The pressure gradients are numerically determined, and the heat transfer rates, in terms of the tube length, are expressed in analytical form. The computational results are presented for different configurations corresponding to selected combinations of relative fin heights and the number of equally spaced fins in the array.

9A694. Developing laminar flow and heat transfer in a square duct with one-walled injection and suction. - GJ Hwang, YC Cheng *(Dept of Power Mech Eng, Natl Tsing Hua Univ, Hsinchu 300, Taiwan, ROC)*, ML Ng *(Energy and Resources Lab, Indust Tech Res Inst, Hsinchu 310, Taiwan, ROC)*. Int J Heat Mass Transfer 36(9) 2429-2440 (Jun 1993).

A numerical study was made to investigate the forced laminar convection in the entrance region of a square duct with one wall subjected to uniform mass transpiration and constant heat flux. Using the concept of pressure deviation and the vorticity-velocity method, the 3D Navier-Stokes equations and the governing energy equations were solved simultaneously. Results show that flow reversal occurs in the flow with strong suction. Typical velocity, pressure and temperature distributions along the flow direction are reported.

9A695. Effects of longitudinal vortex generators on heat transfer and flow loss in turbulent channel flows. - JX Zhu, NK Mitra, M Fiebig *(Inst Thermo- und Fluiddyn, Ruhr-Univ, D-4630 Bochum 1, Germany)*. Int J Heat Mass Transfer 36(9) 2339-2347 (Jun 1993).

The influences of four types of longitudinal vortex generators (delta wing, rectangular wing, delta wing pair and rectangular winglet pair) on heat transfer and flow loss in turbulent channel flows are investigated in the present work. A numerical solver of the Navier-Stokes equations, based on the MAC algorithm, has been extended with the k - ε turbulence model for this study. The results show that the longitudinal vortices produced by the vortex generators elevate significantly the level of turbulence kinetic energy in the flow and strongly disturb the thermal boundary layer.

9A696. Experimental investigations of heat transfer enhancement and flow losses in a channel with double rows of longitudinal vortex generators. - St Tiggelbeck, NK Mitra, M Fiebig *(Inst Thermo- und Fluiddyn, Ruhr-Univ, D-4630 Bochum, Germany)*. Int J Heat Mass Transfer 36(9) 2327-2337 (Jun 1993).

Flow structure, heat transfer, and drag by longitudinal vortices generated by double rows of delta wings in transient channel flow are investigated for the reduction of the gas side heat transfer resistance of compact heat exchangers. The experiments consist of flow visualization by laser light sheets, liquid crystal thermography for local heat transfer and balance measurements for drag. Angle of attack and channel Reynolds number have been varied. Aligned delta winglet double rows show higher heat transfer enhancement than staggered. The critical angle of attack for the formation of longitudinal vortices is smaller behind the second row than behind the first.

9A697. Experimental study of laminar entrance flow and heat transfer in finned tub annuli. - Shou-Shing Hsieh and Chang-Chun Lin *(Dept of Mech Eng, Natl Sun Yat-Sen Univ, Kaohsiung 80424, Taiwan, ROC)*. Int J Heat Mass Transfer 36(9) 2457-2471 (Jun 1993).

In this study, experiments were conducted to investigate the entrance effect of a double-pipe heat exchanger with isoflux inner finned tube. The geometry of the test section varied in fin pitch to height (p/e) ratios from 4 to 12, in fin width to height ratios (w/e) of 0.14 and 0.83, and with two inner diameter to outer diameter ratios (D_i/D_0) of 0.38 - 0.51. Reynolds number (Re) of the flow were 100 - 3000. Results are presented for a range of Reynolds number and for various values of the geometrical parameters. The experimental data were extracted and correlated in the form of Graetz number (Gz) to provide a thermal design basis for engineering application.

9A698. Heat and mass transfer analysis of developing turbulent flow in a square duct. - Hitoshi Sugiyama, Mitsunobu Akiyama *(Dept of Mech Syst Eng, Utsunomiya Univ, Japan)*, Katsuhiro Shibata *(Fuji Heavy Indust, Japan)*. Heat Transfer Japan Res 21(6) 601-614 (Apr 1992).

A numerical analysis has been performed on 3D developing turbulent flow in a square duct using a modified Reynolds stress model and a transport equation for the turbulent flux. Special attention was paid to the relation between the model constants and the Reynolds stress distribution and the developing process of the secondary flow of the second kind. Moreover, using a turbulent heat flux model, the mean Nusselt number was precisely predicted.

9A699. Hot spot locations and temperature distributions in a forced convection photochemical reactor. - Falin Chen *(Inst of Appl Mech, Natl Taiwan Univ, Taipei 10764, Taiwan, ROC)* and AJ Pearlstein *(Dept of Mech and Indust Eng, Univ of Illinois, 1206 W Green St, Urbana IL 61801)*. Int J Heat Mass Transfer 36(8) 2105-2114 (May 1993).

We have computed steady axisymmetric temperature distributions in a tubular photoreactor in which fluid in laminar flow absorbs light from an azimuthally uniform, radially incident light source. In addition to the primary on-axis temperature maximum, a second hot spot forms of the centerline as the optical density γ increases.

This results from a shift of light absorption toward the wall, which is held at a fixed temperature (eg, by forced convection cooling on the outside). At still larger γ the centerline hot spot disappears, leading to a decrease in the maximum temperature and accompanied by an increase in the temperature near the wall. The reduction in maximum centerline temperature may be advantageous for product selectivity and yield in the central core of the reactor, but may be disadvantageous with respect to the formation of light-absorbing deposits on the interior of the tube wall.

9A700. Numerical and experimental study of the forced convection inside a rotating disk-cylinder configuration. - X Ruiz, M Aguilo, J Massons, F Diaz *(Labs Fisica Aplicada Cristallografia Dept Quimica, Univ de Barcelona, 43005 Tarragona, Spain)*. Exp Fluids 14(5) 333-340 (Apr 1993).

In this paper, axisymmetric bulk flow patterns generated by moderate disk rotation and counter-rotation inside a coaxial disk-cylinder configuration with a fixed aspect ratio are obtained both experimentally and numerically. Experimental results are based on chronophotographic visualization and image processing techniques, while numerical results are computed using the full stationary Navier-Stokes equations assuming two different dynamic boundary conditions (no-slip and meridional free-slip) for all rigid walls. A comparative analysis between both numerical distributing and the patterns obtained experimentally is carried out in terms of streamfunction and vorticity meridional distributions.

9A701. Periodically developed flow and heat transfer in a ribbed duct. - S Acharya, S Dutta, TA Myrum, RS Baker *(Dept of Mech Eng, Louisiana State Univ, Baton Rouge LA 70803)*. Int J Heat Mass Transfer 36(8) 2069-2082 (May 1993).

Periodic fully developed flow and heat transfer results from a ribbed cut were obtained experimentally and numerically, using the nonlinear and standard k - ε turbulence model. Predicted recirculation lengths and maximum Nusselt number locations agreed well with the measured values. Both models performed poorly in the separated region just behind the ribs, where the Reynolds stresses were grossly underpredicted, the flow temperatures were overpredicted, and the mean velocity magnitudes were generally underpredicted. The local Nussel numbers were underpredicted by both models.

9A702. Transient conjugated forced convection heat transfer with fully developed laminar flow in pipes. - Kuan-Tzong Lee *(Dept of Mech Eng, Oriental IT, Pan-Chiao, Taipei 22064, Taiwan, ROC)* and Wei-Mon Yan *(Dept of Mech Eng, Hua Fan IT, Shih-Ting, Taipei 22305, Taiwan, ROC)*. Numer Heat Transfer A 23(3) 341-359 (Apr-May 1993).

This work deals with the problem of transient conjugated forced convection heat transfer with fully developed laminar flow in an infinitely long pipe, in which the external surface over a finite length of pipe is subject to a constant wall temperature. The effects are presented of Peclet number, ratios of pipe radii, wall-to-fluid diffusivity, and conductivity on the interfacial heat flux. The predicted results show that the unsteady heat transfer characteristics depend strongly on the ratios of outside and inside radii, wall-to-fluid conductivity, and thermal diffusivity.

402D. NATURAL CONVECTION (EXTERNAL)

9A703. Leading edge effect during transient buoyancy induced flow adjacent to a vertical cylinder. - K Velusamy *(Thermal Hydraul Section, Indira Gandhi Centre for Atomic Res, Kalpakkam 603 102, India)* and VK Garg *(NASA Lewis Res Center, MS 5-11, Cleveland OH 44135)*. Int J Heat Mass Transfer 36(7) 1853-1858 (May 1993).

The rate of propagation of the leading edge effect (LEE) during transient natural convection adjacent to a vertical solid cylinder is estimated from five differnt criteria. The cylinder has an appreciable thermal capacity and is subjected to a sudden heat generation. Numerical results are presented for a wide range of cylinder radii and heat flux values for two fluids, air and water. It is found that unlike the case of a flat plate, there is no unique criterion which would always estimate the fastest rate of propagation of LEE in water. Present results obtained by dropping the curvature terms in the governing equations match very well with previous analytical results for a flat plate.

9A704. Localized solutions of an equation governing Benard-Marangoni convection. - CI Christov *(Inst Nacional Meteorolgia, Ciudad Univ, Madrid, Spain)* and MG Velarde *(Fac Ciencias, Univ Nacional Educacion Distancia, Madrid, Spain)*. Appl Math Model 17(6) 311-320 (Jun 1993).

Provided here is numerical evidence of localized solutions, solitary waves, in a model equation for Benard convection driven by interfacial stresses (Marangoni effect).

402E. NATURAL CONVECTION (ENCLOSURES)

9A705. Analytical solution for transient laminar fully developed free convection in vertical concentric annuli. - MA Al-Nimr *(Dept of Mech Eng, Jordan Univ of Sci and Tech, Irbid, Jordan)*. Int J Heat Mass Transfer 36(9) 2385-2395 (Jun 1993).

Analytical solutions for transient fully developed natural convection in open-ended vertical concentric annuli are presented. Four fundamental boundary conditions have been investigated and the corresponding fundamental solutions are obtained. These four fundamental boundary conditions are obtained by combining each of the two conditions of having one boundary maintained at uniform heat flux or at uniform wall temperature with each of the conditions that the opposite boundary is kept isothermal at the inlet temperature or adiabatic. An expression for the transient Nusselt numbers is given for each case.

9A706. FE analysis of natural convection in horizontal concentric annuli. - Yasumasa Kato *(Res Lab of Asahi Glass Co Ltd, 1150 Matsubarg, Hazawa, Kanagawa-Ku, Yokohama 221, Japan)*, Takahiko Tanahashi *(Dept of Mech Eng, Keio Univ, Japan)*, Katsuya Ota *(Kajima Tech Res Inst, Japan)*. Heat Transfer Japan Res 21(7) 693-704 (1992).

In this paper, a simple FEM scheme is presented which simulates natural convection of incompressible viscous flow. The Navier-Stokes equations in rotational form with a buoyancy effect is simplified by the Boussinesq approximation. The main algorithm of the GSMAC method is employed to obtain time-dependent solutions. Natural convection in concentric horizontal annuli is investigated for various Rayleigh numbers in order to validate the present method. The temperature distributions obtained here are in good agreement with the experimental results.

9A707. Investigation of the temporal thermal performance of the wheel outboard of an aircraft. - CP Desai and K Vafai *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. J Thermophys Heat Transfer 7(2) 377-384 (Apr-Jun 1993).

Three-dimensional transient natural convection flow and heat transfer around the wheel outboard portion of an aircraft brake housing was investigated. The wheel outboard is modeled as an annular cavity with one end open to the ambient surroundings. The temporal development of the flow and temperature fields and its effect on the thermal performance of the brake housing outboard is discussed. The transient results are presented here by means of the velocity and temperature fields and the average Nusselt numbers over the different surfaces of the geometry.

9A708. Natural convection heat transfer in a 3D duct. - A Moutsoglou and MR Park *(Dept of Mech Eng, S Dakota State Univ, Brookings SD 57007)*. J Thermophys Heat Transfer 7(2) 369-376 (Apr-Jun 1993).

A computational analysis is conducted to investigate the 3D heat transfer and flow characteristics of laminar natural convection in a vertical duct, open to the ambient at the top and bottom and enclosed on all four sides. Detailed data are presented for air (Pr = 0.7) in a square duct heated-cooled isothermally or uniformly on one side with the remaining three walls assumed adiabatic. Numerical data are also obtained and presented for comparisons by way of a 2D channel flow approximation. The channel flow model that neglects the slowing down of the streamwise velocities due to the friction of the lateral walls predicts considerably higher local and average Nusselt numbers than the 3D analysis for a square duct. The numerical data are in good agreement with the experimental data of Elenbaas, Wirtz and Stutzman, and Sobel *et al*, but significantly underpredict the experimental data of Sparrow and Bahrami.

9A709. Natural-convection heat transfer in inclined rectangular enclosure. - Teruo Kimura, Masanori Takeuchi *(Fac of Eng, Fukui Univ, Japan)*, Toshiharu Miyanaga *(Graduate Sch of Eng, Fukui Univ, Japan)*. Heat Transfer Japan Res 21(6) 615-630 (Apr 1992).

The effects of thermal conductivity of an inner body on heat-transfer phenomena in an inclined rectangular enclosure have been studied both numerically and experimentally. In the numerical analysis, the ratio of thermal conductivity of the inner body to that of the working fluid was varied parametrically. The flow and temperature fields are presented in detail and the heat-transfer coefficient is discussed from these results. It is clarified here that the inner body with a large thermal conductivity enhances the heat transfer of the enclosure at large inclinations but suppresses the heat transfer for small inclination angles of the enclosure.

9A710. Resonance of natural convection in an enclosure heated periodically from the side. - JL Lage *(Dept of Mech Eng, S Methodist Univ, Dallas TX 75275-0335)* and A Bejan *(Dept of Mech Eng and Mat Sci, Duke Univ, Box 90300, Durham NC 27708-0300)*. Int J Heat Mass Transfer 36(8) 2027 (May 1993).

This is a numerical and theoretical investigation of natural convection in a 2D square enclosure with one side cold and isothermal, and the other side heated with pulsating flux. It is shown numerically that the buoyancy induced circulation resonates to a certain (single) frequency of the pulsating heat input. The resonance is characterized by maximum fluctuations in the total heat transfer rate through the vertical midplane of the cavity. It is shown that the critical frequencies determined numerically can be anticipated based on theoretical grounds, by matching the period of the pulsating heat input to the period of the rotation (circulation) of the enclosed fluid.

9A711. Thermal buoyancy and Marangoni convection in a two fluid layered system. - N Ramachandran *(Univ Space Res Assoc, NASA Marshall Space Flight Center, Huntsville AL 35812)*. J Thermophys Heat Transfer 7(2) 352-360 (Apr-Jun 1993).

Thermal buoyancy and surface tension driven convection is numerically investigated in a system with two immiscible fluids. The geometry investigated has an open cavity configuration with the lighter fluid situated on top of the heavier fluid, forming a stable layered system. The upper fluid meniscus and the interface are assumed to be flat and undeformable in the calculations. The governing equations and boundary-interface conditions are solved by a control volume-based finite difference scheme for two pairs of immiscible fluids; the water-hexadecane system and a so-called generic system. The steady-state calculations predict dramatically different flows when interfacial tension effects are included or excluded from the system model. These differences are particularly appreciable in surface tension-dominated flows, that are typical of microgravity situations. Complex flow patterns, with induced secondary flows, are noticed in both the fluids.

9A712. **Transient cooling of petroleum by natural convection in cylindrical storage tanks I.** Development and testing of a numerical simulator. - MA Cotter *(Automotive Parts Manufs' Assoc, 195 W Mall, Suite 516, Toronto M9C 5K1, ON, Canada)* and ME Charles *(Dept of Chem Eng and Appl Chem, Univ of Toronto, Toronto M5S 1A4, ON, Canada)*. Int J Heat Mass Transfer 36(8) 2165-2174 (May 1993).

The transient natural convection of a warm crude oil contained in a large vertical cylindrical storage tank loaded in a cold environment is investigated. The governing mass, momentum and energy conservation equations, utilizing the Boussinesq approximation for density, are solved numerically in stream function-vorticity form by employing a control volume finite difference method. A temperature-dependent apparent viscosity is employed to model the change in non-Newtonian fluid rheology that occurs with cooling. Good agreement is found between experimental and simulated temperature vs time cooling profiles for discrete locations in the tank.

9A713. **Transient cooling of petroleum by natural convection in cylindrical storage tanks II.** Effect of heat transfer coefficient, aspect ratio and temperature-dependent viscosity. - MA Cotter *(Automotive Parts Manufs' Assoc, 195 W Mall, Suite 516, Toronto M9C 5K1, ON, Canada)* and ME Charles *(Dept of Chem Eng and Appl Chem, Univ of Toronto, Toronto M5S 1A4, ON, Canada)*. Int J Heat Mass Transfer 36(8) 2175-2182 (May 1993).

The transient natural convection of a warm crude oil contained in a large vertical cylindrical storage tank located in a cold environment is investigated numerically. The effect of the external heat transfer coefficient is examined by using four different values. Increasing this parameter is found to increase the rate of heat loss as expected, but only a minor effect on the resulting fluid flow is found. The effect of the tank aspect ratio (height to radius) on the natural convection process is investigated by using four different aspect ratios ranging from 0.25 to 2.0, and is found to affect the flow patterns that develop. The effect of the fluid viscosity is examined for a tank aspect ratio of 0.5 by using five different apparent viscosity-temperature relationships.

402F. THERMALLY UNSTABLE CONFIGURATIONS

9A714. **Buoyant-thermocapillary ... es in medium-Prandtl-number flui... to a horizontal temperature** ... Parmentier, VC Regnier, G L... *Liege Univ, B5 Sart-Tilm... Belgium)*. Int J Heat Mass Transfer 36(9) 2417-2427 (Jun 1993).

Coupled buoyant and thermocapillary instabilities in a fluid layer of infinite horizontal extent bounded below a rigid plane and above by a free flat surface and submitted to a temperature gradient are investigated. A general 3D mathematical formulation is used to determine the linearized perturbated equations of the steady state induced by the temperature gradient. Numerical results are obtained in the case of a horizontal temperature gradient, lower and upper surfaces are adiabatically isolated and the range of the Prandtl number is selected as $[10^{-2}, 10]$. The presence of travelling rolls is exhibited.

9A715. **Convective instability in saturated porous enclosures with a vertical insulating baffle.** - Falin Chen and CY Wang *(Inst of Appl Mech, Natl Taiwan Univ, Taipei 10764, Taiwan, ROC)*. Int J Heat Mass Transfer 36(7) 1897-1904 (May 1993).

The convective instability in 2D enclosures containing a fluid-saturated porous medium with an insulating baffle extending vertically from the bottom boundary is investigated. The baffle influences the stability through its height and its horizontal problem. It is found, in general, that a taller baffle does not necessarily result in a more stable state, the optimum height of the baffle changes as its position varies; a baffle located at the middle or at a position with $\lambda = \sqrt{(k(k+1))}$, $k = 1, 2, \dots$, where λ accounts for the normalized distance from the baffle to the left wall, corresponds to a relatively more stable state; while a baffle coincides with a dividing streamline has no influence on the stability.

9A716. **Finite-amplitude instability of mixed-convection in a heated vertical pipe.** - BB Rogers and LS Yao *(Dept of Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287)*. Int J Heat Mass Transfer 36(9) 2305-2315 (Jun 1993).

The instability of flow in a heated vertical pipe is studied using weakly nonliner instability theory for both stably and unstably stratified cases. It is found that the dominant instability for stably stratified flow is a thermal-buoyant instability, while that of the unstably stratified case is a Rayleigh-Taylor instability. The results of the weakly nonlinear theory predicts supercritical instability for the stably stratified case, in agreement with experimental observations. In this case, it is found that a wide band of wave numbers are linearly unstable soon after the onset of the initial instability. The results of the weakly nonlinear calculations for unstably stratified flow indicate that the flow is potentially subcritically unstable, again in agreement with experimental observations. Analysis of energy transfer in the fundamental wave demonstrates that the thermal-buoyant instability is supercritical because increases in the viscous dissipation rate and the rate of transfer of energy from the fundamental wave back into the mean flow overcome the destabilizing effect of an increase in the rate of buoyant production.

9A717. **Stability of convective motion caused by inhomogeneous internal heat sources.** - AA Kolyshkin *(Dept of Appl Math, Riga Tech Univ, Riga 226010, Latvia)* and R Vaillancourt *(Dept of Math, Univ of Ottawa, Ottawa, ON, K1N 6N5, Canada)*. Arab J Sci Eng 17(4B) 655-662 (Oct 1992).

The stability of a convective fluid motion caused by inhomogeneous heat sources in a tall vertical annulus is investigated in this paper. Critical Grashof numbers are computed for different values of the ratio R of the internal to the external radii of the annulus, and Prandtl numbers for axisymmetric and asymmetric perturbations. Stability increases as the inhomogeneity of the heat sources increases. For strongly inhomogeneous heat sources, there is a transition from the axisymmetric to the asymmetric mode as the Prandtl number grows.

9A718. **Stability of plane Poiseuille flow with temperature dependent viscosity.** - P Schafer and H Herwig *(Inst Thermo- und Fluiddyn, Ruhr-Univ, 4630 Bochum, Germany)*. Int J Heat Mass Transfer 36(9) 2441-2448 (Jun 1993).

Classical linear stability theory is extended to include the effect of temperature dependent viscosity. This effect is studied asymptotically by using a Taylor series expansion of viscosity with respect to temperature. In its general form the asymptotic solution holds for all Newtonian fluids for which the temperature dependence of viscosity is the dominating variable property effect. A shooting technique with Gram-Schmidt orthonormalization for the zero-order equation (classical Orr-Sommerfeld problem) and a multiple shooting method for all other equations are applied to solve the stiff differential equations.

402G. COMBINED NATURAL AND FORCED CONVECTION

9A719. **Experimental studies of forced, combined and natural convection of water in vertical nine-rod bundles with a square lattice.** - MS El-Genk, Bingjing Su, Zhanxiong Guo *(Inst for Space Nucl Power Stud, Dept of Chem and Nucl Eng, Univ of New Mexico, Albuquerque NM 87131)*. Int J Heat Mass Transfer 36(9) 2359-2374 (Jun 1993).

Experiments of upflow- and downflow-forced turbulent and laminar convection natural convection and buoyancy-assisted combined convection of water are performed in uniformly heated, square arrayed, nine-rod bundles having P/D ratios of 1.25, 1.38 and 1.5. In the experiments, Re varies from 250 to 3×10^4, Pr from 3 to 9, Ra_q from 5×10^5 to 3×10^8 for natural convection and from 10^7 to 7×10^8 for combined convection, and Ri from 0.03 to 300. The heat transfer data are correlated in the respective convective regimes, where the heated equivalent diameter is used as the characteristic length in all dimensionless quantities and water properties are evaluated at the mean bulk temperature. A comparison with triangularly arrayed rob bundles shows that for the same flow area per rod, the rod arrangements negligibly affects Nu in both forced and natural convection regimes.

9A720. **Laminar mixed convection flow in a vertical tube.** - A Moutsoglou and YD Kwon *(Dept of Mech Eng, S Dakota State Univ, Brookings SD 57007)*. J Thermophys Heat Transfer 7(2) 361-368 (Apr-Jun 1993).

A computational study is conducted to quantify the buoyancy effects on laminar forced flow of air in a heated-cooled vertical tube. Buoyancy assisting and buoyancy opposing flow cases are considered for heating-cooling rates that provide either uniform wall temperature or uniform heat flux conditions. The nature of the observed effects of various heating-cooling rates and configurations on the velocity and temperature development, as well as on flow reversal, is explained. Critical buoyancy parameters that signal the onset of flow reversal, as well as axial locations where flow reversal first occurs, are determined in the study.

9A721. **Laminar mixed convection over horizontal flat plates with power-law variation in surface temperature.** - WR Risbeck, TS Chen, BF Armaly *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO)*. Int J Heat Mass Transfer 36(7) 1859-1866 (May 1993).

An analysis is performed to study the heat transfer characteristics of laminar mixed convective boundary-layer flow over a semi-infinite horizontal flat plate with non-uniform surface temperatures. The surface temperature is assumed to vary as a power of the axial coordinate measured from the leading edge of the plate. A nonsimilar mixed convection parameter X and a pseudo-similarity variable n are introduced to cast the governing boundary layer equations and their boundary conditions into a system of dimensionless equations which are solved numerically by a weighted finite-difference method. Numerical results are presented for Prandtl numbers of 0.1, 0.7, 7 and 100 and representative values of the exponent n for the power-law variation in wall temperature. It is found that an increase in the Prandtl number and exponent value n increases the local heat transfer rate.

9A722. **Measurements of laminar mixed convection in boundary-layer flow over horizontal and inclined backward-facing steps.** - HI Abu-Mulaweh, BF Armaly, TS Chen *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)*. Int J Heat Mass Transfer 36(7) 1883-1895 (May 1993).

Measurements and predictions of velocity and temperature distributions are presented for buoyancy-assisting mixed convection laminar boundary-layer flow over horizontal and inclined, 2D backward-facing steps. Laser-Doppler velocimeter and cold wire anemometer are used to measure simultaneously the velocity and the temperature distributions, respectively. The inclination angle, on the other hand, affects significantly the temperature and velocity distributions. As the inclination angle from the vertical increases, the local Nusselt number decreases, while the reattachment length and the location of the maximum Nusselt number behind the backward-facing step increase.

9A723. **Numerical analysis of mixed convection at the entrance region of a rectangular duct heated from below.** - U Narusawa *(Dept of Mech Eng, NE Univ, Boston MA 02115)*. Int J Heat Mass Transfer 36(9) 2375-2384 (Jun 1993).

An entrance region of a rectangular duct is examined numerically for a thermally-developing flow between a cooled top and heated bottom boundary. Based on the results, which agree well with previous experimental results, equations for the entrance lengths, L_1 for the onset and L_2 for the full development of mixed convection are proposed. Results on the effects of the sidewall thermal condition as well as the inlet gas temperature are also discussed in relation to thermal transport.

9A724. **Turbulence model of fire-induced air flow in a ventilated tunnel.** - H Xue *(Dept of Civil Eng, Natl Univ, 10 Kent Ridge Crescent, Singapore 0511)*, E Hihara *(Dept of Mech Eng, Univ of Tokyo, 7-3-1 Hongo Bunkyo-ku, Tokyo 113, Japan)*, T Saito *(Dept of Mech Eng, Univ of Tokyo, 70301 Hongo Bunkyo-ku, Tokyo 113, Japan)*. Int J Heat Mass Transfer 36(7) 1739-1748 (May 1993).

The fire-induced air flow in a ventilated tunnel with a local gas burner is investigated experimentally and numerically. To simulate the transient 3D turbulent buoyancy flow, calculations employ the turbulence k - ε model which is modified to take account of the effects of the mean streamline curvature. General curvilinear coordinates are generated for the computation. The prediction is compared with the experimental data and shown to be in reasonable agreement except the region close to the heat source. The present model can also be used to predict the location of the leading edge of the heated air flow.

402I. ROTATING FLUIDS OR SURFACES

9A725. **Effect of wall conduction in reactor wall on the heat and fluid flow in a rotating disk CVD reactor.** - FC Chou and SC Gong *(Dept of Mech Eng, Natl Central Univ, Chung-Li, Taiwan 32054, ROC)*. J Mat Processing Manuf Sci 1(4) 387-398 (Apr 1993).

The effect of conduction in the reactor wall on the steady, laminar, axisymmetric and circumferentially uniform flow and heat transfer in a rotating disk chemical vapor deposition reactor has been studied. The combined effects of buoyancy, rotating speed of the disk, reactor wall thickness and wall cooling rate have been considered. The primary parameters are the wall thickness parameter, the Biot number for convection cooling of the reactor wall, the disk Reynolds number and the Grashof number. It is found that whether the effect of wall conduction significantly affects the flow pattern in the reactor and heat transfer rate on the disk depends on the location of the recirculating vortex. When the vortex is above the disk, the effect of wall conduction is negligible, but if the vortex is near the reactor side wall, the effect of wall conduction cannot be neglected. Even under the frequently used "adiabatic" thermal boundary condition, the effect of wall conduction cannot be neglected in the cases of high rotating speed of the disk.

402K. HIGH SPEED FLOWS

9A726. **Study of a high-speed water jet in a jet-cutting mixing chamber.** - RS Amano, KF Neusen, T Gores *(Dept of Mech Eng, Univ Wisconsin, Milwaukee WI 53201)*. J Mat Processing Manuf Sci 1(4) 355-368 (Apr 1993).

A high-speed water jet is used in many industrial applications. This article presents a method for the computation of the flow in a water-air mixing chamber of a water jet cutting assembly by using a finite volume method. The turbulence model employed here is one based on the Reynolds-stress closure. In improving the computations of the Reynolds stresses, it was discovered that the closure models of the mean strain term of the pressure-strain correlation significantly affect the results in the separating flows. Thus, a tensor consisting of the products of the Reynolds stresses was set up in order to take non-isotropic turbulence into account. Computations have been performed using the above-mentioned method. Although the computations were performed for the present mixing chamber configuration, this method can be used for several different flow and geometric conditions to seek the optimum mixing chamber design of the water jet cutting technology. The results are compared with the experimental data obtained in this study. It was found that the present computational model successfully predicts the air suction rates in a water jet-abrasive mixing chamber.

402M. LIQUID METAL FLOWS

9A727. **Liquid-metal film protection of the reactor chamber first wall in a pulsed thermonuclear reactor.** - SA Berendeyev, VA Bernshtam, DN Kagan, SV Kozyrev, YV Poklonskiy *(Inst of Heat and Mass Transfer, Minsk, Russia)*. Heat Transfer Res 24(3) 333-339 (Apr 1992).

The possibility of using film flows of liquid metals to protect the reactor chamber first wall in a pulsed thermonuclear reactor are considered. To ensure a stable film flow, the use of a magnetic field is suggested. In order to estimate the instability development time, the governing relations obtained for flows without a field have been modified to account for the magnetic field. The magnetic field is shown to improve the characteristics of the film liquid-metal protection of the reactor chamber first wall.

9A728. **Thermogravitational effects on liquid metal heat transfer in a longitudinal magnetic field.** - SI Kovalyov and VG Sviridov *(Inst of Heat and Mass Transfer, Minsk, Russia)*. Heat Transfer Res 24(3) 354-365 (Apr 1992).

The heat transfer behavior of descending mercury flow in a heated tube in a gravity field and in the presence of a strong longitudinal magnetic field is investigated. The effect of thermogravitational convection on heat transfer under these conditions is revealed.

402O. UNSTEADY FLOWS

9A729. **Unsteady laminar natural-convection heat transfer in an enclosure with fins.** - Kengo Sasaguchi *(Dept of Mech Eng, Fac of Eng, Kumamoto Univ, 2-39-1 Kurokami, Kumamoto 860, Japan)*, Hiroyuki Takeo *(Hondo Co Ltd, Japan)*, Hiroyuki Kimura *(Nishinippon Railways Co Ltd, Japan)*. Heat Transfer Japan Res 21(7) 678-692 (1992).

The effects of aspect ratio, Prandtl number, and thermal conductivities of fins on 2D unsteady laminar natural convection in a rectangular cell surrounded by a vertical hot wall, a vertical insulated wall, and two horizontal conducting fins have been studied numerically using the SIMPLER algorithm. Transient velocity and temperature distribution, and timewise variation of the average Nusselt number on the hot wall are compared with those for a cell with nonconducting fins.

9A730. **Unsteady thermal processes accompanying transient flow.** - FI Kalbaliyev, ChM Verdiyev, FA Ragimov *(Russia)*. Heat Transfer Res 24(5) 625-640 (1992).

Experiment results on transient flow mixed convection heat transfer with $P > P_{cr}$, $t_i \le t_m \le t_w$ are given . Based on the heat flux and wall temperature, the oscillatory regime boundary has been determined depending on flow regime parameters and geometric dimensions of the tube. Computational formulae are presented. The presence of both normal and improved heat transfer regimes has been confirmed experimentally.

402P. TRANSPORT MECHANISMS

9A731. **Investigation of multiple stability of forced-flow cooled cryogenic conductors.** - Toshiyuki Amano, Akinori Ohara *(Central Res Lab, Mitsubishi Elec, Japan)*, Atsushi Kamitani, Masakazu Katagiri *(Fac of Eng, Yamagata Univ, Japan)*. Heat Transfer Japan Res 21(6) 556-572 (Apr 1992).

Concerning the behavior of stability margins of forced-flow cooled conductors, it is known experimentally that the multiple-stability regions for certain combinations of operation current, magnetic field, ambient helium pressure, and externally imposed helium flow appear. This work is a study of the mechanism of multiple stability and of the influence of heat transfer on multiple-stability margins by means of our own numerical code. It is obvious that the multiple-stability margins of forced-flow cooled conductors are due to the interaction between enhancement of heat transfer by heating-induced flow and increase of temperatures of conductors and ambient helium.

9A732. Lateral velocity fluctuations and dissipation time scale ratios for prediction of mean and fluctuating temperature fields. - PJ Gehrke and K Bremhorst *(Dept of Mech Eng, Univ of Queensland, QLD 4072, Australia)*. Int J Heat Mass Transfer 36(7) 1943-1952 (May 1993).

Further testing of a previously developed diffusivity-based model for predicting mean and fluctuating temperatures in water and liquid sodium flows downstream of a multi-bore jet block in which one jet is heated is performed but using air as the working fluid. The apparatus used enabled geometric similitude with the previous studies. It was found that the lateral turbulence intensity was a more effective velocity scale to use and a length scale based on lateral velocity fluctuations was more apt. The Prandtl number effect on temperature dissipation rates found previously in water and sodium is extended by the results using air, leading to a simple algebraic relation between the Prandtl number and dissipation time scale ratio. The non-isotropic nature of the flow is identified and is seen to influence the results.

9A733. Mathematical model of glass flow and heat transfer in a platinum downspout. - R Ducharme, P Kapadia *(Dept of Phys, Univ of Essex, Colchester CO4 3SQ, UK)*, F Scarfe *(Electroglass Ltd, 4 Brunel Rd Benfleet, Essex SS7 4PS, UK)*, J Dowden *(Dept of Math, Univ of Essex, Colchester CO4 3SQ, UK)*. Int J Heat Mass Transfer 36(7) 1789-1797 (May 1993).

The possibility of using a heat exchanger system to control the flow of glass through a platinum downspout is investigated. Downspouts are used in place of refractory throats since they avoid some of the problems associated with throats. It is assumed that the flow is predominantly axial and an integral expression for the flow field is obtained. The temperature distribution in the glass is calculated using the finite difference method. The formulation of the heat transfer problem includes a detailed analysis of the anisotropic radiation field in the glass.

9A734. Modelling of the homogeneous turbulence dynamics of stably stratified media. - BA Kolovandin, VU Bondarchuk *(AV Luikov Heat and Mass Transfer Inst, 220072 Minsk, Belarus)*, C Meola, G de Felice *(Fac Eng, Univ Napoli, Napoli, Italy)*. Int J Heat Mass Transfer 36(7) 1953-1968 (May 1993).

Numerical simulation of the dynamics of homogeneous turbulence of a stable stratified fluid in the presence of a vertical constant-density gradient was carried out. The second-order model which is universal with respect to turbulent Reynolds and Peclet numbers and molecular Prandtl number is applied to the numerical simulation of the dynamics of the velocity and density field parameters up to the final stage of decay. At small evolution times Nτ, the results of simulation are compared with the familiar experimental data.

9A735. Solidification of an aqueous salt solution in the presence of thermosolutal convection. - S Chellaiah, RA Waters, MA Zampino *(Dept of Mech Eng, Florida Int Univ, Miami FL 33199)*. Warme Stoffubertragung 28(4) 205-216 (Mar 1993).

The freezing of water-salt (sodium chloride) solution on a vertical wall of a rectangular cavity has been studied experimentally. The influence of thermally and solutally driven [illegible] vection on the freezing process ha[illegible] The spatial and temporal vari[illegible] ure in the solid, mush and [illegible] en recorded. The thermosolutal convective flow strongly influence the rate of freezing. Due to the continuous rejection of salt, a solutally stratified stable region developed at the bottom of the test cell. The thickness of this region increased with the progress of freezing and it was separated from the remaining bulk liquid, when convective flow was present, by a thin interface.

9A736. Thermocapillary breakdown of falling liquid films at high Reynolds numbers. - MS Bohn *(Natl Renewable Energy Lab, 1617 Cole Blvd, Golden CO 80401)* and SH Davis *(Dept of Eng Sci and Appl Math, NWU)*. Int J Heat Mass Transfer 36(7) 1875-1881 (May 1993).

This paper presents a new correlation in which the heat flux required to break a falling liquid film can be determined from the film Reynolds number. The correlation is based on the balance of local forces in the substrate region for high-Reynolds number films. Validation of the correlation required experimental data for breakdown of wavy liquid films at a significantly higher Reynolds number and heat flux than have been presented in the past. These data are also presented in this paper. The results show that the correlation collapses the experimental data for three liquids with widely varying physical properties at film Reynolds numbers up to about 10^4.

402S. POROUS MEDIA

9A737. Free and forced convection boundary layer flow through a porous medium with large suction. - MD Abdus Sattar *(Dept of Math, Dhaka Univ, Dhaka 1000, Bangladesh)*. Int J Energy Res 17(1) 1-7 (Jan 1993).

An analytical study is made of the free and forced convection boundary layer flow past a porous medium bounded by a semi-infinite vertical porous plate. Locally similar solutions are then obtained by a perturbation method for large suction. Solutions for the velocity and temperature distributions are shown graphically for various suction velocities and values of the driving parameter G_r/R^2_e, where G_r is the Grashof number and R_e is the Reynolds number. The corresponding values of the skin friction coefficient and the Nusselt number are finally shown in tabular form.

9A738. Free convection effects on the oscillatory flow of a couple stress fluid through a porous medium. - PS Hiremath and Pm Patil *(Dept of Math, Karnatak Univ, Dharwad 580 003, India)*. Acta Mech 98(1-4) 143-158 (1993).

Effects of free convection currents on the oscillatory flow of a polar fluid through a porous medium, which is bounded by a vertical plane surface of constant temperature, have been studied. The surface absorbs the fluid with a constant suction and the free stream velocity oscillates about a constant mean value. Analytical expressions for the velocity of the angular velocity fields have been obtained, using the regular perturbation technique. The effects of cooling and heating of a polar fluid compared to a Newtonian fluid have also been discussed. The velocity of a polar fluid is found to decrease as compared to the Newtonian fluid.

9A739. Mixed convection along a nonisothermal vertical flat plate embedded in a porous medium: The entire regime. - JC Hsieh, TS Chen, BF Armaly *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)*. Int J Heat Mass Transfer 36(7) 1819-1825 (May 1993).

The problem of mixed convection about a vertical flat plate embedded in a porous medium is analyzed. Nonsimilarity solutions are obtained for the cases of variable wall temperature (VWT) in the form $T_w(x) = T_\infty + ax^n$ and variable surface heat flux (VHF) in the form $q_w(x) = bx^m$. The entire mixed convection regime is covered by two different nonsimilarity parameters $X = [1 + (Ra_x/Pe_x)^{1/2}]^{-1}$ and $Xx = [1 + (Rax_x/Pe^{3/2}{}_x)^{1/3}]^{-1}$, respectively, for VWT and VHF cases, from pure forced convection (X = 1 or Xx = 1) to pure free convection (X = 0 or Xx = 0). It is found that as X or Xx decreases from 1 to 0, the thermal boundary layer thickness increases first then decreases, but the local Nusselt number in the form $Nu_x(Pe^{1/2}{}_x + Ra^{1/2}{}_x)^{-1}$ or $Nu_x(Pe^{1/2}{}_x + Rax\{1/3\}_x)^{-1}$ decreases first and then increases.

9A740. Momentum and heat transfer over a continuous moving surface in a non-Darcian fluid. - A Nakayama *(Dept of Energy and Mech Eng, Shizuoka Univ, 3-5-1 Johoku, Hamamatsu 432, Japan)* and I Pop *(Fac of Math, Univ of Cluj, R-3400 Cluj Cp 253, Romania)*. Warme Stoffubertragung 28(4) 177-184 (Mar 1993).

The momentum and heat transfer characteristics associated with the boundary layer on a continuous moving flat surface in a non-Darcian fluid have been investigated exploiting a local similarity solution procedure. The full boundary layer equations, which describe the effects of convective inertia, solid boundary, and porous inertia in addition to the Darcy flow resistance, were solved using novel transformed variables, deduced from a scale analysis on the momentum and energy conservation equations. Details are provided for the effects of convective inertia and porous inertia on the velocity and temperature profiles. The resulting friction and heat transfer characteristics are found to be substantially different from those of forces convection over a stationary flat plate.

402Y. COMPUTATIONAL TECHNIQUES

9A741. Arbitrary Lagrangian-Eulerian FE model for heat transfer analysis of solidification processes. - S Ghosh *(Dept of Eng Mech, Ohio State Univ, Columbus OH 43210)* and S Moorthy *(Dept of Mech Eng, Univ of Alabama, Tuscaloosa AL 35481)*. Numer Heat Transfer B 23(3) 327-350 (Apr-May 1993).

A heat transfer analysis for solidification problems has been conducted to evaluate the temperature field and the location of the phase-change interface. An arbitrary Lagrangian-Eulerian kinematic description has been utilized in the FE formulation to impart flexibility to the motion of the nodes. By detaching the nodal points from the underlying material, nodes can be monitored to follow the evolving front, while maintaining shapes of the elements. Special numerical techniques to smoothen the deforming front and to avoid continuous remeshing have been introduced. Numerical examples have been solved to establish the validity of the present model and its strength.

9T742. Current trends in heat transfer computations. - AF Emery, RJ Cochran *(Univ of Washington, Seattle WA 98195)*, DW Pepper *(Appl Res Projects, Moorpark CA 93021)*. J Thermophys Heat Transfer 7(2) 193-212 (Apr-Jun 1993).

9A743. Newton-based BEM for nonlinear convective diffusion problems. - BQ Li *(ALCOA Tech Center, 100 Tech DR, ALCOA Center PA 15069)*. Numer Heat Transfer B 23(3) 369-385 (Apr-May 1993).

A Newton-based BEM for the solution of nonlinear convective diffusion problems is presented. The problems are formulated through the use of the exponential transformation. The numerical procedures for the BE implementation of the formulation are discussed, and the treatment of nonlinear boundary conditions using the Newton-Raphson method is described in detail. Three numerical examples are provided. The results agree well with the analytical solutions whenever available. The method is free from numerical oscillations even for high Peclet numbers. The Newton-based iterative scheme, when integrated with the BEM, provides an efficient algorithm for the solution of nonlinear convective diffusion problems and is superior to the successive substitution approximation.

9A744. **Nonuniform grid accuracy test applied to the natural-convection flow within a porous medium cavity.** - DM Manole and JL Lage *(Dept of Mech Eng, S Methodist Univ, Dallas TX)*. Numer Heat Transfer B 23(3) 351-368 (Apr-May 1993).

The accuracy of numerical results obtained by using nonuniform grid distributions is strongly affected by the size of the grid spacing. The present work focuses on a detailed procedure for the accuracy tests of the numerical results obtained by using nonuniform grid distributions. It is shown that the degree of nonuniformity of a certain grid distribution with a fixed number of grid lines also has a strong effect on the numerical results.

9A745. **Solution of Navier-Stokes equations on non-staggered grid.** - AW Date *(Dept of Mech Eng, Indian IT, Powai, Bombay 400 076, India)*. Int J Heat Mass Transfer 36(7) 1913-1922 (May 1993).

When Navier-Stokes equations are solved on a non-staggered grid, the problem of checker board prediction of pressure is encountered. Over the last ten years, the problem has been cured by what is known as the momentum interpolation formula from which is applied for evaluation of the cell-face velocities. In this paper two contributions are made. Firstly it is shown that the momentum interpolation formula is a special case of a more general interpolation relationship that can be derived from a physical principle. In order to achieve unique interpolation practice, the second contribution of this paper relates to pressure-gradient interpolation. The results obtained from pressure-gradient interpolation compare extremely favorably with those obtained using staggered grid.

404B. NUCLEATE POOL BOILING

9A747. **Influence of surface wear on boiling heat transfer.** - YV Bogdanov and SG Obukhov. Heat Transfer Res 24(4) 440-446 (Apr 1992).

Experimental results on boiling heat transfer on new worn surfaces are presented. Distilled water in a free state at saturation temperature was used as a coolant. Stainless steel tubes were used in the experiments. The test elements were heated by alternating electric current.

9A748. **Unified model for the prediction of bubble detachment diameters in boiling systems I. Pool boiling.** - LZ Zeng, JF Klausner *(Dept of Mech Eng, Univ of Florida, Gainesville FL 32611)*, R Mei *(Dept of Aerospace Eng Mech and Eng Sci, Univ of Florida, Gainesville FL 32611)*. Int J Heat Mass Transfer 36(9) 2261-2270 (Jun 1993).

A new model is proposed for the prediction of vapor bubble departure diameters in saturated pool boiling. The model utilizes a force balance which follows a similar form as that used by Klausner *et al* for flow boiling. The vapor bubble growth rate is a necessary input to the model, and its reliable estimation is required to predict accurately departure diameters. It is demonstrated that over the wide range of boiling data considered the departure diameter predicted using the present model is significantly improved over existing correlations.

404E. NUCLEATE FLOW BOILING (EXTERNAL)

9A749. **Film boiling on a horizontal surface.** - VS Granovskiy, AA Sulatskiy, VB Khabenskiy, SM Shmelev *(Russia)*. Heat Transfer Res 24(5) 577-593 (1992).

Saturated liquid film boiling on a face-up horizontal surface is considered. Based on the stability loss condition for phase interface, an expression is obtained for the group which determines the heat transfer intensity. The final form of the expression is refined after correlation of experimental data. Two different mechanisms of bubble generation on the vapor film surface are analyzed which explain the character of the relation obtained.

9A750. **Unified model for the prediction of bubble detachment diameters in boiling systems II. Flow boiling.** - LZ Zeng, JF Klausner, DM Bernhard *(Dept of Mech Eng, Univ of Florida, Gainesville FL 32611)*, R Mei *(Dept of Aerospace Eng and Mech and Eng Sci, Univ of Florida, Gainesville FL 32611)*. Int J Heat Mass Transfer 36(9) 2271-2279 (Jun 1993).

An improved model is proposed for the prediction of departure and lift-off diameters in saturated force convection boiling. The model utilizes a force balance similar to that proposed by Klausner *et al.* One significant improvement is that the inclination angle is determined on a dynamic basis and is not required as an input. Furthermore, it is hypothesized that the surface tension force is small compared to other forces acting on a vapor bubble at the points of departure and lift-off, and thus information on the bubble contact diameter and contact angles is not required. A new data set on mean vapor bubble lift-off diameters and probability density functions (pdfs) for flow boiling of refrigerant R113 on a nichrome heating strip has been obtained using the experimental facility described by Klausner *et al.*

404F. FLOW BOILING (INTERNAL)

9A751. **Concentrations of phases and spectral characteristics of a two-phase flow in bilaterally heated steam generating channels.** - SM Dmitriyev, AA Abramov, YuI Anoshkin, MV Dmitrousov, VYe Kulikov *(Russia)*. Heat Transfer Res 24(5) 594-602 (1992).

The distribution of local quality in the cross section of channels with inner spiral tubes is investigated. A dimensionless relation for the gas quality of a gas-liquid flow depending on the flow rate parameters is obtained. The dependence of the effective frequency and of the time macroscales of gas quality fluctuations on flow regime and geometric parameters are presented.

9A752. **Investigation of postcritical heat transfer for R-12 forced flow through a horizontal tube.** - PV Konstantinov and VV Yagov. Heat Transfer Res 24(4) 447-456 (Apr 1992).

The paper presents the results of experimental investigation into R-12 forced flow heat transfer in a horizontal tube at pressures of 0.5 - 2.6 MPa and mass velocities of 1500 - 2000 kg/(m^{2}s).

9A753. **Limited heat loads and burnout heat transfer in one-sided heated channels.** - VA Divavin, VN Tanchuk, AE Shrubok *(Russia)*. Heat Transfer Res 24(5) 612-624 (1992).

A procedure is described for predicting limiting heat loads in a channel with one side heated, with cooling provided by subcooling water flow. The concept of local and overall burnout heat transfer is introduced for such one-sided loading. The effect of flow regime and operational parameters is investigated.

9A754. **Low-quality dryout in horizontal helical coiled tubes.** - Osamu Watanabe, Naomichi Heya *(Dept of Mech Eng, Aichi IT, Yagusa-cho, Toyota, Japan)*, Yasumitsu Ohmi *(Nippon Denso, Japan)*, Hideomi Fujita *(Dept of Mech Eng, Nagoya Univ, Japan)*. Heat Transfer Japan Res 21(7) 736-746 (1992).

An experimental study was carried out to clarify the low-quality dryout phenomena in helical coiled tubes placed horizontally. The results obtained were as follows. (1) Low-quality dryout is caused by the separation of the liquid and vapor phases and it disappears at the transition from the separated flow to the slug flow regime. (2) Low-quality dryout generally takes place in the lower portion of a non-vertically placed helical coiled tube. (3) A criterion for the disappearance of low-quality dryout has been proposed based on the experiment.

9A755. **Mechanism of enhancement of heat and mass transfer in a vapor-generating channel with a transverse microfin roughness.** - YF Domashev, VF Godunov, GY Struchenko *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(4) 465-470 (Apr 1992).

The physics of the interaction of a micro-finned heated wall and the flow under different boiling conditions are explained, and the conditions for the break off of vapor bubbles in vortical flow zones are analyzed. It is shown that microfins that induce turbulence in only a thin layer are the most efficient in raising the critical heat flux density in emulsion and dispersed-annular flows.

9A756. **Pressure drop in steam-generating channels.** - VG Antipov *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(4) 457-464 (Apr 1992).

Experimental results on pressure drop in steam-water flows in heated channels ar presented. An expression for calculating irreversible pressure losses in a steam-generating pipe operating at pressures from 40 to 140 bar, mass velocities between 200 and 1250 kg/m^2-sec and average void fractions of 0 to 0.8 is suggested.

9A757. **Stability of stratified flow and its transition to other flow regimes.** - LN Persen *(Inst Mekanikk, Univ Trondheim, NTH 7034 Trondheim, Norway)*. Int J Heat Mass Transfer 36(7) 1969-1980 (May 1993).

Stratified two-phase flow in circular pipes has been tested extensively in the literature. The proposed presentation is based on the author's own paper which has the advantage of explicitly expressing the influence of the five parameters that govern the physical process. The investigation will show how the normal depth is determined, that it may be single-valued or double-valued, whereby the possibility of hydraulic jumps is present. It will be shown under what conditions the normal depth is stable or unstable. In particular it will be shown how pipeline geometry will affect the flow. Downward sloping pipelines in the direction of the flow will be discussed in detail. Upward sloping pipelines will also be discussed but in that case the stability of the flow may be overruled by geometrically induced slug flow.

9A758. **Subcooled convective boiling of binary mixtures over an array of heated elements.** - WR McGillis and VP Carey *(Dept of Mech Eng, UCB)*. J Thermophys Heat Transfer 7(2) 346-351 (Apr-Jun 1993).

Boiling data and the critical heat flux conditions are reported for both channel flow and jet impingement flow using varying concentrations of R-11 and R-113. An array of 10 flush-mounted heated elements on one wall of a vertical passage was cooled by subcooled boiling. Data indicate that for channel flow boiling, the addition of R-11 and R-113 does not produce a significant change in the critical heat flux condition. For channel flow boiling, the data indicate that addition of a small amount of a less volatile component slightly increased the critical heat flux, whereas, the addition of a small amount of a more volatile component decreased it. The critical heat flux data for channel flow were also found to agree well with critical heat flux correlations for pure fluids if the mole-weighted mean properties of the mixture were used to compute the critical heat flux from the pure fluid correlation. The significance of the findings of this study with regard to the use of the binary mixtures of dielectric fluids for immersion cooling of electronic components is discussed in this article.

404G. FLOW BOILING, PEAK HEAT FLUX (INTERNAL)

9A759. **Burnout heat transfer in steam generating channels under steady and unsteady conditions.** - II Gromova and VN Smolin *(Russia)*. Heat Transfer Res 24(5) 603-611 (1992).

The burnout heat transfer in curvilinear steam generating channels under steady and unsteady-state conditions and on exposure to a magnetic field is studied. Formulae are suggested for calculating the critical power of the channels.

9A760. **Critical heat flux measurements in a round tube for CFCs and CFC alternatives.** - RM Tain, SC Cheng *(Dept of Mech Eng, Univ of Ottawa, ON K1N 6N5, Canada)*, DC Groeneveld *(Chalk River Lab, Atomic Energy of Canada, Chalk River, ON K0J 1J0, Canada)*. Int J Heat Mass Transfer 36(8) 2039-2049 (May 1993).

Critical heat flux (CHF) measurements have been conducted for HFC-134a, HCFC-123, HCFC-22, CFC-12 and CFC-11 in a multi-fluid loop. The test pressures are up to 2 MPa (corresponding to water equivalent pressure of 7 - 10 MPa) and mass fluxes from 1000 to 4000 kg m^{-2} s^{-1}. The heated length is adjustable from 0.5 to 1 m, the ID of the tubular test section is 4.2 mm, and the critical quality varies from 0.07 to 0.6. The parametric trends of test results are examined and the test results show good agreement with existing CHF prediction methods.

9A761. **Dryout fluxes in annuli with nonuniformly heated inner pipes.** - AM Kichigin and AA Moskalenko *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(4) 471-478 (Apr 1992).

Experimental results on dryout flux densities in flow of water in an 14 mm-8mm annulus, in which the inner tube is heated are described. The heat flux distribution was made to increase or decrease toward the exit. The longitudinal heat release nonuniformity factor was 1.85 to 0.54, respectively, in these two cases. The pressure was 19.6 MPa and the mass velocities were 500 and 2000 kg/m^2-sec. A minimal effect of longitudinal variation of heat release on q_{cr} was found.

9A762. **Effect of turbulence generators on the critical dryout heat flux density in annuli.** - AM Kichigin, SG Povsten', AV Ostapenko *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(3) 408-414 (Apr 1992).

Experimental results on the effect of turbulence generators (promoters on the critical heat flux density q_{cr} are presented. The experiments were performed at 14.7 and 19.6 MPa and a mass velocity of 1000 kg/m^2-sec, the fluids being subcooled water and aqueous fluid with steam qualities x as high as 0.3. The semicircular, 0.5 mm high bumps used as turbulence generators were spaced 7 to 30 mm apart and were installed on the outer, non-heated side of the annulus. We found only minor enhancement of q_{cr} by the turbulence promoters.

404I. FILM BOILING (POOL)

9A763. **Numerical study of liquid film cooling along an inclined plate.** - WM Yan *(Dept of Mech Eng, Hua Fan IT, Shih Ting, Taipei 22305, Taiwan, ROC)* and CY Soong *(Dept of Aeronaut Eng, Chung Cheng IT, Tahsi, Taoyuan 33509, Taiwan, ROC)*. Warme Stoffubertragung 28(4) 233-241 (Mar 1993).

A numerical method of analyzing liquid film cooling along an inclined plate is presented. A marching procedure is employed for solution of the equations of mass, momentum, energy and concentration in the flow. Results for heat and mass transfer characteristics are presented for air-water system. The effect of the inclined angle ϕ, free-stream temperature T_∞, free-stream velocity u_∞, and inlet film thickness δ on the heat and mass transfer along the gas-liquid interface are examined in detail. Results show that an increase in free-stream temperature and velocity causes an increase in interfacial temperature while an increase in inclined angle and inlet film thickness causes a reduction in interfacial temperature.

404K. MIST FLOWS

9A764. **Study on transient characteristics of mist-cooling heat transfer from a horizontal upward-facing surface.** - Hidetoshi Ohkubo and Shigefumi Nishio *(Inst of Indust Sci, Univ of Tokyo, Japan)*. Heat Transfer Japan Res 21(6) 543-555 (Apr 1992).

The effects of cooling rate and thermal conductivity of a heat-transfer plate on mist-cooling heat transfer were investigated experimentally for the high-temperature regions. Experiments were conducted for horizontal upward-facing surfaces made of silver, stainless steel, and fused quartz. It was found that, in the case where the horizontal surfaces face upward, the thermal properties of surface material does not significantly affect the heat-transfer coefficient, but the cooling rate of the surface affects it if the heat capacity of the surface is less than a critical value.

404M. CONDENSATION (STATIC VAPOR)

9A765. **Microscope observations of the initial droplet formation mechanism in dropwise condensation.** - Tadao Haraguchi *(Fac of Eng, Ibaraki Univ, Japan)*, Ryohachi Shimada, Toshiro Takeyama *(Fac of Sci and Eng, Ishinomaki Senshu Univ, Japan)*. Heat Transfer Japan Res 21(6) 573-585 (Apr 1992).

Initial droplet formation in dropwise condensation is one of the important mechanisms for nucleation in phase-change phenomena. Film-fracture hypothesis has been proposed by other researchers and they have estimated the film thickness. But they could not observe the initial droplet formation. Here three experimental studies based on microscopic observations were performed. The authors observed that dropwise condensation nuclei were grown from a very thin film. Film thickness was from 0.1 μm to 0.3 μm and critical droplet size was from 0.8 μm to 1.3 μm. Critical droplet site densities of 1.4 - 2.8 • 10^7 sites/cm^2 were found.

404O. EVAPORATION

9A766. **Binary diffusion and heat transfer in mixed convection pipe flows with film evaporation.** - Wei-Mon Yan *(Dept of Mech Eng, Hua Fan IT, Shih Ting, Taipei 22305, Taiwan, ROC)*. Int J Heat Mass Transfer 36(8) 2115-2123 (May 1993).

A detailed numerical study has been performed to investigate the heat and mass transfer characteristics in laminar mixed convection pipe flows with film evaporation. Both the thermal conditions of constant wall temperature and uniform heat flux are considered. Results for interfacial Nusselt and Sherwood numbers are presented for air-water and air-ethanol systems for various conditions. Predicted results show that heat transfer along the gas-liquid interface is dominated by the transport of latent heat in association with the vaporization of the liquid film.

9A767. **Critical flow and heat transfer in field evaporator pipes.** - MK Bezrodnyy and YV Antoshkov *(Kiev Polytech Inst, Kiev)*. Heat Transfer Res 24(4) 543-548 (Apr 1992).

Relationships governing the flow and heat transfer in a steam-heated field evaporator pipe are derived on the basis of experimental data. Correlations for limits of operating stability of such a pipe are presented.

9A768. **Diffusion controlled evaporation of multicomponent droplet: Theoretical studies on the importance of variable liquid properties.** - R Kneer, M Schneider, B Noll, S Wittig *(Lehrstuhl Inst Thermische Stromungsmaschinen, Univ Karlsruhe (TH), Kaiserstr 12, W-7500 Karlsruhe, Germany)*. Int J Heat Mass Transfer 36(9) 2403-2415 (Jun 1993).

A well-known multicomponent droplet vaporization model, the Diffusion Limit Model, has been extended to account for property variations in the liquid phase. The model has been tested for typical conditions of modern gas turbine combustors. The results for a hexane-tetradecane droplet show that the temperature- and concentration-dependence of the liquid properties affect the vaporization process, especially with regard to a reduced diffusional resistance. Additionally, remarkable variations of the refractive index are observed yielding helpful information for the estimation of errors in optical particle sizing techniques.

9A769. **Heat transfer characteristics of a cranked, evaporative thermosyphon.** - GSH Lock and Jialin Fu *(Dept of Mech Eng, Univ of Alberta, Edmonton T6G 2G8, AB Canada).* Int J Heat Mass Transfer 36(7) 1827-1832 (May 1993).

The paper presents an exploratory study of an offset, evaporative thermosyphon. Laboratory experiments using a small bore rig were conducted for a cranked configuration with the evaporator and condenser aligned vertically. Heat transfer data revealed similarities with the equivalent linear system but also showed up some differences. The heat transfer rates were found to be much higher than those obtained under single-phase conditions. On the other hand, critical heat fluxes were much lower than in the equivalent linear system.

9A770. **Maximum heat-transferring capacity of two-phase thermosiphons with separate vapor and condensate streams.** - IL Pioro *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine).* Heat Transfer Res 24(4) 535-542 (Apr 1992).

Experimental results on the effects of the geometry of the evaporator, the slope of the thermosiphon and the circulation velocity on the maximum heat flux in boiling of water in two phase straight-through thermosiphons, and also photographs of the boiling of water in a rectangular channel are presented.

9A771. **Molecular dynamics study of solid melting and vaporization by laser irradiation.** - Susumu Kotake and Masatugu Kuroki *(Dept of Mech Eng, Univ of Tokyo, Hongo, Tokyo 113, Japan).* Int J Heat Mass Transfer 36(8) 2061-2067 (May 1993).

The molecular processes of the phase change of melting and vaporization of solid materials by laser beam irradiation were studied numerically by using the molecular dynamics method. By absorbing the laser light energy, the solid atoms or molecules are excited in the interatomic or intermolecular potential energy to change their interacting forces. The resulting Hamiltonian equations of atomic or molecular motions are solved with the molecular dynamics method to understand the molecular behavior of the phase changing process. The excitation strength, that is, the laser energy of irradiation has the most predominant effect on the phase change of vaporization and melting.

404R. SOLID-FLUID FLOWS

9A772. **Modelling of the effect of turbulent two-phase flow friction decrease under the influence of dispersed phase elements.** - LV Zakharov, AA Ovchinnikov, NA Nikolayev *(Mech Fac, Kazan Inst of Chem Eng, Kazan 420015, Russia).* Int J Heat Mass Transfer 36(7) 1981-1991 (May 1993).

Consideration is given to the problem concerning the interaction of a continuous turbulent flow with a dispersed impurity uniformly distributed in it with the account of the involvement of particles into energy-intensive fluctuations of the continuous medium. Correlations are obtained relating the drag reduction in the turbulent two-phase flow to the size of particles and dispersed phase concentration. The limitations are established which should be imposed on the concentration size of particles to attain the regime of reduced drag in a two-phase turbulent flow.

9A773. **Numerical method for direct contact melting in transient process.** - Hiki Hong and Akio Saito *(Dept of Mech Eng, Tokyo IT, O-okayama 2-12-1 Meguro-ku, Tokyo 152, Japan).* Int J Heat Mass Transfer 36(8) 2093-2103 (May 1993).

Most of the research on direct contact melting has been carried out on the assumption of steady state or quasi-steady state. Such a methodology, however, is difficult to apply to problems in which the boundary conditions such as the temperature of heating plate or the external force exerted on the solid PCM change abruptly with time. In this study, we show an efficient algorithm to solve the transient behavior of direct contact melting, considering the solid movement by external forces exerted on a solid body as well as that by melting. The result shows good agreement with that by the previous steady state approach, and it is assured that the behavior during the transient process to steady state is very reasonable in a viewpoint of a physical phenomenon.

9A774. **Unsteady heat transfer to pulsatile flow of a dusty viscous incompressible fluid in a channel.** - N Datta, DC Dalal *(Dept of Math, Indian IT, Kharagpur 721 302, India),* SK Mishra *(Balimela Col of Sci and Tech, Balimela 764 051 Orissa, India).* Int J Heat Mass Transfer 36(7) 1783-1788 (May 1993).

The problem of unsteady heat transfer to pulsatile flow of a dusty fluid in a parallel plate channel has been studied. It is observed that the unsteady part of the fluid velocity as well as of the particle phase velocity has a phase lag which increases with increase of ϕ, ie, the volume fraction of the particles. The steady part of the heat transfer at the hotter plate decreases with increase of ϕ whereas it increases with increase of ϕ at the colder plate. The amplitude of the unsteady part of the heat transfer at both the plates decreases with increase of ϕ.

404Y. COMPUTATIONAL TECHNIQUES

9T742. Current trends in heat transfer computations

404Z. EXPERIMENTAL TECHNIQUES

9A775. **Ultrasonic imaging and velocimetry in two-phase pipe flow.** - SL Morris and AD Hill *(Dept of Pet Eng, Univ of Texas, Austin TX 78712).* J Energy Resources Tech 115(2) 108-116 (Jun 1993).

This paper presents the first results of an experimental and theoretical investigation of the feasibility of using ultrasonic measurements in multiphase pipe flow. Extant downhole flow rate measurement technology used in the petroleum industry is not adequate in some multiphase flow regimes, particularly when the well is deviated from vertical. Ultrasonic offers Doppler velocity and imaging capabilities, both of which could be of great value in production logging. Some air-water measurements, both imaging and velocimetry, are presented, along with a discussion of pulsed Doppler theory.

406. Conduction

406A. GENERAL THEORY

9A776. **Engineering assessment to the relaxation time in thermal wave propagation.** - Da Yu Tzou *(Dept of Mech Eng, Univ of New Mexico, Albuquerque NM 87131).* Int J Heat Mass Transfer 36(7) 1845-1841 (May 1993).

The physical significance of the relaxation time in the wave theory of heat conduction is further studied in this work. Thermodynamically, it is confirmed that the relaxation time results from the rate-equation within the mainframe of the second law in the nonequilibrium, irreversible thermodynamics. Mechanically, on the other hand, the relaxation time results from the phase-lag between the heat flux vector and the temperature gradient in a high-rate response. In transition from a diffusion behavior to the wave propagation, lastly, the relaxation time is found to be the physical instant at which the intrinsic length scales merge with each other.

9A777. **Modified Fourier law. Comparison of two approaches.** - VA Cimmelli *(Dipartimento Matematica, Univ Degli Studi Della, Basilcata, Potenza, Italy),* W Kosinski *(Inst of Fund Tech Res, Polish Acad of Sci, Warszawa, Poland),* K Saxton *(Dept of Math Sci, Loyola Univ, New Orleans LA).* Arch Mech 44(4) 409-415 (1992).

The objective of this note is to compare two different models leading to modified Fourier laws. The first model uses the concept of semi-empirical temperature, the second one is built in the framework of extended thermodynamics. For both approaches three experimental curves, namely the specific heat, heat conduction coefficient and second sound speed, all given in terms of the absolute temperature, determine the models. Conditions under which both models lead to similar results are formulated.

406B. STEADY PROBLEMS

9A778. **Steady-state heat transfer from horizontally insulated slabs.** - M Krarti *(Joint Center for Energy Man, CEAE Dept, Univ of Colorado, Boulder CO 80309-0428).* Int J Heat Mass Transfer 36(8) 2135-2145 (May 1993).

A general solution for the steady-state heat conduction problem under a slab-on-grade floor with horizontal insulation is presented. The soil temperature field, the heat flux along the slab, and the total slab heat loss are obtained and analyzed using the Interzone Temperature Profile technique. The derived solution addresses all the common configurations for horizontal insulation of slab-on-grade floors. The effect of the outer inner edge insulation on heat flux variation along the slab floor surface and on total slab heat loss is discussed and analyzed.

9A779. **Steady-state heat transfer from slab-on-grade floors with vertical insulation.** - M Krarti *(Joint Center for Energy Man, CEAE Dept, Univ of Colorado, Boulder CO 80309-0428).* Int J Heat Mass Transfer 36(8) 2147-2155 (May 1993).

The steady-state temperature field distribution beneath a vertically insulated slab is derived using the Interzone Temperature Profile Estimation technique. A water table is considered at a finite depth below the soil surface. The heat flux variation along the slab is discussed as well as the effect of vertical insulation length and value on the total heat losses from the slab-on-grade floor. It is shown that when the depth and or the thermal resistance of the vertical insulation increases, slab heat loss decreases following the law of diminishing returns. The water table level was found to have a significant effect on total slab heat loss.

406C. TRANSIENT PROBLEMS

9A780. Some analytical solutions of time-dependent, continuously operating heat sources. - SM Zubair *(Dept of Mech Eng, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)* and MA Chaudhry *(Math Sci Dept, King Fahd Univ of Pet and Minerals, Dhahran 31261, Saudi Arabia)*. Warme Stoffubertragung **28**(4) 217-223 (Mar 1993).

The amount of heat released in a volume whose extent can be ignored as compared with the dimensions of the surroundings of interest, may be classified as (i) the point-heat source, (ii) the line-heat source, and (iii) the plane-heat source. The temperature solutions of these transient conduction problems in an extended, homogeneous, and isotropic medium, are discussed in closed form. It is found that the present analysis covers well known (classical) solutions as well as some new solutions.

9A781. Unsteady thermal analysis of an injection mold by the BEM. - Satoru Yamamoto, Takaaki Matsuoka, Yoshinori Inoue, Hideroh Takahashi *(Toyota Central R&D Labs, 41-1 Aza Yokomichi, Oaza Nagakute, Nagakute-cho, Aichi-gun, Aichi 480-11, Japan)*. Heat Transfer Japan Res **21**(7) 666-677 (1992).

An unsteady thermal analysis program has been developed to simulate transient heat transfer of molds in computer-aided engineering for injection molding of thermoplastics. The 3D unsteady thermal conduction equation is solved by using the BEM. Heat flux on the cavity and the runner during the cooling stage, which is calculated from 1D thermal analysis by using the finite-difference method, is taken into consideration as boundary conditions. Mold temperatures were calculated for the mold of a box-shaped part and were compared with experimental results. The calculated mold temperatures were in good agreement with the experimental ones during injection molding.

406E. CONTACT RESISTANCE

9A782. Inverse problem of estimating interface conductance between periodically contacting surfaces. - HRB Orlande *(N Carolina State Univ, Raleigh NC 27695)* and MN Ozisik *(Mech and Aerospace Eng Dept, N Carolina State Univ, Raleigh NC 27695)*. J Thermophys Heat Transfer 7(2) 319-325 (Apr-Jun 1993).

The conjugate gradient method of minimization with adjoint equation is used to solve the inverse problem of estimating the timewise variation of interface conductance between periodically contracting solids, under quasisteady-state conditions. It is assumed that no prior information is available on the functional form of the interface conductance, except the magnitude of the period. The accuracy of the inverse analysis is examined by using simulated inexact temperature measurements obtained at the interior of the region. Small periods are usually the most difficult on which to perform an inverse analysis. For such cases, the present method is found to be more accurate and stable then the B-Spline approach.

9A783. Thermal contact conductance of a phase-mixed coating layer by transitional buffering interface. - KC Chung, JW Sheffield, HJ Sauer Jr *(Dept of Mech and Aerospace Eng, Univ of Missouri, Rolla MO 65401)*, TJ O'Keefe *(Dept of Metal Eng, Univ of Missouri, Rolla MO 65401)*, A Williams *(Dept of Mech Eng, Monash Univ, Melbourne, Australia)*. J Thermophys Heat Transfer 7(2) 326-333 (Apr-Jun 1993).

The thermal contact conductances of metallic joints having phase-mixed coating layers applied by a novel transitional buffering interface technique was investigated. This study is restricted to relatively low contact pressure and to microhardness (P/H) ratios, $10^{-4} < P/H < 6 \times 10^{-4}$, where very little data exist. These results are extremely useful for some applications such as electrical contacts in spacecraft. The purposes of this work were 1) to conduct an experimental study to examine four different coating materials, two pure materials, and two phase-mixed materials; and 2) to develop a theoretical model for a phase-mixed coating layer to predict the thermal contact conductance under the first-load cycle. An extensive experimental program was carried out employing four different coating materials, as well as a broad range of surface roughness and microhardness.

406F. ANISOTROPIC MEDIA

9A784. Periodic heat transfer through inhomogeneous media Part 1. Slab. - A Sengupta, MS Sodha, MP Verma, RL Sawhney, M Asthana *(Sch of Energy Stud and Centre of Energy Stud and Res, Devi Ahilya Univ, Indore 452001, India)*. Int J Energy Res **16**(9) 787-802 (Dec 1992).

The paper presents exact analytical solutions of 1D periodic heat conduction through an inhomogeneous slab for a certain class of thermal conductivity profiles (including linear and exponential). The exact analytical solutions for some of these profiles have been compared with those obtained by considering the slab to be made up of a number of homogeneous layers with different thermal conductivities varying from layer to layer and using the layered structure (or matrix multiplication) method. The numerical results arrived at by the layered-structure method converge rapidly (with increasing number of layers considered) to the values obtained from the exact analytical solutions. This gives confidence in the application of the layered-structure method to periodic heat conduction through inhomogeneous slabs. The numerical results have been presented in the form of elements of a 2 x 2 matrix, relating the sinusoidal steady-state temperature and heat flux on the two sides of the slab.

9A785. Steady-state heat conduction problem of the interface crack between dissimilar anisotropic media. - CK Chao and RC Chang *(Dept of Mech Eng, Natl Taiwan IT, Taipei 106, Taiwan, ROC)*. Int J Heat Mass Transfer **36**(8) 2021-2026 (May 1993).

A solution is given for the steady-state heat conduction problem of the interface crack between dissimilar anisotropic media. Based on the Hilbert problem formulation and a special technique of analytical continuation, exact expressions are obtained for the temperature and temperature gradients for both the heat flux prescribed and temperature prescribed boundary conditions. It is found that the temperature gradients near the crack tip always possess the characteristic inverse square tool singularity in rectilinearly anisotropic bodies provided the heat conductivity coefficients are positive definite and symmetric. The strength of heat flux singularities related to the crack dimension is also discussed.

9A786. Two-port network formalism for 3D heat conduction analysis in multilayered media. - PH Leturcq, JM Dorkel, FE Ratolojanahary, S Tounsi *(Lab d'Automatique Anal Syst, CNRS 7, Ave Colonel Roche, 31077 Toulouse Cedex, France)*. Int J Heat Mass Transfer **36**(9) 2317-2326 (Jun 1993).

This paper demonstrates that the two-port network formalism, commonly used to treat 1D heat flow problems in composite slabs, is also applicable to 3D problems in the context of integral transform methods. This provides easy calculation means for temperature and heat flux distributions within multilayered systems. Both spectral and superposition methods are thus presented as examples in a variety of cases of interest to engineers.

406H. MULTIPHASE MEDIA

9A787. Analysis of the effect of the solid layer for the modified chemical vapor deposition process. - YT Lin *(Yvan-Ze IT, Chung-Li, Taiwan, ROC)*, M Choi *(Seoul Natl Univ, Seoul, S Korea)*, R Greif *(Dept of Mech Eng, UCB)*. Warme Stoffubertragung **28**(4) 169-176 (Mar 1993).

The heat transfer problem relative to the modified chemical vapor deposition process has been analyzed and the effects of solid layer thickness, torch speed and tube rotation are studied. The quasi-steady 3D energy equations have been solved for the temperature fields in the gas and the solid layer with a Gaussian heat flux boundary condition on the outer surface. Of particular interest is the effect of the solid layer thickness and the torch speed on inner surface temperature, gas temperature and thermophoretic velocity. The presence of the solid layer and tube rotation reduce the effects of nonuniform torch heating in the circumferential direction and the resulting surface temperatures are very uniform in this direction.

406I. PHASE CHANGE (FREEZING, MELTING)

9A788. Heat transfer in melt spinning of intermetallic materials. - JSJ Chen *(Dept of Mech Eng, Temple Univ, Philadelphia PA 19122)*, WE Frazier *(Adv Metallic and Ceramics Branch, Naval Air Warfare Center, Aircraft Div, Warminster PA 18974)*, AA Tseng *(Dept of Mech Eng, Drexel Univ, Philadelphia PA 19104)*. J Mat Processing Manuf Sci 1(4) 417-429 (Apr 1993).

Analyzes and experiments are performed to investigate heat transfer in melt spinning of intermetallic materials. Previous research efforts in the modeling, the analysis, and the measurement of melt spinning processes are reviewed. The importance of the process parameters, including melt temperature, melt pouring rate, wheel temperature, spinning speed, nozzle-to-wheel gap, and thermal properties of ribbon and wheel, is addressed. A 1D transient mathematical model is developed to predict thermal behavior of melt spinning. The solid-liquid interface velocity and the cooling rate for melt spun $TiAl_3$ are presented. The significance of solidification rate is demonstrated by comparing the macrostructures and microstructures of a rapidly solidified $TiAl_3$ ribbon with a conventionally solidified ingot of the same composition.

9A789. Interface tracking method applied to morphological evolution during phase change. - W Shyy, HS Udaykumar, S-J Liang *(Dept of Aerospace Eng Mech and Eng Sci, Univ of Florida, Gainesville FL 32611)*. Int J Heat Mass Transfer **36**(7) 1833-1844 (May 1993).

The focus of this work is the numerical simulation of interface motion during solidification of pure materials. First, we assess the applicability of the oft-used and quasi-stationary approximation for interface motion. Such an approximation results in poor accuracy for non-trivial Stefan numbers. Next, a generic interface tracking procedure is designed, which overcomes restrictions of single-valuedness of the interface imposed by commonly used mapping methods. The issue of appropriate scaling has been addressed. The Gibbs-Thomson effect for curved interfaces has been included. The evolution of the interface, with the competing mechanisms of undercooling and surface tension is found to culminate in tip-splitting, cusp formation and persistent cellular development.

9A790. Mixture continuum formulation of convection-conduction energy transport in multiconstituent solid-liquid phase change systems for BEM solution techniques. - B Sarler, B Mavko (*Reactor Eng Div, Jozef Stefan Inst, Univ of Ljubljana, Jamova 39, 6111 Ljubljana, Slovenia*), G Kuhn (*Appl Mech, Univ Erlangen-Nuremberg, Egerlandstr 5, D-8520 Erlangen, Germany*). Eng Anal Boundary Elements 11(2) 109-117 (1993).

This paper describes the two nonlinear boundary-domain integral equations for Fourier heat conduction and convection governed energy transport. The equations are compatible with the mixture continuum formulation of an incompressible multiconstituent solid-liquid phase change system. The equations assume the boundary conditions to be functions of thermal field, and thermal conductivity and specific heat to be functions of temperature and species concentrations. The constitutive enthalpy-temperature relation is assumed to be a function of the species concentrations. The presented equations, in connection with a similar integral description for mass, momentum and species conservation, will be used as a basis for the BEM computation of macroscopic transport phenomena characteristic for melting and solidification.

9A791. Numerical modeling of heat transfer in irregular solidification of a liquid. - NI Nikitenko and YN Kol'chik (*Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine*). Heat Transfer Res 24(4) 519-528 (Apr 1992).

A mathematical model and a grid technique for predicting the continuous solidification of liquids in closed vessel, when the phase transition temperature becomes variable, are presented. Results of evaluation of the process of irregular freezing of water in a closed elastic pipe are given.

9A792. Numerical solution of the coupled heat and mass transfer problem of non-planar solidification and melting of aqueous solutions. - M Jochem (*L&C Steinmuller, D-5270 Gummersbach, Germany*) and Ch Korber (*European Patent Office, W-8000 Munchen, Germany*). Warme Stoffubertragung 28(4) 195-204 (Mar 1993).

During freezing of aqueous solutions containing solutes like sodium chloride or glycerol, pure ice is the first solid phase to form. A numerical model is presented for the case of non-planar (dendritic) freezing where local thermodynamic equilibrium can be assumed in the whole "mushy region", allowing a 1D treatment of the coupled heat and mass transfer in this region. Solute diffusion along the resulting interdendritic concentration gradient in the direction of freezing is taken into account by the model. Varying the geometric and thermodynamic boundary conditions, a parameter study was performed for obtaining more information on heat transfer during thawing of regular-shaped samples (plate, cylinder, sphere).

406Y. COMPUTATIONAL TECHNIQUES

9A793. Best approximation method applied to 3D steady-state heat transport. - TV Hromadka II (*Dept of Math, California State Univ, Fullerton CA 92634*) and RJ Whitley (*Dept of Math, UC, Urvine CA*). Adv Eng Software 16(1) 47-51 (1993).

The best approximation method is extended to the numerical solution of 3D steady-state heat transport problems. Two families of trial functions are used in the numerical solution; namely, harmonic polynomials and constant sources. Numerical approximation error is evaluated by means of approximate boundaries whereby error is visualized as a geometric displacement of the problem boundary. The problem considered is the determination of temperatures within a nuclear reactor.

9A794. Iterative CVBEM solution of nonlinear heat transfer problems. - AJ Kassab (*Dept Mech and Aerospace Eng, Univ of Central Florida, Orlando FL 32816-2450*) and S Chesla (*Pratt & Whitney Aircraft, Propulsion Syst Anal, W Palm Beach FL 33410*). Eng Anal Boundary Elements 11(1) 67-75 (1993).

An iterative technique is presented to extend the applicability of the CVBEM to the solution of heat transfer problems with nonlinear radiative boundary conditions. Additionally, nonlinearities arising from the variation of the thermal conductivity with temperature are addressed by means of the Kirchhoff transform. Simple substitution with underrelaxation leads to rapid convergence of the solution. Example problems are presented. The iterative approach is numerically validated and the CVBEM is shown to yield very accurate solutions in few iterations.

9A795. New implementation of the BE technique for time dependent pseudo stationary heat transfer. - JM Houghton (*Dept of Chem Eng, Univ of Bradford, UK*), DB Ingham (*Dept of Appl Math Stud, Univ of Leeds, Leeds LS2 9JT, UK*), PJ Heggs (*Dept Chem Eng, Univ of Bradford, Bradford, UK*). Eng Anal Boundary Elements 11(1) 55-65 (1993).

A new implementation of the BEM solution technique has been devised to investigate time-dependent heat transfer. This new approach has been applied to the problem of oscillatory heat transfer in an isolated fin. A comparison of the results with an existing analytical solution indicates that the BE technique developed in this paper is very efficient. Results are obtained for an aluminium fin over a wide range of heat transfer coefficients, fin dimensions, and amplitude and frequency of the base temperature oscillation of the fin.

406Z. EXPERIMENTAL TECHNIQUES

9A796. Determination of the thermal conductivities of building and insulating materials by the probe method. - YH Hamid (*Fac of Eng, Univ of Khartoum, Khartoum, Sudan*) and OA Hamed (*Dept of Chem and Pet Eng, Fac of Eng, Univ of United Arab Emirates, PO Box 17555, Al-Ain, United Arab Emirates*). Int J Energy Res 16(9) 829-835 (Dec 1992).

A simple and inexpensive electrical circuit based on the transient probe method has been developed for the determination of thermal conductivities of building and insulating materials namely limebrick, gypsum, rockwool and polystyrene foam. The solution of the unsteady state heat conduction equation has been approximated by considering certain simplifying assumptions which have been justified by experimental observations. The overall accuracy of the thermal conductivity measurements is estimated to be within ± 3%.

408. Radiation and combined modes

408B. VIEW FACTORS

9A797. Accurate determination of diffuse view factors between planar surfaces. - A Ambirajan (*Dept of Mech Eng, Univ of Missouri, Rolla MO 65401*) and SP Venkateshan (*Dept of Mech Eng, Indian IT, Madras 600 036, India*). Int J Heat Mass Transfer 36(8) 2203-2208 (May 1993).

The contour double integral formula for the view factor between a pair of finite surfaces is a particularly simple formula to implement numerically. This paper suggests a method to improve the accuracy of the numerical results using this formula, both for non-intersecting surfaces, and for intersecting surfaces. In the latter case particularly, significant improvements in accuracy are achieved using the procedure outlined in the paper.

408C. THEORY OF RADIATIVE PROPERTIES

9A798. Effects of particle size distribution and refractive index on fly-ash radiative properties using a simplified approach. - Fengshan Liu (*Dept of Chem Eng, Queen's Univ, Kingston K7L 3N6, ON, Canada*) and J Swithenbank (*Dept of Mech and Process Eng, Univ of Sheffield, Sheffield S1 3JD, UK*). Int J Heat Mass Transfer 36(7) 1905-1912 (May 1993).

The radiative properties of a fly-ash polydispersion are calculated using a simplified approach based on Mie theory. The experimental data of fly-ash complex refractive index of Goodwin (Infrared optical constants of coal slags, Technical Report T-255, Stanford University, California) are employed in the calculation to take into account the wavelength-dependence of optical constants. The uncertainty in representing the particle size distribution is addressed explicitly. Due to this uncertainty, the uncertainty of the wavelength-integrated Planck mean absorption and scattering coefficients can be over 10%.

408D. INTERCHANGE AMONG SURFACES

See the following:

9A941. Calculation of the shape factor from a small rectangular plane to a triangular surface perpendicular to the rectangular plane without a common edge

408E. INVOLVEMENT OF PARTICIPATING MEDIA

9A799. Analysis of infrared radiation heating of plastics. - Toshiyuki Miyanaga and Yukio Nakano (*Central Res Inst of Elec Power Indust, Japan*). Heat Transfer Japan Res 21(6) 631-647 (Apr 1992).

In order to make more effective use of infrared radiation, we have developed a basic method of predicting the heating effect quantitatively. It presents a unidimensional heat-transfer analysis, taking spectral properties into account. We can estimate the distribution and the temporal variation of temperature inside the plastic plates which are to be heated. This method is applicable to heating systems without vaporization and enables us to predict what kind of emitter is most suitable to use with a particular plastic plate.

9A800. Calculation of heat transfer in a tank-type glassmaking furnace with correction for selectivity of the radiation of furnace gases. - Yel Semikin, AYe Yashin, VD Rumyantsev *(Dnepropetrovsk Metal Inst, Russia)*. Heat Transfer Res 24(5) 696-702 (1992).

Predictions of radiative heat transfer in a tank-type glassmaking furnace, with correction for selectivity of radiation of the furnace gases, are presented. It is shown that correction for the selectivity markedly improves the prediction. The predicted and experimental data for an opening furnace are also presented.

9A801. Discrete ordinates solutions for radiatively participating media in a cylindrical enclosure. - S Jendoubi *(Dept of Mech Eng, Univ of Minnesota, Minneapolis MN 55455)*, HaeOK Skarda Lee *(Propulsion Syst Div, NASA Lewis Res Center, Cleveland OH 44135)*, Tae-Kuk Kim *(Dept of Mech Eng, Chung-Ang Univ, Seoul 156-756, Korea)*. J Thermophys Heat Transfer 7(2) 213-219 (Apr-Jun 1993).

The radiative transfer equation is solved by the r-z discrete ordinates method in the 2D r-z coordinates system. The walls of the enclosure are diffuse, and the participating medium absorbs, emits, and anisotropically scatters the radiative energy. Diffuse wall incidence, isothermal medium emission, and collimated incidence problems are considered. Effects of the scattering phase functions on average incident radiation and net radiative heat fluxes are studied.

9A802. Experimental and theoretical study on the radiation of gases containing dust particles. - J Stasiek *(Tech Univ, Gdansk, Poland)* and MW Collins *(Thermo-Fluids Eng Res Centre, City Univ, Northampton Square, London EC1V 0HB, UK)*. Warme Stoffubertragung 28(4) 185-193 (Mar 1993).

The attenuation of thermal radiation within a dilute cloud of pulverized coal and ash is investigated experimentally and theoretically, for different ranges of particle size. An empirical expression is developed for obtaining the absorptivity and emissivity of a coal-ash cloud. A new nomogram is also presented on the basis of this expression.

9A803. Infrared continuum of pure water vapor: Calculations and high-temperature measurements. - JM Hartmann, MY Perrin *(Lab E M2 C CNRS (UPR288), Ecole Centrale Paris, Grande Voie des Vignes, 92295 Chatenay-Malabry Cedex, France)*, Q Ma *(Center for the Study of Global Habitability, Columbia Univ and Inst for Space Stud, Goddard Space Flight Center, New York NY 10025)*, RH Tipping *(Dept of Phys and Astron, Univ of Alabama, Tuscaloosa AL 35487)*. J Qantitative Spectroscopy Radiative Transfer 49(6) 675-691 (Jun 1993).

We present experimental and theoretical studies of medium infrared absorption by pure water vapor. Measurements have been made in the 1900-2600 cm^{-1} and 3900-4600 cm^{-1} regions, for temperature and pressures in the 500-900 K and 0-70 atm ranges, respectively. They are consistent with available data and enable the determination of continuum absorption parameters. It is shown that calculations with line shapes derived from the impact approximation are very inaccurate. Models accounting for the finite durations of collisions and line-mixing through wavenumber dependent effective broadening parameters are introduced. The latter have been determined using two different approaches, which are (i) empirical determinations from fits of experimental data and (ii) direct predictions from first principles using a statistical approach. Effective broadening parameters obtained using these two different approaches are in satisfactory agreement for both the temperature and wavenumber dependencies. These data are tested by calculation of continua in various spectral regions and the agreement with measured values is satisfactory. The remaining discrepancies probably result from the influence of the internal structures of the absorption bands considered and thus from the influence of line-mixing. Nevertheless, accurate predictions are obtained in wide temperature and spectral ranges when the total absorption at elevated density is considered. This agreement, which is due to the relatively weak continuum absorption and large contributions of nearby lines, makes the present models suitable for most practical applications involving elevated densities.

9A804. Infrared gas radiation from a homogeneously turbulent medium. - F Kritzstein and A Soufiani *(Lab Energetique Moleculaire Macroscopique Combustion, CNRS l'ECP Ecole Centrale Paris, Grande Voie des Vignes, 92295 Chatenay-Malabry, France)*. Int J Heat Mass Transfer 36(7) 1749-1762 (May 1993).

Mean infrared radiation from a turbulent, statistically uniform medium is studied theoretically. A stochastic approach is used in which instantaneous temperature and concentration fluctuations are generated by Fourier transforming various forms of the space-time correlation function. The effect of the shape of the spatial correlation function on the model results is found to be negligible. We discuss first the influence of the spectroscopic parameters of an isolated Lorentz line on mean radiative intensities. It is shown that the effects of turbulence depend strongly on the energy of the lower level of the transition. It is also found that the turbulence contribution to the radiative intensity, when integrated over the entire infrared spectrum, decreases quickly when the mean temperature increases in the range [800 - 2000 K].

9A805. Radiation transport around axisymmetric blunt body vehicles using a modified differential approximation. - Lin C Hartung *(Aerothermodyn Branch, Space Syst Div, NASA Langley Res Center, Hampton VA 23681)* and HA Hassan *(Dept of Mech and Aerospace Eng, N Carolina State Univ, Raleigh NC 27695)*. J Thermophys Heat Transfer 7(2) 220-227 (Apr-Jun 1993).

A moment method for computing 3D radiative transport is applied to axisymmetric flows in thermochemical nonequilibrium. Such flows are representative of proposed aerobrake missions. The method uses P-1 approximation to reduce the governing system of integro-differential equations to a coupled set of partial differential equations. A numerical solution for these equations given actual variations of the radiation properties in thermochemical nonequilibrium blunt body flows is devleoped. Initial results from the method are shown and compared to tangent slab calculations. The agreement between the transport methods is found to be about 10% in the stagnation region with the difference increasing along the flank of the vehicle.

9A806. Radiation trapping simulations using the propagator function method. - JE Lawler, GJ Parker *(Dept of Phys, Univ of Wisconsin, Madison WI 53706)*, WNG Hitchon *(Dept of Elec and Comput Eng, Univ of Wisconsin, Madison WI 53706)*. J Qantitative Spectroscopy Radiative Transfer 49(6) 627-638 (Jun 1993).

An integral method of solving the Holstein-Biberman equation based on a propagator function is described. This method is used to solve the equation with a Lorentz lineshape in an infinite plane parallel geometry and a hollow spherical geometry. The method is ideal for solving for both the time dependent and the steady state density of resonance atoms which results from an arbitrary production rate per unit volume. The propagator function method is 100 times faster than the Monte Carlo method. The greater speed of the propagator function method makes it well suited to fully self-consistent kinetic simulations of glow discharge plasmas.

9A807. Radiative transfer in 3D atmosphere-vegetation media. - RB Myneni *(USRA Assoc, NASA Goddard Space Flight Center, Code 923, Greenbelt MD 20771)* and G Asrar *(EOS Project, NASA Headquarters, Code SE, Washington DC 20546)*. J Qantitative Spectroscopy Radiative Transfer 49(6) 585-598 (Jun 1993).

The problem of radiation transfer in 3D atmosphere-vegetation media is formulated in this paper. The atmosphere is treated as a horizontally homogeneous medium but with spatially varying anisotropic lower boundsry. The boundary condition is defined in terms of vegetation canopy bidirectional reflectance factors to be evaluated from a numerical solution of the 3D canopy radiative transfer equation. Numerical results obtained with the discrete ordinates method are in good agreement with the Monte Carlo results of Pearce and field soybean reflectance data of Ranson et al.

9A808. Refractive index and scattering effects on radiative behavior of a semitransparent layer. - CM Spuckler *(Heat Transfer Branch, NASA Lewis Res Center, Cleveland OH 44135)* and R Siegel *(Lewis Res Acad, NASA Lewis Res Center, Cleveland OH 44135)*. J Thermophys Heat Transfer 7(2) 302-310 (Apr-Jun 1993).

Heat transfer characteristics are analyzed for a plane layer of semitransparent material with refractive index ≥ 1. Energy transfer in the material is by conduction, emission, absorption, and isotropic scattering. The layer surfaces are diffuse intending to model a ceramic layer in high temperature applications. Each side of the layer is heated by radiation and convection. Internal reflections at the boundary surfaces are included. For a refractive index larger than unity, there is internal reflection of some of the energy within the layer. The effect of scattering is examined by comparisons with results from an earlier paper for an absorbing layer. Results are given for a gray medium with a scattering albedo up to 0.999, and for a two-band spectral variation of the albedo with one band having low absorption.

406F. COMBINED RADIATION AND CONVECTION

9A809. Radiative-convective heat transfer in a system of two highly porous plates. - SA Zhdanok, SI Shabunya, VV Martynenko, VG Leytsina *(Inst of Heat and Mass Transfer, Minsk, Russia)*. Heat Transfer Res 24(3) 285-301 (Apr 1992).

An algorithm is suggested for a numerical solution of the problem of radiative-convective heat transfer in a system of highly porous plates. Numerical simulation is carried out over a range of problem parameters. The major parameters affecting the process of radiative-convective heat transfer are revealed.

406G. COMBINED RADIATION AND CONDUCTION

9A810. Analysis of the combined conductive - radiative heat transfer between a surface and a gas-fluidized bed at high temperature. - HM Shafey, AMA El-Ghany, AM Nassib *(Dept of Mech Eng, Assiut Univ, Assiut, Egypt)*. Int J Heat Mass Transfer 36(9) 2281-2292 (Jun 1993).

A theoretical investigation of the combined conductive-radiative wall-to-fluidized bed heat transfer is presented. The packet of emulsion is assumed to be an absorbing, emitting, and scattering nongray medium. Equations of energy and radiative transfer in the packet are solved simultaneously using an iterative numerical method. The bubble is modelled as a hemisphere of gas enclosed by the emulsion and the nongray heat transfer surface. Heat transfer coefficients were calculated for different bed systems in the temperature range 300 - 1000°C. The predictions by the present analysis were in good agreement with available experimental data.

9A811. Flowfield coupled excitation and radiation model for nonequilibrium reacting flows. - TA Gally, LA Carlson, D Green *(Texas A&M Univ, College Station TX 77843)*. J Thermophys Heat Transfer 7(2) 285-293 (Apr-Jun 1993).

A second-order method has been developed to correct a radiative transfer analysis for possible local thermodynamic nonequilibrium effects. This method uses a two-species excitation model for nitrogen with chemical reaction rates obtained from the detailed atomic transition method of Kunc and Soon. Results obtained from this new method show more atomic line radiation than the authors' previous first-order method. As improvements to the flowfield representation used in the computations, a full three-temperature energy model and a recently developed multi-component diffusional model have also been incorporated.

9A812. Thermal conductivities of quantum well structures. - G Chen and CL Tien *(Dept of Mech Eng, UCB)*. J Thermophys Heat Transfer 7(2) 311-318 (Apr-Jun 1993).

This work analyzes the size and the boundary effects of a gallium arsenide- (GaAs) based quantum well (QW) structure on the thermal conductivity of the well material. Calculations show that the order of phonon mean free path (MFP) is equal to or even longer than the typical dimensions of the well (~200 Å or less). Holland's model is applied to match the thermal conductivity data of bulk GaAs from 2 to above 600 K. The equation of phonon radiative transfer developed from Boltzmann transport equation is then introduced for the heat transport in the QW structure. Results show that the thermal conductivity at the quantum well can be of one order-of-magnitude lower than that of its corresponding bulk form at room temperature.

408H. COMBINED RADIATION, CONVECTION, AND CONDUCTION

9A813. Thermal processes in gas-powder laser cladding of metal materials. - VK Pustovalov and DS Bobuchenko *(Byelorussian State Polytech Acad, Minsk 220027, Belarus)*. Int J Heat Mass Transfer 36(9) 2449-2456 (Jun 1993).

Energy absorption, heating, melting and heat transfer in a gas-powder laser cladding of substrate metal powders are theoretically investigated. A system of equations is formulated which describes optical and thermal processes of the gas-powder laser cladding. Based on the numerical solution of the system of equations formulated, spatial temporal temperature distributions in 1D approximation and time dependence of the process parameters for continuous and pulse cladding modes are obtained. Some specific features of the pulse modes of the powdered material cladding are studied.

408Y. COMPUTATIONAL TECHNIQUES

9A814. Computation of radiant heat transfer on a nonorthogonal mesh using the finite-volume method. - EH Chui and GD Raithby *(Dept of Mech Eng, Univ of Waterloo, Waterloo N2L 3G1, Canada)*. Numer Heat Transfer B 23(3) 269-288 (Apr-May 1993).

The finite-volume method has been shown to effectively predict radiant exchange in geometrically simple enclosures where the medium is gray, absorbing, emitting, and scattering. Cartesian and circular cylindrical meshes have always been used. The present article shows that the method applies equally well to geometrically complex enclosures where nonorthogonal, boundary-fitted meshes are used. This development permits radiant heat transfer to be computed on the same mesh employed to solve the equations of fluid motion.

Experimental data on heat transfer coefficients for a shell-and-tube regenerative heat exchanger are presented.

9A818. Some essential principles for adjustment of seal clearances in rotary regenerators. - T Skiepko *(Dept Eng Electromec, Univ Beira Interior, R Marques d'Avila e Bolama, 6200 Covilha, Portugal)*. Heat Transfer Eng 14(2) 27-43 (Apr-Jun 1993).

In the present study, attention is paid to some indispensable principles for making a useful adjustment of seal clearances in a rotary regenerator, illustrated by means of examples. First, the effect of leakages and their distribution within such a heat exchanger on the efficiency of a steam power plant is presented. Second, in order to show in which rotor state seal clearances should be adjusted, appropriate examples of experimental results concerning radial seal clearances in the hot and cold rotor state are compared. Next, on the basis of a leakage network and some experimental data before and after reduction in radial seal clearances, the effect of reduction in seal clearances on the total leakage and its distribution within a rotary regenerator is shown.

9A820. Analysis of capillary-induced rewetting in circular channels with internal grooves. - XF Peng, GP Peterson, XJ Lu *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843)*. J Thermophys Heat Transfer 7(2) 334-339 (Apr-Jun 1993).

A combined theoretical and experimental investigation was conducted to determine the rewetting characteristics of capillary-induced liquid flow in circular channels with microgrooves on the inside surface. This investigation provides a theoretical description of the mechanisms that govern the rewetting of these surfaces, and presents an experimentally verified method by which the location of the rewetting front in the evaporator section of high capacity heat pipes can be determined as a function of the applied heat flux. The rewetting velocity was found to be a function of the thermal properties of the liquid and the channel, the input heat flux, the radii of the groove and the channel, and the location of the liquid front.

9A821. Experimental investigation of an ion-drag pump-assisted capillary loop. - BR Babin, GP Peterson, J Seyed-Yagoobi *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843)*. J Thermophys Heat Transfer 7(2) 340-345 (Apr-Jun 1993).

A ion-drag pump was constructed and calibrated to determine the available pumping pressure as a function of input voltage for various working fluids. The experimental results were then compared with an analytical model and found to predict the ion-drag pump performance to within ± 15%. Using this information, an analytical model capable of predicting the performance enhancement of an ion-drag pump-assisted capillary loop was also developed and compared with the values obtained from experimental tests conducted on a thermal test loop. Although the analytical model slightly overpredicted the performance enhancement resulting from the ion-drag pump, the predicted trends were similar to those obtained from the experimental program.

9A822. Geothermal heat pipe stability: Solution selection by upstreaming and boundary conditions. - MJ McGuinness *(Math Dept, Victoria Univ of Wellington, New Zealand)*, M Blakeley *(DES, Univ of Auckland, New Zealand)*, K Pruess *(LBL)*, MJ O'Sullivan *(DES, Univ of Auckland, New Zealand)*. Transport Porous Media 11(1) 71-100 (Apr 1993).

In a geothermal reservoir, the heat pipe mechanism can transfer heat very efficiently, with vapor rising and liquid falling in comparable quantities, driven by gravity. For a given heat and mass flux that is not too large, there are two possible steady solutions with vapor-liquid counterflow, one liquid-dominated, and one vapor-dominated. Numerical solution of the equations for two-phase vertical counterflow displays intriguing stability behavior. If pressure and saturation are fixed at depth, and heat and mass flux specified at the top, the vapor-dominated solution is almost always obtained. That is, for a variety of boundary values, the solution settles to the vapor-dominated steady-state, and only for very special values is it possible to obtain the liquid-dominated case. Similarly the liquid-dominated solution is almost always obtained if the boundary conditions are reversed, with pressure and saturation fixed at the top and heat and mass flux specified at depth. This behavior is here explained in two complementary ways. It is shown to be a consequence of upstream differencing of the flow terms in the numerical method. It is also shown to be expected behavior for wavelike saturation solutions. Hence the observed behavior is not only a direct consequence of the numerical method used, but is fundamental to geothermal heat pipes.

9A823. Heat and fluid transport in an evaporative capillary pump. - HG Wulz *(Dept of Space Thermal Tech, Dornier GmbH, PO BOX 14 20, D-7990 Friedrichshafen, Germany)* and F Mayinger *(Dept of Thermodyn A, Tech Univ of Munich, Arcisstr 21, D-8000 Munchen 2, Germany)*. Int J Energy Res 16(9) 879-896 (Dec 1992).

The thermal and fluid mechanical properties of an evaporative capillary pump are described by means of characteristics that have been determined by tests. The capillary pump, which has been newly designed for an application in future space projects, serves a double function as the heat absorbing element in a closed loop as well as a pump circulating the working fluid. The working fluids used were CCl_3F (freon R11) and liquid anhydrous ammonia. The paper describes the associated heat and mass transport in the capillary pump, and the physical process of the capillary pumping is explained. Furthermore, a model is introduced which explains the boiling heat transfer in the porous structure of the capillary pump.

9A824. Mechanism of vaporization in reticulate wicks of low-temperature heat pipes. - GR Kudritskiy, YuN Ostrovskiy, VA Antonenko *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(4) 529-534 (Apr 1992).

We present the results of an experimental study of the mechanism of vaporization under conditions simulating heat transfer in a cell of a single-layer screen wick of a low-temperature heat pipe. The experiments involved still and motion-picture photography of the heated wall and photography of scale deposited on that wall under different vaporization conditions. It is shown that vaporization under capillary-suction feed of the wick is very different from nucleate boiling, particularly at high heat flux densities just below a boiling crisis.

9A825. Vapor flow analysis of an axially rotating heat pipe. - A Faghri, S Gogineni, S Thomas *(Dept of Mech Eng and Mat Eng, Wright State Univ, Dayton OH 45435)*. Int J Heat Mass Transfer 36(9) 2293-2303 (Jun 1993).

The vapor flow in an axially rotating heat pipe has been numerically analysed using a 2D axisymmetric model in cylindrical coordinates. A parametric study was conducted for radial Reynolds numbers of 0.01, 4.0, and 20.0, and rotational speeds ranging from 0 to 2800 rpm. The numerical results indicate that the pressure and the axial, radial, and tangential velocities are significantly affected by the rotational speed and the radial Reynolds number. In comparison to non-rotating heat pipes, the radial pressure distributions is no longer uniform. Also, above a certain rotational speed, flow reversal occurs near the centerline of the heat pipe.

