Método de detecção: microlentes gravitacionais

Einstein, 1907 – 1915:
Relatividade geral

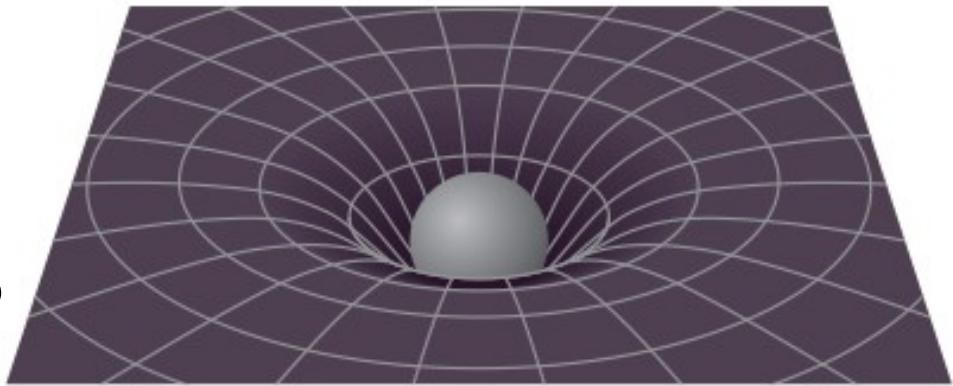

Curvatura do espaço-tempo
é causada pela massa.

Maior gravidade é devida
à maior curvatura

a A two-dimensional representation of “flat” spacetime. The distances between adjacent circles are the same.

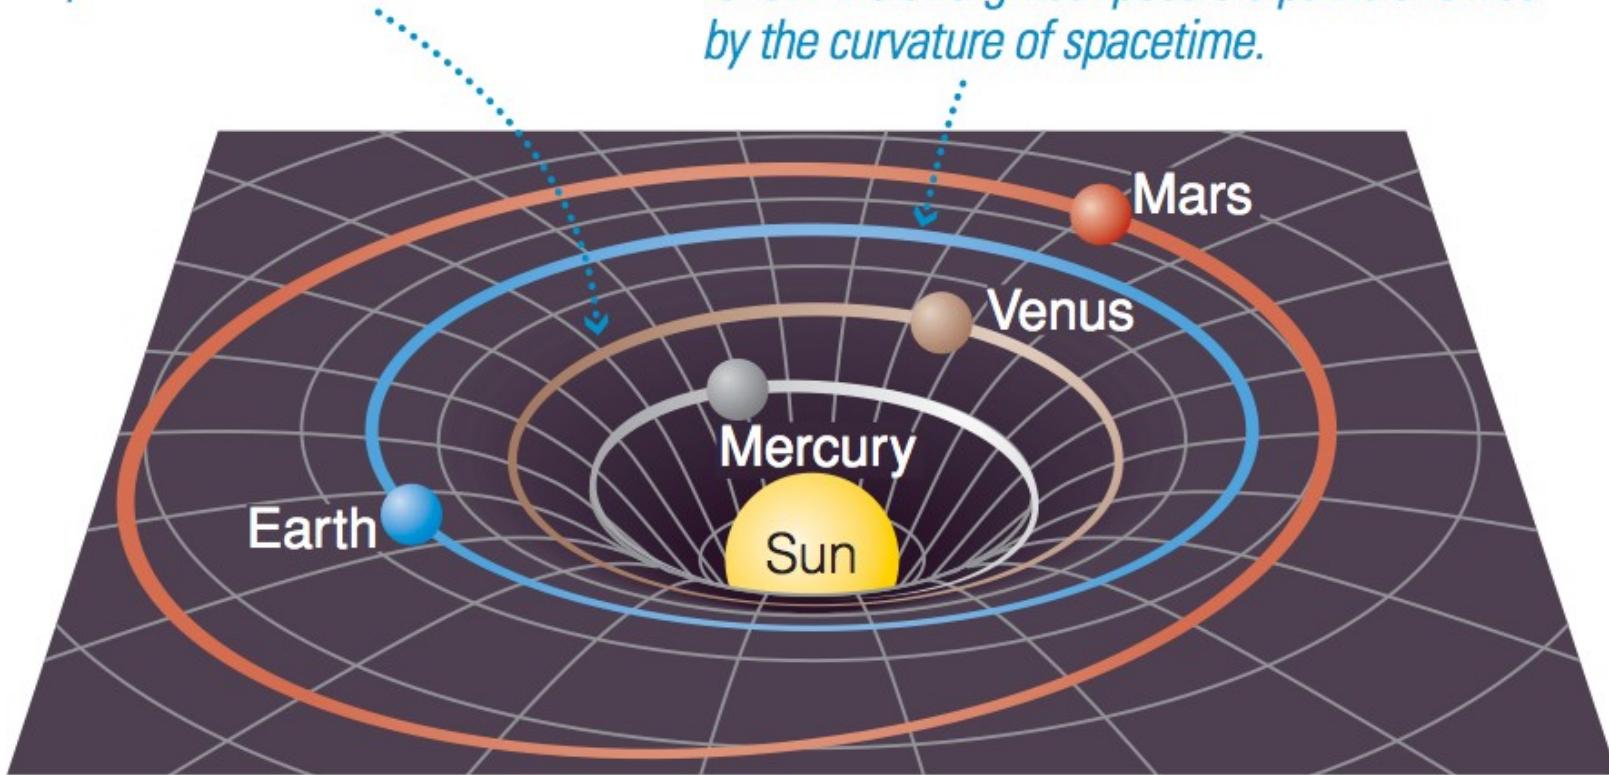

b Gravity arises from curvature of spacetime, represented here by a mass pushing down on the rubber sheet. Notice how the circles become more widely separated near the mass, showing that the curvature is greater as we approach the mass on the sheet.

A massa do Sol curva o espaço-tempo

The mass of the Sun causes spacetime to curve ...

... so freely moving objects (such as planets) follow the straightest possible paths allowed by the curvature of spacetime.

© The cosmic perspective

According to general relativity, planets orbit the Sun for much the same reason that you can make a marble go around in a salad bowl: The planet is going as straight as it can, but the curvature of spacetime causes its path through space to curve.

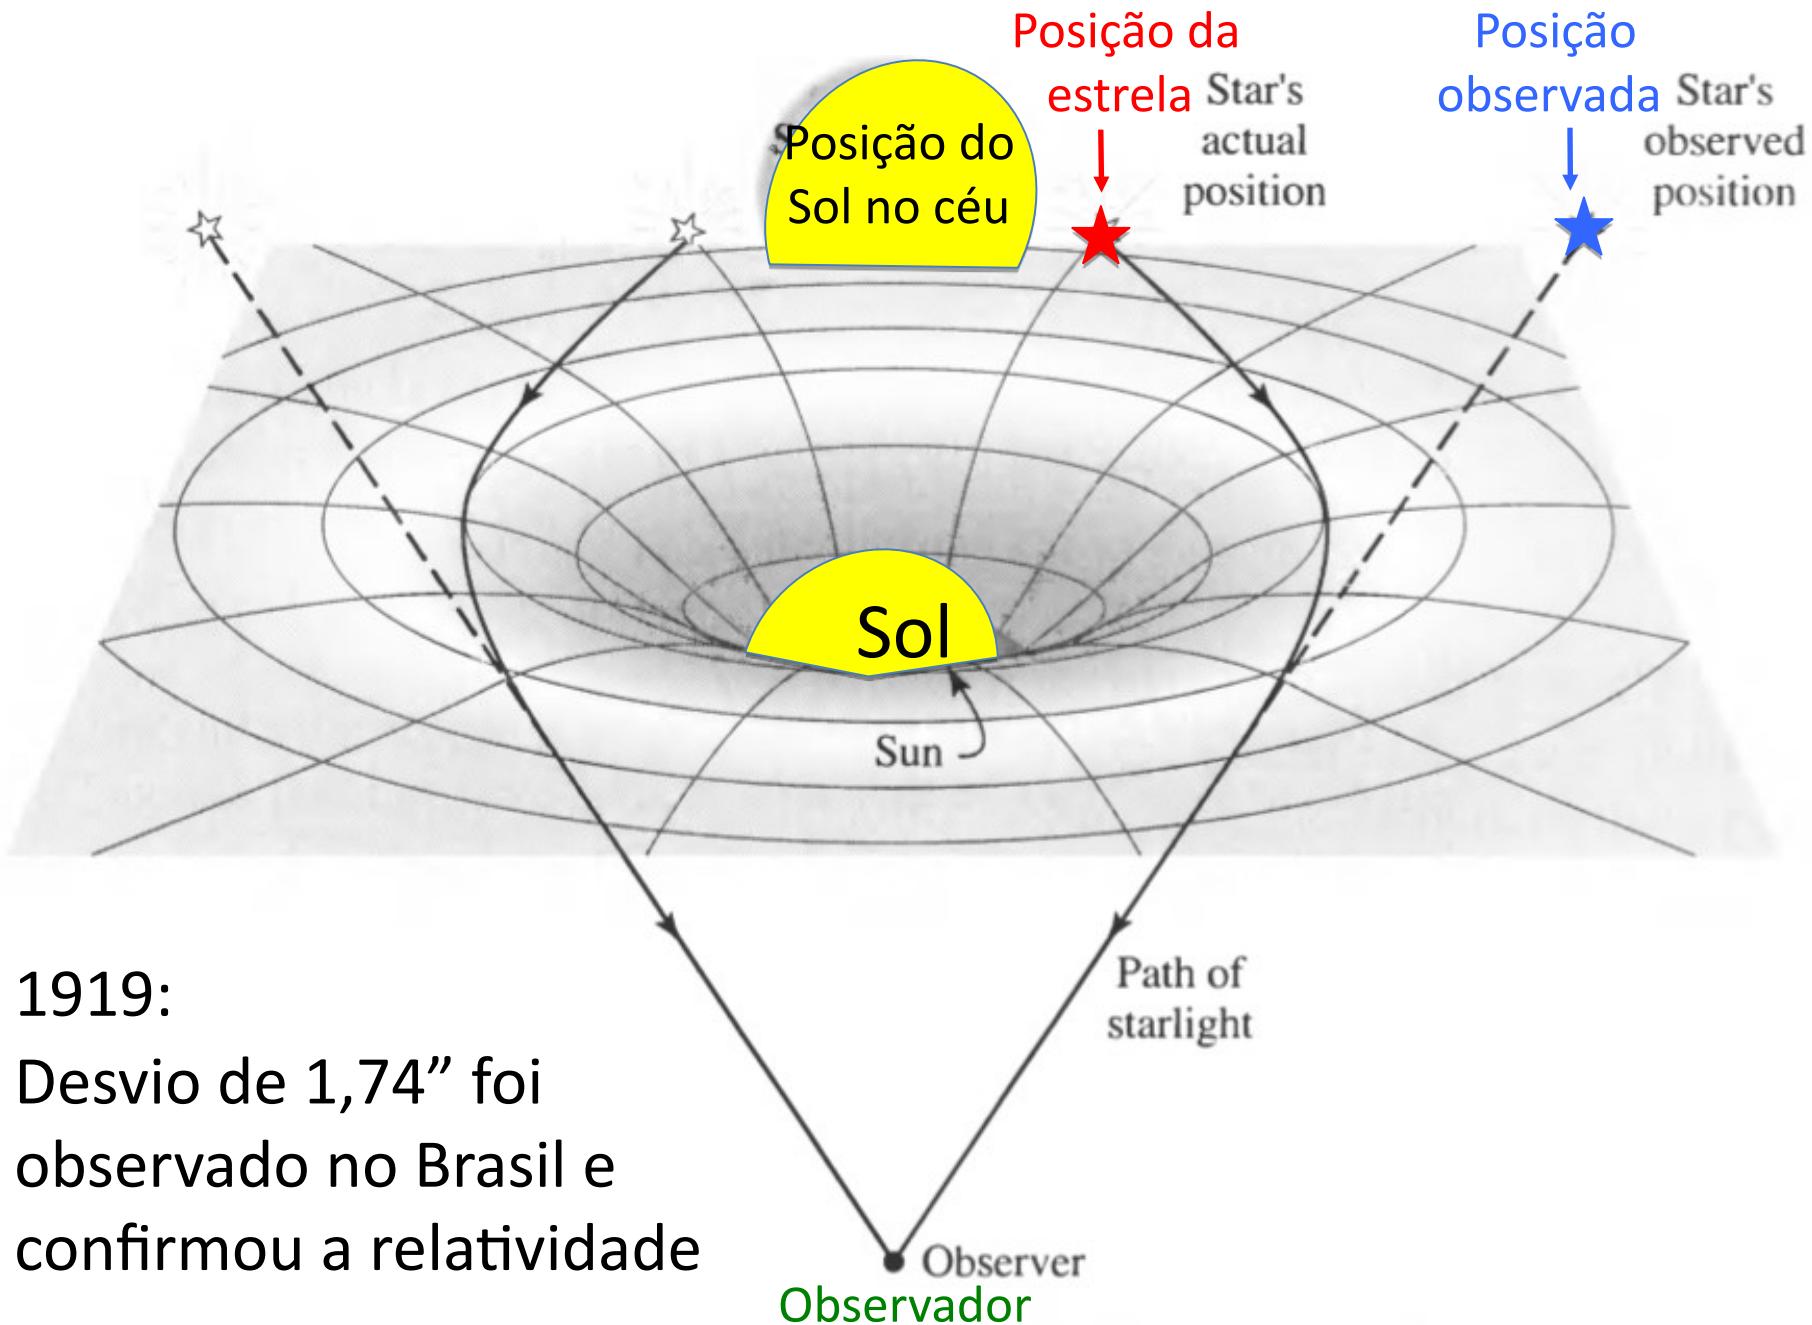

FIGURE 17.5 Bending of starlight measured during a solar eclipse.

