#### **Outline**

- Why is a grid needed?
- Element types.
- Grid types.
- Grid design guidelines.
- Geometry.
- Solution adaption.
- Grid import.

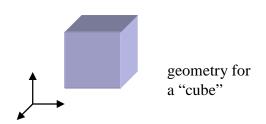

# Why is a grid needed?

- The grid:
  - Designates the cells or elements on which the flow is solved.
  - Is a discrete representation of the geometry of the problem.
  - Has cells grouped into boundary zones where b.c.'s are applied.
- The grid has a significant impact on:
  - Rate of convergence (or even lack of convergence).
  - Solution accuracy.
  - CPU time required.
- Importance of mesh quality for good solutions.
  - Grid density.
  - Adjacent cell length/volume ratios.
  - Skewness.
  - Tet vs. hex.
  - Boundary layer mesh.
  - Mesh refinement through adaption.

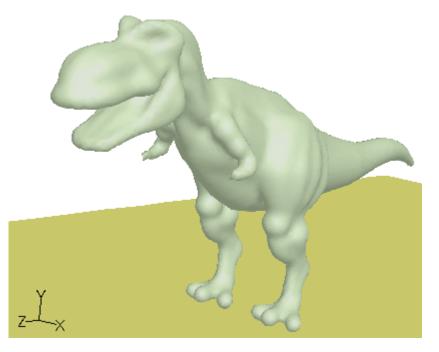

# Geometry

- The starting point for all problems is a "geometry."
- The geometry describes the shape of the problem to be analyzed.
- Can consist of volumes, faces (surfaces), edges (curves) and vertices (points).

Geometry can be very simple...

... or more complex

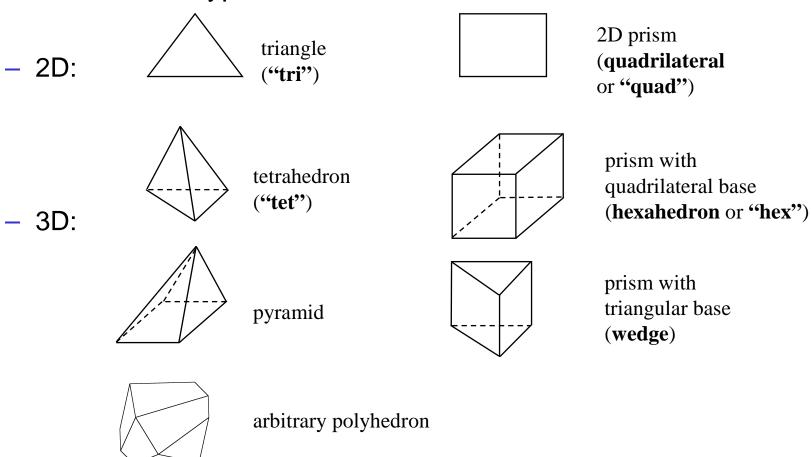

# Geometry creation

- Geometries can be created top-down or bottom-up.
- Top-down refers to an approach where the computational domain is created by performing logical operations on primitive shapes such as cylinders, bricks, and spheres.
- Bottom-up refers to an approach where one first creates vertices (points), connects those to form edges (lines), connects the edges to create faces, and combines the faces to create volumes.
- Geometries can be created using the same pre-processor software that is used to create the grid, or created using other programs (e.g. CAD, graphics).

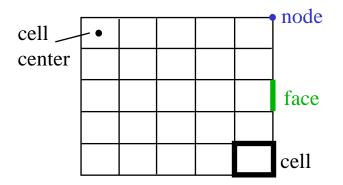

# Typical cell shapes

- Many different cell/element and grid types are available. Choice depends on the problem and the solver capabilities.
- Cell or element types:

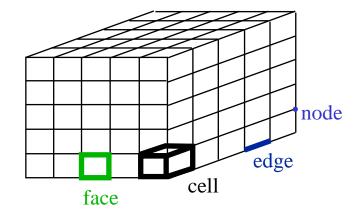

#### **Terminology**

- Cell = control volume into which domain is broken up.
- Node = grid point.
- Cell center = center of a cell.
- Edge = boundary of a face.
- Face = boundary of a cell.
- Zone = grouping of nodes, faces, and cells:
  - Wall boundary zone.
  - Fluid cell zone.
- Domain = group of node, face and cell zones.

