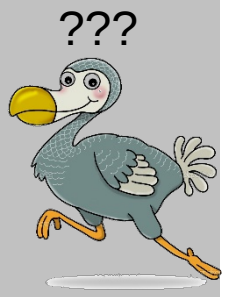
Evolução Cultural



OBJETIVOS

- Examinar a natureza das características biológicas e culturais e indagar se as supostas diferenças sustentam tal separação epistemológica.

- Refletir sobre a necessidade de uma “linguagem comum” para possibilitar o diálogo dentro da ciência => o valor das definições precisas de conceitos para permitir o debate.

- Investigar a possibilidade de aproximação entre áreas do conhecimento atualmente distanciadas, como a Biologia e as Humanidades, utilizando, como estudo de caso, a cultura e a teoria evolutiva.

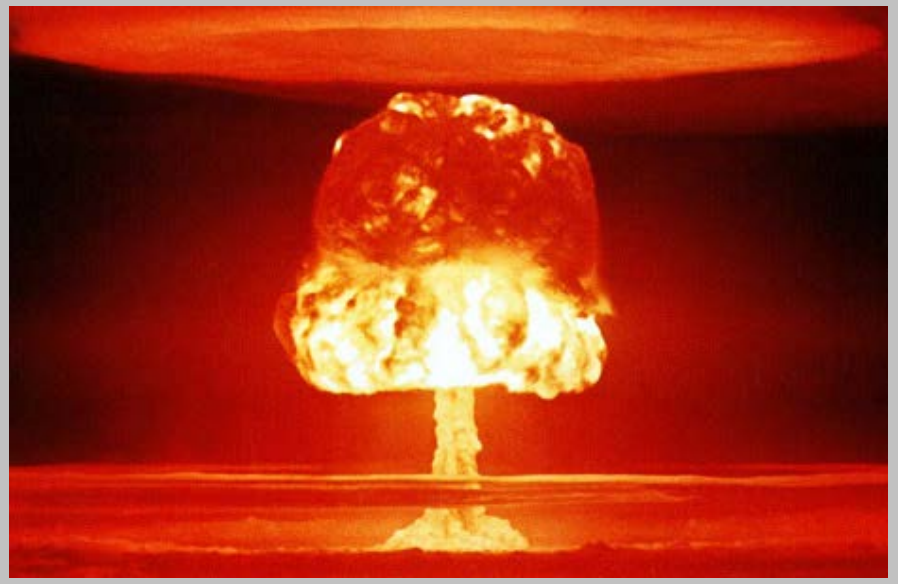
O que é cultura?

O que é cultura?

O que é cultura?



O que é cultura?

Cultura (etimologia) - meados do século XV => "cultivo da terra, ato de preparar a terra para as colheitas", do latim *cultura* - “um cultivo, agricultura", figurativamente "cuidado, cultura, uma honra", do particípio passado do radical *colere* ("para cuidar, guardar; cultivar, cultivar“).

- O sentido figurado de cultura como "*cultivo através da educação, aperfeiçoamento sistemático e refinamento da mente*" é atestado por volta de 1500;

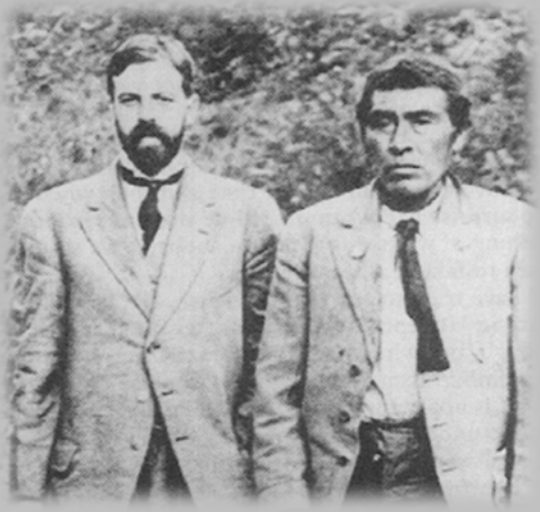
1910 - *antropologia cultural*;
1912 - *difusão cultural*;
1935 - *diversidade cultural*;
1937- *imperialismo cultural*;
1932 - *pluralismo cultural*.

O que é cultura?

Edward Burnett Tylor
(antropólogo, Londres, 1832-1917)

E. B. Tylor (1871), *Primitive Culture, Vol. 1*: **"...todo aquele complexo que inclui conhecimentos, crenças, arte, moral, leis, costumes e quaisquer outras capacidades e hábitos adquiridos pelo *homem* como membro da sociedade".**

O que é cultura?