1911

O astrônomo alemão Erwin Finlay-Freundlich tentou medir a deflexão da luz com placas fotográficas de um eclipse solar obtidas pelo **Observatório Lick**, nos Estados Unidos

1912

Pesquisadores do Observatório Argentino liderados por **Charles Perrine** planejaram registrar um eclipse solar na serra da Mantiqueira, em Minas Gerais. Devido ao mau tempo, nada foi fotografado

1916

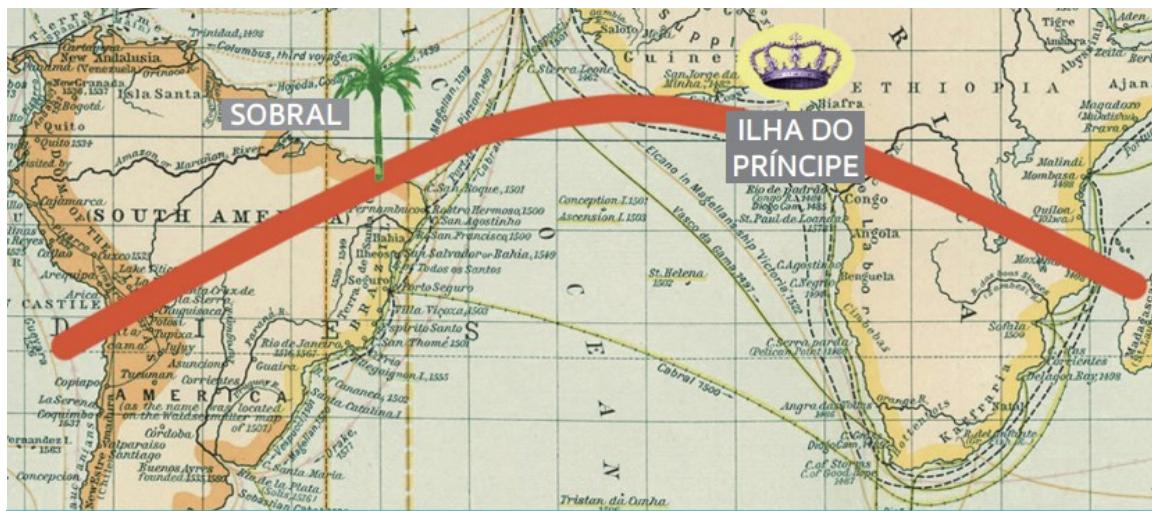

O Observatório Argentino conseguiu registrar um eclipse solar em Tucacas, na Venezuela, mas nenhuma fotografia serviu para comprovar as ideias de Einstein

1918

A equipe do Observatório Lick não conseguiu fotografar o eclipse do Sol nos Estados Unidos porque seus equipamentos estavam presos na Rússia desde 1914

1919

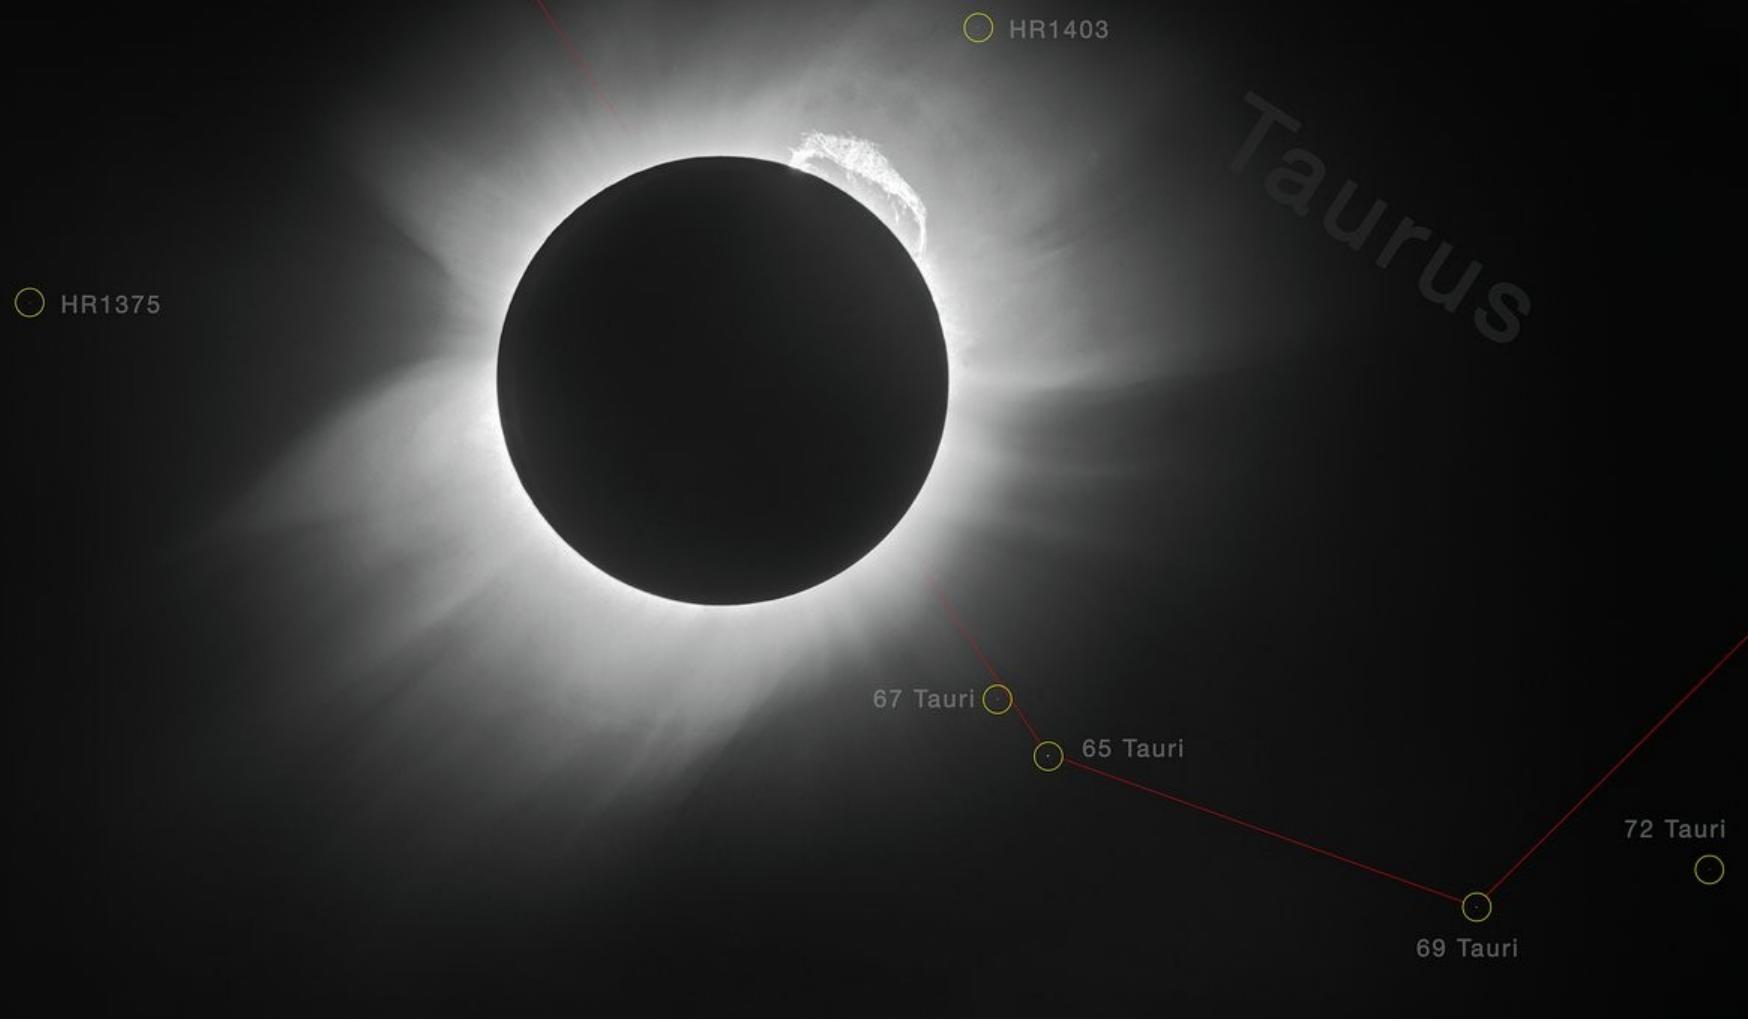

O eclipse que confirmou a ideia de Einstein cruzou a linha equatorial. Foi observado em Sobral e na ilha do Príncipe, na África

1922

Fotografias de um eclipse solar feitas na Ilha Christmas reforçaram os dados obtidos anos antes em Sobral

Difícil de medir. Pela Relatividade Geral, deslocamento de apenas 1,74"

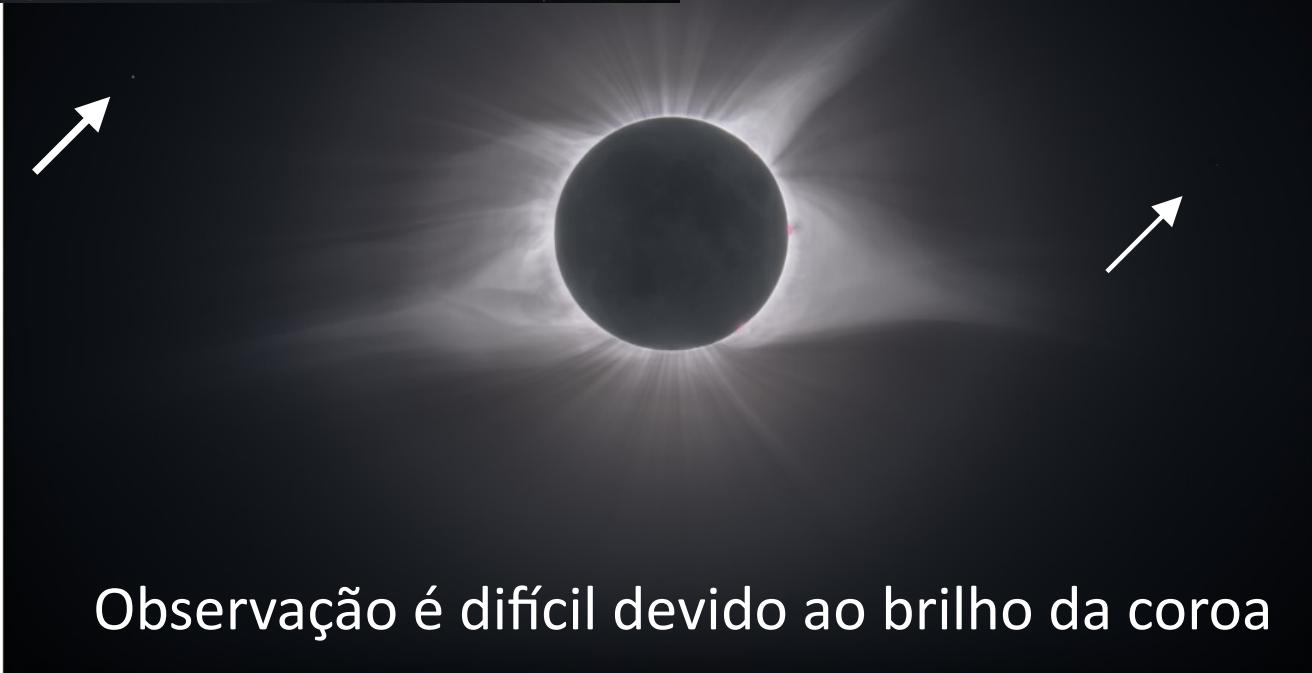

Highest resolution image of the 1919 solar eclipse in Sobral. One copy of a plate from Sobral went to Landessternwarte Heidelberg-Königstuhl, who recently (2019?) scanned theirs as part of the Heidelberg Digitized Astronomical Plates project

eclipse-with-background-stars/](https://www.cloudynights.com/gallery/image/56791-2017-eclipse-with-background-stars/)

