Dedication

We are honored to dedicate this eighth edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction* to Lorraine Williams Pedretti. Lorraine Williams Pedretti was selected by the American Occupational Therapy Association as one of the 100 Influential People in the field of occupational therapy as part of the profession's centennial celebration. Her thoughtfulness, love of her profession, and dedication to the education of her students provided the impetus to embark on the daunting task of writing and editing an original textbook (and ensuing editions) for evaluation and treatment of adults with physical disabilities. As academic colleagues of Professor Pedretti, we were inspired by her example and challenged to accept the responsibility to continue in her footsteps to contribute to the advancement of the profession. It is our hope that our efforts have honored her example and lived up to her faith in us.

We would also like to dedicate this edition to occupational therapy students (past, present, and future) who are the future of our wonderful profession: may you find the happiness and fulfillment that we have as proud occupational therapists.

Foreword

It is an honor and a privilege to write the foreword to the eighth edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction*. I was the book's original author and the primary editor of the first five editions. The book was first published in 1981. It has been widely used by occupational therapy students in the United States and abroad for 36 years. Over this time, it has enjoyed a reputation for its practical and comprehensible writing, and for covering the essential theoretical and practical information needed for clinical practice. As editions progressed, the text evolved to keep pace with changes in the rapidly growing body of knowledge and expanding areas of clinical practice in occupational therapy. It is very gratifying for me to know that this book continues to be an important resource for students, occupational therapy educators, and clinicians in the profession.

I was very pleased that my professional colleagues at San Jose State University, Dr. Heidi McHugh Pendleton and Dr. Winifred Schultz-Krohn, will continue as the book's editors. Dr. Pendleton, who was my student many years ago, joined the faculty of San Jose State University in 1987 after many years of clinical practice, working with clients with physical dysfunction. It was gratifying to witness her professional and academic development, to observe her numerous professional achievements, and to see her earn the doctorate in the field. After serving a term as Chair of the Department of Occupational Therapy at San Jose State University from 2008-2012, she returned to teaching courses in the history and theory of occupational therapy and professional development. She received the Lifetime Achievement Award from the Occupational Therapy Association of California in 2011.

Dr. Winifred Schultz-Krohn came to San Jose State University in 1996 with excellent credentials and qualifications. She has many years of clinical practice in pediatrics, is a board-certified pediatric occupational therapist, and has previous academic experience. She has extensive education and expertise in neurological dysfunction. Professor Schultz-Krohn was awarded the prestigious regional Jefferson Award for more than 17 years of pro bono occupational therapy services to the San Jose Family Homeless Shelter. Her tireless volunteer work ranged from developing and supervising a summer OT fieldwork program to providing practicum and research opportunities to hundreds of occupational therapy students. She received the Outstanding Professor Award for San Jose State University in 2014. Professor Schultz-Krohn is currently Chair of the Department of Occupational Therapy at San Jose State University.

These editors are professional and academic leaders in the field. They have published numerous articles and book chapters and have received many professional awards and recognitions. They have clinical and academic expertise and a wealth of professional knowledge that makes them eminently qualified for their editorial roles. They have done an excellent job in authoring chapters, editing, and coordinating the preparation of the sixth, seventh, and now the eighth editions.

These editors have assembled a roster of excellent contributors: leaders and experts in the occupational therapy profession who are well qualified to write on their respective subjects. As the profession grew and changed, the content and format of the textbook evolved to reflect those changes. Therefore, more contributors were invited to participate in the preparation of each edition. There are over 60 contributors in the eighth edition, 21 of whom are new contributors.

The content of the eighth edition reflects the substantive changes that have occurred in occupational therapy philosophy and practice. The content has been restructured and is based on the new Occupational Therapy Practice Framework-3, with expanded emphasis on evidence-based practice and emerging practice areas. The content reflects new research and theories, new techniques, and current trends in the profession while maintaining a focus on client-centered practice. This edition continues to include case studies, clinical reasoning skills, ethical questions and concerns, factors of cultural diversity, and practice notes that are threaded throughout the book. There is one new chapter: Chapter 49, *Occupational Therapy in Hospice and Palliative Care*; and a new section added to Chapter 7, Section 2, *The Therapeutic Use of Self: Embodying Mindfulness in Occupational Therapy*. The enhanced content will teach the student essential clinical reasoning skills and provoke thinking about potential ethical and cultural considerations in treatment. There is comprehensive coverage of physical dysfunction. Chapters on evaluation of joint range of motion (21) and muscle strength (22) have a whole new look with full color photos and drawings, as well as approaches to simplify and clarify the evaluation processes. Especially exciting is the accompanying Evolve website for students and instructors. This development brings this textbook into the electronic information age and has great potential for independent study by students and as a resource for occupational therapy educators.

Writing and editing a textbook is no small task. It takes a great deal of time, patience, and persistence. It involves dealing with numerous people—editors, contributors, vendors, models, photographers, and artists. I was so fortunate that my worthy colleagues agreed to adopt this textbook and keep the production going after my retirement. I am very grateful that they have produced this excellent work and so pleased that it will continue to be associated with the occupational therapy program of excellence at San Jose State University.

Lorraine Williams Pedretti MS, OT (retired) *Professor Emeritus San Jose State University*

Preface

It was a great honor to be asked to assume the editorship of the eighth edition of *Pedretti's Occupational Therapy: Practice Skills for Physical Dysfunction*. To continue to follow in the footsteps of the inimitable Lorraine Pedretti is at once an awesome responsibility and a rewarding journey. The opportunity to work with authors, each a leading expert in his or her field, continues to be an unparalleled experience of the exceptional ability of stellar occupational therapists to organize their time and unselfishly devote their scholarship to the education of future generations of the profession.

Since the publication of the seventh edition, there have been changes within the profession and within the clinical practice of occupational therapy for clients with physical dysfunction. Many of those changes served to shape the approach we took to the new edition and are reflected within the context of each of the chapters. Our mission and intention was to embrace these changes and continue to honor the primacy of occupation that has been the foundation of this textbook for the past several editions.

The eighth and latest edition is framed and guided by the Occupational Therapy Practice Framework: Domain and Process—3rd (OTPF-3), designed to describe the focus and dynamic process of the profession. Key to the OTPF-3 is its view of the overarching goal of occupational therapy; that is, engagement in occupation to support participation in life. This conceptualization of the importance of occupation is emphasized throughout the text. The concepts of process and practice, evaluation and intervention, performance skills and patterns, contexts and activity demands, client factors, and intervention applications are all thoroughly illustrated throughout.

