# Microrganismos e células – comparação dos tamanhos

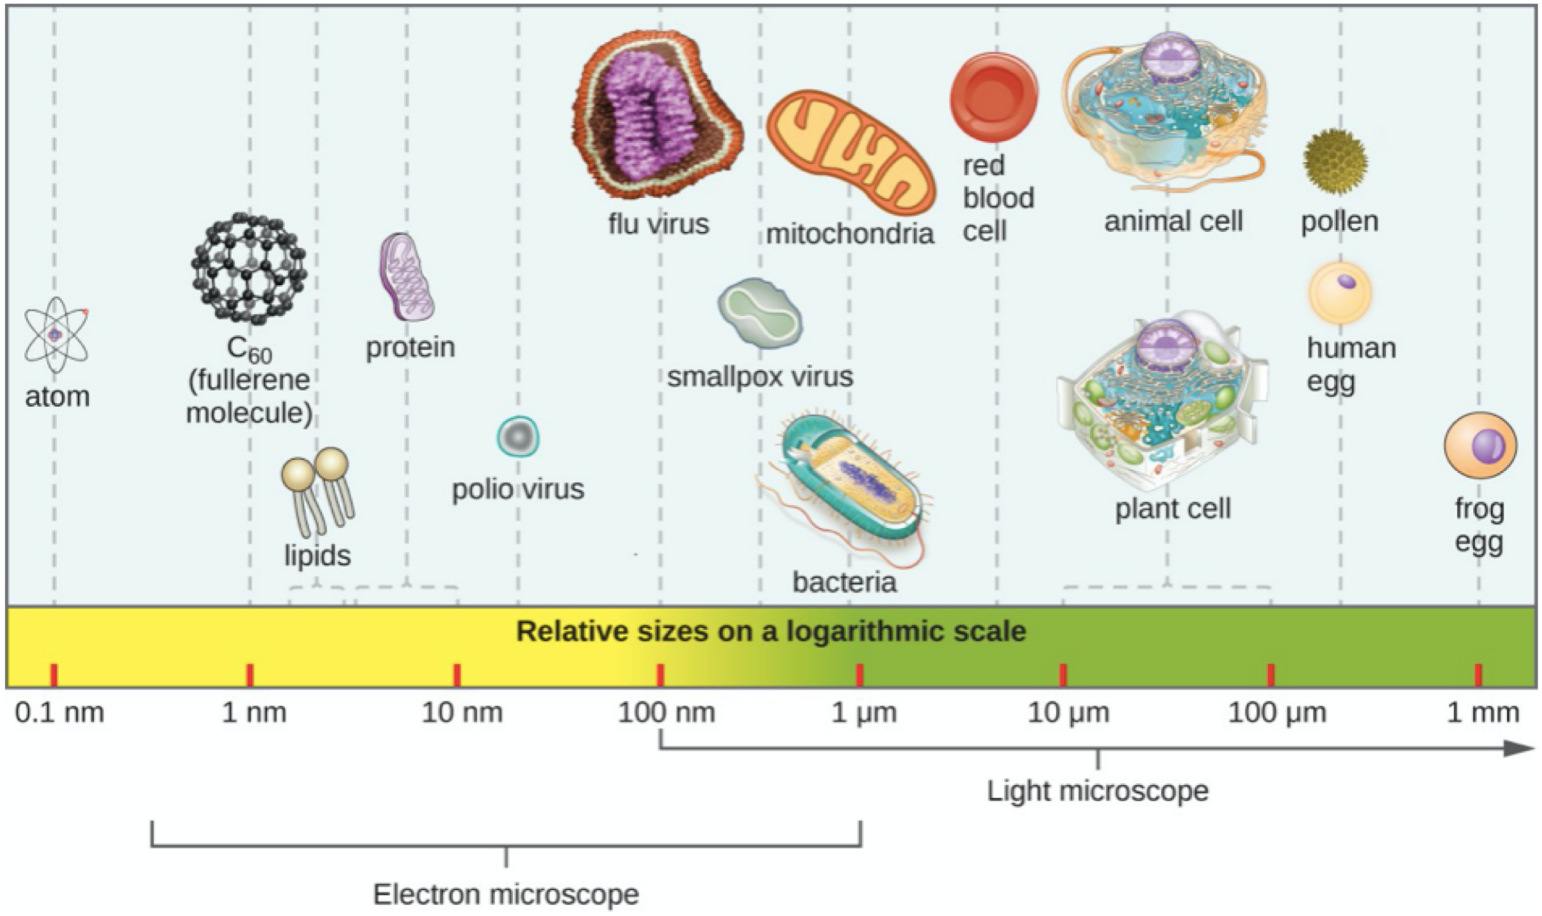

Figure 1. The relative sizes of various microscopic and nonmicroscopic objects. Note that a typical virus measures about 100 nm, 10 times smaller than a typical bacterium (~1 µm), which is at least 10 times smaller than a typical plant or animal cell (~10–100 µm). An object must measure about 100 µm to be visible without a microscope.