410G. DRYING AND FREEZING

9A826. Experimental verification of a heat pump assisted continuous dryer simulation model. - S Clements, Xiguo Jia, P Jolly *(Energy Lab, Univ of Queensland, Walcott St, 4072 Australia)*. Int J Energy Res 17(1) 19-28 (Jan 1993).

The experimental and predicted performance of a prototype heat pump assisted continuous dryer is reported. The dryer was shown to be capable of specific moisture extraction rates (SMERs) of between 1.5 and 2.5 kg/kWh using wetted foam rubber as the test material being dried. The results highlight the importance of maintaining conditions of high relative humidity within the air stream entering the evaporator; an increase in the relative humidity from 30 to 80% was shown to give a two-fold increase in the SMER. The predicted performance of the dryer using a simulation model developed previously by authors was in good agreement with the corresponding measured values.

9A827. Procedure for processing experimental data on drying. - MS Smirnov, AB Kurzayev, PP Lutsik *(Inst of the Food Indust, Moscow, Russia)*. Heat Transfer Res 24(4) 494-500 (Apr 1992).

Work up of experimental data on the drying of a mixture of quartz sand and silica powder is presented. The temperature distribution is approximated by polynomials, whereas the moisture-content distribution is given by an approximate expression for the drying curve.

410I. ENVIRONMENTAL CONDITIONING AND CONTROL

9A828. Change-point principal component analysis. (CP/PCA) Method for predicting energy usage in commerical buildings: The PCA model. - D Ruch, Lu Chen, JS Haberl, DE Claridge *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843)*. J Solar Energy Eng 115(2) 77-84 (May 1993).

A new method for predicting daily whole-building electricity usage in a commercial building has been developed. This method utilizes a Principal Component Analysis (PCA) of intercorrelated influencing parameters (eg, dry-bulb temperature, solar radiation and humidity) to predict electricity consumption in conjunction with a change-point method. This paper describes the PCA procedure and presents the results of its application in conjunction with a change-point regression, to predict whole-building electricity consumption for a commercial grocery store. Comparison of the results with a traditional Multiple Linear Regression (MLR) analysis indicates that a change-point, Principal Component Analysis (CP/PCA) appears to produce a more reliable and physically plausible model than an MLR analysis and offers more insight into the environmental and operational driving forces that influence energy consumption in a commercial building.

9A829. Chemical heat pump based on dehydrogenation and hydrogenation of i-propanol and acetone. - Gyung Kim Tae, Koo Yeo Yeong, Keun Song Hyung *(Chem Process Lab, Korea Inst of Sci and Tech, PO Box 131, Cheongryang Seoul 136-650, Korea)*. Int J Energy Res 16(9) 897-916 (Dec 1992).

A chemical heat pump, based on the reversible reaction couple of the i-propanol-acetone system, was investigated experimentally. The endothermic dehydrogenation of i-propanol occurred at 80°C with a Raney nickel catalyst suspended in the liquid phase. The unreacted i-propanol was separated from gaseous products in a condenser. The exothermic hydrogenation reaction of the acetone was performed at 200°C and 1 atm, in the presence of the Raney nickel catalyst. The positive value (ΔG) of the change of Gibbs free energy can make the dehydrogenation reaction of i-propanol rather difficult. This problem can, though, be overcome by the continuous removal of gaseous acetone and hydrogen products from the reaction medium. The dehydrogenation rate equation of i-propanol was obtained as $V = 0.1\ C_p/(1 + 7.0\ C_A)$. The gas phase hydrogenation reaction of acetone was performed in an exothermic tubular reactor. In order to estimate energy efficiency, a simulation of the separation stage was performed. Based on these experimental and simulation results, the optimal design specifications for the chemical heat pump were determined. The maximum hydrogenation of acetone was obtained when the mole ratio of acetone to hydrogen was 4.0. Energy efficiency was increased when the conversions of hydrogenation and dehydrogenation increased.

9A830. Influence of height above sea level on the COP of air-source heat pumps used for water heating. - JP Meyer and GP Greyvenstein *(Dept of Mech Eng, Potchefstroom Univ for CHE, Private Bag X6001, Potchefstroom 2520, S Africa)*. Heat Transfer Eng 14(2) 44-50 (Apr-Jun 1993).

In some countries (eg, S Africa), important market areas for air-source heat pumps are situated high above sea level, and it is therefore necessary to know what the influence of height is on the performance of heat pumps for water heating. Therefore, a study was conducted that predicts the influence of height on the coefficient of performance (COP) of air-source heat pumps. The results were verified by means of a simulation study. It was concluded that height has little influence on COP if the evaporator of the heat pump is wet on the air side. A more significant weakening in the performance occurs, however, when the air side of the evaporator is dry.

9A831. Infrared imaging results of an excited planar jet. - RB Farrington *(Natl Renewable Energy Lab, Golden CO 80401)*. J Solar Energy Eng 115(2) 85-92 (May 1993).

Planar jets are used for many applications including heating, cooling, and ventiliation. Generally, a planar jet provides good mixing within an enclosure. In building applications, the jet provides both thermal comfort and adequate indoor air quality. Increased mixing rates may reduce short circuiting of conditioned air, eliminate dead zones within the occupied zone, reduce energy costs, increase occupant comfort, and increase indoor air quality. This article discusses how an infrared imaging system was used to demonstrate how jet excitation affected the spread angle and the jet mixing efficiency. Digital data reduction and analysis shows changes in jet isotherms and quantify the increased mixing caused by excitation.

9A832. Measurement of ventilation and aerosol particles in buildings. - SB Riffat and KW Cheong *(Nottingham Sch of Architec, University Park, Nottingham NG7 2RD, UK)*. Int J Energy Res 17(1) 45-55 (Jan 1993).

The work described in this paper is concerned with the measurement of the flow of tracer gas and aerosol particles in rooms. Measurements were carried out in single- and two-zone systems using SF_6 tracer gas and oil-smoke particles. Initial tests were carried out in single-zone system using different arrangements of window opening. Results indicated that tracer-gas exchange rates were generally higher than particle exchange rates. This was due to the fact that the ventilation air entering the zone contained a significant concentration of particles but a neligible quantity of tracer gas.

9A833. Multi-unit heat pump and system. - E Bogdanova and A Grinberg *(Univ of Tech, bul kl Ohridsky 8, Sofia, Bulgaria)*. Int J Energy Res 16(9) 803-810 (Dec 1992).

In the paper, conditions for multi-unit heat pump (MUHP) stationary operation at the level of condenser and evaporator groups and in a system are considered. The matrices describing the equilibrium operation are defined, and the method of their determination are described.

9A834. Solid-gas chemical heat pumps: Field of application and performance of the internal heat of reaction recovery process. - P Neveu and J Castaing *(CNRS, Inst Sci Genie Materiaux Procedes, 52 Ave Villeneuve 66860 Perpignan, Cedex, France)*. Heat Recovery Syst CHP 13(3) 233-251 (May 1993).

With the four components of a chemical heat pump (two solid-gas reactors, an evaporator and a condenser) a cycle of the double-effect type can be applied to continuous refrigeration. The performance of this process is analyzed, allowing the infinite sink temperature and the couples of reactive salts to be used, which depend on the production temperature envisaged, to be selected. The results are presented in a diagram from which may be determined the required source temperature (as a function of the refrigeration temperature), the machine's coefficient of performance, its exergetic efficiency and the equilibrium drop, ie, the power level that can be reached. This process is compared to the double-effect cycle developed on solid adsorption machines.

9A835. Stationary operation of a unit in a multi-unit heat pump system. - E Bogdanova and A Grinberg *(Univ of Tech, bul kl Ohridsky 8, Sofia, Bulgaria)*. Int J Energy Res 16(9) 811-827 (Dec 1992).

In the paper, a method for the determination of the parameters of the units, stationary operating in a multi-unit heat pump system, is presented. This method is used for the consideration of six schemes of hydraulic connection of the heat exchangers in groups.

9A836. Use of simplified system models to measure retrofit energy savings. - S Katipamula and DE Claridge *(Energy Syst Lab, Dept of Mech Eng, Texas A&M Univ, College Station TX 77843)*. J Solar Energy Eng 115(2) 57-68 (May 1993).

The retrofit of dual-duct constant volume systems with energy-efficient variable air volume systems has become common in recent years. In general, the energy savings from such retrofits are estimated by developing a temperature-dependent regression model using whole building preretrofit energy consumption data. Model predictions are then compared with measured post retrofit consumption, to determine the savings. In cases where the preretrofit energy consumption is not available such a method cannot be implemented. This paper describes a method that can be used to calculate savings in such cases. The method is based on use of simplified calibrated system models. A VAV model was developed based on the ASHTRAE TC 4.7 Simplified Energy Analysis Procedure (SEAP) (Knebel, 1983) and calibrated with the postretrofit energy consumption of a large engineering center in Central Texas. The loads from the calibrated VAV model were then used with the DDCV model to estimate the preretrofit energy use, also based on TC 4.7 SEAP, and apparent savings were determined as the difference between the DDCV predicted consumption and measured energy consumption for the postretrofit VAV system.

410L. THERMAL ENERGY STORAGE SYSTEMS

9A837. Phase change thermal storage: Transient behavior analysis of a solar receiver-storage module using the enthalpy method. - C Bellecci *(Dept Fisica, Univ della Calabria, 87030 Rende, Italy)* and M Conti *(Dept Matematica Fisica, Univ Camerino, 62032 Camerino, Italy)*. Int J Heat Mass Transfer 36(8) 2157-2163 (May 1993).

The performance of a Solar Receiver Unit with a built-in thermal storage system is simulated by the enthalpy method. It is shown that accurate results can be obtained with a simplified modelling of the forced convection heat extraction. The results indicate some criteria to determine the optimal size of the storage system.

9A838. Study of the heat transfer behavior of a latent heat thermal energy storage unit with a finned tube. - M Lacroix *(Dept Genie Mec, Univ Sherbrooke, J1K 2R1, PQ, Canada)*. Int J Heat Mass Transfer 36(8) 2083-2092 (May 1993).

A theoretical model for predicting the transient behavior of a shell-and-tube storage unit with the PCM on the shell side and the HTF circulating inside the tubes is presented. The tubes are bare or finned. The multidimensional phase change problem is tackled with an enthalpy based method coupled to the convective heat transfer from the HTF. The numerical model is validated with experimental data. Results show that the annular fins are most effective for moderate mass flow rates and small inlet temperatures.

412. Thermomechanics of solids

412A. GENERAL THEORY

9A839. Compound effect of cutting depth and bit dull on cutters' temperature for polycrystalline diamond compact bits. - Ergun Kuru, Lsu Metu *(Pet Eng Dept, Middle E Tech Univ, Ankara, Turkey)*, AK Wojtanowicz, Lsu Conoco *(Pet Eng Dept, Louisiana State Univ, Baton Rouge LA 70893)*. J Energy Resources Tech 115(2) 124-132 (Jun 1993).

This paper presents a simulation study to evaluate the combined effect of cutting depth (drilling rate) and wear (bit dull) on the thermal response of polycrystalline diamond compact (PDC) cutters under downhole drilling conditions. A new understanding of frictionally generated heat between rock and PDC cutter is introduced from the analysis of forces active on the wearflat and the cutting (leading) surfaces of a cutter. This new concept is used to predict PDC bit performance with the controlled temperature of its cutters. Also demonstrated is the actual impact of these findings on field drilling practices. The example comparison is made by calculating the optimal-control surface. For practical applications, the study reveals that many field failures of PDC bits may have been caused by lack of understanding of operational limits imposed by heat considerations.

412B. THERMOELASTICITY (STEADY AND QUASI-STEADY)

412F. THERMOMAGNETIC AND THERMOELECTRIC EFFECTS

9A840. Thermo-elasto-viscoplasticity of isotropic porous metals. - A Zavaliangos and L Anand *(Dept of Mech Eng, MIT)*. J Mech Phys Solids 41(6) 1087-1118 (Jun 1993).

A rate and temperature dependent elastic-plastic model for isotropic, moderately porous metallic materials is formulated. This model is intended for material rate-sensitivities in the entire range spanning from highly rate-dependent behavior at high homologous temperatures to nearly rate-insensitive behavior at low homologous temperatures. The predictive capabilities of the constitutive models are verified by comparing results from FE calculations against results from physical experiments. Predictions from the computational procedures for both examples agree well with the experimental results. The new state variable rate and temperature dependent constitutive model for microporous materials and the associated computational procedures form a basis for the simulation and design of deformation processing operations. This new capability should be useful for the prediction of formation of defects during both cold-working when the material rate sensitivity is low, as well as hot-working when the material is highly rate sensitive.

412H. THERMAL FATIGUE AND STABILITY

9A841. Thermal cycling damage of metal matrix composites: Analytical study on dimensional change. - Minoru Taya *(Dept of Mech Eng, Univ of Washington, Seattle WA 98195)*, WD Armstrong *(Nagasaki R&D Center, Mitsubishi Heavy Indust LTD, Nagasaki 851-03, Japan)*, M Dunn *(Solid and Struct Mech 1562, Sandia)*. Appl Mech Rev 46(5) 201-210 (May 1993).

An analytical model to predict dimensional changes in thermal cycled metal matrix composites with and without constant stress is proposed. The present model assumes that the temperature-time relation to simulate thermal cycling is of a step-function type and the matrix metal deforms as elastic-plastic-creep material while the fiber remains elastic throughout thermal cycling. Another model is also constructed to simulate the later stage of thermal cycling damage where the debonding of the matrix-fiber interface would presumably take place progressively with number of cycles.

412J. THERMOFRACTURE MECHANICS

9A842. Three-dimensional analysis of thermally loaded cracks. - ST Raveendra, PK Banerjee, GF Dargush *(Dept of Civil Eng, SUNY, Buffalo NY 14260)*. Int J Numer Methods Eng 36(11) 1909-1926 (15 Jun 1993).

The stress intensity factors for cracks in 3D, thermally stressed structures are computed by using the BEM. While many boundary and volume-integral-based formulations are available for the treatment of thermoelastic problems in solids, the present analysis is based on a recently developed boundary-only formulation. The accuracy of the solutions in the present work is improved by using special elements at the crack front that accurately model the variation of displacement, temperature fields and singularity of traction, flux fields.

412L. COMPOSITE MATERIALS

9A843. Aspects of residual thermal stresses in continuous-fiber-reinforced ceramic matrix composites. - KL Powell, PA Smith, JA Yeomans *(Dept of Mat Sci and Eng, Univ of Surrey, Guildford, Surrey GU2 5XH, UK)*. Composites Sci Tech 47(4) 359-367 (1993).

An analytical model is presented that predicts the thermal stresses which arise from mismatch in coefficients of thermal expansion between a fiber and the surrounding matrix in a continuous fiber composite. The model consists of two coaxial isotropic cylinders. Stress transfer between the fiber and the matrix near an unstressed free surface has been modeled by means of a shear-lag analysis. Away from the free surface the theoretical approach satisfies exactly the conditions for equilibrium and continuity of stress at the fiber-matrix interface. Application of the model to a composite consisting of a glass-ceramic calcium aluminosilicate matrix containing unidirectional Nicalon fibers points to a strong dependence of stress on fiber volume fraction. Surface effects are significant for depths of the order of one fiber diameter. Near-surface shear stresses resulting from cooling from the stress-free temperature are sufficiently high to suggest that a portion of the fiber close to the surface is debonded at room temperature. Experimental results acquired with a scanning electron microscope equipped with a heating stage are consistent with this prediction. Consequently, the model has been modified in a simple way to incorporate frictional slip at the interface, according to the Coulomb friction law. Although detailed measurements are limited by the resolution of the technique, experimental evidence suggests that the transfer length is within an order of magnitude of the model prediction.

9A844. Effects of thermal residual stresses and fiber packing on deformation of metal-matrix composites. - T Nakamura *(Dept of Mech Eng, SUNY, Stony Brook NY 11794)* and S Suresh *(Div of Eng, Brown Univ, Providence RI 02912)*. Acta Metall Mat 41(6) 1665-1681 (Jun 1993).

The combined effects of thermal residual stresses and fiber spatial distribution on the deformation of a 6061 aluminum alloy containing a fixed concentration unidirectional boron fibers have been analyzed using detailed FE models. The geometrical structure includes perfectly periodic, uniformly spaced fiber arrangements in square and hexagonal cells, as well as different cells in which either 30 or 60 fibers are randomly placed in the ductile matrix. The results indicate that both fiber packing and thermal residual stresses can have a significant effect on the stress-strain characteristics of the composite. The thermal residual stresses cause pronounced matrix yielding which also influences the apparent overall stiffness of the composite during the initial stages of subsequent far-field loading along the axial and transverse direction.

9A845. Low-temperature flexural dynamic measurements on PEEK, HTA and some of their carbon fibre composites. - RD Adams *(Dept of Mech Eng, Univ of Bristol, Bristol BS8 1TR, UK)* and JM Gaitonde *(Dept of Aerospace Eng, Univ of Bristol, Bristol BS8 1TR, UK)*. Composites Sci Tech 47(3) 271-287 (1993).

Polymers and polymer matrix composites undergo mechanical relaxations which are dependent on the temperature and frequency. A major glass-rubber (α) transition occurs for most structural polymers above 100° C. The work reported here concerns the low-temperature β and γ transitions and their effect on the modulus and mechanical damping of some structural thermoplastic materials. To this end, the flexural moduli and specific damping capacities of unreinforced PEEK, HTA and some unidirectional PEEK-AS4 and HTA-AS4 specimens have been measured between - 196° C and room temperature in vacuo. Specimens containing PEEK show a linear decrease of modulus with temperature whereas those containing HTA show a decrease which incorporates a pronounced drop (as a result of a peak in the damping). Damping results are compared with theoretical predictions which were derived by the use of the viscoelastic correspondence principle. In particular, the derivation of a predictive formula for the transverse damping of a unidirectional composite is presented, and this is shown to produce good results in view of experimental scatter.

9A846. Recent developments of thermosetting polymers for advanced composites. - HD Stenzenberger *(Technochemie GmbH Verfahrenstechnik, D-6915, Dossenheim, Germany)*. Composite Struct 24(3) 219-231 (1993).

The aircraft-industry is the fastest growing market sector for advanced composites. To use fully the potential of advanced composites for demanding structural applications it requires improved properties of its constituents, the carbon fibers and polymer matrix resins. This article emphasizes new developments of thermosetting polymers such as epoxy resins and bismaleimides. The concepts to achieve improved thermosetting polymer matrix resins are new monomers (resins and curing agents), thermoplastic modification, liquid crystalline monomers and impact tolerant interleafed systems. The paper highlights thermoset resins and systems which provide improvements in the areas of moisture absorption, fracture toughness and high temperature stability.

9A847. Residual thermal stresses in filamentary polymer-matrix composites containing an elastomeric interphase. - SD Gardner, CU Pittman Jr *(Dept of Chem Eng, Mississippi State Univ, Mississippi State MS 39762)*, RM Hackett *(Dept of Civil Eng, Univ of Mississippi, University MS 38677)*. J Composite Mat 27(8) 830-860 (1993).

A three-phase micromechanical model based on the method of cells is formulated to characterize residual thermal stresses in filamentary composites containing an interphase between the fiber and the matrix. This is the first such study to incorporate a true three-phase version of the method of cells. The model's performance is critically evaluated using data generated from other micromechanical models. The data correlate the residual thermal stresses in the fiber, interphase and matrix as a function of the interphase thickness and fiber volume fraction within each model composite. The study makes a broad assessment of the stress-attenuating characteristics that each interphase imparts to the graphite-epoxy composites.

9A848. Thermal degradation of an end-capped bismaleimide resin matrix (PMR-15) composite reinforced with pan-based carbon fibres. - ZD Xiang and FR Jones *(Dept of Eng Mat, Univ of Sheffield, Sheffield S10 2TZ, UK)*. Composites Sci Tech 47(3) 209-215 (1993).

Kinetics of thermal degradation of carbon fibre composites based on the PMR-15 resin have been studied in the temperature range of 382 - 457° C both in air and in nitrogen. The decomposition temperature of the matrix occurs at approximately 420° C and is not affected by the surrounding atmosphere. Degradation of the laminates in air, which occurs at a significantly higher rate than in nitrogen, consists of three kinetically different stages. The activation energy of degradation in air has been found to be between 98 and 315 kJ mol^{-1} depending on temperature range. The activation energy for oxidation of the carbon fibres in air is estimated to be 100 kJ mol^{-1}.

412Y. COMPUTATIONAL TECHNIQUES

9A849. Piecewise hierarchical p-version axisymmetric shell element for nonlinear heat conduction in laminated composites. - A Bose and KS Surana *(Dept of Mech Eng, Univ of Kansas, 3013 Learned Hall, Lawrence KS 66045)*. Comput Struct 47(1) 1-18 (3 Apr 1993).

This paper presents a three-node axisymmetric shell FE formulation for nonlinear axisymmetric steady-state heat conduction in laminated composites where the temperature approximation for the laminate is piecewise hierarchical and is derived based on the p-version. The temperature approximation for the element is developed first by establishing a hierarchical temperature approximation for each lamina of the laminate and then by imposing inter-lamina continuity conditions of temperature at the interface between the laminas. Weak formulation of the Fourier heat conduction equation in the cylindrical coordinate system with temperature-dependent thermal conductivities, internal heat generation, film coefficients and radiation effects is constructed and the individual lamina matrices and equivalent nodal heat vectors are derived using this weak formulation and the hierarchical temperature approximation for the laminas. Due to the temperature dependence of thermal conductivities, internal heat generation, film coefficients and radiation parameters; the resulting discretized equations of equilibrium are nonlinear. These equations are solved using the modified Newton-Raphson method. The tangent matrix is derived using the nonlinear equations of equilibrium. Numerical examples are presented to demonstrate the accuracy, efficiency and overall superiority of the present formulation and the extremely good and fast convergence of the iteration process. Comparisons are made with the available results in the literature.

414. Mass transfer

414B. CONVECTION DOMINATED TRANSFER

9A850. Interzonal natural convective heat and mass flow through doorway-like apertures in buildings: Experimental results. - MNA Said, SA Barakat, EA Whidden *(Inst for Res in Construct, NRC, Ottawa K1A 0R6, ON, Canada)*. J Solar Energy Eng **115**(2) 69-76 (May 1993).

This paper presents the results of full-scale experiments in a realistic building to evaluate natural convective heat and mass transfer through doorway-like apertures under small temperature differentials. The zone-to-zone temperature differences were nominally between 1° C and 2.5° C. Heat transfer correlations, coefficient of discharge, and thermal stratification are reported for air (Pr = 0.71), an enclosure aspect ratio of 0.26, aperture height relative to the enclosure height in the range of 0.75 to 1, and aperture width relative to the enclosure width in the range of 0.29 to 0.79. In general, the results extend the validity of previous theoretical and experimental work in the literature to large doorway-like apertures and small temperature differentials across the aperture typical to residential building conditions.

414C. SUBLIMATION OR ABLATION

9A851. Current distribution in the cathode area of an arcjet. - P Durgapal *(NASA Ames Res Center, MS 229-4, Moffett Field CA 94034)*. J Thermophys Heat Transfer 7(2) 241-250 (Apr-Jun 1993).

A theoretical model of the electrode phenomena, leading to the computation of the current density distributions, are spot temperature, spot size, sheath voltage, ablation velocity, and ablation rates, is put forward. Computations for an atmospheric arc, at load currents ranging from 800 to 3000 A, in 1) one segment, and 2) four segment electrode configurations, are conducted. Spot size seems to vary linearly with load current, ranging from 1.82 to 3.22 mm for a rotating arcfoot, as the load current is varied from 800 to 3000 A. Computations for P = 50 atm and I = 6000 A reveal that arc rotation is even more essential in order to save the excessive material ablation. In order to achieve an acceptable level of material ablation at P = 50 atm and I = 6000 A, a rotational frequency of 300 - 400 Hz needs to be achieved.

9A852. Influence of the freezing process on vapor transport during sublimation in vacuum-freeze-drying of macroscopic samples. - M Kochs *(Pierburg GmbH, Alfred-Pierburg-Str 1, D-4040 Neuss 1, Germany)*, Ch Korber, I Heschel, B Nunner *(Helmholtz-Inst Biomed Technik, RWTH, Paulwelsstr 30, D-5100 Aachen, Germany)*. Int J Heat Mass Transfer **36**(7) 1727-1738 (May 1993).

The influence of freezing on mass transfer during subsequent sublimation was examined in macroscopic samples (cm scale). A matrix with regions of pure ice and regions of concentrated solution forms during freezing. In macroscopic samples, resulting from local differences in solidification conditions, this matrix is irregular, leading to local differences in mass transfer properties in the drying sample. Sample segments at positions where solidification started yield small diffusion coefficients, the value increasing with the distance from this position, reaching a maximum in a layer right below the sample surface. A covering layer forms a limiting barrier against vapor transport. In macroscopic samples, a decrease of the applied cooling rate leads to a significant shift of the profile of space dependent diffusion coefficients to higher values and therefore to reduced drying times.

414D. DIFFUSION

9A853. Use of random walk models with spatially variable diffusivity. - JR Hunter, PD Craig, HE Phillips *(Div of Oceanog, CSIRO, GPO Box 1538 Hobart, Tasmania, Australia)*. J Comput Phys **106**(2) 366-376 (Jun 1993).

The random walk technique is commonly used to model diffusion in the environment. For a constant diffusivity K and model time-step δt, the random step should be chosen from a distribution with variance $2K\delta t$. However, if K varies spatially, this choice of step leads to the accumulation of particles in regions of low diffusivity. This problem can be overcome either by the incorporation of an apparent advection velocity, or by transforming to a coordinate system in which the diffusivity is constant. The latter technique requires no immediate approximations, is applicable to any reasonable diffusivity field and is therefore the preferred approach. Three important aspects of model design are discussed: the selection of the random number generator, the time step and the total number of particles.

414E. CONVECTION WITH DIFFUSION

9A854. Comparison of the solidification of aqueous sodium chloride with augmenting and opposing thermosolutal buoyancy forces. - S Chellaiah, MA Zampino *(Dept of Mech Eng, Florida Int Univ, Miami FL 33199)*, RA Waters *(AB_2MT Consult, Miami FL 33156)*. J Mat Processing Manuf Sci 1(4) 399-415 (Apr 1993).

The results of an experimental study to compare and illustrate the effects of thermosolutal convection and augmenting and opposing buoyancy forces on the solidification of aqueous sodium chloride are reported. Three experiments were performed with initial solute concentrations in the hypoeutectic (5%), eutectic (23.3%), and hypereutectic (24.5%) range. For the hypoeutectic solution, solidification causes solute to be redistributed into the bulk melt and divides melt into two distinct regions separated by a double-diffusive interface. In each of these regions, the temperature and concentrations distributions were significantly different. At the eutectic composition, solidification occurs as for a pure substance and hence, only thermally induced natural convection was present. In the bulk melt, there was a stable vertical temperature stratification. During solidification of the hypereutectic solution, solute was not redistributed into the bulk melt, but instead, solid sodium dihydrate crystals were formed.

9A855. Diffusion-controlled mass transfer from a rotating cylinder. - HQ Yang *(CFD Res, 3325-D Triana Blvd, Huntsville AL 35805)*. Numer Heat Transfer A **23**(3) 303-318 (Apr-May 1993).

In the chemical vapor deposition process, the objective is to grow a crystal film as fast as possible, while at the same time ensuring its chemical uniformity and crystal graphic perfection. This paper studies the possible enhancement of diffusion-controlled mass transfer by rotating a cylindrical substrate, which is used in the manufacture of superconductor materials. The numerical inaccuracy associated with the use of the conventional weak conservation form of the Navier-Stokes equations in polar coordinates is shown to be around 15%. It is found that rotation has minor influences on the average mass transfer rate and it generally increases the uniformity of the transport process.

9A856. Effect of axial solid heat conduction and mass diffusion in a rotary heat and mass regenerator. - JY San and SC Hsiau *(Dept of Mech Eng, Natl Chung-Hsing Univ, 250 KuoKuang Rd, Taichung 400, Taiwan, ROC)*. Int J Heat Mass Transfer **36**(8) 2051-2059 (May 1993).

This research analyzes the effect of axial heat conduction and mass diffusion on the performance of a solid desiccant wheel. A 1D transient heat and mass transfer model which contains four nonlinear partial differential equations is developed. The equations are solved using a full-implicit finite-difference method. A limiting case with a zero solid diffusion resistance is considered. The parameter, (λ2/4Ntu/Bi) is found to be the most important factor governing the axial heat conduction and mass diffusion effect.

9A857. Local heat-mass transfer distribution in a square channel with full and v-shaped ribs. - RT Kukreja, SC Lau, RD McMillin *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843-3123)*. Int J Heat Mass Transfer **36**(8) 2013-2020 (May 1993).

Naphthalene sublimation experiments have been conducted to study the turbulent heat-mass transfer characteristics of airflow in a square channel, in which two opposite walls are roughened with aligned arrays of full ribs and V-shaped ribs. The detailed distributions of the local heat-mass transfer coefficient on the ribbed walls and on the smooth walls are obtained. Results show that there are significant spanwise as well as streamwise variations of the local heat-mass transfer coefficient of the exposed surfaces of the ribbed walls in the oblique full rib and V-shaped rib cases.

9A858. Study of the effects of chemical reaction on the modified chemical vapor deposition (MCVD) process. - S Joh, R Greif *(Dept of Mech Eng, UCB)*, YT Lin *(Yuan-Ze IT, Taoyuan, Taiwan)*. J Mat Processing Manuf Sci 1(4) 369-386 (Apr 1993).

A study has been made of the effects of chemical reaction on the heat transfer and the deposition of particles that occurs during the Modified Chemical Vapor Deposition process. The steady-state energy and species equations for the gas ($SiCl_4$) and the particles (SiO_2) have been solved numerically for flow in a tube. The first order reaction rate for $SiCl_4$ has been used to include the reaction energy source that results from exothermic oxidation. Of particular interest are the effects of the inlet gas ($SiCl_4$) concentration flow rate and maximum wall temperature on the temperature and deposition profiles. It is shown that a spike in the temperature profile may occur, which alters the deposition characteristics.

9A859. Theoretical investigation of acoustic enhancement of heat and mass transfer I. Pure oscillating flow. - Man Yeong Ha *(Dept of Mech and Prod Eng, Pusan Natl Univ, 30 Jangjeon-Don Kumjung-Ku, Pusan 609-735, Korea)* and S Yavuzkurt *(Dept of Mech Eng, Penn State)*. Int J Heat Mass Transfer 36(8) 2183-2192 (May 1993).

Effects of an oscillating flow induced by a high intensity acoustic field on heat and mass transfer to and from particles and droplets such as pulverized coal particles and coal-water slurry fuel droplets are investigated. Numerical solutions of 2D, unsteady, laminar conservation equations for mass, momentum and energy transport in the gas phase give the velocity and temperature fields around a particle for different oscillating flows without superposed steady component as a function of time. The local and space-averaged Nusselt numbers depend on the change of imposed oscillating velocity U due to body curvature and flow acceleration. The combined effects of curvature and flow acceleration result in the maximum difference of 9% in the space- and time-average Nusselt number for frequencies of 50, 1000 and 2000 Hz for the acoustic Reynolds number varying between 10 and 100. The present results show about 290% increase in the space- and time-averaged Nusselt number for an acoustic Reynolds number of about 100 compared to that without acoustic field.

9A860. Theoretical investigation of acoustic enhancement of heat and mass transfer II. Oscillating flow with a steady velocity component. - Man Yeong Ha *(Dept of Mech and Prod Eng, Pusan Natl Univ, 30 Jangjeon-Dong Kumjung-Ku, Pusan 609-735, Korea)* and S Yavuzkurt *(Dept of Mech Eng, Penn State)*. Int J Heat Mass Transfer 36(8) 2193-2202 (May 1993).

In order to study the effects of high intensity acoustic fields superposed on a steady flow on heat and mass transfer around spherical particles, a 2D, unsteady computer code which employs the 2D, unsteady conservation of mass, momentum and energy equations for laminar flow in spherical coordinates has been developed. Numerical solutions of these equations give the velocity and temperature fields around the particle for acoustically oscillating flow as a function of acoustic Reynolds number, Strouhal number, and the ratio of the acoustic velocity on the steady slip velocity between the particles and the main flow. The present results show about 85% increase in the space- and time-averaged quasi-steady Nusselt number normalized by its steady value when the ratio of the acoustic velocity to the steady slip velocity is about 5. The results demonstrate a definite enhancement of heat and mass transfer in the presence of high intensity acoustic fields particularly for the case of low steady slip velocity.

414F. DOUBLE DIFFUSION AND OTHER COMBINED EFFECTS

9A861. Double-diffusive convection during solidification of a binary system. - Tatsuo Nishimura *(Dept of Mech Eng, Yamaguchi Univ, Japan)*, Masaki Fujiwara, Hisashi Miyashita *(Dept of Mat Sci and Eng, Toyama Univ, Japan)*. Heat Transfer Japan Res 21(6) 586-600 (Apr 1992).

An experimental study of solidification is performed for a super-eutectic sodium carbonate solution (Na_2CO_3-H_2O) in a confined cavity with varying initial concentrations and temperatures. We show important features of transport processes of heat and species during horizontal solidification by quantitative measurements of temperature and concentration. Initial superheat is found to be responsible for the initiation of the double-diffusive cells. For a higher initial concentration, a larger initial superheat is required for the onset of the double-diffusive cells.

9A862. Experimental and numerical analyses of double diffusive natural convection heated and cooled from opposing vertical walls with an initial condition of a vertically linear concentration gradient. - Katsuyoshi Kamakura *(Toyama Natl Col of Tech, Toyama 939, Japan)* and Hiroyuki Ozoe *(Inst of Adv Mat Stud, Kyushu Univ, Kasuga 816, Japan)*. Int J Heat Mass Transfer 36(8) 2125-2134 (May 1993).

When a solution having a vertically linear concentration gradient is heated from a vertical wall and cooled from an opposing vertical wall, multi-layered roll cells separated by almost-horizontal sharp interfaces are observed. A Galerkin FEM was employed for the numerical analysis of this double diffusive convection. Multi-layered roll cells with sharp and almost-horizontal interfaces were formed in the numerical simulation and then the concentration in each layer became almost uniform. The experiment confirmed the numerical results.

9A863. Study of the effects of macrosegregation and buoyancy-driven flow in binary mixture solidification. - SK Sinha *(Dept of Mech Eng, Delhi IT, Kashmere Gate, Delhi 110 006, India)*, T Sundararajan *(Dept of Mech Eng, Delhi IT, Kanpur 208 016, India)*, VK Garg *(NASA Lewis Res Center, MS 5-11, 21000 Brookpark Rd, Cleveland OH 44135-3191)*. Int J Heat Mass Transfer 36(9) 2349-2358 (Jun 1993).

A generalized anisotropic porous medium approach is developed for modelling the flow, heat and mass transport process during binary mixture solidification. Transient predictions are obtained using FEM, coupled with an implicit time-marching scheme, for solidification inside a 2D rectangular enclosure. A parametric study focusing attention on the effects of solutal buoyancy and thermal buoyancy is presented.

414I. POROUS MEDIA

9A864. Analytical approximation for nonlinear adsorbing solute transport and first-order degradation. - WJP Bosma and SEATM Van der Zee *(Dept Soil Sci and Plant Nutrition, Agri Univ, PO Box 8005, 6700 EC Wageningen, Netherlands)*. Transport Porous Media 11(1) 33-43 (Apr 1993).

Under some constraints, solutes undergoing nonlinear adsorption migrate according to a traveling wave. Analytical traveling wave solutions were used to obtain an approximation for the solute front shape, c(z,t), for the situation of equilibrium nonlinear adsorption and first-order degradation. This approximation describes numerically obtained fronts and breakthrough curves well. It is shown to describe fronts more accurately than a solution based on linearized adsorption. The latter solution accounts neither for the relatively steep downstream solute front nor for the deceleration in time of the nonlinear front.

9A865. Anisotropic thermoconvective effects on the onset of double diffusive convection in a porous medium. - MS Malashetty *(Dept of Math, Gulbarga Univ, 585 106 Karnataka, India)*. Int J Heat Mass Transfer 36(9) 2397-2401 (Jun 1993).

The linear stability of the thermodiffusive equilibrium of a binary mixture of two miscible fluids in a horizontal plane porous layer is investigated. The linear theory is based on the normal mode analysis under the small amplitude assumption. The effect of anisotropic thermo-convective currents on the stability is obtained. The effect of Prandtl number, ratio of diffusivities and separation parameter are presented graphically. It is found that the thermo-convective currents have a stabilizing effect as well as a destabilizing effect with respect to the case in which these currents are absent.

9A866. Diffusion of moisture in deformable porous media. Anisotropic fibrous materials. - J Cid *(Isover Saint-Gobain, CRIR Rantigny, France)*. Transport Porous Media 11(2) 117-138 (May 1993).

This paper presents a study on the deformation of anisotropic fibrous porous media subjected to moistening by water in the liquid phase. The deformation of the medium is studied by applying the concept of effective stress. Given the structure of the medium, the displacement of the solid matrix is not taken into account with respect to the displacement of the liquid phase. The transport equations are derived from the model proposed by Narasimhan. The transport coefficients and the relation between the variation in apparent density and effective stress are obtained by test measurements.

9A867. Calculation of upstream concentrations from downstream data for a two-layer flow. - R Smith *(Dept of Math Sci, Univ of Tech, Loughborough LE11 3TU, UK)*. IMA J Appl Math 50(2) 91-105 (1993).

Is it possible to infer the time-dependent cross-sectionally uniform concentration as the entry to a sampling tube from concentration flux measurements at the exit? Alas, if the shear description within the sampling tube is modelled by a constant-coefficient diffusion equation, the answer is no: the inversion problem is ill-posed. However, the closely related and more accurate telegraph equation can be inverted. As the separation between entry and exit increases, the deconvolution formula grows exponentially and oscillates more rapidly.

9A868. Parabolic approximations of the convection-diffusion equation. - JP Loheac *(Dept Math, Info Syst, Ecole Centrale Lyon, BP 163 69131, Ecully Cedex, France)*, F Nataf *(Centre Math Appl, Ecole Polytech, 91128 Palaiseau Cedex, France)*, M Schatzman *(Lab D'Anal Numer, Univ de Lyon I, 43 Bd du 11 Novembre 1918, 69622 Villeurbanne Cedex, France)*. Math Comput 60(202) 515-530 (Apr 1993).

We propose an approximation of the convection-diffusion operator which consists in the product of two parabolic operators. This approximation is much easier to solve than the full convection-diffusion equation, which is elliptic in space. We prove that this approximation is of order three in the viscosity ad that the classical parabolic approximation is of order one in the viscosity.

9A869. Determination of transfer coefficients by psychrometry. - A Kondjoyan and JD

Daudin *(Inst Natl Rech Agronomique, Sta Rech sur la Viande, Theix 63122, St-Genes-Champanelle, France)*. Int J Heat Mass Transfer 36(7) 1807-1818 (May 1993).

This paper presents a method based on psychrometry for measuring simultaneously heat and mass transfer coefficients in the case of forced convection exchanges between air and a body surface. This method is specially well adapted to bodies of complex shapes. The theoretical aspects are described. Errors linked to data treatments and to measurements are discussed.

416. Combustion

416B. FUNDAMENTALS

9A870. Recent developments in the theory of combustion of gases: A survey. - VN Kryzhanovskiy *(Polytech Inst, Kiev, Ukraine)*. Heat Transfer Res 24(4) 549-571 (Apr 1992).

A survey and analysis of the principal trends in the theory of premixed gas combustion are presented. The conformance of theories to experimental data is assessed critically, specifically in terms of the predicted structure of the laminar flame front and bulk combustion rate under different conditions. A kinetic theory that seems analytically sound, predicts the experimental findings well, and is adaptable to engineering design calculations is developed.

416E. TURBULENT FLAME PROPAGATION, FLAMMABILITY

9A871. Three-component LDV system for measurements of higher statistical moments in turbulent diffusion flames. - EP Hassel *(Fachgebiet Energie und Kraftwekstech, Tech Hochshule, Darmstadt, Germany)*. Forschung Ingenieur 59(4) 61-65 (Apr 1993).

A three-component LDV system was built with the following features: three colors, forward scattering, direction determination, avalanche photodiodes, transient recorder, fast Fourier transform. With this equipment measurements in a free air jet and a turbulent methane nitrogen diffusion flame were made. The following quantities were determined on the axis and on some levels: velocities u_i, spreading rate $r_{(0.5xuc)}/d$, centerline velocity decay u_0/u_c, Reynolds-stress tensor $u'_iu'_j$ and all third order moments $u'_iu'_ju'_k$. These quantities were normalized and compared with literature data and with Reynolds stress model calculations. One of the main objectives of these measurements was the supply of the exit velocity profiles because the predictions below the similarity region depend crucially on the boundary conditions. In this paper details of the equipment and of the data processing are explained and new results are shown.

416F. FLAME STABILITY AND STABILIZATION

9A872. Stabilization mechanism of the lifted jet diffusion flame in the hysteresis region. - Cheng-Kuang Lin *(Aeronaut Res Lab, Chun Shan Inst of Sci and Tech, Taichung, Taiwan, ROC)*, Ming-han Jeng, Yei-Chin Chao *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan, ROC)*. Exp Fluids 14(5) 353-365 (Apr 1993).

Recent experimental efforts focused on near-field coherent vortex dynamics, and their impact on stabilization of a lifted jet diffusion flame in the hysteresis region are reported. Simultaneous jet flow and flame visualizations are conducted first to obtain a global feature of flow-flame interaction. The statistical liftoff heights are calculated by a DIP (digital image processing) method. The gas concentration and velocity distributions induced by the vortex evolution as well as the corresponding flame from motion are deduced from phase-averaged measurements of planar Mie-scattering gas concentration images, LDV and ion-signals, respectively. The planar gas concentration technique employed here extends our previous work (Chao et al 1990, 1991a) to include phase-averaging. Results of the experiments show that the most probable flame base locations in the hysteresis region are at the coherent vortex roll-up and pairing locations. The deeply entrained air lump caused by large-scale vortices during roll-up and pairing is the main obstruction to flame propagation back to the nozzle exit and causes the hysteresis phenomenon.

416J. UNSTEADY COMBUSTION AND COMBUSTION ACOUSTICS

9A873. Issues associated with long-duration high-enthalpy scramjet combustor testing. - MW Thompson and MA Friedman *(Propulsion Group, Aeronaut Dept, Johns Hopkins Univ Appl Phys Lab, Laurel MD 20723)*. J Propulsion Power 9(3) 479-485 (May-Jun 1993).

Long-duration direct connect combustor tests are an essential element in the development of an effective supersonic combustion ramjet (scramjet). While test techniques and analysis methodology have been established for simulated flight Mach numbers at Mach 8 and below, phenomena associated with higher flight simulations require additional attention. In this article, technical issues associated with long-duration high-enthalpy direct-connect scramjet combustor tests are discussed. Since ground tests form the basis by which flight hardware is designed, it is important to quantify the differences between flight and ground test conditions. Analyses are presented herein which characterize the differences between ground test and flight combustor inlet properties. In particular, the effects of dynamic pressure and chemical nonequilibrium kinetics are investigated. Analytical results will also be presented which characterize aspects of the performance of a generic combustor operating at Mach 8, 11, and 12 flight simulations. One, two and three stream-mixing models are used to assess combustor performance and the predictions derived from the various models are contrasted.

416K. SUPERSONIC COMBUSTION

9A874. Experimental supersonic hydrogen combustion employing staged injection behind a rearward facing step. - JD Abbitt III, C Segal *(Dept Aerospace Eng Mech and Eng Sci, Univ of Florida, 231 Aerospace Build, Gainesville FL 32611)*, JC McDaniel, RH Krauss, RB Whitehurst *(Dept of Mech and Aerospace Eng, Univ of Virginia, Charlottesville VA 22903)*. J Propulsion Power 9(3) 472-478 (May-Jun 1993).

An experimental investigation of a Mach 2 combustor has been conducted in order to characterize flow properties in a supersonic reacting flowfield. Hydrogen was injected transversely as staged, underexpanded jets behind a rearward-facing step into a ducted Mach 2 air freestream. The effects of the chemical reaction on the supersonic flowfield was investigated using shadowgraphs, broadband flame emission photography, and planar laser induced fluorescence of OH. The shadowgraphs indicated that the wave pattern in the combustor along with flowfield unsteadiness was strongly affected by the heat release. The broadband flame emission photographs revealed large regions of no combustion in the vicinity of the fuel injectors where fuel-air mixing was insufficient to support combustion. These regions decreased in size as the freestream stagnation temperature was decreased for fixed hydrogen mass flow rate, consistent with an increase in the effective Q-ratio with combustion. The size of the zones containing OH in the planar fluorescence images also increased as the main flow stagnation temperature was decreased. Reaction zones were found in the planar fluorescence images away from regions containing injectant in a nonreacting study of the same geometry, indicating that the pressure rise associated with the reaction forced a large redistribution of the fuel.

9A875. High-temperature supersonic combustion testing with optical diagnostics. - TE Parker, MG Allen, WG Reinecke, HH Legner, RR Foutter, WT Rawlins *(Phys Sci, 20 New England Business Center, Andover MA 01810)*. J Propulsion Power 9(3) 486-492 (May-Jun 1993).

The development of supersonic combustion ramjet (SCRAMJET) engines requires testing using new, nonintrusive, instrumentation methods in high-speed high-enthalpy flow facilities. The stagnation temperatures for very high flight speeds (in excess of 3000 K) make the production of these flows impossible using conventional methods such as resistance heaters or vitiated flows. Similarly, measurements of properties in these flows is difficult since the measurement must be nonintrusive in nature. This article describes a test series using a shock tunnel to produce Mach 3.0 flows with stagnation temperatures in excess of 3000 K and an optical diagnostic set specifically tailored for measurements in supersonic high temperature systems. The test facility includes a hydrogen injection capability which makes combustion tests possible for these flows. This article describes the shock tunnel and its capabilities, provides an overview of the optical diagnostics used in the testing, and discusses the results of both combusting and noncombusting tests.

416O. COMBUSTORS AND AFTERBURNERS

9A876. Numerical simulation of turbine "hot spot" alleviation using film cooling. - DJ Dorney and RL Davis *(United Tech Res Center, Comput and Des Group, E Hartford CT 06108)*. J Propulsion Power 9(3) 329-336 (May-Jun 1993).

Experimental data have shown that combustor hot streaks can lead to pressure side "hot spots" on first-stage turbine rotor blades. In previous numerical studies, it has been shown that unsteady Navier-Stokes procedures can be used to predict the rotor pressure surface temperature increase associated with these combustor hot streaks. In the current investigation, similar 2D and 3D unsteady Navier-Stokes simulations have been performed to demonstrate the use of numerical tools in the optimization of film cooling configurations. In this study, the addition of prudently placed film cooling holes along the rotor pressure surface is shown to significantly diminish the adverse effects of the hot streak. Using a 2D Navier-Stokes procedure, a parametric study was performed to determine the impact of the location of the film cooling holes, fluid injection velocity, and fluid injection angle on the time-averaged rotor surface temperature. The experience gained from these 2D simulations was then applied to a series of 3D simulations in which the effects of the film cooling hole distribution on the rotor pressure surface temperature were studied. The results of these simulations indicate that computational procedures can be used to design feasible film cooling schemes which eliminate the adverse effects of combustor hot streaks.

416Q. LIQUID FUELS

9A877. Aspects of secondary atomization of aluminum-hydrocarbon slurry propellants. - DC Mueller *(Propulsion Eng Res Center, Penn State)* and SR Turns *(Dept of Mech Eng, 114 Res Build E, Penn State)*. J Propulsion Power 9(3) 345-352 (May-Jun 1993).

A theoretical and experimental investigation of the secondary atomization of Al-RP-1 slurry propellants was conducted. Theoretical efforts examined the effects of aluminum particle size in particle shell-crust formation on the surface of a burning slurry droplet. A model was developed for the pressure buildup and mechanical stresses in the shell for the time period after the shell becomes impermeable. Experimental efforts focused on the ignition and combustion of a dilute stream of slurry droplets. Measurements of individual particle diameters and velocities were made at various axial locations in the stream. Radiant emission from the particles was also monitored to determine whether aluminum was actively burning. Experimental aluminum agglomerate ignition times were found to be comparable to theoretical estimates. The experimentally measured minimum initial slurry droplet diameter for secondary atomization was 20-25μm, compared to a theoretical diameter of 35μm.

9A878. Improvement of combustion of gaseous and liquid fuels: A survey. - VN Kryzhanovskiy *(Kiev Polytech Inst, Ukraine)*. Heat Transfer Res 24(5) 703-730 (1992).

The principal trends in developing a theory of combustion and improving the technology of combustion of gaseous and liquid fuels are analyzed. Methods of describing the combustion process in terms of the flame length and of the volumetric rate of heat release, as well as the principal methods of combustion of these fuels are compared. It is shown that uniform distribution of fuel in the air stream prior to combustion is the most important way to improve combustion flames.

416S. FLAME AND FIRE (SPREAD AND EXTINCTION)

9A879. Experimental investigation of the blowout limits of a jet diffusion flame in co-flowing streams of different velocity and composition. - I Wierzba, K Kar, GA Karim *(Dept of Mech Eng, Univ of Calgary, AB, Canada)*. J Energy Resources Tech 115(2) 142-147 (Jun 1993).

The blowout limits of a methane diffusion flame in a co-flowing air-fuel or air-diluent stream were determined for a range of surrounding co-flow stream velocities, both laminar and turbulent, up to ~1.50 m/s. Methane, ethylene, propane and hydrogen were used as the fuels in the surrounding co-flow stream while nitrogen and carbon dioxide were used as diluents. The experimental results shown that velocity of the surrounding stream affects the blowout phenomena significantly. An increase in the stream velocity has a detrimental effect on the blowout limits at very low velocities up to 0.30 m/s (essentially laminar flow) and at velocities higher than 1.50 m/s (turbulent flow). The addition of a fuel to the air stream in most cases enhances the blowout limit of a methane diffusion flame.

9A880. The influence of external heat transfer on flame extinction of dilute sprays. - Shuhn-Shyurng Hou, Chi-Chang Liu, Ta-Hui Lin *(Dept of Mech Eng, Natl Cheng-Kung Univ, Tainan 701, Taiwan, ROC)*. Int J Heat Mass Transfer 36(7) 1867-1874 (May 1993).

The extinction of a dilute spray flame burning in a steady, 1D, low-speed, sufficiently off-stoichiometric, two-phase flow, and experiencing the external heat transfer from the spray to a tube wall upstream is further analyzed. The external heat transfer results in globally external heat loss, excess enthalpy burning and external heat gain, respectively, to the spray system with increasing the wall temperature. However, the droplet gasification provides the overall internal heat loss and heat gain for rich and lean sprays, respectively. Variations of the extinction curves under the influence of transition from overall external heat loss to heat gain, and the jump between the completely and partially prevaporized burnings on flame extinction, are reported and discussed for both lean and rich sprays.

416T. COMBUSTION, FLAME, AND FIRE MODELING

9A881. Control volume FE solution of a confined turbulent diffusion flame. - D Elkaim, M Reggio, R Camarero *(Dept of Mech Eng, Ecole Polytech Montreal, CP 6079 Succ A, Montreal H3C 3A7, PQ Canada)*. Numer Heat Transfer A 23(3) 259-279 (Apr-May 1993).

The control volume FEM in conjunction with the vorticity stream function formulation is used to produce a numerical solution of the confined turbulent diffusion flame. The turbulence is described by the k - ε model with wall functions near solid boundaries. The combustion kinetics are defined by a one-step infinte rate chemical reaction. The validity of the numerical method is assessed by a comparison between present numerical results and experimental data from the literature for a laboratory diffusion flame.

9A882. Modelling of unsteady combustion regimes for polydisperse fuels I. Instability and auto-oscillations. - YA Buyevich, NA Korolyova, IA Natalukha *(Dept of Math Phys, Urals State Univ, Ekaterinburg 620083, Russia)*. Int J Heat Mass Transfer 36(8) 2223-2231 (May 1993).

A general theory of instability and self-oscillating accompanying combustion of polydisperse assemblages of particles is elaborated on the basis of a model including heat and mass balance equations and the kinetic equation governing the particle size distribution. At arbitrary burning kinetics of particles and the particle influx rate they are reduced, under the condition of ideal mixing, to only two functional integrodifferential equations for the dimensionless temperature and oxidant concentration. Steady combustion processes are shown to be unstable in many important situations. The properties of possible slightly nonlinear auto-oscillations are studied in greater detail.

9A883. Modelling of unsteady combustion regimes for polydisperse fuels II. Parametrically controlled combustion. - YA Buyevich, NA Korolyova, IA Natalukha *(Dept of Math Phys, Urals State Univ, Ekaterinburg 620 083, Russia)*. Int J Heat Mass Transfer 36(8) 2233-2238 (May 1993).

Results of computer calculations of essentially nonlinear periodic combustion regimes originating far from the stability boundary are presented. The influence of the parametrical modulation of relevant processing parameters upon the neutral stability and upon the properties of oscillating combustion regimes is investigated. Modulation characteristics which cause either stabilization or destabilization of combustion are determined. Quasiperiodic combustion states forming outside the regions of frequency locking are studied.

9A884. Determination of the 3D temperature field on the spherical piston head in a high-speed internal-combustion engine. - MV Stradomskiy, VA Asmalovskiy, ON Vazhenin, VV Medyanovskiy, AK Gushchin *(Eng Thermophys Inst, Ukrainian Acad of Sci, Kiev, Ukraine)*. Heat Transfer Res 24(3) 415-423 (Apr 1992).

We present a technique for computer calculation of 3D temperature- and heat flux density distributions on the surface of the spherical head of a high-out-put internal combustion engine piston, based on temperatures measured in a limited number of points within the piston. The technique is useful in design of prevention of thermal overload on such pistons and similar devices.

9A885. Influence of nozzle sac volume on diesel spray droplet sizes. - JR Farrar-Khan, GE Andrews, PT Williams *(Dept of Fuel and Energy, Univ of Leeds)*. Proc Inst Mech Eng A 206(A4) 239-248 (1992).

The influence of nozzle sac volume and associated changes in the fuel hole upstream flow on the spray atomization velocity and penetration were studied. Four injectors, designed for applications in 1 liter per cylinder diesel engines, were investigated with the same 215 bar injector nozzle opening pressure and fuel flow quantity. A Malvern 2600c Series diesel spray laser diffraction spray analyzer was used. Significant differences in the spray characteristics were found which helped to explain some of the emission differences between the four injectors.

9A886. Stochastic-experimental investigation of the cyclic pressure variation in a DI single-cylinder diesel engine. - DA Kouremenos, CD Rakopoulos, KG Kotsos *(Thermal Eng Section, Mech Eng Dept, Natl Tech Univ, 42 Patission St, Athens 106 82, Greece)*. Int J Energy Res 16(9) 865-877 (Dec 1992).

This paper presents an analysis of the cycle-by-cycle combustion variation as reflected in the pressure indicator diagram of a single-cylinder, naturally aspirated, four-stroke, direct-injection, Lister LV1 diesel engine. A measuring set-up consisting of piezoelectric transducers with charge amplifiers, in the cylinder and the fuel injection pipeline, and a fast data-acquisition board installed on an IBM-compatible microcomputer was used to gather the data of 650 successive combustion cycles of the cylinder, under various combinations of injection timing and load conditions. The measured data were corrected for drift, and the top dead center of each cycle is determined thermodynamically. The data obtained by this technique were analyzed for the peak pressure, the peak rate of pressure rise, the crank angles at which these maximum values occur, and for the injection timing and ignition delay. The groups of parameters have been further statistically analyzed for averages, standard deviations, probability density functions, autocorrelation and power spectra. Crosscorrelation runs were also performed to observe any cause relationship between cyclic pressure variations and the fuel-injection-system operation. The results of the stochastic analysis technique have proved to be very useful for the investigation and interpretation of the existence of fluctuation phenomena in the diesel internal combustion engine and their cause relationships, thereby aiding the correct interpretation of the relevant experimental results and their associated errors.

9A887. Theoretical study of a variable compression ratio turbocharged diesel engine. - TJ Rychter, A Teodorczyk *(Warsaw Univ Tech, Poland)*, CR Stone, HJ Leonard, N Ladommatos *(Dept of Manuf and Eng Syst, Brunel Univ, Uxbridge, Middlesex, UK)*, SJ Charlton *(Sch of Mech Eng, Univ Bath, UK)*. Proc Inst Mech Eng A **206**(A4) 227-238 (1992).

A variable compression ratio concept that can give a different expansion ratio to the compression ratio has been evaluated by means of a simulation of a turbocharged diesel engine. The compression ratio is controlled by varying the ratio of the connecting rod length to the crank throw, hence the name variable crank radius-connecting rod length engine (VR-LE). The VR-LE mechanism kinematics have been defined and described, and the compression ratio and expansion ratio have been presented as a function of the eccentric phase angle (α_o. A zero dimensional engine simulation that has been the subject of comprehensive validation has been used as the basis of the VR-LE study. The effect of the compression ratio on the engine performance at fixed loads is presented. The principal benefits are a reduction in fuel consumption at part load of about 2% and a reduction in ignition delay that leads to an estimated 6 dB reduction in combustion noise. The study has been conducted within the assumption of a maximum cylinder pressure of 160 bar.

418G. GAS TURBINES

9A888. Optimizations for Brayton-Joule gas turbine cycles. - TH Frost, B Agnew, A Anderson *(Dept of Mech Mat and Manuf Eng, Univ of Newcastle upon Tyne, Newcastle upon Tyne, UK)*. Proc Inst Mech Eng A **206**(A4) 283-288 (1992).

Traditionally, the simple Brayton-Joule cycle has been optimized for maximum output and for minimum compressor and work with intercooling and maximum turbine work with reheat. To these Woods et al have added optimization for peak efficiency of the simple cycle with internal irreversibilities. The results now presented include both maximum output and peak efficiency for both regenerative and intercool-reheat cycles with internal irreversibilities. Two special cases, for a regenerative cycle and for a nonregenerative cycle with both reheat and intercooling, are identified where the conditions for maximum output and peak efficiency coincide.

9A889. Approach to modeling continuous turbine engine operation from startup to shutdown. - MA Chappell *(Arnold Eng Dev Center, Sverdrup Tech, Arnold Air Force Base TN 37389)* and PW McLaughlin *(Simulation and Modeling Workshop, 176 Sunset Dr, Glastonbury CT 06033)*. J Propulsion Power **9**(3) 466-471 (May-Jun 1993).

A generalized turbine engine start simulation (mathematical model) has been developed and demonstrated. The model, designated as ATEST-V3, is capable of simulating engine operation continuously from near static (zero speed) conditions to maximum engine power including windmill starting, spooldown starting, and starter-assisted starting. The enhanced capability to simulate the engine starting process provides the means to characterize and understand engine system operational behavior during critical startup and shutdown operations. ATEST-V3 is based on an aerothermodynamic matching of the major components. The component-matching technique is widely used for steady-state and transient turbine engine simulations that typically exclude subidle and starting operations. The same approach is shown to be applicable to engine starting operations by modeling component behavior continuously from zero to maximum power. The combination of an existing transient engine simulation and a numerically stable component-matching algorithm provided a foundation for extending the simulation capability to subidle engine operation and engine starting. ATEST-V3 was applied to a modern flight-type turbofan engine which demonstrated the capability to simulate windmill, spooldown, and starter-assisted starts at various flight conditions. Finally, a comparison is made between model results and engine test data.

Commercial turbofan engine exhaust nozzle flow analyses. - KS Abdol-Hamid *(Anal Services and Mat, Hampton VA 23666)*, K Uenishi, BD Keith *(ATO-General Elec Aircraft Engines, Cincinnati OH 45201)*, JR Carlson *(Propulsion Aerodyn Branch, Appl Aerodyn Div, NASA Langley Res Center, Hampton VA 23681)*. J Propulsion Power **9**(3) 431-436 (May-Jun 1993).

The recently developed 3D code is able to perform a computational investigation of complex aircraft aerodynamic components. This code was developed for solving the simplified Reynolds-averaged Navier-Stokes equations in a 3D multiblock multizone structured mesh domain. The present analysis was applied to commercial turbofan exhaust flow systems. Solution sensitivity to grid density is presented. Laminar flow solutions were developed for all grids, and two-quation κ-ε solutions were developed for selected grids. Static pressure distribution, mass flow, and thrust quantities were calculated for on-design engine operating conditions. Good agreement between predicted surface static pressures and experimental data was observed at different locations. Mass flow was predicted within 0.2% of experimental data. Thrust forces were typically within 0.6% of experimental data.

418L. IONIC, ELECTRIC, AND PHOTONIC PROPULSION

9A891. Anode power deposition in magnetoplasmadynamic thrusters. - AD Gallimore *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 41809)*, AJ Kelly, RG Jahn *(Elec Propulsion Lab, Princeton)*. J Propulsion Power **9**(3) 361-368 (May-Jun 1993).

Results of anode heat-flux and anode fall measurements from a multimegawatt self-field quasisteady magnetoplasmadynamic (MPD) thruster are presented. Measurements were obtained with argon and helium propellants for a variety of currents and mass flow rates. Anode heat flux was directly measured with thermocouples attached to the inner surface of a hollowed section. Anode falls were determined both from floating probes and through heat flux measurements. Comparison of data acquired through either method shows excellent agreement. Anode falls varied between 4-50 V with anode power fraction reaching 70% with helium at 150 kW, and 50% with argon at 1.9 MW. The anode fall was found to correlate well with electron Hall parameters calculated from triple Langmuir and magnetic probe data collected near the anode. Two possible explanations oro this result are proposed: 1) the establishment of large electric fields at the anode to maintain current conduction across the strong magnetic fields; and 2) anomalous resistivity resulting from the onset of microturbulence in the plasma. To investigate the latter hypothesis, electric field, magnetic field, and current density profiles measured in the vicinity of the anode were incorporated into Ohm's law to estimate the electrical conductivity. Results of this analysis show a substantial deviation of the measured conductivity from that calculated with classical formulas. These results imply that anomalous effects are present in the plasma near the anode.

9A892. Erosion rate diagnostics in ion thrusters using laser induced fluorescence. - CJ Gaeta *(Optical Phys Lab, Hughes Res Lab, Malibu CA 90265)*, JN Matossian *(Plasma Phys Lab, Hughes Res Lab, Malibu CA 90265)*, RS Turley *(Optical Phys Lab, Hughes Res Lab, Malibu CA 90265)*, JR Beattie, JD Williams, WS Williamson *(Plasma Phys Lab, Hughes Res Lab, Malibu CA 90265)*. J Propulsion Power **9**(3) 369-376 (May-Jun 1993).

We have used laser induced fluorescence (LIF) to monitor the charge-exchange ion erosion of the molybdenum accelerator electrode in ion thrusters. This real-time, nonintrusive method was implemented by operating a 30-cm-diam ring-cusp thruster using xenon propellant. With the thruster operating at a total power of 5 kW, laser radiation at a wavelength of 390 nm was directed through the extracted ion beam adjacent to the downstream surface of the molybdenum accelerator electrode. Molybdenum atoms, sputtered from this surface as a result of charge-exchange ion erosion, were excited by the laser radiation. The intensity of the laser-induced fluorescence radiation, which is proportional to the sputter rate of the molybdenum atoms, was measured and correlated with variations in thruster operating conditions such as accelerator electrode voltage, accelerator electrode current, and test facility background pressure. We also demonstrated that the LIF technique has sufficient sensitivity and spatial resolution to evaluate accelerator electrode lifetime in ground-based test facilities.

9A893. Simulating a 1-kW arcjet thruster using a nonlinear active load. - GP Altenburger *(Devilbiss-Ransburg Indust Liquid Syst, Toledo OH 43612)* and RJ King *(Dept of Elec Eng, Univ Toledo, Toledo OH 43606)*. J Propulsion Power **9**(3) 377-381 (May-Jun 1993).

Arcjet thrusters are known to have distinctly nonlinear electrical characteristics with negative incremental resistance throughout their normal operating region. The 1-kW arcjet simulator proposed here is an electronic load bank which accurately mimics these characteristics statically and dynamically up to 40 kHz. A power-processing unit (PPU) was tested using a resistive load bank, the simulator, and a 1-kW arcjet. The simulator was found to be an accurate stand-in for the arcjet during system transient testing, while the resistive load was not. The simulator uses resistors and insulated-gate bipolar transistors to dissipate the PPU output power; a nonlinear feedback is applied to produce the desired v-i characteristics. This feedback is analyzed dynamically. This arcjet simulator allows the development of a new PPU design to a higher level of confidence before beginning testing at an arcjet facility.

452B. FUNDAMENTALS OF FLUID FLOW

9A895. Diffusion in isotropic and anisotropic porous system. Three-dimensional calculations. - M Quintard *(LEPT-ENSAM, URA CNRS, Esplanade des Arts Metiers, 33405 Talence Cedex, France)*. Transport Porous Media 11(2) 187-199 (May 1993).

Effective diffusion coefficients were calculated numerically for 3D unit cells representative of different unconsolidated porous media. These numerical results were compared with the experimental results of Kim for packed beds of glass spheres, mica particles, and an artificial porous medium compound of mylar disks. These 3D numerical results confirm that the porosity is the essential parameter for the determination of the effective diffusion coefficient in the case of unconsolidated isotropic systems. In the case of anisotropic systems, better agreement is obtained between numerical predictions and actual data when the unit cell is 3D rather than 2D.

9A896. Interpretation of capillary pressure curves using invasion percolation theory. - Dengen Zhou *(Dept of Pet Eng, Stanford, Mitchell 360)* and EH Stenby *(Eng Res Centre, IVC-SEP, Inst for Kemitek, Bldg 229 DTH, DK-2800 Lyngby, Denmark)*. Transport Porous Media 11(1) 17-31 (Apr 1993).

Invasion percolation was studied on 3D regular lattices of various node numbers. A new model has been developed to obtain the pore-size distribution from capillary pressure measurements. The new model is superior to the conventional percolation model, since it takes into account the physical trapping of the wetting phase. The irreducible wetting phase saturation includes the film of the wall of the pores, the dead-end pore volume, and the main contribution by pores isolated from the outlet of the medium by the nonwetting phase. This has been related to the node number and the sample 3Ds. Over 100 capillary pressure curves of consolidated media have been collected. Good agreement was obtained between this data set out and our invasion percolation predictions using node numbers of 6-13, as reported by Mishra and Sharma. The pore-throat size distribution function estimated by our new model is broader than from the conventional percolation and the capillary tube models.

9A897. Network model evaluation of permeability and spatial correlation in a real random sphere packing. - SL Bryant *(BP Chem, Bo'ness Rd, Grangemouth Stirlingshire FK3 9XH, UK)*, PR King *(BP Res Centre, Chertsey Rd, Sunbury-on-Thames, Middlesex TW16 7LN, UK)*, DW Mellor *(Kerr-Mellor Assoc, 1 Woodside, Camberley, Surrey GU17 9JJ, UK)*. Transport Porous Media 11(1) 53-70 (Apr 1993).

In principle, network models can replicate exactly the microstructure of porous media. In practice, however, network models have been constructed using various assumptions concerning pore structure. This paper presents a network model of a real, disordered porous medium that invokes no assumptions regarding pore structure. The calculated permeability of the model agrees well with measured permeabilities, providing a new and more rigorous confirmation of the validity of the network approach. Several assumptions commonly used in constructing network models are found to be invalid for a random packing of equal spheres. In addition, the model permits quantification of the effect of pore-scale correlation (departure from randomness) upon permeability. The effect is comparable to reported discrepancies between measured permeabilities and predictions of other network models. The implications of this finding are twofold. First, a key assumption of several theories of transport in porous media, namely that pore dimensions are randomly distributed upon a network, may be invalid for real porous systems. Second, efforts both to model and to measure pore-scale correlations could yield more accurate predictions of permeability.

9A898. Percolation in layered media: A conductivity approach. - A Hansen *(GMCM, URA CNRS 804, Univ de Rennes 1, F-35042 Rennes, Cedex, France)*, EL Hinrichsen *(Center for Industriforskning, PO Box 124, N-0314 Oslo, Norway)*, D Stauffer *(Inst Theor Phys, Univ, D-5000 Cologne 41, Germany)*. Transport Porous Media 11(1) 45-52 (Apr 1993).

Long square-lattice and cubic-lattice samples consisting of many layers are simulated. Within each layer, the concentration of permeable bonds is constant whereas each layer has a different concentration chosen randomly from the interval between the percolation threshold and unit concentration. The conductivity of the random resistor network corresponding to this percolation model is calculated, both parallel and perpendicular to the layers, in both 2D and 3D. For the conductivity parallel to the layers, an effective medium calculation comes within 10% of the true conductivity. For the conductivity perpendicular to the layers, percolation theory is necessary.

9A899. Pore structures and transport properties of sandstone. - C David, M Darot *(EOPGS Lab Mat, 5 Rue Descartes, 67084 Strasbourg Cedex, France)*, D Jeannette *(CGS, 1 Rue Blessig, 67084 Strasbourg Cedex, France)*. Transport Porous Media 11(2) 161-177 (May 1993).

We report laboratory measurements of pore structure, capillarity, water permeability, and electrical conductivity on Fontainbleau sandstone specimens. Experimental, equipment and techniques are described. Water permeability measurements were performed on saturated cores with a 100 MPa permeameter. Various combinations of pore and confining pressures were used and an effective pressure law was determined. Differences between transport properties of the three types of sandstone are related to the microstructural characteristics of the pore network of each rock.

9A900. Stochastic approach for groundwater flow in a semiconfined aquifer subject to random boundary conditions. - MG Satish and Jianting Zhu *(Dept of Civil Eng, Tech Univ, PO Box 1000 Halifax, NS, B3J 2X4, Canada)*. Adv Water Resources 15(6) 329-339 (1992).

A methodology is presented for analyzing the groundwater flow through a shallow semiconfined aquifer with random parameters, governed by the Helmholtz equation and subject to stochastic boundary conditions. Stochasticity in an aquifer parameter is considered along with the stochasticity in the Dirichlet and Neumann boundary conditions. The BEM based on perturbation does not require specification of the probability density function of the parameters but only their expectations, variances and the covariance of the random quantities. The applicability of the method is demonstrated by presenting a groundwater flow example as well as by comparing the numerical results with analytical solutions for a special case without the Neumann boundary condition uncertainty.

9A901. A Lattice model of foam flow in porous media. A percolation approach. - WG Laidlaw, WG Wilson *(Chem Dept, Univ of Calgary, AB, T2N 1N4, Canada)*, DA Coombe *(Comput Model Group, 3512-33rd St NW Calgary, AB, T2L 2A6, Canada)*. Transport Porous Media 11(2) 139-159 (May 1993).

Because fluid flow in porous media is opaque to most observational techniques simulations of the processes occurring in porous media have become important. Typical reservoir simulations treat the flow as taking place in some averaged (Darcy-scale) medium but simulations can also be carried out at the level of the network of pores and throats of the porous medium. We report the results of a pore-scale investigation of mechanisms for the alteration of mobility by foam lamella blockage in a network of these spaces and channels of porous media. An explanation of the shift in breakthrough gas saturation and the deformation of the shape of permeability *vs* saturation curves upon introduction of foam is provided for a variety of blocking mechanisms.

9A902. Two-phase brine mixtures in the geothermal context and the polymer flood model. - R Young *(Appl Math, Indust Res, PO Box 31310, Lower Hutt, New Zealand)*. Transport Porous Media 11(2) 179-185 (May 1993).

Two-phase mixtures of hot brine and steam are important in geothermal reservoirs under exploitation. In a simple model, the flows are described by a parabolic equation for the pressure with a derivative coupling to a pair of wave equations for saturation and salt concentration. We show that the wave speed matrix for the hyperbolic part of the uncoupled system is formally identical to the corresponding matrix in the polymer flood model for oil recovery. For the class of *strongly diffusive* hot brine models the identification is more than formal, so that the wave phenomena predicted for the polymer flood model will also be observed in geothermal reservoirs.

An approach based upon Bayes Theorem has been developed to resolve two major difficulties encountered in earlier experimental investigations concerned with the estimation of parameters for heat transfer in fixed beds. The first difficulty is in obtaining estimates of the Nusselt and Peclet groups with appropriate confidence intervals, and the second is the considerable variation found in the Peclet and Nusselt groups in the range of intermediate Reynolds number. In a new experimental investigation it has been found that estimates of the Peclet and Nusselt groups could be changed in a correlated way without changing the variance of experimental error about the theoretical values, an interaction that precluded the accurate estimation of either parameter. The Baysian approach identified a confidence region linking the Nusselt and Peclet groups from earlier work, and a confidence region for the two parameters obtained in the new investigation; the best estimates were obtained where the two confidence regions overlapped. In the final presentation the parameter values and independent estimates of parameter accuracy were found to be consistent with correlations established on the basis of earlier work, but with greatly improved confidence regions for the Nusselt and Peclet groups expressed as functions of Reynolds number.

452K. RESERVOIR ENGINEERING

9A905. **Displacement of trapped oil from water-wet reservoir rock.** - Dengen Zhou *(Dept of Pet Eng, Stanford, Mitchel 360)* and EH Stenby *(Eng Res Center, IVC-SEP, Inst for Kemitek, Bldg 229 DTH, DK-2800 Lyngby, Denmark)*. Transport Porous Media 11(1) 1-16 (Apr 1993).

Displacement of oil trapped in water-wet reservoirs was analyzed using percolation theory. The critical capillary number of the CDC (Capillary Desaturation Curve) was be predicted based on the pore structure of the medium. The mobilization and stability theories proposed by Stegemeier were used to correlate oil cluster length to the capillary number needed to mobilize the trapped oil. Under the assumption that all pore chambers have the same size, a procedure was developed using the drainage capillary pressure curve and effective accessibility function to predict the CDC curve for a given medium. The prediction of critical capillary numbers was compared with the experimental data from 32 sandstone samples by Chatzis and Morrow. Also, the CDC curve of one sandstone sample was calculated using the procedure developed in this work and compared with the measured data. Very good agreements were obtained.

9A906. **Review of current trends in petroleum reservoir description and assessment of the impacts on oil recovery.** - FJ Fayers and TA Hewett *(Dept of Pet Eng, Stanford)*. Adv Water Resources 15(6) 341-365 (1992).

This paper gives a general review of the problems associated with realistic representation of reservoir heterogeneities and their impacts on current trends in reservoir simulation. The basic three-phase flow equations used in reservoir engineering are summarized and some of the uncertainties associated with the properties of two-phase relative permeabilities are reviewed. The approaches available for averaging both absolute and relative permeabilities in representative elements of volume are summarized, and examples are given of some of their attributes. For large reservoirs, a prediction procedure based on a synthesis from streamline solutions is sometimes attractive.

9A907. **Study of massive water injection by thermoporomechanical coupling model.** - JF Shao, JP Henry *(Lab of Mech of Lille, EUDIL, 59655 Villeneuve d'Ascq, France)*, F Skoczylaz, I Shahrour *(Lab of Mech of Lille, Ecole Centrale Lille, 59651 Villeneuve d'Ascq, France)*. Comput Geotech 15(2) 105-121 (1993).

In this paper, we present a numerical study of the massive water injection in petroleum reservoir. A FE model is developed using a complete coupling algorithm. The thermal convective effect is taken into account. This allows to deal with high fluid flow rate and high temperature variation during the injection time. Evolutions of pore pressure, temperature and rock compaction as function of injection time are studied. The obtained results show that it is possible to use a semi-decoupled model by eliminating some negligible coupling terms.

452L. FLOW STABILITY

9A908. **Boundary and inertia effects on vortex instability of a horizontal mixed convection flow in a porous medium.** - Kun-Nun Lie and Jiin-Yuh Jang *(Dept of Mech Eng, Natl Cheng-Kung Univ, Tainan 70101, Taiwan, ROC)*. Numer Heat Transfer A 23(3) 361-378 (Apr-May 1993).

Non-Darcian effects, including the effects of boundary and inertia, are examined on the flow and vortex instability of a horizontal mixed convective boundary layer flow in a high-porosity medium. In the base flow, the governing conservation equations are solved by using a suitable variable transformation and employing an implicit finite-difference scheme. The stability analysis is based on linear stability theory, and the resulting equations are solved on the basis of the local similarity approximations. The results show that the flow becomes more susceptible to the vortex mode of disturbances as buoyancy force is increased.

9A911. **Modeling of dynamic networks of thin thermoelastic beams.** - JE Lagnese, G Leugering *(Dept of Math, Georgetown Univ, Washington DC 20057)*, EJPG Schmidt *(Dept of Math and Stat, McGill Univ, 805 Sherbrook St W, Montreal, PQ H3A 2K6, Canada)*. Math Methods Appl Sci 16(5) 327-358 (May 1993).

We derive a distributed-parameter model of a thin nonlinear thermoelastic beam in 3D. The beam can also be initially curved and twisted. Our main task is to formulate the nonhomogeneous initial, boundary and node value problem associated with the dynamics of a network of a finite number of such beams. The emphasis here is on a distributed-parameter modeling of the geometric and kinematic node conditions. The forces and couples appearing in the boundary and node conditions can then be viewed as control variables. The analysis of the resulting control systems and their controllability and stabilizability properties is the subject forthcoming papers.

9A912. **3D primary zero-offset reflections.** - P Hubral, J Schleicher *(Geophys Inst, Univ Fridericiana Karlsruhe, Hertzstr 16 Bau 42, D-W7500 Karlsruhe 21, Germany)*, M Tygel *(Dept Mat Appl, Univ Est de Campinas, UNICAMP Caixa PO Box 6065, 13081 Campinas SP, Brazil)*. Geophys 58(5) 692-702 (May 1993).

Zero offset reflections resulting from point sources are often computed on a large scale in 3D laterally inhomogeneous isotropic media with the help of ray theory. The geometrical-spreading factor and the number of caustics that determine the shape of the reflected pulse are then generally obtained by integrating the so-called dynamic ray-tracing system down and up the two-way normal incidence ray. Assuming that this ray is already known, we show that one integration of the dynamic ray-tracing system in a downward direction with only the initial condition of a point source at the earth's surface is in fact sufficient to obtain both results. To establish the Fresnel zone of the zero-offset reflection upon th reflector requires the same single downward integration. By performing a second downward integration (using the initial conditions of a plane wave at the earth's surface) the complete Fresnel volume around the two-way normal ray can be found. This should be known to ascertain the validity of the computed zero-offset event. A careful analysis of the problem as performed here shows that round-trip integrations of the dynamic ray-tracing system following the actually propagating wave front along the two-way normal ray need never be considered. In fact some useful quantities related to the two-way normal ray (eg, the normal-moveout velocity) require only one single integration in one specific direction only. Finally, a two-point ray tracing for normal rays can be derived from one-way dynamic ray tracing.

9A913. **Effects of viscoelasticity on seismic wave propagation in fault zones, near-surface sediments, and inclusions.** - Ik Bum Kang and GA McMechan *(Center for Lithospheric Stud, Univ of Texas at Dallas, PO Box 830688, Richardson TX 75083-0688)*. Bull Seismol Soc Am 83(3) 890-906 (Jun 1993).

By defining anelastic effects through the superposition of relaxation mechanisms, and incorporating them into the wave equation in terms of memory variables, the time-domain computation of responses of viscoelastic media with arbitrary spatial variations is feasible. This approach is applied to simulation of the effects of realistic distribution of compressional and shear wave quality factors (Qp and Qs) in a sequence of viscoelastic models of increasing complexity from a homogeneous medium, to a fault zone, a near-surface attenuating zone, and inclusions with anomalous Qp and Qs values.

9A914. **Ground roll: A potential tool for constraining shallow shear wave structure.** - GI Al-Eqabi and RB Herrmann *(Dept of Earth and Atmos Sci, St Louis Univ, 3507 Laclede, St Louis MO 63103)*. Geophys 58(5) 713-719 (May 1993).

The objective of this study is to demonstrate that a laterally varying shallow S-wave structure, derived from the dispersion of the ground roll, can explain observed lateral variations in the direct S-wave arrival. The data set consists of multichannel seismic refraction data from a USGS-GSC survey in the state of Maine and the province of Quebec. These data exhibit significant lateral changes in the moveout of the ground-roll as well as the S-wave first arrivals. A sequence of surface-wave processing steps are used to obtain a final laterally varying S-wave velocity model. These steps include visual examination of the data, stacking, waveform inversion of selected traces, phase velocity adjustment by cross-correlation, and phase velocity inversion. These models are used to predict the S-wave first arrivals by using 2D ray tracing techniques. Observed and calculated S-wave arrivals match well over 30 km long data paths, where lateral variations in the S-wave velocity in the upper 1-2 km are as much as ± 8 percent. The modeled correlation between the lateral variations in the ground-roll and S-wave arrival demonstrates that a laterally varying structure can be constrained by using surface-wave data. The application of this technique to data from shorter spreads and shallower depths is discussed.

9T915. **Impact of broadband seismology on the understanding of strong motions.** - D Helmberger, D Dreger, R Stead, Hiroo Kanamori *(Seismol Lab, CA IT, Pasadena CA 91125)*. Bull Seismol Soc Am 83(3) 830-850 (Jun 1993).

9A916. **Longitudinal directions in media of arbitrary anisotropy.** - K Helbig *(Kiebitzrain 84, 3000 Honnover 51, Germany)*. Geophys 58(5) 680-691 (May 1993).

A longitudinal direction is one in which three pure modes can propagate. It is known that every medium has at least three longitudinal directions. Every axis of symmetry is such a "bound" longitudinal direction, but in most media there are additional "free" longitudinal directions which do not coincide with symmetry directions. In particular, there are longitudinal directions even in triclinic media that possess no symmetry except the point symmetry. The maximum number of distinct longitudinal directions is thirteen. Similarly, the polarization pattern in the vicinity of a longitudinal direction depends strongly on the type of the longitudinal direction and on the relative magnitude of some off-diagonal stiffnesses. Since the polarization pattern can be observed in suitable vertical seismic profiling surveys, it might be inverted to obtain information on elastic parameters that is difficult to obtain by other means. For orthorhombic symmetry, there are always the three bound longitudinal directions coinciding with the axes. In each plane of symmetry a pair of free longitudinal directions can exist, and there can be four symmetrically disposed free longitudinal directions outside the planes of symmetry. Existence and direction of these free directions follows from simple expressions in the elastic stiffnesses.

9A917. **Modeling teleseismic P-wave propagation in the upper mantle using a parabolic approximation.** - MG Bostock *(Dept of Theor Geophys, Utrecht Univ, PO Box 80 021, 3508 TA Utrecht, Netherlands)*, JC VanDecar *(Geophys Program, Univ of Washington, Seattle WA)*, RK Snieder *(Dept of Theor Geophys, Utrecht Univ, PO Box 80 021, 3508 TA Utrecht, Netherlands)*. Bull Seismol Soc Am 83(3) 756-779 (Jun 1993).

Teleseismic waves propagating in the upper mantle are subject to considerable distortion due to the effects of laterally heterogeneous structure. The magnitude and scale of velocity contrasts representative of features such as subducted slabs may be such that wave diffraction becomes an important process. In this case forward modeling methods based on high-frequency asymptotic approximations to the wave equation will not accurately describe the wavefield. A method is introduced to model the propagation of teleseismic P waves in a laterally heterogeneous upper mantle that accounts for distortion of the initial portion of the wavefield including the effects of multipathing and frequency-dependent diffraction. Numerical examples for a simple 2D subducting slab model demonstrates the application of the method and illustrates the effects of multipathing and diffraction which dominate waveform distortion at high and low frequencies, respectively.

9A918. **O'Doherty-Anstey formula and localization of seismic waves.** - SA Shapiro and H Zien *(Geophys Inst, Univ of Karlsruhe, Hertzstr 16, W-7500 Karlsruhe 21, Germany)*. Geophys 58(5) 736-740 (May 1993).

We have shown that the O'Doherty-Anstey result well known in the framework of multiple scattering in layered media, describes the localization effect, which is probably the main reason for seismic attenuation in sediments. In contrast to other statistical methods we eliminate the problem of ensemble averaging by considering only self-averaged quantities. This is the only way to describe the practical situation with an adequate theory such that measured results become predictable.

454Y. COMPUTATIONAL TECHNIQUES

9A919. **Efficient wave input procedure for infinite media.** - Chongbin Zhao and S Valliappan *(Sch of Civil Eng, Univ of New S Wales, PO Box 1, Kensington NSW 2033, Australia)*. Commun Numer Methods Eng 9(5) 407-415 (May 1993).

An efficient wave input procedure in the finite and infinite element coupled model is presented in this paper. Compared to the previous wave input method, the main advantage of the present wave input procedure lies in its computational efficiency because only a small region of the medium needs to be modeled by FEs. The equivalence between the present wave input procedure and the previous one has been theoretically proven when a harmonic wave propagates vertically in an isotropic homogeneous elastic half-space. In addition, the accuracy of the present wave input method has been evaluated based on the solutions obtained for SH-wave, SV-wave, and P-wave scattering problems in a semicircular canyon for which analytical solutions are already available.

9A920. **Eigenvalues and eigenvectors of linearized elastic inversion.** - Andrea de Nicolao, G Drufuca, F Rocca *(Politec di Milano, Piazza Leonardo Da Vinci 32, 20133 Milano, Italy)*. Geophys 58(5) 670-679 (May 1993).

Small contrasts in the parameters allow the linearization of elastic modeling and inversion. Although this assumption simplifies parameter estimation, it also impoverishes information: a linearized model, besides being an approximation, requires shrinking the data space to precritical angles. This work investigates the two basic questions regarding the type of information that can be retrieved and how to retrieve it. The method is the singular value decomposition of the transfer function between data and parameters. This tool allows a simple interpretation of the information contained in reflections, and it outlines a general estimation procedure. A medium characterized by a uniform background is considered; reflections are linearized according to the Born approximation. P-P reflections are analyzed. The simplicity of the model allows a theoretical study of the effects of velocity errors in the overburden. The analysis is performed for two different sets of elastic parameters. In both cases the conclusion is that only the estimate of one parameter can be accurate while the quality of the estimate of the second parameter critically depends upon the velocity uncertainty and the maximum incident angle; estimation of a third parameter is very difficult.

454Z. EXPLORATIONS AND MEASUREMENTS

9A921. **Determination of Fresnel zones from traveltime measurements.** - P Hubral, J Schleicher *(Geophys Inst, Karlsruhe Univ, Hertzstr 16 Bau 42, 7500 Karlsruhe 21, Germany)*, M Tygel *(Dept Mat Appl, Univ Est de Campinas, UNICAMP Caixa PO Box 6065, 13081 Campinas, SP, Brazil)*, Ch Hanitzsch *(Geophys Inst, Karlsruhe Univ, Hertzstr 16 Bau 42, 7500 Karlsruhe 21, Germany)*. Geophys 58(5) 703-712 (May 1993).

For a horizontally stratified (isotropic) earth, the rms-velocity of a primary reflection is a key parameter for common-midpoint (CMP) stacking, interval-velocity computation (by the Dix formula) and true-amplitude processing (geometrical-spreading compensation). As shown here, it is also a very desirable parameter to determine the Fresnel zone on the reflector from which the primary zero-offset reflection results. Hence, the rms-velocity can contribute to evaluating the resolution of the primary reflection. The situation that applies to a horizontally stratified earth model can be generalized to 3D layered laterally inhomogeneous media. The theory by which Fresnel zones for zero-offset primary reflections can then be determined purely from a traveltime analysis – without knowing the overburden above the considered reflector – is presented. The concept of a projected Fresnel zone is introduced and a simple method of its construction for zero-offset primary reflections is described. The projected Fresnel zone provides the image on the earth's surface (or on the traveltime surface of primary zero-offset reflections) of that part of the subsurface reflector (ie, the actual Fresnel zone) that influences the considered reflection. This image is often required for a seismic stratigraphic analysis. Our main aim is therefore to show the seismic interpreter how easy it is to find the projected Fresnel zone of a zero-offset reflection using nothing more than a standard 3D CMP travel time analysis.

456. Earthquake mechanics

9A922. Ground motion model for the 1989 M 6.9 Loma Prieta earthquake including effects of source, path and site. - JF Schneider *(Elec Power Res Inst, PO Box 10412, Palo Alto CA 94025)*, WJ Silva, C Stark *(Pacific Eng and Anal, 311 Pomona Ave, El Cerrito CA 94530)*. Earthquake Spectra 9(2) 251-287 (May 1993).

The objective of this study is to assess the effects of source finiteness, crustal wave propagation, and site response upon recorded strong ground motions from the 1989 Loma Prieta earthquake. Our analysis uses band limited white noise with random vibration theory to produce site-specific estimates of peak acceleration and response spectral ordinates for both a point-source and finite-source model. Effects of nonlinear soil response are modeled through an equivalent-linear approach. The point-source model additionally accommodates crustal propagation effects in terms of direct-plus-postcritical reflections.

9A923. Earthquake microzoning from soil properties. - APW Hodder *(Dept of Earth Sci, Univ of Waikato, Hamilton, New Zealand)* and MZ Graham *(Dept Earth Sci, Univ of Waikato, Hamilton, New Zealand)*. Earthquake Spectra 9(2) 209-231 (May 1993).

The extent of damage caused by an earthquake in Wellington, New Zealand, in 1968 to buildings erected on a variety of regoliths and foundation materials is correlated with the thickness of the regolith, the depth to the water table and semi-quantitative parameters derived from soil profile descriptions, particularly related to soil type and soil structure. From linear regression correlations, the expected damage for a comparable earthquake elsewhere can be determined. The model was tested for soil data for the Edgecumbe area hit by a damaging earthquake in 1987. The predictions were sufficiently in accord with observations to suggest that soil properties that reflect the geotechnical properties of the upper parts of the regolith, particularly those that measure the shear strength, shear wave velocity, and viscous damping of that material, may be useful for earthquake microzoning purposes in areas where there is a considerable thickness of unconsolidated materials above bedrock.

9A924. Evaluation of seismic design criteria for highway bridges. - E Miranda *(Dept of Civil Eng, Swiss Fed IT, CH-1015 Lausanne, Switzerland)*. Earthquake Spectra 9(2) 233-250 (May 1993).

After an overview of the development of US seismic design specifications for highway bridges an evaluation of current Caltrans and AASHTO seismic criteria is presented. Linear and nonlinear response spectra of ground motions recorded on different soil conditions in the Loma Prieta earthquake and other recent earthquakes are compared with code recommendations. Special emphasis is placed on how present design procedures reduce elastic forces to take into account the energy absorption capacity of the structure, and on the estimation of maximum inelastic deformations. Results indicate that current design recommendations may underestimate strength and deformation demands, particularly for short-period bridges and for bridges on soft soils. Finally, recommendations are made on how seismic design specifications may be improved.

9A926. Generation of a modified Lamb surface wave in the atmosphere by a underwater source. - LA Gasilova, IY Gordeeva, YV Petukhov *(Inst of Appl Phys, Russian Acad of Sci, Russia)*. Sov Phys Acoust 38(6) 567-570 (Nov-Dec 1992).

The dispersion properties of a modified Lamb surface wave propagating along the interface between an isothermal atmosphere and a "heavy" compressible fluid with a depth-invariant density and sound velocity (modeling the ocean) are investigated, and the frequency dependence of the wave excitation coefficients is determined for an underwater point mass source. It is shown that this wave, which exists only below a certain critical frequency, propagates with supersonic velocity above a certain resonance frequency and with subsonic velocity below the same frequency, which corresponds to the intersection of the frequency curves of the phase velocities of the modified Lamb wave and the hydrodynamic surface wave.

9A935. Accident analysis and safety of future fusion devices. - H Loffler *(Gesellschaft Anlagen- und Reaktorsicherheit (GRS), mbH, Schwertnergasse 1, W-5000 Koln 1, Germany)*. Fusion Eng Des 22(1-2) 57-65 (Mar 1993).

In hypothetical beyond design accidents where all engineered safety systems are assumed to fail, fusion undoubtedly is less hazardous then fission. But for more frequent - though very still unlikely - events the sophisticated safety culture of fission is a challenge which must be taken seriously. A containment concept with three barriers is proposed. A scoping study of conceivable event progression shows that several physical phenomena charging the containment come into play in various order for different event progressions. The development of adequate tools for containment safety analysis is encouraged.

9A936. Radiation embrittlement mechanistic modelling. - WA Pavinich *(Groove Eng, 9040 Executive Park Dr, Ste 218, Knoxville TN 37923)*, WL Server *(ATI Consult, 2010 Crow Canyon Place, Ste 160, San Ramon CA 94583)*, T Griesbach *(Elec Power Res, 3412 Hillview Ave, Palo Alto CA 94303)*. Appl Mech Rev 46(5) 162-170 (May 1993).

The mechanistic models of radiation embrittlement for reactor vessel steels are reviewed and direction for improving these models is provided. Improvement in these mechanistic models will lead to predictive expressions for parameters of engineering interest. This paper provides the initial direction of modelling efforts that will improve existing or develop new predictive equations for damage attenuation, temperature effects, thermal annealing, the effect of post weld heat treatment, transition behavior and upper shelf behavior of reactor vessel steels.

506B. SOLAR COLLECTOR MECHANICS

9A937. Dynamic method for solar collector array testing and evaluation with standard database and simulation programs. - B Perers *(Vattenfall Utveckling AB, S-81070 Alvkarleby, Sweden).* Solar Energy 50(6) 517-526 (Jun 1993).

A measurement and evaluation method is described by which standard collector performance parameters can be derived directly from measured outdoor data. Standard programs with routines for multiple regression can be used for the parameter identification. A continuous flow is applied in the collector loop during the test. Data for the whole day can be used. The model is set up for thermal power output (and not efficiency). This forces the parameters to values that are suitable for prediction of long-term performance. The collector model and parameters correspond closely to those used in existing detailed simulation programs such as TRNSYS, WATSUN, or MINSUN.

9A938. Effect of pressure-induced stress on the design of shaped-glass evacuated solar collectors. - JD Garrison *(Phys Dept, San Diego State Univ, San Diego CA 92182-0325).* Solar Energy 50(6) 527-538 (Jun 1993).

Shaped-glass evacuated solar collectors have the lower portion of the turbulent glass vacuum envelope shaped and inside surface mirrored to concentrate sunlight onto an absorber tube in the vacuum. Upon evacuation, stresses are set up in the glass. The maximum surface tensile stress possible in glass, while keeping the probability of fracture small, is of the order of 7 MPa. This low maximum tensile stress places severe limitations on the amount the lower portion of the cross section of a cylindrical glass evacuated solar collector can deviate from circular to provide the concentration. Equations are developed for determining stress in the glass. Results of stress calculations leading to parameters for collector design are presented.

9A939. New design of nontracking seasonally adjusted plane mirror linear trough solar concentrator with a flat horizontal absorber. - RP Goswami, GD Sootha *(Solar Energy Centre, Dept of Non-conventional Energy Sources, Ministry of Power and Non-conventional Energy Sources, B-4, 9th Fl, CGO Complex, Lodi Rd, New Delhi 110 003, India)*, BS Negi *(Dept of Phys, Indian IT, Hauz Khas, New Delhi 110 016, India)*, ZH Zaidi *(Dept of Phys, Jamia Millia Islamic Univ, New Delhi 110 011, India).* Int J Energy Res 16(9) 837-849 (Dec 1992).

This paper presents an optical design based on a single-reflection criterion, and performance characteristics of an east-west aligned nontracking seasonally adjusted linear trough solar concentrator with a flat horizontal absorber, using plane mirror elements. The design procedure allows the use of any desired number of mirror elements to reflect solar energy onto the base absorber in one reflection. The angle of inclination of each mirror element with respect to the absorber surface, and the width of the mirror element, are determined so that a ray incident on the extreme upper edge of the mirror element at a specified angle to the normal to the concentrator aperture (acceptance half-angle), after reflection, strikes the extreme edge of the absorber on the opposite side of the mirror element. Other rays making angles less than the design acceptance half-angle are also reflected onto the base absorber in one reflection. Concentrator designs resulting from this approach appear to have the important characteristic of relatively smaller heights, and hence appear highly cost-effective in terms of the amount of material required for fabrication. Some numerical calculations have been carried out to illustrate the performance of concentrators for different acceptance half-angles. Results obtained are presented in graphic and tabular forms, and are discussed.

9A940. Thermal performance of a flat-plate heat-pipe collector array. - TY Bong, KC Ng, H Bao *(Dept of Mech and Prod Eng, Natl Univ, Singapore 0511).* Solar Energy 50(6) 491-498 (Jun 1993).

This article presents a theoretical model for the determination of the efficiency, the heat removal factor, and the outlet water temperature of a single collector and an array of flat-pipe heat-pipe collectors. The model is validated by on-site testing of 16 heat-pipe collectors under the typical weather conditions in Singapore. Within the operational range of interest of the hot water temperatures, the results show that the proposed model is sufficient to describe the steady-state performance of the collector array.

506D. SOLAR HEAT TRANSFER

9A941. Calculation of the shape factor from a small rectangular plane to a triangular surface perpendicular to the rectangular plane without a common edge. - HL Noboa, D O'Neal, WD Turner *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843).* J Solar Energy Eng 115(2) 117-120 (May 1993).

In developing an analytical model of radiative heat transfer inside attics, the necessity of calculating the shape factor from a small rectangle to a triangle plane may arise. This paper describes a methodology of calculation for such a shape factor from simple relations using shape-factor algebra. The shape factor is calculated using a mirror image of the triangular surface, in such a way that the small rectangular plane is positioned symmetrical between the two triangular surfaces. Numerical results are presented in graphical form.

9A942. Numerical analysis of greenhouse-type solar stills with high inclination. - A Palacio and JL Fernandez *(Inst of Eng UNAM, Ciudad Univ, Coyoacan 04510, Mexico).* Solar Energy 50(6) 469-476 (Jun 1993).

A numerical analysis has been carried out to evaluate the technical feasibility of single effect solar stills with a cover slop of up to 60°. The aim of the research is to establish the overall distillate productivity and the relative importance of the heat and mass transfer mechanisms when water diffusion is minimal and convection dominates. Experimental measurements of the distillate obtained from an already working unit are related to the number results by means of an "equivalent" Prandtl number that simplifies the analysis, allowing for the moist air in the inside of the cavity to be represented as a perfect gas.

9A943. Radiative cooling efficiency of white pigmented paints. - B Orel, M Klanjsek Gunde *(Natl Inst of Chem, PO Box 30, 61115 Ljubljana, Slovenia)*, A Krainer *(Dept of Civil and Architec Eng, Univ at Ljubljana, Slovenia).* Solar Energy 50(6) 477-482 (Jun 1993).

Nocturnal temperature measurements of various infrared selective radiators performing radiative cooling have been carried out. Measured temperature differences between the radiators and ambient temperature were about 10°C. Radiating surfaces have been prepared by applying different kinds of paints on aluminium substrates. It was shown that the addition of a $BaSO_4$ extender in the paint dispersion increased the cooling performance of the paint radiators.

9A944. Temperature distribution inside a solar collector storage tank of finite wall thickness. - MA Al-Nimr *(Dept of Mech Eng, Jordan Univ of Sci and Tech, Irbid, Jordan).* J Solar Energy Eng 115(2) 112-116 (May 1993).

A mathematical model for the transient conjugated behavior of a hot-water storage tank having finite wall thickness is presented. An analytical closed-form solution for the temperature field within the tank is obtained. This solution takes into consideration the axial conduction of heat in both fluid and solid wall and the heat capacity of the solid wall. Plots of the solution show that finite wall thickness tends, as expected, to decrease the thermal stratification within the tank.

506F. OTHER SOLAR ASPECTS

9A945. Comparison of experimental and simulated thermal ratings of drain-back solar water heaters. - JH Davidson, WT Carlson, WS Duff *(Solar Energy Appl Lab, Colorado State Univ, Ft Collins CO 80523)*, PJ Schaefer, WA Beckman, SA Klein *(Solar Energy Lab, Univ of Wisconsin, Madison WI).* J Solar Energy Eng 115(2) 101-105 (May 1993).

Short-term experimental tests of drain-back solar water heaters are compared to ratings obtained using TRNSYS to determine if computer simulations can effectively replace laboratory ratings of solar domestic hot water heating systems. The effectiveness of TRNSYS in predicting changes in ratings due to limited changes in collector area, collector flow rate, recirculation flow rate, storage tank volume, and storage tank design is validated to within ± 10%. Storage tank design is varied by using a stratification manifold in place of the standard drop tube.

9A946. Computerized numerical experimental study of average solar radiation penetration in plant stands. - SG Chen, BY Shao, I Impens *(Dept of Biology, Univ of Antwerpen, UIA B-2610 Wilrijk, Antwerpen, Belgium).* J Qantitative Spectroscopy Radiative Transfer 49(6) 651-658 (Jun 1993).

An important problem in radiation measurements is the averaging of radiant fluxes in horizontal directions. The use of downward cumulative foilage-areal index averaged over a horizontal surface for the calculation of the average penetration of solar radiation in a plant stand underestimates penetration unless the stand is horizontally uniform. Using a computerized numerical experimental method we show that the underestimation of penetration varies with the downward cumulative foilage-areal index, the extinction coefficient, as well as the foliage distribution pattern. The results show that the underestimation is strongly pronounced for some combinations of extinction coefficient and foliage-areal index. It is alwo shown that the use of a penetration value averaged over a horizontal surface (P_{AP}) to invert the stand foilage-areal index (LAI) by means of the logarithm formula LAI = $-\ln(P_{AP})/k$ can cause large underestimation of LAI, especially in the use of large LAI. Numerical results are presented in this paper to provide a basis for calibration.

9A947. Correlations for the yearly or seasonally optimum salt-gradient solar pond in Greece. - KA Antonopoulos and ED Rogdakis *(Dept of Mech Eng, Thermal Eng Section, Natl Tech Univ, 42 Patission St, Athens 106 82, Greece).* Solar Energy 50(5) 417-424 (May 1993).

Simple correlations and corresponding nomographs are presented, which express the maximum useful heat received from salt-gradient solar ponds throughout the year or during a specified season of the year, and the corresponding optimum depth of the nonconvective zone in terms of the thickness of the upper convective zone and the temperature under which the maximum useful heat is received. The correlations are valid for the Athens (Greece) area or for regions with a similar climate, because solar radiation and ambient temperature valid for Athens have been employed, obtained by a statistical process of hourly measurements over a period of about 20 years. Calculations of the useful heat are performed for a great number of values of the parameters of the problem, and the combinations of values that maximize useful heat are selected and used for developing correlations and corresponding nomographs. The correlations presented may be employed in the design of the optimum solar pond under the specific requirements of each application.

9A948. Mathematically integrable parameterization of clear-sky beam and global irradiances and its use in daily irradiation applications. - C Gueymard *(Florida Solar Energy Center, 300 State Rd 401, Cape Canaveral FL 32920)*. Solar Energy 50(5) 385-397 (May 1993).

A simple parameterized clear-sky short-wave irradiance model is derived from a detailed two-band physical model presented earlier. The inputs for the parameterized model (called PSIM) are the solar elevation, the amount of precipitable water (w), the Angstrom turbidity coefficient (β), the station's pressure (or its altitude), and the zonal surface albedo (for which a simple submodel is provided for N America). PSIM is intended to give accurate irradiance estimates in any atmosphere condition whenever $w < 5$ cm and $\beta < 0.45$. The parameterization uses a function of solar elevation that is integrable with time, so that a parameterized daily irradiation model (called DIM) is also obtained. It is also suggested that the original Angstrom's equation (to derive the average global irradiation from the fraction of possible sunshine) be used more extensively with DIM. Finally, it is demonstrated (using data from Albany, NY) that the monthly average beam irradiation may be obtained with a very simple equation from the fraction of possible sunshine and DIM, yielding more accurate estimates than the existing best-performance method.

9A949. Monolithic and mechanical multijunction space solar cells. - RK Jain and DJ Flood *(NASA Lewis Res Center, Cleveland OH 44135)*. J Solar Energy Eng 115(2) 106-111 (May 1993).