To honor the centrality of the client to occupational therapy practice, the chapters begin with case studies, which are then threaded throughout, guiding the reader through the information and relating the content to the specific case descriptions. Thus, the reader is able to experience the clinical reasoning and decision-making skills of the expert clinicians who authored the chapters. Authors of individual chapters were asked to follow the initial presentation of their case studies by crafting several probative or "critical thinking" questions that would pique the readers' curiosity, further motivating their attention to and questioning of the chapter content and consequently facilitating the learning process. Direct answers to these critical thinking questions are provided either within or at the end of each of the chapters.

This textbook, written for an intended audience of occupational therapy graduate students and as a reference for practicing occupational therapists, has always been acknowledged for its practical application and focus on practice. Theory and evidence-based content are presented in each chapter and then applied using case descriptions as a foundation for practice. Occupational therapy's role in health and wellness, as well as prevention, is addressed throughout the text. Similarly, occupational therapy's commitment to the importance of considering cultural and ethnic diversity is reflected in every chapter.

The eighth edition continues to feature the OT Practice Notes and the Ethical Considerations boxes that are highlighted throughout many of the chapters. The information contained in these boxes (pulled from the chapter content) conveys ideas that are relevant to students' future practice areas and thoughts about some of the possible ethical dilemmas and decisions with which they might be confronted. New support materials include the Evolve website, which includes both a link to student-related materials as well as an instructor link with access to the Instructor's Resource Manual and a test bank.

During the process of editing this book, including the stages of envisioning and designing the content and format, selecting the authors, and reading and giving input to their work, we were guided by our commitment to honoring the occupational welfare of our clients, particularly adults with physical disabilities, through excellent preparation of their future occupational therapists. To that end we sought preeminent authors, those who not only had recognition for expertise in their topic area, but who also embraced the primary importance of occupation to their practice and scholarship. Our goal was to engender excitement in the reader for occupational therapy in the area of physical dysfunction, while providing cutting-edge information and promoting models of best practice. Our extensive and rewarding clinical and academic careers in the profession of occupational therapy and our experiences with hard-working and inspiring clients and students served as the inspiration for our best efforts, which we trust are evident in this book.

Heidi McHugh Pendleton

Winifred Schultz-Krohn

Acknowledgments

We would like to thank the authors, past and present, for their exceptional contributions and willingness to continue the tradition of excellence that has come to be associated with the Pedretti book. The impressive list of authors for the eighth edition continues the Pedretti reputation for including nationally and internationally known experts in their topic areas and disciplines. We are fortunate to feature contributions from new authors and included among them are administrators, educators, researchers, and master clinicians.

We would also like to acknowledge the superb contribution of the dedicated editors and staff at Elsevier. We are especially grateful to Jolynn Gower, Content Development Manager; Kellie White, Executive Content Strategist; and Courtney Sprehe, Senior Content Development Specialist, who patiently and painstakingly mentored us through the long and arduous editing process. They are simply outstanding! Our thanks go to Rich Barber, Senior Project Manager, who, with exceptional attention to detail, made sure that the final product reflected the efforts of all involved.

To those publishers and vendors who permitted us to use material from their publications, we extend our sincere gratitude. Photographers and artists, and the clients and models who posed for photographs, are gratefully acknowledged. We are grateful to the contributors who were particularly generous in finding just the right photographs to capture the importance of occupation to participation in life—we thank you!

Finally, we would like to extend heartfelt appreciation to our colleagues, friends, and families, without whose help and support this accomplishment could not have been achieved. Special expressions of *thank you* go to the faculty and staff at San Jose State University, who could be counted upon for their support and good wishes during this process.

Heidi McHugh Pendleton extends her gratitude to her husband, Forrest Pendleton (for immeasurable love and support without which this endeavor could never have succeeded) and to her sisters, Deirdre McHugh and Kathleen McHugh (for a lifetime of support). Her love and appreciation go to all of her nieces, nephews, and stepson, including Dar, Jim, Nicky, Elizabeth, Jimmy D, Megan, Kelsey, Jamie, Jessica, and Katie—their love and enthusiasm make everything possible. She would like to also extend gratitude to her brother-in-law, H. Duncan Mason, MD, and to occupational therapy student, Morgan Gralla, from Towson University, who contributed their expertise to identify and correct inadvertent misinformation in a chapter from the last edition. It is always our intention to present the best information available, and we deeply appreciate feedback from our readers.

Winifred Schultz-Krohn extends a huge thank you to her always supportive, ever-patient husband, Kermit Krohn. His tireless love made the project possible. She is also very grateful for the support and encouragement received from her brother, Tom Schultz; his wife, Barb Fraser; and niece, Sarah; her sister, Donna Friedrich; husband, Don; nephews, Brian and Andrew; Andrew's wife, Kirsten; and grand nephew, Zachary; sister, Nancy Yamasaki; and husband, Bryan.

The co-editors would like to thank each other—great friends at the beginning of the process—we were able to be there for each other, make our own unique contributions, and ultimately sustain our friendship throughout the process, emerging even better friends in the joy of our accomplishment.

PART I

Overview: Occupational Therapy Foundations for Physical Dysfunction

OUTLINE

The Occupational Therapy Practice Framework and the Practice of Occupational Therapy for People With Physical Disabilities

Heidi McHugh Pendleton, Winifred Schultz-Krohn

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Briefly describe the evolution of the Occupational Therapy Practice Framework, from the original OTPF through the OTPF-3.
2. Describe the need for the OTPF-3 in the practice of occupational therapy (OT) for persons with physical disabilities.
3. Describe the fit between the OTPF-3 and the ICF, and explain how they inform and enhance the occupational therapist's understanding of physical disability.
4. Describe the elements of the OTPF-3, including domain and process and their relationship to each other.
5. List and describe the components that make up the OT domain and give examples of each.
6. List and describe the components that make up the OT process and give examples of each.
7. Briefly describe the OT intervention levels, and give an example of each as it might be used in a physical disability practice setting.

Threaded Case Study

Kent and Karen, Part 1

Kent is a highly skilled and very competent occupational therapist with more than 25 years of clinical experience. He works in a large rehabilitation center with adult clients who have physical disabilities. He currently is the supervising occupational therapist on the spinal cord injury (SCI) unit. Through his reading of OT publications,[3,14,15,18,23] attendance at conferences and workshops, and interactions with his OT staff and interning OT students, he has become increasingly knowledgeable about the Occupational Therapy Practice Framework (OTPF) and its current version, the OTPF-3. When the OTPF-3 was published, he initially was annoyed that, among the many challenges to his professional time and efforts, he would have to learn, yet again, a new "language" to provide competent interventions, and that even before he had mastered the first two models, a third, updated edition had appeared. He couldn't help thinking, "Why fix something that isn't broken?" He reluctantly acknowledged the necessity for the change. Now, however, he is impressed by what he has learned so far, and he is convinced that he can no longer postpone delving into and really learning the OTPF-3 and integrating it into his clinical practice.