# Controle microbiano por UVC – diferentes MOs

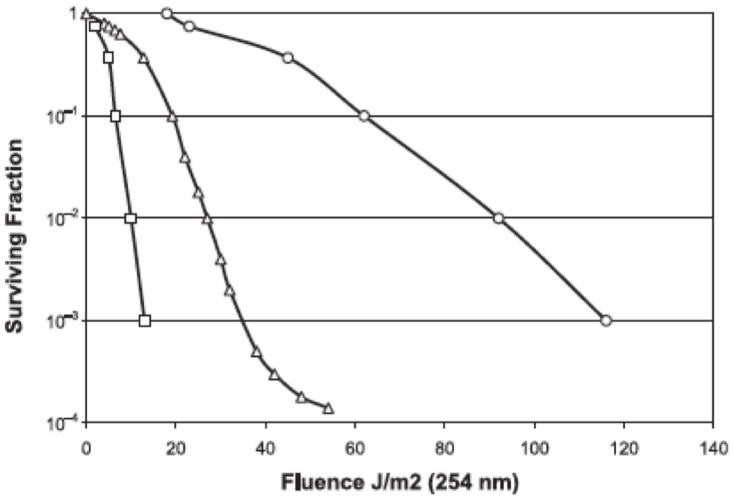

**Figure 2.** Differential UVC (254nm) sensitivity of a wild strain and mutants of *E. coli*. The curves represent the survival of a radiation proficient (B/r, circles) and deficient (Bs, squares) mutant compared to the sensitivity of a wild-type (wt, triangles) *E. coli* (10).

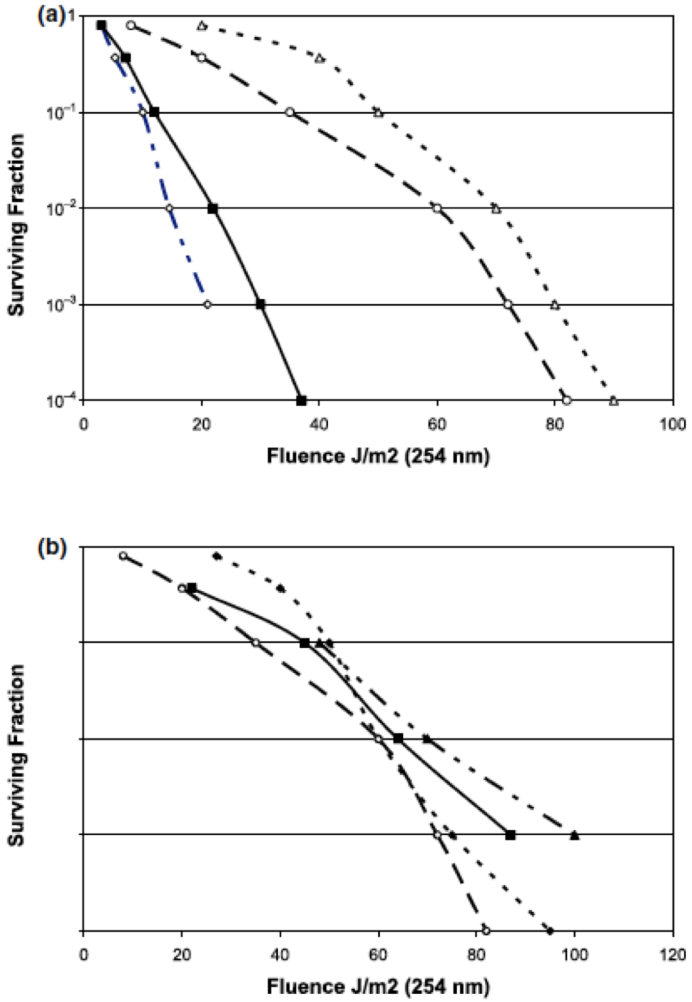

**Figure 3.** UVC (254 nm) sensitivity of several vegetative bacteria relevant to human health. The graph represents that bacterial cell fraction surviving after irradiation at the fluence indicated on the *x*-axis. Data shown is for: (a) *Vibrio cholerae* (diamonds [31]), *Yersinia enterocolitica* (squares [30]), *Salmonella typhi* (triangles [32]); and (b) vegetative cells of *Bacillus anthracis* Sterne (squares [38]), *Shigella sonnei* (diamonds [27]), and *Burkholderia pseudomallei* (triangles [39]). *E. coli* (wt [28]) is included in both panels (circles) for comparison.