High-efficiency, lightweight, radiation-resistant solar cells are essential to meet the large power requirements of future space missions. Single-junction cells are limited in efficiency. Higher cell efficiencies could be realized by developing multijunction, multibandgap solar cells. Monolithic and mechanically stacked tandem solar cells surpassing single-junction cell efficiencies have been fabricated. This article surveys the current status of monolithic and mechanically stacked multi-bandgap space solar cells, and outlines problems yet to be resolved. More information is needed on the effect of temperature and radiation on the cell performance.

9A950. Numerical modeling of reflux solar receivers. - RE Hogan Jr *(Fluid and Thermal Sci Dept, Sandia)*. J Solar Energy Eng 115(2) 93-100 (May 1993).

Using reflux solar receivers to collect solar energy for dish-Stirling electric power generation systems is presently being investigated by several organizations, including Sandia. In support of this program, Sandia has developed two numerical models describing the thermal performance of pool-boiler and heat-pipe reflux receivers. Both models are applicable to axisymmetric geometries and they both consider the radiative and convective energy transfer within the receiver cavity, the conductive and convective energy transfer from the receiver housing, and the energy transfer to the receiver working fluid. The numerical modeling concepts presented are applicable to conventional tube-type solar receivers, as well as to reflux receivers. Good agreement between the two models is demonstrated by comparing the predicted and measured performance of a pool-boiler reflux receiver being tested at Sandia.

9A951. Optimal coupling and feasibility of a solar-powered year-round ejector air conditioner. - M Sokolov and D Hershgal *(Dept of Fluid Mech and Heat Transfer, Fac of Eng, Tel-Aviv Univ, Ramat-Aviv 69978, Israel)*. Solar Energy 50(6) 507-516 (Jun 1993).

An ejector refrigeration system that uses a conventional refrigerant (R-114) is introduced as a possible mechanism for providing solar-based air-conditioning. Optimal coupling conditions between the collector's energy output and energy requirements of the cooling system, are investigated. Operation at such optimal conditions assures maximized overall efficiency. Procedures leading to the evaluation of the performance of a real system are disclosed. Design curves for such a system with R-114 as refrigerant are provided.

9A952. Performance and testing of large-size solar water heater cum solar cooker. - NM Nahar *(Central Arid Zone Res Inst, Jodhpur 342-003, India)*. Int J Energy Res 17(1) 57-67 (Jan 1993).

The performance of a novel device has been tested. The device can be used as a collector cum storage type solar water heater using the winter, and, with minor adjustments, it can be used as a hot-box solar cooker. The device can provide hot water at 50 - 60° C in the evening, which can be maintained at 40 - 45° C until the following morning. It can also be used for cooking food for about 40 people. The efficiencies of the device as a solar water heater and as a solar cooker have been found to be 67•7% and 29•8% respectively. The payback period varies between 1•64 to 5•90 years depending on the fuel it replaces.

9A953. Role of buoyant thermals in salt gradient solar ponds and in convection more generally. - LB Mullett *(42 Grosvenor Ave, Bourne, Lincs PE10 9HU, UK)*. Int J Heat Mass Transfer 36(7) 1923-1941 (May 1993).

It is shown that the well accepted model of double-diffusive convection for strong heating from below a stable salinity gradient does not apply at the very modest level of solar radiation, more especially when part (or even all) of the heat is generated within the fluid. New models are developed in which buoyant thermals play casual roles (as indeed, they do in the case of strong heating). Thermals from all three kinds of boundaries are investigated, and it is found that although there is a limited quantity of fluid in a thermal, connection is retained with the source during its lifetime. Thermal ranges are found to be well defined and increase according to environmental (water) temperature, with a common form of range equation. The equation is calibrated experimentally for each type of thermal. Finally, it is shown that the onset of turbulence at Rayleigh numbers in the region of 5×10^4 to 10^5 marks the transition from laminar Benard-Rayleigh heat flow to quantised flow by thermals.

9A954. Solar position and right ascension. - HD Kambezidis and AE Tsangrassoulis *(Inst of Meteorol and Phys of the Atmos Env, Natl Observatory, PO Box 20048, Athens GR-118 10, Greece)*. Solar Energy 50(5) 415-416 (May 1993).

A new correction for right ascension, proposed by the authors, permits smooth SUNAE algorithm runs, minute by minute, for a period of a year.

9A955. Solar-assisted vapor compression-absorption cascaded air-conditioning systems. - JCV Chinnappa *(68 Mascar St, Upper Mount Gravatt Q 4122, Australia)*, MR Crees, S Srinivasa Murthy, K Srinivasan *(Dept of Civil and Syst Eng, James Cook Univ of N Queensland, Townsville 4811, Australia)*. Solar Energy 50(5) 453-458 (May 1993).

This article describes a hybrid airconditioning system consisting of a conventional R-22 vapor compression refrigeration svstem cascaded with a solar-operated, ammonia-water, vapour absorption system. The condenser of the R-22 system is cooled by the evaporator of the ammonia system. This facilitates operation of the R-22 system at a low condensing temperature and pressure. This is found to yield considerable savings in electrical energy consumption by the compression system.

9A956. Solar-pumped laser and its second harmonic generation. - H Arashi and Y Kaneda *(Res Inst for Sci Measurements, Tohoku Univ, 1-2, 2-Chome Katahira, Sendai, Japan)*. Solar Energy 50(5) 447-451 (May 1993).

Solar radiation concentrated by using a large solar collector was used to optically excite a Nd:YAG laser medium and was successfully converted into coherent laser light. The maximum laser output power attained 60W in multi-mode. This is the highest power so far reported on a solar-pumped laser. Q-switched pulse operation of the cw solar-pumped Nd:YAG laser light was performed by inserting an acousto-optic deflector into the laser cavity. Output pulses of peak power greater than 100 kW and FWHM of 100 ns were obtained at a repetition rate of 1 kHz. Using the pulsed solar-pumped Nd:YAG laser, second harmonics were generated at wavelength of 530 nm by a nonlinear KTP crystal.

9A957. Thermochromic gels for control of insolation. - A Beck, T Hoffmann, W Korner, J Fricke *(Physikalisches Inst, Univ Wurzburg, Am Hubland, D-8700 Wurzburg, Germany)*. Solar Energy 50(5) 407-414 (May 1993).

Thermochromic gels consist of a mixture of water, gelling agent, and a polyether reaction compound. They show a drastic increase of scattering when a characteristic switching temperature is surpassed. The hemispherical transmission consequently decreases from 90 to 50% for a 1-mm thick layer sandwiched between two glass panes. The increase in scattering is caused by a dramatic increase in number density and particle size of created scattering centers. Our measurements cover the directional-directional transmission, as well as the directional-hemispherical transmission and reflection, using a double-beam spectrophotometer with an integrating sphere. The thermochromic material is a low-cost, nontoxic product.

506H. GEOTHERMAL ENERGY

9A958. Drilling experience of K6-2, the high temperature and crooked geothermal well in Kakkonda, Japan. - Seiji Saito *(Japan Metals and Chem, Iwate-ken, Japan)*. J Energy Resources Tech 115(2) 117-123 (Jun 1993).

Well K6-2 was drilled for geothermal production for the Kakkonda No 2 Power Plant (to be built in 1995) at the Kokkanda geothermal field, northern Honshu Island, Japan from 1988 through 1989. The well was planned to be vertical and the target area was a 100 m radius at 2800 m. Mainly, because of the formation inclination, strong bit walk tendency was encountered below 1200 m. Because a pendulum BHA did not help to drop the inclination, downhole motors with bent subs were employed. Totals of six and seven downhole motors for 12 1/4 and 8 1/2 inch hole sections, respectively, were run. The estimated formation temperatures were over 350° C below 1900 m, so two mud cooling towers and 500 m^3 pit were used to cool the returned mud. These systems worked well, but at 2245 m the estimated mud circulation temperature on bottom went up to 150° C and the stator rubber of the downhole motors unbounded and broke up after a one hour run.

506L. OTHER ENERRGY SYSTEMS

9A959. Effect of the fuel-cell unit on the efficiency of a fuel-cell-topped Rankine power cycle. - WR Dunbar *(Dept of Mech Eng and Appl Mech, Univ of Penn, Philadelphia PA 19104-6315)* and RA Gaggioli *(Dept of Mech and Indust Eng, Marquette Univ, Milwaukee WI 53233-2886)*. J Energy Resources Tech 115(2) 105-107 (Jun 1993).

Dunbar, Lior and Gaggioli (1991) proposed a configuration of a fuel-cell-toped electrical Rankine power generating station and analyzed its performance. That study revealed that the fuel-cell topping improved plant efficiency to values up to 62 percent, versus the conventional plane efficiency of 41.5 percent. This work lays the foundation for a thermoeconomic analysis of such systems by relating exergy consumption to fuel-cell unit size, as follows: the relationship between system efficiency (and hence fuel consumption) and fuel-cell unit size is presented for a number of fuel-cell operating conditions; the relationship between fuel flow rate and fuel-cell unit size is shown; and the exergetic effects of the major plant components are discussed as a function of fuel-cell unit size.

9A960. Emf, Maximum power and efficiency of fuel cells. - RA Gaggioli and WR Dunbar *(Dept of Mech Eng, Marquette Univ, Milwaukee WI 53233-2286)*. J Energy Resources Tech 115(2) 100-104 (Jun 1993).

The ideal voltage of steady-flow fuel cells is usually expressed by Emf = $\Delta G°$- nf where $\Delta G°$ is the "Gibbs free energy of reaction" for the oxidation of the fuel at the supposed temperature of operation of the cell. Furthermore, the ideal power of the cell is expressed as the product of the fuel flow rate with this emf. Such viewpoints are flawed in several respects. Rather than with emf, the proper starting place is with power output. The ideal power is that which would be obtained if the fuel were oxidized without irreversible entropy generation. Among other factors, this ideal output depends upon the ratio of oxidant to fuel flow rate (eg, air-fuel ratio) and the percentage of fuel oxidation. Examples are presented which illustrate such affects and their importance for the evaluation of ideal power and of efficiency.

9A961. Integrated resource planning. - F Kreith *(Natl Conference of State Legislatures, Denver CO 80202)*. J Energy Resources Tech 115(2) 80-85 (Jun 1993).

This article presents the essential features of an integrated resource planning process designed to provide energy for societal and industrial needs at least cost. Use of renewable energy sources and energy conservation measures, as well as consideration of social costs, are described. Available data of social costs and estimates for energy costs of conservation measures and renewable energy systems are included.

9A962. Matching and work ratio in elementary thermal power plant theory. - IK Smith *(Dept of Mech Eng and Aeronaut, City Univ, London, UK)*. Proc Inst Mech Eng A 206(A4) 257-262 (1992).

For most thermal power plants, the Carnot cycle efficiency is not the true ideal. Matching the cycle to the source leads to alternative limits and improved perceptions of how practical power plant can be improved. A method of including the work ratio into an ideal cycle analysis is presented which simplifies the estimation of practical power plant efficiencies and highlights the historic course of thermal efficiency improvement.

9A963. Semiempirical model of a building with a passive evaporative cool tower. - B Givoni *(Graduate Sch of Architec and Urban Planning, UCLA)*. Solar Energy 50(5) 425-434 (May 1993).

An experimental mathematical model that calculates the performance of a passive evaporative cool tower (also known as downdraft evaporative chimney), has been developed by Cunningham and Thompson. The model calculates the tower's exit air temperature, flow rate and the speed of the air exiting from the tower, and the diurnal patterns of the indoor temperature of a lightweight building cooled by this system. Initial validation of the model, by comparing predictions with independent measurements of the indoor temperature of the test building, was done by Cunningham *et al.* In its present state the applicability of the model is limited to the use of evaporating pads of the type used in the Tucson study (CELdek) cooling a lightweight building (stud wall construction).

506N. ENERGY STORAGE

9A964. Lead acid battery storage model for hybrid energy systems. - JF Manwell and JG McGowan *(Renewable Energy Res Lab, Univ of Massachusetts, Amherst MA 01003)*. Solar Energy 50(5) 399-405 (May 1993).

This paper describes a new battery model developed for use in time series performance models of hybrid energy systems. The model is intended to overcome some of the difficulties associated with currently used methods. It is based on the approach of chemical kinetics. This model, which can be used for charging and discharging, is specifically concerned with the apparent changes in capacity as a function of charge and discharge rates. Examples of the deviation of the battery model constants and comparison of the new model with those used previously are given. Based on the success of the new model, it has been incorporated into the latest versions of the University of Massachusetts's wind-diesel simulation codes.

506Q. ENERGY DISTRIBUTION (INCL PIPELINES, TRANSMISSION LINES, ETC)

9T965. Aging of energy production and distribution systems. - MM Carroll and PD Spanos *(Dept of Energy Workshop, Rice Univ, Houston TX)*. Appl Mech Rev 46(5) 139-263 (May 1993).

9A966. Integrity assurance of natural gas transmission pipelines. - GJ Posakony *(J-TECH Consult, 1944 Pine St, Richland WA 99352)*. Appl Mech Rev 46(5) 146-150 (May 1993).

Natural gas transmission pipelines have proven to be a safe and efficient means for transporting the trillions of cubic feet of natural gas used annually in the US. Since the peak of construction of these pipelines occurred between 1950 and the mid-1960's, their average age is now over thirty years. However, replacement of these pipelines because of age would be prohibitively expensive and unnecessary. Preventive maintenance and rehabilitation programs put into practice by the pipeline industry provides the key to ensuring the continued integrity of the transmission pipeline system. This article reviews the preventive maintenance practices commonly used by the gas industry.

9T967. Session V Summary: Materials. - S Nemat-Nasser *(Center of Excellence for Adv Mat, Dept of Appl Mech and Eng Sci, UCSD)*. Appl Mech Rev 46(5) 211-212 (May 1993).

9A968. Session VIII Summary: Assessment. - CA Cornell *(Dept of Civil Eng, Stanford)*. Appl Mech Rev 46(5) 262-263 (May 1993).

The working group took its objective to be the formulation of a set of research and development recommendations for assessment of aging energy systems. The material discussed in every session at this workshop has relevance to the assessment of characteristics such as the current state of these facilities or their components. Indeed many of the items we cite will appear elsewhere as well. The focus we have maintained, however, is assessment for the direct purpose of decision making. The decisions may have to do with increasing inspection, monitoring or analysis, or with repair, or even with closure and replacement.

514. Environmental mechanics

9A969. Comparison of mass-loading and elastic plate models of an ice field. - VA Squire *(Dept of Math and Stat, Univ of Otago, PO Box 56, Dunedin, New Zealand)*. Cold Regions Sci Tech 21(3) 219-229 (May 1993).

A comparison is made between the two most common surface boundary conditions used to represent a marginal ice zone through which ocean waves are propagating. Although essentially the same – as the mass-loading model may be regarded as the limit of an elastic plate with no rigidity – the consequences of choosing one or the other boundary conditions are profound. With no rigidity, the wavelength in ice is less than that in the open sea; with the rigidity typical of an ice plate it is usually greater. The few data that exist indicate that a critical angle does occur which suggests that the full elastic plate theory may be necessary, although it is difficult to justify this as anything other than an effective parameterization for an ice field composed of discrete flows.

9A970. Ice pressures on vertical and sloping structures through dimensional analysis and similarity theory. - VM Arunachalam *(WISER Assoc, PO Box 13731 Station A St John's, NF A1B 4G3, Canada)* and DB Muggeridge *(Ocean Eng Res Centre, Memorial Univ of Newfoundland, St John's, NF A1B 3X5, Canada)*. Cold Regions Sci Tech 21(3) 231-245 (May 1993).

Experimental results from laboratory and field tests for ice pressures on vertical indentors and sloping structures have been compiled from original data and reanalyzed using dimensional analysis and similarity theory and equations for ice pressure have been separately derived. The data sets considered for the vertical indentors include most of the data sets contained in the derivation of Sanderson's pressure area curve (except the meso-scale model data), along with additional ones that have appeared in the public domain. The dimensionless pressure for a vertical structure decreased as a function of the product of aspect ratio and dimensionless strain rate. The effective pressure decreased with increasing value of aspect ratio defined in terms of the thickness of ice sheet, with decreasing values of velocity and of Young's modulus of ice.

IX. BIOENGINEERING

550. Biomechanics

550B. SKELETAL SYSTEMS, BONES, JOINTS, LIGAMENTS, ETC

9A971. **Bone and bones, architecture and stress, fossils and osteoporosis.** - CE Oxnard *(Centre for Human Biology, Univ of W Australia, Nedlands 6009, W Australia)*. J Biomech 26(SUPPL 1) 63-79 (1993).

The combined use of architectural and stress technologies in osteological studies is starting to provide the basic biomechanical underpinnings to both evolutionary and applied medical investigations of bone. The architectural investigations, though tested using invasive methods, are aimed at non-invasive ways of obtaining information from radiographs of bones, fossils and people. The stress studies, though initially involving older techniques such as photoelastic stress analysis, now employs FE analysis and, most recently, fast Lagrangian analysis of continua. Taken together, these methods are capable of providing more detailed knowledge of bone form and function that is important a) in revealing functional adaptation in evolutionary studies of fossils and b) for making early diagnosis and understanding pathological fractures in the late stages of osteoporosis.

9A972. **Design and development of an unconstrained dynamic knee simulator.** - CA McLean and AM Ahmed *(Dept of Mech Eng, McGill Univ, Montreal, Canada)*. J Biomech Eng 115(2) 144-148 (May 1993).

A dynamic knee simulation has been developed to allow in-vitro investigation of the mechanical response of the joint corresponding to dynamic functional activities, eg, walking. In the simulator, the controlled inputs are the time-histories of three parameters of a given dynamic activity: the flexion angle, and the flexion-extension moment and tibial axial force components of the foot-to-floor reaction. Satisfactory performance of the simulator has been established for walking gait conditions based on measurements on three fresh-frozen specimens.

9A973. **Improved dynamic model of the human knee joint and its response to impact loading on the lower leg.** - AE Engin *(Dept of Eng Mech, Ohio State Univ, Columbus OH 43210)* and ST Tumer *(Dept of Mech Eng, Middle E Tech Univ, Ankara 06531, Turkey)*. J Biomech Eng 115(2) 137-143 (May 1993).

Almost a decade ago, 3D formulation for the dynamic modeling of an articulating human joint was introduced. Two-dimensional version of this formulation was subsequently applied to the knee joint. However, because of the iterative nature of the solution technique, this model cannot handle impact conditions. In this paper, alternative solution methods are introduced which enable investigation of the response of the human knee to impact loading on the lower leg via an anatomatically based model.

Neuromuscular performance is determined not only by the size of the involved muscles, but also by the ability of the nervous system to appropriately activate the muscles. Adaptive changes in the nervous system in response to training are referred to as neutral adaptation. This article briefly reviews current evidence regarding the neural adaptations during the acquisition of muscle strength, power and motor tasks and will be organized under four main topics; (i) muscle strength gain; neural factors versus hypertrophy, (ii) neural adaptation during power training, (iii) neuromuscular adaptations during the acquisition of a motor task, and (iv) neuromuscular adaptations during a ballistic movement.

9A978. **Optimization of the structure and movement of the legs of animals.** - R McNeill Alexander *(Dept of Pure and Appl Biology, Univ of Leeds, Leeds LS2 9JT, UK)*. J Biomech 26(SUPPL 1) 1-6 (1993).

The legs of animals, and their movements, have presumably been optimized by evolution and/or learning for the functions required of them in life. This paper presents a series of studies in which attempts have been made to formulate optimization problems, to which the legs and their movements may be solutions. These are studies of the ratio of radius to wall thickness in tubular bones; of the strengths of bones; of tendon thickness; of the gaits of turtles and of mammals; and of the technique of human high jumping. They illustrate some serious difficulties that may arise in inverse optimization studies but also show that the approach is helping to improve our understanding of legs and gaits.

An analytical expression for the characteristic recovery time of an erythrocyte subject to an extensional deformation is derived using a previous nonlinear Kelvin-Voigt model. The recovery time thus obtained depends on the initial deformation in agreement with experimental observations, as a result of the nonlinearity of the model. The validity of the analytical results is confirmed using previous experimental data.

9A982. **Aortic pressure estimation with electro-mechanical circulatory assist devices.** - JF Gardner, M Ignatoski, U Tasch, AJ Snyder, DB Geselowitz *(Penn State)*. J Biomech Eng 115(2) 187-194 (May 1993).

An adaptive technique for the estimation of the time history of aortic pressure (from applied voltage and position feedback) has been designed, implemented, and bench tested using the Penn State Electric Ventricular Assist Device (EVAD). This method, known in the field of automatic control as a dynamic observer, utilizes gains which were determined using experimental data collected while the EVAD was running on a mock circulatory system. An adaptive scheme provides the observer with a method of changing its initial conditions on a stroke-by-stroke basis which improves observer performance. In both determining the feedback gains and developing the adaptation scheme, a range of beat rates and pressure loads was taken into account to yield satisfactory observer performance over a range of operating conditions. The observer was implemented, its performance was verified in vitro and results are reported.

9A983. Biaxial mechanical properties of passive right ventricular free wall myocardium. - MS Sacks and CJ Chuong *(Joint Biomed Eng Program, Univ of Texas, Arlington TX 76019)*. J Biomech Eng 115(2) 202-204 (May 1993).

The biaxial mechanical properties of right ventricular free wall (RVFW) myocardium were studied. Tissue specimens were obtained from the sub-epicardium of potassium-arrested hearts and different stretch protocols were used to characterize the myocardium's mechanical response. To assess regional differences, we excised tissue specimens from the conus and sinus regions. The RVFW myocardium was found to be consistently anisotropic, with a greater stiffness along the preferred (or averaged) fiber direction.

9A984. Identification algorithm for systemic arterial parameters with application to total artificial heart control. - TL Ruchti, RH Brown *(Dept of Elec and Comput Eng, Marquette Univ, 1515 W Wisconsin Ave, Milwaukee WI 53233)*, DC Jeutter *(Dept of Biomed Eng, Marquette Univ, 1515 W Wisconsin Ave, Milwaukee WI 53233)*, Xin Feng *(Dept of Elec and Comput Eng, Marquette Univ, 1515 W Wisconsin Ave, Milwaukee WI 53233)*. Ann Biomed Eng 21(3) 221-236 (May-Jun 1993).

A new algorithm for estimating systemic arterial parameters from systolic pressure and flow measurements at the root of the aorta is developed and tested through a systems identification approach. The resulting procedure has direct application to a total artificial heart (TAH) control system currently under development. Identification models, representing the systemic arterial system, are developed from existing work in the area of cardiovascular modeling. Performance of the estimation algorithm was tested on data generated by a higher-order distributed model of the systemic arterial bed using normal canine parameters. Results from model-to-model experiments verify the consistency of the estimates and the ability of the estimator to converge quickly and track dynamically varying parameters.

9T985. 550G. MICROBIOMECHANICS

See the following:

9A989. Pressure propagation in pulsatile flow through random microvascular networks

550I. FLUID MECHANICS OF CIRCULATORY SYSTEMS AND OTHER BODY FLUIDS

9A986. Effects of the bifurcation angle on the steady flow structure in model saccular aneurysms. - Tong Miin Liou, TW Chang, WC Chang *(Dept of Power Mech Eng, Natl Tsing Hua Univ, Hsinchu, Taiwan 300, ROC)*. Exp Fluids 14(5) 289-295 (Apr 1993).

The effects of bifurcation angle on the steady flow structure in a straight terminal aneurysm model with asymmetric outflow through the branches have been characterized quantitatively in terms of laser-Doppler velocimetry (LDV)-measured mean velocity and fluctuating intensity distributions. The bifurcation angles investigated were 60°, 90°, and 140° and the Reynolds number based on the bulk average velocity and diameter of the afferent vessel was 500. It is found that the size of the recirculating zones in the afferent vessel, the flow activity (both mean and fluctuating motions) inside the aneurysm, and the shear stresses acting on the aneurysmal wall increase with increasing bifurcation angle. More importantly, both LDV-measured and flow-visualized results of the present study suggest the presence of a critical bifurcation angle below which the aneurysm is susceptible to thrombosis, whereas above this aneurysm is prone to progression or rupture.

9A987. Faster procedure for deriving regional blood flow by the noninvasive transient thermal clearance method. - M Nitzan *(Dept of Appl Phys and Electro-Optics, Jerusalem Col of Tech, PO Box 16031, Jerusalem 91160, Israel)*, Y Mahler, N Lifshitz *(Dept of Biomed Eng and Instrumentation, Hadassah Univ Hospital, Jerusalem, Israel)*. Ann Biomed Eng 21(3) 259-262 (May-Jun 1993).

The noninvasive transient clearance method provides absolute quantitative measurement of skin blood flow. It is based on thermally insulating the skin under investigation and measuring the time constant of the resultant experimental skin temperature increase. Conventional assessment of the time constant, by measuring the temperature increase until final equilibrium skin temperature is achieved, has the disadvantage of long time of measurement. The time constant of the exponential temperature increase is calculated without obtaining the final equilibrium temperature.

9A988. Mechanics of axially symmetric liposomes. - DC Pamplona *(Dept of Civil Eng, PUC-RJ, Rio de Janeiro CEP 22453, Brazil)* and CR Calladine *(Dept of Eng, Univ of Cambridge, Cambridge CB2 1PZ, UK)*. J Biomech Eng 115(2) 149-159 (May 1993).

Hotani has filmed morphological transformations in unilamellar liposomes, starting from a spherical shape, when the interior volume decreases steadily. Hotani's liposomes showed no evidence of general thermal fluctuations. We use a finite-deformation theory of axisymmetric, quasi-static thin shells to analyze theoretically bifurcations and changes of shape in liposomes under decreasing volume. The main structural action in a lipid bilayer is generally agreed to be its elastic resistance to bending, and it is usual to regard surface deformation as being like that of a 2D liquid.

9A989. Pressure propagation in pulsatile flow through random microvascular networks. - XS He *(Dept of Mech Eng and Mech, Drexel Univ, Philadelphia PA 19104)* and JG Georgiadis *(Dept of Mech and Indust Eng, Univ of Illinois, Urbana IL 61801)*. J Biomech Eng 115(2) 180-186 (May 1993).

A microvascular network with random dimensions of vessels is built on the basis of statistical analysis of conjunctival beds reported in the literature. Our objective is to develop a direct method of evaluating the statistics of the pulsatile hydrodynamic field starting from a priori statistics which mimic the large-scale heterogeneity of the network. The model consists of a symmetric diverging-converging dentritic network of ten levels of vessels, each level described by a truncated Gaussian distribution of vessel diameters and lengths. The results are presented in terms of the mean value and standard deviation of the pressure and flow rate waveforms at two positions along the network. It is shown that the assumed statistical variation of vessel lengths results in flow rate deviations as high as 50% of the mean, while the corresponding effect of vessel diameter variation is much smaller.

9A990. Sternal force-displacement relationship during cardiopulmonary resuscitation. - KG Gruben, AD Guerci, HR Halperin *(Peter Belfer Lab for Cardiac Mech, Cardiology Div of the Dept of Med, Johns Hopkins Univ and Med Inst, Baltimore MD)*, AS Popel *(Dept of Mech Eng, Johns Hopkins Univ and Med Inst, Baltimore MD)*, JE Tsitlik *(Peter Belfer Lab for Cardiac MechCH, Cardiology Div of the Dept of Med, Johns Hopkins Univ and Med Inst, Baltimore MD)*. J Biomech Eng 115(2) 195-201 (May 1993).

A viscoelastic model is presented to describe the dynamic response of the human chest to cyclic loading during manual cardiopulmonary resuscitation (CPR). Sternal force and displacement were measured during 16 clinical resuscitation attempts and during compressions on five CPR training manikins. The model was developed to describe the clinical data and consists of the parallel combination of a spring and dashpot. The manikins' elastic properties were stiffer and both elastic and damping properties were less dependent on displacement than the humans'.

9T991. Subclavian-carotid transposition for the subclavian steal syndrome: In vitro studies. - CM Rodkiewicz, J Centkowski *(Dept of Mech Eng, Univ of Alberta, Edmonton T6G 2G8, AB, Canada)*, S Zajac *(Polish Med Acad, Warsaw, Poland)*. J Biomech Eng 115(2) 205-206 (May 1993).

9A992. Theoretical analysis of the large blood vessel influence on the local tissue temperature decay after pulse heating. - LX Xu *(Dept of Appl Sci, College of State Island-CUNY, Staten Island NY 10301)*, MM Chen *(Dept of Mech and Indust Eng, and Bioeng Fac, Univ of Illinois, Urbana IL 61801)*, KR Holmes *(Dept of Veterinary Biosci and the Bioeng Fac, Univ of Illinois, Urbana IL 61801)*, H Arkin *(Natl Inst for Build Res, Technion, Haifa 32000, Israel)*. J Biomech Eng 115(2) 175-179 (May 1993).

The influence of a large blood vessel (larger than 500 μm in diameter) on the local tissue temperature decay following a point source heating pulse was determined numerically using a sink-source method. It was assumed that the vessel was large enough so that the temperature of blood flowing within it remained essentially constant and was unaffected by any local tissue temperature transients. Computations have been performed for a range of vessel sizes, probe-vessel spacings and local blood perfusion rates. It was found that the influence of a large vessel on the local tissue temperature decay is more sensitive to its size and location rather than to the local blood perfusion rate.

The purpose of this paper is to review current knowledge concerning the long and triple jumps. Much has been learned over the past two decades about techniques in the long jump. Many myths have been dispelled and many training practices have been altered as a result. In all of this, the techniques employed during the takeoff have received little attention. The triple jump is an experimental task with potential for use in studies of human locomotion, of visual perception and control, of the strength of biological materials and of the mechanisms of soft tissue injury.

9A995. **Computer simulation in sport and industry.** - M Hubbard *(Dept of Mech, Aeronaut and Mat Eng, UC, Davis CA 95616).* J Biomech **26**(SUPPL 1) 53-61 (1993).

The last several decades have brought decreases in the specific cost of computer memory and increases in processor throughput. As a result simulation has become correspondingly more important as a component of industrial design and as a method for the study of general biomechanics and sports techniques. This paper illustrates, by way of examples, several of the more important aspects of the application of computer simulation to dynamic problems. Most industrial use of simulation is in the design process. A similar approach is equally valid in biomechanics and sport applications through the incorporation of design variables, which may be easily changed in the model experiment.

APPLIED MECHANICS REVIEWS REPRINTS

Biomimetics: Advancing man-made materials through guidance from nature. AV Srinivasan, GK Haritos, and FL Hedberg. AMR 44(11) Part 1, 463-482 (Nov 1991) Reprint No AMR101 $18

Mechanics Pan-America 1991 (Proc PACAM-2, Valparaiso, Chile, Jan 1991). PA Kittl and DT Mook (eds). AMR 44(11) Part 2 (Nov 1991) Reprint No AMR106 $88 (members $44)

Structural and dynamic behavior of pretwisted rods and beams. A Rosen. AMR 44(12) Part 1, 483-516 (Dec 1991) Reprint No AMR102 $26

Hydroacoustics of transitional boundary-layer flow. GC Lauchle. AMR 44(12) Part 1, 517-531 (Dec 1991) Reprint No AMR103 $16

Index to Volume 44 (1991). Reprint No AMR108 $88 (members $44)

Stress minimum forms for elastic solids. LT Wheeler. AMR 45(1), 1-12 (Jan 1992) Reprint No AMR 107 $14

Micromechanics of composite materials. Special collection edited by AN Guz. AMR 45(2) 13-101 (February 1992) Reprint No AMR104 $54: (1) **Statics of laminated and fibrous composites with bent structures.** SD Akbarov and AN Guz. (2) **Dynamics of laminated and fibrous composites.** AN Guz and NA Shulga. (3) **Stability of fibrous composites.** IY Babich and AN Guz. (4) **Stability of laminated composites.** AN Guz and VN Chekhov.

Microbubble drag reduction in liquid turbulent boundary layers. C Merkle and S Deutsch. AMR 45(3) Part 1, 103-127 (March 1992) Reprint No AMR105 $22

Material Instabilities (22nd Midwestern Mechanics Conference, Rolla MO, Oct 1991) HM Zbib, TG Shawki, RC Batra (eds). AMR 45(3) Part 2 (March 1992) Reprint No AMR110 $66 (members $33)

Heat-transfer control: Principal focus on Japanese Research. T Aihara. AMR 45(4) 129-153 (April 1992) Reprint No AMR109 $16

Optimum dimensions of extended surfaces operating in a convective environment. A Aziz. AMR 45(5) 155-173 (May 1992) Reprint No AMR111 $18

Overview of micro heat pipe research and development. GP Peterson. AMR 45(5) 175-189 (May 1992) Reprint No AMR112 $16

Multiphase poroelastic finite element models for soft tissue structures. BR Simon. AMR 45(6) 191-218 (June 1992) Reprint No AMR114 $22

Dynamics and control of coherent structures in turbulent jets. RR Mankbadi. AMR 45(6) 219-248 (June 1992) Reprint No AMR113 $24

Addendum to: Bibliography of monographs and surveys on shells. W Pietraszkiewicz. AMR 45(6) 249-250 (June 1992) Reprint No AMR115 (free with AMR078 $14)

Romanian sources on applied mechanics. ME Popescu. AMR 45(6) 251-252 (June 1992) Reprint No AMR116 no charge.

Fluorescence thermometry. LJ Dowell. AMR 45(7) 253-260 (July 1992) Reprint No AMR117 $12.00

Micromechanical modelling of quasi-brittle materials behavior. VC Li (ed), 10 articles. AMR 45(8) 261-398 (Aug 1992) Reprint No AMR118 $60.

Recent developments in the force method of structural analysis. A Kaveh AMR45(9) 401-418 (Sep 1992) Reprint No AMR119 $18.

Computational models for high-temperature multi-layered composite plates and shells. AK Noor and WS Burton. AMR 45(10) 419-446 (Oct 1992) Reprint No AMR 120 $22.

Dynamics of periodic and near-periodic structures. Dong Li and H Benaroya. AMR 45(11) 447-460 (Nov 1992) Reprint No AMR121 $16.

Finite element analysis of aeroelasticity of plates and shells. MN Bismarck-Nasr. AMR 45(12) 461-482 (Dec 1992) Reprint No AMR122 $20.

Index to Volume 45 (1992). Reprint No AMR123 $88 (members $44)

Mathematical modeling of transport phenomena during alloy solidification. C Beckermann and R Viskanta. AMR 46(1) 1-28 (Jan 1993) Reprint No AMR124 $22.

Perturbation techniques in phase change heat transfer. A Aziz and VJ Lunardini. AMR 46(2) (Feb 1993) Reprint No AMR125 $28.

US machining and grinding research in the 20th century. R Komanduri, ME Merchant, MC Shaw. AMR 46(3) (Mar 1993) Reprint No AMR 126 $42

Nondestructive testing and structural condition monitoring of mechanical cables. PAA Laura. AMR 46(4) 133-138 (Apr 1993) Reprint No AMR127 $12.

Aging of energy production and distribution systems: DOE Workshop, Rice University, Houston TX, October 11-13, 1992. Edited by MM Carroll and PD Spanos. AMR 46(5) 139-263 (May 1993) Reprint No AMR128 $78.

Applied mechanics of a lunar base. Edited by H Benaroya. AMR 46(6) 265-358 (June 1993) Reprint No AMR129 $65.

Chaos and noise in dynamical systems. Edited by T Kapitaniak and J Brindley. AMR 46(7) 359-444 (July 1993) Reprint No AMR130 $59.

Boundary integral equations in aerodynamics. L Morino. AMR 46(8) 445-466 (August 1993) Reprint No AMR131 $20.

Vibrations of planar curved beams, rings, and arches. P Chidamparam and AW Leissa. AMR 46(9) 467-483 (Sep 1993) Reprint No AMR132 $20.

Subscription: ASME members (without Suppl.) $51 $____

ASME members (with Supplement) $84 $____

non-members (with Supplement) $534 $____

2nd library subscription $99 $____

applied mechanics reviews

AIMS

The primary aim of *AMR* is to serve engineering scientists worldwide by assessing, reviewing, and reporting on advances in a broad range of mechanical engineering sciences. To this end *AMR* publishes (i) state-of-the-art review articles, bibliographic surveys, reviews with a special focus on emerging technology, tutorials, historical perspectives, periodic summaries of trends and advances; (ii) critical reviews of books, software, and databases; (iii) indexed compilations of carefully selected abstracts from high quality research journals; (iv) book-length monographs and symposium proceedings as special issues or supplements; and (v) editorials, announcements, and letters-to-the-editor.

A secondary aim of *AMR* is to serve technical and reference librarians, information specialists, professional engineers, and college professors through reliable, comprehensive, and timely information about all types of books within its subject scope. The annual cumulative index issue of *AMR* together with its monthly classified listings of abstracts is in effect a comprehensive bibliography of the mechanical engineering sciences, including essentially every article in some 50-60 core journals; this core includes all ASME Transaction journals.

SCOPE

The scope of *AMR* encompasses all the engineering sciences represented in the journals and symposia sponsored by the American Society of Mechanical Engineers and is outlined by *AMR*'s Subject Classification Scheme, which is reprinted on the back cover. It includes basic discipline-oriented areas such as dynamics, continuum mechanics, solid and fluid mechanics, structures, heat transfer, tribology, geomechanics, and biomechanics, as well as cross-disciplinary subjects and emerging critical technological areas such as new numerical and computational techniques, systems control technology, engineering design tools, manufacturing technology, materials and energy technology, and environmental engineering.

The American Society of Mechanical Engineers

INFORMATION FOR AUTHORS OF REVIEW ARTICLES

(1) Prospective authors are strongly urged to communicate with one of the Associate Editors or the Editor-in-Chief (TEL 201-882-1170, FAX 201-882-5155) before submitting an article, and to furnish a one-page outline of the proposed article and information as to its type, audience, and probable length. A form, *Prospectus for a Review Article,* is available for this purpose. Refer to the editorials in the January 1985 and March 1991 issues of *AMR* and the box at left for further discussion of *AMR*'s editorial criteria.

(2) *Submit four clean copies* of the manuscript to one of the Associate Editors or to the Editor-in-Chief. (Hold all separate original artwork until the article has been accepted.) All articles will be reviewed critically by at least two independent and anonymous referees chosen by the editor involved. This procedure will be followed even if the article is the result of solicitation or encouragement by the editors, or if the author is also an *AMR* editor. The final decision on publication is made by the Editor-in-Chief upon recommendation of an Associate Editor. If appropriate, the article will carry a footnote saying "Transmitted by Associate Editor . . ."

(3) Submission of a manuscript is a representation that it has not been published previously nor is currently being submitted for publication elsewhere. The authors will be asked to sign a statement *transferring copyright to ASME.* It is the author's responsibility to obtain permission to copy material from other sources, if needed.

(4) There are *no page charges* in *AMR* and no numerical length limitations. The length of the article should be appropriate to the subject and the audience. It is certainly one factor that will be evaluated by the editors and their referees, who may recommend changes (30-120 manuscript pages is typical). Each author of a review article will receive *a year's free subscription to AMR.* After publication the author will receive *100 free reprints* (to be shared if there are several authors). In addition, ASME will distribute reprints singly and in bulk.

(5) Along with the final *manuscript* send the *compuscript on diskette,* if available, (with format identified) incorporating all corrections and additions, and with the tables and figure captions *in place within the text.* If the figures are computer graphics, place them also within the compuscript where they belong. Also, send a head-and-shoulders *photograph and short biographical sketch* (100-200 words) of each author, including grades of ASME membership, if any; include the bio at the end of the compuscript.

(6) *Order of parts:* Title of article, authors' names, authors' institutional affiliations, abstract (200-300 words suitable for abstracting services), table of contents (only if the article is so long that it needs one), list of symbols and abbreviations (if necessary), main text incorporating tables (each starting with a caption) and figure captions (in place where you want them in the text), list of references, biographical sketch, and original figures (if computer graphics, place in text above captions).

(7) *Format (for details request Author Kit):* (a) Paper size: A4 or 8.5×11 inch (220×280 mm). (b) Word processor settings: One column of width 3.4 in (87 mm) leaving rest of page for referee and editorial comments; Type size 10 point (72 point = 6 pica = 1 inch = 25.4 mm) Times Roman or similar proportionally spaced style; Line spacing 12 points. These as-printed *AMR* specifications will help to insure that equations, tables, and figures are properly designed for the available space. (If a typewriter must be used, type double spaced with wide margins). (c) Use metric SI units; with other units in parentheses, if appropriate. (d) Cite references by last name and year; reference list at end alphabetical by author (in 7-point type). (e) Number figures with arabic numerals; design figures for column width (83 mm or 3.1 in), if possible; they should be professionally drawn or computer generated with lettering of consistent size (not smaller than the printed text after reduction); use your wordprocessor to place an empty box of the correct dimensions (or the figure itself, if a computer graphic) in the text above each figure caption. (f) Number tables with roman numerals. (g) Latin letters used as math symbols should be in italics both in text and in displayed equations. Subscripts and superscripts should be 20-30% smaller than letters on the main line. Fractional powers are preferred to root signs, exp(..) to $e^{\cdot\cdot}$, and a solidus (/) for fractions, if that will save vertical space.

(8) *Camera-ready copy:* Typeset (or near-typeset) quality pages or galleys generated by the author (after review and acceptance) would be very much appreciated, and could result in faster publication. Just reproduce the format of published *AMR* review articles (basically, two of the columns defined above per page). Templates and style sheets available for MS Word and Wordperfect.

SPECIAL ISSUES: From time to time Guest Editors are invited to produce Special Issues consisting of 3 or more articles grouped around a common theme. SUPPLEMENTS are booklength monographs or symposium proceedings published as part 2 of a regular issue. Proposals for Special Issues or Supplements are very welcome. GUEST EDITORIALS, LETTERS-TO-THE-EDITORS, ANNOUNCEMENTS: Contact the Editor-in-Chief.

applied mechanics reviews

AN ASSESSMENT OF THE WORLD LITERATURE IN ENGINEERING SCIENCES

Applied Mechanics Reviews (ISSN 0003-6900) is published monthly by the ASME, 345 E 47th St, New York NY 10017. 2nd class postage paid at New York NY and additional mailing offices. POSTMASTER: Send address changes to ASME/AMR, 22 Law Drive, Box 2300, Fairfield NJ 07007-2300. CHANGES OF ADDRESS must be received at ASME seven weeks before they are to be effective. Send old label and new address. SUBSCRIPTION PRICES: $534 (incl Annual Index and Suppl.), single copies $57 (Suppl. or Index $84). Countries outside USA and Canada add $102 for postage ($156 airmail). 2nd library subscription $99. Canadian goods and services tax registration #126 148 048.
Printed in the USA. (7/93)

Thermal buckling of plates and shells

Earl A Thornton

Dept of Mech, Aerospace and Nuclear Engineering
University of Virginia, Charlottesville VA 22903-2442

This review discusses research on thermal buckling of plates and shells since the first work in the 1950s. Elastic thermal buckling of metallic as well as composite plates and shells is described. The role of material thermal properties on thickness and spatial temperature gradients is demonstrated first. Then thermal buckling and postbuckling research for plates, shallow shells and curved panels, cylindrical and conical shells is presented. Analytical, computational and experimental studies are described. Governing equations and formulas for critical buckling temperatures are presented for several practical applications. An assessment of past research is made, and future research needs are highlighted.

1. INTRODUCTION

In the fourth AIAA von Kármán lecture, Nicholas J Hoff, Hoff (1967), describes the evolution of thin-walled aircraft structures from the early days of aviation to the halcyon days of the Apollo program. A recurrent theme throughout his description of aerospace structures history is the engineer grappling with buckling problems of thin-walled structures. An early paper of Professor Hoff, Hoff (1946), traces aerospace buckling problems back to the wood-steel-fabric biplane era where the Euler buckling formula and beam-column theory were used to design struts of biplane wings and wing spars subjected to compressive loads. In the late 1920s solutions to buckling problems played an important role in the advancement of all-metal semi-monocoque construction. For several decades thereafter, engineers struggled with buckling problems of metallic thin-walled plates and shells under mechanical loads. The results of their work led to safe and reliable aircraft that made commercial aviation a worldwide economic success. Indeed, the basic construction ideas of riveted skin-stringer metallic structures made possible by the buckling analyses of the 1920s-1930s prevail today in modern commercial transports.

The importance of thermal effects on aircraft began after World War II with supersonic flight. Aerodynamic heating from supersonic flight induced elevated temperatures that affected material selection and significantly altered structural design practices. Thermal gradients and restrained thermal expansion introduced thermal buckling for the first time. A recent paper, (Thornton, 1992), describes development of thermal structures from the early days of supersonic flight to the more recent challenges presented by hypersonic flight. The development of the National Aerospace Plane (NASP) presents engineers with their greatest thermal structural challenges yet. New advanced metal matrix composites were developed for severe elevated temperature applications. Complex convectively-cooled thin-walled structures subjected to intense local heating provided unprecedented materials and structural modeling challenges. One example of such an extreme instance of a thin-walled structure subjected to intense local heating is the problem of shock-shock interactions.

As hypersonic vehicles accelerate at high speeds in the atmosphere, shocks sweep across the vehicle interacting with local shocks and boundary layers. These interactions expose structural surfaces to severe local pressures and heat fluxes. The first known instance of shock-shock interactions in high speed flight occurred on the X-15 in 1967. In that flight, the intense local heating induced severe local damage on a supporting pylon for a dummy ramjet engine, Thornton (1992). On the NASP these interactions occur on leading edges of integrated engine structures which experience intense, highly localized aerothermal loads. Dechaumphai *et al* (1989) studied issues relevant to the thermal-structure response of hydrogen cooled, super thermal-conducting leading edges subject to intense aerodynamic heating. A thermo-viscoplastic analysis of hypersonic engine structures, Thornton *et al* (1990), showed similar trends with thin-walled convectively cooled structures subjected to high internal pressures and intense local heating. Poleski *et al* (1992) describe a three-dimensional thermal structural analysis of a swept cowl leading edge subjected to skewed shock-shock interference heating. The analysis shows that due to the intense localized heating, the thin elastic leading edge experiences very large local compressive stresses. The high level of these compressive stresses suggests the possibility of localized inelastic behavior and/or local buckling. Clearly these

new, complex problems present structural analysts with new, unprecedented thermal-buckling challenges.

This article describes research on thermal buckling of plates and shells. Elastic thermal buckling is emphasized although recent experience on NASP problems has shown the importance of inelastic buckling. However, the literature available on elastic buckling is much more extensive than for inelastic buckling, and an assessment of these studies was given priority for this review. Thermal buckling of metallic as well as composite plates and shells is considered. Thermal buckling studies of composites are much more recent than for metallics, and recent progress with composites is described.

Temperature levels and their distributions have a major role in thermal buckling. The article begins with a brief description of temperature distributions in thin-walled structures. Then past literature on thermal buckling of plates and shells is described. In each instance, past research is assessed, and research needs are discussed. The article concludes with brief summarizing remarks.

2. TEMPERATURES IN THIN-WALLED STRUCTURES

The determination of temperatures in a thin-walled structure begins with conservation of energy. In the most general form with thermomechanical coupling, Allen (1991), the conservation of energy equation includes terms that represent the conversion of mechanical to thermal energy. In practical aerospace structural heat transfer, thermomechanical coupling is usually neglected. Then the conservation of energy equation involves temperature as the only dependent variable. It may be solved for the temperature distribution independently from the structural problem.

2.1 Structural Heat Transfer

Heat transfer in thin-walled structures is conduction dominated, and the classical heat conduction equation is used:

$$-\frac{\partial}{\partial x_i}\left(k_{ij}\frac{\partial T}{\partial x_j}\right)+\rho c\frac{\partial T}{\partial t}=Q \tag{1}$$

where $T(x_1, x_2, x_3, t)$ is temperature, k_{ij} are the components of the material's thermal conductivity tensor, ρ is the density, c is the specific heat, and Q is the internal heat generation rate per unit volume. The components of the thermal conductivity tensor and the specific heat are temperature dependent. The heat conduction equation is solved subject to an initial condition and boundary conditions on the structure's surface. The initial condition specifies the temperature distribution at time zero. The boundary conditions may consist of s[illegible] surface temperature, specified heat flow, con[illegible] exchange, and radiation heat exchange. T[illegible] written as

$$\begin{aligned}
T_s &= T_s(x_1,x_2,x_3,t) && \text{on } S_1\\
q_i n_i &= -q_s && \text{on } S_2\\
q_i n_i &= h(T_s - T_e) && \text{on } S_3\\
q_i n_i &= \sigma\varepsilon T^4 - \alpha q_r && \text{on } S_4
\end{aligned} \tag{2}$$

where q_i denotes components of heat flux, n_i denotes components of a unit outward normal vector, and S_i(i = 1,4) denotes portions of the surface. The specified surface temperature is T_s, and the specified heat flux (positive into the surface) is q_s. In the convective boundary condition on S_3, the convection coefficient is h, and the convective exchange temperature is T_e. In the radiation boundary condition on S_4, σ is the Stefan-Boltzmann constant, ε is the surface emissivity, α is the surface absorptivity, and q_r is the incident radiation flux. For structural heat transfer with surfaces at significantly different elevated temperatures, radiation exchanges can occur. The determination of radiation exchanges between surfaces is complicated because radiation emitted by a typical surface depends on its surface temperature which is unknown, and the geometrical relationship between surfaces affects the exchanges.

Thus the basic aerospace structural heat transfer problem is nonlinear because of temperature-dependent properties and radiation heat transfer. For practical structures, temperature is determined computationally, most often by finite difference methods (Schuh, 1965) but also by finite element methods (Huebner and Thornton, 1982).

2.2 Temperature Distributions

Complex thin-walled aerospace structures under service conditions rarely experience uniform temperatures. Often, the external heating is non-uniform. For example, leading edges of wings in high speed flight experience high local heating at stagnation points. Moreover, as the external flow traverses the airfoil, aerodynamic heating changes with surface curvature and increases significantly at a transition from laminar to turbulent flow. As mentioned in the Introduction, shock interactions cause intense local heating.

Even if the external heating is nearly uniform, spatial variations in skin temperatures occur due to internal reinforcements such as ribs, stiffeners and frames. At points or lines of attachment of local skin reinforcements, temperatures are lower than nearby skin temperatures because the reinforcement offers a greater material volume to absorb energy and a conduction path for heat transfer to the structure interior. Very early recognition of temperature variations in thin-walled structures was made for supersonic aircraft, Hoff (1951). Boley and Wiener (1960) describe research in the 1950s on temperature distributions and give additional references.

In orbiting space structures, temperatures are unsteady because of the variation of incident heat fluxes with

orbital position, Thornton and Paul (1985). Structural temperatures may experience extremes from +250°F to -250°F for an orbit where the spacecraft passes through the Earth's shadow. Temperatures vary spatially in orbiting structures because of nonuniform incident heat fluxes, structural conduction and radiation heat losses from surfaces. In the vacuum of space, radiation heat transfer is particularly significant. For example, thin cylindrical shells may have major circumferential temperature variations since typically one-half of the cylindrical surface experiences heating from the solar flux while the remaining portion of the surface is shaded. All surfaces of the cylinder, heated and unheated, experience thermal energy losses to space by radiation.

Finally, thermal properties of materials have a major effect on temperature distributions. Metallic and composite materials may have significant differences in thermal properties that yield substantially different temperature distributions.

To gain insight into how the properties of several common aerospace materials affect the temperature of a thin-walled structure, it is helpful to examine a simple heat conduction problem. Consider a thin plate of thickness h with the x,y,z coordinate system located at the middle surface. The initial temperature of the plate is zero. The surface $z = -h/2$ is perfectly insulated, and for time $t > 0$ the surface $z = h/2$ is uniformly heated by a constant heat flux q_s. To understand how material properties affect the temperature gradient through the plate thickness, consider the situation where there is no temperature variation with x and y, *ie* $T(z,t)$. Thermal properties are assumed constant. The solution to the initial/boundary value problem is given by Boley and Weiner (1960) as

$$T(z,t) = \frac{q_s h}{k}\left[\frac{\kappa t}{h^2} + \frac{1}{2}\left(\frac{z}{h}+\frac{1}{2}\right)^2 - \frac{1}{6} - \frac{2}{\pi^2}\sum_{n=1}^{\infty}(-1)^n \exp(-n^2\pi^2\kappa t/h)\cos n\pi\left(\frac{z}{h}+\frac{1}{2}\right)\right] \quad (3)$$

where the thermal diffusivity $\kappa = k/\rho c$. This solution predicts that after an initial transient, temperatures of the top and bottom surfaces of the plate increase linearly with time according to the first term in the square brackets. Thus, the infinite series contributes to the temperature distribution only during the initial transient, and after early time the series contribution becomes negligible. Neglecting the series permits the thickness temperature difference or gradient $\Delta T = T(h/2,t)-T(-h/2,t)$ to be expressed by the simple equation,

$$\Delta T = \frac{q_s h}{2k} \quad (4)$$

Equation 4 shows that the thickness temperature gradient varies linearly with the applied heat flux and plate thickness but inversely with the thermal conductivity. Table I gives thermal properties and thickness temperature gradients predicted for ten metallic and composite plates. Figures 1-2 show

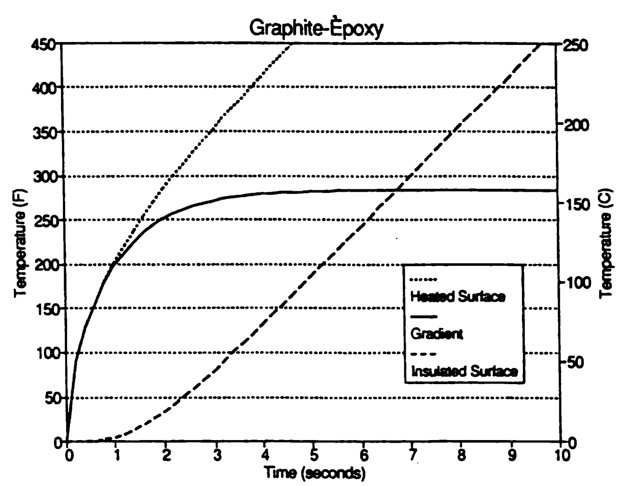

FIG 1 Thermal response of suddenly heated, thin graphite-epoxy plate, q_s = 0.1 BTU/in²-s (16 W/cm²) and h = 0.125 in (0.318 cm).

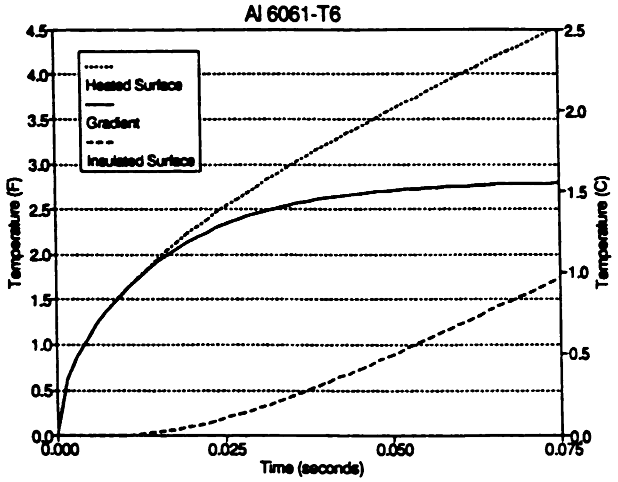

FIG 2 Thermal response of suddenly heated, thin aluminum alloy plate, $q_s = 0.1$ BTU/in^2-s (16 W/cm^2) and $h = 0.125$ in (0.318 cm).

transient temperatures for graphite-epoxy and aluminum plates. Graphite-epoxy and aluminum have the smallest and largest values of thermal conductivity, respectively, and produce extreme values for the temperature gradient. Graphite-epoxy has a very large thickness temperature gradient, and aluminum has a very small temperature gradient. Table I shows, in fact, that the graphite-epoxy composite is exceptional; its thermal conductivity is so low that an extraordinarily large thickness temperature gradient is predicted. Since the practical temperature range of this material is limited to less than 250°F (120°C), it is doubtful that such a large ΔT could ever occur in practice. The other metallics and metallic-based composites show relatively small thickness temperature gradients with titanium showing the largest and aluminum the smallest gradients, respectively. The thickness temperature gradients shown may be regarded

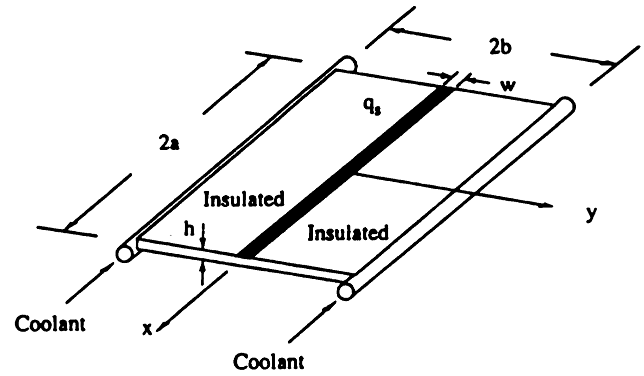

FIG 3 Centrally-heated, edge-cooled plate studied by Heldenfels and Roberts (1952).

as upper bounds since often thermal conductivity increases with increasing temperature, and the insulated boundary condition on the bottom surface will not be realized as energy losses will inevitably occur due to surface convection or radiation heat transfer. In addition, any heat conduction in the x-y plane due to plate supports or non-uniform heating will lessen the thickness temperature gradient. For thin-walled metallic structures, customary practice has been to neglect thickness temperature gradients.

Insight into the effect of thermal properties on the spatial variation of the thin plate temperature, $T(x,y)$, is provided by solution of the linear, unsteady initial/boundary value problem of a plate locally heated, Fig 3. The edges of the plate at $y = \pm b$ are maintained at constant temperature of zero by specified coolant flows. The bottom and top surfaces of the plate are perfectly insulated except along the centerline of the upper plate surface. For time $t > 0$, the plate experiences uniform heating q_s on a narrow strip along the x axis.

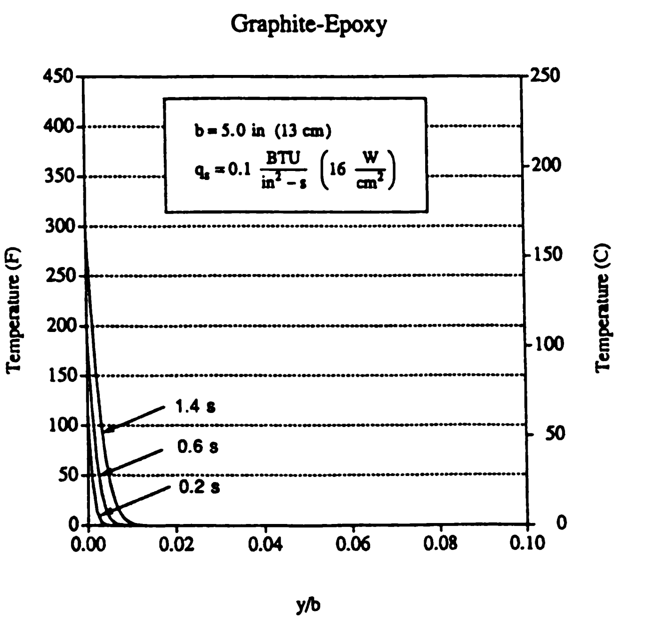

FIG 4 Temperature distribution for locall[illegible]e-epoxy plate, $q_s = 0.1$ BTU/in^2-s (16. W/cr[illegible]).

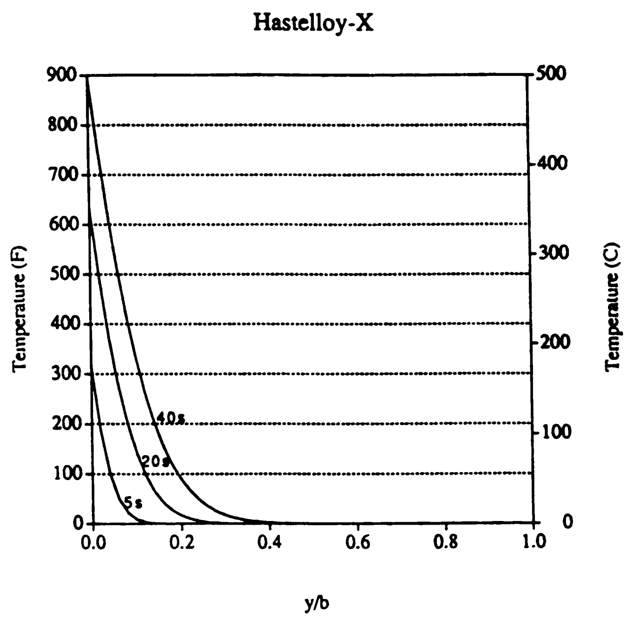

FIG 5 Temperature distribution for locally heated Hastelloy X plate, $q_s = 0.1$ BTU/in^2-s (16. W/cm^2), $b = 5.0$ in (13 cm).

Temperature is assumed uniform through the plate thickness. The solution to the symmetric, one-dimensional conduction problem is given by Carslaw and Jaeger (1980) as,

$$T(y,t) = \frac{q_o(b-y)}{2k} - \frac{8q_o b}{\pi^2 k}\sum_{n=0}^{\infty}\frac{(-1)^n}{(2n+1)}$$

$$\exp\left[-\pi^2(2n+1)^2\kappa t/4b^2\right]\sin\frac{\pi(2n+1)(b-y)}{2b} \tag{5}$$

where $q_o = q_s w/2h$ with w as the width of the heated strip, and as before, κ is the thermal diffusivity. For large time, plate temperatures approach steady-state with the peak temperature at the centerline and a linear decrease to the specified zero values on the plate edges. As with the previous solution, Eq 5 predicts plate transient temperature distributions that depend inversely on the material's thermal conductivity.

Using the thermal properties shown in Table I, transient thermal responses were computed for graphite-epoxy, Hastelloy X, and aluminum, (Figs 4-6). These results indicate the responses of low, medium and high thermal conductivity material plates to local heating. The results show for low thermal conductivity graphite-epoxy (Fig 4) that temperatures rise rapidly with very steep temperature gradients and a highly-localized heated region. On the other hand, for aluminum with high thermal conductivity (Fig 6) temperatures rise more slowly with lower gradients as thermal energy is conducted into the cooler boundaries. The response of the Hastelloy X, a high temperature nickel-based alloy, falls somewhere in between these two extremes, but the material demonstrates high local temperatures, steep gradients and a relatively small heated region. Thin walled structures of this alloy subjected to localized heating are likely to experience inelastic buckling behavior due to the high local temperatures.

These examples demonstrate two types of thermal gradient responses characteristic of thin-walled structures. For low thermal conductivity materials such as graphite-epoxy, high thickness temperature gradients will occur. However, for metals and metal matrix composites, thickness temperature gradients are negligible, and spatial temperature gradients are most likely to occur in applications.

3. THERMAL BUCKLING OF PLATES

This section reviews past research on thermal buckling of rectangular plates. The review is divided into three parts: (1) the plane stress problem, (2) the buckling problem, and (3) the postbuckling problem. Within each part papers are described in chronological order. A survey of thermally induced flexure, buckling and vibration of plates, Tauchert (1991), provided some of the references in this review. A recent review article by Noor and Burton (1992) describes computational models for high temperature multilayered composite plates and shells and lists 448 references.

3.1 The Plane Stress Problem

The classical plane stress problem consists of a thin, perfectly flat, isotropic rectangular plate heated so that the temperature is a function only of the spatial coordinates and time, *ie* $T(x, y, t)$. Since the temperature does not vary through the plate thickness the thermal moment is zero, and the plate remains flat as the temperature changes. A state of plane stress is assumed, and the non-zero stresses σ_x, σ_y, τ_{xy} are functions only of the spatial coordinates and time. Assuming elastic quasi-static behavior with constant properties, the elasticity problem may be formulated in terms of the two non-zero equilibrium equations, the strain-displacement relations and Hooke's law.

Some of the earliest thermal-stress analyses relevant to thermal buckling were concerned with solving the plane stress problem for a steady temperature distribution $T(x, y)$. A popular approach was to introduce an Airy stress function $F(x, y)$ such that

$$\sigma_x = \frac{\partial^2 F}{\partial y^2}$$
$$\sigma_y = \frac{\partial^2 F}{\partial x^2}$$
$$\tau_{xy} = -\frac{\partial^2 F}{\partial x \partial y} \tag{6}$$

Equilibrium is then satisfied, and by using the membrane strain compatibility equation F is a solution of the non-homogeneous biharmonic equation

$$\nabla^4 F = -E\alpha\nabla^2 T \tag{7}$$

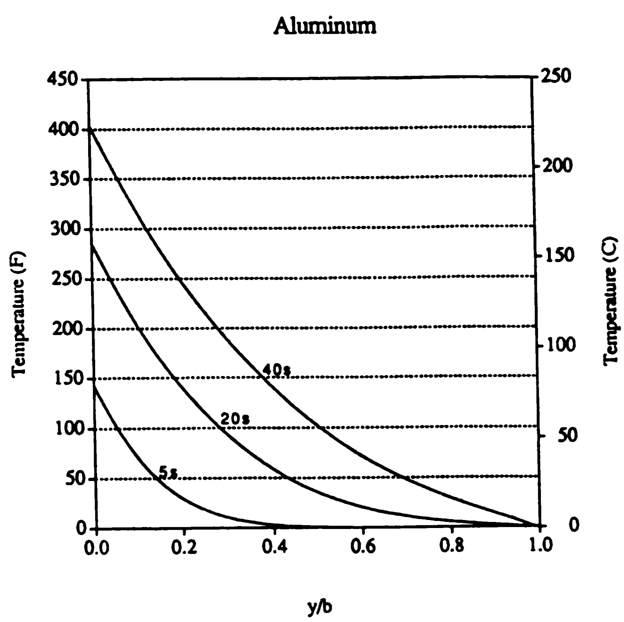

FIG 6 Temperature distribution for locally heated aluminum plate, q_s = 1 BTU/in^2-s (16. W/cm^2), b = 5.0 in (13 cm).

where E is the modulus of elasticity, and α is the coefficient of thermal expansion. The stress function F, of course, must satisfy appropriate boundary conditions on the plate edges.

Heldenfels and Roberts (1952) investigated the plane stress problem theoretically and experimentally. The theoretical studies produced an approximate complementary energy solution for the Airy stress function. In the experimental studies, simple "tentlike" steady-state temperature distributions were introduced by heating a rectangular plate along a centerline with a heating wire and maintaining constant temperature along parallel edges by water flow through coolant tubes (Fig 3). Top and bottom surfaces of the plate were insulated to produce uniform, one-dimensional, linear temperature variations between the heated centerline and cooled parallel edges. In the experimental study, in-plane plate displacements were permitted to occur freely, but out-of-plane displacements were prevented by restraints that forced the plate to remain flat. Thermocouples and strain gages were used to measure temperatures and strains, respectively. Experimental results were found to be in satisfactory agreement with the approximate theoretical results. The results showed important characteristics of the stress distribution. The tentlike temperature distribution (Fig 7) causes the central portion of the plate to be in compression. For example, the stress $\sigma_x(o,y)$ is compressive for $-b/2 < y < b/2$ where the transverse width of the plate is $2b$. For an unrestrained plate, these compressive stresses must be equilibrated by tensile stresses σ_x along the outer regions of the plate. The most important point, however, is that the unrestrained plate may experience thermal buckling due to compressive stresses induced by the spatial temperature gradients.

A few years later Przemieniecki (1959) used characteristic beam vibration modes to derive an approximate solution for the plane stress problem for arbitrary temperature distributions. Two years later, Rao and Johns (1961) compared various solutions for the

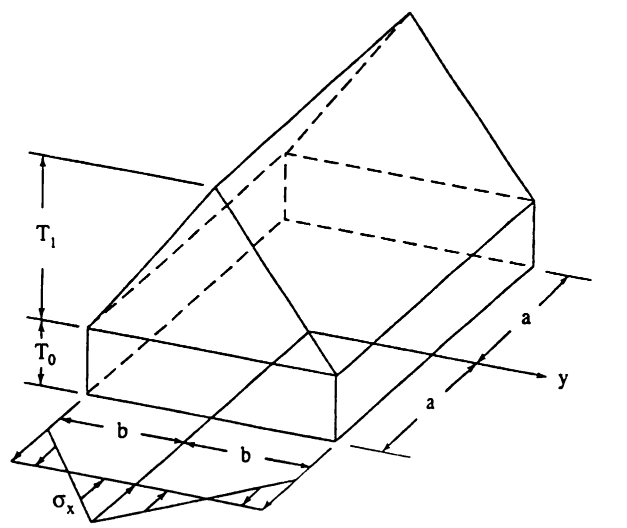

FIG 7 Tentlike tempera[illegible]d axial stresses in Heldenfels and Roberts

plane stress problem assuming a symmetrical temperature variation across the width of the plate. These investigations provided insight into the membrane thermal stress distributions that establish the possibility of thermal buckling due to the local compressive stresses. The plane-stress problem remains important today. In a study of the viscoplastic response of plates due to unsteady heating, Thornton and Kolenski (1991) investigated the plane stress problem using a finite element approach. Plate elastic and inelastic membrane stresses were investigated for prescribed transient temperature distributions. Local yielding significantly alters membrane stress distributions, and for rapid rises of temperature, the nickel-based alloy materials display initially higher yield stresses due to strain rate effects. As temperatures approach elevated values, yield stress and stiffness degrade rapidly and pronounced plastic deformation occurs.

3.2 Buckling

To determine the critical buckling temperature, small transverse bending displacements of the plate are assumed. The stresses obtained from the solution of the uncoupled plane stress problem is used to define the inplane stress resultants N_x, N_y, N_{xy} which are obtained by multiplying the stresses by the plate thickness h. The displacement $w(x,y)$ of the buckled plate is governed by the linear differential equation

$$D\nabla^4 w = N_x \frac{\partial^2 w}{\partial x^2} + 2N_{xy}\frac{\partial^2 w}{\partial x \partial y} + N_y \frac{\partial^2 w}{\partial y^2} \tag{8}$$

where D is the flexural rigidity of the plate, $D = Eh^3/12(1-\upsilon^2)$, and υ is Poisson's ratio. One of the basic thermal buckling solutions to Eq 8 is for a fully-restrained plate with a uniform temperature rise. For a rectangular plate with dimensions $(2a \times 2b)$ subjected to uniform compressive membrane forces N_x and N_y, Timoshenko and Gere (1961) give the critical condition as

$$N_x \frac{m^2\pi^2}{(2a)^2} + N_y \frac{n^2\pi^2}{(2b)^2} = D\left[\frac{m^2\pi^2}{(2a)^2} + \frac{n^2\pi^2}{(2b)^2}\right]^2$$

where m, n denote the number of half-waves in the x and y directions, respectively. Due to a uniform temperature rise ΔT, $N_x = N_y = hE\alpha\Delta T/(1-\upsilon)$ for the fully restrained plate. Thus the critical buckling temperature is determined by substituting for N_x and N_y and solving for ΔT_{cr}

$$\Delta T_{cr} = \frac{\pi^2 D(1-\upsilon)}{4E\alpha h}\left(\frac{m^2}{a^2} + \frac{n^2}{b^2}\right)$$

where the minimum value occurs for $m = n = 1$. Substituting for D yields,

$$\Delta T_{cr} = \frac{\pi^2 h^2}{48(1+\upsilon)\alpha}\left(\frac{1}{a^2}+\frac{1}{b^2}\right) \tag{9}$$

Equation 9 shows that the critical buckling temperature is independent of the material's modulus of elasticity. For thin plates fully-restrained against in-plane displacements, Eq 9 predicts quite small critical buckling temperatures. For example, an aluminum plate with a = 18 in, b = 12 in and h = 0.25 in buckles at a critical temperature $\Delta T_{cr} = 8.4°F$.

Shortly after the Heldenfels and Roberts paper on the plane stress problem was published at NASA Langley, a closely related paper by Gossard, Seide and Roberts (1952) described the buckling and post buckling behavior of the same plate. The paper made two important contributions. First, the critical buckling temperature for the unrestrained plate with the tentlike temperature distribution was determined analytically. Secondly, the post-buckling nonlinear, out-of-plane bending displacement $w(x,y)$ was studied analytically and experimentally.

The critical buckling temperature was obtained for simple supports by the principle of minimum potential energy using a series of trigonometric functions for the transverse displacement. The in-plane displacements are unrestrained. For a panel with aspect ratio of a/b = 1.57, the critical buckling temperature was determined to be

$$T_{1_{cr}} = \frac{5.39\pi^2}{12}\frac{1}{1-\upsilon^2}\frac{1}{\alpha}\frac{h^2}{b^2} \tag{10}$$

In Eq 10, T_{1cr} is the critical value of the temperature differential, the difference T_1 between the center and edge temperatures in a tentlike temperature distribution, Fig 7. The paper also studied the plate's postbuckling behavior which will be described in the next section.

After the Gossard, Seide and Roberts paper, other authors investigated bifurcation thermal buckling of rectangular plates. Hoff (1956) investigated thermal buckling of supersonic wing panels. Temperature and thermal stress distributions due to aerodynamic heating were analyzed for supersonic wing structures. An analytical approach for determining critical thermal buckling stresses for wing cover plates was developed. van der Neut (1957) investigated approximate analysis methods for determining critical buckling temperature for panels with assumed distributions of thermal stress. Klosner and Forray (1958) studied buckling of simply supported plates under an arbitrary symmetrical temperature distribution. In-plane displacements of the plate are assumed to be elastically restrained by supporting edge members. The critical buckling temperature was determined by a Rayleigh-Ritz procedure. Miura (1961) used a similar procedure to obtain the critical buckling temperature when in-plane displacements are completely restrained. Critical buckling temperatures were computed in these two papers for a plate of dimensions $(2a \times 2b)$ and the parabolic temperature distribution,

$$T = T_0 + T_1\left[1-\left(1-\frac{x}{a}\right)^2\right]\left[1-\left(1-\frac{y}{a}\right)^2\right] \tag{11}$$

The results of these two papers showed that the critical buckling temperature is given by Eq 10 in the general form

$$T_{1_{cr}} = \frac{k_T}{1-\upsilon^2}\frac{1}{\alpha}\frac{h^2}{b^2} \tag{12}$$

where $T_{1_{cr}}$ is the critical value of the temperature rise. The thermal buckling coefficient k_T depends on the plate aspect ratio and in-plane boundary restraints. Equation 12 assumes fully restrained simple supports, and that the plate buckles in a single half-wave in each direction. The variation of the critical buckling temperature with the aspect ratio a/b for the parabolic temperature distribution is shown in Fig 8.

Thermal buckling of a simply-supported rectangular panel unrestrained in the plane is considered by Boley and Weiner (1960). The edges $x = 0,2a$ and $y = 0,2b$ are assumed to remain straight. A temperature distribution T T_0-T_1 $\cos \pi y/b$ is assumed. An analytical solution is

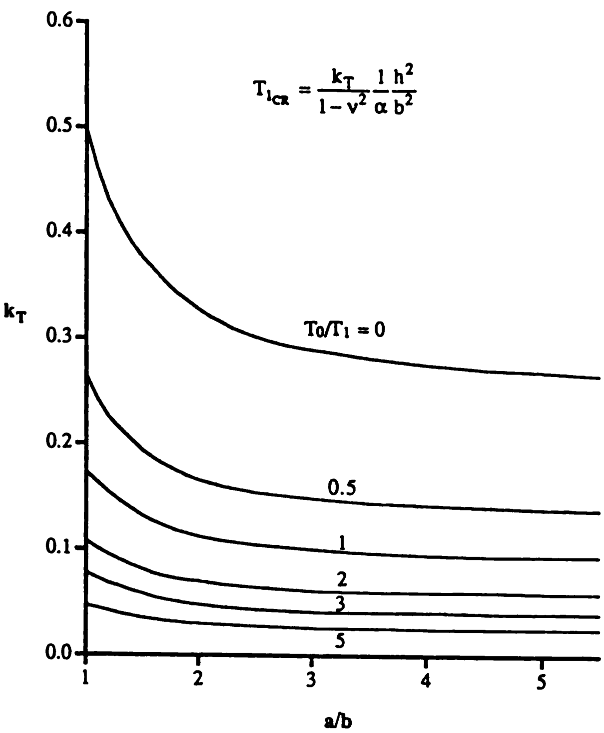

FIG 8 Buckling coefficient for simply-supported, fully-restrained plate with parabolic temperature distribution, Klosner and Forray (1952).

developed by first determining the stress function F that satisfies Eq 7. Then the transverse displacement $w(x,y)$ is expanded in an infinite series where a typical term has the form $A_{mn} \sin(m\pi x/2a) \sin(n\pi y/2b)$. Satisfaction of Eq 8 leads to an infinite determinant for computing the critical values of the buckling temperature T_1. (Note, as with the unrestrained plate of Gossard and Seide, that buckling does not depend on T_o.). The critical temperature has the form

$$\Delta T_{1_c} = \frac{k_1\pi^2}{24}\frac{1}{1-\nu^2}\frac{1}{\alpha}\frac{h^2}{b^2} \tag{13}$$

where k_1 is a function of m and the aspect ratio a/b; m is the number of half-waves in the x direction. A curve is given showing the variation of k_1 with aspect ratio. The minimum value of k_1 is 3.848. For an aspect ratio $a/b < 1.4$, the plate buckles in one half-wave, $m = 1$; for $1.4 < a/b < 2.5$, $m = 2$; for $2.5 < a/b < 3.5$, $m = 3$; etc. The Boley and Weiner text also includes the effect of an axial applied stress σ_X, and an interaction curve is given.

Thermal buckling of parallelogram (skewed) rectangular plates were investigated in the 1970s. For applications to aircraft wings Matsumoto (1973) analyzed parallelogram, shallow curved panels using Galerkin's method for clamped boundary conditions and an arbitrary temperature distribution. Using a measured temperature distribution, buckling temperatures were computed for parallelogram and rectangular panels. The critical buckling temperature for a parallelogram panel was higher than the corresponding rectangular panel. Shallow panel curvature increased buckling temperatures. Prabhu and Durvasula (1974a, b) analyzed skewed, flat plates using a Ritz method. Critical buckling temperatures are given as a function of the skew angle for restrained plates with simple and clamped transverse deflection boundary conditions.

More general analyses of thermal buckling of flat plates were presented in the 1980s. Thermal buckling of initially stressed thick plates was investigated by Chen et al. (1982). The paper shows that transverse shear effects can reduce the plate critical buckling temperature. Bednarczyk and Richter (1985) consider thermal buckling of unrestrained plates with self-equilibrated stresses. They study the influence of the spatial temperature distribution on critical buckling modes and seek the temperature distribution that yields the lowest critical buckling temperature. For square plates, the lowest eigenvalue occurs when the temperature distribution is piecewise constant. An example shows a central square patch of a plate having uniform temperature surrounded by a "picture frame" of zero temperature. The implication of the analyses is that minimum buckling temperatures occur under a condition of localized thermal st[illegible] Bargmann (1985) considers a rectangular flat [illegible] non-uniform temperature distribution and [illegible]d boundary conditions. In-plane forces [illegible] so that the plate edges remain straight during deformation. Stability conditions are derived for: (1) a uniaxial stress field, (2) biaxial combined compression and tension and (3) biaxial combined compression, tension and shear.

In a study of thermal buckling that occurs in the growth process for producing sheets of silicon, Ahmed and Dillon (1987) study thermal buckling of plates with reinforced edges. A prescribed temperature profile, $T(x)$, is assumed. The plane stress problem for the membrane stress is analyzed first, and then the industrial process is modeled as a cantilever plate. The role of the edge stiffeners is examined, and the authors conclude that edge stiffeners can either help or hinder thermal buckling as compared to a flat plate.

Studies of the effects of the environment on laminated composites in the 1970s led to the first thermal buckling analyses of composite plates. Whitney and Ashton (1971) used an energy formulation in conjunction with a Ritz method to determine critical buckling temperatures for restrained angle ply laminates. Flagg and Vinson (1978) used a similar approach to study the effects of moisture and temperature on critical buckling loads. It was shown that these hygrothermal effects reduce critical buckling loads.

Since the 1980s, much thermal buckling research has focused on buckling of composite laminated panels. The book by Whitney (1987) formulates the governing equations for expansional strain effects in laminated plates. Thermal buckling of rectangular plates with symmetric angle-ply laminates are analyzed using the Ritz method. Thermal buckling behavior has been studied also with approximate analytical methods by Tauchert (1987), Tauchert and Huang (1987), Chen and Chen (1987a), Chandrashekhara (1991a), Huang and Tauchert (1990), Sun and Hsu (1990) and Chang and Leu(1991) and computationally by the finite element method by Thangaratnam *et al* (1989), Chen and Chen (1989a,b), Chang and Shiao (1990) and Chang (1990). The effects of various laminated plate parameters have been investigated. A recent collection of papers on thermal effects on structures and materials edited by Birman and Hui (1990) includes additional references on thermally induced buckling of composites. Paley and Aboudi (1991) develop a method for determining critical buckling temperatures for metal matrix composite plates.

3.3 Postbuckling

The 1952 paper by Gossard, Seide and Roberts describes the first theoretical and experimental investigations of thermal postbuckling. When a plate's transverse displacements became large (*eg*, of the order of the plate thickness), stretching of the middle surface may occur. Because of this stretching, the membrane forces change as the plate deforms. The membrane stresses (or the stress function F) and the displacement $w(x, y)$ must be determined simultaneously. The postbuckling theoretical problem is described by von Kármán's equations,

$$h\nabla^4 F = Eh\left[\left(\frac{\partial^2 w}{\partial x \partial y}\right)^2 - \frac{\partial^2 w}{\partial x^2}\frac{\partial^2 w}{\partial y^2}\right] - \nabla^2 N_T$$

$$D\nabla^4 w = h\left[\frac{\partial^2 F}{\partial y^2}\frac{\partial^2 w}{\partial x^2} - 2\frac{\partial^2 F}{\partial x \partial y}\frac{\partial^2 w}{\partial x \partial y} + \frac{\partial^2 F}{\partial x^2}\frac{\partial^2 w}{\partial y^2}\right] - \frac{1}{1-\nu}\nabla^2 M_T \tag{14}$$

where the thermal force per unit length is

$$N_T = E\alpha\int_{-h/2}^{h/2} T(x,y,z)dz \tag{15}$$

and the thermal moment per unit length is

$$M_T = E\alpha\int_{-h/2}^{h/2} T(x,y,z)zdz \tag{16}$$

Equations (14) are solved subject to appropriate boundary conditions, see Boley and Weiner (1960). Gossard, Seide and Roberts (1952) obtain an approximate analytical solution based on the Galerkin method. Two cases are considered: (1) an initially perfectly flat plate, and (2) a plate with an initial deflection. Experimentally, the plate was tested with simple supports for bending displacements, and in-plane displacements were unrestrained. The plate was tested under steady conditions with the tentlike temperature distribution (Fig 7) used by Heldenfels and Roberts (1952). Temperature is assumed constant through the plate thickness, and the thermal moment is zero. The maximum temperature rise during the test was about 150°F, and the critical buckling temperature rise, Eq 10, was slightly less than 200°F. The experimental results showed that the effect of the initial plate deflection was appreciable. The maximum initial deflection was about 18% of the plate thickness. The test results show a strongly nonlinear variation of the plate deflection with the temperature rise even for deflections less than one-half the plate thickness. The largest plate deflection measured was less than a plate thickness. With initial deflections considered, good agreement was obtained between the experimental and theoretical results.

After the Gossard, Seide and Roberts paper, other authors in the 1950s and 1960s investigated thermal postbuckling of plates. Williams (1955,1958) performed a large deflection analysis to determine deflections and membrane stresses for an infinite strip (cylindrical bending) subjected to pressure and temperature variations. Forray and Newman (1962a,b) study the postbuckling behavior of flat simply supported rectangular plates with parabolic temperature variations in x and y. Wilcox and Clemmer (1964) analyzed the large deflections of a simply supported rectangular plate with elastic in-plane deflection restraints. Pressure and temperature changes were considered.

Subsequently, interest in thermal buckling of isotropic plates decreased with only a few papers over the next two decades. Prabhu and Durvasula (1976) investigated thermal post-buckling characteristics of clamped skew plates with restrained edges subjected to planar temperature distributions. Approximate solutions to the nonlinear partial differential equations are obtained by a perturbation method. The results showed that the plate nonlinearity tends to increase with skew angle for both uniform and nonuniform temperature distributions considered. HE Williams (1979) reconsidered the stability conditions for the cylindrical bending problem originally studied by ML Williams in the 1950s. Jones *et al* (1980) investigated thermal postbuckling of flat plates using Berger's approximation to plate bending theory. HE Williams (1982) studies buckling and postbuckling using the "Neale Plate" equations. The unique feature of this approach is the equations used are a generalization of von Kármán's equations in rate form. The approach is used to study thermal buckling of rectangular plates including plasticity.

The effect of temperature-dependent elastic modulus and coefficient of thermal expansion on the post-buckling behavior of heated square plates was investigated by Kamiya and Fukui (1982). Finite difference numerical solutions are obtained for constrained in-plane displacements and simply-supported and clamped edges. The temperature-dependent properties lowered critical buckling temperatures and reduced post-buckling stiffness for increasing temperature and deflection.

Paul (1982) developed a procedure for the prediction of the postbuckling behavior of clamped rectangular plates subjected to arbitrary planar temperature distributions. Design charts and tables are provided for several cases. The report concludes that thermally loaded plates possess considerable postbuckling load carrying capability which is not fully utilized in design practice.

Several recent papers study the thermal postbuckling for laminated composite plates. Huang and Tauchert (1988a, b) analytically study postbuckling behavior of flat angle-ply laminates for spatially symmetric parabolic variation of the plate temperature and uniform temperature. Ply angles are arranged antisymmetrically about the middle surface. The unsymmetric layup causes a coupling between the in-plane displacements u,v and the transverse displacement w. Thus as the temperature increases, out-of-plane displacements increase even for small deflections. Above the critical buckling temperature, transverse displacements increase rapidly as expected. Chen and Chen (1989b, 1991) study thermal postbuckling behavior of laminated composite plates by the finite element method. The influence of composite laminate characteristics on thermal postbuckling is studied first, and then the effects of temperature-dependent properties are considered. Temperature-dependent properties lower predictions of critical buckling temperatures. Librescu and Souza (1991) study the static postbuckling of simply supported, shear deformable composite flat panels exposed to a stationary temperature field and in-plane compressive edge loads.

An analytical approach using Galerkin's method is employed. Numerical results are presented for the postbuckling response of composite panels with an assumed sinusoidal temperature distribution. Meyers and Hyer (1991) analytically study the thermal buckling of flat, symmetrically laminated composite plates for a uniform temperature rise. For the symmetric layup, the plates demonstrate bifurcation buckling behavior similar to an isotropic plate. Effects of support conditions and material axis orientation are studied parametrically. Noor and Peters (1992a) study the postbuckling response of composite plates subjected to combined axial load and a uniform temperature distribution. The analysis is based on a first-order shear deformation, von Kármán nonlinear plate theory and used a mixed finite element formulation. Sensitivity derivatives are used to study the sensitivity of postbuckling to composite plate parameters. Noor and Peters (1992b) also study the thermal postbuckling of thin-walled composite stiffeners. Using the same approach employed in the previous paper, numerical studies are presented for anisotropic stiffeners with Zee and channel sections.

In one of the few recent experimental programs, a paper by Teare and Fields (1992) describes buckling analysis and test correlations of high temperature structural panels. A titanium, stiffened panel was simultaneously heated and subjected to axial compressive forces in a testing machine. Good correlation between test and analysis provided both a validation of the computational methods and verification of the structural concept. A postbuckling test indicated that the panel was capable of withstanding more than 200% of the initial buckling load without permanent deformation. The paper concludes that vehicle weight can be reduced by taking advantage of the postbuckled strength as exhibited in the test.

3.4 Assessment

Since the original investigations of Heldenfels and Roberts (1952) and Gossard, Seide, and Roberts (1952), numerous investigators have studied thermal buckling and thermal postbuckling of plates. Until the 1980s, most studies were performed for isotropic plates, but in the 1970s research was initiated for laminated composite plates. Figure 9 shows the relative number of papers on thermal buckling of metallic and composite plates over the last four decades. Almost all of the work has assumed: (1) perfectly flat initial configurations and (2) elastic behavior. There is a need for further study of buckling of plates with initial imperfections and inelastic behavior. Aerospace designers also need rapid postbuckling analysis methods for both mechanical and thermal loads. With the exception of the original (1952) papers and the recent paper by Teare and Fields, the investigations have been analytical or computational; there have been no further experimental studies. There is a need for further experimental studies of thermally induced buckling for both isotropic materials and laminated composites. Applications to aircraft structures strongly suggest that experimental programs be conducted for plates with spatial temperature variations.

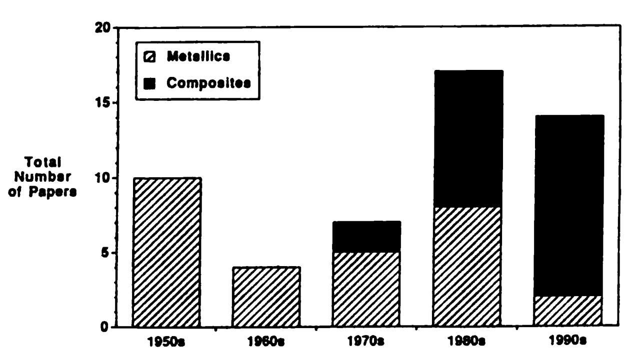

FIG 9 Relative number of papers on thermal buckling of metallic and composite plates.

4. THERMAL BUCKLING OF SHELLS

Buckling of shells has been the subject of extensive research in the aerospace industry because of the widespread use of shell structures in flight vehicles. Analytical, computational and experimental studies have investigated the behavior of shell structures subjected to mechanical loads. Much less research has occurred for buckling and postbuckling of shells in a thermal environment. And yet future designs of airframes for high speed flight and spacecraft structures will have to consider carefully the effect of the thermal environment on structural and material behavior.

There are several excellent textbooks on the theory and buckling of shells, but most classic books do not include temperature in the formulation of the equations nor address thermal buckling. Thus, with a few exceptions, solutions of shell thermal buckling problems appear in papers and reports rather than texts. Furthermore, in contrast to the study of shell buckling under mechanical loads, studies of thermal buckling are relatively more recent. For example, solutions for critical buckling loads of cylinders under axial loads were presented in the early 1900s, but studies of critical buckling temperatures for cylindrical shells were not undertaken until the 1950s. At that time, the design of lightweight structures for high speed flight of aircraft and missiles provided strong motivation for the first studies of thermal buckling. During the early days of supersonic flight, researchers learned that aerodynamic heating raised surface temperatures significantly and induced strong temperature gradients. Consideration of thermal effects on material and structural performance stimulated the first thermal buckling research for shells in the late 1950s and early 1960s. A paper on buckling at high temperatures by NJ Hoff (1957a) describes initial work on thermal buckling of thin circular cylindrical shells. Over thirty years later a survey article by Ziegler and Rammerstorfer (1989) summarizes thermoelastic stability research for elastic and viscoelastic structures including shallow and cylindrical shells. In the same volume, Lukasiewicz (1989) presents a comprehensive review of thermal stresses in shells and discusses thermal buckling. A book by Bushnell (1989) describes a computerized buckling analysis approach of shells for mechanical loads and presents thermal buckling examples. A comprehensive bibliography by Keene and Hetnarski (1990) lists 778 references to publications on thermal stresses in shells.

This section focuses on thermal buckling of shells with particular emphasis on aerospace applications. The review considers: (1) shallow shells, (2) cylindrical shells and (3) conical shells. Within each section papers are described in chronological order.

4.1 Shallow Shells and Curved Panels

The shallow shell idealization is used to consider the effects of curvature on the structural response of shell segments and panels. The idealization permits use of a simplified set of equations similar to the von Kármán equations for flat plates rather than the full shell equations. The classical shallow shell problem consists of a thin, doubly curved surface with curvatures k_x and k_y in the x and y directions, respectively. The temperature T may vary with the spatial coordinates x and y, through the thickness h of the shell, and with time. Typically quasistatic behavior with constant thermal properties is assumed, and published analyses have assumed steady temperature distributions. The non-zero stresses σ_x, σ_y, τ_{xy} are expressed in terms of an Airy stress function $F(x,y)$ by Eq 6 such that the in-plane equilibrium equations are satisfied. Satisfaction of membrane strain compatibility and the remaining transverse equilibrium equation produces for an isotropic material the nonlinear governing equations

$$h\nabla^4 F = Eh\left[\left(\frac{\partial^2 w}{\partial x \partial y}\right)^2 - \frac{\partial^2 w}{\partial x^2}\frac{\partial^2 w}{\partial y^2} - k_x\frac{\partial^2 w}{\partial y^2} - k_y\frac{\partial^2 w}{\partial x^2}\right] - \nabla^2 N_T \tag{17}$$

$$D\nabla^4 w = h\left[\frac{\partial^2 F}{\partial y^2}\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 F}{\partial x^2}\frac{\partial^2 w}{\partial y^2} - 2\frac{\partial^2 F}{\partial x \partial y}\frac{\partial^2 w}{\partial x \partial y} + k_x\frac{\partial^2 F}{\partial y^2} + k_y\frac{\partial^2 F}{\partial x^2}\right] - \frac{1}{1-\nu}\nabla^2 M_T \tag{18}$$

For a perfectly flat plate the curvatures k_x and k_y are zero, and Eqs 17-18 reduce to von Kármán's equations, Eq 14.

Among the earliest solutions of shallow shell equations of this type were studies of "snap-through" buckling of bimetallic spherical shells. Snap-through buckling is a dramatic form of elastic buckling of a shallow shell associated with large transverse deflections and a complete reversal of the curvature of the shell surface. Such shells have applications as temperature-sensitive components in automatic control instruments. Wittrick *et al* (1953) studied the stability of a closed-top bimetallic spherical shallow shell and analyzed the influence of the geometrical and physical parameters on such quantities as minimum arch height for buckling and the buckling temperature. Later, Tsu-tao *et al* (1966) developed a theory for an open bimetallic shallow shell. The critical buckling temperature is related to geometric and physical parameters including the extent of the shell opening. In a later paper Liu (1983) develops analytical solutions for thermal stability of a bimetallic shallow shell with a circular hole at the center and a bimetallic truncated shallow conical shell under a uniform temperature field.

Thermal buckling of isotropic shallow shells of rectangular planforms were studied in the 1960s by Mahayni (1966) and Haydl (1968). Mahayni considers a simply-supported panel with temperature that varies quadratically with x over the panel surface but is constant through the panel thickness. An approximate analytical solution of the nonlinear equations is obtained by Galerkin's method. Haydl considers similar problems by the same approach but with temperature varying sinusoidally with x and y and linearly through the shell thickness. The papers establish approximate analytical expressions for critical buckling temperatures and conditions for snap-through buckling. Haydl, for example, shows that shallow shells can have from one to three equilibrium positions. He demonstrates for an aluminum panel that relatively small temperature gradients (50° to 100°F) between the center and edge of a panel can result in snap-through.

Kamiya (1978) studied the nonlinear bending of shallow sandwich shells using Berger's plate approximation. Using Galerkin's method with sinusoidal spatial and linear thickness temperature variations, the nonlinear displacement response is derived and illustrated for two different panel aspect ratios.

In the last few years the design of lightweight structures from advanced composite materials has initiated thermal buckling studies of laminated curved panels and shells. In recent papers, Chen and Chen (1987b, 1990) have studied thermal buckling of laminated composite cylindrical panels. In the former, the Galerkin method is used to determine the critical temperatures of shallow laminated cylindrical panels subjected to a uniform temperature change. In the latter, thermal buckling behavior of cylindrical laminated plates subjected to a nonuniform temperature field is studied by the finite element method. In the finite element calculations, the temperature is assumed constant through the thickness, and a "tent-like" distribution with y is assumed. A matrix eigenvalue problem is solved to determine critical buckling temperatures. The effects of bending-extension coupling, lamination angle, modulus ratio, plate aspect ratio and radius of curvature on critical buckling temperature are studied.

Huang and Tauchert (1991) study thermally induced large deflections of laminated composite cylindrical and doubly-curved panels using the finite element method. First order shear deformation theory is used, and a uniform temperature rise is assumed. Post-critical equilibrium paths are traced and the strength limits of laminates are predicted using the Tsai-Wu criterion. For certain laminate configurations, the equilibrium path is characterized by the existence of limit-point and/or bifurcation instabilities. Some laminates are found to undergo two snap-throughs prior to failure. Kossira and Haupt (1991) study the buckling of laminated plates and cylindrical shells subjected to combined thermal and mechanical loads using the finite element method. The nonlinear pre- and post-buckling behavior of cylindrical composite shells is studied for three different temperature distributions. The effect of radius of curvature is studied, and computations show that the buckling temperature increases as the radius of curvature decreases. For large ply angles, snap-through behavior is predicted. Chandrashekhara (1991b) studies thermal buckling of anisotropic cylindrically curved panels using Sanders' shell theory extended to laminated shells. First order transverse shear deformation is included. Numerical results are presented using the finite element method, and the effect of various parameters on the critical buckling temperature of a curved graphite-epoxy panel with simple and clamped boundary conditions is demonstrated.

4.2 Cylindrical Shells

Early work on cylindrical shells was initiated to study potential thermal buckling of frame-reinforced fuselages for aircraft in high speed flight. Due to aerodynamic heating, the thin cylindrical shells experience higher temperatures than the heavier reinforcing frames. The hotter shell tends to expand radially more than the

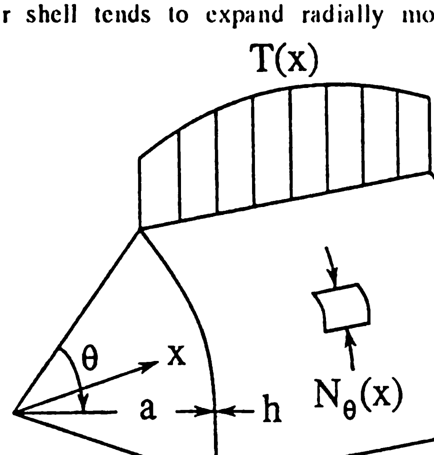

FIG 10 Circumferential membrane force induced by temperature distribution T(x) in cylindrical shell.

restraining frame inducing compressive circumferential membrane stresses $N_\theta(x)$, Fig 10. Initial research was aimed at determination of critical skin temperature levels for buckling due to the compressive membrane stresses. The first papers that studied thermal buckling of cylindrical shells solved the linear Donnell stability equations in uncoupled form:

$$\nabla^4 u = -\frac{\nu}{a}\frac{\partial^3 w}{\partial x^3} + \frac{1}{a^3}\frac{\partial^2 w}{\partial x \partial \theta^2} \tag{19a}$$

$$\nabla^4 v = -\frac{(2+\nu)}{a^2}\frac{\partial^4 w}{\partial x^2 \partial \theta^2} - \frac{1}{a^4}\frac{\partial^3 w}{\partial \theta^3} \tag{19b}$$

$$D\nabla^4 w + \frac{Eh}{a^2}\frac{\partial^4 w}{\partial x^4} - \nabla^4\left(N_x \frac{\partial^2 w}{\partial x^2} + \frac{2}{a}N_{x\theta}\frac{\partial^2 w}{\partial x \partial \theta} + \frac{1}{a^2}N_\theta \frac{\partial^2 w}{\partial \theta^2}\right) = 0 \tag{19c}$$

where a is the shell radius. The membrane forces, N_x, $N_{x\theta}$, and N_θ are obtained from a linear prebuckling analysis. Zuk (1957) described a solution procedure based on taking $N_x = N_{x\theta} = 0$ and assuming a form for N_θ proportional to $E\alpha\Delta T$. The temperature rise ΔT of the shell is assumed uniform. The N_θ membrane force was assumed to vary trigonometrically with x and to be compressive over the length of the shell. Assuming a shape for w that satisfied zero deflection and slope at each end of the shell, he used Galerkin's method to satisfy Eq 19 approximately. The result was an expression that permitted determination of the critical buckling temperature of a clamped cylindrical shell although no numerical results were presented. Later, Johns (1959, 1962) pointed out that circumferential stresses introduced at the junction of a frame and thin shell are localized and decrease rapidly away from the support. He proposed a function for the circumferential stress that decreased exponentially with x. Hoff (1957b) presented an analysis for the buckling of a simply-supported cylindrical shell where the circumferential stresses are determined from a prebuckling analysis. The displacement components u, v, w were assumed as infinite series of trigonometric functions that satisfied simply-supported boundary conditions. At the ends $x = 0, L$ of the shell, the radial and circumferential displacements as well as the axial membrane stress and the axial bending moment were assumed to vanish. The approach leads to an infinite determinant for the critical buckling stress. The prebuckling circumferential membrane force is obtained by first solving for the displacement w from the linear equilibrium equation,

$$\frac{d^4 w}{dx^4} + \frac{12(1-\upsilon^2)}{a^2h^2}w = \frac{12(1-\upsilon^2)}{ah^2}\alpha\Delta T \tag{20}$$

assuming a uniform rise ΔT in the shell temperature. For a steel cylinder with $a/h = 300$, a critical buckling temperature of over 2300°F was computed. The paper concluded that circumferential thermal stresses due to a uniform temperature rise are not likely to cause elastic buckling. In a closely related paper, Anderson (1962a) developed a similar theory to predict the buckling temperature of a uniformly heated, ring-stiffened shell and included axial compression. He used a shell theory by Batdorf and considers both simply supported and clamped shell end conditions. The paper concludes, consistent with Hoff, that buckling of a ring-stiffened cylinder due to uniform temperature alone will not occur for small values of the radius to thickness ratio, a/h. However, the paper notes that for large values of a/h (*eg*, a/h = 2000), such buckling can occur. Sunakawa (1962) also investigated the deformation and buckling of cylindrical shells due to aerodynamic heating. The book by Johns (1965) gives a simple formula for the critical temperature for buckling by circumferential membrane stresses,

$$T_{cr} = k\frac{h}{\alpha a} \tag{21}$$

where for a simple shell with simply supported ends k = 5.3, for a single or multibay shell with clamped ends k = 3.76, and for a multibay shell with simply supported ends k = 2.1.

This early work on cylinders with uniform temperatures was based on applications to fuselages with assumed axisymmetric heating. At about the same time, work began on cylinders nonuniformly heated around their circumference. Previous research on flat plates with spatial temperature gradients, *eg*, Gossard and Seide (1952), had established that thermal buckling could occur for relatively small spatial temperature gradients. Abir and Nardo (1959) investigated thermal buckling of circular cylindrical shells with circumferential temperature gradients. For a simply supported shell, they solved Eqs 19 following the approach employed previously by Hoff (1957b), but they investigated buckling due to the variation of the axial membrane force N_x around the shell circumference, Fig 11. The study concluded that the critical value of the axial thermal stress distribution occurs at a value equal to the critical stress in uniform axial compression. The critical stress for a cylinder in uniform axial compression is $\sigma_x = [3(1-\nu^2)]^{-1/2}\, Eh/a$, Timoshenko and Gere (1961). For a fully restrained cylinder the axial compression stress for a temperature increase ΔT is $\sigma_x = E\alpha\Delta T$. Thus the critical buckling temperature for uniform compression is

$$\Delta T_{cr} = \frac{1}{\left[3\left(1-\nu^2\right)\right]^{1/2}}\frac{h}{\alpha a} \tag{22}$$

Bijlaard and Gallagher (1960) also studied the elastic instability of a cylindrical shell under an arbitrary circumferential variation of axial stress. Their conclusions were consistent with Abir and Nardo.