Deflexão da luz estelar passando a uma distância ξ de uma estrela de massa M (segundo a relatividade geral):

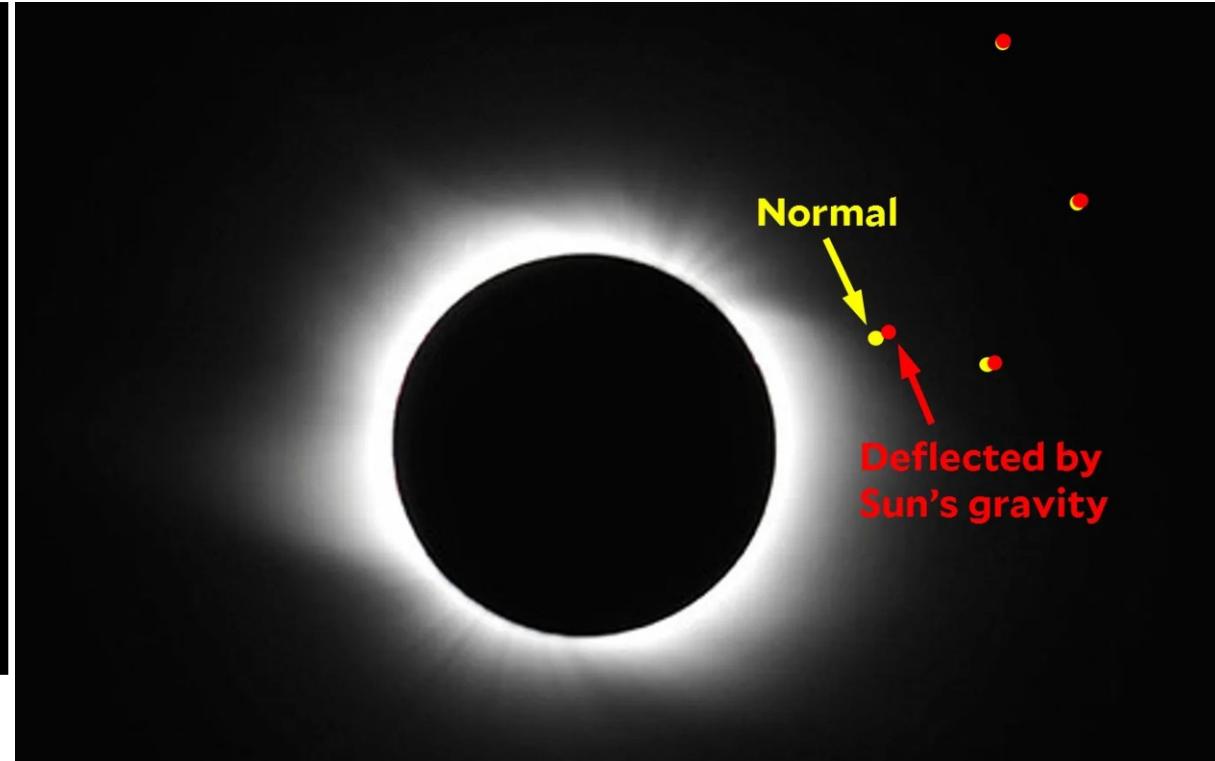

$$\hat{\alpha} = \frac{4GM}{c^2 \xi} = 1,74 \text{ "} \left(\frac{M}{M_{\odot}} \right) \left(\frac{\xi}{R_{\odot}} \right)^{-1}$$

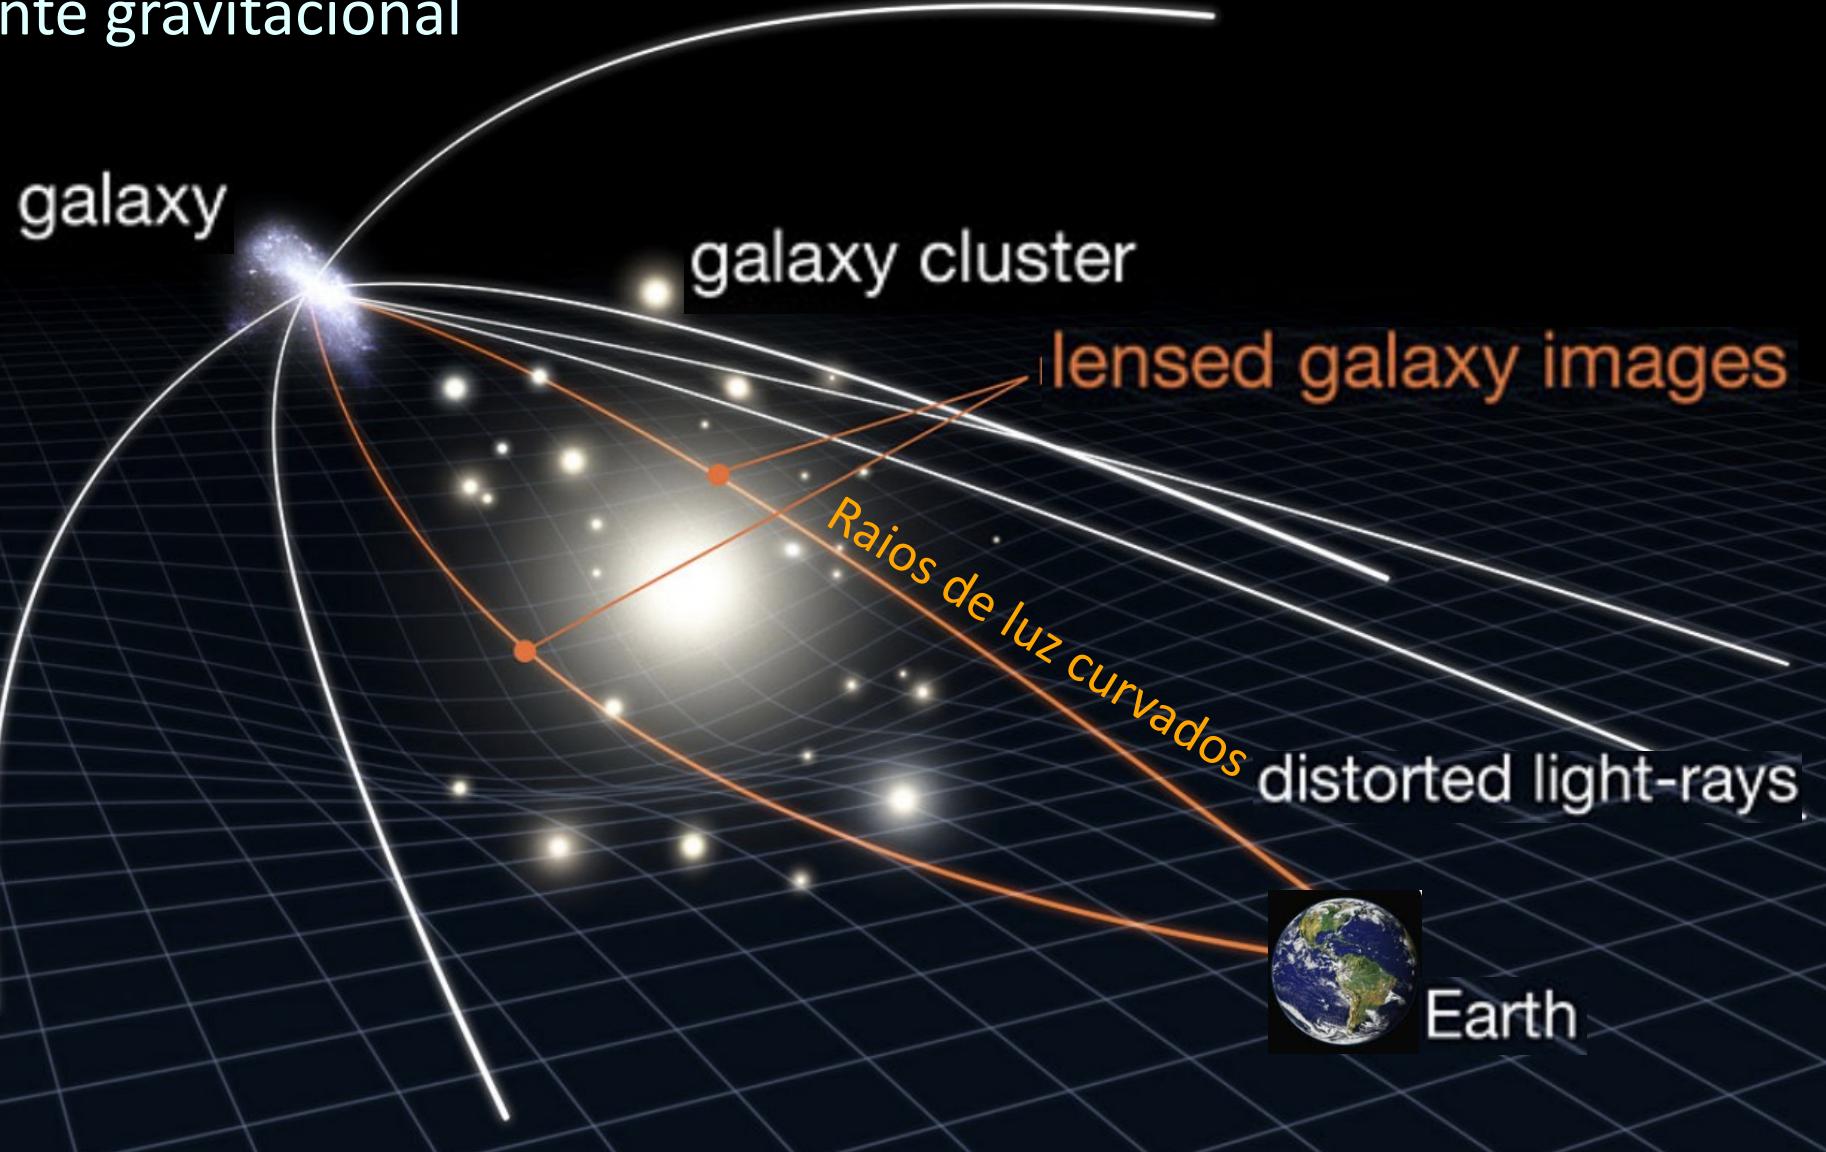

(c) Silvia
Márcia
Barreto
Peixoto

Para o Sol, $\alpha = 1,74 \text{ "}$

Ilustração do efeito de **deflexão** da luz em comparação com a posição “**normal**” das estrelas (quando o Sol não está na linha de visada)

Observador distante de galáxia (**fonte de luz**) e de outra galáxia ou aglomerado de galáxias (**lente**) pode observar o efeito de lente gravitacional

A galáxia luminosa vermelha (LRG 3-757) é a “lente” que distorce a luz de uma galáxia azul (“fonte”) muito mais distante, pelo efeito de lente gravitacional

APOD 21/12/2011: The gravity of a luminous red galaxy (LRG 3-757) has gravitationally distorted the light from a much more distant blue galaxy. More typically, such light bending results in 2 discernible images of the distant galaxy, but here the lens alignment is so precise that the background galaxy is distorted into a horseshoe -- a nearly complete ring. Since such a lensing effect was generally predicted by Einstein over 70 years ago, rings like this are now known as Einstein Rings. The image was taken with the Hubble Space Telescope