Throughout his practice, Kent has found it helpful to relate new or novel OT information he is learning to the relevant circumstances that either he or one of his clients is experiencing; in this way he considers the impact the new information might have on either his own life or that of his client.

Kent has decided that, as he works on learning the OTPF-3 (also referred to as the *Framework*), he will keep in mind one of his recently admitted clients, Karen. Karen is a single, 25-year-old woman who lives alone in her own apartment and works as an administrative assistant for a busy law office. Karen incurred a cervical SCI and now has C6 functional quadriplegia/tetraplegia that necessitates use of a wheelchair for mobility. By keeping Karen in mind, Kent expects not only to learn the changes and updates to the Framework, but also to reinforce his new knowledge by putting it to immediate use in his practice.

Critical Thinking Questions

As you read through the chapter, keep in mind the challenges that learning the OTPF-3 and integrating it into his practice will pose for Kent. Think of strategies you might recommend or use yourself to learn and integrate the information into your practice. In addition, consider the objectives for the chapter, outlined previously, and also these questions:

1. Why was there a need for the OTPF and its subsequent second and third versions, and how do they fill that need?

2. How might the specific information presented about the OTPF-3 apply to Kent or Karen?

3. Are there tools that Kent and other OT practitioners can use to help them learn the OTPF-3 and integrate it into their practice?

The Occupational Therapy Practice Framework: Domain and Process, Third Edition (OTPF-3)—Overview

Many changes have occurred in the practice of occupational therapy for persons with physical disabilities since the publication of the previous edition of *Occupational Therapy: Practice Skills for Physical Dysfunction* in 2014. OT practice settings are increasingly moving away from traditional healthcare environments, such as the hospital and rehabilitation center, and have made significant strides moving more toward the home and community milieus. The provision of OT service has become progressively more client centered, and the concept of occupation is increasingly and proudly named as both the preferred intervention and the desired outcome of the services. Clinicians, researchers, and scholars have sought to implement evidence-based practice by learning more about the benefits of occupation not only to remediate problems after the onset of physical disability, but also to anticipate and prevent physical disability and promote wellness. Not surprisingly, economic concerns have severely shortened the amount of time allotted for OT services, thus necessitating more deliberate and resourceful decisions about how these services can be delivered most effectively.

In response to these changes and many other practice advances, came a change, or evolution, in the language that occupational therapists use to describe what they do and how they do it. This change, in turn, resulted in the document "The Occupational Therapy Practice Framework: Domain and Process," published in 2002 by the American Occupational Therapy Association (AOTA) in the *American Journal of Occupational Therapy* (AJOT).[1] (The model set forth in the document is commonly referred to as the Occupational Therapy Practice Framework [OTPF] or just the Framework.)

The OTPF is a tool developed by the OT profession to more clearly articulate and enhance the understanding of what OT practitioners do (occupational therapy domain) and how they do it (occupational therapy process). The intended beneficiaries of all three editions of the OTPF were envisioned as including not only OT practitioners (an internal audience), but also the recipients of OT services (referred to as clients), other healthcare professionals, and those providing reimbursement for OT services (an external audience).

The first version of the Framework was put into practice, and its relevance and efficacy were assessed; this evaluation resulted in the OTPF-2,[2] which was published in the AJOT in 2008. The same rigorous examination was applied to produce the current version, **"The Occupational Therapy Practice Framework: Domain and Process," third edition (OTPF-3)**, which appeared in the AJOT in 2014.[3]

The OTPF-3 is an important document that every OT practitioner should have and consult frequently. It can be downloaded from the AOTA website (*http://www.aota.org*) by selecting AJOT (under Publications & News at the top of the homepage) and then the March/April 2014 issue; a PDF copy of this document can be downloaded and printed for convenience to members of the AOTA. Another helpful tool for learning the Framework is the introductory article by Youngstrom titled, "The Occupational Therapy Practice Framework: The Evolution of Our Professional Language,"[27] which appeared in the November/December 2002 issue of the AJOT.

It is not the intention of this chapter to supplant the comprehensive OTPF-3 document, but rather, to describe the model and increase the reader's understanding of the OTPF-3 and its relationship to the practice of occupational therapy with adults with physical disabilities. To achieve this, the chapter begins with a discussion of the history of the OTPF-3, followed by sections describing the need for the OTPF-3 and the fit between the OTPF and the World Health Organization's (WHO) ***International Classification of Functioning, Disability, and Health*** **(ICF)**. Next, a detailed description of the Framework is presented, with emphasis on explicating the domain of occupational therapy through examples from the case study and introducing the OT process (discussed in depth in Chapter 3) in the application of the Framework to individuals with physical dysfunction. The types of OT intervention proposed by the Framework 3 are examined and illustrated by examples typically used in physical disabilities practice settings. The chapter concludes with suggestions and strategies for learning the OTPF-3 and an overview of how the latest version of the Framework is integrated as a unifying thread throughout the remaining chapters in the book.

Evolution of the Occupational Therapy Practice Framework

In 1999 the AOTA's Commission on Practice (COP) was charged with reviewing the "Uniform Terminology for Occupational Therapy," third edition (UT-III), a document that had been published by the association 5 years earlier.[4] Under the leadership of its chair, Mary Jane Youngstrom, the COP sought feedback from numerous OT practitioners, scholars, and leaders in the profession about the continued suitability of the UT-III, to determine whether to update the document or to rescind it. Previous editions of the UT, in 1979 and 1989, had been similarly reviewed and updated to reflect changes and the evolving progress of the profession. The reviewers found that the UT-III, although considered a valuable tool for occupational therapists, lacked clarity for both consumers and professionals in associated fields about what occupational therapists do and how they do it. Furthermore, they found that the UT-III did not adequately describe or emphasize OT's focus on occupation, the foundation of the profession.[12]

Given the feedback from the review, the COP determined that a new document was needed, one that would preserve the intent of the UT-III (outlining and naming the constructs of the profession) while providing increased clarity about what occupational therapists and OT assistants do and how they do it. Additionally, it was determined that the new document would refocus attention on the primacy of occupation as the cornerstone of the profession and desired intervention outcomes, in addition to showing the process occupational therapists use to help their clients achieve their occupational goals.

Need for the Occupational Therapy Practice Framework

The original OTPF and the revised versions (OTPF-2 and OTPF-3) make it clear that the profession's central focus and actions are grounded in the concept of occupation. Although some of what occupational therapists do could be construed by clients and other healthcare professionals as similar to or even duplication of the treatment efforts of other disciplines, formally delineating occupation as the overarching goal of all that OT does, and clearly documenting supportive goals intended to achieve that main goal, establishes the profession's unique contribution to client intervention.