In a closely related study, Hill (1959) analytically and experimentally studied buckling of circular cylindrical shells heated along an axial strip. In the analysis, the Donnell shell equations were used and were solved approximately using a Ritz method. A simplified axial thermal stress distribution was assumed where the stress is constant in x but varies around the circumference. In the experiments, aluminum and steel cylinders were locally heated by infrared lamps, and two types of cylinder end conditions were employed. Temperatures were measured with thermocouples, and displacements were measured with Linear Variable Differential Transformers (LVDTs). Cylinder buckling was demonstrated where the buckling deformations depended strongly on the experimental end conditions. For aluminum cylinders with a/h = 430, critical buckling temperatures were relatively low ranging from ΔT = 65°F to 100°F depending on end conditions. Experimental results for the critical buckling temperature were in reasonable agreement with the theoretical calculations. The study showed the difficulty of performing analytical predictions for the thermal buckling stresses due to localized temperature distributions and demonstrated the practical problems of creating experimental end conditions consistent with a mathematical model.

Anderson and Card (1962) described a study where several stainless steel ring-stiffened cylinders were subjected to a pure bending moment and heated rapidly until buckling occurred. For most of the cylinders the heating was non-uniform around the circumference. Temperature and deflections were measured at several locations, and in some tests strains were measured. Strains were successfully measured below 175°F, but data was unreliable for higher temperatures. An elementary thermal stress theory was found to be inadequate for the prediction of the thermal stresses. In a related paper, Anderson (1962b) reviews theoretical and experimental investigations on buckling of cylinders due to both circumferential and axial thermal stresses. The paper notes that the severity of the circumferential thermal stress is strongly dependent on the boundary conditions and suggested the need for additional experimental results. For cylinders that are heated non-

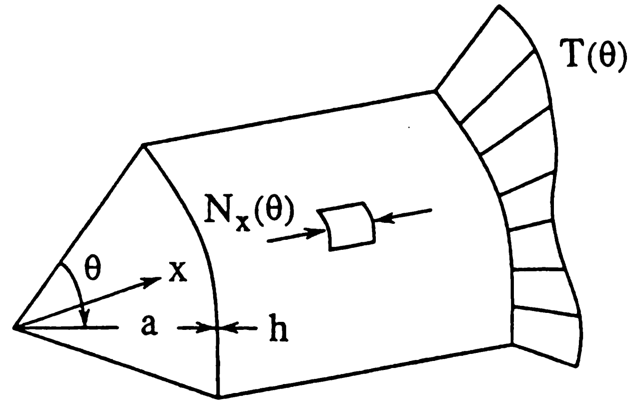

FIG 11 Longitudinal membrane force N_x induced by temperature distribution T(θ) in cylindrical shell.

uniformly, the paper discusses the difficulty of predicting axial thermal stresses and identified the need for research in thermal buckling of longitudinally stiffened cylindrical shells for launch vehicles.

In the mid-1960s, the Stanford University group of NJ Hoff continued to investigate thermal buckling of cylinders. Three papers describe further research on buckling of thin circular cylinders heated along an axial strip. Hoff, Chao and Madsen (1964) analytically study the problem assuming uniform compressive axial stress to occur in a narrow strip while the rest of the shell is stress free. The shell is assumed very long, and Donnell's equations are used. The results of the analysis support the earlier conclusion of Abir and Nardo (1959) that the critical stress of the heated strip is the same as the critical stress of a complete cylindrical shell subjected to uniform compression unless the heated strip is very small. With very narrow heated strips, the critical stress rises rapidly as the strip width decreases. Ross, Mayers and Jaworski (1965) continued and extended the experimental studies initiated by Hill. A series of stainless steel and cold-rolled steel cylinders (a/h = 334 and 291, respectively) were heated along an axial strip by infrared heat lamps. Ends supports were designed to simulate fully-fixed conditions. Instrumentation included thermocouples and a microphone to provide an audio signal at the instant of buckling. The heated width was varied from 1.5% to 18% of the total shell circumference. Tests were conducted by subjecting the cylinders instantaneously to maximum heating from the infrared lamps; axial and circumferential temperature distributions were then recorded until the shell buckled. For the stainless-steel cylinders, buckling temperatures were around 300°F; for the thicker, cold-rolled steel cylinders buckling occurred around 500°F. There was significant scatter in the data. For tests conducted on cylinders having narrow heated strip widths, buckling took place as a sudden localized "snap-through" accompanied by a distinctly audible sound. At larger values of the heated strip width, localized buckling patterns appeared simultaneously within the heated strip at several locations. For tests conducted on the thicker cold-rolled sheet steel cylinders with larger values of the strip width, a different failure mode occurred with a barrel-shaped deformation leading to yielding failure at the clamped support. Computations were performed with the Donnell theory using measured circumferential temperature distributions. Agreement of analysis with experiment was fair, but it was judged good enough for the authors to confirm previous conclusions of several investigators that the buckling temperature corresponding to uniform axial compression provides a lower limit of stability for thin cylindrical shells subjected to highly nonuniform circumferential heating. Hoff and Ross (1967) performed further analysis of the problem using the experimental temperature distributions and obtained reasonable agreement with the experimental data. The consistent trend demonstrated by these analyses was that experimental critical buckling temperatures were consistently *higher* than values predicted by analyses. This trend was in direct contradiction to the well-established trend that for mechanical loads experimental critical buckling values are consistently *lower* than predicted values.

Ross, Hoff, and Horton (1966) conducted additional experiments to address the thermal buckling anomaly. Six stainless-steel cylinders (a/h = 344) and five cold-rolled steel cylinders (a/h = 291) were heated axisymmetrically by an array of twelve infrared heat lamps. The cylinders' ends were longitudinally restrained and clamped. The test procedure was essentially the same as used by Ross *et al* (1965). Upon heating, a test cylinder experienced thermal expansion in the radial direction, and the thin cylindrical shell became barrel-shaped. Ultimately, the shell buckled near the clamped end supports. Comparison of experimental results with the predictions of available shell-buckling theories showed poor agreement. The authors concluded that because the cylinder "barrels out" during heating, the axial compressive stress is reduced resulting in higher critical temperatures than is predicted by linear buckling theory.

Hoff (1965) and Ross (1966) also investigated the use of simple models to explain thermal buckling of shells. Hoff uses a two bar mechanism with a nonlinear spring, and Ross uses a beam-column with a nonlinear spring.

Gellatly, Bijlaard, and Gallagher (1965) investigated thermal buckling of sandwich cylindrical shells for simply and clamped supports. Using the approach of Hoff (1957b), critical buckling temperatures were determined for circumferential stresses varying with x. Numerical results are presented for isotropic and sandwich cylinders.

By the late 1960s and early 1970s, digital computers had become widely used in engineering research, and numerical models were being developed to solve complex problems. Chang and Card (1970,1971) at NASA Langley developed programs for analyzing thermal buckling of orthotropic, multilayered, cylindrical shells stiffened by uniform, equally spaced rings and stringers. Thermal effects are accounted for by specifying axisymmetric temperature distributions in the shell and stiffeners. The theory was developed from strain energy expressions corresponding to nonlinear Donnell-von Kármán displacements, and equilibrium equations were derived by the principle of minimum potential energy. These equations were separated into equations governing axisymmetric prebuckling behavior and equations governing behavior at buckling. The ends of the stiffened cylinder were assumed to be free to expand longitudinally. In the analyses thermal buckling occurs as a consequence of circumferential compressive stresses (Fig 10) introduced by radial restraint at the boundaries (w = 0) and/or from restraints resulting from differences in expansion between the stiffeners and shell. The prebuckling and buckling solutions were based on finite difference discritizations of the shell equations. Thermal buckling behavior of unstiffened, ring-stiffened, stringer-stiffened and ring/stringer-stiffened shells were investigated. For unstiffened cylinders the numerical solutions were validated by comparisons with the analytical solutions of Hoff (1957b) and Sunakawa (1962). Recall that the Hoff analysis (1957b) of a simply supported cylinder under hoop stresses varying in the x direction predicted buckling at a very high temperature. Chang and Card's computer analysis of the same cylinder was unable to determine this critical buckling temperature; no buckling temperature could be found within a practical temperature range. The difference between the two analyses was determined to lie in the assumptions made in the linearized Donnell prebuckling equations employed by Hoff where rotations and derivatives of rotations are neglected. These prebuckling rotations were included in the Chang and Card formulation, but when these terms were suppressed the Chang and Card predictions were in agreement with Hoff. The conclusion was that the prebuckling rotations are required, and for simple supports the buckling temperature is beyond the elastic range. Chang and Card's predictions were in good agreement with Sunakawa's analysis for a clamped cylinder since Sunakawa's shell theory included prebuckling rotations. For ring-stiffened cylinders comparisons were made successfully with Anderson's analysis (1962b). Thermal buckling studies of an aluminum large diameter, longitudinally stiffened cylinder and a titanium ring- and stringer-stiffened cylinder were also conducted.

At about the same time, Bushnell of the Lockheed Palo Alto Research Laboratory was developing a computer program called BOSOR for the general analysis of shells of revolution. Applications of BOSOR to thermal buckling are described in a book (1989) and several papers (1971a, b, 1973). The BOSOR program is based on an energy formulation with the method of finite differences. Axisymmetric ring-stiffened shells are assumed. The program has been used to solve several of the thermal buckling problems discussed previously and other, more complex, thermal buckling problems. Bushnell (1971a) solves the Hoff (1957b) problem of the simply supported cylinder subjected to a uniform temperature rise. Buckling of a ring-stiffened aluminum cylinder subjected to axial compression, external pressure and various temperature distributions is also studied in detail. The effect of ring-out-of-plane bending stiffness on thermal buckling of ring-stiffened cylinders is discussed by Bushnell (1971b) and demonstrated to be important.

Bushnell and Smith (1971) describe calculations of thermal stresses and buckling of nonuniformly heated cylinders and cones. The BOSOR program was used to analyze several cylinder tests including the studies of Hill (1959), Anderson and Card (1962), Ross, Mayers and Jaworski (1965), as well as Ross, Hoff, and Horton (1966). These analyses are valuable because they represent the first systematic comparison of computational results with experimental data. In addition, the computational approach permitted issues to be addressed that previously had been intractable because of limitations of analytical methods. Particular attention was given to the effect of boundary conditions on predicted stress and critical temperatures. For example, the anomaly raised in the experimental study of Ross *et al* (1966) is attributed to undesired flexibility in the experimental boundary condition. The paper also concluded that for shells which are long compared to a "boundary layer $(ah)^{1/2}$", critical temperatures of uniformly heated monocoque cylinders and cones are as sensitive to initial imperfections as are critical axial loads.

In a later paper, Bushnell (1973) uses BOSOR to study thermal buckling of cylinders with axisymmetric thermal discontinuities. The first problem considered was buckling of a cylinder heated halfway along its length. The problem was considered because of questions raised by the Hoff (1957b) problem of thermal buckling due to circumferential stresses. Bushnell reaches the same conclusions that Chang and Card; prebuckling rotations should be included in the analysis, and elastic buckling will not occur for the simply supported cylinder with uniform temperature. The second problem considered was a clamped cylindrical shell (a/h = 2540) analyzed and tested by Johns (1962). A BOSOR analysis (with prebuckling rotations) of the Johns' cylinder predicted a critical temperature of 150°C whereas the experimental value was 324°C. Subsequent investigation showed that the large discrepancy between the computation and test could be explained by the presence of temperature gradients near the boundaries of the cylinder. The paper concludes that critical buckling temperature calculations are sensitive to the shape of the temperature distribution. To obtain good correlation between predictions and tests, temperature distributions have to be measured carefully and the spatial variations included in the analysis.

Two papers in the mid-1970s analyzed thermal buckling of orthotropic cylindrical shells. Gupta and Wang (1973) use a Rayleigh-Ritz approach to analyze a simply-supported orthotropic shell with uniform temperature. Prebuckling rotations are not considered. Parametric studies illustrate the effects of the axial and circumferential coefficients of thermal expansion. Radhamohan and Venkataramana (1975) analyze an orthotropic clamped cylindrical shell using an approach based on Sanders' nonlinear shell theory. Effects of prebuckling rotations, different forms of clamped boundary conditions and other parameters are studied.

A brief paper by Belov (1978) describes an experimental study of stability of cylindrical shells partially filled with liquid. The study was motivated by aerodynamic heating of fuel tanks. In the experimental program, cylindrical shells were subjected to heating and were loaded by axial compression and internal pressure.

Although good agreement between calculations and experiment data is stated, details of the analysis and tests are not given.

In the late 1970s, two test programs on buckling of cylinders with combined mechanical and thermal loads were conducted at the Technion in Israel. Frum and Baruch (1976) describe buckling of cylindrical shells heated along two opposite generators. A series of forty-six tests of aluminum cylinders with a/h = 301 were conducted. End supports were designed to be fully restrained. Axial loads were applied by a hydraulic jack. Two infrared line heaters were installed above and below the shell. The temperature distribution was measured with thermocouples, and displacements were measured with LVDTs. The instant of buckling was detected with a microphone. The effects of the u displacement boundary conditions were studied, and the authors conclude that previous investigators had not treated the condition with enough care. They conclude that the u displacement has a dominant influence on the buckling results. Comparisons of experimental data with computations are only fair. The experimental data was used to construct an axial load-temperature interaction curve. Ari-Gur, Baruch and Singer (1979) describe buckling of cylindrical shells under combined axial preload, nonuniform heating and torque. Similar test cylinders and the test rig employed in the previous study were used after modifications to allow torsion. A series of 35 tests were conducted. A temperature-torque interaction curve was developed from the experimental data.

Studies of thermal buckling of laminated composite circular cylinders began in the 1980s and continue to the present time. So far, the studies have been analytical; experimental studies have not yet been conducted. Wilcox and Ma (1989) use an energy approach to derive a set of equilibrium equations based on classical thin shell theory with Donnell's assumptions. Galerkin's method with an assumed trigonometric variation for w for a simply-supported cylinder leads to a matrix eigenvalue problem. Numerical results are presented for critical buckling temperatures for various composite parameters such as lamination angle. Thangaratnam *et al* (1990) uses the finite element method to conduct parameter studies of a simply supported cylinder with uniform temperature.

Birman (1991) studied the thermally induced dynamic response of reinforced composite cylinders. The study is based upon Donnell's theory of geometrically nonlinear shells and includes axial and ring stiffeners. Solutions are developed for a simply supported cylinder subjected to a uniform rise in temperature. The paper concludes that if a shell is subject to an instantaneous rise in temperature it exhibits stable steady-state oscillations but if the temperature exceeds a critical buckling level, the character of the response [illegible]es and the deflections can increase dramatically.

4.3 Conical Shells

Work on thermal buckling of conical shells began in the mid-1960s and was motivated by aerodynamic heating effects. The analyses typically were based on Donnell-type equations written in terms of a stress function F and the w displacement. A truncated cone with vertex angle 2α is considered. The non-zero stresses are defined in terms of the Airy stress function $F(s, \phi)$ where a point on the middle surface of the shell is defined by the longitudinal coordinate σ and an angular coordinate ϕ defined by

$$\phi = \theta \sin \alpha$$

where θ is the circumferential angular coordinate. The non-zero stresses are

$$\sigma_s = \frac{1}{s}\frac{\partial F}{\partial s} + \frac{1}{s^2}\frac{\partial^2 F}{\partial \phi^2} \qquad \sigma_\theta = \frac{\partial^2 F}{\partial s^2}$$

$$\sigma_{s\theta} = -\frac{1}{\partial s}\left(\frac{1}{s}\frac{\partial F}{\partial \phi}\right) \tag{23}$$

The nonlinear governing equations are

$$\nabla^4 F = E\left[-\frac{1}{s}\left(\cot\alpha + \frac{\partial w}{\partial s} + \frac{1}{s}\frac{\partial^2 w}{\partial \phi^2}\right)\frac{\partial^2 w}{\partial s^2} + \frac{1}{s^2}\left(\frac{\partial^2 w}{\partial s \partial \phi} - \frac{1}{s}\frac{\partial w}{\partial \phi}\right)^2\right] - E\alpha\nabla^2 T \tag{24}$$

$$D\nabla^4 w = h\left[\left(\frac{1}{s}\frac{\partial F}{\partial s} + \frac{1}{s^2}\frac{\partial^2 F}{\partial \phi^2}\right)\frac{\partial^2 w}{\partial s^2} + \frac{1}{s}\left(\cot\alpha + \frac{\partial w}{\partial s} + \frac{1}{s}\frac{\partial^2 w}{\partial \phi^2}\right)\frac{\partial^2 F}{\partial s^2} - 2\frac{\partial}{\partial s}\left(\frac{1}{s}\frac{\partial F}{\partial \phi}\right)\frac{\partial}{\partial s}\left(\frac{1}{s}\frac{\partial w}{\partial \phi}\right)\right] \tag{25}$$

where

$$\nabla^2 = \frac{\partial^2}{\partial s^2} + \frac{1}{s}\frac{\partial}{\partial s} + \frac{1}{s^2}\frac{\partial^2}{\partial \phi^2} \tag{26}$$

In the above, the temperature is assumed uniform through the thickness of the shell, and the thermal moment is zero. For $\alpha = 0$, Eqs 24 and 25 reduce to the von Kármán equations for a flat circular plate.

Some of the earliest analytical and experimental work on conical shells was done by Bendavid and Singer (1967) who studied buckling of truncated conical shells heated along a generator. The work is closely related to Hill's (1959) study of buckling of thin cylindrical shells heated along a strip. Critical buckling temperatures are investigated for axial compressive stresses induced by circumferential temperature distributions. A Rayleigh-Ritz analysis is employed, and numerical results are compared with an experimental study. In the experimental study a steel cone with vertex angle α = 12.4°, thickness h = 0.0155 in and a small opening radius of 6 in was heated along a generator with a quartz lamp.

The experimental temperature distribution varied both in the circumferential and axial directions. Boundary conditions are assumed simply supported, and the ends are assumed restrained in the direction of the generator. The experimental buckling temperature was 103°C and the calculated value was 137°C.

Lu and Chang (1967) calculated thermal stresses and bifurcation buckling temperatures of axisymmetrical and nonsymmetrically heated simply-supported cones. In the axisymmetric case, the temperature varies along the generator which is restrained at the ends. In the other case, the temperature varies circumferentially as well, but the shell is assumed free of axial forces at the ends. A formulation similar to Eqs 24-25 is used, but the nonlinear von Kármán strains are neglected. A Galerkin approach with assumed deflection shapes is used to obtain critical temperatures. The variation of critical temperatures with various shell parameters such as the average radius-thickness ratio, the average radius-height ratio and the cone's vertex angle are evaluated. The radius-thickness ratio has the most significant effect on the critical temperature. In further work, Chang and Lu (1968) included the nonlinear strain terms neglected in their previous paper. The analysis showed that the nonlinear theory predicted lower critical temperatures than the linear theory. A brief discussion is given of an experimental study of a brass cone heated uniformly by heat lamps. The experimental cone had vertex angle $\alpha = 10°$, an average radius to thickness ratio of 500 and a height to average radius ratio of 2. The ends of the cone were assumed simply-supported but restrained against axial expansion. The average experimental buckling temperature for three tests was 128°F, and the predicted value was 98°F.

Bushnell and Smith (1971) used the computer program BOSOR to analyze thermal buckling of conical shell experiments performed by Smith (1964) at Stanford University. Truncated steel conical shells with clamped ends restrained against axial displacement were heated along axial strips of various widths by quartz lamps. Test cones have a wall thickness of 0.0155 in, a small opening radius of 6 in, a large opening radius of 12 in and a slant length of 28 in. Circumferential and axial temperature variations were induced and measured with thermocouples. The instant of buckling was determined by a microphone; buckling occurred with a loud noise. Critical buckling temperatures for eight test specimens varied from about 55°C to over 100°C; the scatter in the data was attributed to initial imperfections in the test specimens. In the analyses, a test was modeled in three ways: as a fully clamped shell, as a simply supported shell, and as a portion of a larger structure which includes the test rig. Using measured critical temperature distributions, axial membrane stress distributions were computed for the three models. Treatment of the test rig as a structure of finite flexibility led to results that were with 5% of those obtained with the assumption that the test rig is rigid. In the stability analysis, the meridional prebuckling membrane stress distribution was assumed to be axisymmetric. Depending on the experimental temperature distribution used, the discrepancy between test and theory for critical temperatures was from 11% to 52%.

Tani (1978) studied the effect of axisymmetric initial deflections on the thermal buckling of shallow, truncated conical shells under uniform heating. The shell is analyzed for two cases where the supports are assumed clamped but may be either constrained or free in the axial direction. A uniform temperature distribution is assumed. Nonlinear buckling equations based on Eqs 17-18 are modified to include initial shell deformations. A central finite difference scheme is used to discritize the equations in the s direction with a cos nq expansion in the circumferential coordinate. Numerical results show that the buckling temperature and number n of circumferential buckling waves of shallow cones with axial constraint vary significantly with the amplitude of axisymmetric initial deflections. Without axial restraint, the initial imperfections have only small effects on the buckling mode. Initial deflection amplitudes equal to plus or minus the shell thickness were studied. In shallow shells, local buckling occurred near the cone edges due to hoop compression. In a further study Tani (1984) analyzed instability of truncated conical shells under combined uniform pressure and uniform temperature. Following the approach of the previous paper, the Donnell-type shell equations with nonlinear prebuckling deflections are solved using a finite difference method. Numerical results show that for shallow conical shells, the critical combination of buckling loads changes with the loading order; for deep conical shells, the critical combination of buckling loads does not change with loading order. Generally, the critical buckling temperature increases with internal pressure.

4.4 Assessment

In the 1950s and 1960s, there was significant research on thermal buckling of metallic shells as aerodynamic heating became important in the design of supersonic aircraft and missiles. Since then, research in thermal buckling of metallic shells has diminished. Beginning in the 1970s, there has been significant growth in the research efforts devoted to thermal buckling of composites. Figure 12 shows a bar graph illustrating the relative research efforts devoted to thermal buckling of metallics and composites as measured by published papers. In the 1990s thermal buckling research so far has been devoted exclusively to composites.

Table II

Experimental Studies of Thermal Buckling of Shells

Cylindrical Experiments	Year	Materials	Loading
1. Hill	1959	Aluminum and steel	Heating Along an Axial Strip
2. Johns	1962	Steel	Axisymmetric Heating
3. Anderson and Card	1962	Stainless steel	Bending Moment and Non-uniform Heating
4. Ross, Mayers and Jaworski	1965	Stainless and cold-rolled steel	Heating Along Axial Strip
5. Ross, Hoff and Horton	1966	Stainless and cold-rolled steel	Heating Along Axial Strip

Cone Experiments			
8. Smith	1964	Steel	Heating Along Axial Strip
9. Bendavid and Singer	1967	Steel	Heating Along Axial Strip

Since the original investigations of Hoff (1957), numerous investigators have studied thermal buckling of shells. Many of the studies have been analytical particularly through the 1950s-1960s, but since 1970 there has been increasing reliance on computational methods. Many of the computer programs such as BOSOR have used finite difference methods, but analyses of composite shells are using the finite element method. There was also an effort made through the 1950s-1970s to investigate thermal buckling of shells experimentally. Table II summarizes experimental studies for cylinders and cones. The vast majority of the experimental studies considered monocoque shells. With the exception of the study by Anderson and Card (1962), there have been no further investigations of stiffened shells. Experimental measurements were typically limited to a modest number of transducers. No data are available for initial imperfections, details of temperature distributions are lacking, and little documentation of post-buckling damage is available. Virtually no strain data was taken in the experiments because of strain gage limitations at elevated temperatures. Most experiments were conducted on steel or stainless steel. There is limited data available for aluminum, and no experiments have studied the buckling of titanium shells. Experimental studies of composite shells have not yet been published.

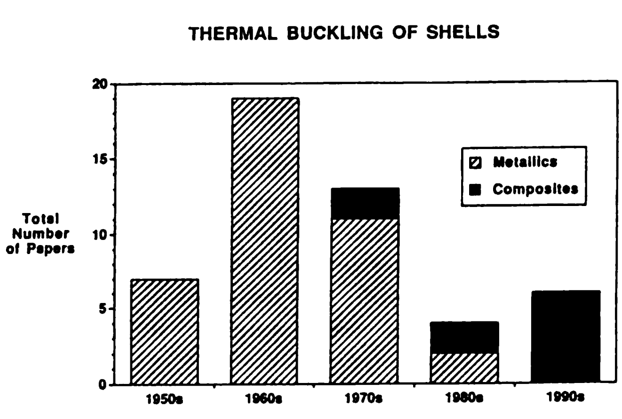

FIG 12 Relative number of papers on thermal buckling of metallic and composite shells.

Details of shell temperature distributions, particularly in stiffened shells, have an important role in the buckling response. The assumption of uniform temperature between stiffeners is usually not a good approximation. Since material properties such as thermal conductivity have significant effects upon the shape of temperature distributions, thermal buckling tests should be conducted using the materials that will be used in actual structures.

With one notable exception, there have been no validation studies of computer analyses of thermal buckling of shells. The exception is the very thorough analyses of several experiments by Bushnell using the computer code BOSOR. Generally, agreement between analytical solutions, computer solutions and experimental data has been only fair to good. A typical reason cited for discrepancies has been uncertainties in experimental boundary conditions. There have been relatively few tests with combined mechanical and thermal loads. For example, no tests of heated cylinders with internal pressures have been reported. There is a need for further experimental studies of thermally induced buckling of shells for both isotropic materials and laminated composites. Applications to aerospace structures strongly suggest the need for experimental programs for unstiffened and stiffened shells with thermal loads as well as combinations of thermal and mechanical loads.

5.0 CONCLUDING REMARKS

Thermal buckling research for plates and shells has been described. The role of material thermal parameters on thickness and spatial temperature gradients was demonstrated first. For metallic and metal matrix composites subjected to surface heating, thickness temperature gradients are small and may be neglected in applications. Indeed, this assumption has been made in most analytical and computational research studies, and it has been validated experimentally. Of the materials considered, only graphite-epoxy which has very low thermal conductivity exhibited an appreciable thickness temperature gradient. However, most materials, particularly in aerospace applications, will experience spatial (in-plane) temperature gradients. Due to localized heating, metals with relatively low thermal conductivity, *eg*, stainless steels, will exhibit high local temperature gradients and are likely to experience inelastic buckling. Metal panels with high thermal conductivity, *eg*, aluminum, tend to have much smaller temperature gradients as they conduct thermal energy to supporting structural members.

The review of research on thermal buckling of plates showed research in the 1950s-1960s was limited to metals. Composite plates were considered first in the 1970s, and since then the majority of research has been for composite plates. The majority of research in the last two decades has been analytical or computational with very few experimental studies. There is a need for further experimental studies of thermally induced buckling for both isotropic materials and laminated composites. Applications to aerospace structures strongly suggest that experimental programs be conducted for plates with spatial temperature variations.

The review of thermal buckling research for shells showed trends similar to thermal plate buckling. Research in the 1950s and 1960s considered only metallic shells. Research on composites began in the 1970s and has become the predominant effort since then. However, the current level of research on thermal buckling of composites is still relatively small compared to the efforts devoted to metallic shells in the 1960s. Many of the early shell thermal buckling studies were analytical, but since the 1970s there has been increasing reliance on computational methods. There was a significant early effort to study thermal shell buckling experimentally although there are deficiencies in the experiments, *eg*, the lack of strain data. Another deficiency has been uncertainties in experimental boundary conditions. So far, there have been no published experimental studies of thermal buckling of composite shells. There is a clear need for such studies for high temperature metallics such as titanium as well as for composite shells. There is also a need for experimental studies of heated cylinders (with and without stiffeners) subjected to mechanical loads including internal pressure. As with plates, the experimental programs should be conducted with spatial temperature distributions.

For both thermal buckling of plates and shells, renewed emphasis should be placed on validation of analytical/computational studies with experimental data. Computational analyses of several thermal-buckling experiments by Bushnell are described in the review. The lessons learned from these analyses include the uncertainties in boundary conditions previously mentioned as well as limitations and/or gaps in experimental data. On the other hand, such comparisons in the past have also identified deficiencies in computational models.

An interesting contrast between buckling due to mechanical and thermal loads is the respective roles of elastic material properties. Critical buckling forces for beams, plates and shells made from isotropic materials are directly proportional to the modulus of elasticity. Critical buckling temperatures for isotropic materials are typically independent of the modulus of elasticity and are inversely proportional to the coefficient of thermal expansion. Thus for optimum performance under combined mechanical and thermal loads, desirable material characteristics are high elastic modulus and low coefficient of thermal expansion. Of materials available, only advanced composites provide the potential for achieving such beneficial characteristics.

ACKNOWLEDGEMENTS

The research efforts of the author are supported in part by the Aerothermal loads Branch and the Aircraft Structures Branch at NASA Langley and the Light Thermal Structures Center at the University of Virginia. The author is most appreciative of the encouragement of his NASA technical monitors Drs Allan R Wieting and James H Starnes, Jr. The author is also grateful for very helpful discussions with Dr Michael P Nemeth of the Aircraft Structures Branch. Max L Blosser of the Aircraft Structures Branch provided important assistance in identifying and obtaining references and valuable discussion of past experimental studies.

Earl A Thornton is Professor of Aerospace Engineering and Director of the Center for Light Thermal Structures at the University of Virginia. He received his PhD in 1968 from Virginia Polytechnic Institute and State University. For over 20 years, he has conducted computational research for aerospace structures at elevated temperatures. He is co-author of the textbook The Finite Element Method for Engineers, *an Associate Fellow in the AIAA, and an Associate Editor of the* Journal of Spacecraft and Rockets.

BOOK REVIEWS

Items with a reviewer byline (coded R) are by AMR's corps of dedicated outside volunteer reviewers. AMR will attempt to get critical reviews of all relevant textbooks, professional books, reference works, and handbooks. Items without a reviewer byline (coded N) are prepared by AMR in-house staff and are largely based on material such as a book's table of contents and editor's preface or foreword. In the interest of timeliness most conference proceedings and multi-author contributed volumes will receive descriptive notes in this fashion. Books deemed to be somewhat peripheral to AMR's basic scope may simply be listed by title (no code; not included in annual index). Also listed by title when first received are books under review.

I. FOUNDATIONS & BASIC METHODS

10R1. Mechanics of Continuous Media. Mechanika osrodkow ciaglych. (Polish). - Czeslaw Rymarz *(Dept of Theory of Continuous Media, Polish Academy of Sci and WAT Military Academy of Tech, Warsaw, Poland)*. 1993. 514 pp. ISBN 83-01-11061-9.

Reviewed by R Wojnar (IPPT, Polish Acad of Sci, Swietokrzyska 21, 00-049 Warszawa, Poland).

Let me begin with some general remarks which arose in my mind after reading this excellent book.

It is well known that in describing a physical phenomenon one can use a number of mathematical models and each of the models only partially explains the phenomenon; eg, in quantum mechanics the nature of the light can be described either by an undulatory or a corpuscular model. Also, in classical continuum mechanics a wave equation describing sound propagation is patterned after the Newton equation of motion of a single particle, (see ch 3 of the reviewed book). These two examples indicate a degree to which one can describe a real phenomenon.

A description of matter was proposed a long time ago by the ancient philosophers Democritus (circa 460-370 BC) and Lucretius (circa 98-55)[1] from one point of view, and by Aristotle (384-322) from another standpoint. The first two thinkers believed that matter is composed of atoms and voids while the third one argued that nature abhors a vacuum. These philosophers stirred up a controversy in the subject that lasted until the beginning of this century. Nowadays we believe that matter is made of particles and fields, and the particles are regarded as some singularities associated with the fields.

The mechanics of continuous media that came into being in eighteenth century [2,3,4] is also based on the concept of a particle. Using contemporary language, this theory replaces a structure of particles (a granular structure) by a homogenized continuous constitution. One performs a smearing-out of material properties of microbodies to obtain the continuous distributions of mass, momentum, angular momentum, and energy of the continuous medium (cf Introduction of the reviewed book).

The book is based on lecture notes for classes taught at WAT (Technical Physics Dept) in Warsaw by Professor Rymarz, well known for his many contributions in the field of mechanics of continuous media. The book goes well beyond what can usually be covered in class and provides an in-depth introduction to several research topics.

There are 12 chapters, three appendices, references, and an index. Every chapter ends with problems and control exercises. The appendices cover tensor calculus, foundations of group theory, differential manifolds, and elements of measure theory.

Chapter 1 deals with dynamic processes in the material bodies. The mechanics of continuous media is treated as a theory describing a phenomenological model of reality. The concept of a material point (which should not be confused with that of atoms and molecules) is introduced, and the Euler and Lagrange descriptions of motion in terms of homeomorphisms are presented.

In chapter 2 a description of finite and infinitesimal deformations is given; also various types of derivatives of the displacement and velocity fields are defined; and a description of deformation in various reference frames is included. Moreover, the fundamental properties of a velocity field listed in the Helmholtz - Zorawski and Kelvin theorems are formulated. Schematic figures showing motion of a continuous medium in various descriptions are also included.

Chapter 3 introduces the laws of motion of a continuous medium, such as the laws of evolution and conservation laws; a variational formulation of these laws and principles is also given. Chapter 4 deals with the principles of classical thermodynamics, the theory of irreversible phenomena, and some modern theories of rational thermodynamics.

Chapter 5 considers classifications of constitutive equations and studies their properties. An apparatus of group theory is used and thermodynamical limitations are discussed. A principle on the principal strains and stresses in an isotropic medium due to Truesdall, Beaker, and Ericksen is also included. Chapter 6 deals with dimensional analysis and similitude theory. In such a theory, the problem of choice of a unit system is the most important one.

Chapter 7 covers fundamental and selected topics of classical fluid mechanics. Both ideal and viscous hydrostatics and hydrodynamics are discussed. Also, integrals of motion due to Bernoulli and Cauchy-Lagrange are given; and a curl theorem due to Helmholtz and a Bierknes theorem on the material derivative of circulation are obtained; the latter theorem is applied to investigate the whirl phenomena in an ocean or in the atmosphere.

In chapter 8 the elements of elasticity theory, both linear and nonlinear, local and non-local, are discussed. Emphasis is placed on wave problems; it is regretted that a stress formulation of linear elastodynamics is only mentioned, Eq (8.128) in the book and [5].

Chapter 9 takes up viscoelastic media; a comprehensive classification of non-Newtonian fluids and rheological materials is given. Also, the properties of polymers are at issue and non-classical effects in viscoelastic non-Newtonian fluids, such as the Poynting, Merrington, and Weissenberg effects are discussed.

Chapter 10 considers plastic bodies. Two groups of theories of an elastoplastic body are distinguished: flow theories and deformation theories. The postulates on stability and plasticity due to Drucker and Ilyushin, respectively, as well as hypotheses on the transformation of an elastic material into a plastic one are discussed. Also, the Levy - von Mises types of flow laws are discussed. Moreover, models of elasto-plastic and elasto-viscous plastic bodies, and associated limit problems are discussed.

Chapter 11 deals with the non-classical models of a continuous media. Special attention is paid to liquid crystals and to defects in solid bodies. The Kroener description (1960) of a dislocation in which the dislocation density represents a non-Euclidean character of space is discussed.

In chapter 12 the continuous media in which a process is produced by non-mechanical loads are dealt with. The effects of diffusion and heat transfer are discussed, and attention is paid to the influence of an electromagnetic field on continuous media. The Lorentz transformation is introduced, and materials with different kinds of susceptibility with regard to electric and magnetic fields (dielectrics, magnetics, ferromagnetics, conductors) are described. Emphasis is given to the interaction of electromagnetic fields with a condensed matter.

The bibliography contains 248 items; the American and European authors are quoted; the works of the Polish school of mechanics are emphasized (almost 1/3 of the items). The subject of thermoelasticity developed in well-known monographs by W Nowacki, cf [6], and of mechanics of stochastic media presented in several sources (eg K Sobczyk [7]).

The book under review is one complementary to other well-known books on continuum mechanics, [8], [9]. Polish students who have been studying from the book praise it as a useful reference in continuum mechanics theory.

Given the wealth of information and a systematic presentation of the subject, *Mechanics of Continuous Media* is highly recommended by this reviewer as a useful academic textbook and a reference book for an engineer and researcher. To make the book accessible to a wider range of students and researchers in the field, an English translation of the book would be beneficial.

10N2. Computational Mechanics-From Concepts to Computations, vol 1. Proceedings of the second Asian-Pacific conference on Computational Mechanics held in Sydney, New South Wales, from August 3-6, 1993.. - Edited by S Valliappan, VA Pulmano, F Tin-Loi *(Univ of New South Wales, Sydney, Australia)*. Balkema, Rotterdam, Netherlands. 1993. ISBN 90-5410-333-7.

Keynote papers include: Modeling in computational structural engineering: An overall view by ER de Arantes e Oliveira and J Bento; A FE analysis of shallow water flow with open boundary condition by T Kodama and M Kawahara; State vector method and symplectic eigensolutions of gyroscopic systems by W Zhong, J Zhu and J Lin; Evolutionary structural optimization with FEA by GP Steven and YM Xie.

Additional papers under the heading, Solid Mechanics, address the following: In elastic local buckling of plates using bubble functions; Harmonic by harmonic method for the postcritical computation of axisymmetric shells; A nonlinear fatigue strength assessment using FEM; Hybrid/mixed FEM for the analysis of metal forming processes; Application of time-domain BEM to elastodynamics analysis; Large deflections of a beam subjected to moment at one end; Analysis of circular cylindrical storage tanks resting on an elastic foundation; Spline finite point method for analysis of laminated composite plates and shells; Analysis of thick laminated composite plates; Transient analysis of plate bending problems by BEM; Shape analysis of unstable structures with constraint conditions; A simple FEM for free vibration of beams on elastic foundation; Stress analysis in a solid with rectangular holes; Estimation of maximum frequency for FE mesh; Computerized Rayleigh-Ritz method for elastic plate analyses; Numerical implementation of Lamb's solution to strip load on elastic half space; Numerical integration of nonlinear dynamic equations using the Newmark scheme; 3D flow with gross deformation of energy absorbing rubber; Local *a-posteriori* error estimates for incompatible elements; FE algorithm for 3D contact problems of turbomachinery blade attachments; A simple approach for cold rolling of foil; A four-node hybrid FE for the analysis of laminated plates; FE analysis of local buckling of a cracked and pin-loaded plate; Spline FE analysis of a butterfly shell roof; A FE algorithm for finite deformation contact problems; Viscoelastic finite strip analysis of folded plate structures; A study on problems of determining curved surface forms using geometrical stiffness; Multi-variable nonlinear quasi-conforming FEM; Fundamental study on nonlinear dynamics of elasto-plastic structures; Elastic contact FE analysis of spiral beval gear meshing; Diffracted acoustic field by rigid plane baffles using integral-equation method; Vibration analysis of a hot roughing mill during asymmetrical rolling; A general numerical method for some singular frictionless line contact problems; Simple analysis of axisymmetrically loaded shells by transfer matrix; Buckling characteristics of single-layer latticed domes; Development of new four node plate and eight node brick elements; A uniform approach to the calculation of eigenvectors; *Invited paper*: Lower and upper bounds for stability limits on geometrically nonlinear prebuckling paths; *Invited paper*: Nonlinear analysis of shells using flat facet FEs; Nonlinear dynamic analysis of flexible beams under large overall motions; FE analysis of orthotropic thick plates; A moderate thick shallow shell hybrid stress element with rational stress mode; An artificial compression method for contact discontinuities; Error estimates of h- and p-convergence in multi field FEs.

Papers under the heading Geomechanics include: Backward Euler and subincrementation schemes in computational plasticity; *Invited paper*: FE analysis for constitutive model with strain softening; Theoretical and numerical modeling of swelling phenomenon of rocks in tunnel excavations; FE analysis of steel grid reinforced embankment on soft Bangkok clay; A new model for nonlinear analysis of vibrating foundations on clays; Ground loss caused by tunnelling for Taipei mass rapid transit system; 3D areal analysis for land subsidence; Numerical analysis of deep excavation in Taipei; Application of spectral collocation method in geomechanics; *Invited paper*: Strain softening effects in the stability analysis of geotechnical problems; New technique of non-linear FE analysis for caisson foundation; *Invited paper*: Constitutive models in nonlinear computational procedures; Multi wedge stability analyses for layered soils; Mechanical behavior after excavation of undergournd space; 3D numerical simulation for dynamic soil-pile foundation-structure interaction; *Invited paper*: Homogenisation techniques for strain localization and interface analysis; Study on the group factor of pile groups; Numerical prediction of side resistance of axially loaded tapered piles; Generalized model for reinforced fill on soft clay; Simulation of stratified rock masses: The Cosserat laminated model; Screening effectiveness of soft in-filled trench using BEM; Bearing capacity of the reinforced soils by rigid plastic FE analysis; A modified Ramberg-Osgood power law; *Invited paper*: Back analysis of non-elastic behavior of soils and heavily-jointed rocks; Identification of coefficient of horizontal subgrade reaction by EK - WGI method; Shaft friction on piles in layered soil; Dynamic analysis of caissons under lateral loads; Discrete-mechanical formulation and simulation analysis of granular mateials; Splitting of rock medium with an explosive charge; Determination of maximum stress location under an arbitrary shaped foundation; A new prediction approach to geotechnical engineering problems; FE approach to lower and upper bound solutions of reinforced soils; and Numerical modeling of mining induced subsidence.

10N3. Computational Mechanics-From Concepts to Computations, vol 2. Proceedings of the second Asian-Pacific conference on Computational Mechanics, held in Sydney, Australia, August 3-6, 1993.. - Edited by S Valliappan, VA Pulmano, F Tin-Loi *(Univ of New South Wales, Sydney, Australia)*. Balkema, Rotterdam, Netherlands. 1993. ISBN 90-5410-333-7.

Topics of volume 2 include: Fracture and damage mechanics; Structural engineering; Optimization-parameter identification; Wave propagation; Earthquake engineering/vibrations; Mass transport/tidal current; Hydrodynamics; Biomechanics and Computational techniques.

Partial contents include: *Fracture and damage mechanics*--Computer experiment on defect accumulation for a llinear arrangement of 2D defects; Parametric variation of stress intensity factors for cracks in lugjoints; Fractal two level FEMs for 2D crack problems; *Invited paper*: 2D damage failure propagation model of jointed rock mass; Fractal analysis of crack distribution; Fraacture energy experiments of rock-concrete and its fractal analysis; *Invited paper*: A coupled seepage-damage analysis model for jointed rock masses; Detection of structual damage by vibration test and neural network techniques; Application of a post-yield crack algorithm; Thermorheological analysis of surface crack in semi-rigid pavements.

Partial structural engineering papers include: Modal coordinate analysis of reinforced concrete structures with local nonlinearity; Branching predictor in bifurcation of 2D elastic frames; Punching shear failure analysis of RC flat plates with spandrel beams by FEM; Developments in FE analysis of single bolted timber joints; FE modeling of horizontally nail-laminated wood beams; Crack analysis of RC structures including tension stiffening; Analysis of concrete structures by FEM-BEM superposition method; Evaluation of plastic deformability for steel beam-columns subjected to sidesway; Relationship between axial load and vibration frequency of plane trusses; Elasto-plastic behavior of reinforced concrete member under high temperature; Temperature distribution in a concrete box culvert using 3D FEM; Joint compatibility problems with the frame method; Optimum design of reinforced concrete shear walls; Ultimate analysis of cable-supported prestressed concrete frames; Knowledge-based approaches for concrete frame building structural design; Elastic lateral-torsional instability of thin-walled beams under the effect of shear; Buckling and post-buckling collapse analysis of space frame structures; Ultimate strength of RC columns of arbitrary cross-sections subjected to biaxial loading; Dynamic structural analysis with nonlinear material models based on internal variables; FE analysis of steel fiber concrete beams; and LCP formulation for large displacement elastoplastic analysis of semirigid frames.

10N4. Computational Methods and Experimental Measures VI, vol 1 (Heat and Fluid Flow) and vol 2 (Stress Analysis). - Edited by CA Brebbia *(Wessex IT, Southampton, UK)* and Carlomagno *(Univ of Naples, Italy)*. Comput Mech, Billerica MA. 1993. 1150 pp. ISBN 1-56252-152-7. $480.00. Info is for two-volume set.

These books contain the edited versions of the papers presented at the Sixth International Conference on Computational Methods and Experimental Measurements, which was held in Siena, Italy, May 3-5, 1993.

Computational methods and experimental measurements as tools applied to the solution of engineering problems share common aims and experiences, and their interaction should play an important and influential role in their respective paths of development. The need for a forum to bring the computational and experimental camps together prompted the establishment, more than 10 years ago, of the present series of conferences.

The books reflect the objectives of this series of conferences. State-of-the-art contributions by authors from many countries report innovative approaches in the fields of numerical methods and experimental studies with particular emphasis on their interaction and potential application to engineering problems.

Topics covered include: Experimental vs analytical or numerical models; Interaction of computer codes and experimental models; Material property characterization through numerical models and experimental prototypes.

10N5. Impact of Computational Mechanics on Engineering Problems. Proceedings of the Seminar on Impact of Computational Mechanics on Engineering Problems, held in Sydney, Australia, August 2, 1993.. - Edited by VA Pulmano and V Murti *(Univ of New South Wales, Australia)*. Balkema, Rotterdam, Netherlands. 1993. ISBN 90-5410-324-8.

Contents include: Solution difficulties in multi-wedge stability analyses; FE analysis of the artificial freezing of sand; A generalized material parameter identification procedure in geotechnical engineering; Fundamental study on in-situ fault traxial compression test of rock mass; Analogy between analysis of flow in pipe networks and slope-deflection in rigid frames; An efficient scheme for land subsidence and negative skin friction; Some applications of homogenization method in rock mechanics; Application of numerical modeling to consequence-of-sliding analysis; Recent advances on numerical analysis of interaction problems: The Australian scene; FEs in biomechanics: Some new developments; Development of a microscopic view traffic flow simulation model for expressway; An adaptive *hp*-FEM in frictional contact problems; FE analysis of steel fiber reinforced cement composites; Measures of fuzziness in FE geotechnical solutions; Computations of vertical soil stresses underneath foundations with curved boundary using parametric mapping technique; Field investigation of mechanical behavior of a shallow tunnel due to ground surface excavation; Complex number expression of 3D deviatoric tensor; Pollutant transport in deformable semi-saturated geomaterials; Design of rock bolts with numerical models; Hardening models: Some implications for elastoplastic analysis by mathematical programming; Fractal analysis on the fracture damage propagation of rock; Fatigue damage analysis of hammer foundation; and Numerical evaluation of bridge approach settlement.

Methods of Engineering Mathematics. - Edward Haug *(The Univ of Iowa IA)* and Kyung K Choi *(The Univ of Iowa)*. Prentice-Hall, Englewood Cliffs NJ. 1993. 575 pp. ISBN 0-13-579061-1. (Under review)

Optimal Control and the Calculus of Variations. - Enid R Pinch *(Math, Univ of Manchester, Manchester, UK)*. Oxford UP, New York. 1993. 232 pp. ISBN 0-19-853217-2. $49.95. (Under review)

II. DYNAMICS & VIBRATION

10N6. Civil Engineering Dynamics-Design, Analysis, Testing and Performance. Society for Earthquake and Civil Engineering Dynamics. - Telford, London. 1990. 506 pp. ISBN 0-86292-327-1. £65 UK and Europe.

This book deals with the design, analysis, testing and dynamic performance of existing or new structures, with special emphasis given to analysis design and test methods. Actual case histories illustrate the principles involved.

The structures considered include buildings, bridges, dams, nuclear power stations, chemical plants, and cable structures. Environmental loads provided by earthquakes and winds are covered, together with manmade vibration, explosion and impact loads. Dynamic testing at full and laboratory scale, and dynamic performance of real structures are given particular attention.

Impact and Explosion: Structural Analysis and Design. - MYH Bangash *(Middlesex Polytech, London, UK)*. CRC Press, Boca Raton FL. 1992. 880 pp. ISBN 0-8493-7742-0. $245.00. (Under review)

Modern Kinematics-Developments in the Last Forty Years. Wiley Series in Design Engineering. - Arthur G Erdman *(Univ of Minnesota MN)*. Wiley, New York. 1993. 604 pp. ISBN 0-471-55459-6. (Under review)

III. AUTOMATIC CONTROL

10R7. Controlled Markov Processes and Viscosity Solutions. - Wendell H Fleming *(Div of Appl Math, Brown Univ, Providence RI 02912)* and H Mete Soner *(Carnegie-Mellon Univ, Schenley Park, Pittsburgh PA 15213)*. Springer, New York. 1993. 428 pp. ISBN 0-387-97927-1.

Reviewed by Tamer Basar (Coordinated Sci Lab, Univ of Illinois, 1308 W Main St, Urbana IL 61801).

This book provides an introductory but exhaustive treatment of the optimal control of Markov processes with perfect state measurements and the viscosity solutions of the Hamilton-Jacobi-Bellman equations associated with the optimal value function.

The approach adopted in the book being that of dynamic programming, the authors first discuss (in chapter I) optimal control of deterministic processes, derivation of the dynamic programming equation for the associated optimal cost function, and its relationship with Pontryagin's maximum principle and the classical calculus of variations. What is emphasized in this chapter is that even though the value function can be shown to satisfy a first-order nonlinear partial differential equation (PDE) (the Hamilton-Jacobi-Bellman equation), it is generally not sufficiently smooth to be viewed as a classical solution of this PDE. What is shown, however -- and this is the topic of chapter II -- is that the value function can always be viewed as a weaker solution of the HJB PDE, interpreted in the viscosity sense. This weak solution (leading though to very strong results) is introduced in precise terms and in a general abstract framework in chapter II, and many of its appealing properties, such as existence, uniqueness, and smoothness are studied in detail for a large class of optimal control problems, including problems with state and control constraints, unbounded control sets, and finite and infinite horizons.

Following these two chapters, the rest of the book (seven chapters) has been devoted to stochastic control problems. Chapter III introduces Markov processes and their evolution operators. It discusses a formal derivation of dynamic programming (DP) equations, and a verification theorem (for the case when the DP equation admits a sufficiently smooth classical solution), in both finite and infinite horizons. These results are then strengthened in Chapter IV for the special case of controlled Markov diffusions in IR^n, in which case the DP equation is a parabolic HJB PDE. When this equation is uniformly parabolic, it admits a unique solution in the classical sense, but if it is not, one has to consider generalized solutions, which are studied carefully (by appropriate approximations and bounding techniques) in the second part of chapter IV. This naturally leads to the next chapter where the visocosity solutions of second-order nonlinear parabolic PDE's are studied and existence and uniqueness results are proven using some tools recently developed by R Jensen.

Chapters VI and VIII discuss extensions in different directions. The first of these deals with logarithmic transformations, which arise naturally when the backward evolution operator of a Markov process depends on some small parameter (say $\varepsilon > 0$), which shows structural change when $\varepsilon = 0$. One application is the "small noise" problem, which is studied in this chapter in some detail. Of particular importance is the derivation of asymptotic series for the solution of the perturbed ($\varepsilon > 0$) problem in terms of solutions and properties of the unperturbed ($\varepsilon = 0$) problem. The discussion of singularity is continued in chapter VII in the study of the convergence of a sequence of viscosity solutions of a perturbed PDE to the viscosity solution of the unperturbed (or equivalently, limiting) one. A recent approach due to Barles and Perthame that circumvents some mathematical difficulties associated with precompactness of the sequence in uniform topology is first presented, and then it is applied to the problem of vanishing viscosity and to a large deviations problem for exit probabilities, in which context an exponential convergence is established. The final chapter on singularities (Chapter VIII) deals with singular stochastic control problems, where the control is not necessarily continuous in time, but is generally of bounded variation. The authors first derive a DP equation for such problems, then prove a verification theorem and establish the viscosity property of the value function. The primary focus is on infinite-horizon problems with no absolutely continuous control, but also discussed is the "mixed" case, as it arises in an optimum portfolio selection problem with transaction costs.

The last chapter of the book (chapter IX) provides a brief introduction to numerical solutions of the HJB PDE. Here two approaches are covered: (1) a finite difference scheme due to H Kushner, applied to the value function of a controlled Markov diffusion on a finite horizon, and (2) approximations based on viscosity solutions. Chapter IX is followed by five appendices, giving some background results on optimization, stochastic processes and differential equations, and semiconvex functions.

As to be expected from the authors, *Controlled Markov Processes and Viscosity Solutions* has been written very competently, with deep mathematical results supported by intuitive explanations and supplemented by various simple but important applications. Because of recent interest in viscosity solutions in the field of nonlinear and robust control (as they arise in nonlinear "H^∞-optimal" control), the book should be of interest not only to researchers in stochastic control, but also those in nonlinear and robust control, and differential games.

10R8. Mechatronics: Electromechanics and Contromechanics. - Denny K Miu *(Dept of Mech, Aerospace and Nucl Eng, UCLA)*. Springer, New York. 1992. 232 pp. ISBN 0-387-97893-3.

Reviewed by Michael K Brown (Interactive Syst Res, Bell Labs, 600 Mountain Ave, Murray Hill NJ 07060).

In the preface, the author describes mechatronics as a field covering such diverse topics as mechanics, electronics, and information. This book, derived from class notes for a graduate course at UCLA, concentrates on the first two of these topics. A cursory examination of the table of contents reveals that the topics are developed from first principles of physics to an introductory level in continuum mechanics

The book contains 232 pages, a small index, and ten chapters. Most chapters have exercises and/or references, there are four appendices. Many of the figures appear to be hand drawn without the aid of a ruler but are clearly readable. After the introductory chapter 1, the remaining chapters are split into two parts entitled "Electromechanics" and "Contromechanics."

Part 1 begins chapter 2 which reviews Newton's second law and the basic physics of mechanical dynamics. Chapters 3 and 4 cover electrostatics, magnetostatics and electromagnetics. DC and stepper motors are introduced in chapter 5. The coverage in those first chapters is strictly at the undergraduate level. The depth of coverage is not great, but is sufficient for a basic introduction.

Chapter 6 breaks away from the classical topics and begins to explore newer territory in the area of piezoelastics. It starts with a description of an incremental linear motor called "inch-worm" motor, which can crawl along a cylindrical shaft by alternately expanding and contracting a set of piezoceramic elements. Other similar motors are described. Discussion continues with topics such as electrical and mechanical properties of piezomaterials, resonance, and electrical equivalent circuit models.

Part II starts with an introduction to linear time-invariant control theory in chapters 7 and 8. Chapter 8 also analyzes continuous and coupled dynamical systems. Chapter 9, "Residual Vibration," introduces principles of optimal control theory specifically aimed at minimization of vibration in point-to-point mechanical positioning. A technique called "Laplace domain synthesis" is described. The technique is applied with minimization of energy and jerk (temporal derivative of acceleration).

The topic returns to piezomaterials in the last chapter, which discusses active damping methods for controlling flexible structures. Active damping is achieved by laminating piezopolymer onto the controlled structures. Some discussions of the resulting kinematics and dynamics are given. This chapter is primarily an overview of the work of CK Lee.

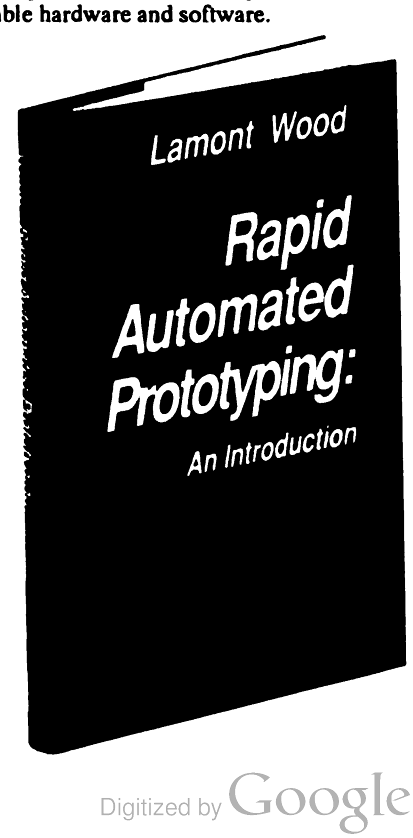
Appendices A, B, and C cover physical units, vector calculus and tensors. Appendix D describes a real control system design for computer disk read-write head positioning. This is a detailed discussion including plots of system performance for a commercially designed system currently in use.

This textbook is probably best suited for teaching at the senior undergraduate or first-year graduate engineering level. Much of the book is written at a level suitable for review, but not sufficient for a first exposure to physics or control theory. Most of the chapters are devoted to this review of classical material. Only chapters 6 and 10, covering piezomaterials, introduce topics not usually found in other textbooks. Some uncommon material is also covered in chapters 8 and 9. *Mechatronics: Electromechanics and Contromechanics* is easy to read for someone familiar with the material covered, but is terse and perhaps difficult reading for a first introduction.

10R9. Rapid Automated Prototyping: An Introduction. - Lamont Wood *(San Antonio TX)*. Indust Press, New York. 1993. 140 pp. ISBN 0-8311-3047-4. $32.95.

Reviewed by Serope Kalpakjian (Mech & Aerospace Eng Dept, Illinois IT, 10 W 32nd St, Chicago IL 60616-3793).

Rapid prototyping, also known as desktop manufacturing or free-form fabrication, is a relatively new technology (since mid 1980s) by which a solid physical model of a part is made directly from a 3D CAD drawing. The time involved is far less than traditional prototyping methods. The process is coming into wide use particularly in the automotive, aerospace, and medical industries. Although equipment costs are substantial, ranging from about $100,000 to $500,000, the technology is particularly suitable for studying and analyzing the esthetic, technical, and functional (including assembly) aspects of product models prior to finalizing their design. In addition to numerous articles in trade magazines and papers in professional journals, books are now beginning to appear on this important subject. The stated purpose of this book by Wood is to provide the reader with full descriptions of each technique and the available hardware and software.



Rapid Automated Prototyping: An Introduction is a slim volume with little and uneven technical content. However, it is replete with data and brief specifications on machines and supplies and their prices, photographs of parts made and the equipment used, vendor addresses and phone numbers, and a great deal of commentary from customers on their experiences with making parts using various rapid prototyping equipment. It also includes a brief glossary.

The seven chapter titles are: Introduction, Stereolithography systems, Selective laser sintering, Fused deposition modeling, Lamination methods, Scanners, and Software. The author is a freelance writer in the high-technology field. His writing style is somewhat casual but straightforward, and more appropriate for technical and trade magazines.

While the book lacks technical depth and has no bibliography, it is nevertheless a good and brief introduction to the subject and useful to manufacturing personnel unfamiliar with the topic. It is successful in giving a brief perspective to help those who are considering rapid prototyping systems for reducing costs and production times. Those interested in this subject should also consider another book, *Automated Fabrication - Improving Productivity in Manufacturing* by Marshall Burns (PTR Prentice Hall, 1993). This 369-page book is much more detailed and comprehensive while addressing basically the same audience.

CAD for Control Systems. - Derek A Linkens *(Dean of Eng, Univ of Sheffield, UK)*. Marcel Dekker, New York. 1993. 600 pp. ISBN 0-8247-9060-X. $150.00. (Under review)

IV. MECHANICS OF SOLIDS

10R10. Elasticity: Theory and Applications, Second Edition. - Adel S Saada *(Civil Eng, Case Western Reserve Univ, Cleveland OH)*. Krieger, Melbourne FL. 1993. 796 pp. ISBN 0-89464-561-7. $119.50.

Reviewed by Oscar L Bowie (Star Route - Box 317, Phippsburg ME 04562).

This textbook on elasticity is a second edition of the author's work written several years ago. The primary addition to the original version of the subject involves the use of complex variable methods in several areas of problem-solving. A basic review of the subject is presented in a manner which will be of special interest to the applied mathematician. The design engineer's interests are not emphasized, although considerable care is given to provide the necessary background to the mathematical arguments. The book is divided into three segments, with deformation and stress occupying the first two parts, respectively. The third part addresses elasticity with its several models and approximations, along with mathematical methods of solutions.

Part I provides the mathematical descriptions of displacements, deformation and strain in a continuous media. The first three chapters are concerned with displacement and linear transformations of points. Matrix algebra is introduced and the corresponding operations and notation are reviewed. Chapter 4 identifies the portions of displacements which can be considered as strain. The components of strain in Cartesian coordinates are defined in both the linear and nonlinear ranges. Following this topic is a chapter on the formulation in terms of Cartesian tensors. Chapter 6 concludes this segment with a detailed treatment of the strain components in terms of orthogonal coordinates.

Part II consists of a single chapter dealing with the analysis of stress. The stress tensor is introduced and it is shown that its components must satisfy three partial differential equations for equilibrium. These requirements are modified by the simplifying assumptions of the two-dimensional theories. The arguments are carried out in both Cartesian and orthogonal curvilinear coordinate systems.

Part III consists of 12 chapters dealing explicitly with elasticity and problem-solving. In chapter 8, the elastic stress-strain relations according to the generalized Hooke's Law are introduced and systematically modified for isotropy, plane stress, plane strain, etc. The boundary-value problems of elasticity are discussed and the equations required for solution are described in terms of both stresses and displacements. In chapter 9, several classical approaches to problem-solving with the use of potentials are reviewed. Both displacement and stress functions are considered. Torsion of prismatic bars is the subject of chapter 10. Saint-Venant's semi-inverse method is applied to a variety of cross-sections. A relatively brief treatment of thick cylinders, disks, and spheres is presented in chapter 11. Several solutions are summarized for cases in which the boundary-value problems are simple. The following two chapters deal with straight and curved beams, respectively. Axial and shearing forces along with bending moments on the ends are considered using Airy's stress function. The results are compared with those of elementary beam theory.

In chapter 14, the stress analysis for semi-infinite solids and plates is presented for several load distributions. The contact problem corresponding to a rigid die in the form of a circular cylinder acting on a semi-infinite medium is analyzed. The stresses in 2D wedges and triangular rectangular retaining walls are derived. Energy principles and the corresponding variational methods are introduced in chapter 15. Such matters as the principle of virtual work, the reciprocal laws, energy theorems, etc are reviewed. Applications of the arguments are provided for wires and beams. The elastic stability of columns and beams under compression and bending is considered in chapter 16. The buckling loads are calculated for several end conditions. Flat plate theory, based on the Kirchhoff assumptions, is reviewed in chapter 17. Bending problems are addressed for several geometric configurations, loading conditions, and edge constraints. In chapter 18 the theory of thin shells is introduced, with emphasis on the role to which differential geometry should be considered. The appropriate mathematical descriptions are reviewed at some length. Stress resultants and couples are then defined along with the corresponding equations of equilibrium and boundary conditions. Applications of the theory are provided primarily for circular cylindrical shells.

The final chapter is concerned with the applications of complex variable theory to the 2D problems. The properties of analytic functions, Cauchy integrals, series representation, the calculus of residues, conformal mapping, etc are reviewed. Applications to the torsion of prismatic bars with several cross-sections are described. The plane problems of elasticity which reduce to the solutions of biharmonic equations are then addressed. The properties of the two analytic functions describing such solutions for simply and multiply-connected regions are reviewed. The arguments are illustrated by several examples, including circular and elliptical holes in large plates.

The author presents an organized review of the subject that introduces the reader to its status 50 years ago. The more recent developments, eg, the role of elasticity solutions in fracture mechanics, problem-solving with the use of FE, etc are not addressed in any detail. However, *Elasticity: Theory and Applications* is well-written and provides a good basic background to the fundamentals.

10R11. Mechanical Behavior of Materials. Engineering Methods for Deformation, Fracture, and Fatigue. - Norman E Dowling *(Col of Eng, VIP)*. Prentice-Hall, Englewood Cliffs NJ. 1993. 775 pp. ISBN 0-13-579046-8.

Reviewed by David W Nicholson (Dept of Mech and Aerospace Eng, Univ of Central Florida, PO Box 25000, Orlando FL 32816).

The text under review is intended for use in a junior course typically entitled *Mechanical Behavior of Materials*. It assumes "Strength of Materials" as a prerequisite. The text competes with several well known books, among which *Mechanical Metallurgy* by Meyers and Chawla comes to mind. It emphasizes the materials viewpoint, in contrast to some books with similar titles that emphasize stress analysis (eg, Fletcher).

The book is very well written and attractively presented, using graphical materials extensively. It incorporates a large number of exercises and a fair number of worked-out problems in the text. Problems are identified for solution using a personal computer, although no software is provided. The topics are presented at a consistent level of sophistication.

The main departure from competing texts seems to be the emphasis on fracture concepts, both for static fracture and fatigue. This makes the text quite attractive to the present reviewer. There is also some discussion of nonmetallic materials and composites.

Chapters 1 through 3 are largely descriptive and qualitative accounts of the microscopic basis for mechanical properties in different types of materials. Chapter 4 presents the basic concepts of stress and strain and of stress-strain relations for elasticity, plasticity, and creep, as well as for anisotropic materials. There is also a brief mention of thermal strains. Chapter 5 gives a very extensive account of the tests needed to evaluate the properties identified in chapter 4. Finally, chapter 6 extends the basic treatment of chapter 4 to complex states of stress.

Chapter 7 presents elementary notions and models for yielding and plasticity. The notion of residual stress is explained. The topic is revisited in chapters 12 and 13, which treat the analysis of plastic deformation in simple members. Chapter 8 gives a very comprehensive account of linear elastic fracture mechanics, including a discussion of testing. Chapter 9 likewise gives a very extensive account of fatigue crack growth. Chapters 9, 10 and 14 discuss fatigue using stress-based and strain-based models such as the Goodman diagram. There is some discussion of remaining life assessment. Finally, chapter 15 discusses creep and damping, starting with elementary viscoelastic models.

The length of the text and the large range of topics covered makes it necessary for the instructor to pick and choose in constructing a course. Some suggestions are given in the preface.

From a pedagogical viewpoint, the text is excellent. Its coverage of fracture is an especially welcome feature. Compared to many texts with similar titles, *Mechanical Behavior of Materials: Engineering Methods for Deformation Fracture and Fatigue* does not emphasize stress analysis or the design of components; instead, it is attractive to intructors wishing to emphasize the materials viewpoint.

10R12. Mechanism Analysis. Simplified Graphical And Analytical Techniques. - Lyndon O Barton *(E I du Pont de Nemours, Wilmington DE)*. Marcel Dekker, New York. 1993. 752 pp. ISBN 0-8247-8794-3. $150.00.

Reviewed by Pradip Sheth (Mech Eng, University of VA, AH Small Bldg for Computer-Aided Engineers, Charlottesvile VA 22901).

This is book on kinematic analysis of mechanisms, written primarily for mechanical design engineers and mechanical design engineering students. The material is presented in five distinct parts.

Part I contains introductory concepts including: definitions of kinematic terminology of higher-lower pairs, Gruebler's equation for degree of freedom, inversion, motion characteristics for planar rotations, and translations. Simple expressions involving graphical interpretations of displacements velocity and acceleration relationships are presented. Vectors and graphical treatment of vector manipulations are introduced.

Part II details graphical techniques for velocity and acceleration analysis of simple mechanisms. The concept of instant centers is introduced, including the relationship between instant centers and velocity analysis. Graphical treatment of coriolis acceleration component is explained. Graphical techniques for differentiation and integration are presented. The use of equivalent linkages to simplify analysis of the higher pair mechanisms by viewing them as equivalent lower pair mechanisms is explained. Graphical procedures for determining centers of curvature of path traced by points in a mechanism are presented.

Part III presents analytical techniques - based upon vectors and complex algebra - for a variety of planar mechanisms. These include variation on the slider crack, the four bar, the quick return mechanism, sliding coupler, and cam-follower systems.

Part IV introduces gears. Spur, helical, Herringbone, bevel, hypoid, rack worm, and annular types are covered, along with the gear terminology. The law of gearing and the involute tooth action are described in detail. Simple, compound, planetary, and epicyclic gear trains are treated. The bevel differential as in the automobile differential is presented.

Part V is devoted to cam systems, including the treatment of motion design of follower systems.

An extensive set of practice problems is provided for all of the chapters in the book. In the Appendix, Fortran programs for the four bar, the slier crank, and the quick return mechanisms and Basic Program for gear design for external gear pair for standard involute tooth profile are presented. Calculator programs for the HP-41C programmable calculator are also included.

An attractive feature of this book is the clear, physical intuitive methods of analyzing mechanisms, including graphical procedures. These graphical methods of mechanism analysis are rapidly disappearing from the undergraduate mechanical design engineering curricula, and perhaps a few examples from this book could indeed be utilized to reinforce the practical nature and the "back of the envelop" quick evaluations of mechanisms.

As a teacher of an undergraduate mechanical engineering course on mechanisms and theory of machines, this reviewer cannot recommend the book as a textbook for adoption in a mechanical engineering degree program because of what is *not* covered in the book. Despite the size (752 pages), the book is devoted primarily to velocity and acceleration analysis of simple mechanisms. Forces (static or dynamic) are not treated. the usefulness of the programmable calculator programs is questionable. The entire treatment offered by this book would cover approximately 35-40% of an undergraduate course on mechanisms. It should also be noted that the place of a course on mechanisms in mechanical engineering curriculum is itself in a state of flux, with increasingly more material on programmable motion control. Systems (stepper and servo motors) and the use of CAE software on PCs add workstations for mechanism design and analysis.

A mechanical engineering *technology* curriculum, on the other hand, may find this book of some merit, perhaps as a reference or as an adjunct to some other textbook. Similarly, this book should also be considered as a library reference in an engineering curriculum and also by the practicing design engineer.

10N13. Deep Foundations on Bored and Auger Piles BAP II. Proceedings of the 2nd International Geotechnical Seminar on Deep Foundations on Bored and Auger Piles held in Ghent, Belgium, June 1-4, 1993.. - Edited by WF Van Impe *(Ghent Univ and Leuven Catholic Univ, Belgium)*. Balkema, Rotterdam, Netherlands. 1993. ISBN 90-5410-313-2.

Keynote lectures address the following: Installation, monitoring and design of caissons by H Brandl; Design of auger displacement piles from in situ tests by M Bustamante and L Gianeselli; Updating realism on large-diameter bored piles by VFB de Mello and N Aoki; Design of bored piles, including negative skin friction and horizontal loading by E Franke; Interaction problems related to the installation of pile groups by S Hansbo; Base capacity of bored piles in sands from in situ tests by VN Ghionna, M Jamiolkowski, R Lancellotta and S Pedroni; Case studies on cast-in-place bored piles and some considerations for design by R Matsui; Settlement prediction for bored pile groups by HG Poulos; and Efficient design of piled rafts by MF Randolph and P Clancy.

Interaction problems related to pile groups. Papers under this heading include: Cap-pile interaction of pile groups; Field tests and analyses on ultimate behavior of lateral loading bored piles; Group action of laterally loaded piles; and Load distribution in bored pile groups.

Installation problems of bored and auguer piles-Monitoring of pile installation-Case studies. Papers include: Bored vs displacement piles in sand-experimental study; Pile foundation for the 'Pont de Normandie'-Special aspects; Influence of the concreting on the bearing capacity; Pile walling with the PCS method; Bored cast-in-situ piles in weathered rocks-Evaluation of design parameters; Instrumentation of pile installation as a management tool; Effect of dosage and exposure time of slurries on perimeter load transfer in bored piles; Case studies concerning installation of large diameter piles used in Romania; Evaluation of the influence of pile execution parameters on the soil condition around the pile shaft of a PCS-pile.

Pile testing, statically and dynamically - Integrity testing. Papers include: The behavior of bored piles subjected to load testing as compared to theoretical estimates; Large diameter bored piles in pyroclastic soils; Aspects of the bearing capacity of root piles in some Brazilian soils; A method of analysis of stress induced displacement in soils with respect to time; Analysis of loading tests of short large-diameter piles; Nonlinear load-settlement behavior of bored piles; Augered cast-in-place pile testing in Southern California; First experiences with statnamic load testing of foundation piles in Europe; Dynamic testing of an instrumented drilled shaft.

Design of bored piles, including negative skin friction and horizontal loading. Partial papers include: Shaft resistance of model pile in granular soil; Evaluation of bearing capacity and settlement of Wolfsholz piles bored into layered subsoil; Bored piles in clay-shale using expansive concrete; The Romanian code for large diameter bored piles; Punching effects for bored piles; Analysis and design of piles under lateral loads; Investigation of horizontal ground massive collapse deformations influence on piles; New promising concept for bored piles and tension piles; Laterally loaded pile analysis using a 3D BEM formulation; Large diameter bored piles for an office building 'Amstelhoek' in Amsterdam; Bearing mechanisms of nodal piles in sand; An hydraulic gradient study of pile's base enlargement.

Settlement behavior of groups of bored or auger piles-Piled rafts. Partial papers include: Tests of auger piles for design of pile-supported rafts; and Development of locked stresses and negative shaft resistance at the piled raft foundation Messeturm Frankfurt/Main.

10N14. Engineering Plastics and Composites, Second Edition. - Edited by WA Woishnis (*Plastics Design Library*). ASM Int, Materials Park OH. 1993. 700 pp. ISBN 0-87170-483-8. $139.00.

This updated version of the popular reference book follows the same format in section one as the first edition, allowing you to quickly look up plastics, reinforced plastics, and resin composites by trade name. This section includes descriptions of each material by class, family, chemical type, composition and supplier, and also includes information on processes (injection or compression molding), comments, features and uses. Property data has been greatly expanded from the first edition, with coverage of mechanical and physical property data for up to 18 properties. Section two provides an index by chemical type, and lists the supplier, trade name, composition, features and uses. Section three provides an alphabetic listing of suppliers and shows the trade names and chemical types they produce. Section four gives complete supplier contact information, including addresses, phone and fax numbers. Includes listings for more than 5000 trade name materials.

10N15. Metallizing of Plastics: A Handbook of Theory and Practice. - Edited by R Suchentrunk. ASM Int, Materials Park OH. 1993. 348 pp. ISBN 087170-306-8. $105.00.

This book describes the use of metallized plastics in the aerospace, automotive, and appliance industries, plus in electronics housing, EMI-RFI shielding and CDs. Also included is information on etching and pretreatment, matching the plastic to the process, the use of swelling agents, and a step-by-step guide to the metallizing processes themselves. Treatment of effluent arising from metallizing operations and methods for extending the life of processing solutions are also covered.

10N16. Nondestructive Evaluation of Concrete in the Infrastructure. - Soc Exp Mech, Bethel CT. 1993. 600 pp. Softbound. ISBN 0-912053-42-9. $110.00.

This conference, held June 9-11, 1993, consisted of presentations by experts in the field. A partial list of topics presented were: Bridge condition assessment by modal flexibility; Damage identification of reinforced concrete shear wall structures; Nondestructive testing of bridge, highway, and airport pavements; electromagnetic properties of concrete for nondestructive testing; Analysis of localization in concrete and rocks through stereophotogrammetry, spleckle laser and replica; Two-dimensional electronic speckle pattern interferometry and concrete fracture processes; Study of acoustic waveguides in reinforced concrete structures; Quantitative ultrasonic evaluation of concrete; Three-dimensional computer vision technique for evaluation of large structural surfaces; Nondestructive evaluation of concrete structures by digital shearography; Advanced NDT methods for concrete structures; A survey of existing and new approaches for the generation of stress waves in concrete; The NDT as a useful tool in the practical quality control of structures; Evaluation of fracture energy by means of in situ pull-off test; Energy dissipation mechanisms associated with rapid fracture of concrete; Comparison between optical microscopy and scanning acoustic microscopy for detecting flaws in concrete, and more.

10N17. Proceedings of the 1993 50th Anniversary Spring Conference of the Society for Experimental Mechanics. - Soc Exp Mech, Bethel CT. 1993. 1300 pp. Softbound. ISBN 0-912053-39-9. $145.00.

The June 1993 Spring Conference marked the 50th year of service by SEM to the experimental mechanics community. The technical program consists of 225 presentations.

Session topics included: Dynamic systems; Holo-interferometry; Strain gage research topics; Contact stress; Electronic packaging; Mechanics and material science of composites I and II; Application of numerical methods to residual stress analysis; Moire methods applied to composites; Application of experimental methods to determination of residual stresses; Fatigue, interface and dynamic fracature; Speckle, Moire interferometry I and II; Applied-industrial applications of photoelasticity I and II; Composites: Time dependence and durability issues; Thermographic measurement for structural assessment; Fracture mechanics I and II; Time dependent models I and II; Fifty years of structural test analysis; Embedded optical fibers in smart structures; Optical methods-Data reduction, transducers and sensors; Fracture in particulate composite materials I and II; Sensors in robotic applications; Sensors for smart structures; Photoelasticity; Analytical methods in mechanics and digital image processing; and Structural testing.

10N18. Processing, Fabrication and Application of Advanced Composites. Proceedings of ASM International's 1993 Conference. - Edited by K Upadhya. ASM Int, Materials Park OH. 1993. 570 pp. ISBN 087170-473-0. $95.00.

In this volume the papers describe real-world applications of putting composites to work. Once thought of as solutions in search of problems, many of these composites are being mainstreamed into commercial applications. Nearly one-third of the book deals with physical and mechanical properties of ceramic matrix composites; other areas covered in detail are processing and characterization of intermetallic matrix composites and metal matrix composites; processing, fabrication and application of polymer matrix composites; fabrications of functionally gradient materials; and processing applications of carbon-carbon composites. Contributing authors hail from university, government and defense research facilities, as well as from aerospace companies across the country.

10N19. Strength of Metals and Alloys. - Edited by DG Brandon, R Chaim, A Rosen. Freund, London. 1993. 1174 pp. $220.00. 2 vols.

10N20. Structural Testing Technology at High Temperature-II. - Soc Exp Mech, Bethel CT. 1993. 100 pp. Softbound. ISBN 0-912053-40-2. $27.00.

This conference is the follow-up to the 1991 (Dayton, Ohio) conference on the same topic.

The proceedings (which will take place in the fall) will contain approximately 28 papers on five topics. Sessions include: High-temperature structural testing I and II, Instrumentation I and II, and materials.

Basic Structural Behaviour. - Barry Hilson (*Civil Eng, Univ of Brighton, UK*). Telford, London. 1992. 112 pp. ISBN 0-7277-1907-6. £12.95 Europe and UK. (Under review)

Composite Materials in Maritime Structures, vol 1 (Fundamental Aspects) and vol 2 (Practical Considerations). Cambridge Ocean Technology Series 4 and 5. - Edited by R Ajit Shenoi and John F Wellicome (*Univ of Southampton, UK*). Cambridge UP, New York. 1993. 688 pp. ISBN 0-521-45153-1; 0-521-45154-X. $125.00. Info is for 2-vol set. (Under review)

Dual Boundary Element Analysis of Crack Growth. Topics in Engineering, Vol 14. - A Portela (*Wessex IT, UK*). Comput Mech, Billerica MA. 1993. 178 pp. ISBN 1-56252-116-0. $88.00. (Under review)

V. MECHANICS OF FLUIDS

10R21. Water and Wastewater Engineering Hydraulics. - TJ Casey (*Civil Eng, Centre for Water Resources Res, Univ Col, Dublin, Ireland*). Oxford UP, New York. 1992. 270 pp. ISBN 0-19-856360-4. $72.95. Paper $35.95.

Reviewed by John Tuzson (Indust Energy Syst, Gas Res Inst, 8600 W Bryn Mawr Ave, Chicago IL 60631).

This very well written book is very utilitarian without excessive verbiage. It contains all the essential information needed by the users of calculation methods without dwelling on the deeper mysteries of the science of fluid mechanics. Such a style, is difficult to keep up. No wonder then, in an effort to simplify the complexity of fluid mechanics fundamentals, a few mistakes slip in. These errors will not mislead readers with some familiarity of the subject, but might confuse some students. Such glitches, for example, include the statement that "flow is obviously rotational where the streamlines are curved," and omissions to state that conservation of momentum applied to a stream tube must be written independently in the three coordinate directions, and that the momentum equations and energy equation are not independent of each other. Switching from cartesian to streamline coordinates without explanation does not help comprehension.

The author's intent is to derive, explain, and computerize hydraulic calculation procedures frequently used in the design of water distribution and wastewater collection systems. Such subjects include steady and variable flow pattern in piping and open channel systems. While based on solid scientific fundamentals, the calculations are supplemented with empirical constants and correlations which assure that the results are realistic. References to data sources are given. Some uncertainties remain, such as the practical numerical value of the water hammer wave propagation velocity when air is admixed. The author has appended computer program listings for all calculation procedures and offers to send computer discs on demand. These could be very helpful.

Considering the large number of symbols used, it would have been helpful to include a list of symbols and their definitions. This would have helped to avoid coincidences such as alpha for sonic velocity and also for the kinetic energy factor. A conceptually confusing coincidence is the designation of y for the elevation of the free surface in channel flow and also for the independent vertical coordinate.

Clarification of "head" would have been desirable; an English word of many meanings and not particularly appropriate, albeit well entrenched, in hydraulics. We read about piezometric head, total head, differential represented by H or h with a profusion of subscripts which offer opportunities for confusion to a novice.

A three page index is adequate but does not contain such words as "phreatic surface."

The material in *Water and Wastewater Engineering Hydraulics* should be very useful to practicing engineers and could also be used as a text for students who plan to specialize in the practical aspects of water distribution and wastewater collection system design and operation.

10N22. Advances in Turbulence IV. Proceedings of the Fourth European Turbulence Conference, June 30-July 3, 1992. - Edited by FTM Nieuwstadt *(Lab for Aero and Hydromech, Delft Univ of Techn, Netherlands)*. Kluwer, Netherlands. 1993. 576 pp. ISBN 0-7923-2282-7. $198.00. £132.

This volume, reprinted from Applied Scientific Research, 50:3-4, contains contributions from the fourth European Turbulence Conference held in Delft on June 30-July 3, 1992. The papers are grouped into the following main topics of the meeting: Dynamical systems and transition; Statistical physics and turbulence; Experiments and novel experimental techniques; Particles and bubbles in turbulence; Simulation methods; Coherent structures, and Turbulence modeling and compressibility effects.

10N23. Computational Fluid Dynamics. von Karman Institute for Fluid Dynamics-Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-04. $211.00.

The aim of this annual lecture series was to provide in-depth presentations on well-established methods and on recent advances in the field of numerical flow simulation. The program was at a specialist level complementary to the Introduction to CFD. This year's program focussed on higher order space discretization methods for the compressible and incompressible flow equations, and related algorithms. The space discretizations studied were finite volume, FE and spectral methods. Applications were covered in the field of both incompressible flow and aerodynamics, including chemically reacting reentry flows.

The course started with an introduction to the theory of hyerbolic conservation laws, including a comparison of the currently used high-resolution TVD finite volume schemes with newly developed 4th order schemes, including application to unstructured grids.

Alternative discretizations which received equal attention were variational methods such as the FEM and spectral methods. Three lectures were devoted to an overview of variational approaches applied in incompressible and compressible fluid dynamics. Similarly, three lectures were devoted to a review of spectral methods and spectral element methods as an extension towards body-fitted domains. The recent progress in multidimensional upwind discretization was surveyed, including status reports of multidimensional scalar advection schemes and wave decompositions for the compressible Euler equations.

Next to the basic discretizations, attention was given to the time integration methods for unsteady flows and to the iterative solution methods for steady state computations. Acceleration techniques based on preconditioned conjugate gradients, GMRES and multigrid were discussed. Special attention was given to the exploitation of parallellism on distributed memory platforms such as the N-cube, the Intel ipsc or clusters of workstations using PVM.

Contents include: By R Sanders, U Houston, TX: High-order non-oscillatory schemes for the compressible Euler equations; A multigrid acceleration technique for computing steady solutions to the equation of compressible flow. By CP Li, NASA Johnson Space Center, USA: Computational techniques for high speed flows with viscous and chemical effects. By R Abgrail, INRIA, Sophia Antipolis, France: ENO schemes on unstructured meshes; By M Rudgyard, Cerfacs, Toulouse, France: Multidimensional wave decompositions for the Euler equations; Cell vertex methods for steady inviscid flow. By H Deconinck, R Strujis and G Bourgois, von Karman Institute, and PL Roe, U Michigan, USA: Compact advection schemes on unstructured grids. By M Hafez, U California, Davis, USA: Variational approaches to CFD: Applications to potential, Euler, and Navier-Stokes equations. By Y Maday, U Pierre and Marie Curie, Paris, France: Introduction to spectral methods, Application to the Stokes problem; and Introduction to spectral methods for hyperbolic system of conservation laws. By D Roose, KU Leuven, Belgium: Distributed memory parallel computers and computational fluid dynamics.

10N24. Computational Methods for Free and Moving Boundary Problems in Heat and Fluid Flow. - Edited by LC Wrobel and CA Brebbia. Comput Mech, Billerica MA. 1993. 412 pp. ISBN 1562521454. $198.00.

The mathematical modeling of free and moving boundary problems is characterized by the presence of one or more surfaces which are initially unknown or move throughout the analysis. The determination of the location of these surfaces is an important part of the solution procedure, generally involving the use of iterative or time-marching algorithms. Examples of practical engineering problems are numerous, eg. nonlinear wave motion, cavitating flows, solidification and melting, and metal casting, to name a few. The present volume concentrates on computational methods of the solution of such problems with emphasis on boundary and finite elements.

Chapter 1 discusses direct iteration and optimization techniques used in conjunction with the BEM for solution of gravity and pressure-driven free surface flow problems. Chapter 2 uses Baiocchi's integral transformation in a fixed domain method for free surface flow in porous media. Chapters 3 and 4 deal with nonlinear wave motion. The former describes a wave model based on the fully nonlinear potential flow equation to study wave motion in shallow water, including wave overturning induced by the ocean bottom or by coastal engineering structures.

The flow about submerged partially or supercavitating axisymmetric bodies both at zero and non-zero angle of attack is considered in chapter 5. Chapter 6 discusses two implementations of the BEM to solve the slow viscous flow of a fluid moving between parallel plates which are in relative motion. The situations in which petroleum reservoir models generate shocks are considered in chapter 7.

When rain runs down a window pane in a stream, it normally meanders instead of going straight. This interesting problem is analyzed in chapter 8, which presents the condition of stable meandering of water rivulets on an inclined smooth plate, derived by the bend theory including the effect of surface tension.

A series of heat flow problems are considered in chapters 9 to 13. Chapter 9, on solidification problems, presents a macroscopic model for the treatment of the macrosegregation process in a binary material, and a microscopic model of the microsegregation process in the secondary arms of a columnar dendritic mushy region. Chapter 10 presents a complete mathematical model for freezing processes in foodstuffs. Modeling of the thermoelectrical behavior of an aluminum electrolytic cell is presented in chapter 11. This model predicts and asseses fundamental variables in cell operation: form and thickness of the frozen bath, heat flows, position of isotherms, electric potentials, and more.

Chapter 12 presents a resume of work involving the isotherm Migration method. Applications include implicit moving boundaries (oxygen diffusion through absorbing tissues) and melting ranges (mushy problems). The modeling of the filling stage of casting processes is the subject of chapter 13, where a 2D FEM to treat non-steady flows of Newtonian fluids, coupled with heat transfer and turbulence, is described.

Chapter 14 discusses the steady, irrotational, ideal fluid flow produced by a submerged source, or sink, from a region containing three homogeneous layers of fluids at different densities with gravity as the restoring force. In chapter 15 the motion and deformation of viscous drops and gas bubbles, which occur in many industrial and biological systems, are studied through a complete double layer boundary integral equation method. Finally, chapter 16 reviews the historical development and state-of-the-art in Green's function structured discrete approximation methods for modeling microscopic and macroscopic transport phenomena in solid-liquid phase-change systems.

All of the contributors to this book are well-known in their respective fields, with many having research histories extending back over 10 to 20 years or longer. Such experience qualifies them to present these major topics of interest in this field.

10N25. Computational Modelling of Free and Moving Boundary Problems II. - Edited by LC

Wroebel and CA Brebbia (*Wessex IT, UK*). Comput Mech, Billerica MA. 1993. 504 pp. ISBN 1853122424. $139.00. £89.

Free and moving boundary problems are of importance in a large variety of physical situations. The common feature is the presence, in the mathematical modeling, of an initially unknown surface which moves throughout the analysis, the determination of which is an essential part of the solution procedure. These nonlinear problems are difficult to solve analytically but for the simplest cases; because of this, a numerical method of solution usually has to be resorted to. Whichever method is chosen, an efficient computational implementation will require advanced features such as grid adaptivity, moving meshes, particle tracking, or other algorithms.

Although the physical problems under consideration can be completely different in nature, there are several common features in their mathematical modeling and computer methods of solution. This book will therefore be of interest to scientists and engineers from a wide variety of fields working on the development of numerical models for free and moving boundary problems. It contains the edited proceedings of papers presented at the Moving Boundaries Conference held in June, 1993.

Parital contents include: Flow through porous media: Transient simulation of water table aquifers using a pressure dependent storage law; Wave propagation: Flow calculations for a ship traveling in the vicinity of a pycnocline; Stokes flow: A BEM solution for the simulation of axisymmetric viscous sintering; Cavitational flow: Potential flow past a bluff body with and without separation; Free surface flow: A porosity method to compute 3D turbulent free surface flows; FE simulation of free surface flows using arbitrary Lagrangian-Eulerian method; Sediment transport: Numerical simulation of coastal changes; Computational hydraulics: Numerical simulation of flooding and drying in a depth-averaged boundary-fitted tidal model; Solidification and melting: Fusion of PCM in finned plane cavities; Metal casting and welding: A coherence between a castings shape and its total solidification time; Inverse problems: The inverse Stefan design problem; Elasticity problems: Stability and bifurcation of plane cracks of arbitrary shapes; Mathematical formulations and computational techniques: Mass transfer in turbulent flow.

10N26. Introduction to the Modeling of Turbulence. von Karman Institute for Fluid Dynamics-Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-02. $211.00.

The purpose of this lecture series was to provide an introduction to the fundamental physical principles of turbulence and of its modeling, and to make a survey of the models currently available and of their domain of application.

Emphasis was given to those models which can be considered ready for application to a range of problems of practical interest and, in particular, to recent advances in second moment closures, but fields of advanced turbulence modeling, such as Large Eddy Simulation and compressible flow turbulence, were also discussed.

Because of its nature and content, the course was valuable to both researchers and practicing engineers interested in acquiring a fundamental knowledge of the problems and opinions in the domain of turbulence modeling in view of its application to their specific field of interest.

Contents include: By BE Launder, UMIST, Manchester, UK: Introduction; An introduction to second moment closure; Modeling force-field effects on turbulence; A new form of second-moment closure; An introduction to single-point closure methodology; Second moment closure: Present...and future?; and Contribution to the modeling of near-wall turbulence.

By MA Leschziner, UMIST, Manchester, UK: Two-equation models for high Reynolds flow number; Two-equation models for low Reynolds number variants; Inclusion of second-moment closures into finite volume solvers; Numerical implementation and performance of Reynolds stress closures in finite volume computations of recirculating and strongly swirling flows; Application to second-moment closure in complex flows; Modeling engineering flows with Reynolds stress turbulence closure; and Turbulence modeling challenges posed by complex flows.

By W Rodi, U Karlsruhe, Germany: Examples of turbulence model applications. By U Schumann, DLR Oberpffaffenhofen, Germany: Direct and LES of turbulence-summary of the state-of-the-art 1993; LES of turbulent diffusion in stably stratified shear flow; and Numerical simulation of turbulent convective flow over wavy terrain. By D Vandromme, U Rouen, France: Turbulence modeling for compressible flows and implementation in Navier-Stokes solvers.

10N27. Measurement Techniques. von Karman Institute for Fluid Dynamics-Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-05. $211.00.

The aim of this annual lecture series was to provide, on the one hand, general concepts widely applicable in experimental techniques; on the other hand, to select a few topics for in-depth discussions. Some of them are of wide use, others represent recent developments in a particular domain. This year's program focuses on general data acquisition principles and treatment as an example of widely used techniques for different kinds of measurements. The specialized topics retained for the present program were: Pressure measurements; Infrared thermography and Liquid crystal techniques; all of which can be categorized as non-intrusive.

The lectures on pressure measurements only dealt with special, recently developed techniques, such as pressure sensitive paints and laser-induced luminescence. The physical properties on which the techniques are based were explained, and possible applications were illustrated with test cases. The other two techniques were devoted to temperature and heat transfer measurements. The physics of each were discussed in an introductory lecture on Infrared Thermography (IT) and Liquid Crystals (LC). The emphasis was placed on IT. The application domain and limitations of IT and LC were discussed and illustrated. The advantages and disadvantages of one technique or detector with respect to another were covered, and methods for data handling and enhancement were proposed. The illustrations were selected to demonstrate the wide applicability in fluid dynamics of the methods presented. Finally, some perspectives for future developments were discussed, such as faster response instruments. It is expected that this lecture series will stimulate research in the development of these tools for flowfield investigations.

Contents include: By RW Ainsworth, Oxford U, UK: Data acquisition in aerodynamic research; Recent developments in fast response aerodynamic probe technology. By F Lemoine and B Leporcq, IMFL, Lille, France: Static pressure measurements for near isentropic flows using laser induced iodine fluorescence. By RC Crites, McDonnell Douglas Aerospace, St Louis, USA: Pressure sensitive paint technique. By D Balageas and A-M Bouchardy, ONERA Chatillon, France: Fundamentals of infrared thermography; Application of infrared thermography in fluid mechanics; Heat transfer quantitative characterization:Passive and active methods; Perspective and future possibilities. By GM Carlomagno, U Naples, Italy: Infrared thermography. By P Ireland, Oxford U, UK: Liquid crystal heat transfer measurements. By G Rau, J Vanhalst and T Arts, von Karman Institute, Belgium: The application of liquid crystal techniques to determine heat transfer rates.

10N28. Methodology of Hypersonic Testing. von Karman Institute for Fluid Dynamics-Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-03. $211.00.

The aim of this course was to present a comprehensive overview of the methods used in hypersonic testing and evaluation, and to explain the principles behind those test techniques. Lectures were presented by seven American scientists with considerable expertise in hypersonic ground testing. They are all directly or closely affillated with the USAF Arnold Engineering and Development Center; thus, a highly coherent and structured set of lectures was developed.

Topics covered include: an introduction to hypersonic aerodynamics with descriptions of chemical and gas dynamic phenomena associated with hypersonic flight; categories and application of various hypersonic ground test facilities; characterization of facility flowfields; measurement techniques (both intrusive and nonintrusive); hypersonic propulsion test principles and facilities; computational techniques and their integration into test programs; ground-test-to-flight data correlation methods, and test program planning.

Lecturers include: AH Boudreau-AEDC; RA Crawford-U Tennessee Space Institute; RK Matthews-Calspan Co/AEDC Operations; JR Maus-Calspan Co/AEDC Operations; VK Smith-Sverdrup Technology Inc/AEDC Group; BM Wettlaufer-Sverdrup Technology/AEDC Group; and WD Williams-Calspan Co/AEDC Operations.

Contents include: Hypersonic overview; Hypersonic flow phenomenology; Hypersonic propulsion characterization; Characterization of flowfields in hypersonic ground test facilities; Aerodynamic and aerothermal facilities; Aeropropulsion facilities; Computational techniques and capabilities; Test and evaluation methods; Materials-structures testing; Aeropropulsion test and evaluation methods; Hypersonic flowfield measurements-nonintrusive; Hypersonic flowfield measurements-intrusive; Hypersonic flight test; Extrapolation of ground test data to flight; Boundary layer transition; Shock-boundary layer-shock interactions; Electromagnetic wave test; Propulsion integration; and Generic test planning.

10N29. Non-Intrusive Measurement Techniques. von Karman Institute for Fluid Dynamics, Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-09. $211.00.

In recent years non-intrusive measurement techniques have been the object of a spectacular development. They are now used in all fields of fluid dynamics and they allow the measurement of many scalar flow parameters as well as velocity. It is the objective of this lecture series to present an up-to-date review of the available techniques and of their implementation in various types of measurement problems in fluid dynamics.

Optical interferometry is an old classic in fluid dynamics, but it recently received considerable attention. This is the reason why lectures present the state of the art of this technique. Lectures are also devoted to a presentation of infrared imaging techniques and their potential. The fast growing domains of laser induced fluorescence (LIF), electron beam fluorescence (EBF), and raman scattering (CARS) are the object of several lectures. Principles as well as applications of these techniques are presented and discussed. Velocity measurements are among the most important ones in fluid dynamics. This is the reason why several courses are devoted to them. The recent developments of laser doppler velocimetry and particle image velocimetry are presented in a series of lectures. Basic principles as well as practical aspects, such as seeding and signal processing, are discussed. This lecture series should allow an overall appraisal of the present potential of available non-intrusive measurement techniques applied to fluid dynamics.

Contents include: By A Deom, ONERA, France: Infrared imaging. By C Dankert, DLR, Germany: Laser induced interferometry; Electron beam fluorescence. By M Pealat, ONERA, France: Raman scattering techniques. By L Lourenco, FAMU-FSU, USA: Particle image velocimetry. By A Boutier, ONERA, France: Laser doppler velocimetry. By W Merzkirch, U of Essen, Germany: Interferometric methods.

10N30. Supercomputing in Fluid Flow. - Edited by TKS Murthy and CA Brebbia *(UK)*. Comput Mech, Billerica MA. 1992. 368 pp. ISBN 0945824599. $180.00. £100.

The speed and power of supercomputers is continually being improved, and new types of architecture and algorithms are simulataneously being developed so that supercomputing applications can take advantage of them. Among all the applications of supercomputing for numerically intensive problems, perhaps the most significant is in computational fluid dynamics (CFD), particularly in the graphic visualization of the fluid flow field. In the problems of the aerodynamics of aircraft, spacecraft and automobiles, mathematical modeling with supercomputing is now a viable alternative for obtaining speedy and less expensive results compared to model testing. This book contains the edited versions of the papers presented at the International Seminar on Supercomputing in Fluid Flow, held in Massachusetts, USA in 1989.

The international flavor of the contents of the book is evidenced by the contributions of authors from nine different countries. The volume presents and discusses advances in the application of supercomputing to numerically intensive problems in the simulation of fluid flow, mainly centered on the solution of the Navier-Stokes or the Euler equations for which several high-level algorithms and codes are now being developed. These new algorithms and codes are required in order to exploit the increasingly sophisticated types of architecture, such as parallel processing and vector processing, which are now available.

Contents include: FE algorithms for the Euler equations on the connection machine; Design of a 3D multidomain Euler code; 3D full Navier-Stokes solvers for incompressible flows past arbitrary geometrics using supercomputers; A unified parallelizable multigrid approach to solve steady Euler- and Navier-Stokes equations; Computation of incompressible fluid flows about bodies with appendages; Simulation of unsteady 3D flows around an automobile and its visualization; Applications of LES to complicated flow fields; Mathematical modeling, numerical solution and visualization of steady 3D swirling fluid flow with turbulence and solid particles; Turbulence modeling for transition studies; Navier-Stokes computations of turbulent transonic flow around aircraft wings; Numerical simulation of 3D viscous transonic flows with separation; Supercomputing in hypersonic flow with non-equilibrium effets; Restructuring CFD algorithms for vector and parallel computers; and Numerical simulation of internal flows in the automotive industry.

10N31. Ventilation. von Karman Institute for Fluid Dynamics, Lecture Series Monographs. - VKI Fluid Dyn, Rhode-St-Genese, Belgium. 1993. ISBN VKI LS 1993-07. $211.00.

Following a general introduction to the subject of ventilation, the lectures in this series dealt with the indoor air quality and the thermal environment in ventilated or air-conditioned spaces identifying the newest information for design rules.

The principles and citeria of ventilation systems are then discussed. Natural and mechanical ventilation and contaminent control methods are covered. Different empirical flow calculations for steady state and time-dependent contaminent generation and air flow rate situations are presented. Their application to sizing of air diffusers, ...al exhausts, filters and air curtains are illustrated in the cases of laboratory fume and biological safety hoods, grinding booths and spray painting rooms.

The theory of age distribution and N-zone models are described. The use of these tools are illustrated in distinguishing different principles, such as displacement or mixing ventilation. Their practical interest in evaulating the effectiveness of ventilation systems are underlined. Emphasis is then given to design methodology and innovative technology in the field of industrial ventilation. In particular are lectures given on dust and dust control systems, field testing, and monitoring aspects. Application of capital and operating cost databases are exemplified through case studies.

The last session of the course demonstrates the benefit of computational fluid dynamics in the scope of ventilation design. Several numerical models developed to simulate the thermo-aeraulic behavior of ventilating systems are presented. Simulations of displacement flow, contaminent transport and flow around obstacles are exemplified. New developments in this field focus on the international benchmark exercise Annexe 20.

Contents include: By G Aubertin, INRS, France: Introduction to the design of ventilation systems. By O Fanger, Technical U of Denmark: Human requirements to the indoor air quality and the thermal environment. By L Olander, National Board of Occupational Safety and Health, Sweden: Ventilation systems. By E Skaret, Norwegian Building Research Institute, Norway: Theory of age distribution; Ventilation models. By H Goodfellow, Environmental and Occupational Health, Canada: Industrial ventilation; Ventilation cost and air cleaning. By PV Nielsen, Aalborg U, Denmark: Computational fluid dynamics (CFD) in ventilation:Theory and 1D test case; CFD in ventilation: Theory and codes; CFD in ventilation: The IEA Annex and 20 Work; Commercial applications of CFD in ventilation; New developments in CFD with relevance to ventilation. By JR Fontaine, INRS, France: CFD in ventilation: A practical approach. By T Bidot, Simulog, France: CFD in ventilation: A practical approach.

Incompressible Computational Fluid Dynamics. Trends and Advances. - Edited by Max D Gunzburger *(VPI)* and Roy A Nicolaides *(Carnegie Mellon Univ)*. Cambridge UP, New York. 1993. 468 pp. ISBN 0-521-40407-X. (Under review)

Topics in Fluid Mechanics. - Rene Chevray *(Columbia Univ)* and Jean Mathieu *(Univ of Lyon I, France)*. Cambridge UP, New York. 1993. 384 pp. ISBN 41082-7. Paper ISBN 42272-8. $125.00. Paper $49.95. (Under review)

VI. HEAT TRANSFER

10R32. Introduction to Thermal Sciences; Second Edition. Thermodynamics, Fluid Dynamics, Heat Transfer. - Frank W Schmidt, R E Henderson, C H Wolgemuth *(Penn State)*. Wiley, New York. 1992. 476 pp. ISBN 0-471-54939-8.

Reviewed by Franklin T Dodge (Div of Mech and Fluids Eng, SWRI, PO Drawer 28510, San Antonio TX 78228-0510).

As the preface states, this textbook is meant to give an overview of thermodynamics, fluid dynamics, and heat transfer to engineering undergraduates who are not mechanical engineering majors, for the purpose of introducing them to the important principles of energy and its use, transfer, and conversion. In order to cover the multitude of topics encompassed by this subject, the authors have generally adopted a scheme in which the principles or theory of a topic are described briefly and then further explained in the form of detailed work examples, including explanatory comments. This is satisfactory for the intended audience, but probably would not be optimal for mechanical engineering majors who are expected to be able to apply the principles to new problems.

The topical coverage of the book is thorough, and the chapters include: Thermodynamic concepts and definitions; Properties of pure substances; System analysis-first and second laws; Control volume analysis; External flow - fluid viscous and thermal effects; Internal flows - fluid viscous and thermal effects; Conduction heat transfer; and Thermal radiation heat transfer. Chapters 6 and 7 are about equally divided between fluid flow and convection heat transfer. These two chapters also include some of the more application-oriented topics, such as heat exchangers. The authors have included example problems throughout the book that should be of interest to civil and electrical engineers. However, the reviewer did not notice, except for one or two homework problems, any coverage of the increasingly important topic of electronic component cooling.

The book is attractively printed with clear, well drawn figures and many photographs. Good use is made of highlighting to emphasize important material. As might be expected of a book written by three authors, the writing style varies from chapter to chapter. For example, the chapters on thermodynamics are dominated by example problems, while the chapters on fluid flow contain a lot of theory and discussion as well as examples. The total amount of material covered appears to be considerably too much for a one semester course, although the authors state that is the book's intended use.

There is presently a wide selection of texts covering the combined "thermal sciences" from which teachers can select. *Introduction to Thermal Sciences* is one of the better ones, and I would not hesitate to recommend it.

VII. EARTH SCIENCES

10R33. Statics and Kinematics of Granular Materials. - R M Nedderman

(Dept of Chem Eng, Univ of Cambridge, Cambridge MA). Cambridge UP, New York. 1992. 352 pp. ISBN 0-521-40435-5.