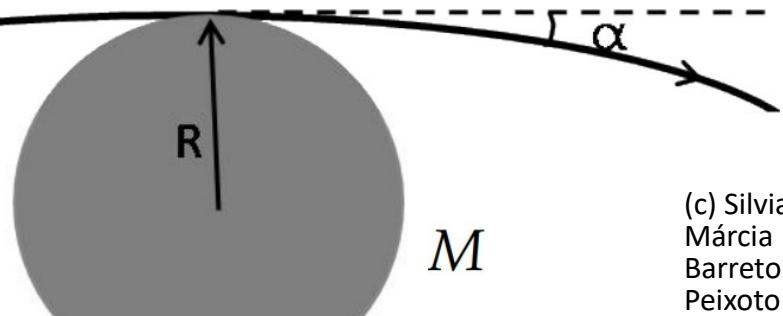

Aglomerado de galáxias Abell 370 é a “lente” que distorce a luz de ~100 galáxias (“fontes”) muito mais distantes

Galaxy cluster Abell 370, located \sim 4 billion light-years away, contains several hundred galaxies tied together by the mutual pull of gravity. Entangled among the galaxies are \sim 100 mysterious-looking arcs of blue light. These are actually distorted images of remote galaxies behind the cluster. These far-flung galaxies are too faint for Hubble to see directly. Instead, the gravity from the cluster acts as a huge lens that magnifies and stretches images of background galaxies

Deflexão da luz a uma distância ξ de estrela de massa M :

$$\hat{\alpha} = \frac{4GM}{c^2 \xi} = 1,74 \text{ ''} \left(\frac{M}{M_\odot} \right) \left(\frac{\xi}{R_\odot} \right)^{-1}$$

Microlentes

Alinhamento perfeito:

θ_E , raio do anel de Einstein

Observer

$$\theta_E = \sqrt{\frac{D_{LS}}{D_S D_L} \frac{4GM_L}{c^2}} \quad (\text{em radianos})$$

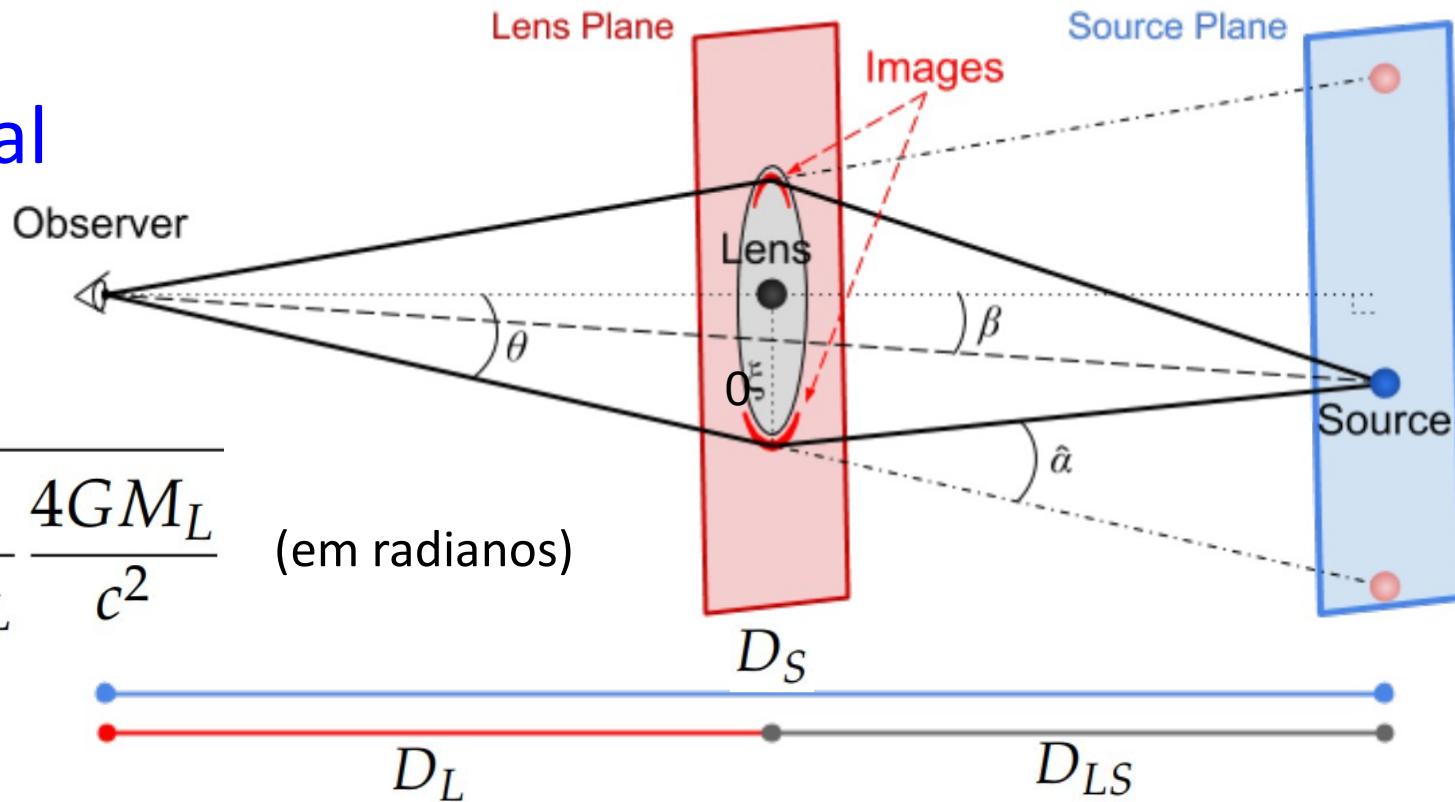

$$\theta_E \sim 3 \times 10^{-4} \text{ ''}$$

Microlente gravitacional

Raio do anel de Einstein:

$$\theta_E = \sqrt{\frac{D_{LS}}{D_S D_L} \frac{4GM_L}{c^2}} \quad (\text{em radianos})$$

Consider an M-dwarf lens star ($M_L = 0.3M_\odot$) at a distance of $D_L = 6.5$ kpc from the Earth, and a source star at a distance $D_S = 8.5$ kpc. The angular Einstein ring radius is

$$\theta_E \approx 0.902 \text{ mas} \left(\frac{M_L}{M_\odot} \right)^{1/2} \left(\frac{10 \text{ kpc}}{D_L} \right)^{1/2} \left(1 - \frac{D_L}{D_S} \right)^{1/2} \sim 300 \mu\text{as} = 0.3 \text{ mas}$$

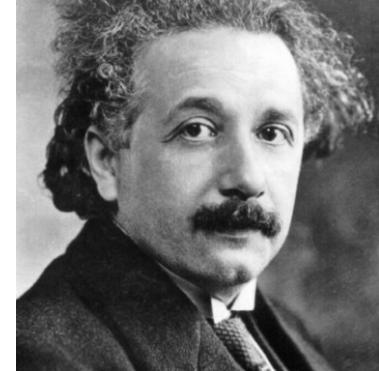

This corresponds to a physical distance on the lens plane of

$$r_E = \theta_E D_L \sim 3 \text{ AU} \left(\frac{M_L}{M_\odot} \right)^{1/2} \sim 1.6 \text{ AU}$$

Microlente gravitacional

Albert Einstein

Science Vol. 84, No. 2188 (Dec. 4, 1936), pp. 506-507

LENS-LIKE ACTION OF A STAR BY THE DEVIATION OF LIGHT IN THE GRAVITATIONAL FIELD

SOME time ago, R. W. Mandl paid me a visit and asked me to publish the results of a little calculation, which I had made at his request. This note complies with his wish.

The light coming from a star *A* traverses the gravitational field of another star *B*, whose radius is R_o . Let there be an observer at a distance D from *B* and at a distance x , small compared with D , from the extended central line \overline{AB} . According to the general theory of relativity, let α_o be the deviation of the light ray passing the star *B* at a distance R_o from its center.

not decrease like $1/D$, but like $1/\sqrt{D}$, as the distance D increases.

Of course, there is no hope of observing this phenomenon directly. First, we shall scarcely ever approach closely enough to such a central line. Second, the angle β will defy the resolving power of our instruments. For, α_o being of the order of magnitude of one second of arc, the angle R_o/D , under which the deviating star *B* is seen, is much smaller. Therefore, the light coming from the luminous circle can not be distinguished by an observer as geometrically different from that coming from the star *B*, but simply will manifest itself as increased apparent brightness of *B*.

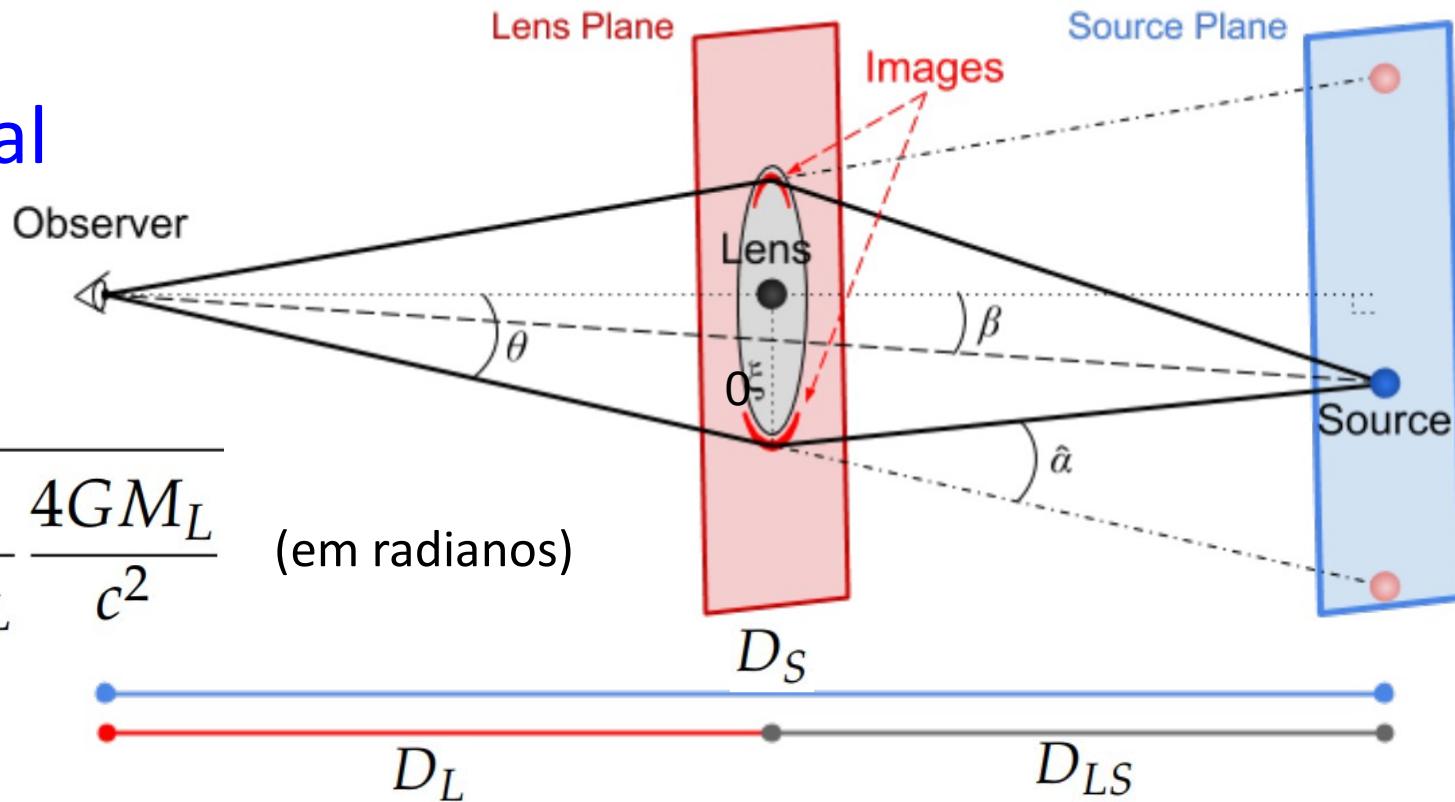

The same will happen, if the observer is situated at a small distance x from the extended central line \overline{AB} .

$\theta_E \sim 0,3\text{mas}$ (segundo Einstein, sem esperança de medida)
Porem, tem efeito de aumento do brilho aparente!