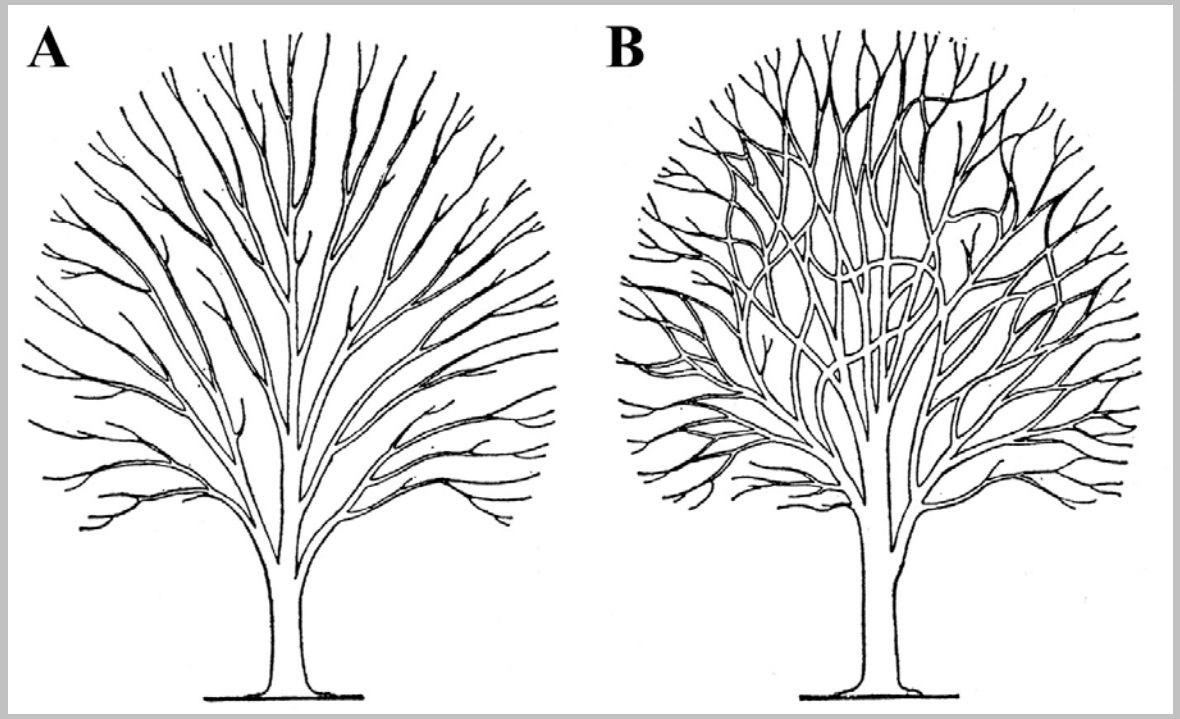


Kroeber (dir.) com **Ishi** (*ca*. 1861-1916), considerado o último membro da tribo dos Yahi, da Califórnia, em 1911

Alfred Louis Kroeber (antropólogo, linguista, arqueólogo da University of California, Berkeley, Hoboken, EUA, 1876-1960)

A. L. Kroeber (1948), *Anthropology*: **"... podemos nos aproximar do [conceito do] que é cultura dizendo que é o que a espécie humana possui e que outras espécies sociais carecem."**

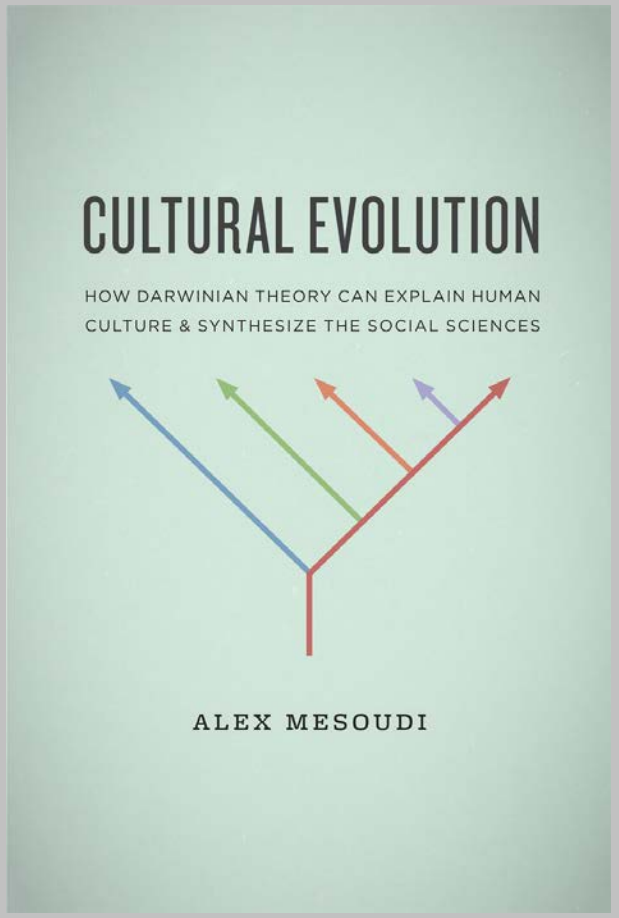
O que é cultura?