Reviewed by Anthony Rosato (Dept Mech & Indust Eng, NJIT, 200 Central Ave, Newark NJ 07102).

The widespread use of granular materials in diverse fields, such as agriculture, pharmaceuticals, coal and mineral handling, chemical processing, metal and ceramic composites, and in natural geophysical flows, has stimulated extensive research into understanding the behavior of these materials. Nedderman attempts to provide a resource, directed to a wide audience (from undergraduates to researchers in the field), in which "principles of granular materials are rigorously treated" from a continuum approach. As the title implies, the book is divided into two parts. Following a brief introduction and a presentation of the usual concepts of stress, strain, and Mohr's circle, chapters 3-7 discuss the statics of granular materials based on Couloumb's yield criterion and flow kinematics. The second part, chapters 8-10, is concerned with flow kinematics. Each chapter includes a succinct introductory summary of what follows. This feature is extremely useful to help the reader place the material within the larger framework of the book.

In chapter 3, the author provides a clear exposition of the ideal Coulomb material, Mohr-Coulomb failure, and active and passive states, concluding with the criterion for failure or slip along a wall. The derivations are presented well with good physical insight. The material flows easily to the next chapter, "Coulomb's Method of Wedges," which starts from an analysis of the force exerted by a cohesionless material on a vertical retaining wall and progresses to twin retaining walls. Assumptions are stated at the outset and reinforced in the explanations so that the reader does not lose sight of the applicability of the method.

Chapter 5 presents Jannsen's original analysis in short form, highlighting its inherent assumptions for the stress distribution in a cylindrical bunker filled with a cohesionless granular material. Included is an analysis of bunkers with arbitrary cross-sections. A discussion of Walker's improved analysis follows with application to conical and wedge-shaped hoppers. Failure of bunkers as a result of a stress jump near the wall at discharge initiation is then demonstrated using Walter's qualitative switch stress treatment. The chapter concludes with a discussion of Enstad's study in a conical hopper for which it is assumed that the minor or principal stress is constant on a spherical surface across the hopper.

Material properties and their influence on flow behavior is treated in chapter 6. After short description of the effects of pressure on densification, a few pages are devoted to particle size analysis which is concluded with a sample problem. The next section briefly touches on permeability related to fluid flow through a granular bed. This topic is oddly placed and does not fit in well with the theme of the chapter and the book in general - kinematic analysis of dry granular flows. Internal failure property measurement and interpretation of shear cell results is discussed; the chapter concludes with a brief note on wall frictional properties.

Chapter 7, "Exact Stress Analysis," examines the stress distributions in granular materials based on the Coulomb yield criterion in a more precise manner. After introducing the basic equations, particular solutions are presented for the asymptotic stress distributions between parallel planes and cylindrical bunkers. Problems associated with the solution technique for fully rough walls and procedures for cohesive materials conclude the section. This is followed by an analysis of the concical hopper in which numerical solutions of the governing equations are explained. In section 7.5, useful comparisons of the distribution factor in cylindrical bins and the radial stress field are made with the approximate results from chapter 5. The method of characteristics is carefully explained in section 7.6, and a variety of different applications are presented in the sections that follow (ie, single retaining walls with and without surcharges, inclined top surfaces and walls, and twin retaining walls). The remainder of the chapter discusses the stress discontinuity in the context of the method of characteristics; the chapter concludes with a more rigorous treatment of the switch stress which was briefly introduced in section 5.9.

Chapter 8 focuses on modeling the velocity field in flowing-discharging granular materials using concepts from plasticity theory. As background, the chapter begins with a brief discussion of kinematic modeling by citing the contributions of Mullins and Litwiniszyn and then detailing the work of Nedderman and Tuzun. The concepts of yield function, plastic potential, and flow rules are introduced and the principle of coaxiality is developed in algebraic form. Evaluation of the radial velocity field in constant cross-section bunkers as well as conical or wedge-shaped hoppers is followed by a prediction of the transition from core to mass flow in conical hoppers. The chapter concludes with a discussion of the method of characteristics and discontinuous velocity fields.

The topic of chapter 9 is the Conical Yield function, which is derived and compared with the Coulomb criterion. This is followed by a discussion of Levy's flow rule used to find the radial stress distribution and velocity fields for radial incompressible hopper flow. The material of this chapter is presented well and the connections made with the analyses in chapter 7 are very helpful.

The final chapter, concerned with the prediction of mass flow rates, begins with a discussion of various mass flow rate correlations and some early theories based on the existence of a "free-fall arch." A well-written discussion of the hour-glass theory as originally developed by Savage, is presented in 10.4, while the effects of rough walls on hopper discharge rates is developed in section 10.5. The remainder of the chapter addresses various related topics such as air-augmented flow, fine powder flows, arching, and flooding.

Statics and Kinematics of Granular Materials provides a very good treatment of this important subject. Concepts and ideas are clearly developed with an emphasis on connections between experiments and theories. The book could be enhanced by incorporating example problems in the chapter discussions to illustrate the theories, by including additional homework problems placed at the end of each chapter rather than the existing compilation of all problems at the end of the book, and by expanding the somewhat narrow list of references. Despite these shortcomings, it is suitable as a text for a graduate level course and the first six chapters could easily be adapted for an upper level undergraduate course. The author has presented a self-contained treatment of the statics and kinematic behavior of particulates and it should be an important resource in this field.

VIII. ENERGY & ENVIRONMENT

10R34. Planning of Geothermal District Heating Systems. - Alberto Piatti *(Techint, Italy),* Carlo Piemonte *(Polytech of Milan, Italy),* Edoardo Szego *(Techint, Italy).* Kluwer, Netherlands. 1992. 328 pp. ISBN 0-7923-1968-0. $129.00. £68.

Reviewed by Gladius Lewis (Dept of Mech Eng, Memphis State Univ, Memphis TN 38152).

The existence of geothermal energy resources in many parts of the world is well known. In recent years, the exploitation of these resources for a variety of end-use(s) has surged. These include: electricity generation in the Imperial Valley and the

Geysers, California, USA; greenhouse warming in Tuscany, Italy; district heating in Reykjavik, Iceland; and refrigeration in Rotorua, New Zealand. Nonetheless, little has appeared in the open literature on the details of the design of existing or planned geothermal energy-driven schemes. Perhaps because of this dearth of information, design of such schemes is usually perceived to be abstruse if not esoteric.

Thus, a simple litmus test of the success of any publication (especially a book, which has any hopes of attracting a wide readership) on the design of such schemes should be the extent to which it is simultaneously easy to read and accurate in its contents. It is against this background that this book has been evaluated by the present reviewer.

The book is arranged into six chapters and two appendices containing details of a computer program that is a necessary adjunct to the text.

The first two chapters set the tone for the style of the book. They contain a brief background to the events that led to and culminated in the writing of the book; a statement of its aims and objectives, which are precisely enunciated as being "to analyze the influence of the different parameters that may affect the energy balances and the economic feasibility of geothermal district heating systems"; and an enumeration of elements of the systems considered (namely, the heat exchanger, heat pump, and peak load boiler) and three research phases. Finally, an outline is presented of the methodology that is followed in the examination of the schemes studied.

There are eight sections in the third chapter, "District Heating Thermal Production Stations Fed by Geothermal Energy: Types of Flow Systems." The first section provides an introduction of the main features and definitions of the energy efficiency for the four "basic flow systems" considered. These are identified as: heat exchanger between the geothermal fluid and the district heating water; heat pump only, with direct connections between the evaporator of the pump and the geothermal fluid; heat pump assisted, with direct evaporation; and heat pump assisted, with indirect evaporation (referred to in the book by the acronyms HE, HPO, HPA-DE, and HPA-IE, respectively).

The next four sections contain details of each of the aforementioned systems, with the authors clearly identifying the conditions under which each may be used; addressing the issue of the relative investment and operating costs; and carefully deriving (making use of appropriate diagrams) expressions for the energy efficiency ratios [(thermal power extracted from the geothermal fluid)/(mechanical power input of heat pump compressor), $P_g/P_m c$; and (base load units total thermal power)/(electric power input of heat pump motor or thermal power of the fuel consumed by the heat pump engine), P_b/P_x] in the case of the HPO, HPA-DE, and HPA-IE systems.

The sixth section contains a comprehensive comparison of the aforemetioned energy efficiency ratios of the different flow systems that use heat umps. Here, the authors have encapsulated the relevant results in the form of suitable graphs. One example are graphs showing the variation of P_b/P_x with district heating water outlet temperature from the heat pump condenser for different combinations of geothermal fluid discharge and district heating water return temperatures in the case of engine- and electricity-driven HPA-DE systems (for a specified geothermal fluid well-head temperature). Based on the results presented in these sections, the authors go on to summarize the main conclusions regarding the relative utility of the HPO, HPA-DE, and HPA-IE systems. Thus, they report that the energy efficiency of a heat pump-only system is lower than that of a heat pump-assisted one, and that a HPA-IE system allows a greater design and operational flexibility, but has a lower efficiency compared to a HPA-DE one.

The seventh section in this chapter deals with the characteristics of the various formats for connecting heat pumps (such as series, parallel, and series-parallel). In the final section, the similarities and differences between the two "basic systems" selected for detailed study in the book (namely, the HPO and the engine- and electricity-driven HPA-DE ones) are presented.

In the first part of the fourth chapter, "Selection of the Application Cases to be Examined," six parameters that are perceived by the authors to exert the greatest influence on the performance (and, hence, the economic viability) of geothermal district heating systems are identified. These are: well-head characteristics [temperature, flow rate, depth, type of fluid, and distance between the well(s) and the heat production station]; supply and return temperatures of the heating network; characteristics of the use of the thermal energy (such as thermal density and peak load power); cost of fuels used by the thermal plants prior to the connection to the geothermal scheme; characteristics of the heat production station (such as type of flow system and type of heat pump prime mover); and cost of fuel and electrical energy used in the heat production system.

In the second part of this chapter, the role of each of these parameters is examined in a qualitative manner. In the third part, a detailed quantitative examination of three of these parameters (which are considered to define the "base cases" for study) is performed. These are: the well-head fluid temperature; district heating temperature; and the type of heat pump prime mover. Then, 21 such "basic cases" are selected, representing three combinations of well-head fluid temperature (and, hence, well-head depth) and maximum delivery and return temperatures of the network; and two types of heat pump prime mover. In addition, the authors selected other cases that allowed sensitivity analyses of six other relevant parameters (such as the type of the geothermal fluid and the number of heat pumps) [when well-head fluid temperature and maximum delivery-return temperatures of the network are held constant].

The final part of this chapter is dedicated to miscellaneous topics. These include: a consideration of the differences in design approach when the constraint is variable total thermal power required by the users and when it is constant total thermal power required by the users; geothermal fluid flow rate; and heat exchanger systems.

The fifth chapter, "Selection of the Input Data for the Examined Cases," presents all the data needed for the analysis of the cases studied. Thus, the chapter contains explanations and details of the technical data (such as well-head temperature of between 30°C and 90°C; a fixed head of 2bar for the pumping units; 85% efficiency for the peak load boilers; and 4320 h/y of heating required); the time schedule for the development of the system (for example, 50% of the user connections to the network during the year in which the network is installed); and expressions that are used to calculate the relevant economic variables (such as distribution network and geothermal well utilities costs) as well actual economic data (such as 0.38ECU/kg for the price of gasoil and 35,000 ECU/year for a clerk's salary).

In the sixth chapter, "Results and Comparisons," results (obtained with the aid of a computer program, GEOTERM, whose flow chart and example output are given in the appendices) are presented for the energy and economic analyses of 96 cases that represent the effect of 7 parameters (such as type of heat pump prime mover, district heating network temperatures, and well-head depth) on the performance of the case (as reflected in the magnitude of both engineering and economic characteristics, such as yearly energy savings, internal rate of return, and steady yearly cash flow). After each set of results, the authors have provided a narrative that contains the conclusions and implications drawn from the results.

The book has many attractive features, such as the conciseness of its presentation; the clearly-drawn, well-annotated, easy-to-read graphs; the sensible use of tables to present results; and the emphasis on the engineering performance-economic feasibility nexus. Its *piece de resistance*, undoubtedly, is the breadth and depth of the sensitivity analyses of the effect of a wide array of relevant parameters on the performance of geothermal district heating systems. The treatment here is certainly comprehensive and probably exhaustive.

My only reservation about this book is one that I offer *en passant*. This is the observation that nothing is included on the geothermal energy resource itself (aspects such as how it arises; methods of measuring the magnitude of the thermal gradient; the relative merits and drawbacks of the dry steam, hot water, and hot dry rock manifestation of the resource; and environmental issues) *vis a vis* its use for district heating. This material (either in a succinct manner in the main body of the text itself or in a more detailed fashion in an appendix) would have added some contexual weight to the book. The issue of environmental impact is particulary apposite.

All things considered, though, *Planning of Geothermal District Heating Systems* is a fine text on a subject which has not received much attention (as far as books are concerned) and which deals with an application that is very attractive in many parts of the world, from Iceland and Italy in the northern hemisphere to Australia and Indonesia in the southern. Thus, the reader for this book is potentially quite large, and this reviewer highly recommends it to thermal systems designer engineers and energy economists alike.

I. FOUNDATIONS & BASIC METHODS

102. Finite element methods

102A. GENERAL THEORY

10A1. Adaptive FE analysis of large strain elastic response. - K Kato, NS Lee, KJ Bathe *(Dept of Mech Eng, MIT)*. Comput Struct 47(4-5) 829-855 (3 Jun 1993).

Some basic studies and developments for adaptive procedures in large strain FE analysis are presented: an evaluation of higher-order elements, two pointwise indicators for errors in stresses, a mesh generator for remeshing on the deformed configuration of the body, and a general mapping scheme for transferring solution variables across models. The methods discussed constitute the ingredients of a proposed adaptive process that is demonstrated in solutions of 2D stress analyses of rubber-like materials including contact conditions.

10A2. Inf-sup test. - D Chapelle and KJ Bathe *(MIT)*. Comput Struct 47(4-5) 537-545 (3 Jun 1993).

We briefly review the inf-sup condition for the FE solution of problems in incompressible elasticity, and then propose a numerical test on whether the inf-sup condition is passed. The evaluation of elements with this test is simple, and various results are presented. This inf-sup test will prove useful for many discretizations of constrained variational problems.

102C. STRUCTURAL APPLICATIONS

10A3. Variable node plate bending element for mat foundation analysis. - CK Choi and HS Kim *(Dept of Civil Eng, Korea Adv Inst of Sci and Tech, Taejon 305-701, Korea)*. Comput Struct 47(3) 371-381 (3 May 1993).

The variable node plate bending element, ie, an element with one or two additional mid-side nodes is used effectively in the analysis of a mat foundation. The variable node elements can generate a nearly ideal grid for mat foundation analysis in which more nodes are defined near the column location where the steep stress gradient is expected. The plate bending element used in this study is based on Mindlin-Reissner plate theory with substitute shear strain fields. The nodal stresses of that element are obtained by local smoothing. The interaction between the soil and the mat foundation is modeled with Winkler springs connected to nodal points in the mat model. The vertical stiffness of the soil material is represented in terms of a modulus of subgrade reaction and is computed in a similar way to the computation of consistent nodal force of uniform surface loading. Several mesh schemes were proposed and tested in order to find the most suitable scheme for mat foundation analysis.

102G. FLUID MECHANICS APPLICATIONS

10A4. Computationally efficient modification of mixed FEMs for flow problems with full transmissivity tensors. - J Koebbe *(Dept of Math and Stat, Utah State Univ, Logan UT 84322-3900)*. Numer Methods PDE 9(4) 339-356 (Jul 1993).

The mixed FEM for approximatly solving flow equations in porous media has received a good deal of attention in the literature. The main idea is to solve for the head-pressure and fluid velocity (Darcy velocity) simultaneously to obtain a higher-order approximation of the fluid velocity. In the case of a diagonal transmissivity tensor the algebraic equations resulting from the discretization can be reduced to a system of algebraic equations for the head-pressure variable alone. This reduction results in a smaller number of unknowns to be solved for an iterative method such as a preconditioned conjugate gradient method. The fluid velocity is then obtained from an algebraic relationship. In the cases of full transmissivity tensor, the algebraic reduction is more difficult. This paper investigates some algorithms resulting from the modification of the mixed FE that take advantage of the mixed FEM for the diagonal tensor case. The resulting schemes are more efficient implementations that maintain the same order of accuracy as the original schemes.

10A5. Element diameter free stability parameters for stabilized methods applied to fluids. - LP Franca *(Lab Nacional Comput Cientifica, LNCC-CNPq, Rua Lauro Muller 455, 22290 Rio de Janeiro RJ, Brazil)* and AL Madureira *(Inst Politenico, Rua Alberto Rangel s/N, 28630 Nova Friburgo RJ, Brazil)*. Comput Methods Appl Mech Eng 105(3) 395-403 (June 1993).

Stability parameters for stabilized methods in fluids are suggested. The computation of the largest eigenvalue of a generalized eigenvalue problem replaces controversial definitions of element diameters and inverse estimate constants, used heretofore to compute these stability parameters. The design is employed in the advective-diffusive method, incompressible Navier-Stokes equations and the Stokes problem.

102J. OTHER APPLICATIONS

10A6. FE analysis of heat transfer in anisotropic solids: Application to manufacturing problems. - P Newnham and S Abrate *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401)*. J Reinforced Plastics Composites 12(8) 854-864 (Aug 1993).

A general formulation for the FE analysis of heat transfer problems in anisotropic laminated composite materials is presented. Two-dimensional analyses using quadrilateral isoparametric elements are performed for two classes of problems: laser cutting of laminates and non-destructive testing using thermography. Results show complex temperature distributions near the laser beam. The size of the heat affected zone fibers relative to the cutting direction. Temperature distributions in laminates with delaminations subjected to heat flow through the thickness, are shown to be strongly affected by the location of the delamination.

10A7. Studies of an interface relaxation domain decomposition technique using FEs on a parallel computer. - KP Wang and JC Bruch Jr *(Dept of Mech and Env Eng, UC, Santa Barbara CA 93106-5070)*. Numer Methods PDE 9(4) 373-394 (Jul 1993).

Studies are presented for an interface relaxation domain decomposition technique using FEs on an iPSC-2 D5 Hypercube Concurrent computer. The general type of problem to be solved is one governed by a partial differential equation. The application of the approach, however, will be extended to a free boundary value problem by appropriate modification of the numerical scheme. Using the domain decomposition technique, the computation domain is subdivided into several subdomains. In addition, on the interfaces between two adjacent subdomains are imposed a continuity condition on one side and an equilibrium condition on the other side. Successive over-relaxation processes are then carried out in all subdomains with a relaxation iterative process imposed on the interfaces. With this domain decomposition technique, the problem can be solved parallelly until convergence is reached both in the interiors and on the interfaces of all subdomains.

10A49. Random vibration of structures by the FEM

102L. SOLUTION ALGORITHMS

10A8. FE spaces with discontinuity capturing Part I. Transport problems with boundary layers. - EG Dutra do Carmo *(Programma Eng Nucl - COPPE-UFRJ CP 68 509 - CEP 21 945, Rio de Janeiro RJ, Brazil)*. Comput Methods Appl Mech Eng 105(3) 299-314 (June 1993).

New FE spaces are proposed for transport problems to accurately approximate the solution inside the boundary layers. To this end, discontinuity capturing functions are introduced with additional dof only in the elements that contain the boundary layers. Numerical results show the high accuracy of the approximate solution in the new spaces with usual meshes.

10A9. Galerkin FE technique for stochastic field problems. - SA Ramu *(Dept of Civil Eng, Indian Inst of Sci, Bangalore 560 012, India)* and R Ganesan *(Dept of Mech Eng, Concordia Univ, Montreal, H3G 1M8, Canada)*. Comput Methods Appl Mech Eng 105(3) 315-331 (June 1993).

A new FEM is developed to analyze the structures with more than one parameter behaving in a stochastic manner. The Galerkin weighted residual method is used. As a generalization, this paper treats the random eigenvalue problem arising when the material property values of the structural systems are having stochastic fluctuations, ie, the measurement errors can be accounted for when probabilistic modeling is used. The free vibration problem of a stochastic beam whose Young's modulus and mass density are distributed stochastically is considered. Using Galerkin's weighted residual procedure, a stochastic FEM is developed and implemented to arrive at a random algebraic eigenvalue problem. The stochastic characteristics of eigensolutions are derived in terms of the stochastic material property variations. Numerical examples are given. It is demonstrated that through this formulation the FE discretization need not be dependent on the characteristics of stochastic fields describing the fluctuations in the material property values. Further, calculation of covariances between stiffness elements, mass elements, etc, is carried out in a relatively simple manner and is more general in nature.

10A10. Implementation of FE nonlinear Galerkin methods using hierarchical bases. - J Laminie, F Pascal, R Temam *(Lab d'Analyse Numerique, Batiment 425, 91405 Orsay Cedex, France)*. Comput Mech 11(5-6) 384-407 (1993).

The nonliner Galerkin methods are investigated in the framework of FE discretization. We first describe the theoretical background in relation with multilevel and FE approximations of the attractors. Then on the computational side, we recall the definition of the hierarchical bases and analyze the structure associated to these bases. Finally we present the scheme and report on numerical experiments performed on 2D equations of the Burgers and Navier-Stokes type. Their consistency with the approximation that we make and with the structure of the algorithm is discussed.

10A11. Numerical solution of the Fokker-Planck equation for nonlinear stochastic systems. - BF Spencer Jr *(Dept of Civil Eng and Geol Sci, Univ of Notre Dame, Notre Dame IN 46556-0767)* and LA Bergman *(Dept of Aeronaut and Astronaut Eng, Univ of Illinois, Urbana IL 61801-0236)*. Nonlinear Dyn 4(4) 357-372 (Aug 1993).

The FEM is applied to the solution of the transient Fokker-Planck equation for several often cited nonlinear stochastic systems accurately giving, for the first time, the joint probability density function of the response for a given initial distribution. The method accommodates nonlinearity in both stiffness and damping as well as both additive and multiplicative excitation, although only the former is considered herein. In contrast to the usual approach of directly solving the backward Kolmogorov equation, when appropriate boundary conditions are prescribed, the probability density function associated with the first passage problem can be directly obtained. Standard numerical methods are employed, and results are shown to be highly accurate. Several systems are examined, including linear, Duffing, and Van der Pol oscillators.

10A12. Parallel FEM with a supercomputer network. - G Yagawa, A Yoshioka, S Yoshimura *(Dept of Nucl Eng, Univ of Tokyo, 7-3-1 Hongo Bunkyo, Tokyo 113, Japan)*, N Soneda *(Central Res Inst, Elec Power Indust, 2-11-1 Iwatokita Komae, Tokyo 201, Japan)*. Comput Struct 47(3) 407-418 (3 May 1993).

Computer simulations are about to replace experiments in various fields, and the scale of the models to be simulated tend to be extremely large. To perform large-scale FE analyses, the authors propose the parallel use of multiple supercomputers connected to one another through a high-speed network. In other words, a supercomputer network is regarded as a parallel computer. As a parallel numerical algorithm for the FE analysis, we adopt the domain decomposition method (DDM) combined with an iterative solver, ie, the conjugate gradient (CG) method, where a whole analysis domain is fictitiously divided into a number of subdomains without overlapping. FE analyses of the subdomains are performed under the constraint of both displacement continuity and force equivalence among subdomains. Such a constraint can be satisfied through iterative calculations such as the CG method. The present DDM-based parallel FE algorithm is combined with the server-client model for data and processor management to have the workload balanced dynamically between the processors, and is implemented first on an engineering workstation (EWS) network and then on a supercomputer network. The accuracy and parallel performance of the present system are tested using the network composed of various EWSs. Finally, it is demonstrated that the present system implemented on the supercomputer network can solve the 3D elasticity problem of over one million dof at an extremely high average speed of 1.74 GFLOPS.

10A13. Recent advances for practical FE analysis. - KJ Bathe *(MIT)*, J Walczak, H Zhang *(ADINA R&D, 71 Elton Ave, Watertown MA 02172)*. Comput Struct 47(4-5) 511-521 (3 Jun 1993).

This paper illustrates some recent advances in FE procedures that are important for practical engineering analysis. Capabilities to solve large FE systems using iterative methods, and some significant advances in FE procedures for the nonlinear analysis of structures and fluids are demonstrated. The emphasis is on presenting solution results that demonstrate the applicability of FE procedures rather than on theoretical developments (which are available in references).

10A14. Relationship between nodal schemes and mixed-hybrid FEs. - JP Hennart *(Dept Metodos Matematicos y Numericos, Inst Investigaciones en Matematicas Aplicadas Sist, Univ Nacional Autonoma, Apartado Postal 20-726, 01000 Mexico)* and E Del Valle *(Dept Ingenieria Nucl, Escuela Superior Fisica Matematicas Inst Politec Nacional, Unidad Profesional "Adolfo Lopez Mateos", 07738 Mexico)*. Numer Methods PDE 9(4) 411-430 (Jul 1993).

The relationships between a general family of nodal schemes and primal nonconforming as well as mixed-hybrid FE formulations are explored in this paper. It is shown in particular that the nodal schemes proposed are quite natural extensions in rectangular geometry of the Raviart-Thomas-Nedelec mixed-hybrid FEs. This paper is a revised and extended version with new numerical results of part of a previous research report.

102N. ELEMENT DEVELOPMENT

10A15. Assumed strain stabilization of the eight node hexahedral element. - T Belytschko and LP Bindeman *(McCormick Sch of Eng and Appl Sci, Dept of Civil Eng, Tech Inst, NWU)*. Comput Methods Appl Mech Eng 105(2) 225-260 (Jun 1993).

An accurate and robust stabilization based on the assumed strain method and an operator orthogonal to constant strain fields is presented for an eight-node hexahedral element with uniform reduced integration. The stabilization forces depend only on the element geometry and material properties. User specified parameters are not needed, yet the assumed strain stabilization is nearly as fast as perturbation type hourglass control in an explicit code. It has an excellent coarse mesh accuracy for linear elastic bending, and is easily incorporated into a nonlinear program. The assumed strain field is also used with four-point integration which does not require stabilization. In addition, two forms of the B-matrix are studied and it is shown that the mean form is more efficient since it passes the patch test in a simplified form.

10A16. Fast algorithm for generating constrained Delaunay triangulations. - SW Sloan *(Dept of Civil Eng and Surveying, Univ of Newcastle, Shortland NSW 2308, Australia)*. Comput Struct 47(3) 441-450 (3 May 1993).

A fast algorithm for generating constrained 2D Delaunay triangulations is described. The scheme permits certain edges to be specified in the final triangulation, such as those that correspond to domain boundaries or natural interfaces, and is suitable for mesh generation and contour plotting applications. Detailed timing statistics indicate that its CPU time requirement is roughly proportional to the number of points in the data set. Subject to the conditions imposed by the edge constraints, the Delaunay scheme automatically avoids the formation of long thin triangles and thus gives high quality grids. A major advantage of the method is that it does not require extra points to be added to the data set in order to ensure that the specified edges are present.

106. Other methods in computational mechanics

10A17. Anti-plane shear crack in a sandwich composite. - Jiun-Der Yu *(Princeton)* and Kuang-Chong Wu *(Inst of Appl Mech, Natl Taiwan Univ, Taipei, Taiwan 10764, ROC)*. Eng Fracture Mech 44(6) 875-885 (Apr 1993).

An analysis of an anti-plane shear crack in a sandwich composite is presented. The sandwich composite is formed by bonding one layer and two half spaces, each being anisotropic and dissimilar. The crack is assumed to be located in the middle layer and is inclined by an angle. The analysis is done by a complex-variable integral equation formulation based on the fundamental solution of a dislocation in the layer. The numerical results for vanishingly thin layers are shown to be consistent with those obtained by the J-integral.

10A18. Evaluation of fracture parameters of composites subjected to thermal shock using the BEM and sensitivity analysis techniques. -

R Chella, R Aithal, N Chandra *(Col of Eng, Florida A&M Univ - Florida State Univ, Tallahassee FL 32316-2175)*. Eng Fracture Mech 44(6) 949-961 (Apr 1993).

Quasi-static crack extension in fiber-reinforced composites subjected to thermal shock is analyzed using the boundary integral equation method, in combination with sensitivity analysis techniques. Buekner's formulation is employed to evaluate the stress intensity factor in a cracked body. This method eliminates the need for special element types to model the crack tip, as well as the use of a large number of elements near the cracked zone of interest. A numerical procedure involving sensitivity analysis techniques based on the adjoint structure approach has been developed to evaluate the energy integrals in the cracked body. Gradients of the functionals of response quantities with respect to variables such as the crack length, necessary for the evaluation of fracture parameters, are determined directly by this method. The numerical differentiation used in other numerical methods, such as the FEM, which requires the repeated solution of the equations for different crack sizes is avoided. Results for stress intensity factors as a function of crack length are presented for various composite systems. These results are in good agreement with analytical results and results from the FEM. The present approach results in significantly improved computational efficiency.

10A19. Standard eigenvalue analysis by BEM. - N Kamiya and E Andoh *(Dept of Mechano-Informatics and Syst Eng, Nagoya Univ, Nagoya 464-01, Japan)*. Commun Numer Methods Eng 9(6) 489-495 (Jun 1993).

A method for analyzing eigenvalues of the Helmholtz equation using a standard existing subroutine for eigenvalue determination is developed in this paper. It is based on the boundary integral equation formulation known as the multiple reciprocity method. The above-mentioned formulation, having polynomial matrices in terms of the eigenvalue as the coefficient matrices, is transformed into the standard-type eigenvalue problem. The resulting formulation makes it possible to determine the required eigenvalues only by boundary discretization without any initial rough estimation.

10A20. Numerical solution of partial differential equations on curved domains by collocation. - JJ van Blerk *(Atomic Energy, PO Box 582, Pretoria 0001, S Africa)* and JF Botha *(Inst for Ground-Water Stud, Univ of the Orange Free State, PO Box 339, Bloemfontein 9300, S Africa)*. Numer Methods PDE 9(4) 357-371 (Jul 1993).

The application of the FE collocation method to 2D and 3D partial differential equations is hampered by the fact that its accuracy depends largely on the position of the collocation points. The method has, in the past, thus mainly been applied to 2D differential equations defined on rectangular domains. In this case the method yields an optimal global convergence rate, when the Gauss-Legendre quadrature points are used as collocation points. It is shown in this paper that the same accuracy can also be achieved in the case of differential equations defined on nonrectangular domains. The only prerequisite for this is to solve the differential equation on a rectangular domain, mapped onto the nonrectangular domain of the differential equation by a bilinear blended map.

10A21. General hyperbolic solver: The CIP method applied to curvilinear coordinate. - Pei-Yuan Wang, Takashi Yabe *(Dept of Electron Eng, Gunma Univ, Tenjin-chou 1-5-1, Kiryu, Gunma 376, Japan)*, Takayuki Aoki *(Dept of Energy Sci, Tokyo IT, Nagatsuta, Midori-ku, Yokohama 227, Japan)*. J Phys Soc Japan 62(6) 1865-1871 (Jun 1993).

A general hyperbolic solver, the CIP method, is extended to curvilinear coordinate systems. Although the coordinate is curvilinear, the velocity components in the Cartesian coordinate are used as dependent variables. The scheme is applied to strong explosion and natural convection heat transfer. The code accurately describes a cylindrically symmetric explosion even with rectangular or distorted grids. The simulation result of heat transfer agrees well with an experimental result.

150. Kinematics and dynamics

150B. KINEMATICS OF RIGID BODIES AND PARTICLES

10A22. Development of a seven DOF crane with three wires: Inverse kinematics of the crane. - Hisashi Osumi, Tamio Arai, Hajime Asama.*(Japan)*. J Japan Soc Precision Eng 59(5) 767-772 (May 1993).

A 7 dof crane with three wires is proposed for automatic heavy parts assembly. The crane can control not only desired position but also orientation of a suspended object. The position and orientation control method of the crane is discussed under a static condition. By solving the simultaneous equations given by the geometrical constraints of the wire lengths and force contraints of gravity, the kinematics is calculated. Since the equations are nonlinear, Newton-Raphson method is used. The kinematic characteristics of the crane is analyzed and the relationship between the desired orientation and the shape of the object is obtained. Redundancy of the crane is used to minimize the maximum value among the three tensions of the wires. The algorithm of the inverse kinematics is proposed and experimental results using a prototype crane prove the verification of the algorithm.

10A23. Inverse problem of the kinematics of a positioner with linear actuators. - NT Monashko *(Odessa)*. J Machinery Manuf Reliab 6 27-29 (1992).

For a known motion of an object of manipulation explicit expressions allowing determination of linear displacements of inlet links of a positioner with linear actuators, are derived.

150D. DYNAMICS OF RIGID BODIES AND PARTICLES

10A24. Oscillations of a rigid body containing an elastic element with distributed parameters. - LD Akulenko *(Moscow, Russia)*. J Appl Math Mech 56(6) 911-919 (1992).

The motions of a hybrid (discrete-continual) system, consisting of a carrier rigid body and an elastic element with distributed parameters fastened to it are investigated. Two types of fastening are considered: 1) both ends are clamped, and 2) one of the ends is clamped while the other is free. A closed system of integro-differential equations is obtained which describes the state of the system under arbitrary initial conditions and forces applied to the rigid body. The perturbed motion of the rigid body in the case of a quasi-linear restoring force is investigated using asymptotic methods. The motions are studied both when there is internal resonance between the oscillations of the rigid body and the natural oscillations of the element, and when there are no such resonances. Qualitative effects are found.

150G. DEFORMABLE BODY DYNAMICS

10A25. Flexible multibody dynamics based on a fully Cartesian system of support coordinates. - N Vukasovic, JT Celigueta, J Garcia de Jalon *(Dept of Appl Mech, Univ of Navarra, Manuel de Lardizabal 15, 20009 San Sebastian, Spain)*, E Bayo *(Dept of Mech Eng, UC, Santa Barbara CA 93106)*. J Mech Des 115(2) 294-299 (Jun 1993).

In this paper we present an extension to flexible multibody systems of a system of fully cartesian coordinates previously used in rigid multibody dynamics. This method is fully compatible with the previous one, keeping most of its advantages in kinematics and dynamics. The deformation in each deformable body is expressed as a linear combination of Ritz vectors with respect to a local frame whose motion is defined by a series of points and vectors that move according to the rigid body motion. Joint constraint equations are formulated through the points and vectors that define each link. These are chosen so that a minimum use of local reference frames is done. The resulting equations of motion are integrated using the trapezoidal rule combined with fixed point iteration. An illustrative example that corresponds to a satellite deployment is presented.

150I. GYRODYNAMICS

10A27. Analytical determination of time-dependent functions of drifts of a triaxial gyrostabilizer. - SV Sokolov *(Rostov-on-Don)*. J Appl Math Mech 56(6) 955-957 (1992).

Equations which describe the time-dependence of the vector of the instantaneous velocity of rotation of a triaxial gyrostabilizer (TGS) platform located on Earth, with respect to the gyroscopical system of coordinates, are obtained within the framework of the precession theory at an arbitrary polynomial dependence of the rate of the drift on overloads. Based on the properties of the TGS and the details of its use we discuss the approximation of these equations from which the analytical time-dependent function of the drift rate of a gyrostabilized platform is found. The results obtained significantly simplify the procedure of solving the problems of identification of the TGS's parameters and estimating its current orientation relative to the specified system of coordinates in inertial navigation systems.

10A28. Global stability of the steady rotations of a solid. - GA Leonov and AV Morozov *(St Petersburg)*. J Appl Math Mech 56(6) 897-901 (1992).

The dynamical Euler equations describing the motion of a non-symmetrical solid about the centre of mass in the field of a constant external moment and a dissipative one are considered. It is assumed that the external moment specified with respect to axes attached to the body acts about the intermediate central axis of inertia of the body. The conditions for global asymptotic stability as well as the stability in total of steady rotations of the solid are obtained.

10A29. Kinetic energy and complementary kinetic energy in gyrodynamics. - FPJ Rimrott *(Dept of Mech Eng, Univ of Toronto, Toronto, ON, M5S 1A4, Canada)*, WM Szczygielski *(Univ of Toronto, Toronto, ON, M5S 1A4, Canada)*, B Tabarrok *(Univ of Victoria, Toronto, BC, Canada)*. J Appl Mech 60(2) 398-405 (Jun 1993).

The concepts of kinetic energy and complementary kinetic energy permit to distinguish between two different formulations of what happens to be the same quantity in Newtonian mechanics. These formulations turn out to play a significant role in gyrodynamics in which they can be used very effectively to establish fundamental equations. It is relatively straightforward to establish a complementary kinetic energy expression. The establishment of the kinetic energy expression is, in spite of its unambiguous definition, more complicated, and a way is presented how to obtain it without too much difficulty. Equations are presented for the more common angle systems, ie, for Euler's angles of the first kind, Cardan angles of the first kind, both because of their fundamental importance, and Cardan angles of the fifth kind because of its prevalence in aeronautics.

10A30. Local boundedness of the perturbed motions of an imperfect gyroscope in gimbals with dissipative and accelerating forces. - SA Belikov *(St Petersburg)*. J Appl Math Mech 56(6) 903-910 (1992).

An unbalanced dynamically symmetrical gyroscope in gimbals with constructive imperfections is considered in a central Newtonian field of forces. It is assumed that there is a moment of forces of viscous friction acting on the axis of rotation of one of the rings of the suspension and an accelerating (electromagnetic) moment applied to the axis of rotation of another ring. The equations of motion have a partial solution for which the basic plane of the frame is perpendicular to the direction from the specified fixed point of the frame to the centre of gravitation, the basic plane of the mantle is parallel to this direction and the rotor rotates with an arbitrary constant angular velocity. The equations of perturbed motions of the reduced system with 2-dof are obtained to within third-order terms at the corresponding position of equilibrium. In the domain of admissible values of the parameters F_0 the characteristic equation of the system is considered and its coefficients are written down. A domain in F_0 is specified in which complex conjugate pairs of the eigenvalues have small moduli of the real parts but the absolute values of the second- to fourth-order off-resonance mistuning between the imaginary parts are not small. For an imperfect gyroscope in gimbals with dissipative and accelerating forces the sufficient conditions of the local uniform boundedness of motions perturbed with respect to the specified partial solution are obtained in this domain. The conditions found provide the local uniform boundedness of solutions irrespective of the forms of higher than the third order in the equations of perturbed motions. These conditions are obtained in the form of constraints for the coefficients of the normal form and, finally, for the original parameters of the system and the real imaginary parts of the eigenvalues. To provide a clear interpretation of the results, special cases when all but two parameters are fixed are analyzed. The domains of local uniform boundedness are constructed in the 2D domains F_0 using a personal computer.

10A31. Nutational stability and core energy of a quasirigid gyrostat. - IM Ross *(Dept of Aeronaut and Astronaut, Naval Postgraduate Sch, Mail Code AA-Ro, Monterey CA 93943)*. J Guidance Control Dyn 16(4) 641-647 (Jul-Aug 1993).

The asymptotic nutational stability of a quasirigid gyrostat is analyzed. The primary purpose of this analysis is to resolve a debate concerning the use of the energy-sink method of analysis for systems containing driven rotors. It is shown that when the work done by the motor torque is not taken into account, the analysis leads to a contradiction even when the total energy is dissipative. A proper application of Landon's original idea yields a relationship between the time rate of change of Hubert's "core energy" and the energy dissipation rate of the damping mechanisms in the spacecraft. The analysis shows that the core energy might increase during a rotor despin condition; hence, the minimality of core energy - a previous criterion - is not always guaranteed. A criterion for the design of the damper to insure dissipation of the core energy is presented; this condition is always satisfied for the case of a constant relative rotor spin speed that facilitates a "closed-form" solution to the nutation angle time history of an axisymmetric gyrostat. The stability condition resulting from this analysis is consistent with the Landon-Iorillo stability criterion.

10A32. Two-axis dry tuned-rotor gyroscopes: Design and technology. - WM Mansour *(McMaster Univ, Hamilton, ON, L8S 4L7, Canada)* and C Lacchini *(DIGICON SA, Gravatai 94000, Rio Grande de Sul, Brazil)*. J Guidance Control Dyn 16(3) 417-425 (May-Jun 1993).

The dry tuned-rotor gyro (DTG) is a 2-dof sensor of angular velocities about two mutually orthogonal axes. It is a relatively recent development in conventional sensor technology. The first tuned two-axis oscillatory gyro was developed in 1945 by the Royal Aircraft Establishment (RAE) in England and was reported in a technical note in 1948. The first oscillogyro was patented by Barnes. Other variations of the DTG were patented by Howe, Krupick et al and Erdley. This class of instrument has been adopted for the control of tracking radar systems; the perforation of petroleum wells; the navigation of ships, aircraft, helicopters, and terrestrial vehicles. Its major application is encountered in the guidance of unmanned space and underwater vehicles. The DTG has several advantages. It requires no fluid to support. It is small in size, can resist radiation, and is amenable to thermal modeling. It can be used in a gimballed or strapdown system. It is low in cost per axis and of reliable technology. There are a few suppliers in the world who dominate the technology of *inertial-quality* DTGs, ie, DTGs of low drifts and high dynamic range, Brown gave a list of such suppliers, together with the technical specifications for their products. DTGs that belong to this class are difficult to acquire and their price is high. This publication reports the latest advances in DTGs.

10A33. Adjoining cell mapping and its recursive unraveling Part I. Description of adaptive and recursive algorithms. - PJ Zufiria *(Dept de Matematica Aplicada a las Tecnologias de la Info, GTI, DSSR, ETSI de Telecommunicacion, UPM, 28040 Madrid, Spain)* and RS Guttalu *(Dept of Mech Eng, USC, Los Angeles CA 90089-1453)*. Nonlinear Dyn 4(3) 207-226 (Jun 1993).

A new type of cell mapping, referred to as an adjoining cell mapping, is developed in this paper for autonomous dynamical systems employing the cellular state space. It is based on an adaptive time integration employed to compute an associated cell mapping for the system. This technique overcomes the problem of determining an appropriate duration of integration time for the simple cell mapping method. Employing the adjoining mapping principle, the first type of algorithm developed here is an *adaptive mapping unraveling algorithm* to determine equilibria and limit cycles of the dynamical system in a way similar to that of the simple cell mapping. The second type of algorithm developed in this paper is a *recursive unraveling algorithm* based on adaptive integration and recursive partitioning of state space into blocks of cells with a view toward its practical implementation. It can find equilibria of the system in the same manner as the simple cell mapping method but is more efficient in locating periodic solutions.

10T34. Adjoining cell mapping and its recursive unraveling, Part II. Application to selected problems. - RS Guttalu *(Dept of Mech Eng, Univ of S California, Los Angeles CA 90089-1453)* and PJ Zufiria *(Dept Matematica Aplicada Tecnologias Info, GTI DSSR ETSI de Telecommun UPM, 28040 Madrid, Spain)*. 10A35. Chaotic attitude motion of gyrostat satellites in a central force field. - X Tong and FPJ Rimrott *(Dept of Mech Eng, Univ of Toronto, ON, Canada)*. Nonlinear Dyn 4(3) 269-278 (Jun 1993).

The nonlinear attitude motion of gyrostat satellites in a central force field is investigated, with particular emphasis on their long-time dynamic behavior for a wide range of parameters. The numbers of equilibrium solutions, as well as their stability, vary with the rotor speed, and bifurcation diagrams have been obtained. Various dynamic behaviors of gyrostat satellites, eg, periodic, quasiperiodic, and chaotic, are studied via the Poincare map technique. It is shown that the rotor speed has a significant effect on the dynamic behavior of gyrostat satellites.

10T36. Constructing invariant tori for two weakly coupled van der Pol oscillators. - DE Gilsinn *(Manuf Eng Lab, Bldg 233 B106, NIST)*. Nonlinear Dyn 4(3) 289-308 (Jun 1993).

10A37. Quasi-harmonic analysis of the behavior of a hardening duffing oscillator subjected to filtered white noise. - PK Koliopulos and SR Bishop *(Dept of Civil Eng, Univ Col London, Gower St, London WC1E 6BT, UK)*. Nonlinear Dyn 4(3) 279-288 (Jun 1993).

The behavior of a hardening Duffing oscillator subjected to narrow band random excitation is examined. The influence of possible jumps, between competing states, on the probability distribution of the response amplitude is addressed. A quasi-harmonic approximation of system behavior is adopted which is capable of reproducing the observed concave shape of probability functions and compares well with predictions obtained via stochastic averaging techniques and with digital simulations.

10A38. Transition of flow-induced cylinder vibrations to chaos. - P Plaschko, E Berger

(Hermann-Fottinger-Inst fur Thermo- und Fluiddyn, Tech Univ Berlin, Germany), K Brod *(Inst fur Tech Akustik, Tech Univ, Berlin, Germany)*. Nonlinear Dyn 4(3) 251-268 (Jun 1993).

Flow-induced oscillations of rigid cylinders exposed to fully developed turbulent flow can be described by a fourth order autonomous system. Among the pertinent constants, the mass ratio is the control parameter governing the transition from limit cycle oscillations to chaotic vibrations. Particular attention is paid to the stability of the limit cycles: it has been found that they lose their stability at the point of appearance of quasi-periodic motion. The documentation of this transition is performed in terms of Lyapunov exponents, phase plots, Fourier spectra, bifurcation diagrams, and Poincare maps. As opposed to the calculation of the Lyapunov exponents where remarkable numerical difficulties were encountered, the investigation of the remaining quantities shows clearly the passage of cylinder motions from limit cycle oscillations to more and more irregular vibrations, leading finally to chaos.

150Y. COMPUTATIONAL TECHNIQUES

10A39. Parametric excitation of computational mode of the leapfrog scheme applied to the Van der Pol equation. - DongSheng Cai *(Inst of Info Sci and Electron, Univ of Tsukuba, Ibaraki 305, Japan)*, Akira Aoyagi *(Fac of Eng, Kyushu Sangyo Univ, 3-1 Matsukadai 2-chome Higashi-ku, Fukuoka 813, Japan)*, Kanji Abe *(Col of Arts and Sci, Univ of Tokyo, Komaba 3-8-1 Meguro-ku, Tokyo 153, Japan)*. J Comput Phys **107**(1) 146-151 (Jul 1993).

The leapfrog scheme is applied to the Van der Pol equation. When the amplitude of oscillation of the physical mode exceeds a critical value, the computational mode is parametrically excited by the physical mode. The growth of the computational mode interrupts the integration based on the leapfrog scheme. The critical amplitude of the physical mode is determined by the linear stability analysis and the parametric excitation theory. The Runge-Kutta smoother eliminating the computational mode enables the longtime integration based on the leapfrog scheme.

10A40. Poisson integration of rigid body systems. - MA Austin *(Dept of Civil Eng and Inst for Syst Res, Univ of Maryland, College Park MD 20742)*, PS Krishnaprasad *(Dept of Elec Eng and Inst for Syst Res, Univ of Maryland, College Park MD 20742)*, Li-Sheng Wang *(Inst of Appl Mech, Natl Taiwan Univ, Taipei, Taiwan, ROC)*. J Comput Phys **107**(1) 105-117 (Jul 1993).

In this paper we discuss the numerical integration of Lie-Poisson systems using the mid-point rule. Since such systems result from the reduction of Hamiltonian systems with symmetry by Lie group actions, we also present examples of reconstruction rules for the full dynamics. A primary motivation is to preserve in the integration process, various conserved quantities of the original dynamics. A main result of this paper is an $O(h^3)$ error estimate for the Lie-Poisson structure, where h is the integration step-size. We note that Lie-Poisson systems appear naturally in many areas of physical science and engineering, including theoretical mechanics of fluids and plasmas, satellite dynamics, and polarization dynamics. In the present paper we consider a series of progressively complicated examples related to rigid body systems. We also consider a dissipative example associated to a Lie-Poisson system. The behavior of the mid-point rule and an associated reconstruction rule is numerically explored.

152. Vibrations of solids (basic)

152A. GENERAL THEORY

10A41. Dynamic behavior of discretized nonconservative systems. - Y Xiong *(Dept of Mech Eng, Univ of British Columbia, Vancouver, BC V6T 1W5, Canada)* and B Tabarrok *(Dept of Mech Eng, Univ of Victoria, Victoria, BC V8W 3P6, Canada)*. J Sound Vib **162**(3) 429-439 (22 Apr 1993).

The dynamic behavior of discretized nonconservative systems is investigated in the present study, and the conclusion drawn by the authors is verified for the problems of this kind. The necessary and sufficient condition for existence of solutions of symmetric and positive-definitive matrices to an inverse eigenvalue problem is obtained. Through analysis of examples, some observations of interest on the characteristic curves and the vibration modes of flutter-type nonconservative systems and the associated conservative ones are presented.

10A42. Modeling of material nonlinearities in steel structures subjected to transient dynamic loading. - AS Elnashai and BA Izzuddin *(Civil Eng Dept, Imperial Col of Sci, Tech, and Medicine, Imperial College Rd, London SW7 2BU, UK)*. Earthquake Eng Struct Dyn **22**(6) 509-532 (Jun 1993).

This paper is concerned with the modeling of the behavior of steel under cyclic and dynamic loading conditions. After a general discussion regarding the requirements for accurate and efficient modeling in dynamics, two models are described and implemented. The bilinear stress-strain constitutive relationship with kinematic hardening is widely used in many computer codes, hence is used for control purposes. The multisurface plasticity model is said to exhibit the important qualities of strain hardening, softening and relaxation to a mean stress. This model is described in detail and notes on model parameter evaluation are given. A number of validation examples are presented, due to the complexity of implementation of the multisurface formulation. This is followed by comparisons between the bilinear response predictions and those of the multisurface model for cyclic and dynamic tests on beam-columns. It is concluded that in the absence of material test data under cyclic loading, the bilinear model provides acceptable accurate response predictions. However, the multisurface model provides a significantly closer fit to experimental results, due to its ability to model a yield plateau and a nonlinear strain hardening regime as well as cyclic degradation. It can also be used for new types of steel where no distinct yield point is observed.

10A43. Multiple scales analysis of nonlinear, localized modes in a cyclic periodic system. - A Vakakis, T Nayfeh, M King *(Dept of Mech and Indust Eng, Univ of Illinois, Urbana IL 61801)*. J Appl Mech **60**(2) 388-397 (Jun 1993).

In this work the nonlinear localized modes of an n-dof nonlinear cyclic system are examined by the averaging method of multiple scales. The set of nonlinear algebraic equations describing the localized modes is derived and is subsequently solved for systems with various numbers of dof. It is shown that nonlinear localized modes exist only for small values of the ratio (k/μ), where k is the linear coupling stiffness and μ is the coefficient of the grounding stiffness nonlinearity. As (k/μ) increases the branches of localized modes become nonlocalized and either bifurcate from "extended" antisymmetric modes in inverse, "multiple" Hamiltonian pitchfork bifurcations (for systems with even-dof), or reach certain limiting values for large values of (k/μ) (for systems with odd-dof). Motion confinement due to nonlinear mode localization is demonstrated by examining the responses of weakly coupled, perfectly periodic cyclic systems caused by external impulses. Finally, the implications of nonlinear mode localization on the active or passive vibration isolation of such structures are discussed.

152B. LINEAR THEORY

10A44. Relationship between fundamental natural frequency and maximum static deflection for various linear vibratory systems. - CW Bert *(Sch of Aerospace and Mech Eng, Univ of Oklahoma, Norman OK 73019)*. J Sound Vib **162**(3) 547-557 (22 Apr 1993).

It is shown that the fundamental natural frequency of a wide variety of discrete and continuous systems is inversely proportional to the gravitational acceleration divided by the maximum static deflection, raised to the 1/2 power. The value of the constant of proportionality is determined for multi dof discrete systems, axially vibrating prismatic and tapered rods, prismatic and tapered slender beams, membranes and thin plates of many planforms. Particular attention is paid to the effects of taper, axial preload, geometry and boundary conditions. The results of this investigation should be useful in predicting the approximate fundamental natural frequency from the static deflection, either calculated or determined experimentally.

10A45. Uncoupling and solving the equations of motion of vibrating linear discrete systems. - SF Felszeghy *(Dept of Mech Eng, California State Univ, Los Angeles CA 90032-8153)*. J Appl Mech **60**(2) 456-462 (Jun 1993).

The equations of motion governing the vibrations of a linear, viscously damped, discrete system are generally mutually coupled. This article examines the problem, when the viscous damping is nonclassical, of how best to uncouple and solve by approximation the governing second-order differential equations of motion. It is shown that when the equations of motion are expressed in normal coordinates, the equations can then be transformed by an orthogonal coordinate transformation to a new generalized coordinate system in which a bound on the relative error introduced in the response by discarding all the coupling terms is a minimum. This approach extends the applicability of undamped modal analysis to certain types of nonclassically damped systems. The analytical results and the effectiveness of the proposed method are illustrated with four examples taken from other previously published approaches to the stated problem.

152D. STOCHASTIC EFFECTS, INCL RANDOM EXCITATION

10A46. Dynamic response of continuous systems including model uncertainty. - WD Iwan *(Div of Eng and Appl Sci, California IT, Pasadena CA 91125)* and H Jensen *(Univ Tecnica Federico, Santa Maria, Valparaiso, Chile)*. J Appl Mech **60**(2) 484-490 (Jun 1993).

This paper presents a technique for obtaining the response of linear continuous systems with parameter uncertainties subjected to deterministic excitation. The parameter uncertainties are modeled as random fields and are assumed to be time independent. The general formulation of the method is developed for a particular class of partial differential equations with random coefficients. Random shape functions are introduced to approximate the solution in the spatial domain and in the random space. A system of linear ordinary differential equations for the unknowns of the problem is derived using the weighted residual method. The system of equations is integrated in time and the response variability is computed. Application of the new method is made to a continuum described by the 1D wave equation in which the stiffness properties exhibit a spatial random variation. Validation calculations show that the results from the method agree well with those obtained by direct numerical integration.

10A47. Equivalent linearization: A suitable tool for analyzing MDOF-systems. - HJ Pradlwarter and GI Schueller *(Inst of Eng Mech, Univ of Innsbruck, Innsbruck, Austria)*. Probab Eng Mech 8(2) 115-126 (1993).

A method for the evaluation of the stochastic response of MDOF-systems, based on the equivalent linearization (EQL) method, is presented. This paper focuses on the applicability and accuracy of EQL within design procedures of realistic structures. A numerical approach for evaluating the linearization coefficients is introduced for the benefit of high flexibility, simplicity, and most realistic modeling of restoring force laws. It is shown that the generally made assumption of a normally distributed response introduces some arbitrariness in the estimated stochastic response. The source and effect of this arbitrariness on the accuracy and convergence of the equivalent linearization procedure is studied and discussed. Finally, the procedure is applied to investigate the effect of damping devices assembled in an eight story building subjected to bi-directional stochastic, ie, earthquake excitation. The stationary solution obtained by Monte Carlo simulation, conventional EQL as well as the present approach are compared and discussed.

10A48. Power spectral density of nonlinear system response: The recursion method. - R Valery Roy *(Dept of Mech Eng, Univ of Delaware, Newark DE 19716)* and PD Spanos *(LB Ryon Chair in Eng, Rice Univ, Houston TX 77251)*. J Appl Mech 60(2) 358-365 (Jun 1993).

Spectral densities of the response of nonlinear systems to white noise excitation are considered. By using a formal solution of the associated Fokker-Planck-Kolmogorov equation, response spectral densities are represented by formal power series expansion for large frequencies. The coefficients of the series, known as the spectral moments are determined in terms of first-order response statistics. Alternatively, a J-fraction representation of spectral densities can be achieved by using a generalization of the Lanczos algorithm for matrix tridiagonalization, known as the "recursion method". Sequences of rational approximations of increasing order are obtained. They are used for numerical calculations regarding the single-well and double-well Duffing oscillators, and Van der Pol type oscillators. Digital simulations demonstrate that the proposed approach can be quite reliable over large variations of the system parameters. Further, it is quite versatile as it can be used for the determination of the spectrum of the response of a broad class of randomly excited nonlinear oscillators, with the sole prerequisite being the availability, in exact or approximate form, of the stationary probability density of the response.

10A49. Random vibration of structures by the FEM. - I Elishakoff and Liping Zhu *(Center for Appl Stochatics Res and Dept of Mech Eng, Flordia Atlantic Univ, Boca Raton FL 33431-0991)*. Comput Methods Appl Mech Eng 105(3) 359-373 (June 1993).

This paper is directed at two objectives: (1) to develop an improved FE formulation of beams subjected to random loading; (2) to provide a benchmark example which can also be solved exactly. Systematic formulation of element and global spectral matrices of both the excitation and response are presented. Two approximations for evaluation of the element spectral densities of excitation are compared with the result of direct numerical calculation. It is shown that, in the benchmark example, the FE and exact solutions are in perfect agreement.

10A50. Control of nonlinear structural dynamic systems: Chaotic vibrations. - EK Hall II *(Aerospace Corp, Los Angeles CA)* and SV Hanagud *(Sch of Aerospace Eng, Georgia Tech)*. J Guidance Control Dyn 16(3) 470-476 (May-Jun 1993).

In recent years, chaotic behavior has been observed in a large number of physical systems. The appearance of these unpredictable, broadband frequency responses in structural dynamic systems presents a possible threat to the integrity of aerospace structures because of their erratic time histories. Thus, the objective of this paper is to investigate the control of chaotic motions through the simple example of a buckled beam. As an initial attempt, a nonlinear control methodology termed feedback linearization was utilized. In this method, the nonlinearities causing chaos are eliminated from the closed-loop system through nonlinear feedback. Although effective in eliminating chaotic motions this scheme does have some disadvantages such as the demand for accurate models and, in general, full state measurements. As an alternative, the feasibility of using smart structural concepts to control chaotic vibrations was examined. This technique utilized the introduction of so-called electronic damping to move the system out of a chaotic parameter region. The method was shown to be feasible and holds promise for future applications. Thus, this work demonstrates that a controller capable of controlling a chaotic system can be developed. From this study, directions for further research in the area of controlling chaotic systems were obtained.

10A51. Control-structure interactions of space station solar dynamic modules. - RD Quinn *(Dept of Mech and Aerospace Eng, Case Western Reserve Univ, Cleveland OH 44106)* and IS Yunis *(Struct Syst Dyn Branch, NASA Lewis Res Center, Cleveland OH 44135)*. J Guidance Control Dyn 16(4) 623-629 (Jul-Aug 1993).

Potential control-structures interaction problems of large flexible multibody structures in the presence of pointing and tracking requirements are addressed. A control approach is introduced for the simultaneous tracking and vibration control of multibody space structures. The application that is discussed is the planned Space Station Freedom configured with solar dynamics modules. The solar dynamic fine-pointing and tracking requirements may necessitate controller frequencies above the structural natural frequencies of space station and the solar dynamic modules themselves. It is well known that this can give rise to control-structure interaction problems if the controller is designed without giving due consideration to the structural dynamics of the system. Possible control-structure interaction problems of Freedom's solar dynamic power systems are investigated. A FE model of Freedom is used to demonstrate these potential control-structure interaction problems and the proposed tracking and vibration control approach.

10A52. Decoupling vibration control of a flexible rotor system with symmetric mass and stiffness properties. - ST Chen and AC Lee *(Dept of Mech Eng, Natl Chiao Tung Univ, Taiwan, ROC)*. J Syst Control Eng 207(I1) 9-14 (1993).

The paper investigates the control problem for a flexible rotor system with symmetric mass and stiffness properties and proposes an internal and external decoupling control scheme to simplify the controller design for such a system, where the existence of gyroscopic effects during rotation is neglected. The whole flexible rotor system can eventually be separated into four flexible subsystems without knowledge of the system parameters, and the control algorithm for each subsystem can be designed and implemented independently. Simulation results demonstrate the effectiveness of using the proposed scheme in conjunction with the optimal modal space control scheme.

10A53. Passive damping for robust feedback control of flexible structures. - R Gueler *(Prod Eng Lab, Matsushita Elec Indust, Osaka 571, Japan)*, AH von Flotow, DW Vos *(Dept of Aeronaut and Astronaut, MIT)*. J Guidance Control Dyn 16(4) 662-667 (Jul-Aug 1993).

This paper investigates the benefits of passive damping in single-input single-output (SISO) and multi-input multi-output (MIMO) feedback controlled structures. Theoretical formulations are derived verifying improved stability robustness characteristics for simple controlled structures on phase margin, gain margin, and root locus properties of a SISO system. Control design techniques for closed-loop bandwidths beyond the first modal frequency require accurate knowledge of the structural dynamics, particularly at crossover. The use of passive damping in the structural design allows for a greater margin of error in pole-zero cancellation at crossover, thus improving the stability robustness. Minimum levels of required passive damping are derived for robust control of uncertain structures. The derivations are extended to suggest application to MIMO systems. Robustness improvements are quantified in case studies for an 8th-order SISO example and an 18th-order MIMO example and compared to the simple derivations.

10T54. Performance of higher harmonic control algorithms for helicopter vibration reduction. - SR Hall *(Dept of Aeronaut and Astronaut, MIT)* and NM Wereley *(BDM International, Arlington VA 22203)*. J Guidance Control Dyn 16(4) 793-797 (Jul-Aug 1993).

10A55. Sensitivity-based characterization and optimization of viscoelastically damped honeycomb structures. - S Kodiyalam *(Solid Mech Lab, Bldg K-1 Rm 2A25, General Electric R&D Center, PO Box 8, Schenectady NY 12301)* and J Molnar *(Mech Anal Group, General Electric Astro Space, Princeton NJ 08543)*. J Guidance Control Dyn 16(3) 484-489 (May-Jun 1993).

Control of dynamic vibrations is critical to the operational success of many aerospace systems. Large space structures, for practical reasons, are lightweight and hence highly flexible. This paper addresses the problem of vibration control of such structures through passive damping, using viscoelastic materials. A new sensitivity-based approach to characterize viscoelastic material property variation with frequency is outlined. It is demonstrated that, using structural optimization techniques, viscoelastically damped honeycomb structures can be tailored to provide weight-effective vibration damping. A spacecraft payload mounting platform is used as the demonstration structure.

10A56. Simulation of active vibroprotective systems. - VV Yablonskii and BO Marder *(Moscow, Russia)*. J Machinery Manuf Reliab 6 76-82 (1992).

A method for active vibration protection of a mechanism, based on decomposing the vector of vibration forces acting in the supports, into the natural forms of vibration of the mechanism viewed as a rigid bogy with elastic ties, is proposed. Also used are wide-band compensation and damping of singled-out components (modal control) with the help of electromechanical feedback. The calculated results show that the efficiency and noise immunity of a modal-control vibroprotective system may be increased as compared with the known results.

10A57. Simultaneous design of active vibration control and passive viscous damping. - MLD Gaudreault, BS Liebst, RL Bagley *(Dept of Aeronaut and Astronaut, Air Force IT, WPAFB)*. J Guidance Control Dyn 16(4) 654-661 (Jul-Aug 1993).

Structural engineers have found that passive damping can reduce the amount of active damping required to control structural vibration. Conversely, improperly designed passive damping can inadvertently increase system reaction times, reducing control effectiveness. This paper presents several techniques for blending active vibration control and passive viscous damping. A closed-form optimal solution for minimizing a quadratic cost functional is derived, but it is shown to be dependent on the initial conditions that produces time-varying damping coefficients. To eliminate the dependence on initial conditions, solution techniques for suboptimal, state independent solutions are developed. The suboptimal solutions require less computation effort, but still give good estimates of the optimal solution. The advantages and disadvantages of the different solution techniques are discussed with respect to computation requirements and robustness. Methods of comparing competing designs are also discussed. Several numerical examples illustrate the similarities and differences of the various techniques. More importantly, the examples demonstrate the significant improvements achievable by simultaneously designing passive and active damping.

10A58. Time integration algorithm for structural dynamics with improved numerical dissipation: The generalized-α method. - J Chung and GM Hulbert *(Dept of Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109-2125)*. J Appl Mech 60(2) 371-375 (Jun 1993).

A new family of time integration algorithms is presented for solving structural dynamics problems. The new method, denoted as the generalized-α method, possesses numerical dissipation that can be controlled by the user. In particular, it is shown that the generalized-α method achieves high-frequency dissipation while minimizing unwanted low-frequency dissipation. Comparisons are given of the generalized-α method with other numerically dissipative time integration methods; these results highlight the improved performance of a new algorithm. The new algorithm can be easily implemented into programs that already include the Newmark and Hilber-Hughes-Taylor-α time integration methods.

10A59. Analysis of vibration spectrum of a Timoshenko beam with boundary damping by the wave method. - MP Coleman *(Dept of Math and Comput Sci, Fairfield Univ, Fairfield CT 06430)* and H Wang *(Dept of Math and Stat, Wichita State Univ, Wichita KS 67208)*. Wave Motion 17(3) 223-239 (May 1993).

The Timoshenko beam is a model of a thick beam and is important in structural engineering. Recently, there has been considerable interest in the analysis and control of the vibration of the Timoshenko beam. The understanding of the spectrum of vibration is fundamental in order to accomplish such research. The classical separation of variables approach leads to complicated transcendental equations which are difficult to analyze. In this paper, we develop the wave propagation method to tackle this problem. Asymptotic estimates for the eigenfrequencies are obtained for a Timoshenko beam with dissipative conditions. Such estimates show that the Timoshenko beam has two branches in its spectrum corresponding to the propagation of waves with two velocities for the displacement and angular rotation variables. The asymptotic estimates are confirmed by numerical computations using a high accuracy Lengendre-tau spectral method.

10A60. Construction of an Euler-Bernoulli beam from spectral data. - BD Lowe *(Dept of Math, Texas A&M Univ, College Station TX 77843-3368)*. J Sound Vib 163(1) 165-171 (8 May 1993).

A numerical method for approximating coefficients in an Euler-Bernoulli beam equation from spectral data is proposed. The technique is based on a shooting method and constructs a beam that has the given spectral data. Numerical examples illustrate the performance of the method.

10A61. Dynamical analysis of a general mass-spring arrangement in beam systems. - I Kaljevic, S Saigal *(Dept of Civil Eng, Carnegie Mellon Univ, Pittsburgh PA 15213)*, CH Broome Jr *(Dept of Civil Eng, Howard Univ, Washington DC 20059)*. J Sound Vib 163(1) 67-81 (8 May 1993).

The free vibration analysis of general structural arrangements consisting of beams with discrete spring mass oscillators is presented. A detailed derivation of the governing differential equation of motion for such systems is presented. The self-adjoint property of the resulting differential operator is shown which assures that the eigenvalues of the dynamical system are both real and positive. The orthogonality conditions for the eigenfunctions are also derived. Two methods, namely, the Green's function method and the particular integral method, are developed to treat the resulting differential equation of motion. Detailed parametric studies are performed to study the vibrational characteristics of general dyanamical systems. A Galerkin method solution is also derived for comparison and for validation of the formulations presented.

10A62. Flexural-torsional behavior of a straight elastic beam subject to terminal moments. - Z Tan and JA Witz *(Dept of Mech Eng, Univ Col, London WC1E 7JE, UK)*. J Appl Mech 60(2) 498-505 (Jun 1993).

This paper discusses the large-displacement flexural-torsional behavior of a straight elastic beam with uniform circular cross-section subject to arbitrary terminal bending and twisting moments. The beam is assumed to be free from any kinematic constraints at both ends. The equilibrium equation is solved analytically with the full expression for curvature to obtain the deformed configuration in a 3D Cartesian coordinate system. The results show the influence of the terminal moments on the beam's deflected configuration.

10A63. Forced nonlinear oscillations of discretely-jointed thin-walled beams. - BA Antuf'ev. Russian Aeronaut 35(3) 72-78 (1992).

We present the approximate solution of the problem on the forced nonlinear transverse oscillations of the thin-walled structure, consisting of the several discretely-jointed shells. We consider the dynamic structural model that represents a number of the linear subsystems interconnected by the equivalent imponderable springs with nonlinear rigid characteristics that are specified by the local pliability of the shells in their attachment points.

10A64. Improved two-node Timoshenko beam FE. - Z Friedman and JB Kosmatka *(Dept of Appl Mech and Eng Sci, UCSD)*. Comput Struct 47(3) 473-481 (3 May 1993).

The stiffness, mass, and consistent force matrices for a simple two-node Timoshenko beam element are developed based upon Hamilton's principle. Cubic and quadratic Lagrangian polynomials are used for the traverse and rotational displacements, respectively, where the polynomials are made interdependent by requiring them to satisfy the two homogeneous differential equations associated with Timoshenko's beam theory. The resulting stiffness matrix, which can be exactly integrated and is free of "shear-locking", is in good agreement with the exact Timoshenko beam stiffness matrix. Numerical results are presented to show that the current element exactly predicts the displacements of a short beam subjected to complex distributed loadings using only one element, and the current element predicts shear and moment resultants and natural frequencies better than existing Timoshenko beam elements.

10A65. Statics, stability, and vibration of non-prismatic beams and columns. - JD Aristizabal-Ochoa *(Dept of Civil Eng and Eng Mech, California State Univ, Fullerton CA 92634)*. J Sound Vib 162(3) 441-455 (22 Apr 1993).

An algorithm that evaluates the static, stability and vibration response of nonprismatic beams and columns is presented. Matrix equations are derived that can be readily included in existing computer programs on the analyses of 2D and 3D framed structures with prismatic and nonprismatic members. It is shown in this paper that the analyses of framed structures with nonprismatic and prismatic members under any loading and support conditions can be carried out once the main stiffness coefficients are determined. Numerical examples on the statics, stability and dynamics of nonprismatic beams are included for easy verification and compared with available results from other anlaytical methods to show the power of the proposed algorithm.

10A66. Studies on dynamic behavior of a beam with symmetrically varying thickness. - PK Roy and N Ganesan *(Machine Dyn Lab, Dept of Appl Mech, Indian IT, Madras 600 036, India)*. Comput Struct 47(2) 265-274 (Apr 1993).

A detailed study has been conducted on the effect of different types of variation in profile and thickness on the amplitude and the dynamic bending stress of a beam under a point harmonic load. The end conditions considered are clamped or simply supported at both the ends. The response has been calculated for the first three modes of vibration. In each case the results obtained for different types of thickness variation are compared with those obtained for a uniform thickness beam. It is observed that a considerable reduction in amplitude and bending stress can be achieved by proper selection of thickness variation.

10A67. Vibroimpact interaction in systems of bars. - VV Klubovich and VN Sakevich *(Vitebsk)*. J Machinery Manuf Reliab 6 13-20 (1992).

The specifics of vibroimpact interaction of nonidentical waveguides are analyzed. It is shown, both theoretically and experimentally, that an increase in the force compressing a pair of interacting waveguides, results in the ratio of the amplitudes of interacting end faces tending to a certain limit. The limiting ratio of the amplitudes of interacting waveguides end faces is determined by the waveguides acoustic parameters and is independent of the ratio of amplitudes of disturbing forces acting on the corresponding waveguides. It is also shown that if the natural frequency of a waveguide-reflector is smaller than that of the waveguide-concentrator connected with an ultrasonic transformer, then the amplitude of relative vibration of interacting end faces is much higher than in the opposite case.

10A68. Whirling of a forced cantilever beam with static deflection II. Superharmonic and subharmonic resonances. - IMK Shyu, RH Plaut, DT Mook *(VPI)*. Nonlinear Dyn 4(4) 337-356 (Aug 1993).

Secondary resonances of a slender, elastic, cantilevered beam subjected to a transverse harmonic load are investigated. The effects of nonlinear curvature, nonlinear inertia, viscous damping and static load are included. Cubic terms in the governing equations lead to subharmonic and superharmonic resonances of order three. The static displacement produced by the weight of the beam introduces quadratic terms in the governing equations, which cause subharmonic and superharmonic resonances of order two. Out-of-plane motion is possible in all of these secondary resonances when the principal moments of inertia of the beam cross section are approximately equal.

10A69. Whirling of a forced cantilevered beam with static deflection I. Primary resonance. - I-MK Shyu, DT Mook, RH Plaut *(VPI)*. Nonlinear Dyn 4(3) 227-249 (Jun 1993).

The response of a slender, elastic, cantilevered beam to a transverse, vertical, harmonic excitation is investigated. The effects of nonlinear curvature, nonlinear inertia, viscous damping and static load are included. Previous work often has neglected the static deflection caused by the weight of the beam, which adds quadratic terms in the governing equations of motion. Galerkin's method is used with three modes and approximate solutions of the temporal equations are obtained by the method of multiple scales. Primary resonance is treated here, and out-of-plane motion is possible in the first and second modes when the principal moments of inertia of the beam cross-section are approximately equal. In Parts II and III, secondary resonances and nonstationary passages through various resonances are considered.

154C. STRINGS, CABLES, CHAINS, AND ROPES

10A70. Lateral vibrations of steel cables including structural damping. - M Raoof and Yu Ping Huang *(Sch of Architec and Civil Eng, S Bank Univ, London, UK)*. Struct Build 99(2) 123-133 (May 1993).

The paper provides theoretical means of predicting structural damping of axially preloaded spiral strands undergoing lateral vibrations due, for example, to vortex-shedding. In line with the previously reported experimental observations and theoretical studies, it is assumed that frequency-independent cable damping arises from the frictional energy dissipation between the individual wires in contact. For pin-ended and axially preloaded spiral strands undergoing plane-section bending, it is now possible to show significant variations of the equivalent damping ratio with the type of strand construction details, length of the cable and mode of vibration. This is in contrast to the traditional approaches, which have invariably assumed a constant damping ratio based on rather limited (and sometimes even questionable) experimental observations.

154F. MEMBRANES

10A71. Modes of a circular membrane of nonuniform radial density. - TM Kalotas and AR Lee *(Dept of Phys, La Trobe Univ, Bundoora, Australia)*. Acustica 78(4) 220-225 (May 1993).

The normal modes of a circular symmetric clamped membrane of arbitrary nonuniform radial mass density are analyzed with the aid of the method of constant density radial segments. Using a 2×2 matrix formalism, a generic mode condition is derived from which the characteristic frequencies and standing wave patterns are directly computed. For the purpose of manipulating these mode frequencies through small changes in membrane density, an explicit first order perturbational connection between these quantities is established. Computed examples are given to demonstrate the results.

10A72. A superposition-Rayleigh-Ritz method for free vibration analysis of non-uniformly tensioned membranes. - MJ Gorman *(Univ of Ottawa, Ottawa, ON K1N 6N5, Canada)* and RK Singhal *(Directorate of Space Mech, Canadian Space Agency, Ottawa, ON K2H 8S2, Canada)*. J Sound Vib 162(3) 489-501 (22 Apr 1993).

An accurate analytical method is described for establishing initial stress distributions in corner tensioned rectangular membranes. With the stress distributions available it is shown how the Rayleigh-Ritz method is employed to obtain membrane free vibration frequencies and mode shapes. The initial stress distributions are obtained by the superposition of three judiciously chosen Airy stress functions. Verification tests are performed to demonstrate that this general computational method gives results in agreement with known classical problems where uniform edge loading is employed. The method described has immediate application in the static and dynamic analysis of large membranes proposed for space antennae.

154G. PLATES

10A73. Approximate 3D analysis of rectangular thick laminated plates: Bending, vibration, and buckling. - YK Cheung and J Kong *(Dept of Civil and Struct Eng, Univ of Hong Kong, Hong Kong, China)*. Comput Struct 47(2) 193-199 (Apr 1993).

A global-local approach is proposed to analyze thick laminated plates. This approach treats a thick laminated plate as a 3D inhomogeneous anisotropic elastic body. The cross-section of a laminated plate is first discretized into conventional eight-node elements. The interpolation function along the span of the plate is defined by the cubic B_3-spline function. The displacement functions can be expressed as the product of the usual isoparametric shape functions and the spline function. A set of global polynomials of an appropriate order is selected to transform the nodal variables of the cross-section to a much smaller set of generalized parameters associated with the polynomials. These parameters can be obtained by means of the standard Rayleigh-Ritz technique. The total number of unknowns involved is drastically reduced with a minor sacrifice of accuracy. The six components of stresses, the fundamental natural frequencies and the critical buckling loads can be determined with acceptable accuracy. Numerical examples are given to demonstrate the accuracy and effectiveness of the global-local procedures.

10A74. Effects of boundary constraints and thickness variations on the vibratory response of rectangular plates. - CW Lim and KM Liew *(Div of Appl Mech, Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263)*. Thin-Walled Struct 17(2) 133-159 (1993).

The present study concentrates on the first known free flexural vibration of doubly-tapered rectangular plates subject to a variety of boundary constraints ranging from a cantilevered plate to a fully clamped plate. The Rayleigh-Ritz minimum total energy approach complemented by the global pb-2 shape functions as the admissible plate displacement amplitude functions is employed. The shape functions are, in principle, the product of a set of mathematically complete 2D polynomials and a basic function. The basic function is formed from a product of the boundary piecewise geometric expressions of the plate each of which is raised to the power of 0, 1 or 2 corresponding to a free, simply supported or clamped edge, respectively. The shape functions satisfy the kinematic boundary conditions at the outset. This proposed computational model has a great advantage over the conventional FE and the finite strip methods in terms of computation cost, numerical preparation and implementation, application versatility, and, in certain aspects, numerical accuracy. Comprehensive numerical results for six classes of plates with selected mode shapes are presented. These results may serve as a benchmark for future reference since no literature can be found for symmetric doubly-tapered plates as considered in this study.

10A75. Exact analytical solutions for the vibrations of sectorial plates with simply-supported radial edges. - CS Huang *(Dept of Civil Eng, Ohio State Univ, Columbus OH 43210)*, AW Leissa *(Dept of Eng Mech, Ohio State Univ, Columbus OH 43210)*, OG McGee *(Dept of Civil Eng, Ohio State Univ, Columbus OH 43210)*. J Appl Mech 60(2) 478-483 (Jun 1993).

The first known exact analytical solutions are derived for the free vibrations of sectorial thin plates having their radial edges simply supported, with arbitrary conditions along their circular edges. This requires satisfying: (1) the differential equation of motion, (2) boundary conditions along the radial and circular edges, and (3) proper regularity conditions at the vertex of the radial edges. The solution to the differential equation involves ordinary and modified Bessel functions of the first and second kinds, of non-integer order, and four constants of integration. Utilizing a careful limiting process, the regularity conditions are invoked to develop two equations of constraint among the four constants for sector angles exceeding 180° (re-entrant corners). Moment singularities for re-entrant corners are shown to be the same as the ones determined by Williams (1952) for statically loaded sectorial plates. Frequency determinants and equations are generated for circular boundaries which are clamped, simply-supported, or free. Nondimensional frequency parameters are presented for all three types of configurations for sector angles of 195°, 210°, 270°, 330°, and 360° (ie, re-entrant corners).

10A76. Large amplitude vibrations of imperfect antisymmetric angle-ply laminated plates. - A Bhimaraddi *(Diversified Computer Eng and Development, Clawson MI 48017)*. J Sound Vib 162(3) 457-470 (22 Apr 1993).

This paper deals with the large amplitude vibrations of imperfect anitsymmetric angle ply and symmetric cross ply laminated plates using the von Karman type nonlinear plate model. The basic plate equations correspond to those of the parabolic shear deformation plate theory. Five governing differential equations of the plate are first reduced to a single nonlinear time differential equations, using the single mode approach to a simply supported plate. This equation involves the quadratic and cubic nonlinearities for imperfect plates. Nonlinear to linear frequency ratios have been obtained using the perturbations method and the exact method. Numerical results indicate that the perturbation methods are unreliable for certain plate problems and lead to wrong conclusions. It has been observed that whether the plate exhibits a hardening or softening type of nonlinearity depends on both the initial imperfection value and the amplitude of vibration.

10A77. Large-amplitude FE flexural vibration of plates-stiffened plates. - SR Rao, AH Sheikh, M Mukhopadhyay *(Dept of Naval Architec, Indian IT, Kharagpur 721 302, India)*. J Acoust Soc Am 93(6) 3250-3257 (Jun 1993).

Large-amplitude free flexural vibration of stiffened and unstiffened plates has been studied by using the FEM. An isoparametric quadratic plate-bending element has been used both for the plate and the stiffener. The dynamic version of von Karman's field equations has been adopted and the formulation has been done in the total Lagrangian coordinate system. The in-plane deformation and inertia have been taken into account. The resulting nonlinear equations have been solved by the direct iteration technique using a linear mode shape as the starting vector. The stiffener has been elegantly modeled so that it can be placed anywhere within the plate element and it need not follow the nodal lines. This has increased the flexibility of the mesh generation considerably. The arbitrary orientation and eccentricity of the stiffener have been incorporated in the formulation. The shear deformation has been incorporated according to Mindlin's hypothesis. Stiffened and unstiffened plates that have various boundary conditions have been analyzed and the results have been compared with those available in the literature.

10A78. Modeling of dynamic networks of thin elastic plates. - JE Lagnese and G Leugering *(Dept of Math, Georgetown Univ, Washington DC 20057)*. Math Methods Appl Sci 16(6) 379-407 (Jun 1993).

The purpose of this paper is to derive junction conditions for networks of thin elastic plates and to analyze the dynamic equations of such networks. Junction conditions for networks of Kirchhoff plates and networks of Reissner-Mindlin plates are derived based on geometric considerations of the deformation at a junction. It is proved that the dynamic system which describes the Reissner-Mindlin network is well-posed is an appropriate energy space. It is further established that the Kirchhoff network is obtained in the limit of the Reissner-Mindlin network as the shear moduli go to infinity.

10A79. Transverse vibration of annular circular and elliptic plates using the characteristic orthogonal polynomials in 2D. - B Singh *(Dept of Math, Univ of Roorkee, Roorkee UP 247 667, India)* and S Chakraverty *(Comput Center, Central Build Res Inst, Roorkee, India)*. J Sound Vib 162(3) 537-546 (22 Apr 1993).

Characteristic orthogonal polynomials in two variables have been generated over the annular region occupied by a circular or elliptic plate satisfying the essential boundary conditions. These are used ot express the displacement in the transverse vibration of the plate. The Rayleigh-Ritz method is then applied to study the fundamental mode of vibration. Comparison has been made with the known results for circular annular plates in some cases. The results for the elliptic annular plate are entirely new and are not available elsewhere. All the results are summarized in tables covering various combinations of the boundary conditions.

10A80. Vibration analysis of annular plates with concentric supports using a variant of Rayleigh-Ritz method. - CM Wang and V Thevendran *(Dept of Civil Eng, Natl Univ of Singapore, Kent Ridge 0511, Singapore)*. J Sound Vib 163(1) 137-149 (8 May 1993).

A variant of the Rayleigh-Ritz method is presented for solving the free vibration problem of annular plates with internal axisymmetric supports. The method is simple, accurate and may be readily programmed and run on a microcomputer. A comprehensive tabulation of the fundamental frequencies is presented for isotropic annular plates with an internal concentric support. Results for full circular plates with concentric supports are also obtained by making the inner radial edge free and permitting the inner radius to become very small.

10A81. Vibration analysis of orthotropic Mindlin plates with edges elastically restrained against rotation. - JH Chung, TY Chung *(Korea Res Inst of Ships and Ocean Eng, Daeduk Sci Town, Daejon, Korea)*, KC Kim *(Dept of Naval Architec, Seoul Natl Univ, Seoul, Korea)*. J Sound Vib 163(1) 151-163 (8 May 1993).

The free vibration analysis of the orthotropic Mindlin plates with edges elastically restrained against rotation has been accomplished using the Rayleigh-Ritz method. Polynomials with properties corresponding to those of the Timoshenko beam functions are introduced as trial functions in the spatial representation of the deflection and rotations of cross sections in two directions of the plates. The results obtained by using polynomials are nearly the same as the Timoshenko beam function results, but were obtained with considerably less numerical efforts.

10A82. Vibrations of multispan all-round clamped stiffened plates by modified dynamic edge effect method. - I Elishakoff *(Center for Appl Stochastic R&D and Dept of Mech Eng, Florida Atlantic Univ, Boca Raton FL 33431-0991)*, A Sternberg *(RAPHAEL, Kiriat Mozkin PO Box 2250, Haifa 31021, Israel)*, TJ Van Baten *(Dept of Aerospace Eng, Delft Univ of Tech, HS 2629 Delft, Netherlands)*. Comput Methods Appl Mech Eng 105(2) 211-223 (Jun 1993).

The modified dynamic edge effect method is applied to dynamic analysis of continuous skin-stringer panels. The number of spans is assumed finite; all panels and interior stringers are identical. The solution procedure involves formulation of two auxiliary problems of the Voigt-Levy type in conjunction with an eigenfrequency wave-number relationship. The treatment yields a pair of transcendental equations in terms of wave numbers. The method has advantages over other approximate approaches in the sense that the number of spans enters one of the transcendental equations explicitly, so that numerical complexity does not increase with it.

10A83. Thickness expansions for higher-order effects in vibrating cylindrical shells. - JG McDaniel *(BBN Syst and Tech, Cambridge MA 02138)* and JH Ginsberg *(Sch of Mech Eng, Georgia Tech)*. J Appl Mech 60(2) 463-469 (Jun 1993).

In the spirit of Mindlin and others who have used series expansions to express transverse dependence in thin bodies, the present work uses Ritz expansions in a variational formulation for cylindrical shell vibrations. By expanding displacements in spatial coordinates, integral expressions for strain and kinetic energy are converted to quadratic sums involving time-dependent generalized coordinates. Hamilton's principle provides ordinary differential equations for these coordinates. This viewpoint yields physical insight into the mechanisms of energy storage and avoids the geometrically thin assumption inherent to many formulations. A set of Legendre polynomials multiplied by a radial factor repesent the radial dependences of displacement components, while circumferential variations are represented by sinusoidal functions. Excellent agreement in natural frequencies is found between this approach and analytical solutions over the entire range of shell thicknesses, including the limiting case of a solid cylinder. Comparisons to several thin shell theories are given, leading to conclusions about the range of validity of these theories.

10A84. Natural frequencies and modes of a circular plate welded to a circular cylindrical shell at arbitrary axial positions. - DT Huang and W Soedel *(Sch of Mech Eng, Purdue)*. J Sound Vib 162(3) 403-427 (22 Apr 1993).

The modal characteristics of a plate shell coupled structure consisting of a simply supported thin circular cylindrical shell and a circular plate which may be joined to the shell at any arbitrary axial position were studied using the receptance method. Line receptances were formulated from the responses of the plate and the shell to line force and line moment loadings distributed harmonically along the interface of the plate and the shell, utilizing natural modes and frequencies of the plate and shell, respectively. The system frequency equation was generated and solved numerically to obtain the natural frequencies and mode shapes of the combined structure under different joining configurations. The effects of length, thicknesses and joining positions on the modal characteristics of the combined structure were investigated. Certain results obtained from the receptance method and a FE program were compared for verification purposes and showed good agreement. The structural coupling behavior between the plate and the shell and the coupling relationship between the line force loading and the line moment loading were explored.

10A85. Natural frequencies and stability of a flexible spinning disk-stationary load system with rigid-body tilting. - Jen-San Chen *(Dept of Mech Eng, Natl Taiwan Univ, Taipei, Taiwan 107)* and DB Bogy *(Comput Mech Lab, Dept of Mech Eng, UCB)*. J Appl Mech 60(2) 470-477 (Jun 1993).

The effects of rigid-body tilting on the natural frequencies and stability of the head-disk interface of a flexible spinning disk are studied both by analysis and numerical computation. Another problem of a stationary flexible disk with rigid body tilting subject to a rotating load system is also studied. In the conventional case without rigid-body tilting, these two problems are mathematically identical except for the additional membrane stress terms arising from the centrifugal force. When the rigid-body tilting is included, however, these two problems differ not only by the centrifugal effect, but also by additional terms which arise from the gyrodynamic effect. After properly defining the inner product between two state vectors, the set of equations of motion is proven to fall into the category of gyroscopic systems. Then the derivatives of the eigenvalues of the coupled system are obtained to provide a better understanding of the numerical results.

10A86. Vibration and damping analysis of pre-twisted composite blades. - S Mohamed Nabi and N Ganesan *(Machine Dyn Lab, Dept of Appl Mech, Indian IT, Madras 600 036, India)*. Comput Struct 47(2) 275-280 (Apr 1993).

Vibration characteristics of pre-twisted composite blades are analyzed using a three-noded triangular cylindrical shell element. The specific example of glass fibre reinforced plastic material is analyzed with its material damping. The effect of different parameters such as pre-twist, fibre orientation, skew angle, taper ratio on natural frequency and system loss factor is investigated. It is found that the maximum fundamental frequency and maximum fundamental loss factor occur at different twist angles and at different fibre orientations. The influence of taper ratio and aspect ratio on 0° and 90° fibre orientations is reported. The effect of skew angle on natural frequency and on system loss factors is seen to be low.

10A87. Vibration and stability of a rotating shaft containing a transverse crack. - SC Huang *(Dept of Mech Eng, Natl Taiwan IT, Taipei, Taiwan 10772, ROC)*, YM Huang *(Dept of Mech Eng, Natl Central Univ, Chung-Li, Taiwan, ROC)*, SH Shieh *(Dept of Mech Eng, Natl Taiwan IT, Taipei, Taiwan 10772, ROC)*. J Sound Vib 162(3) 387-401 (22 Apr 1993).

The dynamic response of a rotating shaft containing a transverse crack is investigated. The local flexibility due to the crack is first evaluated from the theory of fracture mechanics. The results show that an increase of crack depth magnifies the response amplitude as expected. It is discovered that the crack affects the dynamic response more significantly when it occurs near a place where the bending moment exhibits a larger value. From the FFT analysis of the displacement responses, it is seen that the 1Ω and 2Ω components are excited prominently due to crack. Hence, they provide possibly good indices for an online crack monitoring system. The stability of a cracked shaft is examined via the Floquet theory, and the results show that, for an integer multiple of the shaft bending frequency when the crack depth reaches half of the radius. However, a small amount of damping is found to raise effectively the unstable region.

10A88. Lanczos-based technique for exact vibration analysis of skeletal structures. - HA Smith *(Dept of Civil Eng, Stanford)*, DC Sorensen *(Dept of Math Sci, Rice Univ, Houston TX 77251)*, RK Singh *(Dept of Civil Eng, Stanford)*. Int J Numer Methods Eng 36(12) 1987-2000 (30 Jun 1993).

This paper presents and discusses a Lanczos-based eigensolution technique for evaluating the natural frequencies and modes from frequency-dependent eigenproblems in structural dynamics. The new solution technique is used in conjunction with a mixed FE modeling procedure which utilizes both the polynomial and frequency-dependent displacement fields in formulating the system matrices. The method is well suited to the solution of large-scale problems. The new solution methodology presented here is based on the ability to evaluate a specific set of parameterized nonlinear eigenvalue curves at given values of the parameter through an implicitly restarted Lanczos technique. Numerical examples illustrate that the implicitly restarted Lanczos method with secant interpolation accurately evaluates the exact natural frequencies and modes of the nonlinear eigenproblem and verifies that the new eigensolution technique coupled with the mixed FE modeling procedure is more accurate than the conventional FE models. In addition, the eigenvalue technique presented here is shown to be far more computationally efficient on large-scale problems than the determinant search techniques traditionally employed for solving exact vibration problems.

10A89. Vibration of laminated composite arches with deep curvature and arbitrary boundaries. - MS Qatu *(Dept of Mech Eng, Franklin Univ, 201 S Grant Ave, Columbus OH 43215)* and AA Elsharkawy *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. Comput Struct 47(2) 305-311 (Apr 1993).

Exact solutions for the title problem are presented for general boundary conditions. No numerical frequencies are presented using these solutions, instead natural frequencies are obtained using the Ritz method. This method has the important shortcoming that the assumed displacements have to be changed when various boundary conditions are treated. This shortcoming is overcome in this paper by assuming the displacement functions as polynomials having a general form. Accurate frequencies are obtained for arbitrary boundary conditions. The results can be useful for designers, engineers, and researchers who are interested in the problem. The method can also be generalized to plate- and shell-like structures.

10A90. Dynamic analysis of laminates with elliptical cutouts using the hybrid-stress FE. - S Ramakrishna, KM Rao, NS Rao *(Dept of Mech Eng, Indian IT, Kharagpur 721 302, India)*. Comput Struct 47(2) 281-287 (Apr 1993).

An eight-noded hybrid-stress FE is used to analyze the dynamic behavior of laminated plates with elliptical cutouts. The first four natural frequencies are evaluated by varying a number of parameters, such as the fibre orientation, width-to-thickness ratio, hole size and major-to-minor axes ratio.

10A91. Effect of thermal stresses on the vibration of composite cantilevered plates. - JM Klosner and T-H Cheng *(Dept of Mech and Indust Eng, Polytech Univ, Farmingdale NY 11735)*. J Composite Tech Res 15(2) 123-135 (Sum 1993).

This study explores the effects of thermal stresses on the dynamic characteristics of composite cantilevered plates. The induced thermal stresses are determined by appealing to the principle of minimum strain energy, while the Raleigh-Ritz procedure is used to obtain the plate frequencies. Extensive numerical calculations have been carried out in order to gain quantitative understanding of how different choices of aspect ratios and temperature change intensities (T_0) influence the natural frequencies of composite cantilevered plates. It has been shown that the first bending mode frequencies are unaffected by the induced stresses, while the first torsional mode frequencies decrease quite significantly with increasing values of T_0, and therefore with increased magnitudes of the thermal stresses.

10A92. Vibration of clamped moderately thick general cross-ply plates using a generalized Navier approach. - RA Chaudhuri *(Dept of Civil Eng, Univ of Utah, Salt Lake City UT 84112)* and HRH Kabir *(Eng Mech Res Corp, Troy MI 48084)*. Composite Struct 24(4) 311-321 (1993).

A hitherto unavailable analytical solution to the free vibration problem of general cross-ply laminated rigidly clamped rectangular plates, incorporating first-order shear deformation, and rotatory and in-plane inertias into the formulation, is presented. A recently developed boundary continuous displacement based generalized Navier solution technique is used to solve the five highly coupled linear second-order partial differential equations with constant coefficients, and the associated geometric boundary conditions. The assumed solution functions are in the form of double Fourier series, which satisfy the rigidly clamped boundary conditions *a priori* in a manner similar to the conventional Navier method. Convergence characteristics of the natural frequencies of both symmetric and antisymmetric cross-ply plates are numerically established. Other numerical results presented herein include (i) comparison with the corresponding available first-order shear deformation theory-based Galerkin and classical lamination theory-based-boundary discontinuous analytical solutions, and (ii) study of the effects of thickness and aspect ratio on the natural frequencies.

10A93. Free vibrations of foundation beams on two-parameter elastic soil. - C Franciosi and A Masi *(Dept of Struct Eng and Soil Mech, Univ of Basilicata, Via della Tecnica 3, 85100 Potenza, Italy)*. Comput Struct 47(3) 419-426 (3 May 1993).

A FE free vibration analysis of beams on a two-parameter elastic foundation is performed using the exact shape functions. The stiffness matrix and the mass matrix are deduced in closed form for the whole parameter range. Numerical comparisons and examples allow us to check the performance of the proposed FE. A practical example ends the paper.

10A94. Stochastic FE for a beam on a random foundation with uncertain damping under a moving force. - L Fryba *(Inst of Theor and Appl Mech, Acad of Sci, Prague, Czech Republic)*, S Nakagiri, N Yoshikawa *(Dept of Appl Phys and Appl Mech, Inst of Indust Sci, Univ of Tokyo, Tokyo, Japan)*. J Sound Vib 163(1) 31-45 (8 May 1993).

It appears that a stochastic stationary process occurs, viewed by an observer moving together with the moving force. A stochastic FE analysis by means of the first order perturbation and first order second-moment method provides an evaluation of the variance of the deflection and of the bending moment of the beam. The effects of several parameters and of various types of correlation functions are investigated. It is shown that the randomness of the foundation is of greater importance than the uncertainty in the damping. The dynamic and stochastic effects increase with increasing speed of the movement of the force in the subcritical domain, but decrease in the supercritical domain. The coefficient of variation of the deflection of the beam is larger than that if the bending moment at the point of application of the moving force.

154Y. COMPUTATIONAL TECHNIQUES

10A95. Model reduction methods for dynamic analyses of large structures. - B Haggblad *(Dept of Solid Mech, RIT, S-100 44 Stockholm, Sweden)* and L Eriksson *(Corp Res, ASEA Brown Boveri, S-721 78 Vasteras, Sweden)*. Comput Struct 47(4-5) 735-749 (3 Jun 1993).

User-friendly FE pre-processors permit detailed modeling of engineering structures with complicated topologies, often resulting in a much larger number of dof than that motivated by the expected complexity of the structural response. Dynamic analyses of these large-scale models might require a prohibitive amount of CPU time. In particular, the uncoupling of the equations of motion for linear systems with non-proportional damping by means of a complex eigenvector basis is computationally very demanding. We present general model reduction procedures, applicable to whole structures or substructures, that produce a series of reduced models each spanning appropriate subspaces (general Krylov spaces) of the solution space. Crucial steps in such procedures are the selection of basis vectors for the (sub) structures and the control of reduction errors. The set of basis vectors is generated by using a simple physical approach for successively reducing the residual error in the governing equilibrium equations. A frequency window method (shifting) is used to capture the relevant frequency content. The residuals of the equilibrium equations, computed on fully expanded level, are used as reliable measures of the reduction errors. The efficiency of the techniques is demonstrated in some numerical experiments and on a large engineering problem, using a program based on SAP IV.

10A96. Post-processing technique and an a posteriori error estimate for the Newmark Method in dynamic analysis. - N-E Wiberg and XD Li *(Dept of Struct Mech, Chalmers Univ of Tech, S-412 96, Gothenburg, Sweden)*. Earthquake Eng Struct Dyn 22(6) 465-489 (Jun 1993).

In this paper, we present a post-processing technique and an *a posteriori* error estimate for the Newmark method in structural dynamic analysis. By post-processing the Newmark solutions, we derive a simple formulation for linearly varied third-order derivatives. By comparing the Newmark solutions with the exact solutions expanded in the Taylor series, we achieve the local post-processed solutions which are of fifth order accuracy for displacements and fourth-order accuracy for velocities in one step. Based on the post-processing technique, *a posteriori* local error estimates for displacements, velocities and, thus, also the total energy norm error estimate are obtained. If the Newmark solutions are corrected at each step, the post-processed solutions are of third-order accuracy in the global sense, ie, one-order improvement for the original Newmark solutions is achieved. We also discuss a method for estimating the global time integration error. We find that, when the total energy norm is used, the sum of the local error estimates will give a reasonable estimate for the global error. We present numerical studies on a SDOF and a 2 dof example in order to demonstrate the performance of the proposed technique.

10A97. Reciprocal relations in nonlinear vibrations. - VL Berdichevsky *(Sch of Aerospace Eng, Georgia Tech)*. Int J Eng Sci 31(8) 1215-1218 (Aug 1993).

General reciprocal relations between the response of a nonlinear system and the exciting force are derived. A variational principle for the amplitude characteristics of the response is formulated.

10A98. Analysis of continuous box girder bridges including the effects of distortion. - B Kermani *(Acer Consultants, Bristol, UK)* and P Waldron *(Dept of Civil and Struct Eng, Univ of Sheffield, PO Box 600 Mappin St, Sheffield S1 4DU, UK)*. Comput Struct 47(3) 427-440 (3 May 1993).

Torsional warping and distortion of the cross-section are important features of thin-walled beams and must be considered fully in the design of box girder bridges. A method of elastic analysis is developed based on the stiffness approach which includes the effects of warping torsion and distortion in addition to the more familiar actions of bending moment and torsion. The method, which is applicable to straight single cell box girders with at least one axis of symmetry, is demonstrated here in the analysis of three different box girder models for which experimental or analytical results were already available. The method is shown to be easy and economical to use and provides a physical insight into the structural response of thin-walled box girder bridges under general loading conditions.

10A99. Parametric study of cable-stayed bridge response due to traffic-induced vibration. - MA Khalifa *(Dept of Civil Eng, Univ of Nebraska, Lincoln NE 68588-0531)*. Comput Struct 47(2) 321-339 (Apr 1993).

The dynamic response of long-span cable-stayed bridges due to moving traffic loads is investigated utilizing 3D models. Modal analysis is conducted using the deformed dead-load tangent stiffness matrix. A new concept, presented by discretization of cable into several elements, is used to study the effect of cable vibration on bridge dynamics. A computer algorithm is developed to simulate the applied traffic loads for both directions of the bridge deck. The algorithm is flexible in terms of handling different loading capacities, speeds and configurations. Parametric studies are conducted to investigate the effect of cable vibration, damping, vehicle-structure interaction, random roughness of the bridge deck, as well as span length and vehicle-speed. Cases of asymmetric traffic loading clustered in one direction are also considered in order to study the torsional response of the bridge. Results are discussed, summarized and plotted.

10A101. Response statistics of nonlinear, compliant offshore structures by the path integral solution method. - A Naess *(Fac of Civil Eng, Norwegian IT, Rich Birkelands vie IIa, N-7034 Trondheim, Norway)* and JM Johnsen *(Kvaerner Eng, PO Box 222, N-1234 Lysaker, Norway)*. Probab Eng Mech 8(2) 91-106 (1993).

The paper investigates the applicability of the path integral solution method for calculating the response statistics of nonlinear dynamic systems whose equations of motion can be modeled by use of the Ito stochastic differential equations. The state vector process associated with such a model is generally a diffusion process, and the probability density function of the process thus satisfies a Fokker-Planck-Kolmogorov equation. It is shown in the paper that the path integral solution technique combined with an appropriate numerical scheme constitutes a powerful method for solving the Fokker-Planck-Kolmogorov equation with natural boundary conditions. The method distinguishes itself by high accuracy and numerical robustness even at very low probability levels. These features are high-lighted by application to example studies of nonlinear, compliant offshore structures.

10A102. Vibration analysis of composite wing with tip mass using FEs. - In Lee and Jung-Jin Lee *(Dept of Aerospace Eng, Korea Adv Inst of Sci and Tech, Taejon, Korea)*. Comput Struct 47(3) 495-504 (3 May 1993).

The analysis of vibration characteristics, including the natural frequencies and modes for various shaped composite wings with a tip mass and an engine, has been performed using the FEM based on the shear deformable theory. The present analysis presents the effect of tip mass, engine, sweep angle, fiber orientation, and aspect ratio of a composite wing, which is composed of graphite-epoxy laminate with a symmetric stacking sequence, on vibration characteristics. At a specific fiber orientation, the natural frequencies of the two modes approach each other. The natural frequencies of the wing with the tip mass and the engine are lower than those of the wing without the tip mass and the engine. However, for the wing and the tip mass, the natural frequencies of the chordwise mode increase due to the increase of the bending stiffness of the tip mass. This present FEM, which uses eight-node quadrilateral elements, gives very accurate results.

10A103. Dynamic characteristics of liquid motion in partially filled tanks of a spinning spacecraft. - BN Agrawal *(Dept of Aeronaut and Astronaut, Naval Postgraduate Sch, Monterey CA 93943)*. J Guidance Control Dyn 16(4) 636-640 (Jul-Aug 1993).

This paper presents a boundary-layer model to predict dynamic characteristics of liquid motion in partially filled tanks of a spinning spacecraft. The solution is obtained by solving three boundary-value problems: an inviscid fluid problem, a boundary-layer problem, and a viscous correction problem. The boundary-layer solution is obtained analytically, and the solutions to inviscid and viscous correction problems are obtained by using FEMs. The model has been used to predict liquid natural frequencies, mode shapes, damping ratios, and nutation time constants for a spinning spacecraft. The results show that the liquid motion in general will contain significant circulatory motion due to Coriolis forces except in the first azimuth and first elevation modes. Therefore, only these two modes can be represented accurately by equivalent pendulum models. The analytical results predict a sharp drop in nutation time constants for certain spacecraft inertia ratios and tank fill fractions. This phenomenon was also present during on-orbit liquid slosh tests and ground air-bearing tests.