Microlente gravitacional

Raio do anel de Einstein:

$$\theta_E = \sqrt{\frac{D_{LS}}{D_S D_L} \frac{4GM_L}{c^2}} \quad (\text{em radianos})$$

Magnificação do brilho:

$$A = \frac{u^2 + 2}{u\sqrt{u^2 + 4}} \quad u = \beta/\theta_E$$

Exemplos

1) Magnificação mínima: $A = 3/\sqrt{5} \approx 1.34$

2) Magnificação para $u = 0,1 \rightarrow A \sim ...$

Microlente gravitacional: efeito de apenas $\sim 0,3$ mas

Desvio angular pequeno, mas também aumento de brilho

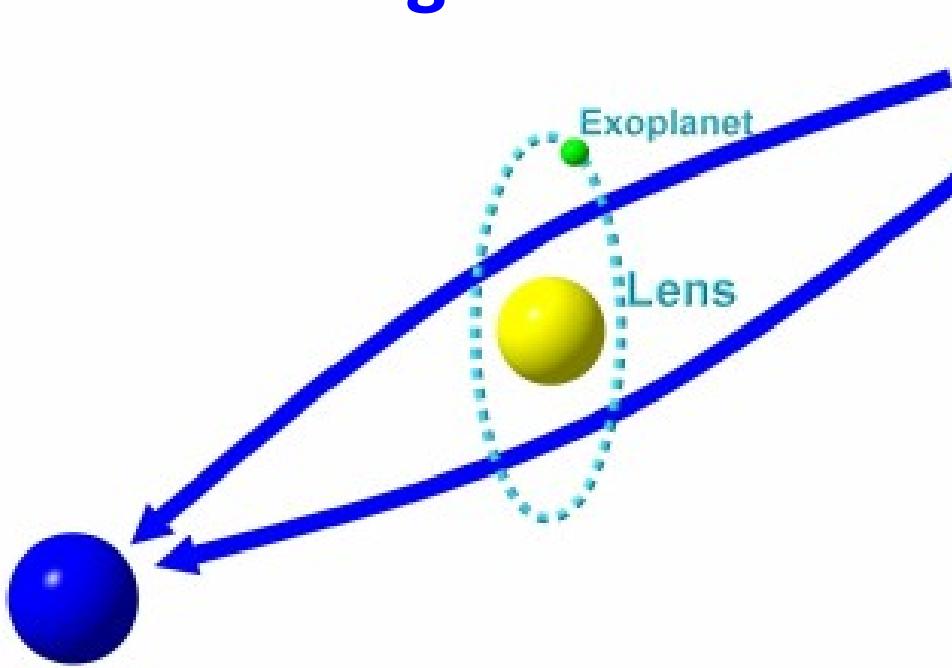

(1) Quando 1 estrela passa frente a outra, o brilho da estrela de fundo aumenta

$$A = \frac{u^2 + 2}{u\sqrt{u^2 + 4}}$$

$$u = \beta/\theta_E$$

1 When a foreground star (red) passes in front of a background star, it brightens the light of the background star. The gravitational field of the foreground star warps space to create a gravitational lens that magnifies light.

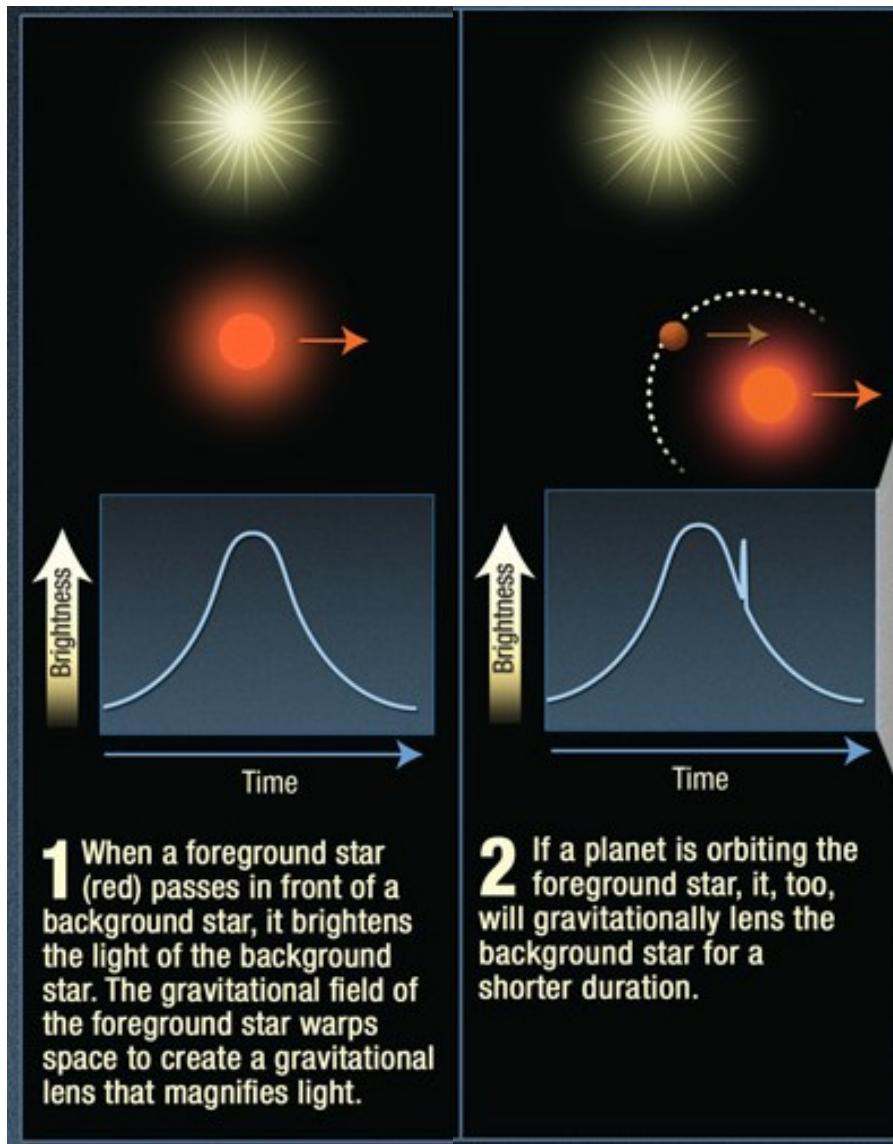

Microlente gravitacional

Desvio angular pequeno, mas também aumento de brilho

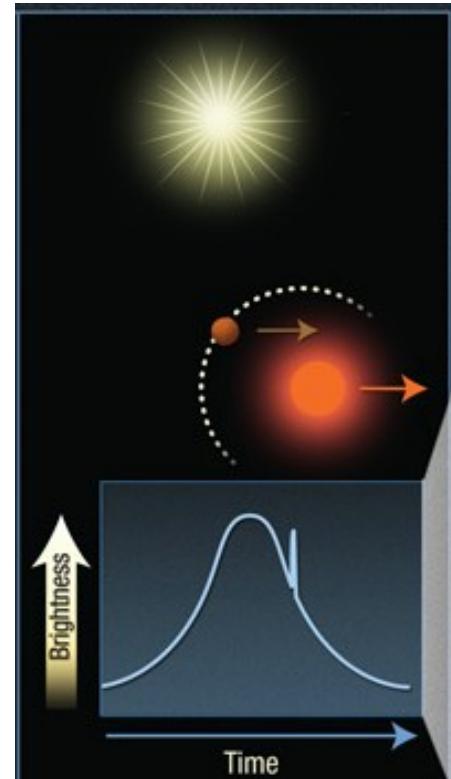

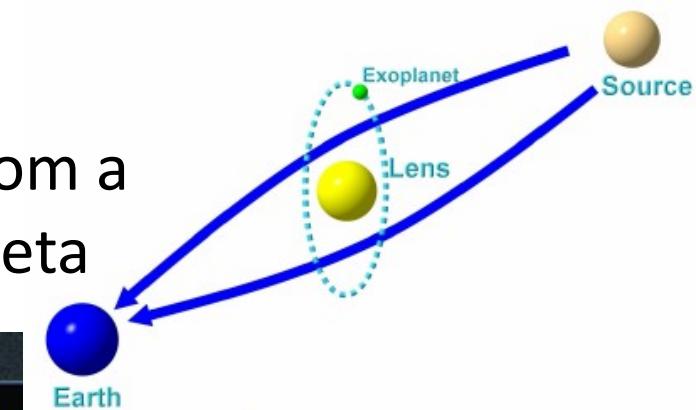

(1) Quando 1 estrela passa frente a outra, o brilho da estrela de fundo aumenta

(2) Se estrela “lente” tem planeta → magnificação adicional do brilho

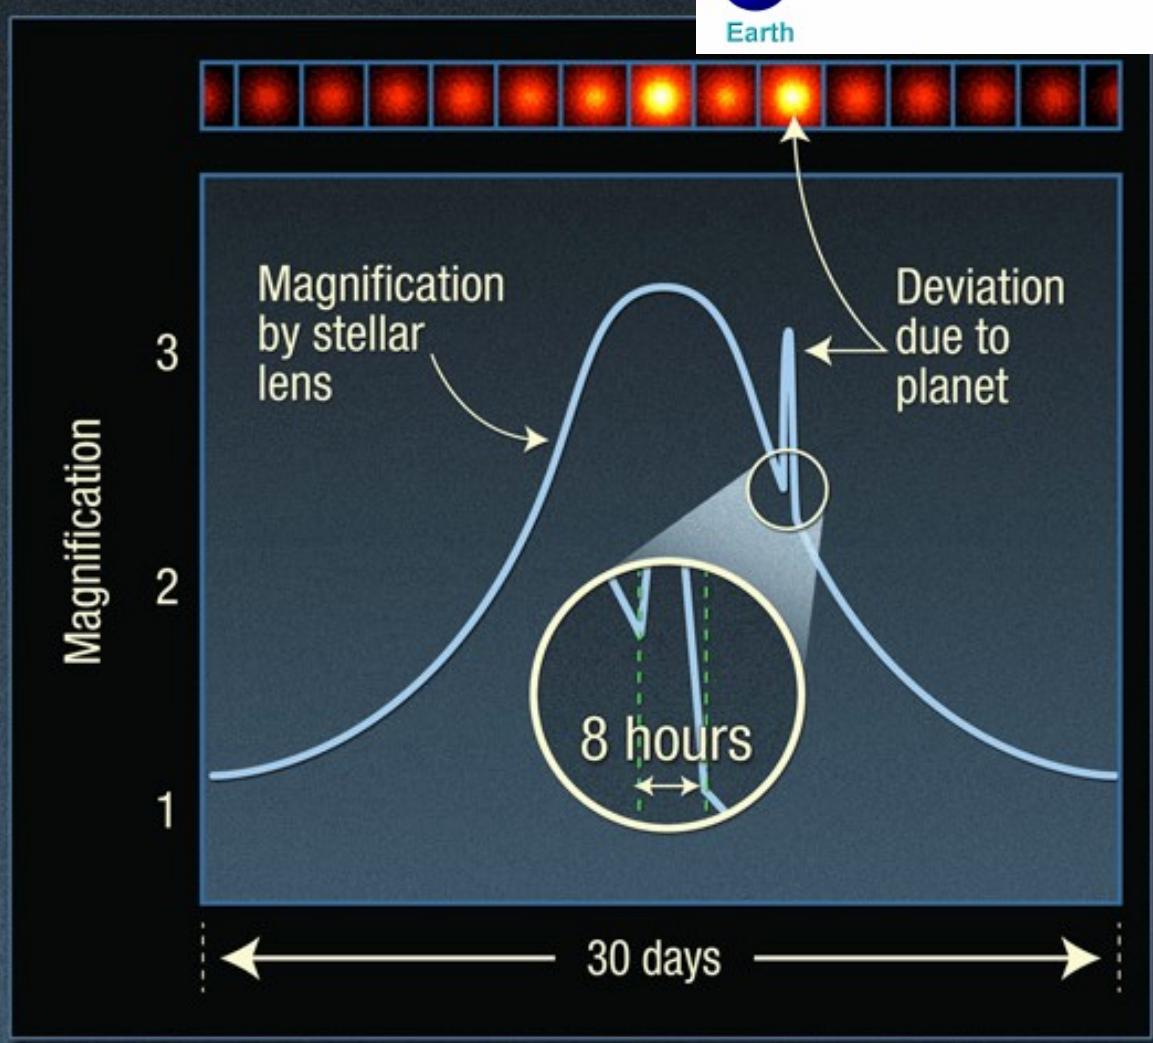

Microlente gravitacional

Magnificação de brilho pelo alinhamento com a estrela e aumento adicional devido ao planeta

2 If a planet is orbiting the foreground star, it, too, will gravitationally lens the background star for a shorter duration.