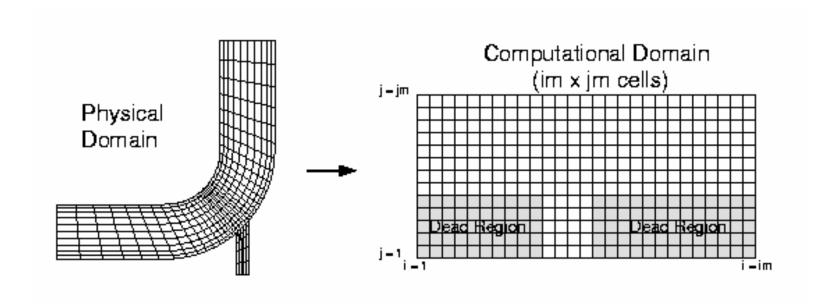

2D computational grid

3D computational grid

# Grid types: structured grid

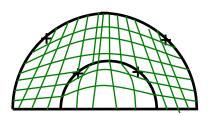

- Single-block, structured grid.
  - i,j,k indexing to locate neighboring cells.
  - Grid lines must pass all through domain.
- Obviously can't be used for very complicated geometries.

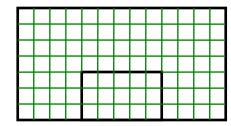

# Face meshing: structured grids

- Different types of hexahedral grids.
- Single-block.
  - The mesh has to be represented in a single block.
  - Connectivity information (identifying cell neighbors) for entire mesh is accessed by three index variables: i, j, k.

Single-block geometry

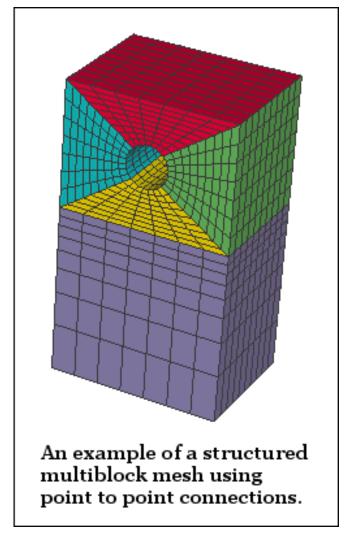

Logical representation.

Single-block meshes may include 180 degree corners.

# Grid types: multiblock

- Multi-block, structured grid.
  - Uses i,j,k indexing within each mesh block.
  - The grid can be made up of (somewhat) arbitrarily-connected blocks.
- More flexible than single block, but still limited.

Source: www.cfdreview.com

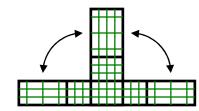

# Face meshing: multiblock

- Different types of hexahedral grids.
  - Multi-block.
  - The mesh can be represented in multiple blocks.

Multi-block geometry

Logical representation.

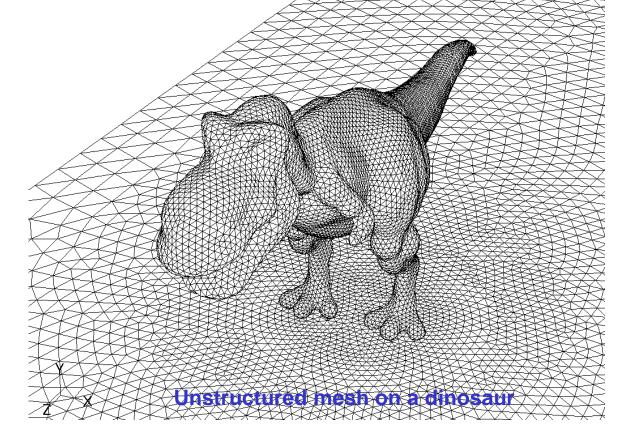

- This structure gives full control of the mesh grading, using edge meshing, with high-quality elements.
- Manual creation of multi-block structures is usually more timeconsuming compared to unstructured meshes.

# Grid types: unstructured

- Unstructured grid.
  - The cells are arranged in an arbitrary fashion.
  - No i,j,k grid index, no constraints on cell layout.

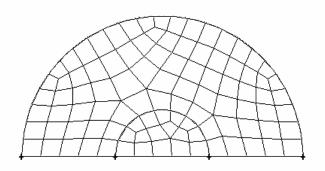

There is some memory and CPU overhead for unstructured

referencing.