10A104. Unsteady aerodynamic response of 2D subsonic and supersonic oscillating cascades with chordwise displacement and flexible deformation. - M Namba and K Toshimitsu *(Dept of Aeronaut and Astronaut, Kyushu Univ, Hakozaki, Higasi-ku Fukuoka 812, Japan)*. J Sound Vib 162(3) 503-527 (22 Apr 1993).

In this paper the double linearization theory applied to lightly loaded 2D subsonic and supersonic cascades undergoing oscillation with chordwise displacement or flexible deformation is presented. Numerical computation based on this theory have been conducted to demonstrate parametric dependence of the unsteady aerodynamic work on blades. The translational oscillation can be destabilized by chordwise displacement for both subsonic and supersonic cascades. The contribution of chordwise displacement to the unsteady aerodynamic work is strongly dependent upon the phase difference between the chordwise and normal components of the blade motion. The unsteady aerodynamic work for flexible blade motion also is substantially influenced by steady loading. For the supersonic cascades, the effect of displacement of Mach line reflection points due to the chordwise blade motion gives a significant contribution to the unsteady aerodynamic force.

10A105. Active distributed damping of flexible structures using piezo-electric actuator-sensors. - F Pourki *(Dept of Mech Eng and Mech, Drexel Univ, Philadelphia PA 19103)*. Mech Res Commun 20(4) 279-285 (Jul-Aug 1993).

The concept of "space stations" and the growing number of space missions, during which, different manned or unmanned manoeuvres are exercised, has led to emergence of so called "adaptive" or "smart structures". In these structures, the principles of control engineering are used, to make the structure adapt to a set of required geometric or dynamic constraints during a manoeuvre. Examples of "adaptive" or "smart structures" are abundant in "organic and biological systems" in nature. For instance, the birds' wings and navigation or steering organs of sea animals are formed in such ways to make them adaptable to variations in their manoeuvres. These "biological structures", embody proper actuators and sensors to vary their performance according to changes in environment, while their bodies support structural integrity and maintain appropriate rigidity. Muscular system, which deploys variable shapes for different tasks is another sophisticated biological example of adaptive structure with biochemical actuation mechanisms.

10A106. Transfer function modeling of damping mechanisms in distributed parameter models. - JC Slater and DJ Inman *(Mech Syst Lab, Dept of Mech and Aerospace Eng, SUNY, Buffalo NY 14260)*. Mech Res Commun 20(4) 287-292 (Jul-Aug 1993).

This work formulates a method for modeling of material damping characteristics in distributed parameter models which may be easily applied to models such as rod, plate, and beam equations. The general linear boundary value vibration equation is modified to incorporate hysteresis effects represented by complex stiffness using the transfer function approach proposed by Golla and Hughes. The governing characteristic equations are decoupled through separation of variables yielding solutions similar to those of undamped classical theory, allowing solution of the steady state as well as transient response. An example problem and solution is provided demonstrating the similarity of the solution to that of the classical theory and the transient response of non-viscous systems.

156O. ISOLATION

10A107. Damped resonant appendages to increase inherent damping in buildings. - R Villaverde and LA Koyama *(Dept of Civil Eng, UC, Irvine CA 92717)*. Earthquake Eng Struct Dyn 22(6) 491-507 (Jun 1993).

It is demonstrated that the addition of a tuned mass-spring-dashpot system with a relatively small mass and a high damping ratio can be an effective way to increase the inherent damping characteristics of buildings and reduce, thus, their response to earthquake excitations. The demonstration is based on a theoretical formulation and on numerical and experimental studies that confirm this formulation. In the theoretical formulation, it is shown that, if certain conditions are satisfied, the damping ratios in two of the modes of the system that is formed by a building and an appendage in resonance are approximately equal to the average of the corresponding damping ratios of the building and the appendage. Based on this finding, it is then shown that an attached appendage with a high damping ratio and tuned to the fundamental frequency of a building may increase the damping ratio in the fundamental mode of the building to a value close to half the damping ratio of the appendage. In the numerical study, the response of a ten-storey shear building is analysed under two different earthquake ground motions with and without the proposed resonant appendages. Appendages with damping ratios of 20 and 30% are considered. In this study, it is found that under one of the ground motions the maximum displacement of the building's roof is reduced 30% with the appendage with 20% damping and 39% with the one with 30% damping. Similarly, with these two appendages the building's base shear is reduced 31 and 41%, respectively. In the experimental study, a wooden three-storey structural model is tested in a shaking table with and without an appendage designed and constructed to have a damping ratio of 52.5%. The test is conducted under random and sinusoidal base excitations. In the shaking table test under random excitation, the attached appendage reduces the response of the model 38.6%, while in that under sinusoidal vibration 45.2%.

10A108. Vibration absorbers for a class of self-excited mechanical systems. - S Natsiavas *(Dept of Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287)*. J Appl Mech 60(2) 382-387 (Jun 1993).

An averaging methodology is employed in studying dynamics of a two-dof nonlinear oscillator. The main system is modeled as a van der Pol oscillator under harmonic forcing. The objective is to reduce its amplitude of oscillation near resonance, by attaching it to a damped vibration absorber with a Duffing spring. It is first shown that substantial reduction in the response amplitude can be achieved in this way. However, for some combinations of the parameters, the low-amplitude periodic motion of the system in the original resonance regime becomes unstable through a Hopf bifurcation of the averaged equations. Direct numerical integration shows that this gives rise to amplitude modulated or chaotic response of the oscillator, with much higher vibration amplitudes than the unstable periodic response, which coexists with these complex motions. Finally, it is shown that the present analysis can be employed in selecting the parameters in ways that exploit the significant practical advantages arising from the presence of the absorber, by predicting and avoiding these instabilities.

156Y. COMPUTATIONAL TECHNIQUES

10A109. Sensitivity based method for structural dynamic model improvement. - RM Lin, H Du, JH Ong *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave 2263, Singapore)*. Comput Struct 47(3) 349-369 (3 May 1993).

Sensitivity analysis, the study of how a structure's dynamic characteristics change with design variables, has been used to predict structural modification effects in design for many decades. In this paper, methods for calculating the eigensensitivity, frequency response function sensitivity and its modified new formulation are presented. The implementation of these sensitivity analyses to the practice of FE model improvement using vibration test data, which is one of the major applications of experimental modal testing, is discussed. Since it is very difficult in practice to measure all the coordinates which are specified in the FE model, sensitivity based methods become essential and are, in fact, the only appropriate methods of tackling the problem of FE model improvement. Comparisons of these methods are made in terms of the amount of measured data required, the speed of convergence and the magnitudes of modeling errors. Also, it is identified that the inverse iteration technique can be effectively used to minimize the computational costs involved. The FE model of a plane truss structure is used in numerical case studies to demonstrate the effectiveness of the applications of these sensitivity based methods to practical engineering structures.

158A. GENERAL THEORY

10A110. Morawetz's method for the decay of the solution of the exterior initial-boundary value problem for the linearized equation of dynamic elasticity. - A Charalambopoulos *(Dept of Math, Natl Tech Univ, Athens, Greece)*. J Elast 31(1) 47-69 (Apr 1993).

In this paper, the behavior of the solution of the time-dependent linearized equation of dynamic elasticity is examined. For the homogeneous problem, it is proved that in the exterior of a star-shaped body on the surface of which the displacement field is zero, the solution decays at the rate t^{1} as the time t tends to infinity. For the nonhomogeneous problem with a harmonic forcing term, it is proved that for large times, the elastic material in the exterior of the body, tends to a harmonic motion, with the period of the external force. The convergence to the steady harmonic state solution is at the rate $t^{1/2}$ as t tends to infinity, and is uniform on bounded sets.

158B. RODS AND BEAMS, ELASTIC

10A111. Numerical prediction of the propagation of elastic waves in longitudinally impacted rods: Applications to Hopkinson testing. - C Bacon *(Lab Mec Phys, Univ de Bordeaux I, 351, cours de la Liberation, 33 405 Talence, Cedex, France)*. Int J Impact Eng 13(4) 527-539 (Nov 1993).

Simple expressions, based on 1D elastic wave theory, are established which permit prediction of normal force and particle velocity at cross-sections of a non-uniform linearly-elastic rod. The initial normal force and particle velocity at each cross-section of that rod must be known. In order to assess the validity of the assumptions, an experimental test on a cone-shaped rod is performed. Numerical results are provided for two different configurations: a rod shaped at one end in order to perform the Hopkinson three-point bend test and a rod heated at one end for a high temperature dynamic test. The given expressions are so easy to program that a common spreadsheet program is sufficient to implement and perform the calculation. They enable the influence of an impedance variation to be quantified *a priori*. In the case of the Hopkinson three-point bend test, the wave distortion is not very important if the rise time is long and the length of the shaped end is short. For a heated rod, the conventional Hopkinson treatment is not available when the temperature is too high. Some effects of an idealized quasi-static specimen for both Hopkinson three-point bend and non-uniform temperature are included.

158C. PLATES AND SHELLS, ELASTIC

10A112. Axisymmetric response of nonlinearly elastic cylindrical shells to dynamic axial loads. - R Gilat, E Feldman, J Aboudi *(Dept of Solid Mech Mat and Struct, Fleishman Fac of Eng, Tel Aviv Univ, Ramat Aviv 69978, Israel)*. Int J Impact Eng 13(4) 545-554 (Nov 1993).

The axisymmetric response of nonlinearly elastic cylindrical shells subjected to dynamic axial loads is analyzed by using an incremental formulation. The material elastic nonlinearity is modeled by the generalized Ramberg-Osgood representation. The time-dependent displacements of the shell are assumed to be governed by nonlinear equations of motion based on the von Karman-Donnell kinematic relations; moreover, both in-surface and out-of-surface inertia terms are included. The finite difference method with respect to the spatial coordinate and the Runge-Kutta method with respect to time are employed to derive a solution. Numerical results demonstrate the effect of the material nonlinearity on the deflections, stiffness matrices and dynamic buckling behavior of cylindrical shells.

158F. SURFACE WAVES

10A113. Propagation of surface waves across a vertical layer with non-rigid contacts. - EN Its and JS Lee *(Dept of Civil and Env Eng, Clarkson Univ, Potsdam NY 13676)*. Int J Eng Sci 31(8) 1151-1163 (Aug 1993).

Propagation of surface waves across a vertical wave barrier inserted between two laterally homogeneous quarter-spaces is considered in this paper. Based on the Green's function technique, an analytical approach is developed to examine the reflection and transmission of Rayleigh surface waves across a composite barrier. The composite barrier consists of a high velocity layer sandwiched between two thin layers of low shear velocity materials. The high velocity layer is represented by differential matrix operators which relate the wave fields on each side of the layer. The low velocity layers are modeled by non-rigid or "unwelded" contact conditions which allow partial sliding at the interfaces. Screening ratios of barriers with various combinations of material, geometric, and non-rigidness parameters are compared and discussed in some detail.

158G. NONLINEAR MOTIONS

10A114. Existence of stationary nonlinear Rayleigh waves. - MF Hamilton, YA Il'insky, EA Zabolotskaya *(Dept of Mech Eng, Univ of Texas, Austin TX 78712-1063)*. J Acoust Soc Am 93(6) 3089-3095 (Jun 1993).

The existence of stationary nonlinear Rayleigh waves is investigated theoretically on the basis of new model equations for the propagation of finite amplitude Rayleigh waves in isotropic solids. The spectral components of the proposed stationary waveforms are governed by coupled quadratic algebraic equations that are similar in form to those used by Parker and Talbot. However, whereas the theoretical investigation of Parker and Talbot predicted the existence of stationary nonlinear Rayleigh waves, the present investigation does not, unless artificial constraints are imposed on the frequency spectrum. Differences between nonlinearity in Rayleigh wave propagation in isotropic solids and nonlinearity in sound wave propagation in fluids is briefly discussed.

158K. ANISOTROPIC MEDIA

10A115. Directional attenuation of SH waves in anisotropic poroelastic inhomogeneous media. - A Ben-Menahem *(Dept of Appl Math and Comput Sci, Weizmann Inst of Sci, Rehovot 76100, Israel)* and RL Gibson Jr *(LGIT-IRIGM, Univ Joseph Fourier, BP 53X, 38041 Grenoble, Cedex, France)*. J Acoust Soc Am 93(6) 3057-3065 (Jun 1993).

The equations of motion for anisotropic poroelastic inhomogeneous media admit separable SH wave motion for the case of azimuthal isotropy coupled with coaxial inhomogeneity and poroelasticity with a diagonal permeability tensor. In homogeneous examples of such media, the low-frequency waves exhibit differential attenuation that is more pronounced along the symmetry axis. If this differential attenuation can be observed, it may be used to determine the permeability of the medium. Media with a vertical gradient of both elastic and permeability properties show different effects. For low-frequency waves, the attenuation acts so as to reverse the effects of elastic parameter gradients on SH wave amplitudes.

10A116. Eigenfunction expansion of the elastic wave Green's function for anisotropic media. - DE Budreck *(Dept of Math, Dept of Aerospace Eng and Eng Mech, Iowa State Univ, Ames IA 50011)*. Quart J Mech Appl Math 46(1) 1-26 (Feb 1993).

We consider the propagation of aves in a 3D, homogeneous, general anisotropic elastic medium of infinite extent. A special representation of the corresponding Green's function is derived. This representation expresses the Green's function as a bilinear expansion in the eigenfunctions of the linear elastic Hookean operator. The expansion follows from a completeness property which these eigenfunctions possess. Since the eigenfunctions of this operator correspond physically to freely-propagating plane waves, the eigenfunction-expansion representation affords a very natural physical interpretation of the Green's function as a modal and angular superposition of these freely-propagating modes. From this representation two additional results are derived: (1) a generalized completeness relation involving the freely-propagating modes which is shown to generate functional transform pairs which use the wave modes as the underlying basis set, and (2) a far-field asymptotic representation of the Green's function as a superposition of products of the freely-propagating modes with geometrically decaying spherical waves. The Green's function representation and generalized completeness relation are valid for elastic media of general anisotropy. The asymptotic representation is here derived within the constraint that the elastic media be isotropic, for which a simple integration-by-parts procedure provides the full expansion.

158L. LAYERED AND NONHOMOGENEOUS MEDIA

10A117. Discontinuity waves cannot describe evanescent waves. - F Bampi *(Inst Matematico di Ing, Univ Genova, Piazzale Kennedy Pad D, 16129 Genova, Italy)* and C Zordan *(Dipt Ing Biofis Electtron, Univ Genova, Via all'Opera Pia 11a, 16145 Genova, Italy)*. Wave Motion 17(3) 213-222 (May 1993).

The problem of oblique incidence of plane waves on a boundary between two linear media is examined in detail especially in connection with generation of evanescent waves. It is shown that, unlike plane waves, evanescent waves are fully determined by two functions, which are to be chosen as the Hilbert transform of each other so as to guarantee an appropriate behavior of the solution at infinity. When such an approach is contrasted with the theory of discontinuity waves, it turns out that the usual information about discontinuities does not suffice for calculating evanescent waves. In conclusion, the oblique incidence problem does not admit a consistent answer within the sole framework of discontinuity waves.

10A118. New stacking layer elements for analyses of reflection and transmission of elastic waves to inhomogeneous layers. - T Ohyoshi *(Dept of Mech Eng, Mining Col, Akita Univ, 1-1 Tegata-Gakuen-Cho, Akita City 010, Japan).* Mech Res Commun 20(4) 353-359 (Jul-Aug 1993).

A new model of a layer element is presented for the analysis of a general inhomogeneous elastic layer. The element is inhomogeneous and its mechanical impedance varies linearly with layer thickness. Stacking of the elements simulates well a real inhomogeneous layer with small number of elements. The analytical formulation of the stacked multi-layer structure is made by the transfer matrix method. Benefits of such the new elements to the analysis are examined by comparison with conventional approximate method of piling up of many homogeneous layers. Studies on reflections and transmission of elastic waves due to inhomogeneous layer have been reported by many researchers. Modern problems related to functionally gradient materials are generally difficult ones to analyze without resorting to some numerical approach. Most analyses of papers relating to an inhomogeneous elastic layer may be classified into two kinds of approaches. One is the approximation by piling up a large number of homogeneous thin layers, which is likely to lead to a large amount of numerical calculations. The other approach is a theoretical analysis using a restricted function to describe the inhomogeneous property inside a material. The function should be chosen so that the governing equations have manageable solutions. To improve such the unsatisfied approaches, the new element is proposed here. Stacking of the elements may improve much the adaptability to various real inhomogeneous solids with small number of elements.

158N. RANDOM WAVES OR MEDIA

10A119. Method for obtaining evolution equations for nonlinear waves in a random medium. - B Gurevich *(VNII Geosys, Varshavskoe Shosse 8, Moscow 113105, Russia),* A Jeffrey *(Dept of Eng Math, Univ of Newcastle upon Tyne, NE1 7RU, UK),* EN Pelinovsky *(Inst of Appl Phys, 48 Ul'anova St 603600 Nizhny, Novgorod, Russia).* Wave Motion 17(3) 287-295 (May 1993).

Most of the methods used to derive deterministic equations governing the evolution of linear waves in random media are based on the mean field approach. For a given linear system of equations with random coefficients this approach results in an approximate deterministic equation (or system) for the mean (averaged over the set of all realizations) field. The coefficients of such equations are associated with the statistical moments of the random coefficients of the initial system. Sometimes similar approaches are also applied to nonlinear problems. However, recently, in a number of examples, it was shown that the mean field approach in nonlinear problems may give the wrong results. The error is related to the infinite growth of the root-mean-square phase fluctuations due to fluctuations of the wave velocity in an inhomogeneous medium. To overcome this effect the idea of eliminating the unbounded growth of phase fluctuations by using an appropriate coordinate transformation was proposed resulting in a method called the "mean waveform method". In the present paper we extend the idea of the mean waveform method in order to develop a systematic approach which enables the construction of an approximate deterministic evolution equation for a given quasi-hyperbolic and quasi-linear system of equations with weak nonlinearity and stationary random coefficients. The applicability of the proposed approach is demonstrated by means of an example.

158Q. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

10A120. Diffraction of SV waves by underground, circular, cylindrical cavities. - VW Lee and J Karl *(Dept of Civil Eng, Univ of Southern California, Los Angeles CA 90089).* Soil Dyn Earthquake Eng 11(8) 445-456 (1992).

The scattering and diffraction of plane SV waves by underground, circular, cylindrical cavities at various depths in an elastic half space is studied in this paper. The cavities, studied here, are at depths of two to five cavity radii, measured from the surface to the center of the cavity. Fourier-Bessel series are used to satisfy the wave equation and the boundary conditions. When the angle of incidence of the plane SV wave exceeds the critical angle, surface waves are generated, which are expanded in terms of Fourier series, which also involve Bessel functions. The surface displacement amplitudes and phases that are presented show that the results depend on the following parameters: (1) The angle of incidence, θ_β; (2) the ratio of cavity depth to the cavity radius, h/a; (3) the dimensionless frequency of the incident SV wave, η; and (4) Poisson's ration, ν. The presence of the cavity in the half space results in significant deviation of both the displacement amplitudes and phases on the nearby half space surface from that of a uniform half space.

10A121. Scattering of ultrasonic wave by cracks in a plate. - SW Liu *(Dept of Mech Eng, Chinese Air Force Acad, Taiwan, ROC)* and SK Datta *(Dept of Mech Eng, CIRES and Center for Space Construct, Univ of Colorado, Boulder CO 80309-0427).* J Appl Mech 60(2) 352-357 (Jun 1993).

A hybrid numerical method combining FEs and the boundary integral representation is used to investigate the transient scattering of ultrasonic waves by a crack in a plate. The incident wave models the guided waves generated by a steel ball impact on the plate. Two surface-breaking cracks and one subsurface crack are studied here. The results show that the location and depth of cracks have measurable effects on the surface responses in time and frequency domains. Also, the scattered fields have distinct differences in three cases.

10A122. Strain localization and bifurcation in a nonlocal continuum. - G Pijaudier-Cabot and A Benallal *(Lab de Mec et Tech, ENS Cachan CNRS, Univ Paris 6, 61, ave du President Wilson, 94235 Cachan Cedex, France).* Int J Solids Struct 30(13) 1761-1775 (1993).

The conditions for localization and wave propagation in a strain softening material described by a nonlocal damage based constitutive relation are derived in closed form. Localization is understood as a bifurcation into a harmonic mode. The criterion for bifurcation is reduced to the classical form of singularity of a pseudo "acoustic tensor"; this tensor is not a material property as it involves the wavelength of the bifurcation mode through the Fourier transform of the weight function used in the definition of the nonlocal damage. A geometrical solution is provided to analyze localization. The conditions for the onset of bifurcation are found to coincide in the nonlocal and in the corresponding local cases. In the nonlocal continuum, the wavelength of the localization mode is constrained to remain below a threshold which is proportional to the characteristic length of the continuum. The analysis in dynamics exhibits the well known property of wave dispersion. In some instances, ie, for large wavelength modes, wave celerities become imaginary, but waves with a sufficiently short wavelength are found to propagate during softening in all the situations.

158Y. COMPUTATIONAL TECHNIQUES

10A123. Direct integration method of elastodynamics using FE time discretization. - Dae Ill Lee and Byung Man Kwak *(Dept of Mech Eng, Korea Adv Inst of Sci and Tech, 373-1 Kuseong-dong Yuseong-ku, Taejon 305-701, Korea).* Comput Struct 47(2) 201-211 (Apr 1993).

The FE time discretization is utilized to develop a new direct integration method. The derived recurrence formula is implicit and self-starting. There are no undetermined parameters which are often used to control stability and accuracy in the traditional direct time integration methods. The method is analytically shown to be unconditionally stable and second-order accurate. The test with a single dof linear model has supported the analysis of convergence and errors. It has been shown that the proposed method gives consistently better response history than the two well-known methods even with larger time steps. A 2-dof Hertzian impact model is solved to show its performance for a typical nonlinear problem. It is concluded that the proposed method works very well with useful properties as expected.

158Z. EXPERIMENTAL TECHNIQUES

10A124. New technique for measuring Rayleigh and Lamb wave speeds. - T Kundu *(Dept of Civil Eng and Eng Mech, Univ of Arizona, Tucson AZ 85721)* and B Maxfield *(Indust Sensors and Actuators, 400 Hester St, San Leandro CA 94577).* J Acoust Soc Am 93(6) 3066-3073 (Jun 1993).

A new technique is proposed in this paper to measure Rayleigh and Lamb wave speeds in solid half-spaces and plates. In this technique two transducers are positioned above the specimen in a pitch-catch orientation. The time of flight of the signal from the transmitter to the receiver is recorded. Then the rate of change of this time as the distance between the reflector and the transducer varies is experimentally determined. This rate remains constant when leaky Rayleigh of Lamb waves are generated but it varies when these waves are not generated. Thus surface waves are detected in an indirect manner. An expression is derived to relate the surface wave speed to the signal flight time change rate with the transducer specimen distance. Using this expression Rayleigh and Lamb wave speeds have been accurately determined in isotropic metals and anisotropic composites.

160. Impact on solids

160B. DYNAMIC CONTACT PROBLEMS

10A125. Bogie impact loads. - M Irvine *(Dept of Civil Eng, Univ of NSW, Sydney, Australia)*. Int J Impact Eng 13(4) 541-544 (Nov 1993).

Simple formulae are presented for the linear elastic and elasto-plastic response of a line of carriages or freight cars that are arrested suddenly. Starting with impact at the leading car, a wave of compression flows along the train during which, ideally, a quarter of a period passes until rest is momentarily achieved. Kinetic energy of the vehicles is changed into strain energy and heat in the couplers. The formulae are approximate but are, nonetheless, useful for design purposes, it being assumed that de-railing does not occur during this collision or buffer incident.

10A126. Dynamic response of a grillage under mass impact. - WQ Shen *(Sch of Syst Eng, Univ of Portsmouth, Porthsmouth PO1 3DJ, UK)* and N Jones *(Impact Res Center, Dept of Mech Eng, Univ of Liverpool, PO Box 147, Liverpool L69 3BX, UK)*. Int J Impact Eng 13(4) 555-565 (Nov 1993).

An approximate theoretical analysis is presented in this paper for the dynamic plastic response of a clamped beam grillage when struck transversely by a mass at the centre which produces large transverse displacements. The theoretical rigid-plastic predictions are compared with some recent experimental results on grillages struck by large masses and the predictions of a quasi-static method of analysis. The influence of inertia is explored for the behavior of a grillage when struck by a small striker travelling with a high velocity.

10A127. Dynamic response of dolos armor units to pendulum impact loads. - BT Rosson *(Dept of Civil Eng, Univ of Nebraska, Lincoln NE 68588)* and JW Tedesco *(Dept of Civil Eng, Auburn Univ, Auburn AL 36849)*. Comput Struct 47(4-5) 641-652 (3 Jun 1993).

Design methods for concrete armor units have come under scrutiny because of several recent breakwater failures. The catastrophic failure of the Sines breakwater in Portugal and other less spectacular failures such as the one at Cresent City, CA have kindled doubts as to the structural integrity of the large dolos concrete armor unit. A major difficulty encountered in rationally designing dolosse (or any other armor unit) is the specification of the loads. The complexity of the *in situ* loading conditions preclude an exact solution. Therefore, the pendulum test was developed to simulate the impact of broken units that are thrown around by the waves. This paper summarizes the results of a comprehensive numerical analysis to determine the states of stress in dolosse, with varying dimensions and concrete properties, subject to pendulum impact loads. A 3D FEM analysis of pendulum impact tests was conducted through implementation of the ADINA FE computer programs. The results of the FEM analyses are used to develop an analytical procedure which accurately predicts the peak tensile stresses in the shank and fluke of dolosse subject to pendulum impacts.

10A128. Newton's and Poisson's rules of percussive dynamics. - JA Batlle *(Dept of Mech Eng, Polytech Univ of Catalunya, 08028 Barcelona, Spain)*. J Appl Mech 60(2) 376-381 (Jun 1993).

Newton's and Poisson's rules are widely used in percursive dynamics because they lead to an "all linear" solution. However, they are in general energetically inconsistent in rough collisions. The equivalence between both rules and a broad condition for them to be energetically consistent is presented for single point collisions in multibody systems with perfect constraints. It is fulfilled in collisions described by equations of motion with constant coefficients - sliding in the same direction or no sliding - and in "balanced" collisions - sliding velocity would not change if friction were negligible - Coulomb's friction and infinite tangential stiffness are assumed at the collision point.

10A129. Predicting the enhanced punching strength of restrained slabs. - JS Kuang *(Dept of Civil and Struct Eng, Hong Kong Univ of Sci and Tech, Clear Water Bay, Kowloon, Hong Kong)*. Mech Res Commun 20(4) 361-366 (Jul-Aug 1993).

It is widely recognized that the punching load-carrying capacity of concrete slabs is significantly increased when the slab edges are restrained against lateral movement. This restraint induces large arching forces within the slab between the supports - a phenomenon of compressive membrane action. It is this arching effect which is responsible for the enhanced strength of the slab. The development of compressive membrane action is considered to be an important aspect of concrete slab behavior which has been ignored in the formulation of punching shear strength provisions in present design requirements. This may lead to a conservative prediction of the ultimate load capacity of a restrained slab as no direct account is taken of the enhancement due to the in-plane restraint in many types of reinforced concrete slab systems, such as bridge decks, flat slab construction, off-shore structures, marine platforms, protective shelters, and nuclear containment vessels. A need exists to develop a physically meaningful and consistent theoretical approach which can properly and clearly present the important structural characteristics of punching shear in concrete slabs with compressive membrane action. The purpose of this study is to present a plastic method of analysis for punching shear of laterally restrained concrete slabs. The proposed analysis allows for the effect of compressive membrane action, and the predictions show good agreement with a wide range of experimental test results.

10A130. Shear and torsional impact of cracked viscoelastic bodies: A numerical integral equation-transform approach. - HG Georgiadis *(Mech Div, Sch of Tech, Aristotle Univ, PO Box 422, 54006 Thessaloniki, Greece)*. Int J Solids Struct 30(14) 1891-1906 (1993).

The transient elastodynamic stress intensity factor was determined for a cracked linearly viscoelastic body under impact loading. Two separate geometries along with associated loading conditions were considered. In the first case, the body is in the form of an infinite strip containing a central finite-length crack and is subjected to antiplane shear tractions. Various strip heights are considered including the possibility of a body of nearly infinite extent. In the second case, the body is of infinite extent containing a finite-length penny-shaped crack and is subjected to radial shear and torsional (twisting) tractions. The analytical parts of the solutions are either given by a previous analysis of HG Georgiadis or are obtained from results by GC Sih through the use of the correspondence principle. The numerical procedure consists of solving integral equations and then inverting the Laplace transformed solution by the Dubner-Abate-Crump technique. Numerical results were given for the standard linear solid by considering several combinations of material constants.

10A131. Steady state axisymmetric penetration of a kinematically hardening thermoviscoplastic target. - RC Batra *(Dept of Mech and Aerospace Eng and Eng Mech, Univ of Missouri, Rolla MO 65401-0249)* and R Jayachandran *(Dept of Mech Eng, MIT)*. Int J Eng Sci 31(9) 1309-1323 (Sep 1993).

We study axisymmetric thermomechanical deformations of a thick target being penetrated by a fast-moving rigid cylindrical rod with a hemispherical nose, and presume that target deformations appear steady to an observer situated at the penetrator nose tip. Both isotropic and kinematic hardening of the target material are considered. It is found that kinematic hardening increases the normal stress acting on the penetrator nose surface and the temperature rise of target particles abutting the penetrator. However, the value of the hydrostatic pressure at a point in the deforming target region is affected very little by the consideration of kinematic hardening. For suitable values of material parameters appearing in the evolution equation of the back-stress, the computed values of the back-stress at target particles abutting the penetrator nose surface equal three times the yield stress of the target material in a quasistatic simple compression test.

160Y. COMPUTATIONAL TECHNIQUES

10A132. Calculation of impact loads for high energy drops of cylindrical containers. - GK Miller *(Idaho Natl Eng Lab, EG&G Idaho, Idaho Falls ID)*. Int J Impact Eng 13(4) 511-526 (Nov 1993).

The regulatory criteria for containers that are used to transport radioactive materials require that the container maintain structural integrity for an accidental drop of up to 30 ft onto a non-yielding surface. Storage containers for radioactive materials are also designed for accidental drops, usually of lesser heights. The design of these containers generally requires a determination of the peak magnitude of the impact force acting on the container. This paper presents an analytical solution that can be used to estimate the primary impact forces for cylindrical containers. Equations are derived for essentially all drop orientations.

10A133. FEM for dynamic contact-impact problems. - RL Taylor *(Dept of Civil Eng, UCB)* and P Papadopoulos *(Dept of Mech Eng, UCB)*. Int J Numer Methods Eng 36(12) 2123-2140 (30 Jun 1993).

This paper addresses the formulation and discrete approximation of dynamic contact-impact initial-value problems. The continuous problem is presented in the context of nonlinear kinematics. Standard semi-discrete time integrators are introduced and are shown to be unsuccessful in modeling the kinematic constraints imposed on the interacting bodies during persistent contact. A procedure that bypasses the aforementioned difficulty is proposed by means of a novel variational formulation. Numerical simulations are conducted and the results are reported and discussed.

10A134. Splitting pinball method for contact-impact problems. - T Belytschko and IS Yeh *(Dept of Civil Eng, McCormick Sch of Eng and Appl Sci, Tech Inst, NWU)*. Comput Methods Appl Mech Eng 105(3) 375-393 (June 1993).

In the pinball contact-impact algorithm, the interpenetration check is simplified by enforcing it only on a set of spheres emebedded within the elements. In the splitting pinball adaptation of this algorithm, the parent pinball is split into a hierarchy of descendent pinballs whenever interpenetration of the parent pinballs is detected. The interpenetration check is then applied to the descendent pinballs and contact forces are generated. This provides a better representation of the contact surface for thin shell elements. The implementation of the method with a penalty contact method is described and examples are given. It is also shown that the method easily and automatically handles edge-to-edge, edge-to-surface, and self-surface contact without any user specification.

162. Waves in Incompressible fluids

162A. GENERAL THEORY

10A135. Simplified model for wave height and set-up in the surf zone. - RH Swift *(Res Center, ABP Res and Consultancy, Maritime Way, Southampton SO1 1AE, UK)*. Coastal Eng 19(3-4) 189-206 (May 1993).

Based upon a simple extension of the analytical solution by Dally et al, a closed form expression has been developed for the variation of long-crested regular wave heights in the surf zone including the effect of set-up. The expression predicts wave height and set-up values which compare favorably with experimental data.

10A136. Theta functions and the dispersion relations of periodic waves. - Kwok W Chow *(Dept of Math, Univ of Arizona, Tucson AZ 85721)*. J Phys Soc Japan 62(6) 2007-2011 (Jun 1993).

The phase speeds or the dispersion relations for the periodic waves of certain nonlinear evolution equations can be expressed in remarkably compact forms by using theta functions.

10A137. Unified theory of nonlinear wave propagation in two-layer fluid systems

162C. NONLINEAR, FINITE AMPLITUDE, AND SOLITARY WAVES

10A137. Unified theory of nonlinear wave propagation in two-layer fluid systems. - Yoshimasa Matsuno *(Dept of Phys, Fac of Liberal Arts, Yamaguchi Univ, Yamaguchi 753)*. J Phys Soc Japan 62(6) 1902-1916 (Jun 1993).

A unified theory is presented which describes nonlinear wave propagation in two-layer inviscid and incompressible fluid of arbitrary depth. We consider the 2D systems, in which a layer of lighter fluid overlies a layer of heavier one resting on a flat bottom. The two cases of rigid and free upper boundaries are dealt with separately. We derive approximate nonlinear evolution equations (NEEs) for interfacial and free surface elevations on the basis of a systematic perturbation method with respect to the steepness parameter. We also discuss on NEEs arising from various limiting cases of fluid depth and compare them with existing NEEs. It is found that our theory includes almost all existing nonlinear theories as special cases.

162D. GRAVITY WAVES (INCL BREAKING, ETC)

10A138. Wave scattering over uneven depth using the mild-slope equation. - PG Chamberlain *(Dept of Eng Sci, Univ of Oxford, Parks Rd, Oxford OX1 3PJ, UK)*. Wave Motion 17(3) 267-285 (May 1993).

This paper examines the scattering of a train of small-amplitude harmonic surface waves on water by 1D topography, using the multi-slope equation. The associated boundary value problem is converted into a pair of integral equations whose solutions are approximated by variational techniques, which also supply error bounds. Excellent approximations to the reflection and transmission coefficients and to the free surface shape are produced with only 2D or 3D trial spaces, by choosing these spaces to be problem dependent. The bed profiles considered include localized humps and taluds which join two horizontal planes at different depths.

162F. CAPILLARY WAVES AND WAVES IN THIN FILMS

10A139. Capillary-gravity solitary waves with damped oscillations. - F Dias and G Iooss *(Inst Non-Lineaire, UMR CNRS 129, Univ de Nice Sophia-Antipolis, 06108 Nice Cedex 2, France)*. Physica D 65(4) 399-423 (15 Jun 1993).

Capillary-gravity solitary waves with damped oscillations are studied analytically. The analysis follows the work of Iooss and Kirchgassner who proved that these waves exist for all values of the Froude number smaller than one. The water-wave problem is reduced to a system of ordinary differential equations by using the center manifold theorem. The normal form of this reduced system can be obtained and a good approximation to these waves for small amplitude is constructed. The limit as the water depth becomes infinite is considered as a special case. A comparison with existing numerical results is made for small-amplitude waves.

10A140. Construction of stationary waves on a falling film. - H-C Chang *(Dept of Chem Eng, Univ of Notre Dame, Notre Dame IL 46556)*, EA Demekhin, DI Kopelevich *(Dept of Appl Math, Krasnodar Polytech Inst, Krasnodar 350072, Russia)*. Comput Mech 11(5-6) 313-322 (1993).

Waves on a film falling down a vertical wall exhibit many distinct features. They tend to be locally stationary over several wavelengths, viz they travel with constant speeds and shapes over a long distance. In the limit of very long (solitary) waves, these stationary waves also exhibit two length scales with small and short capillary waves running ahead of a large tear-drop shaped hump. We present a spectral-element method for this difficult multi-scale free surface problem. A boundary layer approximation of the equation of motion allows a Fourier expansion in the streamwise direction in conjunction with a domain decomposition in the direction normal to the wall that eliminates numerical instability. This mixed method hence enjoys both the exponential convergence rate of a spectral technique and the numerical advantage provided by a compactly supported basis which yields sparse projected differential operators. All stationary wave families, parameterized by the wavelength, are then constructed using a Newton continuation scheme. The constructed waves are favorably compared to experimentally measured wave shapes.

10A141. Excitation of capillary waves by longer waves. - KM Watson *(Marine Phys Lab, Scripps Inst of Oceanog, UCSD)* and JB McBride *(Sci Appl Int, 10260 Campus Point Dr, San Diego CA 92121)*. J Fluid Mech 250 103-119 (May 1993).

At low wind speeds the shortest capillary waves appear to be generated hydrodynamically and not by the wind. This phenomenon is investigated using a Hamiltonian representation of the surface wave dynamics. A perturbation technique of Kolmogorov is used to transform away non-resonant, nonlinear interactions. Resonant interactions are treated by the Hasselmann transport equation, applied to the transformed variables. Calculated spectra show reasonable agreement with the observations of Jahne & Riemer (1990).

162H. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

10A142. Interaction of short-crested random waves and large-scale currents. - TS Hedges, RG Tickell, J Akrigg *(Dept of Civil Eng, Univ of Liverpool, PO Box 147, Liverpool, L69 3BX, UK)*. Coastal Eng 19(3-4) 207-221 (May 1993).

Methods are outlined for determining the transformations to directional wave spectra induced by large-scale currents. The problems considered are those where waves move from quiescent water on to a current, or from one current region to another. Situations involving wave generation on currents are not discussed. The principle of wave action conservation is used to relate the wave energy densities in the two regions, and an equilibrium range constraint is applied to the high frequency tail of the transformed spectrum in instances where wave action is not conserved and energy is dissipated by wave breaking. Examples are presented which highlight how current-induced wave refraction and energy dissipation may have important consequences for the transformed spectrum.

10A143. Two-dimensional wave-scattering problems involving parallel-walled ducts. - P McIver *(Dept of Math Sci, Loughborough Univ of Tech, Loughborough, LE11 3TU, UK)* and AD Rawlins *(Dept of Math and Stats, Brunel Univ, Uxbridge, Middlesex, UB8 3PH, UK)*. Quart J Mech Appl Math 46(1) 89-116 (Feb 1993).

A previously-published solution for the 2D scattering of long waves by a parallel-walled duct, obtained by an informal application of the method of matched asymptotic expansions, is known to be incorrect. Here a formal procedure is used to obtain the correct solution. The power of the method is further illustrated by obtaining solutions for two other related 2D problems which have no known exact solutions. The first is scattering by a rectangular inlet in an otherwise plane wall and the second is a variation on this problem with barriers projecting out from the inlet.

10A144. Steady trapped solutions to forced long-short interaction equation. - Mitsuaki Funakoshi *(Res Inst for Appl Mech, Kyushu Univ, Kasuga, Fukuoka 816, Japan)*. J Phys Soc Japan 62(6) 1993-2006 (Jun 1993).

In a two-layer fluid system, both wave generation by bottom topography and resonant interaction between two wave modes are examined simultaneously. An evolution equation is derived which describes not only the resonant interaction between long internal mode and the wave packet of short surface mode, but also the generation of internal mode due to the resonant motion of the fluid relative to a bottom unevenness of large horizontal scale. According to this equation, steady coupled waves trapped by a localized symmetric bottom unevenness of sech-type are computed numerically both for positive and negative unevenness. Consequently, in addition to symmetric waves with one or two peaks in short-wave envelope, a variety of waves with many peaks, antisymmetric waves, and asymmetric waves are found.

10A145. Lagrangian FE analysis of time-dependent viscous free-surface flow using an automatic remeshing technique: Application to metal casting flow. - F Muttin, T Coupez, M Bellet, JL Chenot *(Ecole Natl Superieure des Mines de Paris, Centre de Mise en Forme des Mat CNRS UA1374, 06904 Sophia, Antipolis, France).* Int J Numer Methods Eng 36(12) 2001-2015 (30 Jun 1993).

The Navier-Stokes incompressible model is used to describe 2D metal casting flow. Such flows involve moving free boundaries. A new numerical algorithm has been developed using the Lagrangian FEM. It allows treatment of flows with moderate Reynolds number. The main feature is to avoid the calculation of the convective term, together with an automatic remeshing technique, to cure the mesh distortions. The problem of the free oscillation of a liquid is treated to verify the formulation. An application of this method to the computation of an industrial metal casting flow situation is presented.

10A146. Mathematical and numerical modeling of shallow water flow. - VI Agoshkov *(Inst of Numer Math, Russian Acad of Sci, Moskow, Russia)*, D Ambrosi *(Dept of Eng Aerospace, Polytech of Milano, Milan, Italy)*, V Pennati *(Central Ricerca Hydraul and Struct, ENEL, Milan, Italy)*, A Quarteroni *(Dept of Math, Polytech of Milano, Milan, Italy)*, F Saleri *(Central Ricerca, Cviluppo e Studi Superior in Sardegna, Calgliari, Italy).* Comput Mech 11(5-6) 280-299 (1993).

This paper deals with shallow water equations. We discuss the mathematical model, the admissible boundary conditions, some popular numerical methods in the specialized literature, as well as we propose new approaches based on fractional step and finite element methods.

10A147. Approximate and numerical solutions of a gaseous flow with shocks. - RR Sharma *(Dept of Appl Math, IT, Banaras Hindu Univ, Varanasi-221 005, India)*, VD Sharma *(Dept of Math, IIT, Bombay 76, India)*, BD Pandey *(Dept of Math, Ohio State Univ, Marion Campus, Columbus OH)*, P Shukla *(Dept of Appl Math, IT, Banaras Hindu Univ, Marion Campus, Varanasi-221 005, India).* Quart J Mech Appl Math 46(1) 141-152 (Feb 1993).

A technique is provided to obtain a closed-form approximate solution and a fast-converging numerical solution to unsteady non-isentropic gas flow with two shock boundaries. The approximate treatment is found to be very close to the numerical solution.

10A148. Infinite system of compatibility conditions along a shock ray. - R Ravindran and P Prasad *(Dept of Math, Indian Inst of Sci, Bangalore 560 012, India).* Quart J Mech Appl Math 46(1) 131-140 (Feb 1993).

To study the position and strength of a shock discontinuity as it propagates into a medium at rest, an infinite system of compatibility conditions can be derived. Each of these involves derivatives of a single flow variable and is in the form of a transport equation along shock rays. For 2D shock propagation, the first two compatibility conditions are derived in detail.

10A149. Limitations of linear theory for sonic boom calculations. - CM Darden *(Vehicle Integration Branch, Adv Vehicles Div, NASA Langley Res Center, Hampton VA 23665).* J Aircraft 30(3) 309-314 (May-Jun 1993).

Current sonic boom minimization theories have been reviewed to emphasize the capabilities and flexibilities of the methods. Preliminary comparisons of sonic booms predicted for two Mach 3 concepts illustrate the benefits of shaping. Finally, for very simple bodies of revolution, sonic boom predictions were made using two methods: a modified linear theory method and a nonlinear method for both far-field N-waves and midfield signature shapes. Preliminary analysis on these simple bodies verified that current modified linear theory prediction methods become inadequate for predicting midfield signatures for Mach numbers above three. The importance of impulse in sonic boom response and the importance of 3D effects which could not be simulated with the bodies of revolution will determine the validity of current modified linear theory methods in predicting midfield signatures at lower Mach numbers.

10A150. Plane compression front steepening in nonlinear media forms both a shock and a reflected wave. - CL Morfey *(Inst of Sound and Vib Res, Univ of Southampton, Southampton SO9 5NH, UK)* and VW Sparrow *(Graduate Program in Acoust, 157 Hammond Bldg, Penn State).* J Acoust Soc Am 93(6) 3085-3088 (Jun 1993).

An exact solution is given for the reflected wave formed in a nonlinear medium when a plane compression front steepens into a shock. The solution predicts both a shock and a reflected wave. In the small-amplitude limit the reflected wave strength varies as $(\delta P)^3$, where δP is the strength of the initial wave front.

10A151. Electric discharge excited blast waves in a flat subsonic nozzle. - P Luchini *(Inst Gasdinamica Fac Ingegneria, Univ Naples, P le Tecchio 80, Naples 80125, Italy).* AIAA J 31(6) 1060-1067 (Jun 1993).

The persistence of pressure waves generated by an electric discharge in the throat of a subsonic nozzle is studied analytically and numerically with particular reference to the operation of the high-power EUREKA excimer laser under construction at the national Italian ENEA Frascati laboratories. The attention is focused on transverse waves traveling parallel to the discharge electrodes. After some analytical estimates, a quasi-2D numerical simulation is presented for the propagation of these waves in the anticipated geometry of the discharge chamber of the EUREKA laser. The possibility of reflection of pressure waves on the thermal slug left behind by the previous discharge is also considered.

10A152. Multidimensional upwind schemes based on fluctuation-splitting for systems of conservation laws. - H Deconinck, H Paillere, R Struijs *(CFD Group, von Karman Inst for Fluid Dyn)*, PL Roe *(Aerospace Dept, Univ of Michigan).* Comput Mech 11(5-6) 323-340 (1993).

A class of truly multidimensional upwind schemes for the computation of inviscid compressible flows is presented here, applicable to unstructured cell-vertex grids. These methods use very compact stencils and produce sharp resolution of discontinuities with no overshoots.

10A153. New outflow model for cylindrical shells conveying fluid. - VB Nguyen, MP Paidoussis, AK Misra *(Dept of Mech Eng, McGill Univ, Montreal, PQ, H3A 2K6, Canada).* J Fluids Struct 7(4) 417-419 (May 1993).

A new so-called outflow model is presented, which overcomes some numerical difficulties encountered with previous models in solving problems of cylindrical shells conveying fluid. Numerical results are given to illustrate convergence of the solution obtained with the new model.

10A154. Sloshing frequencies. - DV Evans and CM Linton *(Sch of Math, Univ of Bristol, University Walk, Bristol, BS8 1TW, UK).* Quart J Mech Appl Math 46(1) 71-87 (Feb 1993).

The normal frequencies of oscillation of fluid inside certain containers are calculated by expressing the velocity potential as a linear combination of harmonic functions each of which satisfies the free-surface boundary condition. The unknown coefficients are then determined by the application of the bottom boundary condition. This is done for three different geometries; a 2D cylinder with semicircular cross-section, a cylinder with semicircular cross-section of finite length and a hemisphere. The method is also used to solve the interior Dirichlet problem the solutions of which correspond to the "irregular frequencies' that occur when solving the exterior forcing problem using a source distribution to represent the velocity potential. The method provides accurate results for the lower frequencies by truncation of simple homogeneous infinite systems of equations.

10A155. Vortex-induced vibrations of a long flexible circular cylinder. - D Brika and A Laneville *(Dept de genie Mec, Univ de Sherbrooke, Sherbrooke, PQ, J1K 2R1, Canada).* J Fluid Mech 250 481-508 (May 1993).

In an experimental study of the vortex-induced oscillations of a long flexible circular cylinder, the observed stationary amplitudes describe an hysteresis loop partially different from earlier studies. Each branch of the loop is associated with a vortex shedding mode and, as a jump from one branch to the other occurs, the phase difference between the cylinder displacement and the vortex shedding undergoes an abrupt change. The critical flow velocities at which the jump occurs concur with the flow visualization observations of Williamson & Roshko (1988) on the vortex shedding modes near the fundamental synchronization region. Impulsive regimes, obtained at a given flow velocity with the cylinder initially at rest or pre-excited, and progressive regimes resulting from a variation of the flow velocity, are examined. The occurence of bifurcations is detected for a flow velocity range in the case of the impulsive regimes. The coordinates of the bifurcations define a boundary between two vortex shedding modes, a boundary that verifies the critical curve obtained by Williamson & Roshko (1988). The experimental set-up of this study simulates half the wavelength of a vibrating cable, eliminates the end effects present in oscillating rigid cylinder set-up and has one of the lowest damping ratios reported for the study of this phenomenon.

10A156. Dynamical stability of cylinders placed in cross-flow. - J Planchard and B Thomas *(Electricite de France, Etudes et Rech, 1, Ave du General de Gaulle, 92141 Clamart, France)*. J Fluids Struct 7(4) 321-339 (May 1993).

The aim of this paper is to investigate the dynamical stability of an elastic tube bundle placed in a cross-flow which is governed by the Navier-Stokes equations. The stability of this coupled system is derived from the study of a quadratic eigenvalue problem arising in the linearized equations. The instability occurs when the real part of one of these eigenvalues becomes positive; the steady state is then replaced by a time-periodic state which is stable (Hopf bifurcation phenomenon).

10A157. Dynamics of a rotatable cylinder with splitter plate in uniform flow. - JC Xu, M Sen, M Gad-El-Hak *(Dept of Aerospace and Mech Eng, Univ of Notre Dame, Notre Dame IN 46556)*. J Fluids Struct 7(4) 401-416 (May 1993).

This is a numerical study of the dynamics of a rotatable cylinder-splitter-plate body sumerged in a uniform flow, with emphasis on fluid-structure interaction. The 2D, incompressible, unsteady Navier-Stokes equations expressed in terms of stream function and vorticity are solved by using a finite-difference method on a numerically generated, boundary-fitted, moving curvilinear coordinate system. The flow field is solved in conjunction with the rotational dynamics of the body. It is found that for subcritical Reynolds numbers, the splitter plate aligns itself in the flow direction. On increasing the Reynolds number, a symmetry-breaking bifurcation appears and the splitter plate migrates to a stable off-axis position. On further increasing the Reynolds number, there is a Hopf bifurcation after which the flow becomes unsteady and the body exhibits finite-amplitude oscillations. Various subharmonics become evident in the oscillation spectra at higher Reynolds numbers.

The effect of the steady second-order velocities on the drift forces and moments acting on marine structures in waves and a (small) current is considered. The second-order velocities are found to arise due to first-order evanescent modes and linear body responses. Their contributions to the horizontal drift forces and yaw moment, obtained by pressure integration at the body, and to the yaw drift moment, obtained by integrating the angular momentum flux in the far field, are expressed entirely in terms of the linear first-order solution. The second-order velocities may considerably increase the forward speed part of the mean yaw moment on realistic marine structures, with the most important contribution occurring where the wave spectrum often has its maximal value. The contribution to the horizontal forces obtained by pressure integration is, however, always found to be small. The horizontal drift forces obtained by the linear momentum flux in the far field are independent of the second-order velocities, provided that there is no velocity circulation in the fluid.

10A161. Evaluation and extension of the flutter-margin method for flight flutter prediction. - SJ Price *(Dept of Mech Eng, McGill Univ, Montreal, PQ, Canada)* and BHK Lee *(High Speed Aerodyn Lab, Inst for Aerospace Res, Ottawa, ON, Canada)*. J Aircraft 30(3) 395-402 (May-Jun 1993).

For a binary flutter the so called flutter-margin method is a good way of extrapolating from subcritical flight test data to estimate the flutter speed; the best estimates are obtained with a linear extrapolation. Good estimates of the flutter speed can be obtained from data at speeds as slow as 50% of the flutter speed. The flutter-margin is shown to be relatively insensitive to errors in the damping measurements, but is very sensitive to errors in frequency measurements. It does not give good predictions of the flutter speed when the instability is dominated by a single dof mechanism. A new for of flutter-margin has been developed for a trinary flutter, which also varies in a sensibly linear manner with dynamic pressure; it is also relatively insensitive to errors in damping, but is very sensitive to errors in frequency.

10A162. Large-amplitude FE flutter analysis of composite panels in hypersonic flow. - CE Gray Jr *(Fac Eng Div, NASA Langley Res Center, Hampton VA 23681)* and Chuh Mei *(Dept of Mech Eng and Mech, Old Dominion Univ, Norfolk VA 23529)*. AIAA J 31(6) 1090-1099 (Jun 1993).

A FE approach is presented for determining the nonlinear flutter characteristics of 3D thin laminated composite panels using the full third-order piston, transverse loading, aerodynamic theory. The unsteady, hypersonic, aerodynamic theory and the von Karman large-deflection plate theory are used to formulate the aeroelasticity problem. Nonlinear flutter analyses are performed to assess the influence of the higher order aerodynamic theory on the structure's limit-cycle amplitude and the dynamic pressure of the flow velocity. A solution procedure is presented to solve the nonlinear panel flutter FE equations. Nonlinear flutter analyses are performed for different boundary support conditions and for various system parameters: aspect ratio a/b; material orthotropic ratio, lamination angle θ, and number of layers; Mach number M; flow mass density to panel mass density ratio μ/M; dynamic pressure λ; and maximum deflection to thickness ratio c/h. The large-amplitude panel flutter results for the full third-order piston aerodynamic theory are presented to assess the influence of the nonlinear aerodynamic theory.

10A163. Supersonic flutter analysis of composite plates and shells. - RMV Pidaparti *(Dept of Mech Eng, Purdue)* and HTY Yang *(Dept of Aeronaut Astronaut and Eng, Purdue)*. AIAA J 31(6) 1109-1117 (Jun 1993).

A high-precision doubly curved quadrilateral thin shell FE is used for studying the supersonic flutter behavior of laminated composite plates and shells. The composite material property is included using classical lamination theory, and the supersonic aerodynamic effect is included using linearized piston theory. To reduce the number of dof of the FE aeroelastic system, the normal modes approach is adopted. Results are presented to illustrate the behavior of flutter characteristics for composite plates and curved panels, and composite cylindrical and conical shells. Parametric studies concerning the effects of boundary conditions, fiber orientation, degree of orthotropy, and flow angle on the flutter characteristics are presented for a series of selected examples. The accuracy, efficiency, and applicability of the present FEM are demonstrated by illustrative examples, and, whenever possible, the results are compared to alternative solutions available in the literature.

10A164. Arbitrary Lagrangian-Eulerian velocity potential formulation for fluid-structure interaction. - C Nitikitpaiboon and KJ Bathe *(MIT)*. Comput Struct 47(4-5) 871-891 (3 Jun 1993).

Finite-element formulations for fluid-structure interaction, assuming an inviscid fluid, can be classified into two major categories: displacement-based formulations and potential-based formulations. Although displacement-based formulations have been used widely, the methods suffer from the presence of spurious calculation modes and locking behavior. Potential-based formulations are inherently irrotatinal and do not have the difficulties of the displacement-based formulations. Nevertheless most of the applications of these methods are still limited to cases with relatively small motions. We introduce in this paper an arbitrary Lagrangian-Eulerian formulation using the velocity potential and the density as fluid variables. The formulation can be applied to problems in which the fluid undergoes very large boundary motions and can be used equally well for both compressible and incompressible fluids.

168. Astronautics (celestial and orbital mechanics)

158A. GENERAL THEORY

10A165. **Review of planetary and satellite theories.** - PK Seidelmann *(US Naval Observatory)*. Celest Mech **56**(1-2) 1-12 (1993).

Planetary and satellite theories have been historically and are presently intimately related to the available computing capabilities, the accuracy of observational data, and the requirements of the astronomical community. Thus, the development of computers made it possible to replace planetary and lunar general theories with numerical integrations, or special perturbation methods. In turn, the availability of inexpensive small computers and high-speed computers with inexpensive memory stimulated the requirement to change from numerical integration back to general theories, or representative ephemerides, where the ephemerides could be calculated for a given data rather than using a table look-up process. In parallel with this progression, the observational accuracy has improved such that general theories cannot presently achieve the accuracy of the observations, and, in turn, it appears that in some cases the models and methods of numerical integration also need to be improved for the accuracies of the observations.

168D. CELESTIAL MECHANICS

10A166. **Computer-aided analysis of the Sitnikov problem.** - J Hagel *(CERN, SL-AP, CH-1211 Geneva 23, Switzerland)* and T Trenkler *(Tech Univ, Petersgasse 16, A-8010 Graz, Austria)*. Celest Mech **56**(1-2) 81-98 (1993).

We deal with the problem of a zero mass body oscillating perpendicular to a plane in which two heavy bodies of equal mass orbit each other on Keplerian ellipses. The zero mass body intersects the primaries plane at the system barycenter. This problem is commonly known as the Sitnikov Problem. In this work we are looking for a first integral related to the oscillatory motion of the zero mass body. This is done by first expressing the equation of motion by a second order polynomial differential equation using a Chebyshev approximation techniques. Next we search for an autonomous mapping of the canonical variables over one period of the primaries. For that we discretize the time dependent coefficient functions in a certain number of Dirac Delta Functions and we concentrate the elementary mappings related to the single Delta Function Pulses. Finally for the so obtained polynomial mapping we look for an integral also in polynomial form. The invariant curves in the 2D phase space of the canonical variables are investigated as function of the primaries eccentricity and their initial phase.

10A167. **Numerical results to the Sitnikov-problem.** - R Dvorak *(Inst of Astron, Univ of Vienna, Turkenschanzstr 17, A-1180 Vienna)*. Celest Mech **56**(1-2) 71-80 (1993).

We present numerical results of the so-called Sitnikov-problem, a special case of the 3D elliptic restricted three-body problem. Here the two primaries have equal masses and the third body moves perpendicular to the plane of the primaries' orbit through their barycenter. The circular problem is integrable through elliptic integrals; the elliptic case offers a surprisingly great variety of motions which are until now not very well known. Very interesting work was done by J Moser in connection with the original Sitnikov-paper itself, but the results are only valid for special types of orbits. As the perturbation approach needs to have small parameters in the system we took in our experiments as initial conditions for the work moderate eccentricities for the primaries' orbit ($0.33 \le e_{primaries} \le 0.66$) and also a range of initial conditions for the distance of the 3rd body (= the planet) from very close to the primaries orbital plane of motion up to distance 2 times the semi-major axes of their orbit. To visualize the complexity of motions we present some special orbits and show also the development of Poincare surfaces of section with the eccentricity as a parameter. Finally, a table shows the structure of the phase space for these moderately chosen eccentricities.

168G. ORBITAL MECHANICS

10A168. **Stability of outer planetary orbits around binary stars: A comparison of Hill's and Laplace's stability criteria.** - A Kubala, D Black *(Lunar and Planetary Inst, Houston TX 77058)*, V Szebehely *(Univ of Texas, Austin TX 78712)*. Celest Mech **56**(1-2) 51-68 (1993).

A comparison is made between the stability criteria of Hill and that of Laplace to determine the stability of outer planetary orbits encircling binary stars. The restricted, analytically determined results of Hill's method by Szebehely and coworkers and the general, numerically integrated results of Laplace's method by Graziani and Black are compared for varying values of the mass parameter $\mu = m_2/(m_1 + m_2)$. For $0 \le \mu \le 0.15$, the closest orbit (lower limit of radius) an outer planet in a binary system can have and still remain stable is determined by Hill's stability criterion. For $\mu > 0.15$, the critical radius is determined by Laplace's stability criterion. It appears that the Graziani-Black stability criterion describes the critical orbit within a few percent for all values of μ.

10A169. **Stable orbits about the martian moons.** - WE Wiesel *(Air Force IT, WPAFB)*. J Guidance Control Dyn **16**(3) 434-440 (May-Jun 1993).

A dynamics of a satellite of Phobos or Deimos is developed that includes Mars' gravity and oblateness and the moon's orbital eccentricity and its nonspherical shape. Two special cases of the dynamics are studied. If the moon's eccentricity is zero, then we have an autonomous system and families of periodic orbits exist. If the eccentricity is not zero, we have a time-periodic dynamical system which still permits isolated periodic orbits. The zero eccentricity periodic orbits are constructed and found to be stable at any period. In addition, the most important nonzero eccentricity period orbits are given. Sensitivity to poorly known system parameters is explored, and accuracy requirements for spacecraft insertion maneuvers are established. Stable orbits exist about both moons and are well enough known to be used by unmanned spacecraft.

10A170. **Stable planetary orbits around one component in nearby binary stars II.** - D Benest *(OCA, Observatoire de Nice, BP 229 F-06304 NICE, Cedex 4, France)*. Celest Mech **56**(1-2) 45-50 (1993).

Numerical simulations are made within the framework of the plane restricted three-body problem in order to find out if stable orbits for planets around one of the two components in double stars can exist. For any given set of initial parameters (the mass ratio of the two stars and the eccentricity of their orbit around each other), the phase-space of initial positions and velocities is systematically explored. In previous works, systematic exploration of the circular model as well as studies of more realistic (elliptic) cases such as Sun-Jupiter and the nearby α Centauri and Sirius systems, large stable planetary orbits were found to exist around both components of the binary, up to distances from each star of the order or more than half the binary's periastron separation. The first results presented here for the η Coronae Borealis system confirm the previous studies.

168K. STABILITY AND CONTROL

10A171. **Pointing accuracy of a dual-spin satellite due to torsional appendage vibrations.** - MC Stabb and AL Schlack *(Dept of Eng Mech and Astronaut, Univ of Wisconsin, 1415 Johnson Dr, Madison WI 53706)*. J Guidance Control Dyn **16**(4) 630-635 (Jul-Aug 1993).

This paper deals with the attitude motion of a dual-spin satellite with a finite sized rigid body attached to the end of a flexible beam. The equations of motion are derived using Lagrange's equations and are solved using the perturbation technique known as the Krylov-Bogoliubov-Mitropolsky method. The special case of torsional flexibility is presented in its entirety. The relationships between the satellite, beam and tip mass parameters, and pointing accuracy of the satellite are examined.

10T172. **Rotational motion and guidance system approximations in optimizable operational launch vehicle simulations.** - RA Luke *(Aerospace Corp, Albuquerque NM 87119)*. J Guidance Control Dyn **16**(3) 477-483 (May-Jun 1993).

168Y. COMPUTATIONAL TECHNIQUES

10A174. Application of KAM theory to the planetary three body problem. - P Robutel *(Bureau des Longitudes, Equipe Astron et Syst Dyn, 77 Ave Denfert-Rochereau, 75014 Paris, France)*. Celest Mech 56(1-2) 197-199 (1993).

In 1963 Arnold proved a theorem of conservation of invariant tori, in degenerate quasi-integrable Hamiltonian systems (Arnold, 1963). Then, he applied this theorem to the planetary problem; he used Leverier's tables and asymptotic expansions of the perturbative function in the semi-major axes. He obtained a result of stability in the planar problems of two planets, in the asymptotic case, when the ratio of the semi-major axes goes to zero. In Arnold's paper, a statement is made about the general case, but the computation does not appear in the paper.

10A175. Fourth-order solution of the ideal resonance problem. - B Erdi *(Dept of Astron, Eotvos Univ, Budapest, Hungary)* and J Kovacs *(Gothard Observatory of the Eotvos Univ, Szombathely, Hungary)*. Celest Mech 56(1-2) 221-230 (1993).

The second-order solution of the Ideal Resonance Problem, obtained by Henrard and Wauthier (1988), is developed further to fourth order applying the same method. The solutions for the critical argument and the momentum are expressed in terms of elementary functions depending on the time variable of the pendulum as independent variable. This variable is related to the original time variable through a "Kepler-equation". An explicit solution is given for this equation in terms of elliptic integrals and functions. The fourth-order formal solution is compared with numerical solutions obtained from direct numerical integrations of the equations of motion for two specific Hamiltonians.

10A176. Frequency analysis of a dynamical system. - J Laskar *(Bureau des Longitudes, Equipe Astron et Syst Dyn, 77 Ave Denfert-Rochereau, F75014 Paris, France)*. Celest Mech 56(1-2) 191-196 (1993).

Frequency analysis is a new method for analyzing the stability of orbits in a conservative dynamical system. It was first devised in order to study the stability of the solar system. It is a powerful method for analyzing weakly chaotic motion in Hamiltonian systems or symplectic maps. For regular motions, it yields an analytical representation of the solutions. In cases of 2 dof system with monotonous torsion, precise numerical criterions for the destruction of KAM tori can be found. For a 4D symplectic map, plotting the frequency map in the frequency plane provides a clear representation of the global dynamics and describes the actual Arnold web of the system.

10A177. Generalized Lyapunov exponents indicators in Hamiltonian dynamics: An application to a double star system. - E Lohinger, C Froeschle *(Observatoire de la Cote d'Azur, BP 229, 06304 Nice Cedex 4, France)*, R Dvorak *(Inst of Astron, Univ of Vienna, Turkenschanzstr 17, 1180 Wien, Austria)*. Celest Mech 56(1-2) 315-322 (1993).

The Lyapunov characteristic numbers which are defined as the mean value of the distribution of the local variations of the tangent vectors to the flow ($=\ln\alpha^i_k$) (see Froeschle, 1984) have been found to be sensitive indicators of stochasticity. So we computed the distribution of these local variations and determined the moments of higher order for the integrable and stochastic regions in a binary star system with $\mu = 0.5$.

10A178. Generalized Lyapunov-characteristic indicators and corresponding Kolmogorov like entropy of the standard mapping. - C Froeschle, CH Froeschle, E Lohinger *(Observatoire, Cote d'Azur, BP 229, 06304 Nice Cedex 4, France)*. Celest Mech 56(1-2) 307-314 (1993).

Lyapunov characteristic indicators are currently defined as the mean, ie, the first moment, of the distribution of the local variations of the tangent vector to the flow. Higher moments of the distribution give further information about the fluctuations around the average.

10A179. Global solution of the N-body problem. - LK Babazanjanz *(Astron Obs, St Petersburg State Univ, Bibliotech Pl2 Petrodvorets, St Petersburg 198904, Russia)*. Celest Mech 56(3) 427-449 (1993).

In connection with the publication (Wang Qiu-Dong, 1991) the Poincare type methods of obtaining the maximal solution of different equations are discussed. In particular, it is shown that the Wang Qiu-Dong's *global solution of the N-body problem* has been obtained in Babadzanjanz (1979). First the more general results on differential equations have been published in Babadzanjanz (1978).

10A180. Introduction to Hamiltonian dynamical systems and practical perturbation methods: New insight by successive elimination of perturbation harmonics. - A Morbidelli *(Dept Math, FUNDP, 8 Rempart de la Vierge, B-5000 Namur, Belgique)*. Celest Mech 56(1-2) 177-190 (1993).

Among the studies on dynamical systems one can generally recognize two different approaches: a theoretical approach, where the general properties of such systems are investigated, along the lines opened by the KAM and the Nekhoroshev theorems, and a more applicative approach, where practical perturbation techniques are developed and applied in order to achieve a satisfactory description of some given specific systems of interest. This last approach is the most common one in Celestial Mechanics.

10A181. Local integrals and the plane motion of a point in rotating systems. - VA Antonov *(Inst of Theor Astron, 10 Kutuzov Quay, St Petersburg 191187, Russia)* and FT Shamshiev *(Astron Dept, Tashkent Univ, 700095 TashGU, Tashkent-95, Uzbekistan)*. Celest Mech 56(3) 451-469 (1993).

This paper deals with the plane motion of a star in the gravitational field of a system which is in a steady state and rotates with a constant angular velocity. For these systems a class of potentials permitting a local integral, linear with respect to the velocity components, has been found. The concept of the local integral itself was introduced by one of the authors of the present paper (Antonov, 1981). A detailed model has been constructed. The corresponding domain of the particle motion and the form of the trajectory coil have been determined. The result is compared with the motion in a more realistic potential.

10A182. Onset of chaotic motion in the restricted problem of three bodies. - RH Smith and V Szebehley *(Univ of Texas, Austin TX)*. Celest Mech 56(3) 409-425 (1993).

A full characterization of a nonintegrable dynamic system requires an investigation into the chaotic properties of that system. One such system, the restricted problem of three bodies, has been studied for over two centuries, yet few studies have examined the chaotic nature of some of its trajectories. This paper examines and classifies the onset of chaotic motion in the restricted three-body problem through the use of Poincare surfaces of section, Liapunov characteristic numbers, power spectral density analysis, and a newly developed technique called numerical irreversibility. The chaotic motion is found to be intermittent and becomes first evident when the Jacobian constant is slightly higher than C_2.

10A183. Recent progress in the theory and application of symplectic integrators. - Haruo Yoshida *(Natl Astronomical Observatory, Mitaka, Tokyo 181, Japan)*. Celest Mech 56(1-2) 27-43 (1993).

In this paper various aspect of symplectic integrators are reviewed. Symplectic integrators are numerical integration methods for Hamiltonian systems which are designed to conserve the symplectic structure exactly as the original flow. These are explicit symplectic schemes for systems of the form $H = T(p) + V(q)$, and implicit schemes for general Hamiltonian systems. As a general property, symplectic integrators conserve the energy quite well and therefore an artificial damping (excitation) caused by the accumulation of the local truncation error cannot occur. Symplectic integrators have been applied to the Kepler problem, the motion of minor bodies in the solar system and the long-term evolution of outer planets.

10A184. Resonant motion in the restricted three body problem. - JD Hadjidemetriou *(Dept of Theor Mech, Univ of Thessaloniki, GR-540 06 Thessaloniki, Greece)*. Celest Mech 56(1-2) 201-219 (1993).

The resonant structure of the restricted three body problem for the Sun-Jupiter asteroid system in the plane is studied, both for a circular and an elliptic orbit of Jupiter. Three typical resonances are studied, the 2:1, 3:1, and 4:1 mean motion resonance of the asteroid with Jupiter. The structure of the phase space is topologically different in these cases. These are typical for all other resonances in the asteroid problem. In each case we start with the unperturbed two-body system "Sun-asteroid" and we study the continuation of the periodic orbits when the perturbation due to a circular orbit of Jupiter is introduced. Families of periodic orbits of the first and of the second kind are presented. The structure of the phase space on a surface of section is also given. Next, we study the families of periodic orbits of the asteroid in the elliptic restricted problem with the eccentricity of Jupiter as a parameter. These orbits bifurcate from the families of the circular problem. Finally, we compare the above families of periodic orbits with the corresponding families of fixed points of the averaged problem. Different averaged Hamiltonians are considered in each resonance and the range of validity of each model is discussed.

172A. GENERAL THEORY

10A185. Low-frequency vibrations and radiation of a circular plate. - RI Veitsman and EV Zinov'ev *(AA Blagonravov Inst of Mech Eng,* *Russian Acad of Sci, Moscow, Russia).* Acoust Phys 39(1) 15-19 (Jan-Feb 1993).

The low-frequency vibrations of a circular elastic plate in an unbounded acoustic medium are calculated by expanding the unknown solution of the problem in normal modes of vibration of the plate in vacuum. The load exerted by the surrounding fluid is taken into account as an additional mass and is determined by the numerical solution of the Neumann problem for the Helmholtz equation. The velocity of the plate and the pressure and energy flux in the fluid are analyzed. Cases in which the fluid occupies all space or a half-space bounded by a baffle are discussed, along with the two types of edge conditions: a free edge and a rigidly built-in edge.

10A186. Nonlinear acoustoelastic properties of granular media. - IY Belyaeva, VY Zaitsev, LA Ostrovskii *(Inst of Appl Phys, Russian Acad of Sci, Moscow, Russia).* Acoust Phys 39(1) 11-15 (Jan-Feb 1993).

The nonlinear properties of a medium consisting of randomly packed spherical granules are investigated, where the interstitial pore space can be occupied by a fluid. The equation of state of the medium is derived, and the dependence of nonlinearity parameters on the properties of the granule material, the characteristics of the fluid, and the initial static strain is analyzed. It is shown that granular media have an anomalously high nonlinearity in comparison with homogeneous materials. Experimental data obtained for model samples of granular media are in good quantitative agreement with the theoretical conclusions. Published results of full-scale experiments to determine the nonlinear characteristics of loose rock are also in good agreement with the theoretical estimates.

10A187. Optical theorem for a plate-stratified fluid system. - IV Andronov *(State Univ, St Petersburg).* Acoust Phys 39(1) 5-7 (Jan-Feb 1993).

An analog of the optical theorem is formulated for a 3D system that contains an infinite plate in addition to a scattering obstacle, and in which additional scattering channels are created by stratification of the acoustic medium.

172B. SOUND GENERATION BY MOVING SURFACES

10A188. Propeller noise reduction by means of unsymmetrical blade-spacing. - W Dobrzynski *(Deutsche Forschungsanstalt fur Luft und Raumfahrt DLR, Inst fur Entwurfsaerodyn, Abteilung Technische Akustik Flughafen, 3300 Braunschweig, Germany).* J Sound Vib 163(1) 123-136 (8 May 1993).

The noise reduction potential of propellers with circumferentially unsymmetrical blade spacing is predicted on theoretical grounds and substantiated through both aerodynamic and aeroacoustic full scale wind tunnel experiments. To avoid potential balancing problems such propellers have two pairs of opposite blades, each such pair constituting a symmetric two-blade propeller. Spacing angles between these individual blade pairs are optimized towards achieving minimum A-weighted noise radiation in the plane of rotation. The result is then compared with the corresponding noise level from a symmetrical reference propeller with the same total number of geometrically identical blades. The study reveals that the value of the optimum spacing angle depends almost entirely on the operational helical blade tip Mach number assuming values of about 40° at a Mach number of 0.5 and decreasing to 15° at a Mach number of 0.8.

10A189. Sound generation by rotating stall in centrifugal turbomachines. - DE Thompson *(Appl Res Lab, University Park PA 16801),* L Mongeau *(Sch of Mech Eng, Purdue),* DK McLaughlin *(Penn State).* J Sound Vib 163(1) 1-30 (8 May 1993).

Experiments were conducted in order to investigate the relatively low frequency aerodynamic sound generating mechanism in centrifugal turbomachines. A facility consisting of a centrifugal water pump impeller with various discharge configurations and an inlet duct was designed and built for the experiments. Air was used as the fluid medium. The inlet duct provided a controlled, quiet inflow to the impeller. Measurements of the acoustic noise radiated in the pump surroundings were made in parallel with fluid dynamic measurements in order to establish correlations. The most significant conclusion reached is that a form of rotating stall dominated the low frequency noise production in various configurations with no outlet diffuser or casing.

172C. SOUND GENERATION BY FLOW

172E. SOUND WAVES IN LIQUIDS (UNDERWATER ACOUSTICS)

10A190. Active and passive acoustic behavior of bubble clouds at the ocean's surface. - A Prosperetti *(Dept of Mech Eng, Johns Hopkins Univ, Baltimore MD 21218),* NQ Lu *(Appl Phys Lab, Submarine Tech, Hydrodyn Group, Johns Hopkins Rd, Laurel MD 20723-6099),* HS Kim *(Acoust Lab, Korea Res Inst of Ships and Ocean Eng, Daeduk Science Town, PO Box 1, Daejeon 305-606, Korea).* J Acoust Soc Am 93(6) 3117-3127 (Jun 1993).

The emission and scattering of sound from bubble clouds is studied theoretically. It is shown that clouds having a size and air content similar to what might be expected as a consequence of the breaking of ocean waves can oscillate at frequencies as low as 100 Hz and below. Thus cloud oscillations may furnish an explanation of the substantial amount of low-frequency wind-dependent oceanic ambient noise observed experimentally. Detailed results for the backscattering from bubble clouds – particularly at low grazing angles – are also presented and shown to be largely compatible with oceanic data. Although the cloud model used here is idealized (a uniform hemispherical cloud under a plane water free-surface), it is shown that the results are relatively robust in terms of bubble size, distribution, and total air content. A similar insensitivity to cloud shape is found in a companion paper.

10A191. Backscattering of underwater noise by bubble clouds. - K Sarkar and A Prosperetti *(Dept of Mech Eng, Johns Hopkins Univ, Baltimore MD 21218).* J Acoust Soc Am 93(6) 3128-3138 (Jun 1993).

This paper is a continuation of an earlier one in which the low-frequency backscattering of sound by hemispherical bubble clouds at the ocean's surface was studied. Here, clouds of various geometrical shapes (spheroids, spherical segments, cones, cylinders, ellipsoids) are considered and results in substantial agreement with the earlier ones and with the experiments of Chapman and Harris are found. The implication is that the backscattering levels are not strongly dependent on the shape of the clouds, which strengthens the earlier conclusion that bubble clouds produced by breaking waves can very well be responsible for the unexpectedly high backscattering levels observed experimentally. The accuracy of the Born approximation used by others for similar problems is also examined in the light of the exact results. Significant differences are found for gas concentrations by volume of the order of 0.01% or higher. Finally, shallow nonaxisymmetric plumes are briefly considered.

10A192. Plane vibrations and radiation of an elastic layer lying on a liquid half-space. - JD Kaplunov and DG Markushevich *(Inst for Problems in Mech, Russian Acad of Sci, pr Vernadskogo 101, 117526 Moscow, Russia).* Wave Motion 17(3) 199-211 (May 1993).

Forced vibrations and acoustic radiation of an elastic layer lying on a liquid half-space are investigated. The vibration frequency is assumed to be outside the range of applicability of the classical theory of plates. The case of plane strain is considered. The main results of the paper are concerned with the description of hydroelastic high-frequency long-wave vibrations arising in a neighborhood of the so-called "thickness stretch response frequencies". These frequencies are of particular interest since jumps of the radiation power are observed at such frequencies. Simple approximate formulas for the long-wave component of vibrations and for the radiation power jumps are obtained. It is shown that their height depends significantly on the Poisson ratio of the material of the layer. The efficiency of approximations based on the asymptotic method is tested by comparing the results of direct numerical computations.

10A193. Riemann invariant characteristic method for the solution of the nonlinear field in front of a partially reflecting boundary. - P Caine *(Dept of Math and Comput Sci, Univ of Salford, Manchester M5 4WT, UK)* and M West *(Dept of Appl Acout, Univ of Salford, Manchester M5 4WT, UK).* Appl Acoust 39(4) 277-289 (1993).

A nonlinear relationship between the pressure and the particle velocity at an air fluid interface is derived under the assumption that propagation in the fluid is exclusively outgoing. The derivation employs Riemann invariants. The relationship is then incorporated with the author's existing interior scheme for nonlinear propagation (NLPP method) to allow a solution for a large amplitude acoustic pulse incident at a fluid interface.

10A194. Underwater sound generated by heavy rainfall. - JA Nystuen, CC McGlothin, MS Cook *(Dept of Oceanog, Naval Postgraduate Sch, Monterey CA 93943).* J Acoust Soc Am 93(6) 3169-3177 (Jun 1993).

The underwater acoustic signature of heavy rainfall is very different from that of light rainfall. During heavy rainfall sound levels are observed to rise with increasing rainfall rate at all frequencies monitored (4 - 21 kHz) and the 15 - kHz spectral peak observed during light rainfall is absent. The sound levels are most highly correlated ($r \approx 0.8$) with heavy rainfall rate for frequencies less than 10 kHz. Lower correlations between sound levels and heavy rainfall rate were observed for frequencies above 10 kHz under several different conditions. When wind speed exceeds 10 m/s, wave breaking mixes bubbles downward and creates a layer of bubbles. This bubble layer attenuates subsequent surface-generated sound (from the raindrop splashes) for frequencies above 10 kHz. Extremely heavy rainfall (total rainfall above 150 mm/h) also generates a subsurface bubble layer. This rainfall-generated bubble layer is evidence of rainfall-induced turbulent mixing of the ocean surface layer and has implications for air-sea exchange processes (momentum, heat, and gas exchange). Finally, previous studies have shown that light rain generates acoustic energy above 10 kHz and that this sound is poorly correlated with total rainfall rate. A simple empirical acoustic rainfall rate algorithm for heavy rain is offered. This algorithm may be site specific. Furthermore, it overestimates rainfall rate early in the rain events examined here (convective rain events), and then underestimates rainfall rate later in the same events. This observation is shown to be consistent with likely changes in the drop size distribution during the lifetime of the rain event. The sound produced by large drops within heavy rain (drop diameter greater than 2.2 mm) is shown to dominate the underwater sound field. The empirical acoustic rainfall rate algorithm is therefore more correctly a measure of the rainfall rate from large raindrops. Fortunately, the rainfall rate from large raindrops is highly correlated with the total rainfall rate, making acoustic monitoring of underwater sound an effective measure of rainfall rate in oceanic regions.

10A195. Application of the Wigner Distribution to the identification of structure-borne noise components. - TJ Wahl and JS Bolton *(Ray W Herrick Lab, Purdue)*. J Sound Vib 163(1) 101-122 (8 May 1993).

In this paper it is shown that time frequency analysis of a transient structural response may be used to identify the wave types carrying the significant energy through a structure. The identification of various wave types is possible since each is characterized by its own dispersion relation, with the result that each wave type may be associated with characteristic features in the time frequency domain representation of a structural response. In the work described here, the Wigner Distribution has been used to obtain time frequency representations of structural transient responses. Practical aspects of the Wigner Distribution are discussed briefly, and examples of its application to the analysis of transient structural responses are given. Additionally, time frequency filtering techniques are described that can be used both to detect the presence of and to quantify the energy carried by both nondispersive and dispersive waves.

10A196. Low frequency acoustic ground impedance measurement techniques. - MW Sprague, R Raspet, HE Bass *(Phys Acoust Res Group, Dept of Phys and Astron, Univ of Mississippi MS 38677)*, JM Sabatier *(Natl Center for Phys Acoust, Univ of Mississippi MS 38677)*. Appl Acoust 39(4) 307-325 (1993).

The low frequency (below 150 Hz) acoustic ground impedance was determined on a large uncultivated field using an impedance meter, the probe microphone method, a modified Biot-Stoll type calculation, and the phase gradient method. The impedance measured with the impedance meter has lower real and imaginary parts than the impedance determined from the probe microphone measurements. The modified Biot-Stoll type description of acoustic to seismic transfer based upon seismic and acoustic measurements gives an impedance which is consistent with probe microphone meaurements. The impedance measured by the phase gradient method is largely consistent with the other measurements, but shows much more structure. This structure is believed to be caused by unwanted reflections during the measurement procedure rather than by actual structure in the ground impedance undetected by the other methods.

10A197. Radiation of Lamb waves by a system of internal stress sources in an isotropic elastic layer. - KA Chishko *(Physicotech Inst of Low Temp, Ukrainian Acad of Sci)*. Acoust Phys 39(1) 80-84 (Jan-Feb 1993).

Expressions are obtained for the spectral composition and space-time profile of acoustic radiation formed by Lamb waves radiated from an arbitrary system of dynamic sources of internal stresses concentrated in a finite zone of an isotropic elastic layer. The example of Lamb waves radiated by a system of moving dislocation loops is discussed.

10A198. Transmission and dissipation of sound waves in tube bundles. - XY Huang and MA Heckl *(Dept of Math, Keele Univ, Keele, UK)*. Acustica 78(4) 191-200 (May 1993).

Analytical and numerical studies have been undertaken in this paper to examine the transmission and dissipation of sound waves in tube bundles. The tube bundles consist of parallel layers of tube rows submerged in a viscous fluid. The individual tube rows act like acoustic diffraction gratings; their scattering behavior is described by grating theory which has been extended in two ways: (i) the motions of the individual tubes are taken into account, (ii) the dissipation at the tube-fluid interfaces is included. A layered medium consisting of several spaced tube rows has been considered and results for the transmission and reflection coefficient are presented. The calculations are based on an iteration scheme where multiple backward and forward scattering at each row is taken into account. Despite the fact that only a finite number of tube rows was considered, the formation of passing and stopping bands, which are expected to be found in the transmission spectrum of a periodic medium, can be recognized. Stopping bands occur around frequencies where integral multiples of half a wavelength in the surrounding fluid coincide with the spacing of the tube rows.

10A199. Coherence of acoustic scattering from a dynamic rough surface. - DR Dowling *(Dept of Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109)* and DR Jackson *(Appl Phys Lab Col of Ocean and Fishery Sci, Univ of Washington, Seattle WA 98105)*. J Acoust Soc Am 93(6) 3149-3157 (Jun 1993).

Numerical studies of the angular and temporal coherence of rough-surface acoustic scattering are presented at kh = 12, 20, and 32, and where k is the acoustic wave number and h is the root-mean-square surface height fluctuation. The computations are based on point-source illumination of a 1D pressure-release Pierson-Moskowitz dynamic rough surface, and the Kirchhoff approximation. In the region near specular, for a source-location grazing angle of 20°, the angular variation of the scattered field coherence is found to predominantly depend on the product of k and a fixed length scale. The computed results show only a mild dependence on kh. For the same geometry, the temporal variation of the scattered field coherence is found to depend predominantly on ($g\delta t/U$)kh, where g is the acceleration of gravity, δt is the time shift, and U is the wind speed. A general method for scaling the scattered field coherence in terms of k, δt, U, and the angular separation of the field points is suggested based on the findings. The effects of wind direction and surface-wave frequency cutoff on acoustic scattering are also noted.

10A200. Slow wave propagation in air-filled permeable solids. - PB Nagy *(Dept of Welding Eng, Ohio State Univ, Columbus OH 43210)*. J Acoust Soc Am 93(6) 3224-3234 (Jun 1993).

The propagation of slow compressional waves in air-saturated permeable solids was studied by experimental means between 10 and 500 kHz. The velocity and attenuation coefficient were measured as functions of frequency from the insertion delay and loss of airborne ultrasonic waves transmitted through thin slabs of 1-5 mm in thickness. Porous ceramics of 2-70 Darcy and natural rocks of 200-700 mDarcy permeability were tested. In the low-frequency (diffuse) regime, the experimental results are consistent with theoretical predictions; the phase velocity and attenuation coefficient are essentially determined by the permeability of the specimen and both increase proportionally to the square root of frequency. In the high-frequency (propagating) regime, the experimental results are consistent with the theoretical predictions for the phase velocity but not for the attenuation coefficient. The phase velocity asymptotically approaches a maximum value determined by the tortuosity of the specimen while the attenuation coefficient becomes linearly proportional to frequency instead of the expected square-root relationship. It is suggested that the observed discrepancy is due to the irregular pore geometry that significantly reduces the high-frequency dynamic permeability of the specimens.

10A201. Sound attenuation in a coarse granular medium. - D Wu, ZW Qian, D Shao *(Inst of Acoustics, Acad Sinica, Beijing 100080, Peoples Rep of China)*. J Sound Vib 162(3) 529-535 (22 Apr 1993).

In order to investigate the deviation of the spherical particle model from practical granular media in nature, the sound attenuation in a kind of water saturated riverbed coarse sand was measured in the high frequency range 40-600 kHz. The results reveal that the rough surface and non-spherical shape factors of the sand particles have strong effects on the acoustic attenuation under experimental conditions in which βR is greater than 60 in the whole frequency range and in which kR is not far less than 1 when the frequency is higher than 300 or 400 kHz, where β is the viscous wavenumber, k is the compressional wavenumber and R is the average radius of the sand particles.

10A202. Ultrasonic propagation, scattering, and defocusing in suspensions. - J Adach, RC Chivers, LW Anson *(Dept of Phys, Univ of Surrey, Guilford, Surrey GU2 5XH, UK)*. J Acoust Soc Am 93(6) 3208-3219 (Jun 1993).

Fine resolution narrow-band pressure amplitude distribution measurements have been performed using a hydrophone in the field of a weakly focused bowl transducer radiating into castor oil and 1% and 2% by volume suspensions of 320-μm polystyrene beads in castor oil over the frequency range 1.0 to 2.5 MHz at 20° C. The axial distributions permitted determination of the excess attenuation due to scattering in the suspensions as a function of frequency. The frequency range included a resonance. The excess attenuation measured was compared with the theoretical predictions of Waterman and Truell and good agreement was obtained. The values of the excess attenuation obtained were used to predict axial pressure amplitude distributions in the suspension. Although the excess attenuation was determined from far-field measurements, the agreement between the predicted axial distributions and those measured experimentally extended well into the near field. Lateral distributions were measured at seven frequencies at the position of the geometrical center of curvature of the source and at the position of the true focus in the 1% suspension. Comparison with similar scans in castor oil alone revealed no detectable defocusing due to the presence of the scatterers.

172H. REFLECTION, REFRACTION, DIFFRACTION, AND SCATTERING

10A203. Acoustic scattering from a rough sphere. - P-A Jansson *(Div of Mech, Chalmers*

Univ of Tech, S-412 96 Goteborg, Sweden). J Acoust Soc Am 93(6) 3032-3042 (Jun 1993).

The scattering of a plane acoustic wave from a random rough sphere is studied using the null field approach. The starting point is an integral representation derived from the Helmholtz equation. The incident field, the scattered field, and the free-space Green's function are all expanded in terms of suitably chosen basis functions. In this way a relation between the incident and the scattered fields is obtained, which is expressed by the transition matrix (T matrix). The scattered field is expanded in a power series of a small parameter, namely the product of the wave number and the root-mean-square height of the irregularities. Analytical expressions for the leading terms of the series have been calculated. In particular, ensemble averages of the far-field amplitude and scattering cross section have been determined. As the analytical results are somewhat complicated, some numerical results are presented. Numerical computations of higher-order terms indicate that the convergence of the series is satisfactory as long as the root-mean-square height is small compared to a correlation length describing the average distance between the peaks of the surface.

10A204. Acoustical field in a space with obstacles part II: Propagation between buildings. - E Walerian and R Janczur *(Inst of Fund Tech Res, Polish Acad of Sci, Warsaw, Poland).* Acustica 78(4) 210-219 (May 1993).

The patterns of the computer simulation program, for calculating noise levels in an urban area are presented. Having the layout of the urban system geometry, the reflection and transmission coefficients of the objects, and the traffic parameters (flow density, typical noise spectrum) it is possible, by the use of this simulation program, to forecast the noise level on building facades.

10A205. Analysis of scattering from structures containing a variety of length scales using a source-model technique. - E Erez *(Kibbutz Ein Hashofet, Israel)* and Y Leviatan *(Dept of Elec Eng Tech, Israel IT, Haifa 32000, Israel).* J Acoust Soc Am 93(6) 3027-3031 (Jun 1993).

Fictitious source models have been applied extensively in recent years to a variety of electromagnetic and acoustic wave scattering problems. This paper is introducing an extension of the source-model technique that facilitates the solution to problems subsuming scatterers that contain a variety of length scales. This extension is in tune with the source-model technique philosophy of using simple sources the fields of which are analytically derivable. It amounts to letting the coordinates of some of the source centers assume complex values. Positioned in complex space, the simple sources radiate beam-type fields, which are more localized and are better approximations of the scattering from the smooth expanses of the structure. The coordinates of the other source centers retain their conventional real values. These latter sources are used, of course, to approximate the fields in the vicinity of the more rapidly varying expanses of the structure. The new approach is applied to analyze acoustic scattering from a structure comprising two adjacent pressure-release spheres of different size. It is found to render the solution computationally more effective at the expense of only a slight increase in its complexity.

10A206. Comparison of the Rayleigh and T-matrix theories of scattering of sound from an elastic shell. - L Kazandjian *(Commissariat a l'Energie Atomique, Centre d'Etudes de Vaujours-Moronvilliers, BP 7 77181, Courtry, France).* J Acoust Soc Am 93(6) 3139-3148 (Jun 1993).

The Rayleigh and T-matrix mathematical formalisms of scattering of sound from an elastic shell are established and compared. It is shown that the two formalisms have a unique solution and are theoretically equivalent when used to calculate the pressure field sufficiently far away from the obstacle. From a numerical point of view, the closeness of the results obtained with the two methods does not depend on the validity of the Rayleigh hypothesis. These results enable one to analyze the validity of the wave superposition and retracted boundary integral formalisms when the auxiliary retracted surface is located inside the inscribed sphere. Some comments are made about the numerical results expected from these methods.

10A207. Large membrane array scattering. - GA Kriegsmann *(Dept of Math Center for Appl Math and Stat, NJIT, Newark NJ 07102)* and CL Scandrett *(Dept of Math, Naval Postgraduate Sch, Monterey CA 93942).* J Acoust Soc Am 93(6) 3043-3048 (Jun 1993).

The scattering of a time harmonic acoustic wave by an array of N identical baffled membranes is considered in the limit as $N \to \infty$. The method of matched asymptotic expansions is used to construct an inner and outer expansion; the inner expansion contains the physics of the local periodic structure and the outer expansion has the proper behavior in the far field. The matching process is used to determine a set of unknown coefficients in the analysis and the result is a far-field pattern for the structure that blends the physics of both expansions. In particular, the far-field pattern is highly localized about the Bragg or mode angles of the inner representation. The maximum value of this function is directly proportional to the reflection coefficient determined numerically from the inner problem. Several numerical examples are presented illustrating these features. Moreover, it is observed that the asymptotic theory agrees quite well with the exact answer (obtained by using a finite scheme) when N = 3.

10A208. Time domain Green functions technique for a point source over a dissipative stratified half-space with a phase velocity mismatch at the surface. - Sailing He, Yidong Hu, S Strom *(Dept of Electromagnetic Theory, RIT, S-10044 Stockholm, Sweden).* Wave Motion 17(3) 241-254 (May 1993).

A point source over a dissipative stratified half-space with a discontinuity for both the phase velocity and the dissipation coefficient at the surface is considered. The axial symmetry of the problem is exploited in a spatial Hankel transform. The Green functions technique based on wave splitting is used to solve both the direct and inverse problems in the time domain. A Green tensor is introduced which directly maps the physical incident field outside the inhomogeneous half-space to the internal split fields. The PDEs for the Green functions are derived. In the direct problem, the internal fields are calculated as well as the reflected field. The phase velocity is reconstructed in the inverse problem. Simultaneous reconstruction of the phase velocity and dissipation coefficient using two different values of the Hankel transform parameter is analyzed. Two special cases, namely a point source over a homogeneous non-dissipative half-space and over a homogeneous dissipative half-space, are discussed and it is shown that the solution for the reflected fields is given by Volterra equations of the second kind.

10A209. Transient acoustic pressure radiated from a finite duct. - P Stepanishen and RA Tougas Jr *(Dept of Ocean Eng, Univ of Rhode Island, Kingston RI 02881).* J Acoust Soc Am 93(6) 3074-3084 (Jun 1993).

The time-dependent pressure radiated from a finite, rigid, circular duct of constant cross section is determined for the specified motion (velocity or acceleration) of a piston source at the inner end of the duct. The internal field is represented as an eigenfunction expansion over the duct cross section, and a time- and space-dependent Green's function is used to develop a generalized boundary condition which describes the effect of the external surroundings at the duct exit. Solution of this boundary value problem results in a duct transfer function which is then cascaded with the transfer function connecting the duct exit port and a selected external field point. In this paper, inversion to the time domain is accomplished via the FFT algorithm. Numerical examples demonstrating the external time-dependent pressure are presented based upon the specification of a gated sinewave piston acceleration over an assumed piston spatial profile. The numerical results show that the time-dependent pressure for the cross modes develops its peak value off-axis and is always zero on-axis, while the plane wave mode peaks on-axis.

172I. ACOUSTIC PROPERTIES OF MATERIALS

10A210. Influence of lightweight partitions on the loss factor of concrete floors in multistorey buildings. - RA Novak *(Dept of Build Tech, RIT, S-100 44 Stockholm, Sweden).* Appl Acoust 39(4) 253-264 (1993).

It is shown that the presence of lightweight walls have an influence on the loss factor of concrete floors, especially at low frequencies. Measurement results and theoretical deliberations also show that the coupling loss factor depends on the design and construction of the walls. Furthermore, it is shown that the coupling loss factor increase is due mainly to the energy transmission through the partitions as longitudinal waves; the bending waves are less significant in this respect.

10A211. Multiple diffraction at edges and right angle wedges. - E Walerian *(Inst of Fund Tech Res, Polish Acad of Sci, Warsaw, Poland).* Acustica 78(4) 201-209 (May 1993).

The paper offers a procedure for the calculation of double and higher order diffraction at edges and right angle wedges, in the high frequency approximation. Such effects appear when double walled screens are erected along highways, and when waves are diffracted at the sides of buildings.

172J. NOISE CONTROL AND REDUCTION (INCL ACTIVE CONTROL)

10A212. Broadband active acoustic absorbing coating with an adaptive digital controller. - Zhen Wu, Xiao-Qi Bao, VK Varadan, VV Varadan *(Dept of Eng Sci and Mech, Center for the Eng of Elec and Acoust Mat, Penn State).* Smart Mat Struct 2(1) 40-46 (Mar 1993).

A modified active acoustic coating system using an adaptive digital controller has been developed for absorbing the sound incident on an underwater object. The redesigned control system, featuring a digital delay-line feedforward scheme, is predicted theoretically and verified experimentally to have a broader control bandwidth than the analog phase-shifter system which was developed previously. Another significant improvement to the system is the use of a multichannel delay-line network to achieve on-board monitoring of sound reflection from the coating, so that the system performance can be self-evaluated and then optimized by adjusting its control parameters. The adaptive adjustment function is realized through software on a personal computer interfaced with the digital delay-line network. This adaptive digital controller design enables the active absorbing coating to achieve a high echo reduction over a wide frequency band. The experimental implementation and testing of the active coating system was conducted in a water-filled pulse tube for normally incident plane waves. An echo reduction above 30dB was achieved in an operating frequency range from 4-11 kHz.

10A213. Experimental study implementing model reference active structural acoustic control. - RL Clark, GP Gibbs, CR Fuller *(Mech Eng Dept, VPI)*. J Acoust Soc Am 93(6) 3258-3264 (Jun 1993).

Model reference active structural acoustic control is experimentally investigated in this study for physical systems characterized by stationary, narrow-band disturbances in which the acoustic field remains relatively unchanged. The filtered-x version of the multichannel adaptive least-mean-square algorithm was implemented on a TMS320C25 digital signal processing board to achieve the desired control approach, and control inputs were generated with piezoelectric actuators. Model reference control provides the designer with a method of replacing acoustic error sensors such as microphones located in the far-field with error sensors such as accelerometers located on the surface of the structure. As opposed to driving the response of the structure to zero at the coordinates of the accelerometers, the response is driven to some predetermined "reference" value corresponding to the desired far-field acoustic directivity pattern. In essence, the uncontrolled structure is adaptively modified to behave like the reference structure under acoustic control conditions. Results from this study indicate that the same acoustic directivity pattern can be achieved with model reference control, and the only requirement is that the number of structural sensors used in the control approach is at least equal to the number of control actuators required to achieve the desired acoustic directivity pattern.

172Y. COMPUTATIONAL TECHNIQUES

10A214. Analysis of axisymmetric waves propagating along a hollow cylindrical ultrasonic transmission line. - Nobuhiro Kanbe, Yoshiro Tomikawa, Kazunari Adachi *(Dept of Elec and Info Eng, Yamagata Univ, Yonezawa, Yamagata 992, Japan)*, Takehiro Takano *(Dept of Commun Eng, Tohoku IT, Sendai, Miyagi 982, Japan)*. J Acoust Soc Am 93(6) 3235-3241 (Jun 1993).

A new ultrasonic device for feeding powder with the use of a hollow acrylic cylinder, on which an axisymmetric progressive elastic wave is excited, has previously been proposed. Its characteristics have also been reported. To find vibrational behaviors of the hollow cylinder for feeding powder, the elliptic particle movement on the inside surface was analyzed. The authors have found many forms of elliptic motion. Some of them can move objects inside the cylinder toward the vibration source, as expected, but, on the contrary, the others move in the wave propagation direction.

10A215. Application of the Gaussian beam approach to sound propagation in the atmosphere: Theory and experiments. - Y Gabillet, H Schroeder *(Centre Sci Tech du Batiment, 38400 St-Martin-d'Heres, France)*, GA Daigle, A L'Esperance *(Inst for Microstruct Sci, NRC, Ottawa, ON, K1A 0R6, Canada)*. J Acoust Soc Am 93(6) 3105-3116 (Jun 1993).

The Gaussian beam approach solves the wave equation in the neighborhood of the conventional rays using the parabolic approximation. The solution associates with each ray a beam having a Gaussian amplitude profile normal to the ray. The approximate overall solution for a given source is then constructed by a superposition of Gaussian beams along nearby rays. The solution removes ray-tracing artifacts such as perfect shadows and infinite energy at caustics without the computational difficulties of numerical solutions to the wave equation. In this paper, the Gaussian beam approach is applied to atmospheric sound propagation in the presence of refraction above a ground surface. A brief overview of the method is presented. Calculations obtained from Gaussian beam tracing are compared to those obtained from the fast field program and to experimental measurements. The experiments were made above a concave surface indoors that simulates propagation under downward refraction (inversion or downwind) in the cases of a hard and finite impedance surface. These experiments include measurements in the presence of a barrier. Measurements were also made in a wind tunnel in the presence of wind and temperature gradients. The results suggest that beam tracing can be applied to complex atmospheric sound propagation problems with advantages over conventional ray tracing and full-wave solutions.

10A216. Approximate evaluation of the spectral density integral for a large planar array of rectangular sensors excited by turbulent flow. - W Thompson Jr *(Dept of Eng Sci and Mech and Appl Res Lab, Penn State)* and RE Montgomery *(Underwater Sound Reference Detachment, Naval Research Lab, PO Box 568337, Orlando FL 32856-8337)*. J Acoust Soc Am 93(6) 3201-3207 (Jun 1993).

An approximate numerical procedure has been developed for rapidly evaluating the spectral density integral that predicts the output of a planar array of many sensors excited by turbulent boundary layer pressure fluctuations. This procedure is particularly useful in cases where the transfer function factor of the integrand is not a simple function of the wave numbers in the flow and transverse directions. The procedure exploits the facts that the entire integrand is a separable function of these two wave numbers and, when the number of sensors is large, the array function factor of the integrand is a rapidly varying function of wave number, characterized by many similar shaped lobes. In addition, a model for multilayered media is employed to provide the transfer function for boundary conditions that closely correspond to reality. Results generated by this procedure were compared to those from an exact evaluation of the integral which is possible if the transfer function is taken to be constant; there was agreement to within 0.2 dB or better over a broad frequency interval. Some results for a realistic transfer function are presented, such as the case of an elastomeric layer backed by an elastic plate with the sensors embedded at an arbitrary position within the layer.

10A217. Evaluation of the Kirchhoff approximation in predicting the axial impulse response of hard and soft disks. - GV Norton *(Naval Res Lab, Stennis Space Center, MS 39529-5004)*, JC Novarini *(Planning Systems, Inc, 115 Christian Lane, Slidell LA 70458-1350)*, RS Keiffer *(Naval Res Lab, Stennis Space Center, MS 39529-5004)*. J Acoust Soc Am 93(6) 3049-3056 (Jun 1993).

To test the ability of the Kirchhoff approximation for estimating the various components in the near-field impulse response of a circular disk, the predictions from a time domain formulation of the Helmholtz-Kirchhoff solution are benchmarked against results obtained via the Fourier synthesis of highly accurate frequency domain solutions. In these numerical experiments, a collocated point source and receiver lie on the symmetry axis of an acoustically hard (rigid) or soft (pressure release) disk. A time-domain analysis is carried out in order to unambiguously evaluate the Kirchhoff approximation for different components of the scattered field. It is found that, while Helmholtz-Kirchhoff predicts the correct reflected component, it fails to accurately predict the strength of the diffracted component. The magnitude of the error depends on whether the disk is soft or hard and on the source-receiver height above the disk. The error in the diffracted component exceeds, in some cases, 100%. Furthermore, it is observed that the Helmholtz-Kirchhoff approach does not include the secondary or multiply diffracted arrivals which are more pronounced for the hard disk.

10A218. Validity of the wedge assemblage method for pressure-release sinusoids. - RS Keiffer *(Naval Res Lab, Stennis Space Center MS 39529-5004)*. J Acoust Soc Am 93(6) 3158-3168 (Jun 1993).

In the past, the wedge assemblage (WA) method for calculating the acoustic scattering from rough, long-crested, or corrugated surfaces has been compared with both experimental data and exact theory with good results. Nevertheless, significant questions about what physics is included in the method and its realm of validity remain unanswered. In this paper, the WA method is applied to scattering from pressure-release sinusoidal surfaces in order to further explore these topics. Comparisons with accurate benchmark calculations are carried out over a broad range of kh and kΛ (k is the acoustic wave number; h and Λ are the amplitude and wavelength of the sinusoid, respectively) indicate that the primary limitation of the WA method stems from its current failure to include multiple scattering effects. It is also shown that quite good agreement with the benchmark can be achieved by a "diffraction-only" WA model even when $kh \ll 1$ and "reflectionlike" scattering patterns are observed.