This is not to say that before the OTPF, OT practitioners did not recognize or focus on occupation or occupational goals with their clients—most did. However, in the physical disabilities practice setting, with the reductionistic, bottom-up approach and pervasive influence of the medical model, occupation was seldom mentioned or linked to what was being done in OT. A premium seemed to be placed on "medical speak," and it was difficult, if not impossible, to document occupational performance or occupational goals using the types of documentation characteristic of physical disabilities practice settings. Kent, the therapist from the case study, still occasionally experiences the medical team members' heightened interest when he reports muscle grades and sensory status, and their quizzical, glazed-over looks when he describes his clients' difficulties resuming homemaking, leisure, or other home and community skills. The OTPF-3 provides a means of communicating to healthcare professionals who are not occupational therapists that engagement in occupation should be the primary outcome of all intervention.

The OTPF-3 provides a language and structure that communicates occupation more meaningfully. It empowers occupational therapists to restructure evaluation, progress, and other documentation forms to reflect the primacy of occupation in what OT does, and it shows the interaction of all the aspects that contribute to supporting or constraining the client's participation. Thus, by clearly showing and articulating the comprehensive nature of OT's domain of practice to clients, healthcare professionals, and other interested parties, occupational therapists enlist support and demand for their services and, most importantly, ensure that clients receive the unique and important services that OT provides. Equally important, the OTPF-3 positions the client as a collaborator with the occupational therapist at every step of the process, thereby empowering the individual as a change agent and reframing the image of the client as a passive recipient of services.[13]

Fit Between the OTPF-3 and the *International Classification of Functioning, Disability, and Health* (ICF)

There appears to be an excellent fit between the OTPF (all editions) and the ICF. About the same time the UT-III was being studied for continued suitability for contemporary language and practice, the World Health Organization (WHO) was revising its language and classification model. The result, the *International Classification of Functioning, Disability, and Health*, contributes to the understanding of the complexity of having a physical disability.[26] The ICF "moved away from being a 'consequences of disease' classification to become a 'components of health' classification,"[26] progressing from impairment, disability, and handicap to body functions and structures, activities, and participation. In the ICF, *body structures* refers to the anatomic parts of the body, and *body functions* refers to a person's physiological and psychological functions. Also considered in this model is the impact of environmental and personal factors as they relate to functioning. The ICF adopted a universal model that considers health along a continuum that shows the potential for everyone to have a disability. WHO perceived this as a radical shift—from emphasizing people's disabilities to focusing on their level of health.

The ICF also provides support and reinforcement for OT to specifically address activity and activity limitations encountered by people with disabilities.[26] In addition, it describes the importance of participation in life situations, or *domains,* including (1) learning and applying knowledge; (2) general tasks and task demands; (3) communication; (4) movement; (5) self-care; (6) domestic life areas; (7) interpersonal interactions; (8) major life areas associated with work, school, and family life; and (9) community, social, and civic life. All of these domains are historically familiar areas of concern and intervention for the OT profession. Although a physical disability may compromise a person's ability to reach up to brush his or her hair, the ICF redirects the service provider to also consider activity limitations that may result in restricted participation in desired life situations, such as sports or parenting. A problem with a person's bodily structure, such as paralysis or a missing limb, is recognized as a potentially limiting factor, but that is not the focus of intervention.

OT practitioners believe that intervention provided for people with physical disabilities should extend beyond a focus on recovery of physical skills and address the person's engagement, or active participation, in occupations. This viewpoint is the cornerstone of the OTPF-3 and previous versions. Such active participation in occupation is interdependent on the client's psychological and social well-being, which must be simultaneously addressed through the OT intervention. This orientation is congruent with the emphasis reflected in the ICF.

In many instances the language of the UT-III was different from that used and understood by the external audience of other healthcare professionals. Similarly, the terminology of the previous WHO classification frequently differed from that used by the audience with which the organization was trying to communicate (eg, healthcare professionals and other service providers). The goals of the new WHO classifications, the ICF, are to increase communication and understanding about the experience of having a disability and unify services. In a similar manner, the original OTPF, and now the updated OTPF-3, was designed to increase others' knowledge and understanding of the OT profession and, where appropriate, to incorporate the language of the ICF, as will be seen in the following discussion of the OT domain and process.

Detailed information on the ICF can be found in the document referenced in this chapter,[26] or an overview of the document can be downloaded from *http://www.who.int/icf/cfm*. A helpful resource for learning the ICF is the Beginners Guide to the ICF, which can also be accessed at the website *http://www.who.int/classifications/icf*. Additional and annually updated documents on the ICF also are available at this website.

The OTPF-3: Description

The OTPF-3 is composed of two interrelated parts, the domain and the process. The **domain** comprises the focus and factors addressed by the profession, and the **process** describes how occupational therapy does what it does (evaluation, intervention, and outcomes)—in other words, how it puts the domain into practice. Central to both parts is the essential concept of occupation. The definition of occupation used by the developers of the original Framework is:

Activities … of everyday life, named, organized, and given value and meaning by individuals and a culture. Occupation is everything people do to occupy themselves, including looking after themselves, … enjoying life, … and contributing to the social and economic fabric of their communities.[16]

The revised Frameworks (both the OTPF-2 and OTPF-3), rather than adopting a single definition, used several definitions found in the OT literature[2,3] (OTPF-3, pp. S5–S6). The committee charged with producing the OTPF-3 ultimately suggested that an array of selected definitions of the term *occupation*, offered by the scholars of the profession, would add to an understanding of this core concept (see OTPF-3, pp. S5–S6).[3] In adopting the essence of these definitions, the developers of the OTPF-3 characterized the profession's focus on occupation in a dynamic and action-oriented form, which they articulated as "achieving health, well-being and participation in life through engagement in occupation"[3] (OTPF-3, p. S2). This phrase links the two parts of the Framework, providing the unifying theme or focus of the OT domain and the overarching target outcome of the OT process—an inextricable linkage between domain and process that the authors of the OTPF-3 described as "transactional"[3] (OTPF-3, p. S4).

The Occupational Therapy Domain

The domain of occupational therapy encompasses the gamut of what occupational therapists do, along with the primary concern and focus of the profession's efforts. Everything that occupational therapy does or is concerned about, as depicted in the domain of the OTPF-3, is directed at supporting the client's engagement in meaningful occupation that ultimately affects the health, well-being, and life satisfaction of that individual.