A) Evolução biológica; B) Evolução cultural, segundo *Kroeber* (1948)

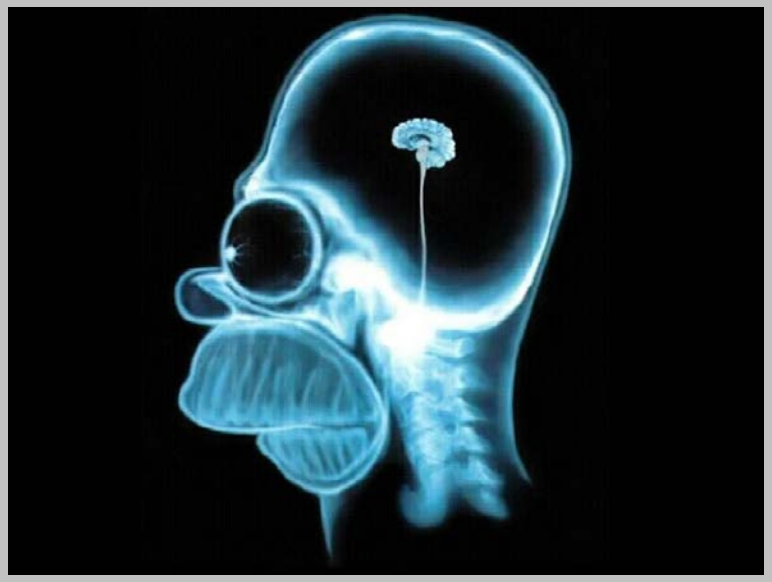
O que é cultura?

Alex Mesoudi (psicólogo, University of Exeter - Cornwall *campus*, UK)



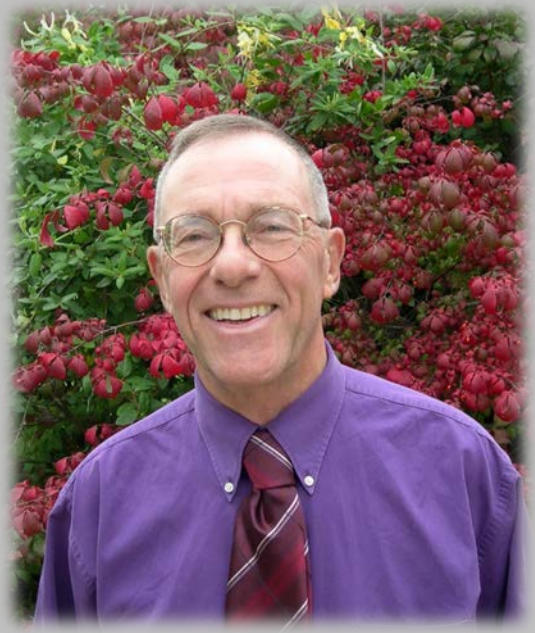
A. Mesoudi (2011: pp. 2-3), *Cultural Evolution: How Darwinian Theory Can Explain Human Culture and Synthesize the Social Sciences [= Evolução cultural: como a teoria darwiniana pode explicar a cultura humana e sintetizar as ciências sociais]*: **"...cultura é informação que é adquirida de outros indivíduos por meio de mecanismos de transmissão social, tal como a imitação, o aprendizado ou a linguagem"**.

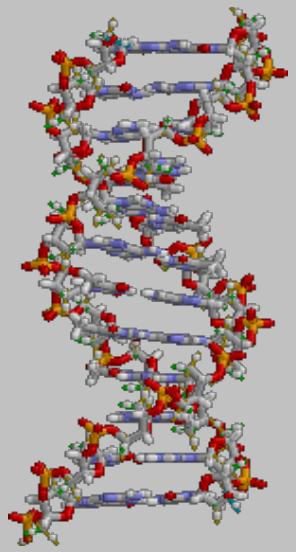
Biologia e Cultura – Formas de arquivamento da informação



O que é evolução?

Douglas J. Futuyma (1986), *Evolutionary Biology*: “No sentido mais amplo, a evolução é apenas mudar e, por isso, é onipresente; galáxias, linguagens e sistemas políticos, todos evoluem. Já evolução biológica... **é a mudança nas propriedades das populações de organismos que transcendem o tempo de vida de um único indivíduo**. A ontogenia de um indivíduo não é considerada evolução; os organismos individuais não evoluem. Alterações nas populações que são consideradas evolutivas são aquelas **que são herdadas por meio do material genético, a partir de uma geração para a seguinte**.”





Hall, B. K. & Hallgrímsson, B., eds. (2008). *Strickberger's Evolution* (4th ed.): “A evolução é **a mudança das características hereditárias de populações biológicas ao longo de gerações sucessivas**.”