# Face meshing: unstructured grids

- Different types of hexahedral grids.
  - Unstructured.
  - The mesh has no logical representation.

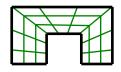

**Unstructured Grid** 

# Face meshing: quad examples

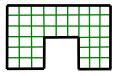

Quad: Map.

Quad: Submap.

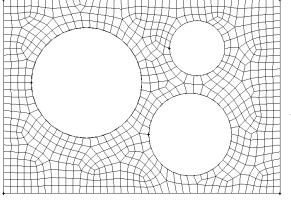

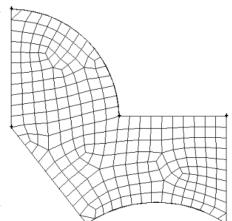

Quad: Tri-Primitive.

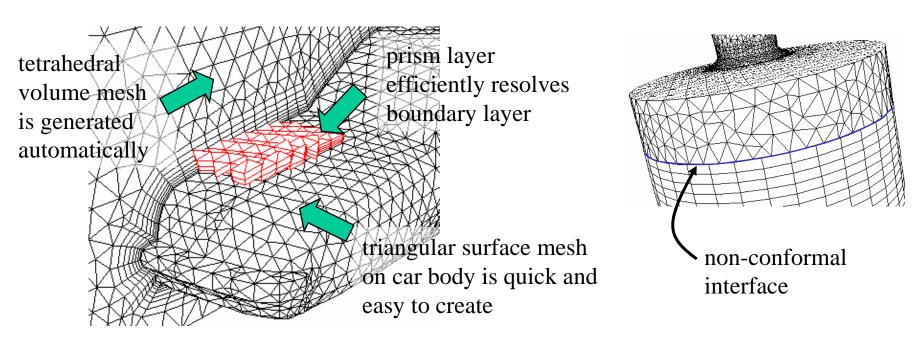

Quad: Pave and Tri-Pave.

# Grid types: hybrid

- Hybrid grid.
  - Use the most appropriate cell type in any combination.
    - Triangles and quadrilaterals in 2D.
    - Tetrahedra, prisms and pyramids in 3D.
  - Can be non-conformal: grids lines don't need to match at block boundaries.

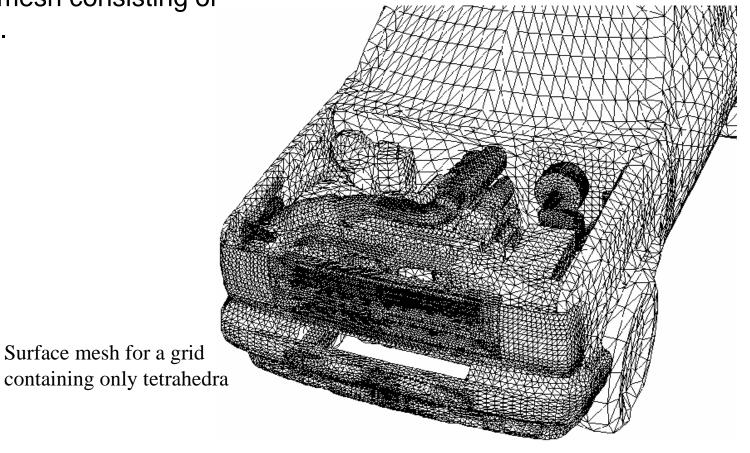

#### Tetrahedral mesh

 Start from 3D boundary mesh containing only triangular faces.

 Generate mesh consisting of tetrahedra.

#### **Complex Geometries**

# Zonal hybrid mesh

- Flow alignment well defined in specific regions.
- Start from 3D boundary and volume mesh:
  - Triangular and quadrilateral faces.
  - Hexahedral cells.
- Generate zonal hybrid mesh, using:
  - Tetrahedra.
  - Existing hexahedra.
  - Transition elements: pyramids.