The five broad areas, or categories, of concern that constitute the OT domain are occupations, client factors, performance skills, performance patterns, and context and environment (Fig. 1.1). In the first two editions of the Framework, activity demands constituted a sixth category in the domain. However, in the OTPF-3, it was removed from that position and "placed in the overview of the process to augment the discussion of the occupational therapy practitioner's basic skill of activity analysis"[3] (OTPF-3, p. S2). The developers of the OTPF-3 pointed out that there is a complex interplay among all of these areas or aspects of the domain, that no single part is more critical than another, and that all aspects are viewed as influencing engagement in occupations. Furthermore, the success of the OT process (evaluation, intervention, and targeted outcomes) is incumbent on the occupational therapist's expert knowledge of all aspects of the domain. The expert practice of occupational therapy requires the therapeutic use of self, clinical reasoning (knowledge of theory and evidence), and skills in activity analysis and activity demands to create the overview that guides each step of the process.

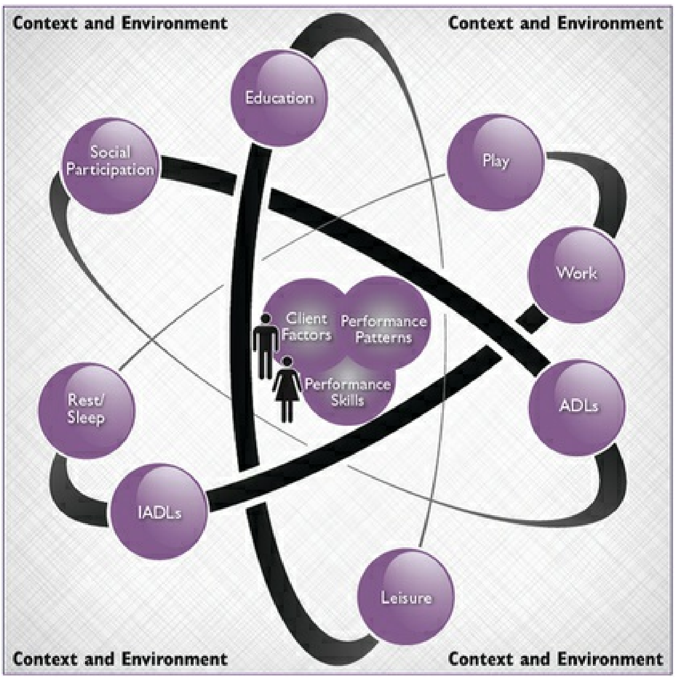

FIG 1.1 Occupational therapy domain. (From the American Occupational Therapy Association: Occupational therapy practice framework: domain and process, *Am J Occup Ther* March/April[Suppl]:S4, 2014.)

Occupations

Occupational therapists frequently use the terms *occupation* and *activity* interchangeably. In the Framework, the term *occupation* encompasses the term *activity*. **Occupations** may be characterized as being meaningful and goal directed but not necessarily considered by the individual to be of central importance to her or his life. Similarly, occupations may also be viewed as (1) activities in which the client engages, (2) activities that have the added qualitative criteria of giving meaning to the person's life and contributing to his or her identity, and (3) activities the individual looks forward to engaging in. For example, Karen, Kent's client with quadriplegia, regards herself as an excellent and dedicated clothes and accessories shopper; holidays and celebrations always include her engagement in her treasured occupation of shopping. Kent, on the other hand, regards the activity of shopping for clothes as important only to keep himself clothed and maintain social acceptance. Kent avoids the activity whenever possible. Each engages in this activity to support participation in life but with a qualitatively different attitude and level of enthusiasm. In the OTPF-3, both of these closely related terms are used, to recognize that individual clients determine the occupations he or she regards as meaningful and those that are simply necessary or are activities that support the person's participation in life. For Kent, shopping is a necessary occupation or activity, but for Karen, it is a favorite occupation.

The occupation category of the domain includes eight comprehensive types of human activities or occupations. Each is outlined in the following discussion; a list of typical activities included in each type is provided; and examples from the physical disability perspective, as provided by Karen's circumstances, are presented.

Threaded Case Study

Kent and Karen, Part 2

As Kent perused the list of activities of daily living (ADLs) in Table 1 of the OTPF-3, he noted that virtually every category, with the exception of eating (which involves the ability to keep and manipulate food in the mouth and the ability to swallow), would be a concern for his client, Karen, because of the nature and extent of her SCI disability. When Kent discussed this list with Karen, she viewed practically all as necessary activities, but she personally valued feeding, sexual activity, and personal hygiene and grooming as being extremely important to her satisfactory participation in life. Karen was a little surprised to learn that sexual activity was included. “So this is occupational therapy?” she thought. “Maybe I'll wait awhile before I talk about this topic, but it's good to know I'm expected to be interested.”

For the present, Karen turned her attention to and took particular interest in the activities included in the personal hygiene and grooming category and its detailed description:

Obtaining and using supplies, removing body hair (use of razors, tweezers, lotions, etc.), applying and removing cosmetics, washing, drying, combing, styling, brushing and trimming hair; caring for nails (hands and feet), caring for skin, ears, eyes, and nose, applying deodorant, cleaning mouth, brushing and flossing teeth; or removing, cleaning, and reinserting dental orthotics and prosthetics[3] (OTPF-3, p. S19).

The numerous details reminded her of how important all these grooming activities were to her, and they indicated the scope of the daily activities she would like to address in OT. Of particular concern to Karen were the grooming activities of plucking her eyebrows and styling her hair; these were bodily care activities she regarded as very personal. In fact, she was reluctant to let anyone do these for her. Although under similar circumstances Kent might have gladly deferred these two ADLs, it was clear that Karen would prioritize them as personally meaningful occupational goals.

In studying the list of ADLs, Kent noted that, just like personal hygiene and grooming, each ADL item listed had a similarly helpful definition and detailed list of examples in the tables throughout the OTPF-3 document. He remembered reading that these lists were provided to give a few examples, that they were not to be considered exhaustive, and in fact, that there was an expectation that the lists would be modified and expanded on as the Framework became more familiar and integrated into practice.

ADLs (also referred to as personal activities of daily living [PADLs] or *basic activities of daily living* [BADLs]) are activities that have to do with accomplishing one's own personal body care. The body care activities included in the ADL category are bathing/showering, toileting and toileting hygiene, dressing, swallowing/eating, feeding, functional mobility, personal device care, personal hygiene and grooming, and sexual activity.

Instrumental activities of daily living (IADLs) are “activities to support daily life within the home and community that often require more complex interactions than those used in ADLs”[3] (OTPF-3, p. S19). The specific IADLs included in the domain are care of others (including selecting and supervising caregivers), care of pets, childrearing, communication management, driving and community mobility, financial management, health management and maintenance, home establishment and management, meal preparation and cleanup, religious and spiritual activities and expression, safety and emergency maintenance, and shopping.