Origem das Espécies (1859, cap. 13): "Pode valer a pena ilustrar esta visão da classificação, tomando o exemplo das línguas. Se possuíssemos um pedigree (filogenia) perfeito da humanidade, um arranjo genealógico das raças do homem, teríamos a melhor classificação das várias línguas hoje faladas em todo o mundo; e se todas as línguas extintas e todos os dialetos intermediários que mudam lentamente fossem incluídos, esse arranjo seria, eu acho, um único possível. No entanto, pode ser que uma linguagem muito antiga tenha alterado pouco e tenha dado origem a poucas línguas novas, enquanto que outras (devido à disseminação e posterior isolamento) se alteraram muito e deram origem a muitas novas línguas e dialetos. Os vários graus de diferença entre as línguas do mesmo estoque (ancestral) devem ser expressas por grupos subordinados a grupos; mas o arranjo apropriado, ou mesmo possível, ainda seria o genealógico; e isso seria totalmente natural, pois conectaria todas as línguas, extintas e modernas, pelas afinidades mais próximas, o que revelaria a filiação e a origem de cada língua".

ORIGINAL PAPER

Social learning in juvenile lemon sharks, *Negaprion brevirostris*

Received: 8 November 2011 / Revised: 14 June 2012 / Accepted: 7 August 2012 / Published online: 30 August 2012

Abstract Social learning is taxonomically widespread and can provide distinct behavioural advantages, such as in finding food or avoiding predators more efficiently. Although extensively studied in bony fishes, no such empirical evidence exists for cartilaginous fishes. Our aim in this study was to experimentally investigate the social learning capabilities of juvenile lemon sharks, *Negaprion brevirostris*. We designed a novel food task, where sharks were required to enter a start zone and subsequently make physical contact with a target in order to receive a food reward. Naive sharks were then able to interact with and observe (a) pre-trained sharks, that is, 'demonstrators', or (b) sharks with no previous experience, that is, 'sham demonstrators'. On completion, observer sharks were then isolated and tested individually in a similar task. During the exposure phase observers paired with 'demonstrator' sharks performed a greater number of task-related behaviours and made significantly more transitions from the start zone to the target, than observers paired with 'sham demonstrators'. When tested in isolation, observers previously paired with 'demonstrator' sharks completed a greater number of trials and made contact with the target significantly more often than observers previously paired with 'sham demonstrators'. Such experience also tended to result in faster overall task performance. These results indicate that juvenile lemon sharks, like numerous other animals, are capable of using socially derived information to learn about novel features in their environment. The results likely have important implications for behavioural processes, ecotourism and fisheries.

Introduction

Group living among wild animals is a widespread phenomenon and can provide distinct behavioural advantages such as enhanced foraging, reduced predation risk and social learning (Krause and Ruxton 2002). In the context of animal research, social learning can be defined as any process through which one individual (the demonstrator)

Through syntax, i.e., the combination of words into larger phrases, language can express a limitless number of messages. Data in great apes, our closest-living relatives, are central to the reconstruction of syntax's phylogenetic origins, yet are currently lacking. Here, we provide evidence for syntactic-like structuring in chimpanzee communication. Chimpanzees produce "*alarm-huus*" when surprised and "*waa-barks*" when potentially recruiting conspecifics during aggression or hunting. Anecdotal data suggested chimpanzees combine these calls specifically when encountering snakes. Using snake presentations, we confirm call combinations are produced when individuals encounter snakes and find that more individuals join the caller after hearing the combination. To test the meaning-bearing nature of the call combination, we use playbacks of artificially-constructed call combinations and both independent calls. Chimpanzees react most strongly to call combinations, showing longer looking responses, compared with both independent calls. We propose the "*alarm-huu + waa-bark*" represents a compositional syntactic-like structure, where the meaning of the call combination is derived from the meaning of its parts. Our work suggests that compositional structures may not have evolved de novo in the human lineage, but that the cognitive building-blocks facilitating syntax may have been present in our last common ancestor with chimpanzees.

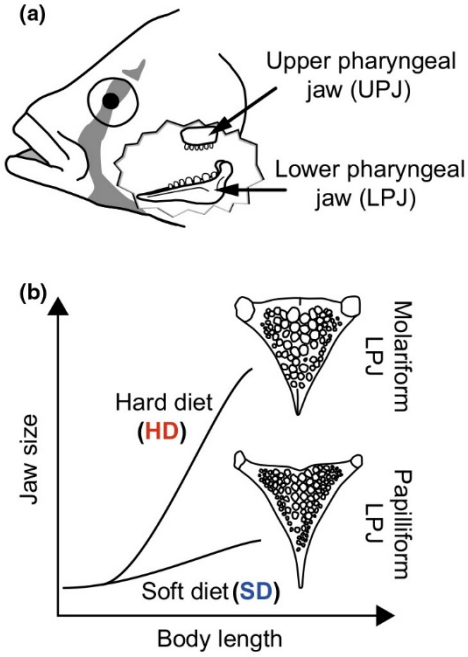

Fig. 1 Cichlid fishes possess a mechanically robust pharyngeal jaw apparatus. (a) The PJA is comprised of a pair of upper pharyngeal jaws (UPJ) that articulate directly with the neurocranium and the lower pharyngeal jaw (LPJ), which is formed by the suturing of the 5th ceratobranchial arches. (b) For the cichlid *Astatoreochromis alluaudi*, the mechanical properties of the diet influence LPJ development, whereby individuals fed a soft diet develop a smaller, more slender papilliform LPJ, the baseline condition, while individuals fed a hard diet develop a larger, more robust molariform LPJ that withstands increased biting forces. Image modified from Hoogerhoud (1984).