Microlente gravitacional: escalas de tempo

Escala de tempo

$$t_E = \frac{\theta_E}{\mu_{LS}}$$

θ_E : raio do anel de Einstein
 μ_{LS} : movimento próprio entre fonte S e lente L

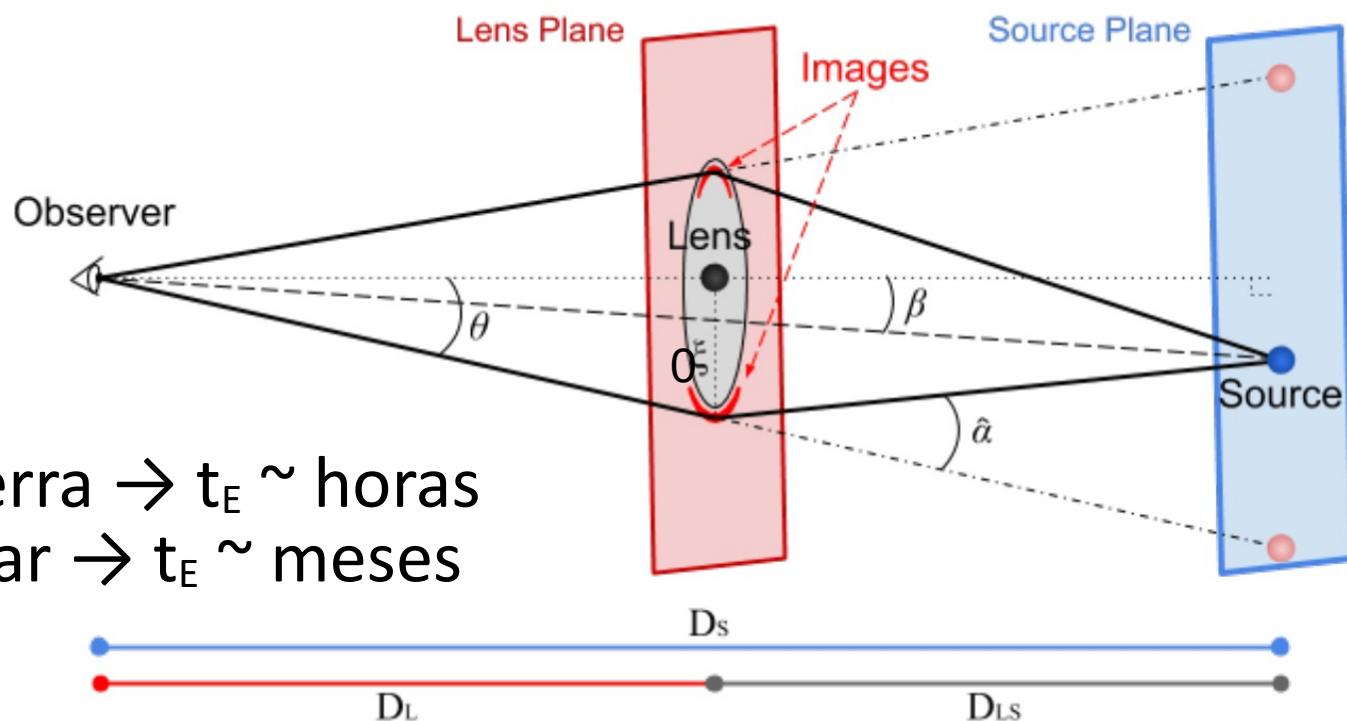

$$\theta_E = \sqrt{\frac{D_{LS}}{D_S D_L} \frac{4GM_L}{c^2}} \approx 0.902 \text{ mas} \left(\frac{M_L}{M_\odot} \right)^{1/2} \left(\frac{10 \text{ kpc}}{D_L} \right)^{1/2} \left(1 - \frac{D_L}{D_S} \right)^{1/2} \sim 300 \mu\text{as}$$

Usando um mov. próprio típico

$$\mu_{LS} \sim 15 \mu\text{as/d}$$

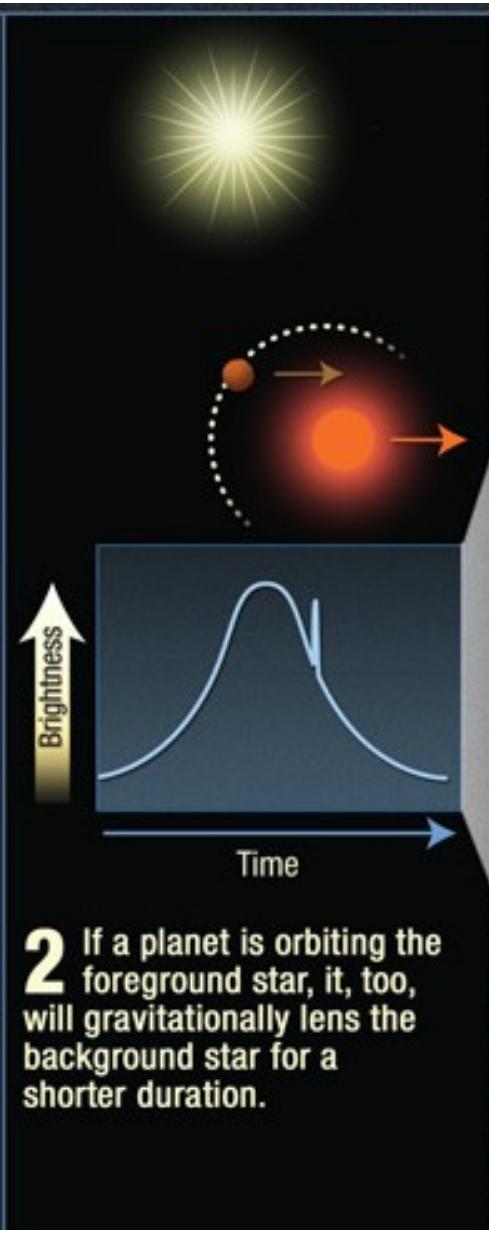

M_L = massa da Terra $\rightarrow t_E \sim$ horas

M_L = 1 massa solar $\rightarrow t_E \sim$ meses

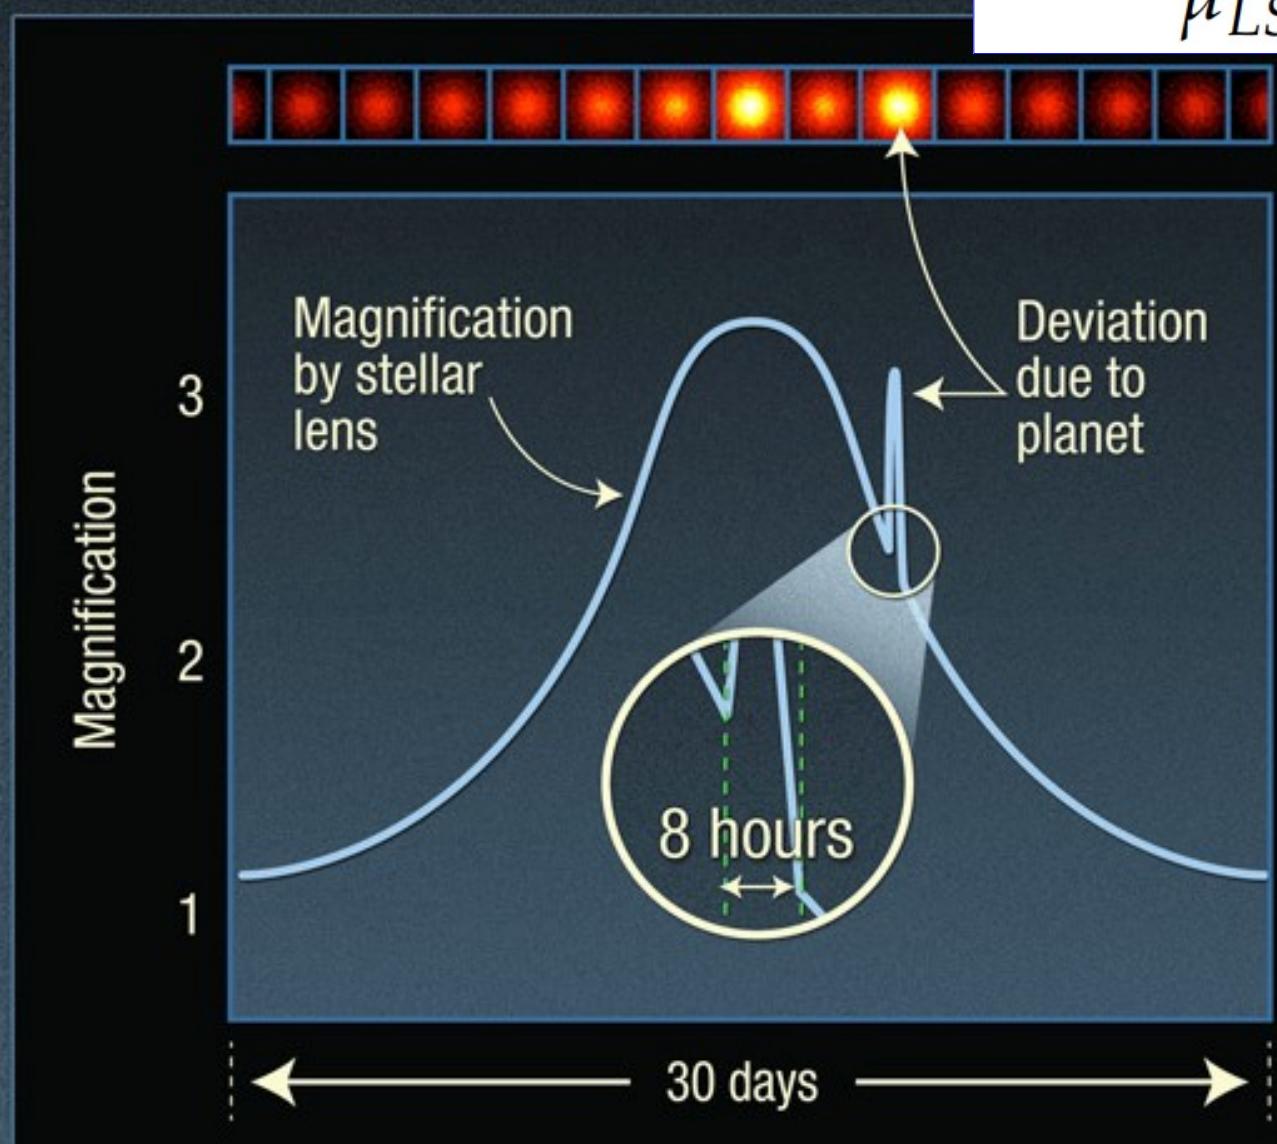

Microlente gravitacional: escalas de tempo

$$t_E = \frac{\theta_E}{\mu_{LS}}$$

2 If a planet is orbiting the foreground star, it, too, will gravitationally lens the background star for a shorter duration.