Knowing that the IADL shopping was certain to be a priority occupation for Karen, Kent made a note of the full description of shopping from the corresponding lists of IADLs in Table 1 of the OTPF-3. Shopping is described there as “Preparing shopping lists (grocery and other); selecting, purchasing, and transporting items; selecting method of payment and completing money transactions; included are Internet shopping and related use of electronic devices such as computers, cell phones and tablets”[3] (OTPF-3, p. S20). This is not as detailed as some descriptions, but it is a good start for looking at the related activities that would have to be addressed if Kent and Karen were to collaborate on Karen's resumption of engagement in shopping. Kent also noted that the occupation category of driving and community mobility included both driving and the use of public transportation, another IADL that would be important to explore with Karen as she contemplates returning to paid work. In fact, the entire list of IADLs held numerous concerns to be addressed in OT.

Rest and sleep, recognized as an occupation in the OTPF-3, “includes activities related to obtaining restorative rest and sleep to support healthy, active engagement in other occupations”[3] (OTPF-3, p. S20). The component activities constituting rest and sleep include rest, sleep preparation, and sleep participation (see Chapter 13 for an expanded discussion of this important occupation). Karen's sleep occupations will be significantly changed as a result of her diagnosis. To name just two of the concerns OT will have to address, she will need to be repositioned frequently during the night for skin precautions, and equipment will have to be set up to manage her bladder function while she sleeps.

Education is an occupation that includes “activities needed for learning and participating in the environment”[3] (OTPF-3, p. S20). Specific education activity subcategories include formal education participation, informal personal educational needs or interests exploration (beyond formal education), and informal personal education participation. Table 1 of the OTPF-3 includes more details about the specific activities in each of these subcategories.

Work includes activities associated with both paid work and volunteer efforts (see Chapter 14). Specific categories of activities and concerns related to the occupation of work include employment interests and pursuits, employment seeking and acquisition, job performance, retirement preparation and adjustment, volunteer exploration, and volunteer participation[3] (OTPF-3, pp. S20–S21).

Activities associated with the occupation play are described as "any spontaneous or organized activity that provides enjoyment, entertainment, amusement, or diversion."[19] Considered under this area of occupation are play exploration and play participation[3] (OTPF-3, p. S21).

Leisure is defined as "nonobligatory activity that is intrinsically motivated and engaged in during discretionary time, that is, time not committed to obligatory occupations such as work, self-care or sleep."[19] Leisure exploration and leisure participation are the major categories of activity in leisure occupations[3] (OTPF-3, p. S21) (see Chapter 16). Karen shared with Kent her interests in spending leisure time listening to music, traveling, antiquing, swimming, playing bridge, and reading books. As Kent was studying the description of leisure, it occurred to him that for Karen, shopping might be characterized as a leisure occupation in addition to an IADL. It probably would depend on the circumstances or context in which she engaged in the shopping, he thought—another parameter of the OTPF-3 domain he would be learning.

Social participation is another occupation that encompasses the "interweaving of occupations to support desired engagement in community and family activities as well as those involving peers and friends[7]; also, involvement in a subset of activities that involve social situations with others[5] and that support social interdependence.[7] Social participation can occur in person or through remote technologies, such as telephone calls, computer interaction, and video conferencing"[3] (OTPF-3, p. S21). The occupation of social participation further encompasses engaging in activities that result in successful interaction at the community, family, and peer/friend levels. (Just as for previously discussed occupations, see the OTPF-3, Table 1, for definitions and more detailed information about the breadth of activities that constitute OT's involvement in work, play, leisure, and social participation.)

Like Kent, readers currently learning the OTPF-3 could benefit from studying the expanded lists to broaden their understanding of the OT domain. As Kent studied these sections of Table 1, he found it helpful to make note of the content of each one that included specific activities that would be relevant to Karen when she engaged in the occupations. For example, Kent considered the range of job skills and work routines necessary for Karen to return to her paid position as an administrative assistant. He also made a list of similar concerns involved in resumption of her preferred play and leisure occupations, including swimming, reading, and board games. Kent was reminded of the importance of considering the activities that can support or constrain Karen's continued social participation in her community as a Girl Scout leader, in her family as the oldest daughter, and with her treasured circle of friends.

Performance Skills and Performance Patterns

Remember that throughout the OTPF-3 document, there is no correct or incorrect order in which to study or follow the areas of the domain—there is no hierarchy: "All aspects of the domain transact to support achieving health, well-being, and participation in life through engagement in occupation"[3] (OTPF-3, p. S4). With this in mind, the next main areas of the domain to consider are performance skills and performance patterns. Both are related to the client's performance capabilities in the areas of occupation previously described, and they can be viewed as the actions and behaviors observed by the occupational therapist as the client engages in occupations.

The category of performance skills includes three components of concern: motor skills, process skills, and social interaction skills. The client's successful engagement in occupation or occupational performance depends on his or her having or achieving adequate ability in performance skills. In the OTPF-3, performance skills are defined as "observable elements of action that have an implicit functional purpose; skills are considered a classification for actions, encompassing multiple capacities (body functions and bodily structures) and when combined, underlie the ability to participate in the desired occupations and activities"[3] (OTPF-3, p. S25). Briefly, **performance skills** are the abilities clients demonstrate in the actions they perform. Problems in any of the three areas of performance skills are the focus for formulating short-term goals or objectives to reach the long-term goal of addressing participation in occupation.

Motor skills consist of actions or behaviors a client uses to move and physically interact with tasks, objects, contexts, and environments, including planning, sequencing, and executing new and novel movements. In Table 3 of the OTPF-3, motor skills are defined as "occupational performance skills observed as the person interacts with and moves task objects and self around the task environment"[7] (eg, activity of daily living [ADL] motor skills, school motor skills). Examples of motor skills include coordinating body movements to complete a job task, anticipating or adjusting posture and body position in response to environmental circumstances such as obstacles, and manipulating keys or a lock to open a door.

Kent observed Karen as she played a game of bridge with friends one afternoon in the OT clinic. Observing her performance skills, particularly her motor skills, Kent noted that Karen looped one elbow around the upright of her wheelchair, leaned her trunk toward the table, reached her other arm toward the cardholder, and successfully grasped a card, using tenodesis grasp, after three unsuccessful attempts. Kent perceived this as indicating that Karen felt the need to calibrate her attempts and endure or persist (see Chapter 36).

The OTPF-3 defines process skills as "occupational performance skills (eg, ADL process skills, school process skills) observed as a person (1) selects, interacts with, and uses task tools and materials; (2) carries out individual actions and steps; and (3) modifies performance when problems are encountered."[7] Simply stated, process skills are observable actions taken to manage and modify the occupational task; for example, using knowledge, attending to and discerning solutions to problems with, and organizing the task, including choosing appropriate tools and methods for performing the task.

Kent also observed Karen's process skills as she set up her cardholder so that her cards were not visible to her opponents (selecting and gathering proper equipment and arranging the space), perused her cards, paused, rearranged them using her tenodesis hand splint/orthotic device (attending to the task, using knowledge of the rules of bridge, and selection of proper equipment), and then stated her bid (demonstrating discernment, choosing, and problem solving).