CLADISTIC METHODS IN TEXTUAL, LINGUISTIC, AND PHYLOGENETIC ANALYSIS

NORMAN I. PLATNICK AND H. DON CAMERON

Abstract

Platnick, N. I. (Department of Entomology, The American Museum of Natural History, New York, New York 10024) and H. D. Cameron (Department of Classical Studies and Museum of Zoology, The University of Michigan, Ann Arbor, Michigan 48104) 1977. Cladistic methods in textual, linguistic, and phylogenetic analysis. Syst. Zool. 26:380–385.—The concept that historical interrelationships can be demonstrated only by the presence of shared innovations is fundamental to the fields of textual and linguistic, as well as phylogenetic, reconstruction. All three fields utilize analogous procedures in which data are organized into transformation series of homologous character states, the polarity of these transformation series is determined by out-group comparison, and shared innovations are used to construct internested series of three-taxon statements that operate at a level of generality above that of specific ancestor-descendant hypotheses. The acceptance of these methods as the standard operational tools in separate fields suggests that cladistic analysis is a general comparative method applicable to all studies of historical interrelationships based on ancestor-descendant sequences, and that biologists concerned with such questions can ill afford to ignore cladistic theory and methods. [Phylogeny reconstruction; phylogenetic systematics; cladism.]

Evolução cultural – Produção Textual

(bonnes ou mauvaises), accessoires du texte tels que titres ou division en chapitres, etc. Le XVIIIe siècle applique, sans le formuler de façon absolument nette, le principe selon lequel « la communauté des caractéristiques (de quelque nature qu'elles soient) implique la communauté d'origine ».

§ 5. LA GÉNÉALOGIE DES MANUSCRITS ET LES PREMIERS STEMMES

Au XIXe siècle, on voit se dessiner peu à peu un principe nouveau : « La communauté des leçons implique la communauté d'origine ». C'est une précision apportée au précédent, ou plutôt une restriction dans le sens des données internes, et une étape dans la voie qui mène à la méthode des fautes communes.

En effet, la notion de « classe » élaborée au XVIIIe siècle contient en germe la méthode généalogique, celle qui consiste à déterminer ces relations des manuscrits comme ancêtres et descendants et se fonde sur les relations pour restituer le texte en reconstituant les exemplaires perdus, et notamment l'original, par l'accord de leurs descendants indépendants. Cependant les « caractéristiques communes » qui définissent la « classe » représentent une notion très extensive et indifférenciée, puisqu'elle inclut à la fois les caractéristiques externes et les caractéristiques internes. C'est donc un point de bifurcation, d'où l'on peut partir dans deux directions différentes.

Si on limite les caractéristiques communes à celles qui consistent en données externes, on s'achemine vers les méthodes généalogiques qui se fondent notamment sur les accidents matériels et les données codicologiques : nous en parlerons plus loin.

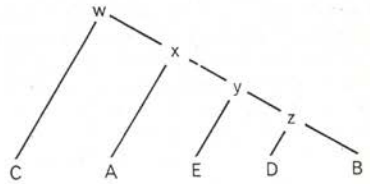
Si au contraire on restreint les caractéristiques communes à celles qui portent sur la teneur du texte, on se dirige vers les méthodes généalogiques qui se fondent sur les données internes, celles dont nous parlerons maintenant.

Le premier pas dans cette direction consiste à prendre comme caractéristiques communes *les leçons*, toutes les leçons, indifféremment les bonnes ou les mauvaises, les authentiques et les inauthentiques; c'est à ce stade que l'on en restera pendant la première moitié du XIXe siècle, et beaucoup de critiques s'y attarderont jusqu'à la fin du siècle. L'étape suivante, qui sera d'ailleurs atteinte graduellement, consistera en une précision nouvelle : les

leçons communes qui révèlent les relations généalogiques des manuscrits ne seront plus n'importe lesquelles, mais seulement les *fautives*, et cette note restrictive, excluant les « bonnes » leçons, conduira finalement à la méthode « des fautes communes ».