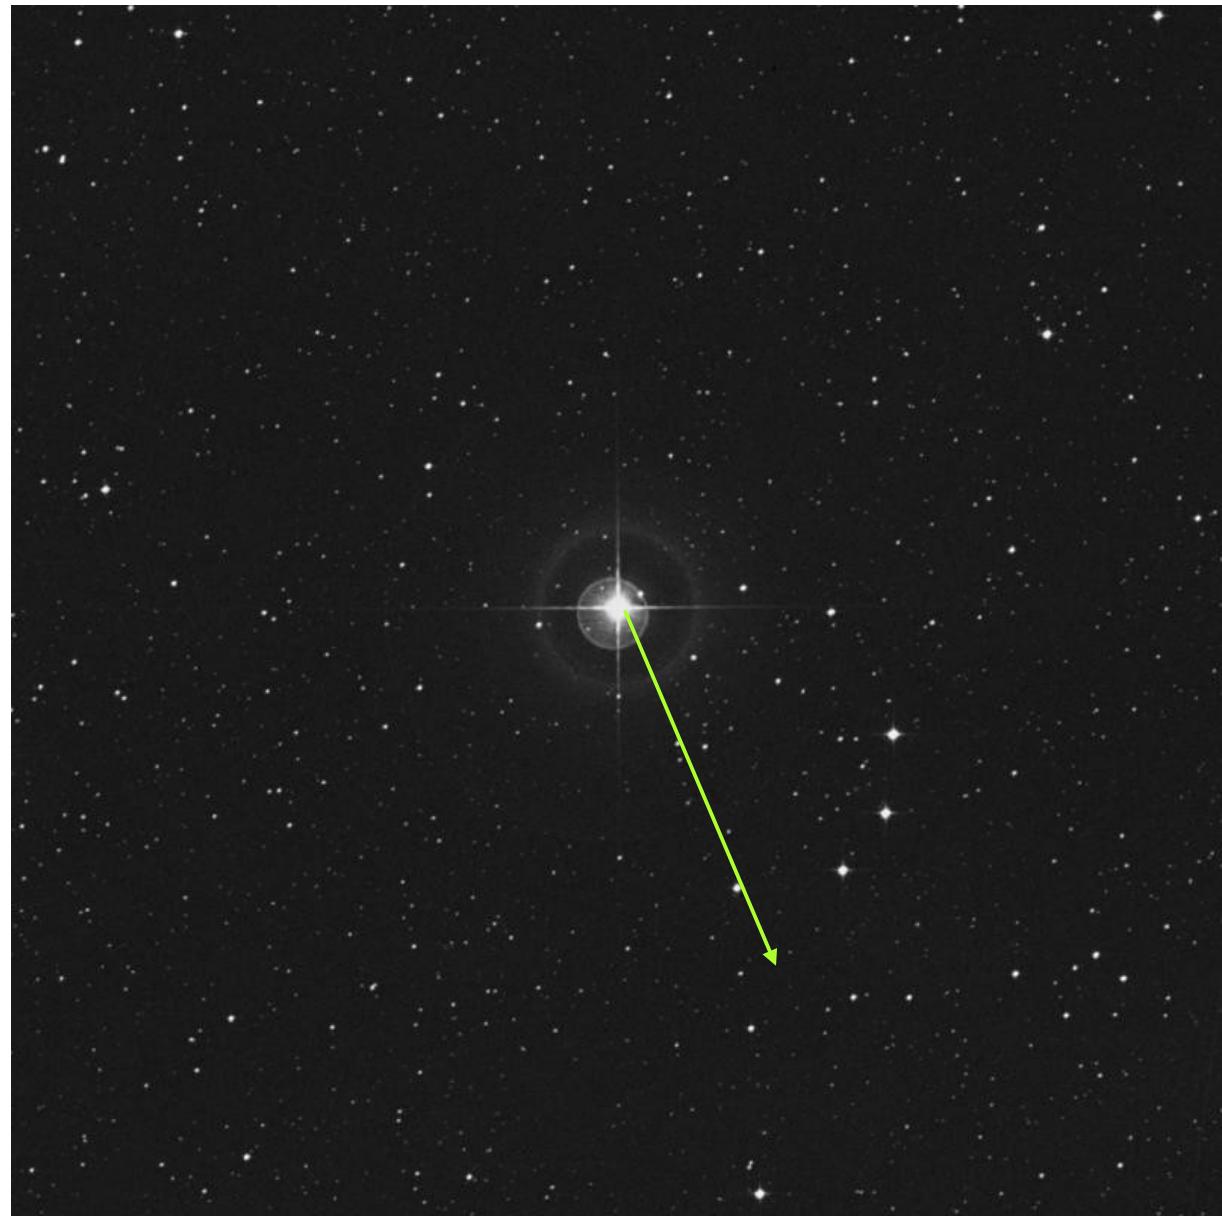

Estrelas são fontes quase pontuais → alinhamento perfeito é muito improvável (p.ex., nos próximos 1000 anos a *18 Sco* não ficará alinhada)

→ Procurar campos densos de estrelas

Imagen do *Digitized Sky Survey* de 0.5x0.5 graus (30x30 min de arco) ao redor da gêmea solar *18 Sco*.

O movimento próprio da estrela é de 0,2" / ano em A.R. e -0,5" / ano em Declinação. O percurso nos próximos 1000 anos é mostrado pela seta.

Chances de observar *microlensing* no bojo Galáctico $\sim 10^{-6}$

O futuro de exoplanetas via Microlensing: **Nancy Grace Roman Space Telescope (former WFIRST)**

Kepler: D = 0,95m - optical

Stars: 100 thousand within 3000 light years

Nancy (WFIRST): D = 2,4 m – optical to IR. Launch: 5/2027 ?
Stars: 200 million within \sim 20000 light years (Galactic center)

Instrumentos

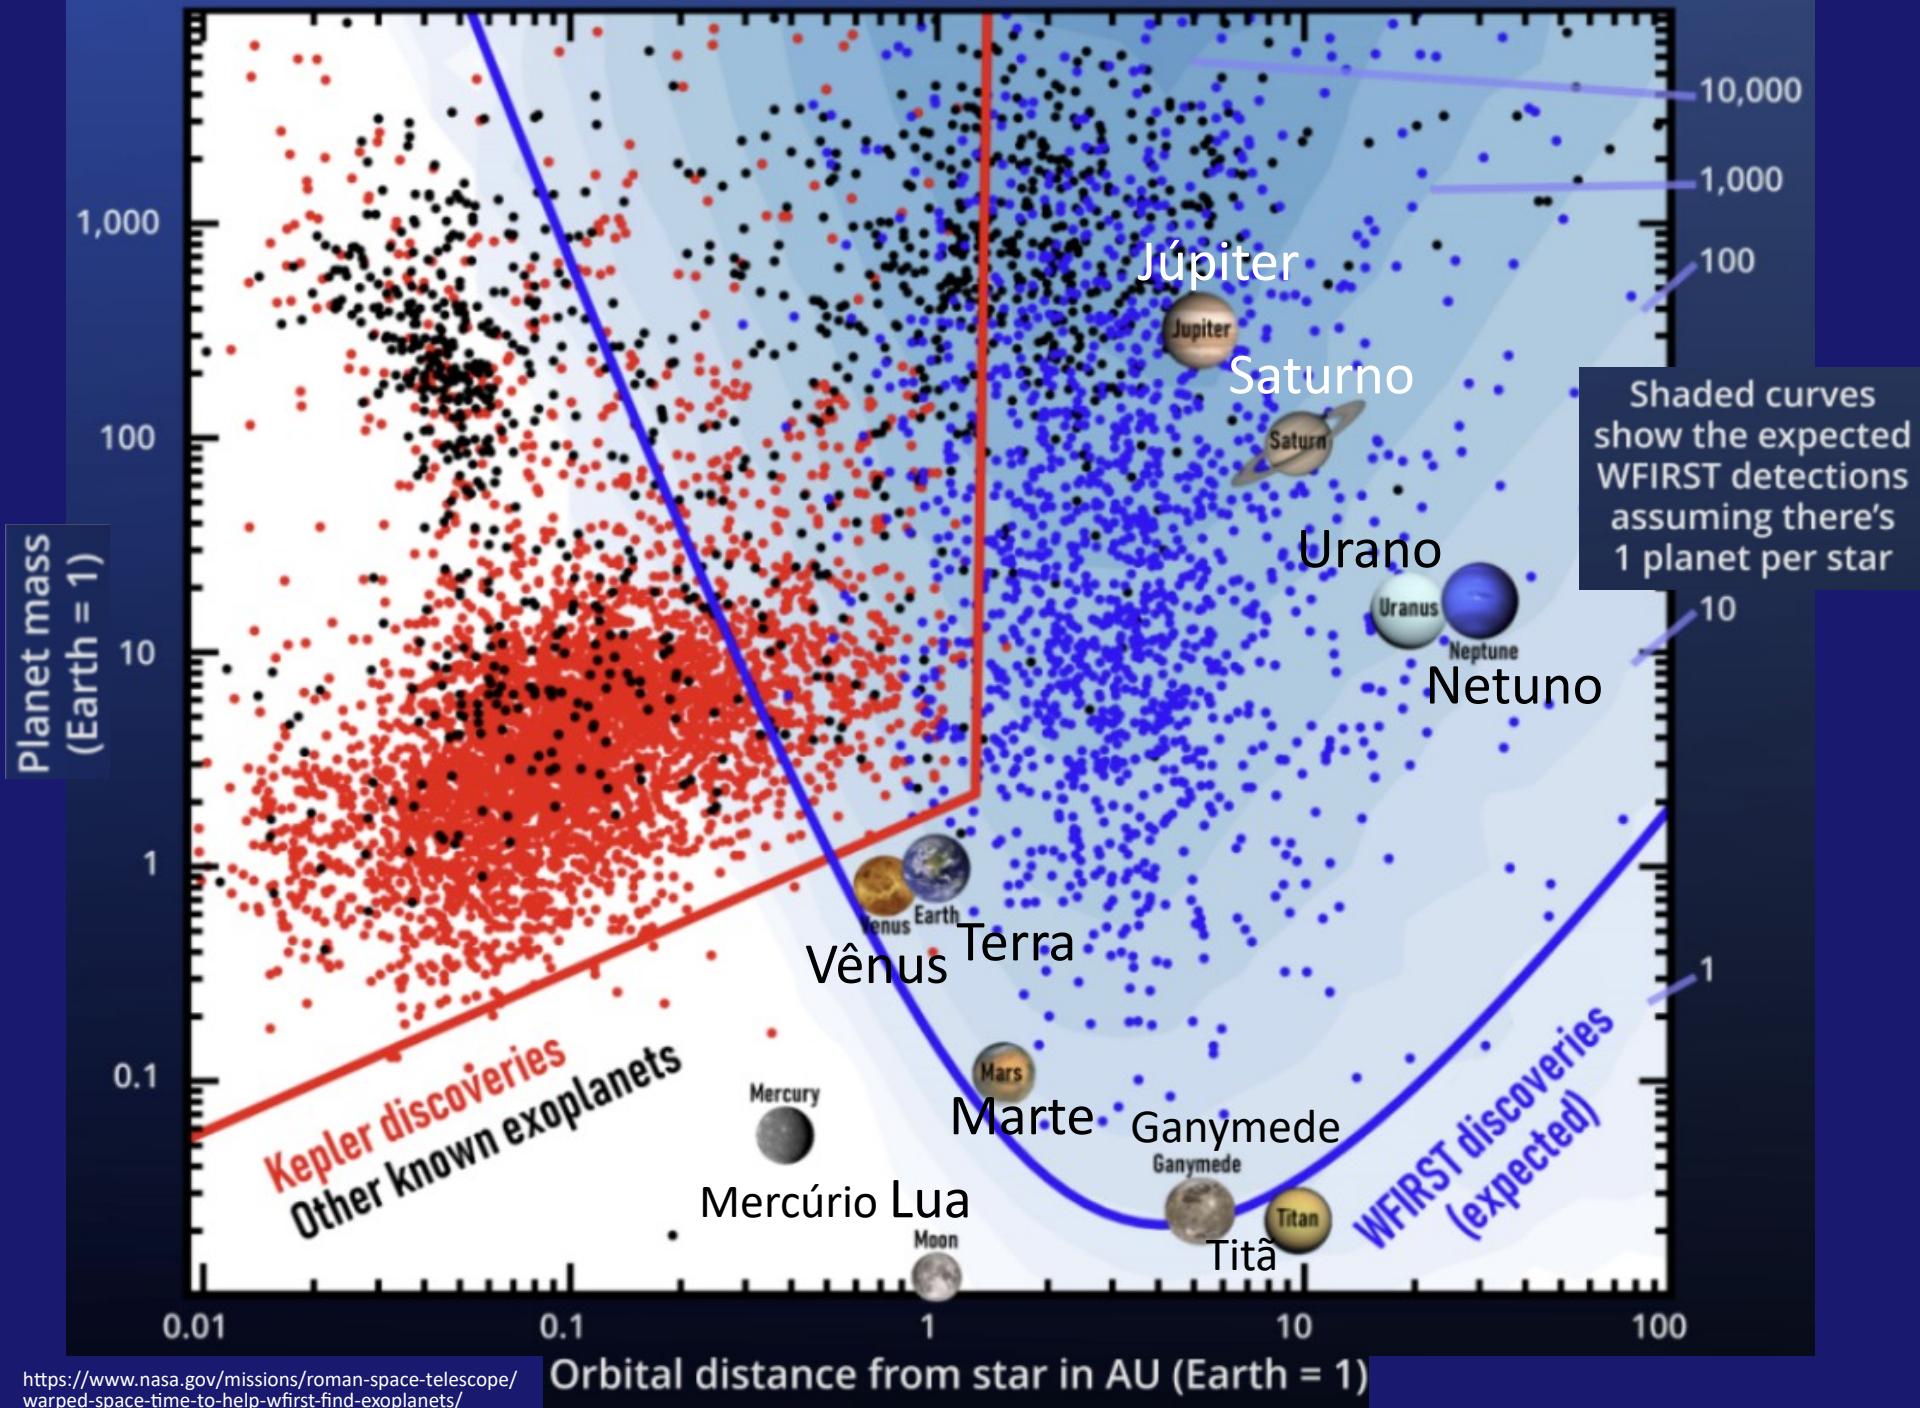

O telescópio transportará dois instrumentos

Wide-Field Instrument (WFI)

O Wide-Field Instrument (WFI) é uma câmera de 300,8 megapixels que fornece multibanda visível para imagens até infravermelho próximo (0,48 a 2,30μm) [18] usando um filtro de banda larga e seis filtros de banda estreita. Uma matriz de plano focal baseada em HgCdTe captura um campo de visão de 0,28 graus quadrados com uma escala de pixels de 110 milissegundos de arco. A matriz de detectores é composta por 18 detectores H4RG-10 fornecidos pela Teledyne . [19] Este instrumento também carrega conjuntos de prismas de alta dispersão e de baixa dispersão para espectroscopia sem fenda de campo amplo.