Social interaction skills, the third category of performance skills, are "skills observed during the ongoing stream of a social exchange."[7] These observable behaviors indicate how the client conveys his or her intentions and needs and coordinates social behavior to interact with people. Such skills could include asking for information, expressing emotion, and interacting with or relating to others in a manner that supports engagement in the occupation at hand.

During the card game Kent was able to observe a wide array of examples of Karen's social interaction skills. He saw Karen furrowing her brow; squinting her eyes shut in a thoughtful, cogitating manner; pursing her lips; and showing neither happiness nor despair on her face as she studied her cards in the cardholder (expressing affect consistent with the activity of card playing and thus demonstrating or displaying appropriate emotions and cognitive skill in determining her next strategy). As she reached for the cards, the holder moved out of her reach; she turned and asked the friend next to her to push it back, cautioning her in a smiling and light manner, "Don't you dare look!" (demonstrating her ability to multitask—asking for assistance and simultaneously using socially acceptable teasing behavior [social interaction skills] that enlists an opponent's cooperation in preserving the secrecy of her cards, thus conveying or disclosing the image of a savvy card player). Her observable performance skills supported Karen's continued inclusion with friends in a favorite leisure occupation.

Each of these particular motor skills, process skills, and social interaction skills categories has detailed lists of representative skills annotated with definitions, descriptions, and examples (see OTPF-3, Table 3).[3]

Performance patterns are observable patterns of behavior that support or constrain the client's engagement in occupation. Types or categories of patterns include habits, routines, roles, and rituals. In the OTPF-3, the habits of an individual are described as "automatic behavior that is integrated into more complex patterns that enable people to function on a day-to-day basis"[3]; they can be "useful, dominating, or impoverished and either support or interfere with performance in areas of occupation"[3] (OTPF-3, p. S27). Examples of habits listed in Table 4 of the OTPF-3 include automatically putting car keys in the same place and spontaneously looking both ways before crossing the street[3] (OTPF-3, p. S27). Routines reflect the "patterns of behavior that are observable, regular, repetitive, and that provide structure for daily life. Furthermore, routines can be satisfying, promoting, or damaging. Routines require momentary time commitment and are embedded in cultural and ecological contexts"[3] (OTPF-3, p. S27). Routines show how the individual configures or sequences occupations throughout his or her daily life. Habits typically contribute (positively or negatively) to a person's occupational routines, and both are established with repetition over time. The role category of performance patterns is regarded as being composed of "sets of behaviors expected by society, shaped by culture, and may be further conceptualized and defined by the client"[3] (OTPF-3, p. S27). Rituals are described as "symbolic actions with spiritual, cultural, or social meaning, contributing to the client's identity and reinforcing values and beliefs. Rituals have a strong affective component and represent a collection of events"[3] (OTPF-3, p. S27). Table 4 of the OTPF-3 outlines definitions and examples of performance patterns for organizations and populations (OTPF-3, p. S27).

Performance patterns for the individual, and the ways these can support (or, by inference, hinder) occupational performance, are further illustrated in Part 3 of the Kent and Karen case study.

Threaded Case Study

Kent and Karen, Part 3

Some might view Karen's engagement in the occupation of paid work as an example of the role of worker. Inherent in this role are accepted norms that customarily include regular attendance, timely adherence to schedules, and acceptance of responsibility for completing assignments. Karen's work role is consistent with the sets of behaviors that would be expected of an administrative assistant at a busy law firm, including arriving at work on time, handling e-mail and other correspondence in a professional manner, managing the office budget and payroll according to accepted audit practices, and interacting with her supervisors, co-workers, and supervisees in a fair and respectful manner, to name just a few. In tribute to her stellar work performance, a ritual that has evolved as part of Karen's work role experience at the law office is the annual Holiday Shopping Day. Karen and her three administrative assistant colleagues are given the Friday before the holiday off with pay. A town car picks them up at their homes and transports them to the downtown shopping district, where they are given a generous gift card, a spa morning, lunch at a downtown restaurant, an afternoon of shopping, and town car transportation home at the end of the day.

Karen's workday routine involves waking at 6:30 am; showering, grooming, and dressing; driving to work, with a stop for breakfast on the way; and arriving at her workplace early (at 7:45 am) for an 8:00 am expected work start. A habit that Karen regards as beneficial to her workday routine is her scrupulous use of her day planner to record appointments, phone numbers, and additions to her things-to-do list. Another habit she believes contributes to the success of her workday routine is selecting her clothes the night before to save time in the morning, thus ensuring a punctual arrival at work. A habit that negatively affects her daily work routine is hitting the snooze button on her cell phone clock app. Both Kent and Karen recognize that although Karen may resume her work occupation or worker role, her SCI has substantially altered her ability to carry out expected behaviors and her customary habits and routines; she will have to develop the ability to establish new and expanded habits and routines. Successful integration of these new habits and routines will undoubtedly determine the continuation of Karen's participation in the highly anticipated and beloved Holiday Shopping Day ritual.

Karen's occupational performance, performance skills, and patterns will be significantly influenced by the next two main areas of the domain to be discussed: contexts and environments, and client factors.

Contexts and Environments

The OTPF-3 states that a "client's engagement in occupation takes place within a social and physical environment situated within context."[3] **Environment** "refers to the external physical and social conditions that surround the client and in which the client's daily life occupations occur"[3] (OTPF-3, p. S28). The physical environment includes the natural and the constructed, nonhuman environments and the objects in them, and the social environment that encompasses the presence, relationships, and expectations of persons, groups, and organizations with whom the client has contact"[3] (OTPF-3, p. S28). **Contexts** are regarded as the variety of interrelated conditions, circumstances, or events that surround and influence the client and in which the client's daily life occupations take place. Contexts can either support or constrain health, well-being, and participation in life through engagement in occupation. In the OTPF-3 domain, contexts are composed of four categories, or types: cultural, personal, temporal, and virtual. One of the categories of context is regarded as external to the individual (ie, the virtual context); some are viewed as internal to the client (eg, personal context). Some contexts, such as culture, provide an external expectation of behavior that is often converted into an internal belief. Table 5 in the OTPF-3 provides detailed definitions and examples of each of these categories. For example, the category of context labeled "personal" context describes "features of the individual that are not part of the health status"[3] (OTPF-3, p. S28). Personal context includes age, gender, socioeconomic status, and educational status; it also can include group membership (eg, volunteers, employees) and population membership (eg, members of society)[3] (OTPF-3, p. S28).