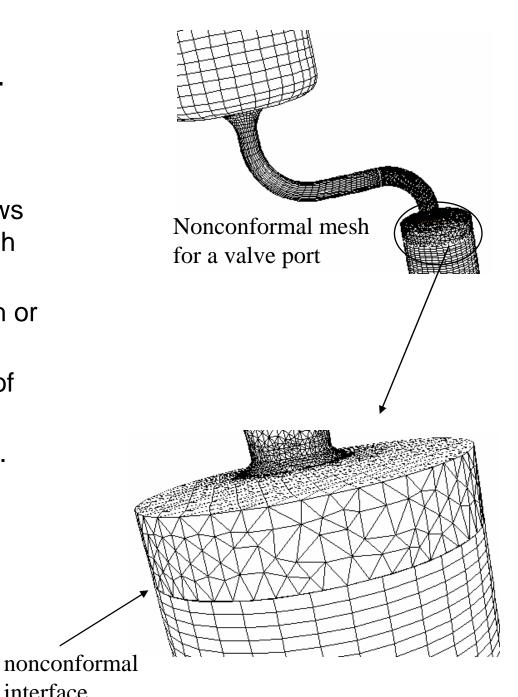

Surface mesh for a grid containing hexahedra, pyramids, and tetrahedra (and prisms)

#### Nonconformal mesh

- Parametric study of complex geometries.
- Nonconformal capability allows you to replace portion of mesh being changed.
- Start from 3D boundary mesh or volume mesh.
- Add or replace certain parts of mesh.
- Remesh volume if necessary.

interface

# Mesh naming conventions - topology

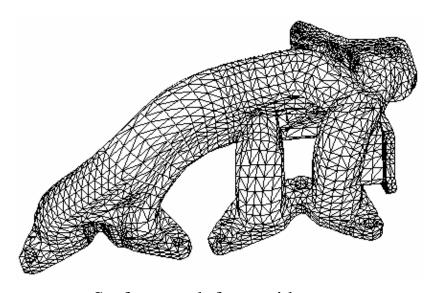

- Structured mesh: the mesh follows a structured i,j,k convention.
- Unstructured mesh: no regularity to the mesh.
- Multiblock: the mesh consists of multiple blocks, each of which can be either structured or unstructured.

# Mesh naming conventions – cell type

- Tri mesh: mesh consisting entirely of triangular elements.
- Quad mesh: consists entirely of quadrilateral elements.
- Hex mesh: consists entirely of hexahedral elements.
- Tet mesh: mesh with only tetrahedral elements.
- Hybrid mesh: mesh with one of the following:
  - Triangles and quadrilaterals in 2D.
  - Any combination of tetrahedra, prisms, pyramids in 3D.
  - Boundary layer mesh: prizms at walls and tetrahedra everywhere else.
  - Hexcore: hexahedra in center and other cell types at walls.
- Polyhedral mesh: consists of arbitrary polyhedra.
- Nonconformal mesh: mesh in which grid nodes do not match up along an interface.

# Mesh generation process

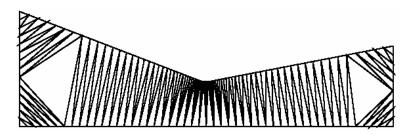

- 1. Create, read (or import) boundary mesh(es).
- 2. Check quality of boundary mesh.
- 3. Improve and repair boundary mesh.
- 4. Generate volume mesh.
- Perform further refinement if required.
- 6. Inspect quality of volume mesh.
- 7. Remove sliver and degenerate cells.
- 8. Save volume mesh.

Surface mesh for a grid containing only tetrahedra

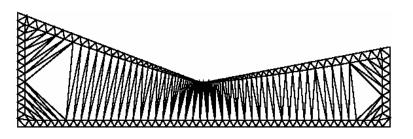

# Tri/tet grid generation process

- Two phases:
  - Initial mesh generation:
     Triangulate boundary mesh.

 Refinement on initial mesh: Insert new nodes.

Boundary refinement

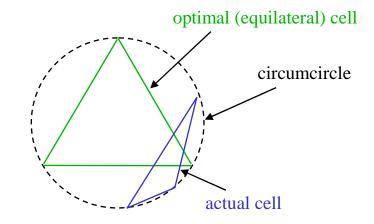

Cell zone refinement

#### Mesh quality

- For the same cell count, hexahedral meshes will give more accurate solutions, especially if the grid lines are aligned with the flow.
- The mesh density should be high enough to capture all relevant flow features.
- The mesh adjacent to the wall should be fine enough to resolve the boundary layer flow. In boundary layers, quad, hex, and prism/wedge cells are preferred over tri's, tets, or pyramids.
- Three measures of quality:
  - Skewness.
  - Smoothness (change in size).
  - Aspect ratio.