172Z. EXPERIMENTAL TECHNIQUES

10A219. Error estimates for free-decay damping measurements. - F Orduna-Bustamante and RR Boullosa *(Seccion de Acust, Centro de Instrument, Univ Nacional Autonoma, Apdo Postal 70-186, Mexico DF, Mexico)*. J Acoust Soc Am 93(6) 3265-3270 (Jun 1993).

An estimate is presented of the errors introduced by digital sampling of an analog time signal when the logarithmic decrement method is used to measure damping. Some computer simulations were made in order to verify that the error estimate is adequate. Other factors that influence the error in the measured damping ratio, such as noise and the value of the damping ratio, are also studied by computer simulation. It is shown that, on average, the digital sampling error depends mainly on the total number of sampled points, but that it is affected also by the ratio between the sampling frequency and the frequency of the signal. Digital sampling errors combined with the errors introduced by different signal-to-noise ratios impose bounds to the values of the damping ratio that can be measured accurately. It is also shown that the optimum number of data points, when digital sampling error is combined with noise, varies according to the signal-to-noise ratios and the value of the damping ratio. A brief discussion of other decay methods compared to the logarithmic decrement method is also given.

10A220. Method of measuring the dynamic flow resistance and reactance of porous materials. - Mingzhang Ren *(Dept of Mech Eng, Xi'an Jiaotong Univ, Shaanxi, Peoples Rep of China)* and F Jacobsen *(Acoust Lab, Tech Univ, Bldg 352, DK-2800 Lyngby, Denmark)*. Appl Acoust 39(4) 265-276 (1993).

A method of measuring the frequency dependent flow resistance and reactance of porous materials in a duct is presented and examined. The method involves measuring the transfer function between the signals from two microphones placed on either side of a sample of the material. The validity of the method is tested by comparing measured values of the surface impedance of the material with values predicted from the measured flow resistance and reactance.

10A221. Temperature fluctuations and gradients in a liquid sample as a source of errors

in ultrasound velocity measurements. - S Ernst, W Marczak, R Manikowski *(Inst of Chem, Silesian Univ, Szkolna 9, 40-006 Katowice, Poland)*. Acoust Lett 16(8) 177-183 (Feb 1993).

Temperature gradients were measured at 283, 293 and 303K in the sample cell of an ultrasound velocimeter of sing-around type. They were found to be considerably higher than the measured short-time temperature fluctuations and quite close to the long-time ones. The velocity errors caused by temperature gradients are similar to the residual errors of the calibration line, and since the gradients are not reproducible they cannot be reduced by making appropriate corrections.

Automatica 29(3) 707-721 (May 1993).

10A224. Robustness bounds for linear systems under uncertainty: Eigenvalues inside a wedge. - TR Alt *(Space Sta Div, McDonnell Douglas Aerospace, 5301 Bolsa Ave MS 15-1, Huntington Beach CA 92465)* and F Jabbari *(Dept of Mech and Aerospace Eng, UC, Irvine CA 92717)*. J Guidance Control Dyn 16(4) 695-701 (Jul-Aug 1993).

This paper deals with robustness bounds for linear systems with uncertainty, where both stability and a measure of performance robustness are desired. Here, performance robustness is defined by guaranteeing that the eigenvalues of the perturbed system remain in a specific region in the complex plane such as a wedge. Using standard Lyapunov techniques, for analysis, bounds on the uncertain parameters are obtained that guarantee that the system eigenvalues remain in the desired region, whereas for synthesis, bounds and state feedback gains can also be obtained that place the closed loop system eigenvalues in the desired region. An optimization algorithm is also presented that was successfully used in the examples.

10A225. Robustness evaluation of a flexible aircraft control system. - MR Anderson *(Dept of Aerospace and Ocean Eng, VPI)*. J Guidance Control Dyn 16(3) 564-571 (May-Jun 1993).

The structured singular value analysis technique is used to generate stability and performance robustness guidelines for multivariable, flexible aircraft flight control systems. A stability augmentation and structural mode control system, designed using the same classical technique as on the original production aircraft, is evaluated to produce the new guidelines. Stability margins are computed for simultaneous gain and phase uncertainty in each of the control system feedback loops. Performance weighing filters are chosen specifically from military flying qualities specifications. The results of this research define exactly how robust a control system of this type should be, such that any performance improvements achieved using more advanced design techniques can be compared directly.

10T226. Design of a robust estimator for target tracking. - ET Kim *(Flight Control Dept, Korean Aerospace Res Inst, Teadok Science Town, Taejon, S Korea)* and D Andrisani II *(Sch of Aeronaut and Astronaut, Purdue)*. J Guidance Control Dyn 16(3) 595-597 (May-Jun 1993).

10A227. Maximizing the efficiency of wave-energy plant using complex-conjugate control. - P Nebel *(Dept of Mech Eng, Univ of Edinburgh)*. J Syst Control Eng 206(I4) 225-236 (1992).

A method of determining the hydrodynamic coefficients of a floating wave-energy absorber is outlined, and the coefficients of a Salter's duck are measured experimentally. A complex-conjugate synthesizer, derived from these coefficients, is used both theoretically and experimentally to predict and to measure the efficiency of a duck in unidirectional monochromatic waves. The synthesis produces a higher efficiency over a greater bandwidth than has been achieved before. The reason for the improvement in efficiency is explained, and conclusions are drawn about the implications of complex-conjugate control for predicting practical engineering constraints on the design of a full-sized wave-energy absorber.

10A228. Multiple-input, multiple-output time-series models from short data records. - JJ Hollkamp *(Wright Lab, WL-FIBGC, WPAFB)*. J Guidance Control Dyn 16(3) 549-556 (May-Jun 1993).

An algorithm to estimate multiple-input, multiple-output, time-series models for structural system identification using short time histories is presented. The method uses order overspecification to reduce estimation bias and automatically sorts identified system modes from computational modes. The system natural frequencies, damping factors, mode shapes, and modal participation factors are estimated and can be used to reconstruct single-input, single-output models for every input-output pair. Experimental data from a large cantilevered flexible truss are used to demonstrate the technique. Modal estimates are comparable to those obtained using accepted methods such as the eigensystem realization algorithm.

10A229. Wind identification along a flight trajectory, Part 3. Two-dimensional dynamic approach. - A Miele, T Wang, CY Tzeng *(Aero-Astronaut Group, Rice Univ, Houston TX)*, WW Melvin *(Delta Airlines, Atlanta GA)*. J Optim Theory Appl 77(1) 1-30 (Apr 1993).

This paper deals with the identification of the wind profile along a flight trajectory by means of a 2D dynamic approach. In this approach, the wind velocity components are computed as the difference between the inertial velocity components and the airspeed components. The airspeed profile as well as the nominal thrust, drag, and lift profiles are obtained from the available DFDR measurements. The actual values of the thrust, drag, and lift are assumed to be proportional to the respective nominal values via multiplicative parameters, called the thrust, drag, and lift factors. The thrust, drag, and lift factors plus the inertial velocity components at impact are determined by matching the flight trajectory computed from DFDR data with the flight trajectory available from ATCR data. This leads to a least-square problem which is solved analytically under the additional requirement of closeness of the multiplicative factors to unity.

200F. SENSITIVITY

10A230. Comparison of methods for design sensitivity analysis for optimal control of thermal systems. - JM House *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*, JS Arora *(Dept of Civil and Env Eng, Univ of Iowa, Iowa City IA 52242)*, TF Smith *(Dept of Mech Eng, Univ of Iowa, Iowa City IA 52242)*. Optimal Control Appl Methods 14(1) 17-37 (Jan-Mar 1993).

The objective of this study is to examine two analytical methods for the design sensitivity analysis of optimal control problems and to develop the analyses necessary for the application of the methods to thermal systems. The two methods are the direct differentiation method and the adjoint variable method. Results for these methods are compared with those obtained using central finite difference approximations for design sensitivity analysis. The adjoint variable method has the potential to reduce significantly computational times for design sensitivity analysis while sacrificing only a small amount of accuracy. As the number of functionals requiring design sensitivity analysis increases, however, the adjoint variable method becomes less attractive and the direct differentiation method becomes more attractive.

10A231. Simple discrete-time regulator minimizing sensitivity. - A Tarczynski *(Sch of Electron and Manuf Syst Eng, Univ of Westminister, 115 New Cavendish St, London W1M 8JS, UK)*. Automatica 29(3) 793-796 (May 1993).

A simple algorithm for minimizing sensitivity of SISO discrete-time control systems is presented. The method delivers an explicit solution for the controller. It allows the designer to maintain control over the order of the controller. Another advantage of the method is that it offers significant flexibility in weighting sensitivity and complementary sensitivity functions in the performance criterion as the weights do not have to be the magnitudes of some transfer functions.

10T232. Controller design with regional pole constraints: Hyperbolic and horizontal strip

regions. - Y William Wang and DS Bernstein *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109)*. J Guidance Control Dyn 16(4) 784-787 (Jul-Aug 1993).

10A233. Frequency domain design for robust performance under parametric, unstructured, or mixed uncertainties. - S Jayasuriya *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843-3123)*. J Dyn Syst Meas Control 115(2B) 439-451 (Jun 1993).

This article looks at direct frequency domain design for satisfying robust performance objectives in uncertain, linear time invariant (LTI) plants embedded in a single feedback loop. The uncertain plants may be described by parametric, nonparametric (or unstructured), or mixed uncertain models. Quantitative Feedback Theory (QFT) is one frequency domain design methodology that is direct and is equally effective with any of these models. It can be separated from other frequency domain robust control methods such as H^∞ optimal control, μ synthesis, and LQG-LTR for at least (i) its emphasis on cost of feedback measured in terms of controller bandwidth, (ii) its ability to deal nonconservatively with parametric, nonparametric and mixed uncertainty models, and (iii) its utilization of both amplitude and phase of the loop transfer function, pointwise in frequency, for the quantification of robust performance. An exposition of these attributes, unique to QFT, and the basic design methodology, coupled with a recently developed mathematical framework and some existence results for the standard single-loop QFT problem are the salient features of this paper.

10A234. Lead-lag compensator design by the Hough transform. - Yen-Ting Hsu, Yau-Tarng Juang *(Dept of Elec Eng, Natl Central Univ, Chung-Li, Taiwan 32054, ROC)*, Te-Ping Tsai *(Chung Shan Inst of Sci and Tech, PO Box 90008-16-17 Lungtan, Taoyuan, Taiwan, ROC)*. Syst Control Lett 20(5) 365-372 (May 1993).

The frequency response of a compensator can be expressed as a curve in the complex plane. The Hough transform is very useful in finding a mathematical model which matches the curve in a plane very well. We combine these two concepts to generate a new method of compensator design. Two examples are illustrated to explain the design procedure and results.

10A235. Maneuver and vibration control of hybrid coordinate systems using Lyapunov stability theory. - JL Junkins *(Dept of Aerospace Eng, Texas A&M Univ, College Station TX 77843)* and Hyochoong Bang *(Dept of Aeronaut and Astronaut, Naval Postgraduate Sch, Monterey CA)*. J Guidance Control Dyn 16(4) 668-676 (Jul-Aug 1993).

In this study, we present a generalized control law design methodology that covers a large class of systems, especially flexible structures by hybrid discrete-distributed coordinate systems. The Lyapunov stability theory is used to develop globally stabilizing control laws. A hybrid version of Hamilton's canonical equations is introduced, which provides a direct path to designing stabilizing control laws for general nonlinear hybrid systems. The usual loss of robustness due to model reduction is overcome by this Lyapunov approach, which does not require truncation of the flexible systems into finite dimensional discrete systems.

10A236. Robust pole assignment in a specified region using output feedback. - Myungho Oh, Da-Wei Gu, SK Spurgeon *(Dept of Eng, Univ of Leicester, University Rd, Leicester LE1 7RH, UK)*. Optimal Control Appl Methods 14(1) 57-66 (Jan-Mar 1993).

An output feedback pole assignment method is presented which seeks to achieve a robust solution where the assigned poles are as insensitive as possible to perturbations in the closed-loop system. The freedom available to obtain a robust solution is realized by assigning poles not to exact locations but within specified regions of the complex plane. The problem is formulated as a nonlinear programming problem with a set of nonlinear constraints of matrix-valued functions as well as a set of linear constraints. A numerical algorithm is presented in two forms and the results obtained are compared with those generated from other algorithms for a series of test examples taken from the literature.

200I. MODELLING AND SIMULATION

10T237. Analytical development of an equivalent system mismatch function. - MR Anderson *(Dept of Aerospace and Ocean Eng, 215 Randolph Hall, VPI)*. J Guidance Control Dyn 16(4) 712-716 (Jul-Aug 1993).

10A238. Inverse simulation of large-amplitude aircraft maneuvers. - C Gao *(Chung Shien Inst of Sci and Tech, Taiwan, ROC)* and RA Hess *(Dept of Mech, Aeronaut and Mat Eng, UC, Davis CA 95616)*. J Guidance Control Dyn 16(4) 733-737 (Jul-Aug 1993).

Inverse simulation techniques are computational methods that determine the control inputs to a dynamic system that will produce desired system outputs. Such techniques can be useful tools for the analysis and evaluation of problems associated with maneuvering flight. As opposed to current inverse simulation methods that require numerical time differentiation in their implementation, the proposed technique is essentially an integration algorithm. It is applicable to cases where the number of inputs equals or exceeds the number of constrained outputs. The algorithm is exercised in determining the trim condition and then the control inputs that force a nonlinear model of an F-16 fighter to complete large-amplitude maneuvers.

10A239. Reflections on engineering systems and bond graphs. - RC Rosenberg *(Dept of Mech Eng, Michigan State Univ, E Lansing MI 48824)*. J Dyn Syst Meas Control 115(2B) 242-251 (Jun 1993).

An important aspect of modern engineering systems is their great diversity. Often they include interactions among different physical domains, contain control sub-systems, and are large-scale and complex. The bond graph is a powerful and versatile tool that can help the engineer to design modern engineering systems. Three issues are explored from a bond graph perspective: modeling of engineering systems, simulation of their behavior, and teaching about engineering systems. It is the author's observation that bond graph methodology is one of the most useful engineering system techniques available and belongs in the problem-solving tool kit of every mechanical engineer. This paper develops a rationale for this viewpoint both for readers familiar with bond graph methods and for readers to whom they are new.

200J. ADAPTIVE AND LEARNING SYSTEMS

10A241. Composite adaptive control of flexible joint robots. - Jing Yuan and Y Stepanenko *(Dept of Mech Eng, Univ of Victoria, Victoria, BC, V8W 3P9, Canada)*. Automatica 29(3) 609-619 (May 1993).

A composite adaptive controller is developed for flexible joint robots with inertia parameter uncertainty. It does not require any restrictions on the joint stiffness, since a full-order dynamic model is used in the design and stability analysis. Previously published results based on the fourth-order model require at least joint jerk feedback and derivatives of the manipulator regressor (up to the second-order). In contrast, the proposed adaptive controller requires at most joint acceleration feedback. Its adaptive law is of the same complexity as the well-known Slotine and Li's algorithm for rigid-body robots. Asymptotic stability of the adaptive controller is established in the Lyapunov sense. Simulation results are included to demonstrate the tracking performance.

10A242. Evolution of adaptive control. - ID Landau *(Lab d'Automat de Grenoble, INPG-CNRS, Groupement de Rech Automat, ENSIEG-BP 46 38402, St-Martin d'Heres, France)*. J Dyn Syst Meas Control 115(2B) 381-391 (Jun 1993).

The evolution of the adaptive control algorithms driven by the results obtained in the application of the 1st generation of adaptive controllers (model reference adaptive control, self-tuning minimum variance) is examined. Research in the field of adaptive control has been directed, on the one hand, toward the development of a robust general purpose adaptive controller and, on the other, towards the extension of the model reference adaptive control approach to nonlinear systems. Research has also investigated the stability-passivity approach for developing dedicated adaptive control algorithms for particular classes of nonlinear plants (eg, rigid robots). The paper will review the results obtained in these directions both from the theoretical and the practial points of view. In the final part, current research directions will be included.

10A243. Learning control of robot manipulators. - R Horowitz *(Dept of Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2B) 402-411 (Jun 1993).

Learning control encompasses a class of control algorithms for programmable machines such as robots which attain, through an iterative process, the motor dexterity that enables the machine to execute complex tasks. In this paper we discuss the use of function identification and adaptive control algorithms in learning controllers for robot manipulators. In particular, we discuss the similarities and differences between betterment learning schemes, repetitive controllers and adaptive learning schemes based on integral transforms. The stability and convergence properties of adaptive learning algorithms based on integral transforms are highlighted and experimental results illustrating some of these properties are presented.

10A244. Low velocity friction compensation and feedforward solution based on repetitive control. - ED Tung *(Dept of Mech Eng, UCB)*, G Anwar *(Integrated Motions, Berkeley CA)*, M

Tomizuka *(Dept of Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2A) 279-284 (Jun 1993).

One of the most significant sources of tracking error for an X-Y table is static friction, a nonlinear disturbance at low velocity. In traversing a circular profile, an X-Y table encounters zero velocity crossings at 90° intervals around the circle, leaving relatively large tracking errors referred to as "quadrant glitches". To learn the control input which eliminates errors caused by stiction, repetitive control, a subclass of learning control, is employed. Experiments, conducted on the X-Y bed of a CNC milling machine, demonstrate that near-perfect tracking can be achieved in twelve cycles or less. Of particular interest is the velocity command input generated by repetitive control. The input containt feedforward information for developing perfect trajectories at low velocities.

10T245. Milito-Cruz adaptive control scheme for Markov chains. - VS Borkar *(Dept of Elec Eng, Indian Inst of Sci, Bangalore, India)*. J Optim Theory Appl 77(2) 387-397 (May 1993).

10A246. Robust adaptive control of revolute flexible-joint manipulators using sliding technique. - Chi-Man Kwan and KS Yeung *(Dept of Elec Eng, Univ of Texas, Box 19016, Arlington TX 76019)*. Syst Control Lett 20(4) 279-288 (Apr 1993).

In this paper, we present a 3-step procedure to robustly control the revolute flexible-joint manipulator in the presence of parameter variations and bounded input disturbances such as torque ripples. By treating the difference of motor angle and link angles as the input to the rigid link part of the manipulator dynamics, our first step is to design a smooth adaptive reference signal for this input to globally stabilize the rigid subsystem. The second step is to drive the difference of motor and link angles to this desired reference signal exponentially by using sliding control. In the third step we exploit the model reduction capability of sliding control to perform the stability analysis. It is well-known that sliding control can reduce the system order by n if the number of control inputs is n. The exploitation of this property of sliding control makes our stability analysis a lot simpler than other approaches. Global stability in the sense of Lyapunov can be guaranteed and errors in link position and velocity are driven to zero when the system is in sliding mode. No weak elasticity assumption is needed.

10A247. State space self-tuning controller with integral action. - P Desai *(Sch of Eng and Eng Tech, Penn State Univ, Erie PA 16523-0203)* and AK Mahalanabis *(Dept of Elec Eng, Penn State)*. Optimal Control Appl Methods 13(4) 301-319 (Oct-Dec 1992).

The paper is concerned with the problem of designing a state space self-tuning controller with integral action for a class of unknown linear stochastic systems. The observer form of the innovations model of the system is used along with a single-stage *quadratic-in-state-and-control* performance index which includes a cross-weighting between system states and inputs. This results in a *proportional estimated state plus integral output* $(P + I)$ controller in an incremental form. While it is analogous to the LQG-theory-based optimal adaptive controller in structure, computational simplification is achieved by the choice of a single-stage performance index and a direct estimation of the state estimator gain matrix. The new controller has the advantages of being applicable to both single-input and single-output and multi-input and multi-output minimum phase and non-minimum phase systems. The results are illustrated numerically through two simulation examples.

10A248. Suitable generalized predictive adaptive controller case study: Control of a flexible arm. - M M'Saad, L Dugard, SH Hammad *(Lab d'Automat de Grenoble, ENSIEG - INPG, BP 46, 38402, St-Martin-d'Heres, France)*. Automatica 29(3) 589-608 (May 1993).

This paper presents an adaptive control case study involving a flexible arm. The underlying control design consists in a judicious combination of the pole placement concept and the generalized predictive control design. The former allows one to incorporate a suitable tracking capability while the latter is more advisable from practical use point of view. A particular emphasis is put on the fundamental design features of the adaptive controller, namely the tracking capability, the adaptation alertness and the robustness with respect to reduced order modeling.

In the spirit of practical applicability, design transparency and quantitative specifications, this paper presents a new robust decentralized control design framework – model reference quantitative feedback design (MRQFD) – for multivariable control systems with large plant uncertainty and strong cross-coupling. The MRQFD method provides a connection between Rosenbrock's Nyquist array and Horowitz's quantitative feedback theory. There are two main stages in the MRQFD method. First, an internal model reference loop, based on non-negative matrix theory, is used to obtain robust generalized diagonal dominance and hence the reduction of uncertainty in the resultant compensated internal loop system. Then a single-loop quantitative feedback design scheme is applied to solve the resulting series of individual loops to guarantee the satisfaction of predefined MIMO quantitative specifications. The design procedure can be carried out either in the direct or in the inverse plant domains, as in Rosenbrock's Nyquist array. The conditons of robust diagonal stabilization are also given for the MRQFD framework. The effectiveness of the MRQFD method and its ease of application are demonstrated by a 3 × 3 uncertain multivariable example.

The problem of determining overall optimized control schedules for a class of cascade water supply systems containing only fixed speed pumps is examined. The system control is by nature an on-off type. The optimal scheduling problem can be formulated as dynamical optimal control problems with purely discrete symbols, discrete controls, and also with continuous intermediate variables interrelated in a highly nonlinear way. An efficient problem solver is proposed. Its high efficiency is achieved by exploiting, through a suitable decomposition, certain structural properties of the problem. Lagrange relaxation is applied in order to break down the time structure of discrete control variables. The decomposition also enables consideration of mixed integer optimization on purely static grounds. The dynamical optimization constitutes only that part of the solver which deals with entirely continuous variables. There is a duality gap in the problem. However, certain but not complete, information obtained through solving the dual problem (dual optimal information) is close to that which corresponds to the true (primal) optimal solution. This is an important property of the scheduling problem, which together with the problem structure creates a basis for the solver design.

10A255. Computation of the digital LQG regulator and tracker for time-varying sys-

tems. - LG Van Willigenburg *(Dept of Agri Eng and Phys Agrotechnion, Wageningen Univ, Bomenweg 4, 6703 HD Wageningen, Netherlands).* Optimal Control Appl Methods 13(4) 289-299 (Oct-Dec 1992).

Digital optimal control problems, ie, problems where a continuous-time system is controlled by a digital computer, are very often approximated by either discrete-time or continuous-time optimal control problems. A digital controller based on one of these approximations requires a *small sampling time* and constitutes only an *approximate solution.* The digital LQG regulator and tracker constitute solutions to real digital control problems which involve sampled-data, piecewise constant controls and integral criteria. Until now only the numerical computation of the digital LQG regulator in the case of time-invariant system and criterion matrices has been considered in the literature. The control of nonlinear stochastic systems about state trajectories is very often performed by an LQG regulator based on the linearized dynamics about the trajectory, which constitutes a *time-varying system.* We present a numerical procedure to compute the digital LQG regulator and a tracker in the case where the system and criterion matrices are time-varying. Finally we present a numerical example.

10A256. Control of motion of complex mechanical systems. Synthesis of algorithms on the basis of Euler equations. - PD Krut'ko *(Moscow, Russia).* J Machinery Manuf Reliab 6 83-90 (1992).

Adaptive algorithms for controlling motion of objects modeled by the Euler equations, are synthesized. The algorithms are of non-traditional structure and make the systems weakly sensitive to parameters variations and external disturbances. The structure of the algorithms is found by optimizing the systems in the minimum-acceleration-energy criterion. The algorithms may be used for automatic control of motion of mechanical and aeromechanical objects, as well as of stabilized and controlled platforms, with respect to their centers of masses.

10A257. Disturbance model for control-structure optimization with full state feedback. - GL Slater *(Dept of Aerospace Eng and Eng Mech, Univ of Cincinnati, ML No 70, Cincinnati OH 45221)* and MD McLaren *(Space Syst-LORAL, M-S G75, Palo Alto CA 94303).* J Guidance Control Dyn 16(3) 523-533 (May-Jun 1993).

This paper deals with a technique for the integrated optimization of structure and control in the design of flexible spacecraft and other flexible systems. This current approach uses the concept of response to dynamic constraints to establish tradeoffs between control energy and structural mass. This approach gives a concise variational methodology to total system optimization and eliminates the need to specify rather arbitrary trade-offs between control energy and structural mass. Results give an explicit dependency between structural stiffness (hence mass), disturbance magnitude, control energy available, and deflection constraints. For the special case of linear controls and quadratic constraints the problem reduces to a standard linear quadratic regulator problem plus a structure optimization. The method is general, however, and can be extended to more general problems such as output feedback, nonlinear controls, and slew optimization.

10A258. Feedback control of minimum-time optimal control problems using neural networks. - CJ Goh, J Edwards *(Dept of Math, Univ of W Australia, Nedlands, W Australia 6009, Australia),* AY Zomaya *(Dept of Elec and Electron Eng, Univ of W Australia, Nedlands, W Australia 6009, Australia).* Optimal Control Appl Methods 14(1) 1-16 (Jan-Mar 1993).

This paper presents an optimal feedback controller capable of driving a nonlinear control system from an arbitrary initial state to a fixed final state in minimum time. The controller is based on a feedforward multilayer neural network trained repeatedly using open-loop optimal control data which densely span the field of extremals of the nonlinear system. The effectiveness of the controller is clearly demonstrated by a simulation on a two-link robot manipulator. The effect of sensor-actuator noise and parameter variation is also included to confirm the robustness of the controller.

10T259. First-order models for satellite survivability optimization. - ML Howard *(Tracor Aerospace, Austin TX 78725).* J Guidance Control Dyn 16(3) 462-469 (May-Jun 1993).

10A260. General adaptive guidance using nonlinear programming constraint-solving methods. - L Skalecki *(Consult Eng, Boeing Defense & Space Group, 7264 Beresford Ave, Parma OH 44130)* and M Martin *(Space Transportation Syst, Boeing Defense & Space Group, PO Box 3999, MS 8C-09, Seattle WA 98124).* J Guidance Control Dyn 16(3) 517-522 (May-Jun 1993).

An adaptive, general-purpose, constraint-solving guidance algorithm has been developed by the authors in response to the requirements for the advanced launch system. The algorithm can be used for all mission phases for a wide range of space transportation vehicles without code modification because of the general formulation of the nonlinear programming problem, and the general trajectory simulation used to predict constraint values. The approach allows onboard retargeting for severe weather and changes in payload or mission parameters, increasing flight reliability and dependability, while reducing the amount of preflight analysis that must be performed. The algorithm is described in general in this paper. Three-dof closed-loop simulation results are presented for application of the algorithm to advanced launch system ascent, re-entry of a low lift-to-drag vehicle, and Mars aerobraking. Flight processor throughput requirement data are shown for each of these applications.

10A261. Inverse dynamics approach to trajectory optimization for an aerospace plane. - Ping Lu *(Dept of Aerospace Eng and Eng Mech, Iowa State Univ, Ames IA 50011).* J Guidance Control Dyn 16(4) 726-732 (Jul-Aug 1993).

An inverse dynamics approach for trajectory optimization is proposed. This technique can be useful in many difficult trajectory optimization and control problems. The application of the approach is exemplified by ascent trajectory optimization for an aerospace plane. Both minimum-fuel and minimax types of performance indices are considered. When rocket augmentation is available for ascent, it is shown that accurate orbital insertion can be achieved through the inverse control of the rocket in the presence of disturbances.

10A262. Linear quadratic Gaussian-loop transfer recovery design for a helicopter in low-speed flight. - JJ Gribble *(Dept of Electron and Elec Eng, Univ of Glasgow, G12 8QQ, UK).* J Guidance Control Dyn 16(4) 754-761 (Jul-Aug 1993).

A control law for a helicopter in low-speed flight is designed using the linear quadratic Gaussian-loop transfer recovery method. The specifications are adapted from a subset of the US Army helicopter handling qualities requirements. The design model consists of the rigid-body dynamics linearized about the 30 kt forward flight condition, together with a simplified, low-order representation of actuator and rotor dynamics. Evaluation is performed using higher-order models, obtained by linearization about several different points in the flight envelope, covering the speed range from 10 to 50 kt. These models contain more accurate representations of the high-frequency actuator and rotor modes. The final selection of the numerical values of the linear quadratic parameters is made by numerical optimization of the loop shape. It is found that the specifications considered can be satisfied for all of the evaluation models without gain scheduling.

10A263. Near-optimal observer-based control of discrete two-time-scale systems. - Ming-Shyan Wang, Tzuu-Hseng S. Li, York-Yih Sun *(Control System Lab, Dept of Elec Eng, Natl Cheng-Kung Univ, Tainan, Taiwan 70101, ROC).* J Franklin Inst 330(4) 651-663 (Jul 1993).

The design of near-optimal observer-based controllers for discrete two-time-scale systems with inaccesssible states is considered. The controller is established by the design of the controllers of slow and fast subsystems via the quasi-steady-state method. The stability bound of the singular perturbation parameter and the value of the minimum performance index for the actual closed-loop system are determined. A digital flight control system of a twin-engine aircraft is used to demonstrate the desired scheme.

10A264. Nonlinear optimal regulator problem. - CJ Goh *(Dept of Math, Univ of W Australia, Nedlands, W Australia 6009, Australia).* Automatica 29(3) 751-756 (May 1993).

The linear quadratic regulator is one of the most widely used tools for control systems design. Many real world systems, however, are inherently nonlinear and can only be optimally regulated using a nonlinear controller. This is, in general, much more difficult to achieve than the linear quadratic case. In this paper we show that a nonlinear feedback controller can be synthesized by appropriate training of a feedforward neural network to satisfy the corresponding nonlinear Hamilton-Jacobi-Bellman (HJB) partial differential equation in a restricted domain of the state space. Asymptotic stability of the closed-loop system is shown to be a natural consequence of the HJB equation.

10A265. Optimal discrete-time dynamic output-feedback design: A w-domain approach. - Cheolkeun Ha, Uy-Loi Ly *(Dept of Aeronaut and Astronaut, Univ of Washington, Seattle WA 98195),* MC Berg *(Dept of Mech Eng, Univ of Washington, Seattle WA 98195).* J Guidance Control Dyn 16(3) 534-540 (May-Jun 1993).

An alternative method for optimal digital control design is described in this paper. The method is based on the usage of the w-transform and has many attractive design features. One of these is its immediate connection with frequency loop-shaping techniques that are now popular and effective for multivariable control synthesis in the continuous-time domain. Furthermore, any design algorithms originally developed for continuous-time systems can now be immediately extended to the discrete-time domain. The main results presented in this paper are the exact problem formulation and solution of an optimal discrete-time dynamic output-feedback design in the w domain involving a quadratic performance index to random disturbances. In addition, necessary conditions for optimality are obtained for the numerical solution of the optimal output-feedback compensator design. A numerical example is presented illustrating its application to the design of a low-order dynamic compensator in a stability augmentation system of a commercial transport.

10A266. Optimal impulsive intercept with low-thrust rendezvous return. - CA Lembeck *(NASA Johnson Space Center, Houston TX 77058)* and JE Prussing *(Univ of Illinois, Urbana IL 61801).* J Guidance Control Dyn 16(3) 426-433 (May-Jun 1993).

Primer vector theory is used to investigate a specific class of minimum-fuel spacecraft trajectory problems in which high- and low-thrust propulsion systems are utilized sequentially. The problem considered assumes a spacecraft initially on-station is an established orbit about the earth. It is desired to intercept a predetermined position in space in a timely manner for collision avoidance or platform surveillance, using an optimal high-thrust program. The spacecraft then returns to the original orbit station using optimal low-thrust propulsion. Fixed-time minimum-fuel solutions are obtained using the Clohessy-Wiltshire linearized dynamic model. In the time-open case, the optimal final time is unbounded. For this case a composite performance index involving both fuel consumption and the final time is minimized to obtain optimal finite-time solutions.

10A269. Quasi-closed-form solution to the time-optimal rigid spacecraft reorientation problem. - RM Byers *(Dept of Mech and Aerospace Eng, Univ of Central Florida, Orlando FL 32816)* and SR Vadali *(Dept of Aerospace Eng, Texas A&M Univ, College Station TX 77843)*. J Guidance Control Dyn 16(3) 453-461 (May-Jun 1993).

The problem of slewing a rigid body from an arbitrary initial orientation to a desired target orientation in minimum time is addressed. The nature of the time-optimal solution is observed via an open-loop solution using the switch time-optimization algorithm developed by Meier and Bryson. Conclusions as to the number and timing of control switches are drawn and substantiated analytically. The solution of the kinematic differential equations for Euler parameters is examined for systems in which the applied torque is much greater than the nonlinear terms in Euler's equations. An approximate solution to these equations is used to construct the state transition matrix as a function of a given control sequence and control intervals. This allows a rapid solution for the required switch times for all admissible control sequences. Uncoupled switching functions can be generated given the approximate switch times for the optimal sequence. The resulting feedforward-feedback control is suitable for online computation.

10T270. Riccati equation approach to the singular LQG problem. - Y Halevi *(Dept of Mech Eng, Ohio State Univ, 206 W 18th Ave, Columbus OH 43210-1107)*, WM Haddad *(Dept of Mech and Aerospace Eng, Florida IT, Melbourne FL 32902)*, DS Bernstein *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109-2140)*. Automatica 29(3) 773-778 (May 1993).

10A271. Saturating and time-optimal feedback controls. - M Bikdash *(Bradley Dept of Elec Eng, VPI)*, EM Cliff *(Dept of Aerospace and Ocean Eng, VPI)*, AH Nayfeh *(Dept of Eng Sci and Mech, VPI)*. J Guidance Control Dyn 16(3) 541-548 (May-Jun 1993).

The open-loop solution of the soft-constrained time-optimal control problem can be efficiently computed in terms of the controllability Grammian matrix, but a closed-loop implementation was found to be cumbersome. This control was observed to have a saturation property strongly reminiscent of the hard-constrained time-optimal control problem. In this paper, we present a theoretical justification for the observed saturation and propose a modification of the problem statement that gives a suboptimal solution and results in a drastically simpler implementation of the feedback time-optimal soft-constrained control. Moreover, we generalize the proposed approach to generate a family of saturating control laws occupying a middle ground between linear state-feed-back and hard-constrained time-optimal controls. For illustration, we consider the simultaneous slewing and vibration suppression of an undamped flexible beam that is reducible to a marginally stable linear system. As an example, we design a simple and elegant feedback control law where the regulation time and control amplitude saturate like the square root of the norm of the state vector.

10A272. Singular control in minimum time spacecraft reorientation. - H Seywald and RR Kumar *(Spacecraft Control Branch, NASA Langley Res Center, 17 Research Dr, Hampton VA)*. J Guidance Control Dyn 16(4) 686-694 (Jul-Aug 1993).

Time-optimal solutions for the reorientation of an inertially symmetric rigid spacecraft with independent three-axes controls are investigated. All possible optimal control strategies are identified. These include bang-bang solutions, finite-order singular arcs and infinite-order singular arcs. Necessary conditions for optimality of finite-order singular arcs are presented. Nonoptimality of principal-axis rotation for rest-to-rest minimum time reorientation is proved. Numerical examples of time-optimal solutions with finite- and infinite-order singular arcs are presented. A simple example of "a car in a parking lot" is discussed. It clearly illustrates that infinite-order singular control may be the "unique" solution to an optimal control problem and cannot be ignored when choosing the optimal control strategies.

10A273. Terminal repeller unconstrained subenergy tunneling (TRUST) for fast global optimization. - BC Cetin *(Dept of Elec Eng, California IT, Pasadena CA)*, J Barhen *(Nonlinear Sci and Info Processing Group, JPL)*, JW Burdick *(Dept of Mech Eng, California IT, Pasadena CA)*. J Optim Theory Appl 77(1) 97-126 (Apr 1993).

A new method for unconstrained global function optimization, acronymed TRUST, is introduced. This method formulates optimization as the solution of a deterministic dynamical system incorporating terminal repellers and a novel subenergy tunneling function. Benchmark tests comparing this method to other global optimization procedures are presented, and the TRUST algorithm is shown to be substantially faster. The TRUST formulation leads to a simple stopping criterion. In addition, the structure of the equations enables an implementation of the algorithm in analog VLSI hardware, in the vein of artificial neural networks, for further substantial speed enhancement.

10A274. Time-optimal three-axis reorientation of a rigid spacecraft. - KD Bilimoria *(Aerospace Res Center, Arizona State Univ, Tempe AZ 85287)* and Bong Wie *(Dept of Mech and Aerospace Eng, Arizona State Univ, Tempe AZ 85287)*. J Guidance Control Dyn 16(3) 446-452 (May-Jun 1993).

New results are presented for the minimum-time rest-to-rest reorientation control problem of a rigid spacecraft with independent three-axis control. It is shown that in general the eigenaxis rotation maneuver is not time optimal. An inertially symmetric (eg, spherical or cubical) rigid body is examined to demonstrate that an eigenaxis rotation about a control axis of even such a simple body is not time optimal. The computed optimal solution is bang-bang in all three control components and has a significant nutational component of motion. The total number of switches is found to be a function of the specified reorientation angle.

202C. NONLINEAR SYSTEMS

10A275. Analysis and control of nonlinear systems. - JK Hedrick *(Dept of Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2B) 351-361 (Jun 1993).

This paper describes my work on nonlinear analysis and control over the last twenty years. The first part of the paper concerns the development of nonlinear analysis tools for predicting stability and forced response characteristics of high speed ground vehicles. The principal motivation was to develop an alternative to "brute force" time domain simulation. The developed tools were extensions of "describing function" or "equivalent linearization" methods for both periodic and stochastic excitation. The "statistical linearization" analysis tools were then extended and applied to design control laws for nonlinear stochastic regulators. The second part of the paper was motivated by control system design for highly nonlinear, multivariable systems, such as automotive powertrain control and aircraft flight control. For these classes of systems, statistical linearization procedures are computationally cumbersome and also provide no stability or robustness guarantees. A method which has proven extremely powerful, both theoretically and experimentally, is "sliding control." This technique is a form of input-output linearization that directly incorporates model error information with stability and performance measures. My students and I found several difficulties in the direct application of this method to automotive and aircraft control. This paper describes our solutions to the problems of repeated model differentiation, differentiation of model error, undesirable "internal dynamics" and systems with saturating control inputs.

10A276. Control of uncertain nonlinear systems. - M Corless *(Sch of Aeronaut and Astronaut, Purdue)*. J Dyn Syst Meas Control 115(2B) 362-372 (Jun 1993).

This paper describes some of my research in the analysis and control of nonlinear uncertain systems in which the uncertainties are modeled deterministically rather than stochastically. The main applications are to mechanical-aerospace systems, such as robots and spacecraft; the underlying theoretical approach is based on Lyapunov theory.

10A277. Elaboration of a control law for switching nonlinear systems. - V Abadie and G Dauphin-Tanguy *(Ecole Central de Lille, LAIL, URA CNRS D 1440, BP 48 Cite Scientifique, 59651 Villeneuve d'Ascq, Cedex, France)*. J Franklin Inst 330(4) 685-693 (Jul 1993).

The purpose of this paper is to elaborate upon a control law for a class of nonlinear system with Boolean inputs. First the affine system is studied, and then the control law is calculated by an input-output feedback linearization, assuming the system is continuous. The final control law is then determined by a discretization of the input vector. The results are applied to an asynchronous machine and its power electronics control system.

10A278. One approach to the control of uncertain systems. - G Leitmann *(Col of Eng, UCB)*. J Dyn Syst Meas Control 115(2B) 373-380 (Jun 1993).

This paper is a personal history of one area of research with which I have been concerned over the past twenty years and which continues to attract my albeit waning attention, the control of dynamical systems based on uncertain models. Thus, it is a subjective account of various factors which I believe to have steered me to approach the problem via a constructive use of Lyapunov stability theory.

10A279. Torque regulation of induction motors. - R Ortega *(Univ de Tech, Heudiasyc URA CNRS 817, BP 233 60206 Compiegne, Cedex, France)* and G Espinosa *(Univ Nacional Autonoma, DEPFI, PO Box 70-256, DF, Mexico)*. Automatica 29(3) 621-633 (May 1993).

A controller design methodology to solve an output tracking problem for a class of systems described by its Euler-Lagrange equations with less control actions than dof was recently presented by Ortega and Espinosa. The procedure is based on the idea of "shaping" the total energy of the closed-loop system with the nice feature that it achieves the tracking objective without the need of cancelling dynamics but by associating a natural reference ("steady state") behavior for all state variables. In this paper we use the procedure to solve the problem of torque regulation of a nonlinear induction motor model which includes both electrical and mechanical dynamics. We derive a nonlinear state observer plus state feedback control that insures exponential stability provided the desired torque does not exceed a given value. The latter condition can be removed if the motor full state is measurable. An adaptive version of the scheme that does not require exact knowledge of the rotor resistance or load torque is also shown to be asymptotically convergent. Three key features of the proposed scheme are: first, it attains the field orientation objective of the highly successful "vector control" strategies. Second, using the energy balance equation of the induction motor, identifies the nonlinear terms that represent "workless forces" to avoid (intrinsically nonrobust) exact cancellation of model nonlinearities. Third, the control law calculation is extremely simple and globally defined, thus the strategy is applicable for all motor operation regimes including start-up. Some simulation results illustrate the controller performance.

10A280. Design of digital tracking controllers. - Masayoshi Tomizuka *(Dept of Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2B) 412-418 (Jun 1993).

This paper describes my work on the design of digital tracking controllers over the past two decades. In tracking control, the control object must be moved along a time varying desired output and the transient path error must be minimized. Tracking control is discussed for the following two typical situations: one is the situation where the desired output is known in advance and the other is where the desired output itself is not known but has a certain known property, eg, it is periodic with a known period. Control algorithms for dealing with these situations will be reviewed and applications to mechanical systems are discussed.

10A281. Precision tracking control of discrete time nonminimum-phase systems. - Chia-Hsiang Menq and Jin-jae Chen *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. J Dyn Syst Meas Control 115(2A) 238-245 (Jun 1993).

In this paper, a precision tracking control scheme for linear discrete time nonminimum-phase systems is proposed. This control scheme consists of a preview filter, a tracking-performance filter, a command feedforward controller, and a feedback controller. A command feedforward controller, whose design is based on the minimal order inverse model of the plant being controlled, will result in a completely decoupled system. The preview filter is introduced to compensate the phase and gain errors induced by the nonminimum phase zeros or lightly damped zeros of the system. Using the command feedforward controller along with the proposed preview filter, the tracking performance of the proposed control scheme can be characterized by the frequency response of the tracking-performance filter. For the design of the preview filter, a generalized Nth order preview filter and its associated penalty function that quantifies the tracking error of a design are defined. It is shown that, given the desired bandwidth and the order of the preview filter, the optimal solution for the design of the preview filter can be obtained explicitly. The proposed control scheme together with the optimal preview filter is shown to be very effective in achieving precision tracking control of discrete time MIMO nonminimum phase systems. It is also shown that the tracking performance is improved as the order N of the preview filter is increased.

202E. DISTRIBUTED PARAMETER AND DELAYED SYSTEMS

10A282. Controlled motion in an elastic world. - WJ Book *(George W Woodruff Sch of Mech Eng, Georgia Tech)*. J Dyn Syst Meas Control 115(2B) 252-261 (Jun 1993).

The flexibility of the drives and structures of controlled motion systems are presented as an obstacle to be overcome in the design of high performance motion systems, particularly manipulator arms. The task and the measure of performance to be applied determine the technology appropriate to overcome this obstacle. Included in the technologies proposed are control algorithms (feedback and feedforward), passive damping enhancement, operational strategies, and structural design. Modeling of the distributed, nonlinear system is difficult, and alternative approaches are discussed. The author presents personal perspectives on the history, status and future directions in this area.

10A283. Vibration and robust control of symmetric flexible systems. - Song-Tsuen Chen and An-Chen Lee *(Dept of Mech Eng, Natl Chiao Tung Univ, 1001 Ta Hsueh Rd, Hsinchu 30049, Taiwan, ROC)*. J Guidance Control Dyn 16(4) 677-685 (Jul-Aug 1993).

The use of symmetry in the vibration analysis and control of symmetric flexible systems is investigated. For a symmetric flexible system with actuators-sensors being systematically allocated, an internal and external decoupling control scheme is developed to simplify the controller design. The whole flexible system can be separated into two uncoupled subsystems under the decoupling scheme, and the control algorithm for each subsystem can be designed and implemented independently. Consider the case of a direct output feedback based controller design with actuators and sensors collocated. Two robustness properties of this controller, ie, full-order closed-loop stability and reliable control, are exploited. For demonstrative purposes, the optimal modal space approach is adopted for controller design of each subsystem and to illustrate the advantages of the decoupling control scheme. Simulation results of the control of a uniform simply supported beam are given to show the effectiveness of this proposed scheme.

10A284. Decoupling control based on the modified root locus approach. - Feng-Sheng Wang *(Autom Res Center, Natl Chung Cheng Univ, Chiayi 621, Taiwan, ROC)*. Optimal Control Appl Methods 14(1) 39-55 (Jan-Mar 1993).

Two control strategies, unity-feedback, and modified Smith predictor configuations, are introduced to design non-square decoupling control systems. The complete decoupler has the same function structure for both systems. The root locus approach is extended to design the multiloop controllers for both configurations. Pole-zero cancellation is not included in the design procedures for the respective control strategies, so the control laws can handle minimum or non-minimum phase reachable decoupling processes. The tuning region of the appropriate decoupling control configuration is determined through internal stability analysis. From the analysis we observe that if the product of the tuning parameter and the pseudogain of the subsystem is much smaller than unity, the control effects for the two decoupling control systems are no different. Since both decoupling controllers are essentially based on the process model, the control strategies are implemented in adaptive control schemes in the simulation examples.

10A285. Discrete-time repetitive control system design using the regeneration spectrum. - FR Shaw and K Srinivasan *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. J Dyn Syst Meas Control 115(2A) 228-237 (Jun 1993).

The stability, transient response, and stability robustness of discrete-time repetitive control systems characterized by large values of the time delay inherent in such systems are examined here using a function of frequency termed the regeneration spectrum. The ability to infer different aspects of controlled system performance from the regeneration spectrum, and its ease of computation, makes it a valuable tool for controller analysis and synthesis. A design procedure for discrete-time repetitive control systems, based on the regeneration spectrum, is outlined and a controller form suggested to effectively handle the trade-off between the different aspects of controlled system behavior. The controller design procedure is applied to an electrohydraulic material testing application characterized by strong nonlinearities, and shown experimentally to be effective in improving the controlled system performance.

10A287. Linear, multivariable robust control with a μ perspective. - A Packard *(Mech Eng, UCB)*, J Doyle *(Elec Eng, Caltech, Pasadena, CA)*, G Balas *(Aerospace Eng, Univ of Minnesota, Minneapolis, MN)*. J Dyn Syst Meas Control 115(2B) 426-438 (Jun 1993).

The structured singular value is a linear algebra tool developed to study a particular class of matrix perturbation problems arising in robust feedback control of multi-variable systems. These perturbations are called linear fractional, and are a natural way to model many types of uncertainty in linear systems, including state-space parameter uncertainty, multiplicative and additive unmodeled dynamics uncertainty, and coprime factor and gap metric uncertainty. The structured singular value theory provides a natural extension of classical SISO robustness measures and concepts to MIMO systems. The structured singular value analysis, coupled with approximate synthesis methods, make it possible to study the tradeoff between performance and uncertainty that occurs in all feedback systems. In MIMO systems, the complexity of the spatial interactions in the loop gains make it difficult to heuristically quantify the tradeoffs that must occur. This paper will look at the role played by the structured singular value (and its computable bounds) in answering these questions, as well as its role in the general robust, multivariable control analysis and design problem.

10T288. Multi-step ahead prediction based on the principle of concatenation. - MO Koynak *(Bogazici Univ, Bebek, Istanbul, Turkey)*. J Syst Control Eng 207(I1) 57-62 (1993).

10A289. Robust internal model control. - YZ Tsypkin *(Inst of Control Sc, Moscow 117342, Russia)*. J Dyn Syst Meas Control 115(2B) 419-425 (Jun 1993).

This paper discusses the method of control systems design for dynamic plants under bounded uncertainty. The structure of these systems coincides with the structure of systems with an internal model. But the choice of an internal model and a controller depends on the demand of the bounded decrease of system sensitivity to the change of plant characteristics and external action and on the demand of modal control. The absorption principle is used for the synthesis of a controller of such robust modal control systems. The realization conditions of robust systems of modal control are stated.

10A290. Robust time-delay control. - T Singh and SR Vadali *(Aerospace Eng, Texas A&M Univ, College Station TX 77843-3141)*. J Dyn Syst Meas Control 115(2A) 303-306 (Jun 1993).

A method is presented to minimize residual vibration of structures or lightly damped servomechanisms. The method, referred to as the proportional plus multiple delay (PPMD) control, involves the use of multiple time delays in conjunction with a proportional part to cancel the dynamics of the system in a robust fashion. An interesting characteristic of the controller involves addition of a basic single time-delay control unit in cascade to the existing controller, for every additional requirement of robustness. It is shown that the proposed time-delay controller produces results that are exactly the same as those obtained by the shaped input technique. In addition, it is simpler to arrive at the relative amplitudes of the time-delayed signals for any number of delays even in a multi-input setting.

10A291. Strong diagonal dominance by quantitative feedback theory. - RA Perez *(Dept of Mech Eng, Univ of Wisconsin, Milwaukee WI 53201)*, ODI Nwokah, DF Thompson *(Sch of Mech Eng, Purdue)*. J Dyn Syst Meas Control 115(2A) 246-252 (Jun 1993).

This paper uses strong diagonal dominance theory to obtain a systematic solution of the MIMO-QFT problem by an n times solution of the SISO-QFT sensitivity constraint problem. This is analogous to the current MIMO-QFT formulation that requires an n times solution for the elements of the closed-loop transfer matrix. Of equal but independent interest is the establishment of the first early verifiable existence and uniqueness conditions for robust diagonal stabilizability.

10A292. Synthesis and evaluation of an H_2 control law for a hovering helicopter. - MC Takahashi *(Aeroflightdyn Directorate, US Army Aviation Syst Command, MS-211-2, NASA Ames Res Center, Moffett Field CA 94035)*. J Guidance Control Dyn 16(3) 579-584 (May-Jun 1993).

The design and simulator evaluation of a rate-command flight-control law for a UH-60 helicopter in near-hover flight conditions are described. The multivariable control law was synthesized using an H_2 method, which, through weighting functions, directly shapes the singular values of the sensitivity $(I + GK)^{-1}$, complementary sensitivity $GK(I + GK)^{-1}$, and control input $K(I + GK)^{-1}$ transfer-function matrices. The design was implemented on the vertical motion simulator, and four low-speed hover tasks were used to evaluate the control system characteristics. The pilot comments indicated good decoupling and quick response characteristics, but also revealed a mild pilot-induced oscillation tendency in the roll axis.

10T293. Extremal vehicle reorientation maneuvers: Symmetries and group properties. - S Bocvarov, FH Lutze, EM Cliff *(Aerospace and Ocean Eng Dept, VPI)*. J Guidance Control Dyn 16(4) 648-653 (Jul-Aug 1993).

10A294. Generalized guidance law for collision courses. - Y Baba, M Yamaguchi *(Dept of Aerospace Eng, Natl Defense Acad, Yokosuka 239, Japan)*, RM Howe *(Dept of Aerospace Eng, Univ of Michigan, Ann Arbor MI 48109)*. J Guidance Control Dyn 16(3) 511-516 (May-Jun 1993).

A new generalized guidance law for collision courses is presented. When the missile and target axial accelerations or decelerations are constant, there exists a rectilinear collision course. The guidance law presented, which is called the true guidance law, gives theoretical lateral acceleration commands to guide the missile on a collision course. However, since it is very difficult to realize the true guidance law on most existing tactical missiles, this paper shows a method for simply implementing the guidance law, which is called the simplified guidance law. The small perturbation equation of the true guidance law shows that the definition of an effective navigation constant is the same expression as that in the case of conventional proportional navigation. The performance of the two guidance laws presented is compared with that of proportional navigation using simulation studies of a simple model of a short range air-to-air missile. The simulation results show that the guidance laws presented can intercept the target using far smaller lateral acceleration commands than prepared for proportional navigation. The inner launch envelope shows that the guidance laws presented provide an overall performance improvement over proportional navigation.

10A295. Guidance for an aerocapture maneuver. - JG Gurley *(Syst Lab Directorate, Space and Commun Group, Hughes Aircraft, 10901 Savona Rd, Los Angeles CA 90077)*. J Guidance Control Dyn 16(3) 505-510 (May-Jun 1993).

Aerocapture, which has been described as "essential for cost-effective space transportation," imposes severe guidance and control problems. A closed-loop control law is formulated that provides stable control in the presence of reasonable errors in approach guidance and in knowledge of the atmospheric density profile. Navigational accuracy requirements can be satisfied by a combination of approach tracking and onboard inertial measurements, supplemented, in the case of a Mars encounter, by a radar altimeter or its functional equivalent.

10A296. Quaternion-based rate-amplitude tracking system with application to gimbal attitude control. - H Weiss *(Rafael, PO Box 2250, Haifa 31021, Israel)*. J Guidance Control Dyn 16(4) 609-616 (Jul-Aug 1993).

The paper deals with rate and attitude control of a rigid body. The discussed control system contains an inner velocity loop that tracks the desired rate and an outer attitude loop that tracks the desired attitude command. The control algorithm uses quaternions as a measure of attitude errors to achieve tracking via instantaneous eigenaxis rotation. The paper discusses the stability of the new algorithm and presents its application to multiaxis gimbal attitude control.

10A297. The active control of panel vibrations with piezoelectric actuators. - J D'Cruz *(Aeronaut Res Lab, Defence Sci and Tech Org, 506 Lorimer St, Fishermen's Bend, Vic 3207, Australia).* J Intelligent Mat Syst Struct **4**(3) 398-402 (Jul 1993).

The active control of vibration using point actuators has received much attention. Presented here is a means by which panel vibrations may be controlled through the action of a distributed actuator. The actuator consists of a single-sheet piezoceramic adhesively bonded to the surface of the panel. Control is achieved by a digital control law that artificially increases the damping of the modes which dominate the panel response, the sensing being provided by a single accelerometer mounted on the panel surface. Presented are the results that demonstrate the effectiveness of the control law-piezoceramic actuator combination. In order to show that a reduction in vibration levels is also achieved at points other than at the sensing accelerometer, acceleration levels are monitored at other points on the plate. The results show that the panel vibrations may indeed be successfully controlled through the action of the distributed piezoceramic actuator.

10A298. Alternative approximations for integrated control-structure aeroservoelastic synthesis. - E Livne *(Dept of Aeronaut and Astronaut, Univ of Washington, Seattle WA 98195).* AIAA J **31**(6) 1100-1108 (Jun 1993).

A discussion of alternative complex pole and gust response approximations is presented, motivated by the need to extend nonlinear programming-approximation concepts optimization methodology from structural synthesis for the integrated control-structure synthesis of aeroservoelastic systems. Two new approximations are presented for the high-order, weakly damped linear time-invariant systems representing actively controlled airplanes in high-speed flight. They are compared with Taylor series, differential equations, and Rayleigh quotient approximations. The accuracy and computational efficiency of the alternative approximations are discussed. Although the development has been motivated by aeroservoelasticity and the examples used are from that domain, the new approximations are general and applicable to a wide range of control problems.

10A299. Applications of optimal control to advanced automotive suspension design. - D Hrovat *(Res Staff, Ford Motor, Dearborn MI 48121).* J Dyn Syst Meas Control **115**(2B) 328-342 (Jun 1993).

The paper surveys applications of optimal control techniques to the design of active suspensions, starting from simple quarter-car, 1D models, which are followed by their half-car, 2D, and full-car, 3D, counterparts. The emphasis is on linear-quadratic optimal control and automotive vehicles.

10A300. Design approaches for shaping polyvinylidene fluoride sensors in active structural acoustic control. - RL Clark *(Dept of Mech Eng and Mat Sci, Duke Univ, Durham NC 27708-0300),* RA Burdisso, CR Fuller *(Dept of Mech Eng, VPI).* J Intelligent Mat Syst Struct **4**(3) 354-365 (Jul 1993).

A design methodology is presented for shaping structural polyvinylidene fluoride sensors for active structural acoustic control applications. A structural PVDF sensor yielding a controlled response equivalent to that obtained when implementing a microphone error sensor perpendicular to the surface of a simply supported beam was designed and tested. In addition, the equivalent PVDF sensor design approach for the simply supported plate is presented; however, practical limitations in achieving the desired 3D polarization profile prevent physical impelmentation. Results from tests conducted on the simply supported beam demonstrate that PVDF structural sensors can be designed to achieve directional acoustic control of structure-borne sound. While this design approach is currently limited to structures whose response can be described as a function of 1D, the potential for applications in more complex structures is readily achieved upon determining a practical method of varying the polarization profile of the material as a function of 2D.

10A301. Development of control laws for an orbiting tethered antenna-reflector system test scale model. - Zhong Li and PM Bainum *(Dept of Mech Eng, Howard Univ, Washington DC 20059).* J Intelligent Mat Syst Struct **4**(3) 343-353 (Jul 1993).

Tethered systems can be used to change the geometry and inertial characteristics of space structural systems to meet the gravity gradient stability requirements. The control law design for an orbiting shallow spherical shell (antenna and reflector) system connected by a massive and flexible tether to a subsatellite is investigated in this article. The subsatellite is nominally deployed below the antenna along the yaw axis at a sufficient distance to provide a favorable composite moment of inertia ratio for gravitational stabilization. It is assumed that the tether would be deployed through the end of a rigid boom attached to the shell apex. The tension control strategy is used for stationkeeping and deployment and the control gains are obtained based on the structural data for a future proposed real space antenna and reflector. In order to prove the feasibility of this concept, a test scale model for an in-orbit experiment is also studied. The scale model should be small enough so that it could be accommodated within the volume and size limitations of the space shuttle cargo bay. Since the orbital angular velocity (determined by the orbital altitude of the space shuttle), tether diameter, etc, may not be directly scaled, the control gains will be adjusted to fit the requirements for the scale model.

10A302. ER fluid applications to vibration control devices and an adaptive neural-net controller. - Shin Morishita *(Dept of Naval Architec and Ocean Eng, Yokohama Natl Univ, 156 Tokiwadai Hodogaya-ku, Yokohama 240, Japan)* and Tamaki Ura *(Inst of Indust Sci, Univ of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106, Japan).* J Intelligent Mat Syst Struct **4**(3) 366-372 (Jul 1993).

This article describes several applications of electro-rheological (ER) fluid to vibration control actuators and an adaptive neural-net control system suitable for the controller of ER actuators. ER fluid a kind of colloidal suspension, and has a notable characteristic feature in that its apparent viscosity can be controlled in response to applied electric field strength. Viscosity can be varied in a wide range and the response time is very short, as short as several milliseconds. According to previous studies, one promising application is a controllable damper. In the present article, four applications are proposed: a shock absorber system for automobiles, a squeeze film damper bearing for rotational machines, a dynamic damper for multi-dof structures and a vibration isolator. Furthermore, an adaptive neural-net control system, composed of a forward model network for structural identification and a controller network, was introduced for the control system of these ER actuators.

10A303. Influence of a locally applied electro-rheological fluid layer on vibration of a simple cantilever beam. - Gong Haiqing, Lim Mong King, Tan Bee Cher *(Sch of Mech and Prod Eng, Nanyang Tech Univ, Nanyang Ave, Singapore 2263).* J Intelligent Mat Syst Struct **4**(3) 379-384 (Jul 1993).

This experimental work is concerned with the vibration characteristics of a cantilever beam locally linked by an electro-rheological fluid layer to ground. Such a novel vibration control strategy can drastically change the vibration characteristics of the beam system, owing to the mechanism that the locally applied ER fluid layer serves as a complex spring and thus change the stiffness matrix, or the structural configuration, of the original beam system under the electric field. It is found that the vibration characteristics of the cantilever beam with the locally applied ER fluid layer treatment is more sensitive to the electric field than a sandwich beam. The influence of the nonlinear deformation of the ER fluid due to the presence of the yield stress on the vibration of the cantilever beam is also investigated.

10A304. Integrated design and control of laminated hybrid plates with dynamic response and buckling objectives. - IS Sadek *(Dept of Math Sci, Univ of N Carolina, Wilmington NC 28403),* JM Sloss, S Adali *(Dept of Math, UC, Santa Barbara CA 93106),* JC Bruch Jr *(Dept of Mech and Env Eng, UC, Santa Barbara CA 93106).* J Sound Vib **163**(1) 57-66 (8 May 1993).

An integrated approach is given to determine to optimal level of hybridization and feedback control force for symmetric, cross-ply laminates. The optimization objectives are the maximization of the biaxial buckling load and the minimization of the vibrational energy subject to constraints on the thickness and control energy. The plate is constructed as a sandwich hybrid laminate with outer and inner layers being constructed from high stiffness and low stiffness materials, respectively. Comparative numerical results are given for hybrid and nonhybrid laminates, and the similarities and differences between them are discussed. It is observed that a low stiffness and inexpensive material such as glass fiber reinforced plastics can be used in inner layers with minimal effect on the performance of the plate and substantial material cost savings.

10A305. Integrated structure-control-aerodynamic synthesis of actively controlled composite wings. - E Livne *(Dept Aeronaut and Astronaut, Univ of Washington, Seattle WA 98195),* LA Schmit, PP Friedmann *(Mech Aerospace and Nucl Eng, UCLA).* J Aircraft **30**(3) 387-394 (May-Jun 1993).

A new multi-disciplinary optimization capability for integrated synthesis of actively controlled composite wings is reviewed. it is shown that the nonlinear programming approximation concepts approach to design optimization, combined with appropriate simplified analysis techniques for the different disciplines, make multidisciplinary wing synthesis both feasible and practical for the conceptual and preliminary design stages. The composite wing of a remotely piloted vehicle is used for numerical experimentation. Synthesis studies with design variables and constraints that span the disciplines of structures, control, and aerodynamics are presented. These studies provide new insight into the complex nature of multidisciplinary interactions in wing designs.

10A306. Optimal open-closed loop control of mechanical systems with structural damping. - RS Esfandiari *(Mech Eng Dept, California State Univ, Long Beach CA 90840),* IS Sadek *(Dept of Math Sci, Univ of N Carolina, Wilmington NC 28403),* JM Sloss *(Dept of Math, UC, Santa Barbara CA 93106).* J Sound Vib **163**(1) 47-56 (8 May 1993).

A technique is proposed to actively damp out the undesired vibrations via open and closed loop control A performance measure, involving energy at terminal time, as well as open and closed loop control efforts, is introduced. The closed loop control law is assumed to be of proportional type and the optimal open loop control relative to the performance measure is obtained by using the techniques of calculus of variations. Subsequently, the corresponding optimal closed loop control is found numerically. The proposed method is applied to a beam exhibiting structural damping, and the numerical results are presented in graphical form. The effectiveness of a feedback control in the presence of an open loop control is also discussed.

10A307. Quantitative feedback theory applied to the design of a rotorcraft flight control system. - RA Hess and PJ Gorder *(Dept of Mech, Aeronaut, and Mat Eng, UC, Davis CA 95616)*. J Guidance Control Dyn 16(4) 748-753 (Jul-Aug 1993).

Quantitative feedback theory describes a frequency-domain technique for the design of multiple-input multiple-output control systems that meet time- or frequency-domain performance criteria when specified uncertainty exists in the linear description of the vehicle dynamics. Quantitative feedback theory is applied to the design of the longitudinal flight control system for a linear model of the AH-64 rotorcraft incorporating uncertainty. In this model, the uncertainty is assigned and is assumed to be attributable to actual uncertainty in the dynamic model and to the changes in the vehicle aerodynamic characteristics that occur near hover. The model includes an approximation to the rotor and actuator dynamics. The design example indicates the manner in which handling qualities criteria may be incorporated into the design of realistic rotorcraft control systems in which significant uncertainty exists in the vehicle model.

10A308. Reaction wheel low-speed compensation using a dither signal. - JB Stetson Jr *(General Electric Astro Space Div, Princeton NJ 08543)*. J Guidance Control Dyn 16(4) 617-622 (Jul-Aug 1993).

A method for improving low-speed reaction wheel performance on a three-axis controlled spacecraft is presented. The method combines a constant amplitude offset with an unbiased, oscillating dither to harmonically linearize rolling solid friction dynamics. The complete, nonlinear rolling solid friction dynamics using an analytic modification to the experimentally verified Dahl solid friction model were analyzed using the dual-input describing function method to assess the benefits of dither compensation. The modified analytic solid friction model was experimentally verified with a small dc servomotor actuated reaction wheel assembly. Using dither compensation abrupt static friction disturbances are eliminated and near linear behavior through zero rate can be achieved. Simulated vehicle response to a wheel rate reversal shows that when the dither and offset compensation is used, elastic modes are not significantly excited, and the uncompensated attitude error reduces by 34:1.

10A309. Vibration control of a laminated plate with piezoelectric sensor-actuator: FE formulation and modal analysis. - Woo-Seok Hwang, Hyun Chul Park, Woonbong Hwang *(Dept of Mech Eng, Pohang Inst of Sci and Tech, PO Box 125, Pohang 790-600, Korea)*. J Intelligent Mat Syst Struct 4(3) 317-329 (Jul 1993).

The combined effects of passive and active control on the vibration control of a composite laminated plate with piezoelectric sensors and actuators are investigated. FE formulation modal and analysis are presented. Classical laminated plate theory with the induced strain actuation and Hamilton's principle are used to formulate the equation of motion of the system. The total charge developed on the sensor layer is calculated from the direct piezoelectric equation. The equations of motion and the total charge are discretized with 4-node, 12-dof quadrilateral plate bending elements. The stiffness and damping property changes of composite structures by varying the layer angles are used as a passive control method. Piezoelectric sensors and actuators with negative velocity feedback control are used as an active control method. By numerical simulation, the effects of stiffness and damping property changes of composite structures and the effects of sensor and actuator division on the response of the structure and the performance of the vibration control are investigated. Since active control and passive control affect each other, the active control and the passive control should be considered simultaneously in designing the efficient adaptive structures.

10A310. Vibration suppression for large scale adaptive truss structures using direct output feedback control. - Lyan-Ywan Lu *(Natl Center for Res on Earthquake Eng, Natl Taiwan Univ, Taipei, Taiwan, ROC)*, Senol Utku *(Dept of Civil and Env Eng, Duke Univ, Durham NC 27706)*, BK Wada *(Appl Tech Section, JPL)*. J Intelligent Mat Syst Struct 4(3) 385-397 (Jul 1993).

In this article, the vibration control of adaptive truss structures, where the control actuation is provided by length adjustable active members, is formulated as a direct output feedback control problem. A control method named Model Truncated Output Feedback (MTOF) is presented. The method allows the control feedback gain to be determined in a decoupled and truncated modal space in which only the critical vibration modes are retained. The on-board computation required by MTOF is minimal; thus, the method is favorable for the applications of vibration control of large scale structures. The truncation of the modal space inevitably introduces spillover effect during the control process. In this article, the effect is quantified in terms of active member locations, and it is shown that the optimal placement of active members, which minimizes the spillover effect (and thus, maximizes the control performance), can be sought. The problem of optimally selecting the locations of active members is also treated.

204D. PROCESS CONTROL

10A311. Control of machining processes. - AG Ulsoy and Y Koren *(Dept of Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109-2125)*. J Dyn Syst Meas Control 115(2B) 301-308 (Jun 1993).

This paper reviews the important recent research contributions for control of machining processes (eg, turning, milling, drilling, and grinding). The major research accomplishments are reviewed from the perspective of a hierarchical control system structure which considers servo, process, and supervisory control levels. The use and benefits of advanced control methods (eg, optimal control, adaptive control) are highlighted and illustrated with examples from research work conducted by the authors. Also included are observations on how significant the research to date has been in terms of industrial impact, and speculations on how this research area will develop in the coming decade.

10A312. Lateral and longitudinal dynamic behavior and control of moving webs. - GE Young and KN Reid *(Sch of Mech and Aerospace Eng, Oklahoma State Univ, Stillwater OK 74078)*. J Dyn Syst Meas Control 115(2B) 309-317 (Jun 1993).

A web refers to any material in continuous flexible strip form which is either endless or very long compared to its width, and very wide compared to its thickness. This paper discusses the dynamic analysis and control of the lateral and longitudinal motions of a moving web which correspond to fluctuations perpendicular and parallel, respectively, to the primary direction of web transport. Historical perspectives are provided, from the early work of Osborne Reynolds in the late 1800s to current research. An overview of the control of both lateral and longitudinal web motion, which includes the control of tension, is presented. Present limitations in understanding and controlling lateral and longitudinal web behavior are discussed. The Journal of Dynamic Systems, Measurement, and Control has played a pivotal role in the advancement of research in this area.

204E. POWER SYSTEMS

10A313. Engine control using cylinder pressure: Past, present, and future. - DJ Powell *(Mech Eng, Stanford)*. J Dyn Syst Meas Control 115(2B) 343-350 (Jun 1993).

Research into the use of cylinder pressure measurements from reciprocating internal combustion engines for real time automotive engine control has been investigated for the last 20 years. The measurement has been investigated for spark timing, fuel-air ratio control, charge temperature measurements, and misfire detection. The cost of the sensors has inhibited widespread use in production vehicles; however, it was introduced in domestic Japanese production for spark control five years ago. Its use for misfire detection is also being actively considered.

204F. FLUIDIC SYSTEMS, PNEUMATICS

10A314. Evaluation of an electrohydraulic forge valve behavior using a CAD package. - J Watton *(Sch of Eng, Univ of Wales, Col of Cardiff, PO Box 917, Cardiff CF2 1XH, UK)* and J Nelson *(Simtek Res, Banbury, Oxford, UK)*. Appl Math Model 17(7) 355-368 (Jul 1993).

An electrohydaulic system of the type used to control the position of a forging press cylinder is studied analytically and experimentally. The main control component is a flow bypass valve that controls flow rate into and out of the main hydraulic line and is of the poppet-following type. The steady-state pressure-flow characteristics of the bypass valve with an existing seated poppet is compared with a new vee notch poppet design intended to improve the steady-state characteristic and hence the closed-loop press cylinder position response characteristic. Dynamic modeling of the flow bypass valve is then considered and the transient performance is assessed for the two poppet designs and with the valve in an idealized circuit. The complete system dynamic model is then established and a recently developed CAD package is used to simulate the position response of the press cylinder. Both poppet designs are studied, and it is deduced that there is a negligible difference in transient performance, attributable to unique features of the control system. Good comparisons between simulation and experimental results were achieved.

10A315. Advanced NC verification via massively parallel raycasting. - JP Menon *(TS Watson Res Center, IBM Res Div, Yorktown Heights NY 10598)* and DM Robinson *(Sibley Sch of Mech and Aerospace Eng, Cornell)*. Manuf Rev 6(2) 141-154 (Jun 1993).

Numerical control (NC) verifiers are computer programs that seek to determine automatically whether an NC machining program, when executed in a given machining environment, will produce a specified part from specified stock without undesirable side effects. NC verifiers that detect spatial errors, such as cutter collisions, have been under development for more than a decade, but they suffer from restricted geometric coverage, poor performance, and incomplete error-condition tests. This article describes a new method of NC verification using ray representations (ray-reps) in combination with the RayCasting Engine (RCE), a new, highly parallel computer for processing ray-reps. The ray-rep-RCE combination removes many of the current limitations in spatial verification, and extends the range of verifiable phenomena to include part tolerance assessment, machining dynamics, and spatial sensing (touch-sense probing). The publicly available P2NC verifier, which uses the PADL-2 solid modeling system as a geometry engine, has been modified to use the RCE as a geometric evaluator and accelerator.

10A316. Interaction between the actuators in loaded multi-channel electrohydraulic drives. - S Ramachandran *(Aircraft Controls Div, Moog, E Aurora NY 14052)* and P Dransfield *(Dept of Mech Eng, Monash Univ, Clayton, Vic 3168, Australia)*. J Dyn Syst Meas Control 115(2A) 291-302 (Jun 1993).

This paper describes some of the interaction effects arising between two electrohydraulic servoactuator systems operating to sustain predetermined and separate force programs on a cantilever beam load system. The work is intended to be relevant to the simultaneous multi-channel drive situations of structure fatigue testing rigs, flight simulators, industrial robots and some machine tools. Simulation and experimental responses of a single-actuator system for a few locations of the drive on the beam and of the two-actuator system for a number of location combustions are presented, compared and discussed. Combinations of step inputs of desired force were used to excite the system. Simulation and experimental responses show reasonable agreement. Interaction and its effects are quantified in terms of dynamic characteristics of the force responses of the actuators measured from the simulation and experimental results. The model for simulation was obtained via power bond graph modeling technique. The results show that the interaction modifies the responses of the actuators, and that the level of interaction, its magnitude and nature are functions of the relative positions of the actuators. Interactions and its effects are also examined using simulation for a three-actuator force control system. The results confirm the earlier observation.

10A317. Modeling and state estimator design issues for model-based monitoring systems. - JL Stein *(Dept of Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109-2125)*. J Dyn Syst Meas Control 115(2B) 318-327 (Jun 1993).

The Journal of Dynamic Systems, Measurement, and Control has a rich history in the areas of system modeling, control theory, and system design. In this paper, I demonstrate the primary importance of modeling to the design and performance of model-based (dynamic, observer-based) monitoring systems. The focus is on monitoring rather than diagnostics, but the results show, nevertheless, that good monitoring systems impact the design and performance of diagnostic systems. Modeling procedures, some based on results from the automated modeling literature, are developed to produce not only simple, accurate models to improve estimation accuracy, but also to utilize existing sensors to measure accessible signals, generate models for which estimation techniques exist, and finally to produce models that reduce the complexity of the diagnostic task, thus reducing the heavy reliance on empirical rule-based decision systems. In addition, for model-based monitors based on deterministic state estimators, a design procedure is described to control the shape of the transient error and the steady-state bias error of the estimates. This procedure utilizes a performance index, which accounts for many of the realistic problems encountered in implementing these systems, such as model uncertainty, round-off errors, and unknown initial conditions. Machine tool drive systems are used to motivate and illustrate the monitoring ideas and techniques. Model-based monitoring appears, despite its current limited use in machine monitoring, to hold great potential as the basis for high-performance, low-cost machine monitoring systems.

10A318. Robust control for servo-mechanisms under inexact friction compensation. - C Canudas de Wit *(Lab D'Automatique de Grenoble, BP 46, 38402 St-Martin d'Heres, France)*. Automatica 29(3) 757-761 (May 1993).

Uncertainties in the parameters but also in the structure of the friction model may lead to inexact friction compensation in servo-mechanisms. This will lead to differences between the predicted friction and the real friction forces, provoking, in certain cases (overcompensation) an oscillatory behavior. This paper proposes a new control scheme seeking to strengthen the closed-loop system properties in the eventuality of friction overcompensation. This control design has the advantage that, in the case of friction overcompensation, the oscillations can be reduced in amplitude and modified in frequency independently of the closed-loop system specifications.

10A319. Computer as liberator: The rise of mechanical system control. - DM Auslander *(Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2B) 234-238 (Jun 1993).

In this essay, on the observance of the 50th anniversary of the founding of ASME's Dynamic Systems and Control Division, I try to connect the technology of control to the way in which control practitioners think. Despite some tension between the conclusions implied in the introductory paragraphs and conclusions drawn later in the essay, I have left them to stand in their original form to emphasize tensions in control thinking, for which the source might not be apparent. The opinions expressed here are strictly my own, but I must acknowledge the creative proddings of my colleagues in getting these thoughts recorded at all.

204K. SOFTWARE, EXPERT SYSTEMS, ARTIFICIAL INTELLIGENCE

10A320. Angular position control of objects using a transputer-based vision system and fuzzy logic techniques. - H Ekerol and DC Hodgson *(Sch of Manuf and Mech Eng, Univ of Birmingham)*. J Syst Control Eng 207(I1) 47-55 (1993).

A demonstrator system for closed-loop control of rectangular objects by non-contacting means is developed. The system consists of a transputer-based vision system and two power air jets actuated by piezoelectric translators. The first air jet is employed to give the initial angular displacement and the second for correcting any positional errors during the passage of the object in front of it. The overall control algorithm employs fuzzy logic techniques. The potential use of the system in industry for collating soft or brittle products moving on conveyer belts, before being fed into cartoning machinery, is also discussed.

10A321. Intelligent control systems: Are they for real?. - R Shoureshi *(Sch of Mech Eng, Purdue)*. J Dyn Syst Meas Control 115(2B) 392-401 (Jun 1993).

The fundamental concept of feedback to control dynamic systems has played a major role in many areas of engineering. Increases in complexity and more stringent requirements have introduced new challenges for control systems. This paper presents an introduction to and appreciation for intelligent control systems, their application areas, and justifies their need. Specific problem related to automated human comfort control is discussed. Some analytical derivations related to neural networks and fuzzy optimal control as elements of proposed intelligent control systems, along with experimental results, are presented. A brief glossary of common terminology used in this area is included.

10A322. Neurocontrol design and analysis for a multivariable aircraft control problem. - T Troudet *(Struct and Mat Dept, Sverdrup Tech, Brook Park OH 44142)*, S Garg, W Merrill *(Adv Controls Tech Branch, NASA Lewis Res Center, Cleveland OH 44135)*. J Guidance Control Dyn 16(4) 738-747 (Jul-Aug 1993).

The feasibility of using artificial neural networks as control systems for modern, complex aerospace vehicles is investigated via an aircraft control design study. The problem considered is that of designing a controller for an integrated airframe and propulsion longitudinal dynamics model of a modern fighter aircraft to provide independent control of pitch rate and airspeed responses to pilot command inputs. An explicit model-following controller using H_∞ control design techniques is first designed to gain insight into the control problem as well as to provide a baseline for evaluation of the neurocontroller. Using the model of the desired dynamics as a command generator, a multilayer feedforward neural network is trained to control the vehicle model within the physical limitations of the actuator dynamics. This is achieved by minimizing an objective function that is a weighted sum of tracking errors and control input commands and rates. To gain insight into the neurocontrol design, linearized representations of the neurocontroller are analyzed along a commanded trajectory. Linear robustness analysis tools are then applied to the linearized neurocontroller models and to the baseline H_∞ based controller. Robustness issues of the neurocontrol design are identified and addressed in the context of neural training. Future areas of research are identified to enhance the practical applicability of neural networks to flight control design.

10A323. Predictive sliding control with fuzzy logic for fuel-injected automotive engines. - S-K Nam *(Agency for Defence Dev of Korea, Taejon, Korea)*, M-H Lee, W-S Yoo *(Dept of Mech Eng, Pusan Natl Univ, Pusan, Korea)*. J Syst Control Eng 206(14) 237-244 (1992).

An alternative algorithm is proposed for a variable-structure control to design a closed-loop fuel-injection system. Sliding control using fuzzy logic is combined with current oxygen sensors to maintain the stoichiometric air-fuel ratio. Predictive control is also introduced to compensate for the time delay in the combustion process. This synthesis provides a practical and flexible design for an engine controller because its hybrid structure meets given robustness and performance requirements. The potential of the proposed algorithm is shown through real-time simulations utilizing both a typical engine-only model on an AD-100 computer and an implemented controller on an Intel 80C186 with an 80C187 processor.

10A324. Real-time expert system for fault-tolerant supervisory control. - K Ramamurthi *(Process Des and Control, Semiconductor Process and Des Center, Texas Instruments, Dallas TX 75265)* and AM Agogino *(Dept of Mech Eng, UCB)*. J Dyn Syst Meas Control 115(2A) 219-227 (Jun 1993).

Many mechanical systems are sufficiently complex that it is impractical to describe their dynamics by exact mathematical models. In the presence of such modeling uncertainties, advanced controllers like adaptive controllers perform better than linear feedback controllers since they actively reduce the uncertainty by online parameter estimation. Unfortunately, the advanced control strategies, due to their lack of robustness, can become unstable in the presence of unpredictable external disturbances, and hence, there exists a need for a fault-tolerant approach to preserve the overall system integrity even at the cost of design performance. This motivated the research, presented in this paper, to investigate the suitability of the IDES (Influence Diagram Based Expert System) as an expert supervisory controller to predict incipient instability, a significant failure mode, and take corrective action in real-time when closed loop stability appears to be in danger. The expert supervisory control scheme is demonstrated on a model-referenced adaptive controller as applied to robotic manipulator. The real-time expert system, with the information from sensors dynamically optimizes the cost of control and as a result chooses between a robust auxiliary controller and the nonrobust adaptive controller depending on inferences made from the observable variables. IDES, as a real-time expert supervisory controller, preserves the stability of the system even under potentially destabilizing unexpected disturbances, exhibiting on demand a fault-tolerant behavior by trading design performance for overall system integrity. The results indicate the potential for influence diagram expert systems in monitoring and controlling mechanical systems where exact mathematical modes are difficult or not practical to obtain.

10A325. Review of expert systems for process planning of cold forging. - Guobin Yang *(Nichidai Corp, Takigi, Tanabe-cho, Tuzuki-gun, Kyoto 610-03, Japan)* and Kozo Osakada *(Fac of Eng Sci, Osaka Univ, 1-1 Machikaneyama-cho, Toyonaka, Osaka 560, Japan)*. Manuf Rev 6(2) 101-113 (Jun 1993).

The authors present the state of the art in expert systems for cold forging process planning and discuss goals for future systems. First, they conduct an extensive historical review of research activities in computer-aided process planning of forging. They then present the current status of expert systems for cold forging process planning, using the system developed at Osaka University as an example. Finally, they discuss areas for continued and more in-depth research in this area.

10A326. Electromechanical properties of smart materials. - RE Newnham and GR Ruschau *(Mat Res Lab, Penn State)*. J Intelligent Mat Syst Struct 4(3) 289-294 (Jul 1993).

A smart material is one that can perform both sensor and actuator functions. This definition allows for some flexibility in deciding how to qualify a material as "smart", since the fundamental mechanisms of operation may differ greatly between types of smart materials. From the point of view of an electroceramist, piezoelectric materials, which show reversible electromechanical coupling, may be thought of as "naturally" smart materials since the same piezoelectric material may act as a sensor and/or an actuator. Piezoelectric single crystals, polymers, and poled poly-crystalline ceramics all show good electromechanical coupling. In addition, they may be combined in a composite material that exaggerates their beneficial properties by eliminating their detrimental properties. Some common piezoelectric materials are reviewed, along with some examples of smart materials that incorporate piezoelectric ceramics.

10A327. Safety critical systems: so what ...?. - PA Bennett *(Centre for Software Eng, Flixborough, Scunthorpe)*. J Syst Control Eng 206(14) 197-205 (1992).

Safety critical systems contain advanced computer, microprocessor and software technologies to a degree of sophistication that is frequently beyond the understanding of many practicing engineers. Many of these systems control the safe operation of everyday things such as anti-lock braking on cars, personnel lifts and trains, as well as industrial process and fly-by-wire aircraft. This paper describes the nature, processes, standards and assessment methods currently being employed with safety critical systems, and addresses various questions that the practicing engineer may ask. It demonstrates that although the technology and methods may be novel, concerns surrounding the evaluation of safety critical systems are yet another instance of the age-old dilemma involved in exercising engineering judgement.

10A328. Self-service banking and mechatronics: The first twenty years. - J Dinsdale *(Dept of Appl Phys and Electron and Manuf Eng, Univ of Dundee)* and AJ Hutcheon *(NCR Manuf, Dundee)*. J Syst Control Eng 207(11) 1-8 (1993).

The past two decades have seen a remarkable increase in the automation of banking operations and financial transactions. A comparative examination of modern automated teller machines (ATMs) and electronic banking systems alongside the mechanical machines in use less than half a century ago illustrates how this rapid introduction of advanced technology has been made possible through the interaction of mechanical engineering (especially mechanisms), electronic actuators and sensors, and computer software, an activity which has become known as "mechatronics". The paper describes the evolution of the modern ATM, highlighting the interdisciplinary engineering skills that are necessary to achieve the performance goals of speed, reliability, security and user-friendliness.

10A329. Macroscopic phenomenological formulation for coupled electromechanical effects in piezoelectricity. - XD Zhang and CA Rogers *(Center for Intelligent Mat Syst and Struct, VPI)*. J Intelligent Mat Syst Struct 4(3) 307-316 (Jul 1993).

A phenomenological formulation of polarization reversal of piezoelectric materials is proposed based on the dynamics of domain switching. This formulation provides a method to describe the hysteresis in piezoelectricity as well as in electromagnetics. It is shown that a good approach to describe the nonlinear induced strain-field behavior and electromechanical hysteresis in piezoelectricity is by combining the macroscopic phenomenological aspects with the microscopic material properties. A 1D thermo-electro-mechanical constitutive model for piezo-ceramics which undergo polarization reversal is presented using a continuum mechanics approach. This model is based on thermodynamic principles and reflects the essence of the electromechanical behavior of piezoceramics in a simple form. It is illustrated that this theory can describe the electromechanical behavior of piezoceramics simply and reasonably well.

204R. FAULT DIAGNOSIS, FAILURE DETECTION, AND ISOLATION

10A330. Automated fault analysis for hydraulic systems Part 1. Fundamentals. - RM Atkinson, MR Montakhab, KDA Pillay, DJ Woollons *(Sch of Eng, Univ of Exeter)*, PA Hogan, CR Burrows, KA Edge *(Fluid Power Centre, Univ of Bath)*. J Syst Control Eng 206(14) 207-214 (1992).

Early expert systems for fault analysis tended to be based on shallow, heuristic knowledge. For success in engineering applications, it is argued that the complementary knowledge of the underlying principles (deep knowledge) should also be modeled. An object-oriented software library representing models of components of hydraulic circuits is being built using deep knowledge alone. The software modules within this library are reusable for the construction of model-based expert systems for the performance of failure mode and effects analysis and fault tree analysis on any arbitrary hydraulic circuit.

10A331. Automated fault analysis for hydraulic systems Part 2: Applications. - PA Hogan, CR Burrows, KA Edge *(Fluid Power Centre, Univ of Bath)*, RM Atkinson, MR Montakhab, DJ Woollons *(Sch of Eng, Univ of Exeter)*. J Syst Control Eng 206(14) 215-224 (1992).

The paper provides further details of the automated failure modes and effects analysis (FMEA) program outlined in Part 1. Some of the more difficult development problems are discussed, and solutions are presented. The functionality of the program was tested through application to two experimental rigs, namely a closed-loop hydrostatic transmission with a dynamometer and a regenerative pump test rig. Non-destructive faults, such as abnormally low relief valve settings and excessive loads, were manually inserted into these rigs, and the measured effects were compared with the predictions from the program to validate the software. The difference in complexity and configuration evident in the two examples considered serves to highlight the generality of the approach. The ease of reconfigurability of the software reflects the key aim of producing a program cable of analyzing a wide range of hydraulic circuits.

10A332. Prediction of the service life of pneumatic rubber-cord elastic elements subjected to complex loading. - VG Tsyss and VV Ustinov *(Omsk, Russia)*. J Machinery Manuf Reliab 6 97-101 (1992).

The problem of prediction of the service life of pneumatic rubber-cord elastic elements is considered. Methods for solving the problem are developed on the basis of the generalized fatigue curves and reduction of real operational modes to an equivalent one. An example is presented.

10A333. Safety of sophisticated technological systems. - AN Severtsev *(Moscow, Russia)*. J Machinery Manuf Reliab 6 30-36 (1992).

Qualitative problems of safety are considered from the methodological point of view. Safety criteria and indicators aiming the researcher at their formalization, are defined, and attested. The temporal affluence criterion determining safe operation of systems, is considered in detail.

10A334. Sensor failure detection and isolation in flexible structures using system realization redundancy. - DC Zimmerman *(Dept of Aerospace Eng, Mech and Eng Sci, Univ of Florida, Gainsville FL 32611)* and TL Lyde *(Subsyst Eng, Lockheed, Marietta GA)*. J Guidance Control Dyn 16(3) 490-497 (May-Jun 1993).

Sensor failure detection and isolation for flexible structures is approached from a system realization perspective. Instead of using hardware or analytical model redundancy, system realization is utilized to provide an experimental based model redundancy. The failure detection and isolation algorithm utilizes the eigensystem realization algorithm to determine a minimum-order state-space realization of the structure in the presence of noisy measurements. The failure detection and isolation algorithm utilizes statistical comparisons of successive realizations to detect and isolate the failed sensor component. Because of the nature in which the failure detection and isolation is formulated, it is also possible to classify the failure mode of the sensor. Results are presented using both numerically simulated and actual experimental data.

10A335. Design of actuators based on biased magnetostrictive rare earth-iron alloys. - N Lhermet, F Claeyssen *(Cedrat Rech, 10 ch du Pre-Carre, 38240 Meylan, France)*, P Wendling *(Magsoft, 1223 People's Ave, Troy NY 12180)*, G Grosso *(Eramer, ZI du Camp Laurent, 83500 La Seyne sur Mer, France)*. J Intelligent Mat Syst Struct 4(3) 337-342 (Jul 1993).

The objective of this article is to present the results of a comparative study, including modeling and prototypes, on the different means to generate a high bias field in Terfenol-D. The aim of the research was to get bias field higher or equal to 80 kA/m. Among all the possible types of bias, only three types appear able to produce a high enough field. This has led to three different prototypes. To design them, an extensive effort of modeling has been required, FLUX2D and FLUX3D softwares have been used for the bias design; ATILA code has been used for the electromechanical design. A first prototype has a bias done by DC current in the coil surrounding the rods. The second prototype has a 100 kA/m bias done by a permanent magnet configuration of the series type. The third prototype is equipped with a new magnet configuration, providing about 90 kA/m bias. Finally, it appears that all these solutions work as well as expected and have their own advantages.

10A336. Piezoelectric actuator models for active sound and vibration control of cylinders. - HC Lester *(Struct Acoust Branch, NASA Langley Res Center, Hampton VA 23681-0001)* and Sylvie Lefebvre *(MATRA, Guyancourt, BP n°235 F-78052, St-Quentin-en-Yvelines Cedex, France)*. J Intelligent Mat Syst Struct 4(3) 295-306 (Jul 1993).

Analytical models for piezoelectric actuators, adapted from flat plate concepts, are developed for noise and vibration control applications associated with vibrating circular cylinders. The loadings applied to the cylinder by the piezoelectric actuators for the bending and in-plane force models are approximated by line moment and line force distributions, respectively, acting on the perimeter of the actuator patch area. Coupling between the cylinder and interior acoustic cavity is examined by studying the modal spectra, particularly for the low-order cylinder modes that couple efficiently with the cavity at low frequencies. Within the scope of this study, the in-plane force model produced a more favorable distribution of low-order modes, necessary for efficient interior noise control, than did the bending model.

10A337. Miniature mobile robot using piezo vibration for mobility in a thin tube. - Shin-ichi Aoshima, Takeshi Tsujimura, Tetsuro Yabuta *(NTT Transmission Syst Lab, Ibaraki-Ken 319-11, Japan)*. J Dyn Syst Meas Control 115(2A) 270-278 (Jun 1993).

This paper proposes a miniature mobile robot that uses piezo vibration to move within a thin tube. The robot consists of a piezo bimorph with elastic fins attached at an angle. Robot movement is driven by differences in the friction of the fin's against the tube wall between the forward and backward fin movements induced by piezo vibration. After analyzing the dynamics of the piezo elements, we analyzed the robot's mobile mechanism by extending Hamilton's principle using the dynamic results of the piezo vibration analysis. Measurements of both mobile velocity and tractive force of an experimental robot agree closely with theoretical results. This indicates that the proposed dynamic mobile mechanism accurately expresses robot motion within a thin tube.

10A338. Comparative study in linearized robot models. - A Swarup and M Gopal *(Dept of Elec Eng, Indian IT, New Delhi 110 016, India)*. J Intelligent & Robotic Syst 7(3) 287-300 (June 1993).

For representing the input-output behavior of a robot manipulator by a linear time-invariant model, four direct linearization schemes are (i) state linearization, (ii) linearization based on an identification method, (iii) linearization based on neglecting velocity-dependent and gravity terms and (iv) linearization based on neglecting the velocity-dependent term only (rate linearization). In order to make an appropriate choice of linear model for the development of real-time control, these schemes are extensively studied in this paper. It is shown that the rate linearization method leads to a satisfactory tradeoff between computation, accuracy, and stability. In the case of high velocity motions, a combination of state linearization and rate linearization is proposed.

10A339. Determining the effects of Coulomb friction on the dynamics of bearings and transmissions in robot mechanisms. - A Gogoussis and M Donath *(Productivity Center, Dept of Mech Eng, 111 Church St SE, Univ of Minnesota, Minneapolis MN 55455)*. J Mech Des 115(2) 231-240 (Jun 1993).

The general guidelines for analyzing friction at the joints will be discussed. It will be shown that friction can be related to the joint coordinates and their first and second time derivatives. The resulting extended robot dynamics formulation will be investigated as it applies to the inverse and forward robot dynamics problems. The analytical dependency of Coulomb friction on joint interactions is explicitly examined. As an illustration of friction effects in transmissions, we elaborate on the friction in harmonic drives and develop a method for its evaluation. The effect of friction in the bearings on the dynamics is also considered and a quantitative characterization of several specific cases is provided. This study is significant to understanding the design and control issues as they relate to achieving high speed precision robot motion.

10A340. Inverse dynamics of a flexible robot arm by optimal control. - T Kokkinis and M Sahraian *(Dept of Mech and Env Eng, UC, Santa Barbara CA 93106)*. J Mech Des 115(2) 289-293 (Jun 1993).

The problem of end-point positioning of flexible arms is discussed. Because of the nonminimum phase nature of the problem, inversion fails to produce bounded joint torques. Bounded noncausal joint torques for achieving the task of end-point tracking for a multilink arm are found using optimal control theory. The torques obtained have no high-frequency content, and are suitable for practical applications. The method is illustrated by simulation of a single-link arm, for which stability and robustness considerations for design are given.

10A341. Kinematic and dynamic synthesis of geared robotic mechanisms. - Dar-Zen Chen and Lung-Wen Tsai *(Mech Eng Dept and Syst Res Center, Univ of Maryland, College Park MD 20742)*. J Mech Des 115(2) 241-246 (Jun 1993).

This paper describes a methodology for the design of geared robotic mechanisms. It is shown that certain gear-coupled manipulators can be designed to possess kinematic isotropy property at a given end-effector position. For these gear-coupled manipulators, the train values can be treated as a product of two-stage gear reductions. The second-stage reduction can be uniquely determined from the kinematic isotropic condition, while the first-stage reduction can be determined from dynamic consideration. This approach, through proper choice of gear ratios, can provide these gear-coupled manipulators with desired kinematic and dynamic characteristics.

10A342. Kinematic modules for singularity free movement with three Cartesian freedoms. - GL Long, JM McCarthy *(Mech and Aerospace Eng, UC, Irvine CA 92717)*, RP Paul *(Comput and Info Sci, Univ of Pennsylvania, Philadelphia PA 19104)*. J Mech Des 115(2) 207-213 (Jun 1993).

The singularity conditions of three-revolute-joint serial chain manipulators are investigated by considering the motion of an arbitrary point on a terminal link. A distinction is made between singular configurations and singular surfaces. Of particular interest is a class of 3R manipulators - each manipulator within this class forms a third-order screw system. We outline the structural requirements for this 3R class, and then determine the singularity conditions for several cases. For several manipulators within this 3R class, we describe a strategy to develop four-revolute-joint kinematic modules for singularity-free movement with three Cartesian freedoms. The algorithm to control the kinematic modules is simple and can be implemented in real-time.

10A343. Mapping of kinematic and dynamic parameters for coupled manipulators. - Zhiming Ji and Ming C Leu *(Dept of Mech and Indust Eng, NJIT, Newark NJ 07102)*. J Mech Des 115(2) 283-288 (Jun 1993).

The concept of the mapping matrix is used in this paper for establishing relationships of torque, speed, Jacobian, and compliance of these manipulators with those obtained with conventional methods. A method of constructing the mapping matrix systematically is discussed. Two examples show that the proposed method is easy to implement.

10A344. Optimal control of a flexible manipulator. - W Szyszkowski and D Youck *(Dept of Mech Eng, Univ of Saskatchewan, Saskatoon, S7N 0W0, Canada)*. Comput Struct 47(4-5) 801-813 (3 Jun 1993).

Manipulators handling payload masses several times larger than their own weight are considered. The optimal control rule, based on rigid body dynamics, is used to minimize the time of slewing maneuver of a single link. The performance of such control is simulated using ADINA. The influence of various flexibility parameters on the performance of the optimal control is discussed.

10A345. Stability of conventional controller design for flexible manipulators. - L Tang *(Mech Dyn, Ann Arbor MI 48187)* and SB Skaar *(Dept of Aerospace and Mech Eng, Univ of Notre Dame, Notre Dame IN 46556)*. J Appl Mech 60(2) 491-497 (Jun 1993).

The paper investigates the independent joint control of flexible manipulators which are acted upon by gravity. Both finite-dimensional coordinates, and infinite-dimensional, spatially varying, distributed coordinates are used to describe the deformation of of the flexible links. The effects of the flexibility on the closed-loop system behavior in the presence of both derivative and integral feedback control are studied both in the Laplace transform domain using the linearized model of the original nonlinear system and in the time domain using the original nonlinear model. The use of infinite-dimensional coordinates is shown to be especially effective in obtaining the frequency domain characteristics of the linearized model because the exact frequency content of the linearized system may be extracted without involving the difficult order reduction problem. The problem of convergence onto an incorrect solution which is associated with using the eigenvectors of a clamped-free beam as the comparison functions in approximating the motion of the flexible arm is demonstrated and various factors affecting the performance of the flexible manipulator, such as control gains and material damping, are studied.

10A346. State estimation in robotic manipulators: Some experimental results. - S Nicosia *(Dept Ing Electtron II, Univ Roma Tor Vergata, via O Raimondo 00173, Rome, Italy)*, A Tornambe *(Fondazione Ugo Bordoni, via Baldassarre Castiglione 59, 00142 Rome, Italy)*, P Valigi *(Dept Ing Elettron II, Univ Roma Tor Vergata, via O Raimondo 00173, Rome, Italy)*. J Intelligent & Robotic Syst 7(3) 321-351 (June 1993).

A simple asymptotic observer is proposed for the estimation of the generalized velocities of a robotic manipulator. The singular perturbation theory is used in the stability analysis of the error dynamics. High-gains are used in the attenuation of the nonlinearities characterizing the dynamic behavior of the robot. The accuracy of the proposed algorithm is illustrated in simulation runs and verified through some experimental tests.

10A347. Workspace of a general geometry planar 3-dof platform-type manipulator. - GR Pennock and DJ Kassner *(Sch of Mech Eng, Purdue)*. J Mech Des 115(2) 269-276 (Jun 1993).

This paper focuses on the direct workspace problems of a general geometry fully-parallel-actuated, planar 3-dof platform type manipulator. A set of equations are presented that determine the workspace as a function of the platform orientation. The reachable positions of the end-effector point, for a specified platform orientation, are analyzed. The paper includes a detailed discussion of the total primary workspaces of the manipulator. The approach adopted here is to regard the manipulator as a combination of three planar, three-revolute open chains. For the sake of completeness, the influence of special manipulator geometry on the workspace is also discussed. Finally, the paper includes the conditions that cause stationary configurations of the manipulator. Insight into these undesirable configurations is provided by a study of the location of the absolute instant center of the platform.

206F. SENSORS AND CONTROLS

10A348. Controls of servomotors for carry hospital robots. - Sangho Jin, Ichiro Kimura, Keigo Watanabe *(Dept of Mech Eng, Fac of Sci and Eng, Saga Univ, Honjomachi-1, Saga 840, Japan)*. J Intelligent & Robotic Syst 7(3) 353-369 (June 1993).

Two methods for controlling servomotors with pulse encoders are presented for improving the movement of a carry hospital robot (CHR) along a desired line. Some simulation studies have been executed for the design of a PI controller or optimal regulator for the control of the DC servomotor. By applying the simulation results, we actually design a PI controller in an analogue circuit and experimentally compare the results of the PI control with those of a PLL (Phase Locked Loop) control. It is then clarified that the latter approach is effective in improving the accuracy of the CHR.

10A349. Design and performance studies of model-based variable-structure adaptive controllers for industrial manipulators. - SK Tso and PL Law *(Dept of Elec and Electron Eng, Univ of Hong Kong)*. J Syst Control Eng 206(14) 245-262 (1992).

A model-based variable-structure adaptive control scheme recently proposed for the trajectory tracking of robot manipulators has shown significant promise. By actual implementation with a commercial manipulator, the practical means for improvement are examined, the design trade-offs are systematically explored, and the distinguishing features of the performance achievable in the improved version are brought out and compared with those of earlier schemes.

10A350. Experiments on the tracking control of a flexible one-link manipulator. - Chia-Hsiang Menq and Jack Zhijie Xia *(Dept of Mech Eng, Ohio State Univ, Columbus OH 43210)*. J

Dyn Syst Meas Control 115(2A) 306-308 (Jun 1993).

Experimental study on the tracking control of a flexible one-link manipulator is reported in this paper. A tracking control scheme is developed based on the system transfer function. In the proposed control scheme, the desired control input for a given end-point trajectory is obtained by using a command feedforward controller instead of solving the inverse dynamic equations of the system. The proposed control scheme requires small amount of computations and can be easily implemented for real time control. The experimental results are presented, which shows very good tracking performance.

10A351. Localization of hybrid controllers for manipulation on unknown constraints. - JS Bay *(Bradley Dept of Elec Eng, VPI)* and Hooshang Hemami *(Dept of Elec Eng, Ohio State Univ, Columbus OH 43210)*. J Intelligent & Robotic Syst 7(3) 301-320 (June 1993).

A robotic control problem is proposed in which a six dof manipulator is to explore the surface of an object which is *a priori* unknown to the controller. Choice of an exploration strategy is discussed. The exploration strategy developed uses the maximal freedom of choice allowed under the restrictions of the problem. In particular, it is shown that any admissible reference trajectory can be used, provided it lies in a 2D manifold which maps continuously into the surface. The inverse kinematic velocity problem is then solved using pseudo-inverses which fully exploit the redundancy of the system. The controller used as an example uses computed torque for linearization and compliant motion theory for movement along the desired path. The solution to the inverse kinematic problem together with the on-line generation of "selection-mappings" constitute a hybrid force-velocity controller. Successful exploration is shown to depend heavily on reliable force control, so PI force feedback is also proposed. Simulation and experimental results demonstrate the effectiveness of the overall design.

10A352. Variable-structure linear-model-following control of manipulators. - SK Tso, ML Lai, PL Law *(Dept of Elec and Electron Eng, Univ of Hong Kong, Hong Kong)*. J Syst Control Eng 207(I1) 35-45 (1993).

The paper describes the interaction between modeling, control, and adaptation of a variable-structure model-following method applied to highly nonlinear plants. The method is particularly appealing in the control of high-performance robot manipulators. The problems concerned with its application are discussed with reference to the use of a controller in a commercial manipulator as a case study.

10A353. Vision and touch sensors for dimensional inspection. - M Nashman *(Robot Syst Div, Bldg 220, Rm B124, NIST)*. Manuf Rev 6(2) 155-162 (Jun 1993).

In the manufacturing process, various sensors can be used for the dimensional inspection of part geometry. The sensors detect discrepancies between a machined part and its specified geometry as defined in a computer-aided design (CAD) model or other model data base. The part is then either accepted or rejected and sent to scrap or rework as part of the inspection process. Within this system, vision and touch sensors can be used in combination, which adds significantly to their effectiveness and the body of knowledge that can be obtained from them. However, the use of multiple sensors is relatively new and few commercially available coordinate measuring machines (CMMs) have multiple sensor capabilities. In light of these conditions, the author considers the current use of vision and touch sensors in dimensional inspection and suggests several strategies for developing CMMs with multiple sensor capabilities, using the system currently under development at the NIST as an example.