Instrumento Coronagráfico (CGI)

O Instrumento Coronagráfico (CGI) é um coronógrafo de alto contraste que cobre comprimentos de onda mais curtos (575 nm a 825 nm) usando tecnologia de supressão de luz estelar de espelho duplo deformável. Pretende-se obter uma supressão de parte por bilhão da luz estelar para permitir a detecção e espectroscopia de planetas com uma separação visual de apenas 0,15 segundos de arco de suas estrelas hospedeiras. [20]

Método de detecção: imageamento

Planetas são muito fracos. A detecção só é possível bloqueando a luz da estrela-mãe: CORONOGRAFIA

Gemini Planet Imager

GPI imaging of the planetary system HR 8799 in the near-infrared K band, showing 3 of the 4 planets. (Planet b is outside the field of view shown here, off to the left.) These data were obtained on November 17, 2013 during the first week of operation of GPI and in relatively challenging weather conditions, but with GPI's advanced adaptive optics system and coronagraph the planets can still be clearly seen. Credit: Christian Marois (NRC Canada), Patrick Ingraham (Stanford University) and the GPI Team.

GPI spectroscopy of planets c and d in the HR 8799 system. While earlier work showed that the planets have similar overall brightness and colors, these newly-measured spectra show surprisingly large differences. The spectrum of planet d increases smoothly from 1.9-2.2 microns while planet c's spectrum shows a sharper kink upwards just beyond 2 microns. These new GPI results indicate that these similar-mass and equal-age planets nonetheless have significant differences in atmospheric properties, for instance more open spaces between patchy cloud cover on planet c versus uniform cloud cover on planet d, or perhaps differences in atmospheric chemistry. These data are helping refine and improve a new generation of atmospheric models to explain these effects. © Patrick Ingraham, Mark Marley, Didier Saumon and the GPI Team.

- Both are powerful instruments
- Sphere is faster (in 1 shot Y, J, H spectra & photometry in K)
- GPI can take spectra in K band

GPI 1.0 vs Sphere

Latest News

May 2022

GPI 1.0 has been shipped on May 6th to the University of Notre Dame in Indiana, where the upgrades will be taking place.

August 2020

GPI 1.0 is decommissioned at Gemini South, after being in nearly continuous operation since 2013.

What is GPI 2.0?

Gemini Planet Imager 2.0 (GPI 2.0) is an upgrade of the GPI instrument previously located at Gemini South. The upgrade includes an enhanced high-sensitivity wavefront sensor, new coronagraph masks with smaller inner working angles or higher throughput, new spectrographic modes, and software/operability improvements. GPI 2.0 is an extreme adaptive-optics imaging polarimeter and integral-field spectrometer, which will provide diffraction-limited data between 0.97 and 2.4 microns with a Strehl Ratio in H-band of ~0.9 down to 12th magnitude stars and will continue to operate, albeit with a decreased performance, beyond the 14th magnitude. The system should provide contrast ratios of 10^7 for companions at separations of 0.2-1.0" in a 1-2 hour observation thanks to an upgrade of its coronagraph. The science instrument will also be upgraded to provide a single-shot YJHK spectroscopy at R~12 and higher spectral resolution in single bands (R~40 in H-band). The control software will be updated to significantly increase the efficiency and robustness of GPI operations. The dual-beam polarimetry will remain unchanged. GPI 2.0 will still be capable of detecting point sources down to H=20, with $\geq 5\sigma$, in 1 hour in absence of photon noise from a bright companion.

- AO operable 0-14th mag, with a graceful degradation after 13th mag
- Strehl ratio 0.9 for stars brighter than H=12 **With this configuration, GPI will become competitive:**
- contrast ratio 10⁷ at separations 0.2-1.0"
- wavelength range 0.97-2.4μm - lower mass planets in younger stars
- plane options - higher mass planets in older stars
- coronagraphy (APLC)
- direct (no APLC)
- non-redundant mask (NRM)
- IFU spectroscopy - closer (4 - 10 AU) orbits
- single-shot YJHK at R~12
- single-band at R~40
- 2.7" square field of view
- 0.014" per lenslet spatial sampling - distribution peak of giant planets around solar-type stars
- polarimetry - differentiate between cold-start (core accretion) and hot-start (disk collapse) formation models
- dual-channel polarimetry
- Y, J, H and K bands - very young stars & transitional disks
- planet variability and abundances
- AGN jets, both spectroscopic and polarimetric
- asteroids & other solar system bodies

Imagen infravermelha do Observatório Europeu do Sul, mostrando o disco de detritos ao redor da estrela jovem Beta Pictoris (23 Myr) e o planeta Beta Pictoris b, descoberto inicialmente em 2008.

Planeta (a partir da estrela)	Massa	Semieixo maior (UA)	Período orbital (d)	Excentricidade orbital	Inclinação (°)	Raio
b	$12_{-3}^{+4} M_J$	$9,2_{-1,5}^{+0,4}$	7890 ± 1000	$\sim 0,1$	$89,01 + 0,36$	$1,65 R_J$

Evidence for an additional planet in the β Pictoris system

A.-M. Lagrange [✉](#), Nadège Meunier, Pascal Rubini, Miriam Keppler, Franck Galland, Eric Chapellier,

Novo planeta descoberto em Agosto de 2019, Beta Pictoris c, usando o método de velocidades radiais, com 10 anos de observações obtidas com o HARPS/ESO

The Beta Pictoris planetary system

Companion (in order from star)	Mass	Semimajor axis (AU)	Orbital period (days)	Eccentricity	Inclination	Radius
c	$9 M_J$	2.7	1200	0.24	—	—
Inner belt			6.4 AU		$\sim 89^\circ$	—
b	$12_{-3}^{+4} M_J$	$9.2_{-1.5}^{+0.4}$	7890 ± 1000	~0.1	$89.01 + 0.36^\circ$	$1.65 R_J$
secondary disk			130+ AU		$89 \pm 1^\circ$	—
main disk			16–1450/1835 AU		$89 \pm 1^\circ$	— 65

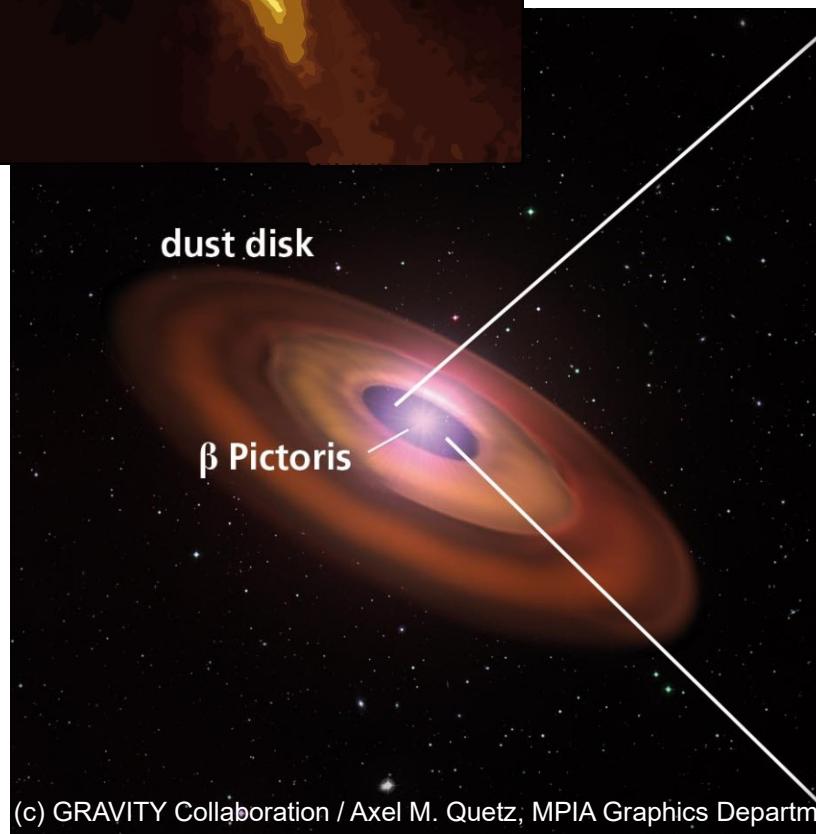

Direct confirmation of the radial-velocity planet β Pictoris c

M. Nowak^{1,2}, S. Lacour^{3,7}, A.-M. Lagrange⁴, P. Rubini²⁴, J. Wang¹⁰, T. Stolker²⁷, R. Abuter⁷, A. Amorim

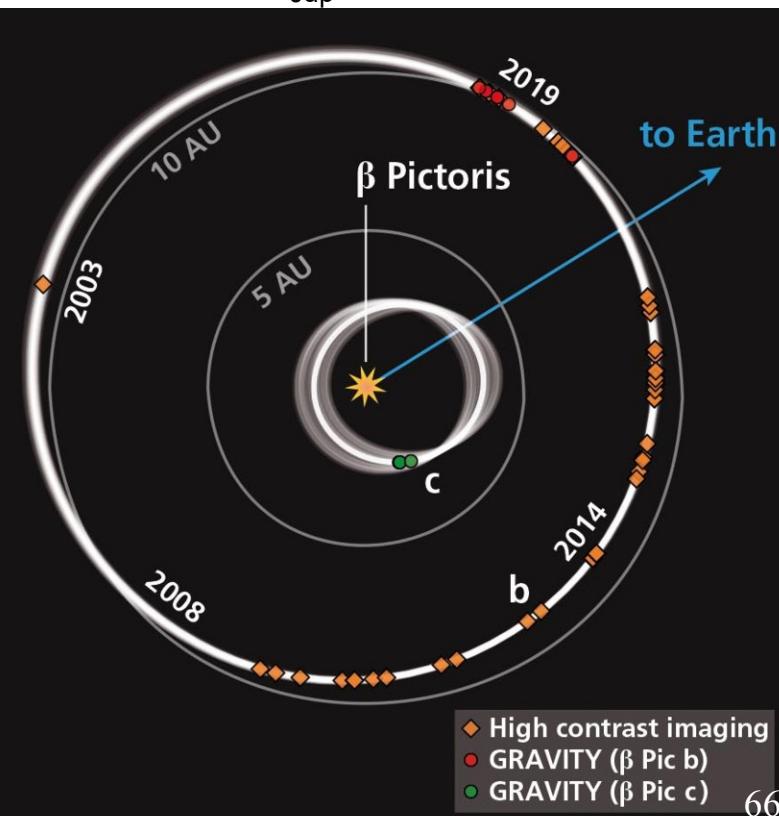

Atualização (2020) para as massas:

β Pictoris c: $8.2 \pm 0.8 M_{Jup}$,

β Pictoris b: $9.0 \pm 1.6 M_{Jup}$

Futuro: Roman Space Telescope (WFIRST), 2027

Futuro: Habitable Worlds Observatory (HWO), 2040?

- 9 star systems **within 10 light-years** of Earth,
- 22 star systems within 12 light-years of Earth,
- 40 star systems within 15 light-years of Earth,
- and **95 star systems within 20 light-years** of Earth.

Futuro: Habitable Worlds Observatory (HWO), 2040?

- that launches as early as the late 2030s/early 2040s,
- that's on-budget and on-time,
- that possesses the necessary architecture to achieve its observational goals without needing a starshade,
- that's fully refuelable and whose instruments are fully serviceable and replaceable,
- that could have a starshade added to it at any point in the future,
- and that quite possibly images enough “Earth-like” planets to discover at least one (and maybe even more than one) exoplanet that’s actually inhabited.

Futuro: Habitable Worlds Observatory (HWO), 2040?

Sample	F	G	K	M
Tier A	14	15	17	1
Tier B	15	23	11	2
Tier C	37	17	12	0
Total (A+B+C)	66	55	40	3

Serão observadas principalmente estrelas de tipo solar (F, G, K).

Grupo SAMPA/IAG-USP deve ajudar a caracterizar as propriedades das estrelas *target* do HWO