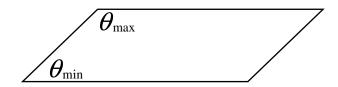

# Mesh quality: skewness

- Two methods for determining skewness:
  - Based on the equilateral volume:
    - Skewness =  $\frac{\text{optimal cell size} \text{cell size}}{\text{optimal cell size}}$
    - Applies only to triangles and tetrahedra.
    - Default method for tris and tets.

- 2. Based on the deviation from a normalized equilateral angle:
  - ormalized equilateral angle:

    Skewness (for a quad) =  $\max \left[ \frac{\theta_{\text{max}} 90}{90}, \frac{90 \theta_{\text{min}}}{90} \right]$
  - Applies to all cell and face shapes.
  - Always used for prisms and pyramids.

#### Equiangle skewness

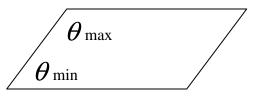

- Common measure of quality is based on equiangle skew.
- Definition of equiangle skew:

$$\max \left[ \frac{\theta_{\text{max}} - \theta_{\text{e}}}{180 - \theta_{\text{e}}}, \frac{\theta_{\text{e}} - \theta_{\text{min}}}{\theta_{\text{e}}} \right]$$

#### where:

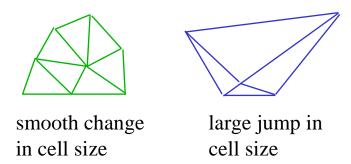

- $-\theta_{max}$  = largest angle in face or cell.
- $-\theta_{min}$  = smallest angle in face or cell.
- $-\theta_{\rm e}$  = angle for equiangular face or cell.
  - e.g., 60 for triangle, 90 for square.
- Range of skewness:

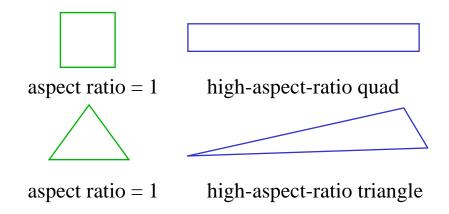

# Mesh quality: smoothness and aspect ratio

Change in size should be gradual (smooth).

 Aspect ratio is ratio of longest edge length to shortest edge length. Equal to 1 (ideal) for an equilateral triangle or a square.

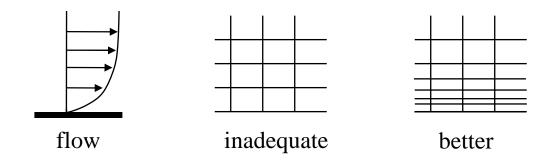

# Striving for quality

- A poor quality grid will cause inaccurate solutions and/or slow convergence.
- Minimize equiangle skew:
  - Hex and quad cells: skewness should not exceed 0.85.
  - Tri's: skewness should not exceed 0.85.
  - Tets: skewness should not exceed 0.9.
- Minimize local variations in cell size:
  - E.g. adjacent cells should not have 'size ratio' greater than 20%.
- If such violations exist: delete mesh, perform necessary decomposition and/or pre-mesh edges and faces, and remesh.

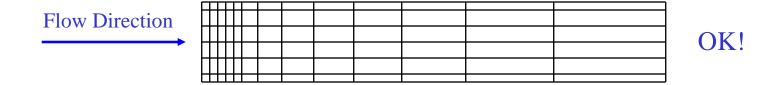

Value of	0-0.25	0.25-0.50	0.50-0.80	0.80-0.95	0.95-0.99	0.99-1.00
Skewness						
Cell Quality	excellent	good	acceptable	poor	sliver	degenerate

# Grid design guidelines: resolution

Pertinent flow features should be adequately resolved.

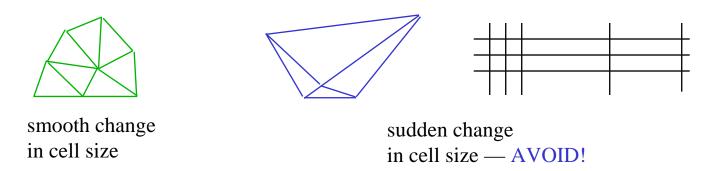

- Cell aspect ratio (width/height) should be near one where flow is multi-dimensional.
- Quad/hex cells can be stretched where flow is fully-developed and essentially one-dimensional.