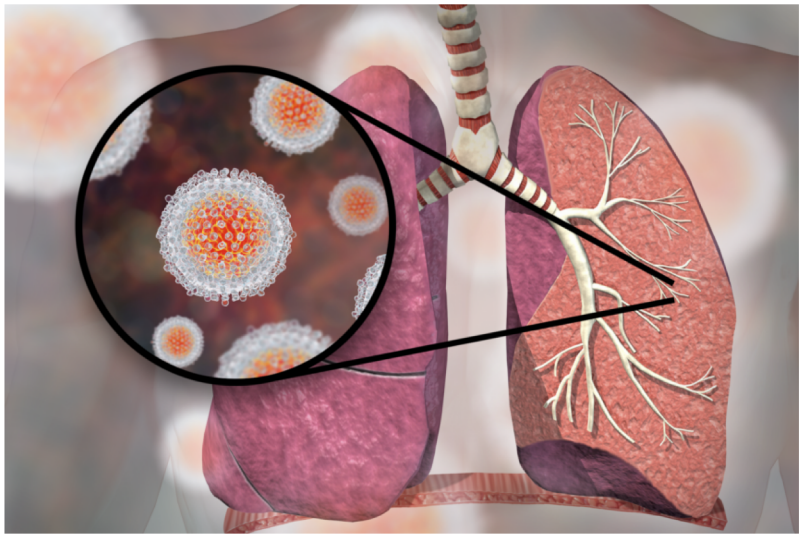
6 475 lung transplants reported in 2018

6% increase vs 2017

# HCV+ organs for HCV- patients



In the US, 1000 patients die yearly while waiting for heart or lung transplantation.

Direct-acting antivirals (DAAs) for HCV treatment "has raised the possibility of substantially increasing the donor organ pool by enabling the transplantation of hearts and lungs from HCV-infected donors into recipients who do not have HCV infection."

"In our trial, hearts and lungs from HCV-infected donors were transplanted safely with excellent graft function at 6 and 12 months," the authors concluded. "However, longer-term data are needed to fully define the risk-benefit profile."

Ex-Vivo Lung Perfusion: The Toronto Method

Copy link Vote

Terrance Ku

### Description

Illustrated is the Toronto method of ex-vivo lung perfusion (EVLP). The donor lung is cannulated on the pulmonary artery and the atrial cuff. Oxygenated perfusate exits from the atrial cannula into the reservoir. The centrifugal pump then propels the perfusate through a deoxygenator and heat exchanger. Lastly, the perfusate returns through a leukocyte filter into the pulmonary cannula. EVLP serves as a platform to assess and potentially treat grafts with therapeutics prior to transplantation.

## Inactivating hepatitis C virus in donor lungs using light therapies during normothermic ex vivo lung perfusion

Marcos Galasso[1], Jordan J. Feld[2], Yui Watanabe[1], Mauricio Pipkin[1], Cara Summers[1], Aadil Ali[1], Robert Qaqish[1], Manyin Chen[1], Rafaela V.P. Ribeiro[1], Khaled Ramadan[1], Layla Pires[1], Vanderlei S. Bagnato[3], Cristina Kurachi[3], Vera Cherepanov[2], Gray Moonen[1], Anajara Gazzalle[1], Thomas K. Waddell[1], Mingyao Liu[1], Shaf Keshavjee[1], Brian C. Wilson[4], Atul Humar[5] & Marcelo Cypel[1,5]

Availability of organs is a limiting factor for lung transplantation, leading to substantial mortality rates on the wait list. Use of organs from donors with transmissible viral infections, such as hepatitis C virus (HCV), would increase organ donation, but these organs are generally not offered for transplantation due to a high risk of transmission. Here, we develop a method for treatment of HCV-infected human donor lungs that prevents HCV transmission. Physical viral clearance in combination with germicidal light-based therapies during normothermic ex-vivo Lung Perfusion (EVLP), a method for assessment and treatment of injured donor lungs, inactivates HCV virus in a short period of time. Such treatment is shown to be safe using a large animal EVLP-to-lung transplantation model. This strategy of treating viral infection in a donor organ during preservation could significantly increase the availability of organs for transplantation and encourages further clinical development.

| Waitlist* time, days | 42 (13–169) | 17 (13–133) |

Data are median (IQR) or n (%). *Canadian waitlist status: status 1, patients stable on low concentration of oxygen; status 2, patients requiring high oxygen concentrations or pulmonary hypertension or both; status 3, patients with a rapid decline in lung function, generally hospitalised on ward or in intensive care.

***Table 2:*** **Recipient characteristics**

day-1 viral load, e is the natural logarithm, x is time variable, and a is the slope of the curve when plotted on a logarithmic axis. We assigned viral loads that were less than the limit of quantitation to a nominal value of 1·0 $\log_{10}$ IU/mL. We calculated viral load doubling time for each patient using the equation (ln2)/a. We compared doubling times between groups using the Mann–Whitney *U* test. All statistical analyses were done with GraphPad Prism 8 or R 3.5.0, with summary statistics within groups presented as median values with IQRs (for numerical data) or counts and percentages (for categorical data).