Cette évolution dans les idées se fit lentement et non sans hésitations : c'est dans un dessein de clarté que nous la résumons ainsi de façon schématique. Nous rencontrons en particulier, dans la première moitié du XIXe siècle et même dans sa plus grande partie chez certains critiques, une méthode bâtarde qui, ne pouvant se débarrasser de la conception qualitative héritée du passé, la combine curieusement avec la notion généalogique proprement dite. Le processus est le suivant. On range d'abord les manuscrits dans l'ordre de leur qualité décroissante, et il est d'usage de placer les bons à gauche et les mauvais à droite. Puis on considère qu'à chaque étape de la descente dans la hiérarchie qualitative correspond un ancêtre nouveau, moins bon que le précédent.

Supposons, par exemple, que nous ayons affaire aux manuscrits ABCDE, qui se rangent, du meilleur au pire, dans l'ordre CAEBD. On admet que le meilleur, C, descend directement de l'ancêtre commun *w*, dont il est le fidèle reflet, tandis que tous les autres, AEBD, procèdent d'un collatéral moins bon *x*; de celui-ci, A qui est le meilleur des mauvais, descend directement, tandis que les autres, EDB, dérivent encore une fois d'un collatéral moins soigné, *y*; et ainsi de suite, indéfiniment. Il en résulte un schéma du type que voici :



De la sorte, un classement purement qualitatif est accompagné d'une superstructure qui lui donne un aspect faussement généalogique.

On trouve aussi, dans cette première moitié du XIXe siècle où règne une certaine confusion, des schémas proprement généalogiques, et l'intérêt que

Evolução cultural – Produção Textual

Le premier pas dans cette direction consiste à prendre comme caractéristiques communes *les leçons*, toutes les leçons, indifféremment les bonnes ou les mauvaises, les authentiques et les inauthentiques; c'est à ce stade que l'on en restera pendant la première moitié du XIX^e^ siècle, et beaucoup de critiques s'y attarderont jusqu'à la fin du siècle. L'étape suivante, qui sera d'ailleurs atteinte graduellement, consistera en une précision nouvelle : les leçons communes qui révèlent les relations généalogiques des manuscrits ne seront plus n'importe lesquelles, mais seulement les *fautives*, et cette note restrictive, excluant les « bonnes » leçons, conduira finalement à la méthode « des fautes communes ».

O primeiro passo nesta direção consiste em tomar como características comuns as interpretações (versões), todas as interpretações, sejam elas boas ou ruins, as autênticas e as falsas; é neste estágio que estamos na primeira metade do século XIX e no qual muitos críticos ficarão até o fim do século. O próximo passo, que será atingido gradualmente, consistirá de uma nova precisão: **as versões comuns não serão aquelas mais significativas para revelar as relações genealógicas dos manuscritos, mas apenas aquelas *errôneas***, e esse detalhe restritivo que, excluindo as 'boas' interpretações, conduzirá finalmente ao método dos "***erros compartilhados***".

Informação filogenética está nas sinapomorfias!

Evolução cultural – Produção Textual

groupe lacunaire; le plus simple est donc d'épurer la collation avant de s'en servir, et d'éliminer d'emblée les lieux variants où une proportion notable des manuscrits font défaut.

§ 4. LES ANOMALIES

Abordons maintenant les anomalies proprement dites. Elles sont de deux sortes : les unes effacent dans un manuscrit des fautes qu'il devrait tenir de ses ancêtres, et les autres lui communiquent au contraire des fautes qui ont été commises par un collatéral et qu'il ne devrait pas contenir.

Au moment où il cherche à reconstituer l'enchaînement, le critique n'a pas à se demander quelles causes ont bien pu effacer des fautes ou les communiquer indûment et s'il faut incriminer la contamination ou le hasard; c'est une question qu'il se posera plus tard. Pour l'instant, il constate seulement les effets de causes inconnues, et s'efforce de découvrir la généalogie normale.

Expliquons les perturbations produites par les deux sortes d'anomalies que nous venons de dire; nous n'avons pas la prétention de passer en revue la variété infinie des éventualités qui peuvent survenir, et nous voudrions seulement illustrer le principe à l'aide d'exemples faciles à comprendre.

Nous ferons remarquer au passage que les anomalies sont visibles ou non, selon les circonstances. L'anomalie, en effet, saute aux yeux si elle se traduit par des groupes qui chevauchent les uns sur les autres, ce qui ne se produit jamais quand la généalogie est normale. Mais par malheur il y a des anomalies qui laissent aux groupes leur agencement harmonieux, de sorte que rien ne trahit leur présence. Un critique pointilleux pourrait donc soutenir que théoriquement un épais nuage d'incertitude plane sur tout arbre généalogique. Mais il ne faut pas exagérer. Nous dirons quelles précautions il convient de prendre et comment évaluer raisonnablement la marge d'incertitude.

a) Les fautes ancestrales effacées

Pour expliquer les perturbations que produit dans l'enchaînement l'anomalie qui efface des fautes ou variantes ancestrales, raisonnons sur un exemple : il sera facile d'en tirer la loi générale.

Plaçons-nous comme d'habitude d'abord dans l'orientation réelle, et parlons en termes de fautes.