10A354. Geometry of interference with application to obstacle avoidance. - YJ Choi, CD Crane III, GK Matthew, J Duffy *(Center for Intelligent Machines and Robotics, Dept of Mech Eng, Univ of Florida, Gainesville FL)*. J Mech Des 115(2) 300-305 (Jun 1993).

A mapping which transforms the relative displacements of one object with respect to a reference object into image points has been developed by interpreting the relative displacement in terms of affine coordinates. The mapping provides a novel mathematical tool that solves interference problems of objects in 3D space. By use of this mapping, the geometrical condition of interference of objects is represented by simple inequalities. The inverse mapping provides the means of avoiding interference and can be utilized for articulation of robot arms so as to avoid collision with obstacles.

10A355. Solving the robotic "pick and place" findpath problem. - Wei Li and Bo Zhang *(Dept of Comput Sci, Natl Lab for Intelligent Tech and Syst, Tsinghua Univ, Beijing 100084, Peoples Rep of China)*. Manuf Rev 6(2) 114-128 (Jun 1993).

This article presents a practical approach for solving the findpath problem for industrial robots, and entails determining the path through space that a robot will follow in completing its tasks. The findpath problem consists of two phases, mapping and quick search. Mapping is based upon defining the fundamental obstacles in a workspace and their images in configuration space. The search phase consists of building a free subspace by slice configuration of these obstacles, in which a model of each obstacle is generated by evaluating slices of the area under consideration, and then planning a collision-free path. To achieve these objectives, the authors propose an analytical model for mapping fundamental obstacles. For more complex obstacles, they discuss several mapping algorithms and linear interpolation. The proposed approach, combining the analytical model with the algorithms and interpolation, can be used in real-time path planning for robot transfer movements, consisting of a robotic gripper and its playload, over a range of industrial applications.

10A356. Swing-up control of inverted pendulum using pseudo-state feedback. - K Furuta, M Yamakita *(Dept of Control Eng, Tokyo IT, Japan)*, S Kobayashi *(NSK Limited, Japan)*. J Syst Control Eng 206(I4) 263-269 (1992).

Swing-up control, that is the transfer of a pendulum from a pendant state to the inverted one, is a good laboratory experiment of optimal control theory for nonlinear control systems. The optimal control can be determined by the maximum principle and obtained as a function of time. Since the control is, however, determined in a feedforward fashion, the control is not robust to disturbances and uncertainties of the system, and the transfer of the state of the pendulum is not assured. In the paper, a robust swing-up control using a subspace projected from the whole state space is proposed. Based on the projected state space or pseudo-state, the control input is determined depending on the partitioning of the state as a bang-bang type control. The control algorithm is applied for a new type of pendulum (TITech pendulum), and the effectiveness and robustness of the proposed control are examined by experiments.

10A357. Qualitative template matching using dynamic process models for state transition recognition of robotic assembly. - BJ McCarragher *(Austral Natl Univ, Canberra, Australia)* and H Asada *(Center for Info-Driven Mech Syst, MIT)*. J Dyn Syst Meas Control 115(2A) 261-269 (Jun 1993).

This paper presents a model-based approach to the recognition of discrete state transitions for robotic assembly. Sensor signals, in particular, force and moment, are interpreted with reference to the physical model of an assembly process in order to recognize the state of assembly in real time. Assembly is a dynamic as well as a geometric process. Here, the model-based approach is applied to the unique problems of the dynamics generated by geometric interactions in an assembly process. First, a new method for the modeling of the assembly process is presented. In contrast to the traditional quasi-static treatment of assembly, the new method incorporates the dynamic nature of the process to highlight the discrete changes of state, eg, gain and loss of contact. Second, a qualitative recognition method is developed to understand a time series of force signals. The qualitative technique allows for quick identification of the change of state because dynamic modeling provides much richer and more copious information than the traditional quasi-static modeling. A network presentation is used to compactly present the modelling state transition information. Lastly, experimental results are given to demonstrate the recognition method. Successful transition recognition was accomplished in a very short period of time: 7-10 ms.

10A358. Model reference adaptive inverse control of a single link flexible robot. - S Wu and S Cetinkunt *(Dept of Mech Eng, Univ of Illinois, Chicago IL 60680)*. Comput Struct 47(2) 213-223 (Apr 1993).

A new model reference adaptive inverse control algorithm is proposed for the end point position control of flexible manipulators. This controller forms a series model reference adaptive system where an estimated system inverse is placed in the feed forward path to provide an inverse control through regulation of controller parameters. It differs from other model reference control strategies in that a signal synthesis loop is included to compensate for the estimation error of the inverse controller and the output tracking error, and to improve stability. The stability of the overall control system is shown to be guaranteed using hyperstability theory. The proposed control scheme is applied to control the tip position of a single link flexible robot. A non-dimensionalized model is developed. Its zero-order hold equivalence in discrete time domain is described by an auto-regressive and moving average form. A lattice filter is utilized as a deconvolution filter. The time-delay behavior from the driving torque to the robot tip position due to robot structural flexibility is investigated.

10A359. Use of linked lists in the simulation of controller-structure interaction. - R Quan *(Frank J Seiler Lab, US Air Force Acad, Colorado Springs CO 80840).* Comput Struct 47(2) 225-231 (Apr 1993).

An algorithm for the computer simulation of large space structures under active control is considered. Linked lists are used in a matrix data structure to implement the trapezoidal rule on system differential equations. The use of the trapezoidal rule ensures that the numerical stability is equivalent to the system stability, which is essential for this type of simulation. The sparsity of the system matrices is exploited by the linked lists, and the algorithm efficiently steps through the lists in an orderly fashion. Results of simulations on a NASA large space structure experiment are reported.

10A360. Dejavu: Case-based reasoning for mechanical design. - T Bardasz *(Computervision Corp, Bldg 14-13, 14 Crosby Dr, Bedford MA 01730)* and I Zeid *(Dept of Mech Eng, Northeastern Univ, Boston MA 02115).* AI Eng Des Anal Manuf 7(2) 111-124 (1993).

The architecture and implementation of a mechanical designer's assistant shell called DEJAVU is presented. The architecture is based on an integration of design and CAD with some of the more well known concepts in case-based reasoning (CBR). DEJAVU provides a flexible and cognitively intuitive approach for acquiring and utilizing design knowledge. It is a domain independent mechanical design shell that can incrementally acquire design knowledge in the domain of the user. DEJAVU provides a desigu environment that can learn from the designer until it can begin to perform design tasks autonomously or semi-autonomously. The main components of DEJAVU are a knowledge base of design plans, an evaluation module in the form of a design plan system, and a blackboard-based adaptation module. The existence of these components are derived from the utilization of a CBR architecture. DEJAVU is the first step in developing a robust designer's assistant shell for mechanical design problems. One of the major contributions of DEJAVU is the development of a clean architecture for the utilization of case-based reasoning in a mechanical designer's assistant shell. In addition, the components of the architecture have been developed, tailored or modified from a general CBR context into a more synergistic relationship with mechanical design.

10A361. Dispelling the manufacturing myth. - Chun Zhang and Hsu-Pin Wang *(Dept of Indust Eng, Univ of Iowa, 4106 Eng Bldg, Iowa City IA 52242).* Manuf Rev 6(1) 60-71 (Mar 1993).

Tolerance design and synthesis is a major task in product and process design now under extensive study because of the increasing demand for quality products and the growing requirements for automation in machining and assembly. Optimum tolerance design and synthesis ensures good quality products at low cost. This article provides an analysis of the tolerance optimization problem in three parts. First, the tolerance synthesis problem was formulated as a nonlinear discrete optimiztion model that had as its objective minimum manufacturing cost. Second, the discrete optimization model was treated as a continuous optimization model and was solved with the sequential quadratic programming (SQP) method. Optimality of the continuous model was examined to understand the characteristics of the problem. Third, a simulated annealing (SA) algorithm was coded to solve the discrete tolerance optimization model, and was compared with the SQP method on a range of problems. The SA algorithm appears to be effective choice, particularly for problems with a wide process capability range or nonoverlapping cost curves.

10A362. Efficient design for service considerations. - A Subramani and P Dewhurst *(Dept of Indust and Manuf Eng, Univ of Rhode Island, Gilbreth Hall, Kingston RI 02881).* Manuf Rev 6(1) 40-47 (Mar 1993).

Future serviceability is an important facet of product design that affects a manufacturer's profit, warranty costs, customer satisfaction, product life, and market share. In this article, the authors propose a generic scheme, based on the costs and labor involved in service work, to assess this important area early in the product concept and design stages. Several metrics are developed in the scheme to measure the effects of variables such as service time, parts cost and accessibility, and labor cost, for developing efficient design strategies. Two examples of commonly occurring automotive service tasks are evaluated using the metrics to assess the efficiency of design and service in automotive engineering and to test the suitability of the metrics.

10A363. Process planning and concurrent engineering system for PCBs. - Jong-Shin Liau and RE Young *(Group for Intelligent Syst in Design and Manuf, Dept of Indust Eng, N Carolina State Univ, Campus Box 7906, Raleigh NC 27695).* Manuf Rev 6(1) 25-39 (Mar 1993).

With continuous advancements in the development of electronics components and automatic assembly machines, the design and manufacture of printed circuit boards (PCBs) has become more versatile and complex. This increasing complexity, coupled with frequent enhancements in the PCB manufacturing environment [especially the success of surface mount devices (SMDs)], and continuing inefficiency in planning time, has led to the need for more sophisticated computer-aided process planning (CAPP) systems for PCB assembly. Most existing CAPP systems generate a process plan from design inputs, but do not provide feedback to the design process. In contrast, concurrent engineering is an approach to design and manufacturing that takes into account not only the functionality of a product but also its manufacturability. By applying concurrent engineering criteria to PCB design and production, the authors have developed a process planning and concurrent engineering system, called PACE, that uses PCB process planning knowledge formulated as constraints to build interactive process plans and to assess their manufacturability. PACE was constructed using the Spark constraint modeling language and environment, and not only generates process plans for PCB assembly from design attributes, but also detects inconsistencies between the PCB design and the production facility. Thus, concurrent engineering concepts are enforced in the design stage. An example is presented in the article to illustrate the application of the PACE system.

10A364. Tool for optimal manufacturing design decisions. - DL Thurston and SK Essington *(Dept of General Eng, Decision Syst Lab, Univ of Illinois, Urbana IL 61801).* Manuf Rev 6(1) 48-59 (Mar 1993).

Interest in concurrent engineering has arisen because design engineers have realized that they need to integrate manufacturing cost considerations directly into the engineering design process. When optimizing designs for manufacturing, engineers should develop a design that offers the best combination of mechanical performance and manufacturing costs. Weighted average methods, frequently used for optimizing designs, have the limitation of not accurately reflecting the nonlinear value imparted by various design attributes and the decision maker's sometime reluctance to make trade-offs between attributes. In this article, the authors present a computer-based aid for design decisions that accurately considers multiple design attributes simultaneously. A spreadsheet interface facilitates the analysis of design alternatives in a form that is readily used by design engineers. The authors do not present a new method for manufacturing cost estimation, but rather one for directly integrating cost estimation procedures into the design decision-making process. They demonstrate that this tool provides engineers with the means to formulate a multiattribute design optimization problem, compare the relative merits of alternative materials and designs, and determine the optimal material and component geometry. The sensitivity analysis capabilities of the spreadsheet for variations in production volume and the user's willingness to make trade-offs between attributes are also demonstrated.

10A365. Development of a flexible assembly center. - Masahito Uno, Ichiro Taniguchi, Koichi Sugimoto, Toru Mita, Siyuki Sakaue, Hisashi Onari. J Japan Soc Precision Eng 59(5) 737-742 (May 1993).

The authors created a flexible assembly center that can be organized to meet the needs of various assembly operations. For this, a precision autonomous robot that does not require a teaching process was developed. The flexible assembly center is composed of multiple table robots, arm robots, and part-tool feeders, and has the following characteristics: (1) complicated operations can be performed by using the flexible arm and table setup. (2) The positioning accuracy necessary for precision assembly can be maintained through the use of direct drive mechanisms and auto-calibration, without requiring a teaching process. (3) Precise operation can be accomplished autonomously by real-time control with visual and force sensor feedback. This system is particularly effective for production systems involving frequent setup changes.

10A366. From robots to design. - DE Whitney *(Charles Stark Draper Lab, Cambridge MA 02139)*. J Dyn Syst Meas Control 115(2B) 262-270 (Jun 1993).

This paper describes the evolution of the author's research focus from a single manufacturing technology, robots, to a broader and less technical focus on design processes. This evolution was not haphazard, but was prompted by technical and nontechnical lessons acquired while performing research and attempting to apply it in industrial settings. The inability of any one technology to solve a wide range of problems, and the inability of technology alone to impact the complexities of manufacturing are among the facts learned. What follows is a rather personal account of this evolution.

10A367. Integration of coordinate measuring machines within a design and manufacturing environment. - AJ Medland, G Mullineux, C Butler, BE Jones *(Dept of Manuf and Eng Syst, Brunel Univ, Uxbridge, Middlesex)*. Proc Inst Mech Eng B 207(B2) 91-98 (1993).

The role of the coordinate measuring machine within the inspection process has changed throughout its brief development. With its integration with industrial computer aided design (CAD) systems, its role is to change yet again. This paper presents the difficulties and limitations of current practice and identifies the inputs and decisions that need to be made within an integrated manufacturing environment. A research program was undertaken to investigate an approach based upon intelligent communications between systems. This led to the creation of a demonstration system that was employed in the measurement of industrial components. A case study, using a standard test block, is included to illustrate the processes undertaken. This includes feature identification, probe calibration and selection strategies and automatic re-routing to minimize changes in probes and orientations. It is proposed that the approach demonstrated can be incorporated within a concurrent engineering environment to provide feedback and information about machine adjustments through a constraint modeling process.

10A368. Intelligent inspection planning and computer aided inspection. - JDT Tannock, H Lee, DR Cox, JH Sims Williams *(Dept of Mech Eng, Univ of Bristol)*. Proc Inst Mech Eng B 207(B2) 99-104 (1993).

Quality inspection is the source of vital information for business control and improvement in manufacturing. This paper describes research at the University of Bristol, in collaboration with Rolls-Royce plc, to develop automated inspection planning and computer aided inspection applications. The inspection planning system involves the representation of inspection features and the manufacturing process model, together with an automated planning mechanism driven by rule-based plan reasoning. The shop-floor computer aided inspection workstation uses hand-held instruments interfaced to a computer, and provides flexible, interactive assistance for the dimensional inspection task. Batch and component traceability and control, together with a range of quality information storage and reporting functions, are provided.

10A369. Making circuits more than once: The manufacturing challenges of electronics intensive products. - DJ Williams, PP Conway, DC Whalley *(Dept of Manuf Eng, Loughborough Univ of Tech)*. Proc Inst Mech Eng B 207(B2) 83-90 (1993).

This paper is a review of some of the problems facing manufacturers of current and future generation electronic products. It presents a brief overview of work carried out by the Interconnection Group at Loughborough in the support of manufacturing industry, and in particular defines some of the limitations of the manufacturing processes. The paper closes by identifying research areas that can be addressed by the academic community to assist industry in its efforts to maintain competitiveness. Research areas focused on are conventional packaging, multi-chip modules and some aspects of the organization of international manufacture.

10A370. Modeling and control of manufacturing processes: Getting more involved. - DE Hardt *(Lab for Manuf and Productivity, MIT)*. J Dyn Syst Meas Control 115(2B) 291-300 (Jun 1993).

The discipline of control has had numerous yet sporadic contacts with the manufacturing world over the past few decades, almost always as an afterthought or addendum, and typically in the role of machine and not as process control. Much of this detachment comes from an absence of control techniques that can deal directly with the actual manufacturing process, ie, a material transformation process that produces a desired object both in terms of specific geometry and internal properties. Instead, most efforts have focused on using existing methods on process independent problems, such as position control and trajectory following, or on straightforward process parameter control, thereby only indirectly influencing the actual process output. This paper presents the reasons behind and the means to eliminate this estrangement, using the author's own research as an example of a more direct approach to process modeling and control.

10A371. Practical implications in the calibration of translational tables. - E Mainsah, PJ Sullivan, KJ Stout *(Sch of Manuf and Mech Eng, Univ of Birmingham, Edgbaston, Birmingham B15 2TT, UK)*. Manuf Rev 6(2) 129-140 (Jun 1993).

The accuracy and repeatability of translational tables, as ascertained through consistent and systematic calibration, are vital parameters that form the basis of the decision to choose any particular translational table for use in the 2D or 3D assessment of the topography of engineering surfaces. The absence of an international table calibration standard designed to cope with the specifics of surface topography analysis can lead to problems with the traceability of individual calibrations. This article assesses the procedures for determining the accuracy and repeatability of positioning translational tables in the x- and y-axes and shows how calibration errors can be analyzed and minimized. The authors review and quantify measurement errors that occur both as a result of the calibration system (which in this case is a laser interferometer) and the system operator. These include errors introduced by temperature, relative humidity, and pressure changes in ambient conditions, leading to a change in the refractive index of air. This affects the measurements taken, and may lead to the thermal expansion of the table resulting in virtual table translation. A simplified equation is derived that brings together earlier results by Edlen, Jones, and Birch and Downs, and that can be used in a laboratory for correcting errors introduced to the laser measurement system due to changes in temperature, pressure, relative humidity, and carbon dioxide concentration. Preliminary results show that the model is satisfactory, especially in situations where errors in the region of one ppm are acceptable.

208H. MANAGEMENT AND ECONOMICS

10A372. Decomposition approach to the public transport scheduling problem. - W Grega *(Inst of Autom, Univ of Mining and Metall, 30-059 Krakow, Al Mickiewicza 30-BI, Poland)*. Automatica 29(3) 745-750 (May 1993).

This paper presents a new approach for solving timetable optimization problems. The original problem is decomposed into subproblems along the discrete time axis. For each subproblem the motion of vehicles is described by treating headways between them as the state variables. The layover times at the terminals are considered as the decision variables. This model allows the implementation of optimal control theory with quadratic criterion and technical constraints imposed on the state and control. The problem is to obtain after a fixed number of trips a desired configuration of headways and to "glue" partial timetables together creating the final timetable. A numerical example is given to illustrate the idea.

10A373. Impact of manufacturing practices on the global bicycle industry. - R Suri, JL Sanders, PC Rao *(Dept of Indust Eng, Univ of Wisconsin, 1513 University Ave, Madison WI 53706)*, A Mody *(World Bank, Room S 4141, 1818 H St NW, Washington DC 20433)*. Manuf Rev 6(1) 14-24 (Mar 1993).

This article presents the findings of a study on the impact of modern manufacturing technologies and managerial practices on global competitiveness in the bicycle industry. Three classes of countries were studied: developed countries (DCs), newly industrialized economies (NIEs), and less developed countries (LDCs). Based on extensive literature surveys and on-site interviews, analytical models were developed that enable prediction of manufacturing costs in the three types of countries. Some of the study findings include the following observations: NIEs are currently the most cost competitive countries; massive infusions of state-of-the-art technologies can have dysfunctional consequences for LDCs; and gains from automation for all three types of countries are greater when it is introduced after implementing total quality control (TQC) and just-in-time (JIT) manufacturing practices. Although a DC firm gains significantly TQC and JIT, product cost differences continue to be substantial, implying that DCs need to target additional criteria to remain competitive. It is also shown that by focusing on flexible manufacturing methods, firms can attain greater product flexibility and shorter lead times without prohibitive increases in costs. While some of these findings are not new, the study provides substantial quantitative evidence to back up these statements. In addition, the methodology presented here should be of interest to researchers, because it presents a systematic way to quantify many of the managerial practices essential to the competitiveness of modern firms.

10A374. Construction of two-phase equilibria in a non-elliptic hyperelastic material. - E Fried *(Dept of Eng Sci and Mech, Penn State)*. J Elast 31(2) 71-123 (May 1993).

This work focuses on the construction of equilibrated two-phase antiplane shear deformations of a non-elliptic isotropic and incompressible hyperelastic material. It is shown that this material can sustain metastable, two-phase equilibria which are neither piecewise homogeneous nor axisymmetric but, rather, involve nonplanar interfaces which completely segregate inhomogeneously deformed material in distinct elliptic phases. These results are obtained by studying a constrained boundary value problem involving an interface across which the deformation gradient jumps. The boundary value problem is recast as an integral equation and conditions on the interface sufficient to guarantee the existence of a solution to this equation are obtained. The constraints, which enforce the segregation of material in the two elliptic phases, are then studied. Sufficient conditions for their satisfaction are also secured. These involve additional restrictions on the interface across which the deformation gradient jumps – which, with all restrictions satisfied, constitutes a phase boundary. An uncountably infinite number of such phase boundaries are shown to exist. It is demonstrated that, for each of these, there exists a solution – unique up to an additive constant – for the constrained boundary value problem. As an illustration, approximate solutions which correspond to a particular class of phase boundaries are then constructed. Finally, the kinetics and stability of an arbitrary element within this class of phase boundaries are analyzed in the context of a quasistatic motion.

250E. STRESS CONCENTRATIONS AND SINGULARITIES

10A375. Analysis of stress singularities at the corner point of square hole and rigid square inclusion in elastic plates by conformal mapping. - H Ishikawa and Y Kohno *(Dept of Mech and Control Eng, Univ of Electro-Commun, 1-5-1 Chofugaoka Chofu, Tokyo 182, Japan)*. Int J Eng Sci 31(8) 1197-1213 (Aug 1993).

The plane elastostatic problem of a square hole and a rigid square inclusion in the infinite plate under tension loading are examined by the conformal mapping and Goursat stress functions. A new method is developed for the calculation of the orders of singularity and the stress intensity factors of a singular point, such as the corners of a square hole and square inclusion (non-rotation) in the elastic plates submitted to an overall tension at infinity. Coefficients of Goursat stress functions are determined, respectively, for the number m of terms of the finite series of the function for the conformal mapping. Then, the two types of the orders of stress singularities λ_I and λ_{II} which correspond to Mode I (opening mode) and Mode II (in-plane shear mode) deformations, respectively, are determined and their numerical results are in good agreement with the exact solutions by Williams. Also the stress intensity factors K_I and K_{II} are determined for arbitrary equivalent Poisson's ratio κ. Singular stress and displacement fields corresponding to Mode I and Mode II deformations around a corner point of a square hole and a rigid square inclusion are also obtained.

10A376. Westergaard stress functions for displacement-prescribed crack problems I. - H Tada *(Washington Univ, St Louis MO 63130)*, HA Ernst *(Sch of Mech Eng, Georgia Tech)*, PC Paris *(Washington Univ, St Louis MO 63130)*. Int J Fracture 61(1) 39-52 (1 May 1993).

The single stress function approach of Westergaard has been effective for a certain class of stress-prescribed crack problems. In the present study, the Westergaard approach was successfully extended to displacement-prescribed crack problems. The method presented, which requires no more than the evaluation of integrals, significantly simplifies the analysis. The method is easily extended to crack problems involving displacement-prescribed and stress-prescribed conditions. This initial study laid the ground work for the subsequent extension to the mixed problem.

250F. ELASTIC IMPERFECTIONS (DISLOCATIONS, ETC)

10A377. Green's function for the elastic field of an edge dislocation in a finite orthotropic medium. - A El-Azab and NM Ghoniem *(Mech Aerospace and Nucl Eng Dept 46-147G Eng IV, UCLA)*. Int J Fracture 61(1) 17-37 (1 May 1993).

A fundamental solution of plane elasticity in a finite domain is developed in this paper. A closed-form Green's function for the elastic field of an edge dislocation of arbitrary Burger's vector at an arbitrary point in an orthotropic finite elastic domain, that is free of traction, is presented. The method is based on the classical theory of potential fields, with an additional distribution of surface dislocations to satisfy the free traction boundary conditions. A solution is first developed for a dislocation in a semi-infinite half-plane. The resulting field is composed of two parts: a singular contribution from the original dislocation, and a regular component associated with the surface distribution. The Schwarz-Christoffel transformation is then utilized to map the field quantities to a finite, polygonal domain. A closed form solution containing Jacobi elliptic functions is developed for rectangular domains, and applications of the method to problems of fracture and plasticity are emphasized.

10A378. Overall elastic response of materials containing spherical inhomogeneities. - GJ Rodin *(Dept of Aerospace Eng and Eng Mech, Univ of Texas, Austin TX 78712)*. Int J Solids Struct 30(14) 1849-1863 (1993).

It is proposed to determine the overall response of linear elastic materials containing non-intersecting spherical inhomogeneities without altering the microscopic geometry of a given representative volume element. In the proposed method, a system of integral equations formulated for such an element is accurately approximated by a system of linear algebraic equations.

250G. VARIATIONAL AND ENERGY METHODS

10A379. Energy extremum principle for local action. - V Minutolo and L Nunziante *(Univ di Napoli "Frederico II", Dip di Scienza della Construzioni, Piazzale V Tecchio n80, 80125 Fuorigrotta Napoli, Italy)*. Int J Solids Struct 30(13) 1717-1723 (1993).

This work describes the solution in terms of the energy of the mixed boundary problem, formulated for the elastic body subjected to prescribed boundary displacements field. The extremum theorems herein proved are particular corollaries of the classical reciprocity theorems. Let us consider a part, δV_P, of the unconstrained boundary containing point P one which a displacement field u_P shall be prescribed. The displacement is produced by tractions acting a part, δV_P, of the unconstrained boundary containing a point Q and disjoined from δV_P. The strain energy of the body in this elastic state is greater than the strain energy produced by boundary forces acting on δV_P and creating the same displacement field u_P there. The lower bound theorem herein proved gives a quantification of Boussinesque's local perturbation principle and a measure of the stain energy related to local action. The theorem applies both for structures and solids.

10A380. Global extremum principle for the analysis of solids composed of softening material. - JE Taylor *(Dept of Aerospace Eng, Col of Eng, Univ of Michigan, Ann Arbor MI 48109)*. Int J Solids Struct 30(15) 2057-2069 (1993).

An extremum principle is presented covering problems in solid mechanics equilibrium analysis for piecewise linear softening materials. Problems formulated according to this principle are expressed on a mixed "stress and deformation" form. The mechanics interpretation is limited according to linear deformation kinematics. More specialized models, such as *an extremum principle in mixed form for linearly elastic materials*, an equivalent to the *minimum complementary energy principle*, and a statement of a *bound theorem of Limit Analysis* are identified as special cases within the general formulation. Numerical results are presented for two examples of 1D structures made of inhomogeneous, softening material. The evolution of material degradation is demonstrated via a set of solutions obtained for increasing load. Each solution of the set is produced from a single application of a general purpose computer program for constrained nonlinear programming problems, operating on a FE interpretation of the nonlinear continuum.

250H. CONTACT PROBLEMS AND INCLUSIONS

10A381. Dundurs correspondence between cavities and rigid inclusions. - X Markenscoff *(Dept of Appl Mech and Eng Sci, UCSD)*. J Appl Mech 60(2) 260-264 (Jun 1993).

In plane elasticity the solutions of the stress field of rigid inclusion problems yield the solutions of cavity problems loaded by uniform shear tractions $\sigma = 2\mu(\Omega - \omega_0)|_{\kappa = -1}$, where Ω is the rotation of the inclusion and ω_0 the rotation of the material (evaluated at $\kappa = -1$), k being the Kolosov constant). It is proved that *if the limit of the stress field for the inclusion problem exists at $\kappa = -1$, then it corresponds to a constant rotation field.*

10A382. Virtual contact loading method for elastic contact problems. - Hua Zhao, Zhong-Hua Li, Zhen-Bang Kuang *(Inst of Eng Mech, Xi'an Jiaotong Univ, Xi'an 710049, Peoples Rep of China)*. Commun Numer Methods Eng 9(6) 455-461 (Jun 1993).

The virtual contact loading method, a highly efficient numerical method to solve elastic contact problems, is proposed in this paper. Having applied virtual loads on the possible contact region (PCR) of a structure system, we carried out the usual FE calculations only once and made a local iteration analysis in PCR then the contact region (shape and size), contact state (stick, slide or mixed), contact normal and shear stress distributions, and the stress and displacement fields in contact bodies were all obtained simultaneously. This method is very simple and easy to use. The elastic problems for cylinder-cylinder are solved in this paper and the results agree well with those in previous work.

250I. ANISOTROPIC MEDIA

10A383. Eigenvalues for a self-equilibrated, semi-infinite, anisotropic elastic strip. - EC Crafter, RM Heise, CO Horgan, JG Simmonds *(Dept of Appl Math, Univ of Virginia, Charlottesville VA 22903)*. J Appl Mech 60(2) 276-281 (Jun 1993).

The linear theory of elasticity is used to study an homogeneous anisotropic semi-infinite strip, free of tractions on its long sides and subject to edge loads or displacements that produce stresses that decay in the axial direction. If one seeks solutions for the (dimensionless) Airy stress function of the form $\phi = e^{-\gamma x}F(y)$, γ constant, than one is led to a fourth-order eigenvalue problem for F(y) with complex eigenvalues γ. This problem, considered previously by Choi and Horgan (1977), is the anisotropic analog of the eigenvalue problem for the Fadle-Papkovich eigenfunctions arising in the isotropic case. The decay rate for Saint-Venant end effects is given by the eigenvalue with smallest positive real part. For an isotropic strip, where the material is described by two elastic constants (Young's modulus and Poisson's ratio), the associated eigencondition is *independent* of these constants. For transversely isotropic (or specially orthotropic) materials, described by *four* elastic constants, the eigencondition depends only on *one* elastic parameter. Here, we treat the fully anisotropic strip described by *six* elastic constants and show that the eigencondition depends on only *two* elastic parameters. Tables and graphs for a scaled complex-valued eigenvalue are presented. These data allow one to determine the Saint-Venant decay length for the *fully anisotropic* strip, as we illustrate by a numerical example for an end-loaded off-axis graphite-epoxy strip.

250K. RESIDUAL STRESSES

10A384. Residual stress in an elastic body: A theory for small strains and arbitrary rotations. - A Hoger *(Dept of Appl Mech and Eng Sci, UCSD)*. J Elast 31(1) 1-24 (Apr 1993).

Residual stress is the stress present in a body which is in mechanical equilibrium in the absence of external loading. Thus the residual stress is symmetric, satisfies the equilibrium equation with zero body force, and on the surface of the body the associated traction vanishes. This zero traction condition causes the residual stress to be dependent on body geometry. It is of interest to note that a nonzero residual stress field cannot be uniform. This follows from Signorini's mean stress theorem and the fact that the external forces vanish. In this paper a general theory for elastic materials is presented in which the strains are presumed to be small, but arbitrarily large rotations are allowed. No assumptions are made concerning the origin of the residual stress; in particular, it need not be the result of prior elastic behavior. In Section 2 standard results are gathered which will be used in the remainder of the paper. In Section 3 the derivation of a constitutive equation for a compressible elastic material with residual stress is presented for the case of small strains and arbitrary rotations. The response function for the Piola-Kirchhoff stress is expressed in terms of the right stretch tensor and linearized under the assumption that the right stretch is close to the identity tensor. It is shown that this constitutive equation reduces to that of the classical linearized theory with residual stress when the rotations are also assumed to be close to unity. The use of the right stretch for the linearization, rather than the Cauchy-Green deformation tensor, is briefly discussed. The section closes with the derivation of the linearized response function for Cauchy stress. In Section 4 incompressible elastic materials with residual stress are considered. As was done for compressible materials, a constitutive equation is derived for these materials under the assumption of small strains and arbitrary rotations. For incompressible materials the stress response function is defined only for those deformations that satisfy the constraint of incompressibility, ie, those deformations for which the determinant of the right stretch is one. This set of admissible deformations is not open, so the standard approach of linearizing the stress response cannot be used becase it involves differentiating the response function. An approach formulated by Marlow is employed to perform the linearization by use of the manifold structure of the set of right stretch tensors associated with admissible deformations. The basic field equations for small strain, arbitrary rotation elastostatics with residual stress are collected in Section 5.

250Y. COMPUTATIONAL TECHNIQUES

10A385. Appropriate boundary conditions for FE-modeled elastic half-plane. - HL Bjarnehed *(Div of Solid Mech, Chalmers Univ of Tech, S-412 96 Goteborg, Sweden)*. Commun Numer Methods Eng 9(6) 497-501 (Jun 1993).

The completely adhesive contact between an FE-modeled orthotropic half-plane and a vertically loaded rigid flat punch is studied. Interface normal and shear-stress distributions between the punch and half-plane are FE-calculated and compared for some sets of half-plane boundary conditions frequently used in the literature for contact problems with friction. These results are compared with analytical solutions, and appropriate half-plane boundary conditions are recommended for frictional contact problems.

10A386. Effective BE approach for higher order singularities. - Xiao-yan Lei, Xiuxi Wang, Mao-kuang Huang *(Dept of Mech, Univ of Sci and Tech of China, Anhui, Hefei 230026, Peoples Rep of China)*. Int J Solids Struct 30(15) 2109-2115 (1993).

The paper presents a new BE approach which introduces a "source line". It is very effective for higher order singularity. The scheme will be discussed in some detail with plane elasticity. Numerical results for meshes with unequal BEs are reported. Higher precision than the general BEM is obtained for both deflection and force.

10A387. FE procedure for axisymmetric elastomeric solids under general loading. - RE Marusak *(MicroFab Technologies, 1104 Summit Ave Suite 110, Plano TX 75074)* and EB Becker *(Dept of Aerospace Eng and Eng Mech, Univ of Texas, Austin TX 78712)*. Int J Numer Methods Eng 36(12) 2031-2084 (30 Jun 1993).

A FE procedure, which utilizes Fourier series, is developed to compute the large deformations and deflections in axisymmetric elastomeric solids subjected to non-axisymmetric loading. Nearly incompressible and incompressible, isotropic strain energy density functions describe the elastic properties. The nearly incompressible functions become compatible with an analytical integration scheme by using a novel variable to approximate the dilatation. A large spherical elastomeric bearing is analyzed with this procedure.

252. Viscoelasticity

10A388. Stress analysis for rolling contact between two viscoelastic cylinders. - Guangqiu Wang *(BMW & Rolls Royce Aero Engines GmbH, D-8044 Lohhof, Munchen, Germany)* and K Knothe *(Aerospace Inst, Tech Univ, D-1000 Berlin 10, Germany)*. J Appl Mech 60(2) 310-317 (Jun 1993).

The 2D viscoelastic rolling contact with Coulomb's dry friction is considered for steady-state rolling. A so-called standard linear solid (three parameter model) is used to characterize the viscoelastic material behavior. Rolling contact stresses between two rolling cylinders are investigated by a BEM, based on the half-space theory. Numerical results are presented including the stress distribution at the contact surfaces and in viscoelastic bodies as well as rolling resistance.

10A389. Self-consistent modeling of visco-elastic polycrystals: Application to irradiation creep and growth. - PA Turner and CN Tome *(Fac Sci Exactas, Eng y Agrimensura, Univ Natl, Pellegrini 250, 2000 Rosario, Argentina)*. J Mech Phys Solids 41(7) 1191-1211 (Jul 1993).

We present a model that permits the simulation of the transient response of polycrystalline aggregates to externally imposed loads and temperature gradients. The mechanical response of the constitutive grains includes elastic, Newtonian (linearly viscous), thermal and growth terms. The formulation explicitly accounts for the anisotropy in the elastic, creep, thermal and growth properties of both grains and polycrystals, and describes the time evolution of the overall visco-elastic moduli and of the internal stresses. It also provides, as limit cases, the correct overall elastic, thermal, creep and growth moduli of the polycrystal. The model is applied to analyse the characteristics of irradiation creep and growth in reactor tubes subjected to hydrostatic pressure. The influence of texture, grain anisotropy, grain shape, and thermal stresses over the predicted polycrystal response, and especially over the transient regime, is analysed in detail.

10A390. Application of BEM to geotechnical analysis. - T Shinokawa *(Eng Res Inst, Sato Kogyo, 47-3 Sanda, Atsugi, Kanagawa, Japan)* and Y Mitsui *(Dept of Architec and Civil Eng, Fac of Eng, Shinshu Univ, 500 Wakasato, Nagano, Japan)*. Comput Struct 47(2) 179-187 (Apr 1993).

A numerical method of viscoelastic boundary element analysis using the time marching method is presented and is combined with FEM. Some numerical examples in the viscoelastic analysis are presented to confirm the applicability of the BEM to geotechnical analysis. As an application of BEM to practical geotechnical engineering, the stability of a pillar (an area between two tunnels when they cross obliquely) is examined using the elastic BE analysis. It is concluded that BEM can be efficiently applied in practical geotechnical analysis.

10A391. Quasi-elastic computation of viscoelastic bodies under cyclic loading and its appli-

cation for polymers with ADINA. - Linan Qiao *(Iwan N Stranski Inst, Tech Univ, Berlin, Germany)*. Comput Struct 47(4-5) 757-765 (3 Jun 1993).

A method for quasi-elastic computation of viscoelastic bodies under cyclical loading is suggested. At first, a quasi-Young's modulus is put forward which depends on the loading frequency of the viscoelastic body. Then the method is applied to a polymer material with viscoelastic features using the ADINA program.

10A392. Simultaneous use of 4 × 4 and 2 × 2 bilinear stress elements for viscoelastic flows. - GC Georgiou *(Dept of Math, Univ of Cyprus, Kallipoleos 75, PO Box 537, Nicosia, Cyprus)* and MJ Crochet *(Unit of Appl Mech, Univ Catholique, 2 Place du Levant, B-1348 Louvain-la-Neuve, Belgium)*. Comput Mech 11(5-6) 341-354 (1993).

Mixed FEs for viscoelastic flows based on a 4 × 4 sub-linear interpolation for the extra stress components satisfy the Babuska-Brezzi condition and are highly stable. They have been proved to be quite satisfactory in solving problems with strong stress boundary layers. In this work, we examined the simultaneous use of 4 × 4 and 2 × 2 bilinear stress elements in an attempt to reduce the computational cost without sacrificing the accuracy. The 4 × 4 bilinear elements are employed in regions where the stress field is anticipated to be steep while the 2 × 2 elements carry the burden elsewhere with a much smaller number of stress nodes. Additional constraints along the sides shared by different elements are necessary in order to preserve conformity. The method is applied to the creeping flow of a Maxwell fluid around a sphere falling along the axis of a cylindrical tubes. Results are given for three mixed FE formulations: the Galerkin method, the consistent streamline-upwind-Petrov-Galerkin method and the non-consistent streamline-upwind method. Particular emphasis is given on the calculated drag correction factors. The effect of the sphere-cylinder diameter ratio is also examined.

254A. GENERAL THEORY

10A393. Computational modeling of single crystals. - AM Cuitino and M Ortiz *(Div of Eng, Brown Univ, Providence RI 02912)*. Model Simulation Mat Sci Eng 1(3) 225-263 (Apr 1993).

The physical basis of computationally tractable models of crystalline plasticity is reviewed. A statistical mechanical model of dislocation motion through forest dislocations is formulated. Following Franciosi and co-workers, the strength of the short-range obstacles introduced by the forest dislocations is allowed to depend on the mode of interaction. The kinetic equations governing dislocation motion are solved in closed form for monotonic loading, with transients in the density of forest dislocations accounted for. This solution, coupled with suitable equations of evolution for the dislocation densities, provides a complete description of the hardening of crystals under monotonic loading. Detailed comparisons with experiment demonstrate the predictive capabilities of the theory. An adaptive FE formulation for the analysis of ductile single crystals is also developed. Calculations of the near-tip fields in Cu single crystals illustrate the versatility of the method.

10A394. Internal variable theory of inelastic behavior derived from the uniaxial rigid-perfectly plastic law. - G Romano, L Rosati, F Marotti de Sciarra *(Dept Scienza Costruzioni Fac Ingegneria, Univ Napoli Federico II, 80125 Piazzale Tecchio, Napoli, Italy)*. Int J Eng Sci 31(8) 1105-1120 (Aug 1993).

In the general framework provided by the internal variable theories of associated inelastic behavior the formulation of constitutive relations is addressed in this paper. Attention is focused on the basic properties of the evolution relation involving rates of internal variables and dual thermodynamic forces. It is shown that a suitable generalization of the uniaxial rigid-perfectly plastic law can be performed by introducing the definition of step-shaped constitutive maps. This definition allows us to derive a general theory of associated inelastic behavior with its characteristic properties: convexity of the elastic locus, normality rule, existence of a sublinear dissipation functional and of a canonical yield functional. Finally the formulation of the constitutive relation in terms of yield functionals and related inelastic multipliers is discussed. The analysis is performed on the basis of a chain rule of subdifferential calculus, recently contributed by the authors, which provides an effective tool to develop the theory of Kuhn-Tucker vectors in optimization problems.

254C. NONLINEAR AND FINITE DEFORMATION PROBLEMS

10A395. Evolution of the anistropy of a polycrystalline aggregate. - Ying Zhang *(Army High Performance Comput Res Center, Univ of Minnesota, Minneapolis MN 55415)* and JT Jenkins *(Dept of Theor and Appl Mech, Cornell)*. J Mech Phys Solids 41(7) 1213-1243 (Jul 1993).

The macroscopic properties of a polycrystalline aggregate depend upon the orientational distribution of the single crystals. Here we determine how this distribution of orientations is established for a single crystal whose deformation is assumed to be identical to that of the aggregate. We first derive the equation of evolution for the orientation of a single crystal of arbitrary type that deforms through the mechanism of rate independent crystallographic slip. We then introduce an orientational distribution function to characterize how the orientations of the single crystals are distributed, and derive the equation of evolution for this function. We further consider an approximate representation of the orientational distribution function and derive the linear, first-order ordinary differential equations for the evolution of the coefficients associated with the anisotropic term of the representation. Solutions to these equations can be obtained numerically. These may be used, for example, to describe the development of anisotropy in numerical simulations of metal forming processes.

10A396. Ship bow response in high energy collisions. - H Kierkegaard *(Dept of Ocean Eng, Tech Univ, DK-2800 Lyngby, Denmark)*. Marine Struct 6(4) 359-376 (1993).

A mathematical method for calculating force-indentation relations has been derived for high energy collisions involving ship bow structures. The theory is based on axial crushing mechanisms for basic elements such as L-, T- and X-elements. The internal energy is determined for these elements under the assumption of a rigid plastic material. The energy is related to an external mean crushing force. Stiffened plates are included in the crushing mechanism by introducing an orthotropic plastic plate theory. In a numerical calculation, the bow structure is modelled as an assembly of basic axial elements. The total crushing force is calculated in a simple time simulation, where the strain effect on the flow stress is included. The structure is crushed from the front, and the simulation procedure is able to handle rigid body motions of crushed and non-crushed structure. The calculated collision forces are compared with results from model tests and good agreements are found. Furthermore, a calculation for a longitudinal stiffened bow is given and discussed.

10A397. Thermal expansion coefficient and specific heat at constant strain for finite plastic deformation. - CW Bert and S Huang *(Sch of Aerospace and Mech Eng, Univ of Oklahoma, Norman OK 73019-0601)*. J Appl Mech 60(2) 449-455 (Jun 1993).

General expressions for thermal expansion coefficient and specific heat at constant strain in the case of finite plastic deformation are derived from a general analysis of thermodynamics and finite plasticity theory. The present results show that these two thermal parameters are dependent, in a very complicated way, on the mechanical behavior of the material, such as the plastic yielding and flow, work-hardening and stress-strain relation. They are not constants but vary with the stress state, deformation state, and deformation history. It is shown that previously published experimental observations on thermal expansion coefficient can be described by the theory presented in this paper.

10A398. Hardening rule between stress resultants and generalized plastic strains for thin plates of power-law hardening materials. - CH Chou, J Pan *(Mech Eng and Appl Mech, Univ of Michigan, Ann Arbor MI 48109)*, SC Tang *(Ford Motor, Dearborn MI 48121)*. J Appl Mech 60(2) 548-554 (Jun 1993).

For power-law hardening materials, a stress resultant constitutive law of incremental plasticity nature for thin plates is constructed. The yield function in the stress resultant space is approximated in quadratic form and an equivalent stress resultant is defined. One of two parameters in the yield function is analytically determined based on the concept of complementary potential surface. The other is determined by the least square method to fit the complementary potential surface of Chou et al, (1991). In analogy to the work of Hill (1979), the equivalent work-conjugate generalized plastic strain rate is derived. Finally, the hardening rule between the equivalent stress resultant and generalized plastic strain is obtained based on the results of Chou et al, (1991) for power-law materials under proportional straining conditions.

254G. WORK HARDENING

10A399. Anisotropic strain hardening in polycrystalline copper and aluminium. - F Hess *(Mat Sci Center, Dept of General Phys, Rijksuniversiteit Groningen, Nijenborgh 4, 9747*

AG Groningen, Netherlands). Int J Plasticity 9(4) 405-420 (May 1993).

A new viscoplastic model for the plastic stress-strain behavior of fcc metals is presented. In this model the strain hardening results from increasing dislocation densities. The observed stagnation of strain hardening after strain reversals is explained by a lowering of the increase in dislocations due to annihilation of dislocations with opposite polarity. The model is applied to Bauschinger and x-y tests on commerical copper and aluminium, and to cyclic tests on copper. The theoretical results are in good agreement with the measurements.

10A400. New approach to the Koiter's inequality for shakedown. - J Atkociunas *(Dept of Struct Mech, Vilnius Tech Univ, Vilnius, Lithuania).* Mech Res Commun 20(4) 301-308 (Jul-Aug 1993).

An elastic-perfectly plastic discrete structure subject to cyclic loading is considered, the physical parameters being prescribed. The loading defined by the limits of variation is assumed to cause shakedown of the structure. Residual displacements are related to the history of loading. The energy bounds of possible states of shakedown are usually included in the constraints of the mathematical models of problems for the estimation of displacements. The minimum value of the elastic potential of the residual forces and the maximum value of energy dissipation are within these bounds, only the variation limits of cyclic loading being prescribed. The reliability of the results obtained by solving mathematical optimization problems for determining the variation limits of residual displacements largely depends on the accuracy of these energy values. The well known Koiter's inequality that enables to approximately determine the upper bounds of energy dissipation is not valid when the values of safety coefficients at shakedown approach a unity. The minimum energy principle of residual forces of a fictitious structure obeying the holonomic law permits the upper bound of energy dissipation to be defined more accurately even within the scope of Koiter's inequality.

10A401. Temperature dependence of the residual strength and ductility of a type-316 LN austenitic stainless-steel after prior cold work by tension and swaging. - KG Samuel, SL Mannan *(Mat Dev Div, Indira Gandhi Centre for Atomic Res, Kalpakkam 603 102, India)*, VM Radhakrishnan *(Dept of Metall Eng, Indian IT, Madras 600 036, India).* J Mat Processing Tech 38(3) 517-526 (May 1993).

The influence of temperature and prior cold work on the residual tensile strength and ductility of a type-316 LN austenitic stainless-steel has been studied in the temperature range 300-1123 K after prior deformation at room temperature by tension and swaging. In general, it was observed that the effect of prior cold work by different modes of deformation on the mechanical response of the material has a qualitatively common trend of increasing the strength and reducing the ductility. A structure-sensitivity parameter (the ratio of the yield strength of the prior cold-worked material to that of the as-received material at a given temperature) is proposed and found to increase with temperature and the degree of prior cold work. The additional strengthening of the structure in the temperature range up to 823 K is considered to arise due to dislocation interaction with solutes or precipitates. The decrease of the structure-senstivity parameter above 823 K is attributed to dynamic recovery processes and/or the absence of dislocation solute interaction.

254H. CYCLIC AND VARIABLE LOADING

10A402. Effective stresses and microstructure in cyclically deformed 316L austenitic stainless steel: Effect of temperature and nitrogen content. - J-B Vogt, T Magnin, J Foct *(Lab de Metall, Univ de Lille I, URA CNRS 234, Bat C6, F-59655 Villeneuve d'Ascq, Cedex, France).* Fatigue Fracture Eng Mat Struct 16(5) 555-564 (May 1993).

This paper reports a study on the factors influencing dislocation slip during cyclic deformation of 316L austenitic stainless steel. TEM investigations show that low temperature and interstitial nitrogen content favor planar slip and lead to higher effective stress values. Measurements of effective and internal stresses with the Handfield-Dickson technique indicate that the contribution of nitrogen in the effective component is more important than that of temperature. It is deduced that nitrogen acts through a pinning effect, while low temperature exerts an effect on friction stress. The results also suggest that cyclic plasticity could modify the short range order leading to a redistribution of nitrogen.

254I. VISCO- AND ELASTO-PLASTIC MEDIA

10A403. Elastoplastic modeling for the ductile behavior of polycrystalline sodium chloride with SUVIC. - M Aubertin and DE Gill *(Dept of Mineral Eng, Ecole Polytech, CP 6079, Succ A, Montreal, PQ, H3C 3A7, Canada).* Int J Plasticity 9(4) 479-505 (May 1993).

A unified viscoplastic model with evolutionary state variables, called SUVIC, is reduced to its rate-independent counterpart, and is applied to the inelastic behavior of polycrystalline sodium chloride (salt) in the ductile regime. The proposed model includes a von Mises-type yield criterion, an associated flow rule, and three state variables, producing a mixed (kinematic and isotropic) hardening. The evolution laws are expressed through a particular formulation of the Voce law, which is mathematically similar to the Armstrong-Frederick formulation used in numerous mechanical models. This rate-independent version of SUVIC is a simple extension of the well-known two-surface models and can be reduced to various classical elastoplastic models.

10A404. Study on plastic shakedown of structures Part I. Basic properties. - C Polizzotto *(Dipartimento Ing Strutturale & Geotec, DISEG, Univ Palermo, I-90128 Palermo, Italy).* J Appl Mech 60(2) 318-323 (Jun 1993).

For a continuous elastic-perfectly plastic solid body subjected to a combination of cyclic (mechanical and/or kinematical) load and of a steady (mechanical) load such as to produce plastic shakedown (ie, alternating plasticity), a number of characterizing properties are established and discussed. The conditions for the body's transition from plastic shakedown to ratchetting are also addressed.

10A405. Study on plastic shakedown of structures Part II. Theorems. - C Polizzotto *(Dipartimento Ing Strutturale & Geotec, DISEG, Univ Palermo, I-90128 Palermo, Italy).* J Appl Mech 60(2) 324-330 (Jun 1993).

For a continuous elastic-perfectly plastic solid body subjected to a combination of cyclic (mechanical and/or kinematical) load and of a steady (mechanical) load, two theorems of plastic shakedown are presented, one stating a necessary condition, another stating a sufficient condition. The problem of the direct determination of the plastic shakedown boundary is also briefly adressed.

10A406. Collective micro shear processes and plastic instabilities in crystalline and amorphous structures. - H Neuhauser *(Inst fur Metallphys, und Nukleare Festkorperphys, Tech Univ, Mendelssohnstr 3, D-3300 Braunschweig, Germany).* Int J Plasticity 9(4) 421-435 (May 1993).

The mechanisms that may lead to plastic instabilities are reviewed briefly, and their intimate connection with localization of plastic shear is emphasized. The combination of macro and micro experiments, ie, analysis of stress fluctuations and serrations, and of slip and shear band evolution during deformation, for investigations of these mechanisms is demonstrated with examples of LUDERS and PORTEVIN-LeCHATELIER band propagation in single glide oriented crystals, and of shear band formation in predeformed mono- and polycrystals as well as amorphous materials. The problems connected with collective effects of the micro units of deformation (ie, dislocations in crystalline, local shear transformations in amorphous materials) are indicated, and the necessity to study the mechanism of transfer of slip (shear) to neighboring regions is stressed.

254Y. COMPUTATIONAL TECHNIQUES

10A407. Computational aspects of large elastoplastic deformations in the presence of anisotropy and plastic spin. - B Loret, F Hammoum *(Natl Polytechnic Inst, Inst of Mech, BP 53X, 38041 Grenoble Cedex, France)*, YF Dafalias *(Dept of Civil Eng, UC, Davis CA 95616).* Comput Methods Appl Mech Eng 105(2) 151-180 (Jun 1993).

A constitutive framework for large elastoplastic deformations is briefly presented, along the lines of Mandel's theory, in a form most appropriate for computational convenience. A general purpose stress-point algorithm is adapted to the present large deformation framework. An accuracy analysis is carried out and the performance of several variants are compared, particularly those related to the anisotropic intensity and plastic spin in reference to two specific anisotropic models. The effect of elastic deformations on the overall response is demonstrated for special loading paths.

10A408. Discontinuous displacement approximation for capturing plastic localization. - R Larsson, K Runesson *(Dept of Struct Mech, Chalmers Univ of Tech, S-41296 Goteborg, Sweden)*, NS Ottosen *(Dept of Solid Mech, Univ of Lund, Box 118, S-22100 Lund, Sweden).* Int J Numer Methods Eng 36(12) 2087-2105 (30 Jun 1993).

It is proposed to capture localized plastic deformation via the inclusion of regularized displacement discontinuities at element boundaries (interfaces) of the FE subdivision. The regularization is based on a kinematic assumption for an interface that resembles that which is pertinent to the classical shear band concept. As a by-product of the regularization, an intrinsic band width is introduced as a "constitutive" property rather than a geometric feature on the FE mesh. In this way the spurious mesh sensitivity, which is obtained when the displacement approximation is continuous, can be avoided. Another consequence is that the interfacial relation between the elements is derived directly from the conventional constitutive properties of the continuously deforming material. An interesting feature is that the acoustic tensor will not only play a role for diagnosing discontinuous bifurcation but will also serve as the tangent stiffness tensor of the interface (up to within a scalar factor). An analytical investigation of the behavior of the interface is carried out and it is shown that dilatation may indeed accompany slip within a "shear" band for a general plasticity model. The significance of proper mesh alignment is demonstrated for a simple problem in plane strain and plane stress. It is shown that a unique structural post-peak response (in accordance with nonlinear fracture mechanics) can be achieved when the plastic softening modulus is properly related to the bandwidth. The paper concludes with a numerical simulation of the gradual development of a shear band in a soil slope.

10A409. Numerical approach for nonclassical plasticity. - X Peng and J Fan *(Dept of Eng Mech, Chongqing Univ, Chongqing 630044, Peoples Rep of China)*. Comput Struct 47(2) 313-320 (Apr 1993).

A new incremental form of constitutive equation and the corresponding nonlinear FEM approach are developed based on an endochronic constitutive equation without using a yield surface; a kind of nonclassical theory of plasticity. Compared with the numerical method proposed elsewhere, the new algorithm greatly reduces the error induced in the numerical process, especially in the region of initial extremely small inelastic strain with its slope of stress-plastic strain curve being sufficiently large. The residual stress field of an autofrettaged thick-walled cylinder and the cyclic stress responses of a notched plate are then analyzed.

254Z. EXPERIMENTAL TECHNIQUES

10A410. Numerical analysis of high strain rate splitting-tensile tests. - ML Hughes *(Air Force Civil Eng Support Agency, Tyndall AFB FL 32403)*, JW Tedesco *(Dept of Civil Eng, Auburn Univ, Auburn AL 36849)*, CA Ross *(Graduate Eng Center,Univ of Florida, PO Box 1918, Elgin AFB FL 32542-1918)*. Comput Struct 47(4-5) 653-671 (3 Jun 1993).

Experimental splitting-tension tests were conducted on 2-in diameter concrete specimens in a Split Hopkinson Pressure Bar at strain rates of 4.4, 10.6, and 14.7-sec. The specimens were instrumented with electrical resistance strain gages and break circuits to detect crack initiation crack growth. Experimental results indicate that there is a shift of crack initiation time relative to the peak stress. Also, experimental strength vs strain rate data reveal that the dynamic tensile strength of concrete is significantly higher than the static tensile strength. A comprehensive numerical analysis was conducted on the splitting-tensile experiments to investigate the effects of varying the uniaxial tensile strength of the concrete on the crack initiation time, stress state, crack growth characteristics, and failure mode in the concrete specimens. The results of the numerical analyses are used to enhance the understanding of concrete tensile strength strain rate sensitivity.

256A. GENERAL THEORY

10A411. Geometrical description of particle distributions in materials. - JB Parse and JA Wert *(Dept of Material Sci and Eng, Univ of Virginia, Charlottesville VA 22903-2442)*. Model Simulation Mat Sci Eng 1(3) 275-296 (Apr 1993).

This paper describes a geometrical technique, based on the Dirichlet tessellation, for quantitative characterization of inhomogeneities in the spatial distribution of second-phase particles. The Dirichlet tessellation representation allows a detailed, statistical description of particle distribution properties, including local particle density and vector nearest-neighbor distances. Extension of the tessellation technique by specifying a distance over which second-phase particles are assumed to interact mechanically (particle interaction distance) facilitates quantitative characterization of particle clustering by allowing evaluation of characteristics such as the fraction of particles clustered, and the number, size, and spatial distribution of clusters. The tessellation and clustering characteristics of several types of computer-generated particle arrays (random, clustered, and hexagonal cellular) are presented. The effects of plane-strain deformation on the tessellation and clustering characteristics of the particle arrays have been examined. Tessellation and clustering characteristics of the random particle arrays are insensitive to plane-strain deformation. Several tessellation and clustering characteristics of the clustered and hexagonal-cellular particle arrays exhibit varying behavior with increasing plane-strain deformation. These changes in tessellation and clustering characteristics may be understood by considering the effects of deformation on the various types of inhomogeneous particle distributions.

10A412. Symmetric model of stress-strain hysteresis loops in shape memory alloys. - Krzysztof Wilmanski *(Physikalische Ingenieurwissenschaft, Tech Univ, Strasse des 17 Juni 135, D-1000 Berlin 12, Germany)*. Int J Eng Sci 31(8) 1121-1138 (Aug 1993).

The paper contains the construction of phenomenological model of processes, appearing during the stress-induced isothermal martensitic phase transformations in shape memory materials. In contrast to earlier papers on this subject, the Gibbs free energy is assumed to contain the contribution of the energy of pattern formation. This contribution is constructed in such a way that changes of internal variables are identical in yield and recovery (symmetric model), as suggested by experimental results. It is shown that such a Gibbs free energy together with the principle of least work and an assumption on admissible classes of processes, yields a unique description of internal loops of force-elongation diagrams. It is also demonstrated that the present model reproduces qualitatively all paths appearing in tensile experiments carried on shape memory single crystals in hard loading devices.

256D. CARBON FIBER REINFORCED MEDIA

10A414. Carbon fibers from oriented polyethylene precursors. - Dong Zhang *(Textile Mat Res Lab, Univ of Tennessee, Knoxville TN 37996-1900)*. J Thermoplastic Composite Mat 6 38-48 (Jan 1993).

In this research, an effort is made to produce carbon fibers from a highly ordered and oriented polyethylene fiber. Sulfonation of the fiber is studied as a method of stabilizing this thermoplastic fiber for higher temperatures of carbonization. The effect of time, temperature, tension and medium of sulfonation is being studied systematically. The progress of reactions and the extent of stabilization is studied by thermal analyses (Differential Scanning Calorimetry and Thermogravimetric Analysis). Other techniques like Scanning Electron Microscopy and Instron Tension Testing are used to investigate the changes in morphology of the fibers with stabilization treatment. Also, the properties of the carbon fibers produced from these precursors are investigated.

10A415. Concrete reinforced with up to 0.2 vol% of short carbon fibres. - Pu-Woei Chen and DDL Chung *(Composite Mat Res Lab, SUNY, Furnas Hall, Buffalo NY 14260)*. Composites 24(1) 33-52 (1993).

The use of short pitch-based carbon fibres (0.5% by weight of cement, 0.189 volume % (vol%) of concrete), together with a dispersant, chemical agents and silica fume, in concrete with fine and coarse aggregates resulted in a flexural strength increase of 85%, a flexural toughness increase of 205%, a compressive strength increase of 22%, and a material price increase of 39%. The slump was 102 mm (4 in) at the optimum water-cement ratio of 0.50. The air content was 6%, so the freeze-thaw durability was increased, even in the absence of an air entrainer. The aggregate size had little effect on the above properties. The minimum carbon fibre content for flexural strength increase was 0.1 vol%, although the flexural toughness was still increased below this fibre volume fraction. The optimum fibre length was such that the mean fibre length decreased from 12 mm before mixing to 7 mm after mixing, which used a Hobart mixer. The drying shrinkage was decreased by up to 90%. The electrical resistivity was decreased by up to 83%.

10A416. Effect of carbon coating on mechanical strength of SiC whisker-reinforced alumina composites. - I Thompson and VD

Krstic *(Dept of Mat and Metall Eng, Queen's Univ, Kingston, ON, K7L 3N6, Canada)*. Theor Appl Fracture Mech 19(1) 61-67 (Jun 1993).

Microstructure and mechanical response of alumina matrix reinforced with carbon coated and uncoated SiC whiskers were examined. Carbon coating was used in order to modify the interface and possibly relax the residual thermal stresses developed on cooling from the hot-pressing temperature. Crack propagation behavior and interfacial properties of the composite were studied using scanning and transmission electron microscopy. Resistance to fracture were assessed by using four point bend test and failure load were determined using four point chevron notched beam and double cantilever beam specimens. The improvement in fracture resistance in carbon coated whisker composites was attributed to whisker pull out, crack bridging and crack deflection.

10A417. Effect of processing conditions on the properties of carbon fiber-LaRC TPI composites made by suspension prepregging. - TH Yu and RM Davis *(Dept of Chem Eng, VPI)*. J Thermoplastic Composite Mat 6 62-90 (Jan 1993).

Unidirectional carbon fiber-LaRC TPI composites were made by prepregging carbon fiber tow with particles of LaRC TPI suspended in aqueous solutions of the ammonium salt of the LaRC TPI polyamic acid. The prepregging was followed by drying and consolidation steps designed to facilitate water removal. The effects of processing conditions on composite properties were investigated. The processing conditions included the degree of overlap of the fiber bundle in the prepreg, the fiber tension during prepregging, and the use of vacuum during the consolidation step. It was found that volume % increased with increasing fiber tension and that consolidation under vacuum resulted in composites with void content as low as 0.14 volume %. Fourier transform infrared spectroscopy and thermogravimetric analysis coupled with mass spectroscopy established that most of the water was removed from the prepreg and most of the polyamic acid was converted to polyimide prior to consolidation. The properties of the resulting unidirectional laminates were quite reproducible. Shear moduli were comparable to those for graphite and fiber-epoxy and graphite-fiber and PEEK laminates.

10A418. Hybrid composites based on polyethylene and carbon fibres Part 6. Tensile and fatigue behavior. - AAJM Peijs and JMM de Kok *(Center for Polymers and Composites, Univ of Tech, PO Box 513, 5600 MB Eindhoven, Netherlands)*. Composites 24(1) 19-32 (1993).

The tensile and fatigue behavior of undirectional carbon-high-performance polyethylene-epoxy hybrid composites has been studied, including the effect of hybrid design and surface treatment of the high-performance polyethylene (HP-PE) fibres. Results indicated that the tensile behavior of carbon-HP-PE hybrids in both monotonic and fatigue testing can be interpreted, adopting the conventional "constant strain" model for hybrid composites. Deviations from this constant strain model, so-called hybrid effects, were observed in monotonic tensile testing for those hybrid systems with the highest degree of fibre dispersion, incorporating either untreated or treated HP-PE fibres, whereas only the latter displayed synergistic fatigue performance. Hybrid effects under tensile loading conditions were in reasonable agreement with calculations accounting for statistical effects and stress concentrations as determined by FE analyses.

10A419. Strength of carbon-epoxy laminates with countersunk hole. - C-G Aronsson *(Dept of Mech Eng, Linkoping IT, S-581 83 Linkoping, Sweden)*. Composite Struct 24(4) 283-289 (1993).

The aim of this study is to predict the static strength of carbon-epoxy laminates with countersunk hole. Also, three-point bend (TPB) specimens with the same lay-up were analyzed. For this purpose, the notched strength of the laminates was analyzed by a damage zone model (DZM), where damage around the notch is represented by an "equivalent crack" with cohesive forces acting between the crack surfaces. The DZM requiring only basic properties of the laminate such as unnotched tensile strength, σ_0, fracture energy, $G^x{}_c$, and stiffnesses of the laminate. However, the complex geometry around the countersunk hole implies that both σ_0 and $G^x{}_c$ will vary in this area, and in order to avoid this problem an approximate geometry of the countersunk hole is used in the DZM calculations. With this approximation, good agreement between experimental and calculated strength was observed for the laminates with countersunk hole. This was also the case for the TPB specimens.

256F. OTHER FIBER REINFORCED MEDIA

10A420. Axisymmetric micromechanics of elastic-perfectly plastic fibrous composites under uniaxial tension loading. - Jong-Won Lee *(Korea Aerospace Res Inst, PO Box 15, Daeduck Science Town, Daejun 305-606, Korea)* and DH Allen *(Center for Mech of Composites, Texas A&M Univ, College Station TX 77843)*. Int J Plasticity 9(4) 437-460 (May 1993).

The uniaxial response of a continuous fiber elastic-perfectly plastic composite is modeled herein as a two-element composite cylinder. An axisymmetric analytical micromechanics solution is obtained for the rate-independent elastic-plastic response of the two-element composite cylinder subjected to tensile loading in the fiber direction for the case wherein the core fiber is assumed to be a transversely isotropic elastic-plastic material obeying Tsai-Hill's yield criterion, with yielding simulating fiber failure. The matrix is assumed to be an isotropic elastic-plastic material obeying Tresca's yield criterion. It is found that there are three different circumstances that depend on the fiber and matrix properties: (1) fiber yield, followed by matrix yielding; (2) complete matrix yield, followed by fiber yielding; and (3) partial matrix yield, followed by fiber yielding, followed by complete matrix yield. The order in which these phenomena occur is shown to have a pronounced effect on the predicted uniaxial effective composite response.

10A421. Elastoplastic constitutive relations for fiber-reinforced solids. - G deBotton and PP Castaneda *(Dept of Mech Eng and Appl Mech, Univ of Pennsylvania, 220 Towne Bldg, 220 S 33rd St, Philadelphia PA 19104)*. Int J Solids Struct 30(14) 1865-1890 (1993).

In this paper, we make use of a procedure for estimating the effective properties of nonlinear composite materials, proposed recently by Ponte Castaneda, to study the effective constitutive behavior of ductile, fiber-reinforced composites. Both estimates and rigorous bounds are obtained for the effective energy functions of multiple-phase, fiber composites with general ductile behaviors (in the context of deformation theory of plasticity) for the isotropic constituent phases. The resulting expressions for the energy functions may be differentiated in a straightforward manner to obtain corresponding estimates for the anisotropic effective stress-strain relations. Explicit calculations are carried out for the case of an aluminum-matrix composite reinforced with boron fibers. The results reveal some interesting features distinguishing the constitutive behavior of ductile-matrix, fiber-reinforced composites from that of linear-elastic, fiber-reinforced composites. One such feature is the strong coupling between the dilatational and distortional modes for the ductile fiber composites. Finally, comparisons are made with available experimental data.

10A422. Indentation of laminated filament-wound composite tubes. - S Li, PD Soden, SR Reid *(UMIST, UK)*, MJ Hinton *(DRA RARDE, UK)*. Composites 24(5) 407-421 (Jul 1993).

The FEM has been used to analyse the behavior of thin-walled, 100 mm diameter filament-wound GRP tubes supported on a flat plate and indented with a 50 mm diameter spherical indenter. The tube wall was treated as an angle-ply laminate and a half-tube model was employed with appropriate rotational symmetry conditions. The strain results were compared with those from a quarter-tube monolithic material model (homogeneous throughout and orthotropic with principal axes coincident with the axial and circumferential directions). The theoretical predictions were compared with experimental results. Local resin cracks occurred under the indenter. Two-cover (four-layer), 1 mm thick, ± 55° and ± 75° winding angle tubes finally failed at large indenter displacements by local shell buckling caused by the development of local axial compressive forces some distance away from the indenter. Four-cover (eight-layer), 2 mm thick, ± 55° tubes delaminated under the indenter and failed by shell fracture, again some distance away from the indenter.

10A423. Microstructural image analysis applied to fibre composite materials: A review. - FJ Guild *(Queen Mary & Westfield Col, UK)* and J Summerscales *(Univ of Plymouth, UK)*. Composites 24(5) 383-393 (Jul 1993).

Current definition of the microstructure of fibre-reinforced composite materials is usually limited to the definition of the materials used and the proportion and orientation of the fibres. Significant differences can be achieved within such a definition, particularly in respect of the spatial distribution of fibres within the material. The microstructure-mechanics relationship is gaining importance as the discipline of mesomechanics. Recent advances in computer hardware, and in software for image processing and analysis, have permitted the rapid definition of spatial microstructural parameters. This paper reviews the preparation of samples for optical microscopy and the use of image analysis for the definition of microstructure in fibre-reinforced composites.

10A424. Modeling damage in plain weave fabric-reinforced composite material. - DM Blackletter *(Univ of Idaho, Moscow ID 83843)*, DE Walrath, AC Hansen *(Univ of Wyoming, Laramie WY 82071)*. J Composite Tech Res 15(2) 136-142 (Sum 1993).

A method for describing damage propagation in a woven fabric-reinforced composite material subjected to tension or shear loading is presented. A 3D unit cell description of a plain weave graphite-epoxy fabric reinforced composite was constructed. From this description, FE models were generated. An incremental iterating FE algorithm was developed to analyze loading response. This FE program included capabilities to model nonlinear constitutive material behavior and a scheme to estimate the effects of damage propagation by stiffness reduction. Tension and shear loadings were modeled. Results from the FE analysis compared favorably with experimental data. Nonlinear shear stress-strain behavior of the fabric composite was shown to be principally caused by damage propagation rather than by plastic deformation of the matrix.

10A425. Review of recent research in the former Soviet Union on fibrous composites. - RP Dickenson *(Univ of Greenwich, UK)* and MR Hill *(Loughborough Univ of Tech, UK)*. Composites 24(5) 379-382 (Jul 1993).

Research into fibrous composites in the former Soviet Union is reviewed for the period 1982-1992. Carbon-carbon materials were used widely in the Soviet space program and had comparable properties to Western composites, although production methods were inferior. Metal-matrix materials also has properties up to Western levels; a significant amount of research was found on the fibre-matrix interface. Research on ceramic-ceramic composites was at a very early stage.

10A426. Simple material model for unidirectionally aligned fiber reinforced composites. - SFM Abd-El-Naby *(3 Iashac Yacoub St, Zamalek 11211, Cairo, Egypt)*, L Hollaway, M Gunn *(Dept of Civil Eng, Univ of Surrey, Guildford, Surrey GU2 5XH, UK)*. Composite Struct 24(4) 323-331 (1993).

A material model for the nonlinear behavior of composite materials is proposed. The model combines the linear elastic fiber properties with the nonlinear behavior of the matrix in order to obtain the average properties of the composite. The interaction between the fiber and the matrix is considered using stress partitioning factors, which are based on the experimental behavior of the material.

10A427. Some further considerations of the theory of fibre debonding and pull-out from an elastic matrix Part 1. Constant interfacial frictional shear stress. - SY Fu *(Inst of Metal Res, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, BL Zhou *(Inst of Metal Res and Int Center for Mat Phys, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, X Chen, CF Xu *(Inst of Metal Res, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, GH He, CW Lung *(Inst of Metal Res and Int Center for Mat Phys, Acad Sinica, Shenyang 110015, Peoples Rep of China)*. Composites 24(1) 5-11 (1993).

In this paper, some further considerations of the theory of fibre debonding and pull-out from an elastic matrix are performed. The form of the fibre tensile stress and of the interfacial shear stress disbribution along the embedded fibre length is determined and its dependence on fibre and matrix elastic properties, fibre volume fraction and embedded fibre length is shown for each case. According to this theory, the fibre-matrix interface can start to debond from the loaded fibre end and/or the embedded fibre end. The maximum fibre pull-out stress necessary to cause complete debonding and eventual pull-out is determined and its dependence on fibre and matrix elastic properties, fibre volume fraction, embedded fibre length and the ratio between the frictional shear stress and the interfacial shear strength is described in detail. This theory can be used to determine easily the shear strength of the interfacial bond and the interfacial frictional shear stress.

10A428. Some further considerations of the theroy of fibre debonding and pull-out from an elastic matrix Part 2. Non-constant interfacial frictional shear stress. - SY Fu *(Inst of Metal Res, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, BL Zhou *(Inst of Metal Res and Int Center for Mat Phys, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, X Chen *(Inst of Metal Res, Acad Sinica, Shenyang 110015, Peoples Rep of China)*, GH He, CW Lung *(Inst of Metal Res and Int Center for Mat Phys, Acad Sinica, Shenyang 110015, Peoples Rep of China)*. Composites 24(1) 13-17 (1993).

Solutions for fibre debonding and pull-out from an elastic matrix have previously been obtained under the condition that the interfacial frictional shear stress is independent of the bond length. However, this condition is not strictly valid. In this paper, an analysis of fibre debonding and pull-out is carried out by considering the dependence of the interfacial frictional shear stress on bond length. The maximum fibre pull-out stress necessary to cause complete debonding and eventual pull-out is determined to be dependent on the fibre-to-matrix elastic modulus ratio, the interfacial shear strength, the interfacial frictional coefficient, the fibre volume fraction and the embedded fibre length. Excellent agreement between the present theoretical analyses and existing experimental results is obtained.

10A429. 3D FE progressive failure analysis of composite laminates under axial extension. - YS Reddy *(Dept of Eng Sci and Mech, VPI)* and JN Reddy *(Dept of Mech Eng, Texas A&M Univ, College Station TX 77843)*. J Composite Tech Res 15(2) 73-87 (Sum 1993).

A 3D progressive failure algorithm is developed where the Layerwise Laminate Theory of Reddy is used for kinematic description. The FE model based on the layerwise theory predicts both inplane and interlaminar stresses with the same accuracy as that of a conventional 3D FE model. Besides, it provides a convenient format for modeling the 3D stress fields in composite laminates. The progressive failure algorithm is based on the assumption that the material behaves like a stable progressively fracturing solid. The stiffness reduction is carried out at the reduced integration gauss points of the FE mesh depending on the mode of failure. A parametric study is conducted to investigate the effect of out-of-plane material properties, 3D stiffness reduction methods, and boundary conditions on the failure loads and strains of a composite laminate under axial extension. The results indicate that different parameters have a different degree of influence on the failure loads and strains. Finally, the predictive ability of various phenomenological failure criteria is evaluated in the light of experimental results available in the literature, and the predictions of the Layerwise Laminate Theory are compared with those of the First-Order Shear Deformation Theory. The study concludes that the 3D stress analysis is necessary to predict accurately the failure behavior of composite laminates.

10A430. Adhesion improvement in polypropylene-aluminum laminates. - W Chinsirikul, TC Chung, IR Harrison *(Polymer Sci Program, Dept of Mat Sci and Eng, Penn State)*. J Thermoplastic Composite Mat 6 18-28 (Jan 1993).

Laminates or laminar composites provide materials with useful mechanical properties. There are many possible combinations of materials, and desired laminate properties can often be achieved by choosing appropriate components. In this study, polymer-metal laminates were selected as potential materials of interest, since such laminates should combine the drawability of polymers and the high modulus of metal. The matrix chosen is polypropylene (PP), and the reinforcing element is aluminum (Al); this pair was selected as part of a search for materials with exceptional specific properties.

10A431. Analysis of delamination in cross-ply laminates initiating from impact induced matrix cracking. - SA Salpekar *(Anal Services and Mat, Hampton VA 23666)*. J Composite Tech Res 15(2) 88-94 (Sum 1993).

Several 2D FE analyses of $(0_2/90_8/0_2)$ glass-epoxy and graphite-epoxy composite laminates were performed to investigate some of the characteristics of damage development due to an impact load. A cross section through the thickness of the laminate with fixed ends, and carrying a transverse load in the center, was analyzed. Inclined matrix cracks, such as those produced by a low-velocity impact, were modeled in the 90° ply group. The introduction of the matrix cracks caused large interlaminar tensile and shear stresses in the vicinity of both crack tips in the 0/90 and 90/0 interfaces. The large interlaminar stresses at the ends of the matrix cracks indicate that matrix cracking may give rise to delamination. The ratio of Mode I to total strain energy release rate, G_I/G_{total}, at the beginning of delamination, calculated at the two (top and bottom) matrix crack tips was 60 and 28%, respectively, in the glass-epoxy laminate. The corresponding ratio was 97 and 77% in the graphite-epoxy laminate. Thus, a significant Mode I component of strain energy release rate may be present at the delamination initiation due to an impact load. The value of strain energy release rate at either crack tip increased due to an increase in the delamination length at the other crack tip and may give rise to an unstable delamination growth under constant load.

10A432. Analysis of matrix cracking and local delamination in $(0/\theta/-\theta)_s$ graphite epoxy laminates under tensile load. - SA Salpekar *(Anal Services and Mat, Hampton VA 23666-0001)* and TK O'Brien *(US Army Vehicle Struct Directorate, NASA Langley Res Center, Hampton VA 23665)*. J Composite Tech Res 15(2) 95-100 (Sum 1993).

Several 3D element analyses of $(0/\theta/-\theta)_s$ graphite epoxy laminates, where θ = 15, 20, 25, 30, and 45°, subjected to axial tensile load, were performed. The interlaminar stresses in the $\theta/-\theta$ interface were calculated with and without a matrix crack in the central $-\theta$ plies. The interlaminar normal stress changes from a small compressive stress when no matrix crack is present to a high tensile stress at the intersection of the matrix crack and the free edge. The analysis of the local delamination from the $-\theta$ matrix crack indicates a high strain energy release rate and a localized Mode I component near the free edge, within one-ply distance from the matrix crack. To examine the stress state causing the matrix cracking, the maximum principal normal stress in a plane perpendicular to the fiber direction in the $-\theta$ ply was calculated in an uncracked laminate. The corresponding shear stress parallel to the fiber was also calculated. The principal normal stress at the laminate edge increased through the ply thickness and reached a very high tensile value at the $\theta/-\theta$ interface indicating that the crack in the $-\theta$ ply may initiate at the $\theta/-\theta$ interface. Predicted crack profiles on the laminate edge in the $-\theta$ ply were constructed from the principal stress directions. The cracks were found to be more curved for layups with smaller θ angles, which is consistent with experimental observations in the literature.

10A433. Composite sandwich construction with syntactic foam core. A practical assessment of post-impact damage and residual strength. - C Hiel, D Dittman, O Ishai *(EEM Branch, NASA Ames Res Center, Moffet Field CA 94035)*. Composites 24(5) 447-450 (Jul 1993).

The purpose of this note is to report on a successful inspection method for sandwich panels with syntactic foam core and to summarize a procedure for the practical assessment of post-impact damage and residual strength.

10A434. First-ply failure of laminated composite plates. - D Bruno, G Spadea, R Zinno *(Dept of Struct Eng, Univ of Calabria, 87030 Arcavacata di Rende, Cosenza, Italy)*. Theor Appl Fracture Mech 19(1) 29-48 (Jun 1993).

Composite laminates offer superior carrying capacity. Reliable application of such structures requires a knowledge of their stress-strain and failure behavior. Past treatments involved assumptions in both the stress and failure analyses; they become increasingly more difficult when the failure of the microstructure constituents is to be included in the continuum analysis of the laminates. Recognizing the conventional failure criteria used for composite material analyses, this work adopts the first-ply failure criterion by application of a polynomial function and the FE procedure. The laminates are modeled by the Reissner-Mindlin plate theory that accounts for moderate rotation. This is because shear effects are more pronounced in composite laminates whose transverse shear modulus is low relative to the Young's modulus. Failure loads are obtained for different laminate thicknesses, stacking sequences and aspect ratios and different failure criteria. The results show that predictions made from the maximum stress criterion are nearly the same as the other, except for those obtained by the Hill criterion.

10A435. Indentation-flexure and low-velocity impact damage in graphite epoxy laminates. - YS Kwon and BV Sankar *(Dept of Aerospace Eng Mech and Eng Sci, Univ of Florida, Gainesville FL 32611-2031)*. J Composite Tech Res 15(2) 101-111 (Sum 1993).

Static indentation-flexure and low-velocity impact tests were performed on quasi-isotropic and cross-ply graphite-epoxy composite laminates. The load-deflection relations in static tests and impact force history in impact tests were recorded. The damage was assessed by using ultrasonic C-scanning and photo-micrographic techniques. Some features of the static behavior were explained by simple analytical models. A good correlation existed between the load-deflection curves for static and impact loading. It was found that results from a few static indentation-flexure tests can be used to predict the impact force history and delamination radius in composite laminates due to low-velocity impact.

10A436. Interlaminar stresses around hole boundaries of composite laminates subjected to in-plane loading. - WJ Yen and C Hwu *(Inst of Aeronaut and Astronaut, Natl Cheng Kung Univ, Tainan, Taiwan 70101 ROC)*. Composite Struct 24(4) 299-310 (1993).

Due to the complex stress state near the curvilinear edge of composite laminates, 3D FE analysis is usually applied even if it is time consuming. In this paper, in order to save computer time and storage, an asymptotic analysis is employed to separate the 3D problem into two plane problems. One is an interior problem, the other is a boundary layer problem. The former is treated by classical lamination theory and is solved by a special BE, the latter is then solved by the FE developed for the generalized plane deformation problems. When the ratio of laminate thickness to hole diameter is small, the solutions for the laminates containing a circular hole are in good agreement with those obtained by the 3D FEM.

10A437. Sublaminate analysis method for predicting disbond and delamination loads in composite structures. - G Flanagan *(Grumman Aircraft Syst Div, MS B44-35, Bethpage NY 11714)*. J Reinforced Plastics Composites 12(8) 876-887 (Aug 1993).

A novel analysis method has been developed with the goal of providing accurate assessments of the forces that can delaminate composite laminates and bonded structures. The method uses interconnecting high-order plates to represent the cross section of a structural element. The plates can be both stacked and connected end-to-end. When stacked, the interfacial tractions generated between the plates can be calculated, providing a measure of the delamination stresses. The plate equations are solved exactly, thus giving accurate numerical results even in cases where the stress gradients are steep. The plate theory used incorporates a linear distribution through the thickness for the u, v, and w displacements. This set of assumed displacements makes the plate shear deformable, and allows stretching in the thickness direction. Consequently, both shearing and normal tractions can be computed at the interfaces between stacked plates.

256J. MICROMECHANICS

10A438. Micromechanics as a basis of random elastic continuum approximations. - M Ostoja-Starzewski *(Dept of Mat Sci and Mech, Michigan State Univ, E Lansing MI 48824-1226)*. Probab Eng Mech 8(2) 107-114 (1993).

The problem of the determination of stochastic constitutive laws for input to continuum-type boundary value problems is analyzed from the standpoint of the micromechanics of polycrystals and matrix-inclusion composites. Passage to a sought-for random continuum is based on a scale dependent window playing the role of a Representative Volume Element (RVE). It turns out that an elastic microstructure with piecewise continuous realization of random tensor fields of stiffness cannot be uniquely approximated by a random field of stiffness with continuous realizations. Rather, two random continuum fields may be introduced to bound the material response from above and from below. As the size of the RVE relative to the crystal size increases to infinity, both fields converge to a deterministic continuum with a progressively decreasing strength of fluctuations. Since the RVE corresponds to a single FE cell not infinitely larger than the crystal size, two random fields are to be used to bound the solution of a given boundary value problem at a given scale of resolution. The method applies to a number of other elastic microstructures, and provides the basis for stochastic finite differences and elements. The latter point is illustrated by an example of a stochastic boundary value problem of a heterogeneous membrane.

256L. MACROSCOPIC CHARACTERIZATION

10A439. Effective elastic moduli of microcracked composite materials. - Y Huang, KX Hu, A Chandra *(Dept of Aerospace and Mech Eng, Univ of Arizona, Tucson AZ 85721)*. Int J Solids Struct 30(14) 1907-1918 (1993).

The self-consistent mechanics method has been widely used to estimate the macroscopic elastic moduli of solids containing microvoids and inclusions. Another method based on the crack energy release and potential energy balance has also been used to estimate the overall elastic moduli of a microcracked solid. It is shown here that these two approaches are equivalent for microcracked solids, thus one can take advantage of both methods to estimate the elastic moduli of inclusion-crack-matrix composites, ie, microcracked composite material. A solid containing spherical inclusions and randomly distributed penny-shaped cracks is then studied. The effective elastic moduli of a solid with spherical inclusions and parallel-distributed penny-shaped cracks are also studied. It is established that the effects of inclusions and microcracks on overall moduli are approximately decoupled for stiff inclusions, which are in most metal matrix composites. This conclusion is particularly useful since one may then obtain the moduli of composites by a simple two-step estimation. For compliant inclusions, including the limiting cases of voids, the decoupling does not hold.

10A440. Mechanical properties of non-crimped fabric-based composites. - PJ Hogg, A Ahmadnia, FJ Guild *(Queen Mary & Westfield Col, UK)*. Composites 24(5) 423-432 (Jul 1993).

The mechanical properties of composites prepared from two types of non-crimped fabric (NCF), namely biaxial, ± 45° and quadriaxial with a 0°, ± 45°, 90°, - 45° ply sequence, are examined as a function of fabric weight and compared with those of alternative composite forms. In general, the properties of NCF laminates decrease slightly as the areal weight of the fabric increases. Laminates produced from biaxial fabrics exhibit superior properties for a given volume fraction of reinforcement than do laminates produced using woven rovings or continuous fibre prepregs, while quadriaxial NCF laminates have equivalent properties to woven roving laminates at certain orientations but, unlike woven roving laminates, retain their properties when rotated through 45°. Biaxial NCFs loaded at 45° to the fibre and quadriaxial fabrics produce composites with superior properties to those predicted using FE and laminate analysis for idealized laminates based on the same results.

10A441. Mechanical properties of squeeze-cast zinc alloy matrix composites containing α-alumina fibres. - HX Zhu and SK Liu *(SW Jiatong Univ, Peoples Rep of China)*. Composites 24(5) 437-442 (Jul 1993).

α-Alumina fibre-reinforced ZA12 alloy matrix composites, with fibre volume fractions ranging from 7.5 to 30% were manufactured by squeeze casting. The alumina fibres were homogeneously distributed in the matrix and had a planar-random orientation. Mechanical properties of the composites such as hardness, tensile strength, Young's modulus, elongation and wear resistance were measured and the effect of fibre volume fraction on these properties was investigated. At room temperature the hardness, Young's modulus and wear resistance increased with increasing volume fraction of alumina fibres, but the other properties were inferior. At elevated temperature (above 80° C) the tensile strengths of the composites were higher than that of the matrix alloy.

10A442. Mechanical properties of triaxially braided composites: Experimental and analytical results. - JE Masters *(Lockheed Eng and Sci, NASA Langley Res Center, Mail Stop 188E, Hampton VA 23681)*, RL Foye *(Dept of Mech Eng, N Carolina A&T State Univ, Greensboro NC 27411)*, CM Pastore *(Dept of Textile Eng Chem and Sci, N Carolina State Univ, NCSU Box 8301, Greensboro NC 27695-8301)*, YA Gowayed *(Dept of Textile Eng, Auburn Univ, NCSU Box 8301, Auburn AL 36849)*. J Composite Tech Res 15(2) 112-122 (Sum 1993).

This paper investigates the unnotched tensile properties of 2D triaxial braid-reinforced composites from both an experimental and an analytical viewpoint. The materials are graphite fibers in an epoxy matrix. The unit cell structure of the triaxial braid was discussed with the assistance of computer analysis of the microgeometry. Photomicrographs of braid geometry were used to improve upon the computer graphics representations of unit cells. These unit cells were used to predict the elastic moduli with various degrees of sophistication. The simple and the complex analyses were generally in agreement, but none adequately matched the experimental results for all the braids.

10A443. Sensitivities and optimal design of hexagonal array fiber composites with respect to interphase properties. - SN Gulrajani and S Mukherjee *(Dept of Theor and Appl Mech, Cornell)*. Int J Solids Struct 30(15) 2009-2026 (1993).

The focus of this paper is the calculation of sensitivities of stresses at an interphase between a fiber and matrix, in a hexagonal cell of a fiber-reinforced composite, with respect to interphase stiffnesses, and the use of these sensitivities to carry out optimal design of the interphase stiffnesses. The interphase is modeled here as a spring layer. Sensitivities are of interest in the design of composites since interphase properties can substantially affect the mechanical and thermal behavior of the composite. The sensitivity calculations are carried out here by using the direct differentiation approach of the corresponding BEM formulation of the problem. Optimization calculations are carried out by coupling the standard and sensitivity analyses to an optimizer. The optimizer chosen here uses sequential quadratic programming to obtain the desired optimal values of interphase stiffnesses that minimize the possibility of failure of a composite under prescribed loading. Numerical results for sensitivities and optimization, for some illustrative examples, are presented in this paper.

10A444. Volume resistivity and mechanical properties of electrically conductive long fiber composites. - ME Weber and MR Kamal *(Polymer McGill, Dept of Chem Eng, McGill Univ, 3480 Univ St, Montreal PQ, H3A 2A7, Canada)*. J Reinforced Plastics Composites 12(8) 844-853 (Aug 1993).

Long, electrically conductive nickel-coated graphite fibers were employed to produce thermoplastic composites by compounding and processing with polypropylene resin. The fibers were blended into the resin in a Brabender mixer and the resulting composite was compression molded into square plaques. The fiber loading was varied from 2 to 20 weight percent. The effects of fiber loading on electrical and impact properties were studied and related to the composite microstructure. A device was constructed to measure the volume resistivity of the samples in two planes, longitudinal and latitudinal. A large initial density in resistivity occurs as fibers are added to the insulating matrix. Beyond some critical loading, the resistivity reaches a minimum and begins to level off. The resistivity is identical in the two perpendicular planes. Examination of the microstructure reveals that the fiber orientation is fairly random in the composite, which results in a uniform resistivity in two planes. Fiber attrition is more significant at low loadings where the mixing shear is greater. Impact tests show that the addition of the fiber results in an increase in sample stiffness, thereby reducing the force and energy needed to break the samples.

10A445. Comparison of eight variations of a higher-order theory for cylindrical shells. - RA Smith *(Flight Vehicles Branch, Weapons Flight Mech Div, Wright Lab, Elgin Air Force Base FL 32542)* and AN Palazotto *(Aeronaut and Astronaut Dept, Air Force IT, WPAFB)*. AIAA J 31(6) 1125-1132 (Jun 1993).

Eight variations of a geometrically nonlinear higher-order transverse shear deformation (HTSD) theory were developed for composite shells. Three attributes were varied to produce the eight variations. These attributes included: 1) the order of the thickness expansions used to approximate the shell shape factors, 2) the order of the assumed linear displacement field, and 3) the nonlinearity of transverse shear strain. Several cylindrical shell problems were investigated using a FE code with a 36-dof cylindrical shell element. MACSYMA, a symbolic manipulation code, was used to formulate the element independent stiffness arrays for each variation of the theory. When all nonlinear strain displacement terms for transverse shear were included for thin shallow isotropic cylindrical shells, the theory predicted a more flexible response during collapse. Higher-order thickness expansions had negligible effect on results. For deep shells nonlinearity was limited to in-plane strain-displacement relations. This quasinonlinear HTSD theory produced a more flexible response during collapse when the order of approximation of shell shape factor terms was increased.

10A446. Interlaminar stresses around a hole in symmetric cross-ply laminates under bending-torsion. - Chu-Cheng Ko and Chien-Chang Lin *(Inst of Appl Math, Natl Chung-Hsing Univ, Taichung, Taiwan 40227, ROC)*. AIAA J 31(6) 1118-1124 (Jun 1993).

An efficient approximate solution for calculating the complete state of stress around a circular hole in symmetric cross-ply laminates under a set of far-field bending and torsion is presented. This approach is based on the boundary-layer theory in conjunction with Lekhnitskii's solutions for anisotropic plates and the principle of minimum complementary energy. All of the boundary conditions around the hole edge of each ply and traction continuity at the ply interface are exactly satisfied. Numerical examples are compared with the NASTRAN FE solutions to demonstrate the efficiency and accuracy of the current method.

10A447. Performance enhancement of concrete through the use of waste injection molding pellets: A preliminary study of viability. - B Lennon, VM Karbhari, H Allen *(Center for Composite Mat and Dept of Civil Eng, Univ of Delaware, Newark DE 19716)*. J Thermoplastic Composite Mat 6 49-61 (Jan 1993).

The recycling of advanced polymers and composites is a major problem facing the composites industry due not only to problems related to the actual process itself but also to liability issues associated with reuse. This article presents the initial results of an ongoing investigation aimed at the reuse of waste pellets as aggregate in concrete to increase the compression strength and ductility of the resulting concrete. A variety of glass-filled materials, including nylon, polycarbonate, and polypropylene - as well as unreinforced polymers such as PET and PEEK - were used. Materials were substituted for traditional stone aggregate at a range of levels including complete replacement. Results demonstrate the viability of such use, and the article discusses implications in terms of future applications, as well as advances needed, in order to make this approach a reality.

Use of piezoelectric films in detecting and monitoring damage in composites. - SC Galea, WK Chiu, JJ Paul *(Defense Sci and Tech Org, Aeronaut Res Lab, Aircraft Struct and Mat Div, 506 Lorimer St, Fishermens Bend 3207, Victoria, Australia)*. J Intelligent Mat Syst Struct 4(3) 330-336 (Jul 1993).

The increasing emphasis over the past few years on intelligent material systems and structures has resulted in a significant research effort in the areas of embedded and bonded sensors and actuators. Of the many sensing materials available, piezoelectric sensors offer a number of advantages. The sensor output, proportional to changes in surface displacement over a large area, can be used to interpret variations in structural and material properties, ie, the compliance of the material. This type of sensor has also been used as an ultrasonic transducer. It offers the advantage of having a low structural impedance, thus giving an accurate measurement of the change in area, and consequently can only be used as an actuator on flexible structural systems. The aim of this article is to demonstrate the use of piezoelectric film sensors such as a structural integrity monitoring device for composite materials.

In order to apply the maximum thermal stress equation to water-quenching thermal shock tests of ceramics in practice, a novel method for evaluating the heat transmission behavior and measuring the effective heat transfer coefficient was proposed. Zirconia ceramic, whose heat conductivity does not change over a wide temperature range, was used for the study. In this experiment, the change of temperature at two different positions in the specimen was measured after water quenching. The dependences of heat transmission behavior on time and surface temperature were discussed. The present method made it possible to obtain the effective heat transfer coefficient data which clarify the relationship between the intrinsic properties of ceramics and the critical quenching temperature difference.

10A451. Interactions among cracks and rigid lines near a free surface. - Kai Xiong Hu and Abhijit Chandra *(Dept of Aerospace and Mech Eng, Univ of Arizona, Aero Bldg 16, Tucson AZ 85721)*. Int J Solids Struct 30(14) 1919-1937 (1993).

Cracks and rigid-line inclusions, or anticracks, are commonly observed in many engineering materials, such as intermetallics and ceramic composites. Interactions among these cracks and rigid lines can significantly affect the strength of these materials. Strength degradation due to finishing operations, such as grinding, also depend to a large extent on these interactions near a free surface and their associated surface and subsurface damage evolutions. Accordingly, modeling of interactions among general systems of cracks and rigid lines in the vicinity of a free surface, subject to general loading conditions, is the main thrust of this paper. An integral equation approach based on the fundamental solutions due to point loads and point dislocations in an elastic half space is utilized for this purpose. The integral equations are reduced to a system of linear equations consisting of the distributions of Burger's dislocation vectors and forces on the cracks and the anticracks, respectively. The proposed solution procedure also allows direct determination of the rigid-body rotations for the rigid lines. The results obtained from the present analysis are first verified against existing results for a single crack or rigid line near a free surface. The amplification and shielding effects on stress intensity factors due to interactions among various distributions of cracks and rigid lines are then investigated. Such interactions near a free surface play crucial roles in surface and subsurface damage evolutions during high-speed machining of ceramic materials.

10A452. Length effect of rods under three-point bending for determining the Weibull parameters of brittle materials. - SL Fok and J Smart *(Dept of Eng, Univ of Manchester, Manchester M13 9PL, UK)*. Probab Eng Mech 8(2) 67-73 (1993).

Brittle materials, such as ceramics, are commonly characterized using two parameters: one is a measure of the strength, the other a measure of the scatter. To determine these parameters three-point bending tests of circular rods are often used and the parameters determined using simple bending theory. However, the simple bending theory can be a poor representation of the stresses near the loading point particularly for small length:diameter ratio. To overcome the shortcomings of the simple theory, FE analyses have been performed for rods of varying length:diameter ratio and correction factors for the simple theory have been determined. These factors depend on both the length:depth ratio and the material property defining the scatter.

10A454. Overview on polymer composites for friction and wear application. - K Friedrich, Z Lu, AM Hager *(Inst for Composite Mat, Univ of Kaiserslautern, D-6750 Kaiserlautern, Germany)*. Theor Appl Fracture Mech 19(1) 1-11 (Jun 1993).

Composite materials are used more frequently as structural components that are required to sustain friction and wear loadings in service. Many of these composites consist of short fibers embedded in a metallic, polymeric or ceramic matrix. Others have a continuous fiber reinforced structure, arranged in the form of multidirectional laminates or woven fabrics. This overview delves on polymer matrix composites and describes the principal microstructural details of short fiber and thermoplastic matrix composites in addition to their friction and wear properties as a function of both microstructural composition and external testing conditions. Special attention is focussed on the effects of different polymer matrices, fiber reinforcements, and additional internal lubricants on the coefficient of friction and the specific wear rate of these materials when sliding against hard steel counterparts.

10A455. Stiffness characteristics of twisted cords for cord-rubber composites. - RMV Pidaparti *(Dept of Mech Eng, Purdue Univ, Indianapolis IN 46202)*. Composite Struct 24(4) 291-298 (1993).

A FE model is presented to predict the stiffness characteristics of twisted cords by treating them as structures and considering the stiffness couplings due to extension-bending-torsional deformations. The axial, bending, and torsional stiffnesses are calculated for both the aramid-cord and steel-cord, and compared to an approximate expression with good agreement where applicable. To illustrate the stiffness behavior, all three stiffnesses are presented with variations in the number of twists per unit length, the surrounding rubber modulus and the thickness. The stiffness couplings among the extension, bending, and twisting deformations are presented for aramid-cords with varying number of twists per unit length and rubber thickness. The results illustrate that stiffness characteristics are strongly dependent upon the number of twists per unit length, type of cord, surrounding rubber layer thickness, and modulus. The stiffness couplings presented illustrate the mechanisms of load transfer, which are important for understanding failure mechanisms of cords, and cord-rubber composites.

10A456. Vibration welding of polyamide 66. - H Potente, M Uebbing, E Lewandowski *(FB 10-Kunststofftechnologie, Univ GH Paderborn, Pohlweg 47-49, 4749 Paderborn, Germany)*. J Thermoplastic Composite Mat 6 2-17 (Jan 1993).

Working on the basis of a parameter study of standard PA 66 material, comparative investigations were conducted into material modifications using heat stabilizers, glass fibers and minerals. The evaluation criterion applied for the weld quality was the short-time welding factor, this being the quotient of the weld strength and the strength of the base material. With standard material, a weld strength almost equivalent to the strength of the base material was attained. With heat-stabilized and mineral-filled material, the welding factor fell to fs = 0.9. Glass-fiber-reinforced PA achieved a maximum value of fs = 0.58, which, in terms of absolute value, corresponds approximately to the base material strength of standard polyamide. Microtome section investigations show how the different weld results come about.

10A457. Analytical formulae for calculating stresses in unidirectional cross-ply unbalanced laminates. - Zhu Caisheng *(Dept of Mech Eng, Monash Univ, Clayton, Vic 3168, Australia)*, M Heller *(Aeronaut Res Labs, Dept of Defence, Fishermens Bend, Vic 3207, Australia)*, YC Lam *(Dept of Mech Eng, Monash Univ, Clayton, Vic 3168, Australia)*. Composite Struct 24(4) 333-343 (1993).

A multilayer theory has been developed for unidirectional-cross-ply unbalanced laminates subjected to surface shear tractions, using the assumption of plane strain. The analytical solution for the stress field in the laminate is obtained and it is shown that the stresses in each layer are in good agreement with the results of a 3D FE analysis. Approximate formulae for the analytical stresses are also derived for a laminate subjected to an offset distributed force at one end. The accuracy of this solution is shown by comparison with a 3D FE analysis.

10A458. CDI: Linking material property databases to analysis codes. - WJ Rasdorf, LK Spainhour *(Dept of Civil Eng, N Carolina State Univ, Raleigh NC 27695)*, EM Patton, BP Burns *(Mech and Struct Branch, Army Res Lab, Aberdeen Proving Grounds, Aberdeen MD 21005)*. Adv Eng Software 16(3) 145-152 (1993).

Integration among programs designed to solve complex engineering problems is often lacking, and this is particularly a problem in the area of thick composite material analysis, and design where a large volume of input must be provided. Another problem is the lack of an archival repository in which to store input information in a generic format. To address these problems, we have developed a prototype of a FE material property reprocessing system, called the composites database interface (CDI). In this computer-aided analysis system, a materials database is integrated with several software components, including commercially available FE analysis (FEA) programs and preprocessors, and tools for manipulating and using composite materials data, resulting in the transfer of 2D and 3D composite materials property data into an FEA program. This paper presents the capabilities of this system, discusses the overall system integration through R:BASE, and provides a civil engineering application involving the design of a large cylindrical tank to illustrate the execution of the CDI system's various components. The paper ends by discussing the current status of this computer-aided analysis system.

10A459. Review of multiaxial-biaxial loading tests for composite materials. - AS Chen and FL Matthews *(Imperial Col, UK)*. Composites 24(5) 395-406 (Jul 1993).

Multiaxial-biaxial loading tests of fibre-reinforced polymer-matrix composite materials are reviewed, and results of these experimental investigations under both monotonic and cyclic loadings are discussed. It is noted that composite materials could exhibit complicated behavior in the biaxial loading conditions which often exist in engineering practice. The importance of biaxial loading tests of composites is indicated by this assessment.

10A460. Axisymmetric problems of a partially embedded rod with radial deformation. - RYS Pak and AT Gobert *(Dept of Civil, Env and Architec Eng, Univ of Colorado, Boulder CO 80309-0428)*. Int J Solids Struct 30(13) 1745-1759 (1993).

A new mathematical formulation is presented for the analysis of a partially embedded rod under torsionless axisymmetric loadings. With an account of both the axial and radial compatibilities between the rod and the embedding medium through the use of a higher-order rod theory, the 3D load-transfer problem is reduced to a pair of Fredholm integral equations of the second kind whose solutions are computed. By virtue of the present formulation, a variety of physical loading-boundary conditions which were inhibited in past treatments can be evaluated. A comprehensive set of numerical results appropriate to different axial loading conditions, material parameters, and geometric configurations for the problem are provided as illustrations.

10A461. Viscoelastic response of a strand. - TA Conway *(Dept of Mech Eng, Univ of Akron, Akron OH 44325-3903)* and GA Costello *(Dept of Theor and Appl Mech, Univ of Illinois, Urbana IL 61801)*. J Appl Mech 60(2) 534-540 (Jun 1993).

A method is presented in which the axial viscoelastic response of a multiple filament strand, constrained by a no-end rotation boundary condition, may be predicted. This method is an initial attempt to describe the time-dependent response of the multilayer strand by incorporating the stress relaxation data for a linearly viscoelastic construction material. Specifically, a strand consisting of a core filament, six filaments in the second layer, and twelve filaments in the outer layer is analyzed. This analysis could, however, include any number of layers of filaments where each layer has a concentric helix radius. The particular material used in this paper is polymethyl methacrylate (PMMA). The stress relaxation method for PMMA is modeled analytically using the Schapery collocation method which determines the constant coefficient values for the elements of a Wiechert response model. Since this is a first approximation model, the approach is limited to linear viscoelasticity.