# Grid design guidelines: smoothness

Change in cell/element size should be gradual (smooth).

Ideally, the maximum change in grid spacing should be <20%:</li>

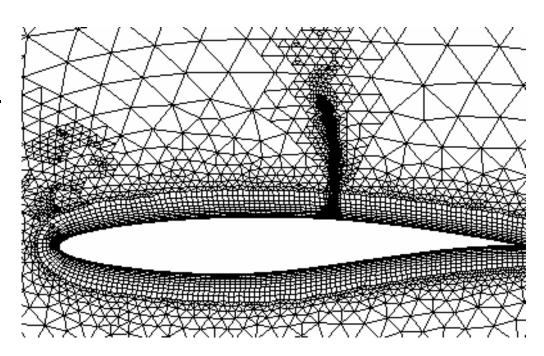

$$\frac{\Delta x_{i+1}}{\Delta x_{i}} \leq 1.2$$

# Grid design guidelines: total cell count

- More cells can give higher accuracy. The downside is increased memory and CPU time.
- To keep cell count down:
  - Use a non-uniform grid to cluster cells only where they are needed.
  - Use solution adaption to further refine only selected areas.
- Cell counts of the order:
  - 1E4 are relatively small problems.
  - 1E5 are intermediate size problems.
  - 1E6 are large. Such problems can be efficiently run using multiple
     CPUs, but mesh generation and post-processing may become slow.
  - 1E7 are huge and should be avoided if possible. However, they are common in aerospace and automotive applications.
  - 1E8 and more are department of defense style applications.

#### Solution adaption

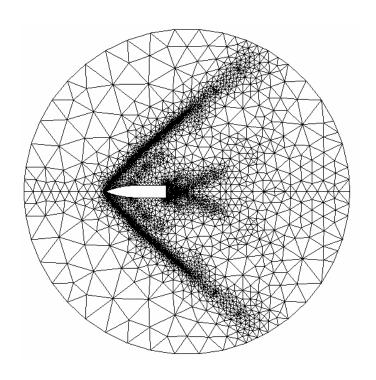

- How do you ensure adequate grid resolution, when you don't necessarily know the flow features? Solution-based grid adaption!
- The grid can be refined or coarsened by the solver based on the developing flow:
  - Solution values.
  - Gradients.
  - Along a boundary.
  - Inside a certain region.

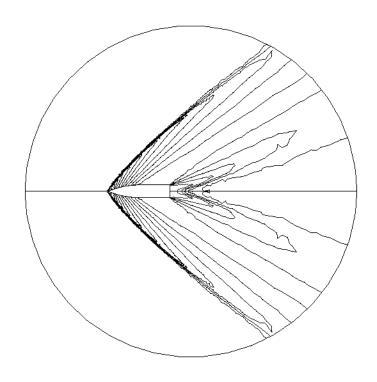

#### **Grid adaption**

- Grid adaption adds more cells where needed to resolve the flow field.
- Fluent adapts on cells listed in register. Registers can be defined based on:
  - Gradients of flow or user-defined variables.
  - Isovalues of flow or user-defined variables.
  - All cells on a boundary.
  - All cells in a region.
  - Cell volumes or volume changes.
  - y<sup>+</sup> in cells adjacent to walls.
- To assist adaption process, you can:
  - Combine adaption registers.
  - Draw contours of adaption function.
  - Display cells marked for adaption.
  - Limit adaption based on cell size and number of cells.

# Adaption example: final grid and solution

2D planar shell - final grid

2D planar shell - contours of pressure final grid

#### Main sources of errors

- Mesh too coarse.
- High skewness.
- Large jumps in volume between adjacent cells.
- Large aspect ratios.
- Interpolation errors at non-conformal interfaces.
- Inappropriate boundary layer mesh.

# **Summary**

- Design and construction of a quality grid is crucial to the success of the CFD analysis.
- Appropriate choice of grid type depends on:
  - Geometric complexity.
  - Flow field.
  - Cell and element types supported by solver.
- Hybrid meshing offers the greatest flexibility.
- Take advantage of solution adaption.