Au moment où il cherche à reconstituer l'enchaînement, le critique n'a pas à se demander quelles causes ont bien pu effacer des fautes ou les communiquer indûment et s'il faut incriminer la contamination ou le hasard; c'est une question qu'il se posera plus tard. Pour l'instant, il constate seulement les effets de causes inconnues, et s'efforce de découvrir la généalogie normale.

Quando o crítico procura reconstruir o encadeamento [dos manuscritos ou versões], ele não tem que se questionar quais as causas que poderiam ter apagado os erros ou tê-los comunicado de forma inadequada e atribuir se foi por contaminação ou por acaso; isso é uma questão que será apresentada mais tarde. *Por enquanto, ele constata apenas os efeitos de causas desconhecidas e se empenha para descobrir a genealogia normal*.

O processo causal subjacente aos padrões não deve interferir na geração das hipóteses de homologia e na construção da árvore.

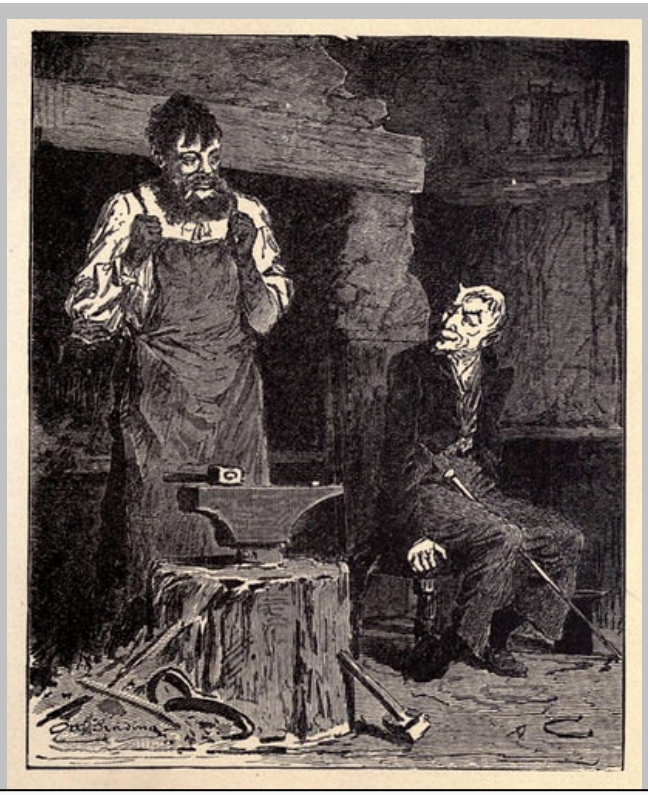

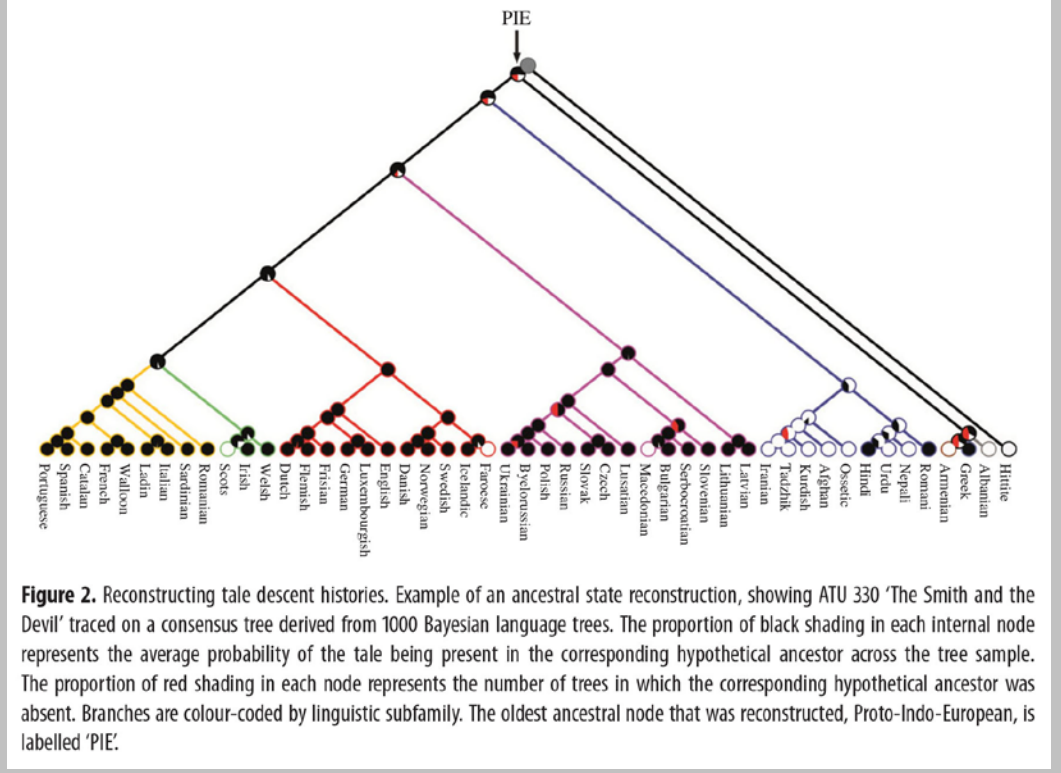

Figure 2. Reconstructing tale descent histories. Example of an ancestral state reconstruction, showing ATU 330 'The Smith and the Devil' traced on a consensus tree derived from 1000 Bayesian language trees. The proportion of black shading in each internal node represents the average probability of the tale being present in the corresponding hypothetical ancestor across the tree sample. The proportion of red shading in each node represents the number of trees in which the corresponding hypothetical ancestor was absent. Branches are colour-coded by linguistic subfamily. The oldest ancestral node that was reconstructed, Proto-Indo-European, is labelled 'PIE'.

The Phylogeny of Little Red Riding Hood

Jamshid J. Tehrani*

Department of Anthropology and Centre for the Coevolution of Biology and Culture, Durham University, Science Site, South Road, Durham, United Kingdom

Abstract

Researchers have long been fascinated by the strong continuities evident in the oral traditions associated with different cultures. According to the 'historic-geographic' school, it is possible to classify similar tales into "international types" and trace them back to their original archetypes. However, critics argue that folktale traditions are fundamentally fluid, and that most international types are artificial constructs. Here, these issues are addressed using phylogenetic methods that were originally developed to reconstruct evolutionary relationships among biological species, and which have been recently applied to a range of cultural phenomena. The study focuses on one of the most debated international types in the literature: ATU 333, 'Little Red Riding Hood'. A number of variants of ATU 333 have been recorded in European oral traditions, and it has been suggested that the group may include tales from other regions, including Africa and East Asia. However, in many of these cases, it is difficult to differentiate ATU 333 from another widespread international folktale, ATU 123, 'The Wolf and the Kids'. To shed more light on these relationships, data on 58 folktales were analysed using cladistic, Bayesian and phylogenetic network-based methods. The results demonstrate that, contrary to the claims made by critics of the historic-geographic approach, it is possible to identify ATU 333 and ATU 123 as distinct international types. They further suggest that most of the African tales can be classified as variants of ATU 123, while the East Asian tales probably evolved by blending together elements of both ATU 333 and ATU 123. These findings demonstrate that phylogenetic methods provide a powerful set of tools for testing hypotheses about cross-cultural relationships among folktales, and point towards exciting new directions for research into the transmission and evolution of oral narratives.

We present, to our knowledge, the first quantitative evidence that music and genes may have coevolved by demonstrating significant correlations between traditional group-level folk songs and mitochondrial DNA variation among nine indigenous populations of Taiwan. These correlations were of comparable magnitude to those between language and genes for the same populations, although music and language were not significantly correlated with one another. An examination of population structure for genetics showed stronger parallels to music than to language. Overall, the results suggest that music might have a sufficient time-depth to retrace ancient population movements and, additionally, that it might be capturing different aspects of population history than language. Music may therefore have the potential to serve as a novel marker of human migrations to complement genes, language and other markers.

1. Introduction

As human populations migrate to new regions of the world, their evolutionary divergence leaves its mark on both genes and culture. Correlations between cultural markers such as language and genetic markers such as mitochondrial, Y chromosome or autosomal DNA demonstrate that these features can co-migrate and coevolve over the course of thousands of years [1–3]. The same coevolutionary process has been proposed for music and genes [4–7], not least because music is a universal feature of human cultures [8,9] and because it shows quantifiable diversity both within and between populations [10,11]. However, this hypothesis has been criticized on the grounds that music evolution might occur at too rapid a rate [12] and therefore that music's time depth might be too shallow to be correlated with something as ancient and slowly evolving as genes. Although a few studies have found suggestive parallels between music and genes [5,13–15], none have demonstrated a statistically significant correlation between them. We wanted to examine this relationship quantitatively for the first time, to our knowledge, and explore whether music might have the potential to serve as a new type of marker for the study of human population history.

We decided to examine Taiwan as a test case as it has several clear advantages for such an analysis. Taiwan has a small number of well-characterized indigenous populations that are located in geographically distinct regions of the island [16]. These populations have been well studied musically, linguistically and genetically such that there exists ample material for performing correlational analyses. The indigenous musics have been extensively recorded and archived by ethnomusicologists since the 1920s [17–21], and genetic analyses of mitochondrial DNA (mtDNA) haplotypes for most of the indigenous groups have been published [22]. Therefore, the degree of musical and genetic sampling makes Taiwan an ideal case for analysis. In addition to this, Taiwan has been the focal point of theories about one of the most significant migrational events in human history, namely the expansion of the Austronesian-speaking peoples