Each of these contexts and environments, as they pertain to Karen's specific circumstances, will significantly affect her future engagement in occupation. Karen's physical environment includes aspects that will support her engagement in occupation, including an accessible work site; a reliable and accessible system of public transportation in her neighborhood; and a well-appointed downtown area of stores, shops, and restaurants within wheelchair distance. Aspects of her physical environment that may interfere with resumption of occupations include Karen's second floor apartment and small bathroom, which are inaccessible to a wheelchair. Supportive aspects of Karen's personal context are her college education in business and the fact that she has unemployment insurance, which will supplement her sick leave and continue her health coverage. From a social environment perspective, Karen is supported both by her family and her friends; additionally, her employer and co-workers are anxious to have her come back to the law firm. The mainstream American cultural context in which Karen was reared—which values and supports the concept of hard work overcoming adversity (doing rather than being) and the importance of independence (individualism)—seemingly motivates Karen to resume engagement in previous levels of occupation for full participation in all environments and contexts and, ultimately, occupations of her life.[7]

Given the difficulty that resuming Karen's shopping occupation may present, Kent suggested the possibility of using online shopping for some items. Although interested, Karen indicated that her preference was to shop "in the real world" instead of using the virtual context of computers and airways. Karen's ultimate decisions no doubt will be influenced by the changes she experiences in her temporal contexts as she experiences and adjusts to the increased amounts of time (and the scheduling of and around the time of others) required to accomplish basic daily routines that, in turn, support her engagement in preferred occupations.

Client Factors

The OTPF-3 describes **client factors** in a manner similar to the ICF.[3,20] There are three categories in this portion of the OTPF-3: values, beliefs, and spirituality; body functions; and body structures. These three elements are regarded as residing within the client, and they may affect or influence the performance of occupations.[3] Client factors may be affected by performance skills, performance patterns, and contexts and environments; in addition, they may have a cyclical/reciprocal relationship with and profound effect on the client's ability in those areas and, ultimately, satisfactory performance of occupations.

The client factor category of values, beliefs, and spirituality is described as encompassing the client's perceptions, motivations, and related meaning that influence or are influenced by engagement in occupations.[3] Table 2 of the OTPF-3 describes values as beliefs and commitments, derived from culture, about what is good, right, and important to do (eg, commitment to family), whereas beliefs are described as cognitive content held as true by the client (eg, hard work pays off).[3] The third aspect, spirituality, is described as representing "the way individuals seek and express meaning and purpose, and the way they experience connectedness to the moment, to self, to others, to nature, and to the significant or sacred."[17,22] For example, Karen's values, including her strong work ethic and her beliefs and spirituality, provide her the reassurance that her SCI was part of a higher power's plan for her and that she will be given the strength to cope and succeed.

The body structure category refers to the integrity of the actual body part, such as the integrity of the eye for vision (see Chapter 24) or the integrity of a limb (see Chapter 43). When the integrity of the body structure is compromised, this can affect function or require alternative approaches to engagement in activities, such as enlarged print for persons with macular degeneration or the use of a prosthesis for a person who sustained a below-elbow amputation. It is unlikely that this category of the domain would apply to Karen because the integrity of her body structures is not necessarily compromised by her diagnosis. Should she develop a pressure sore, a possible complication of SCI in which the integrity of a body structure (ie, the skin) is compromised, her ability to engage in occupation could become significantly limited, requiring alternative approaches, such as positioning devices and adaptive equipment to compensate for the need to stay off the pressure sore.

The body function category of client factors refers to the physiological and psychological functions of the body. It includes a variety of systems, such as neuromusculoskeletal and movement-related functions. This category of body functions includes muscle function, which in turn includes muscle strength. A distinction is made between body functions and performance skills. As was described earlier, performance skills are observed as the client engages in an occupation or activity. The category of body function refers to the available ability of the client's body to function. For example, a client may have the available neuromuscular function (client factor of body function; specifically, muscle strength) to hold a comb and bring the comb to the top of the head, and also the strength to pull the comb through the hair, but when you ask the client to comb his hair (an activity), you observe that he has difficulty with manipulating the comb in his hand (motor skill of manipulation) and with using the comb smoothly to comb his hair (motor skill of flow). In the OTPF-3, these motor skills are considered performance skills.

In Karen's case, the absence of functioning muscles in her hands necessitates the use of a functional hand splint or adaptive writing device to enable her to sign a credit card receipt, a required action in her shopping occupation. To use a wrist-driven flexor hinge (ie, tenodesis) hand splint to hold the pen, she must have adequate body function; in this case, fair or better muscle strength in her radial wrist extensors. However, Karen must also have adequate performance skills, including the motor skills to exert enough force to adequately write her name; the cognitive or discerning skills to select a type of pen that requires minimum effort to operate; and the social interaction skills to ask sales personnel for a firm writing surface (clipboard) for her lap to compensate for the inaccessibility of the checkout counter.

The mental functions group includes affective, cognitive, and perceptual abilities. This group also includes the experience of self and body image (see Chapters 6, 25, and 26). A client such as Karen who has sustained a physically disabling injury frequently may have an altered self-concept, lowered self-esteem, depression, anxiety, decreased coping skills, and other problems with emotional functions after the injury[21,22] (see Chapter 6). Sensory functions and pain also are included in the body functions category (see Chapters 23 and 28).

Neuromuscular and movement-related functions refer to the available strength range of motion and movement (see Chapters 19 through 22); however, they do not refer to the client's application of these factors to activities or occupations, as was seen in the example of Karen signing a credit card receipt as part of engaging in the occupation of shopping. The body functions category also refers to the ability of the cardiovascular, respiratory, digestive, metabolic, and genitourinary systems to function to support client participation. These are further described in both the OTPF-3 and the ICF. Table 2 in the OTPF-3 presents a more detailed description of each function included in this category.[3]

The Occupational Therapy Process

As mentioned, the OTPF-3 consists of two parts, the domain and the process. From a very general perspective, the domain describes the scope of practice, or answers the question, "What does an occupational therapist do?" The process describes the methods of providing OT services, or answers the question, "How does an occupational therapist provide occupational therapy services?"

The process is outlined briefly here for continuity (Fig. 1.2); the reader is referred to Chapter 3 for a more in-depth discussion. The primary focus of the OTPF-3 process is **evaluation** of the client's occupational abilities and needs to determine and provide services (**intervention**) that foster and support occupational performance (**targeted outcomes**). Throughout the process the focus is on occupation; the evaluation begins with determining the client's occupational profile and occupational history. Preferred intervention methods are occupation based, and the overall outcome of the process is achievement of the client's health, well-being, and participation in life through engagement in occupation. Throughout each step of the process, the therapist is guided by the knowledge and skills learned and perfected over the course of his or her career, including the skills associated with clinical reasoning, therapeutic use of self, activity analysis, and activity demands.

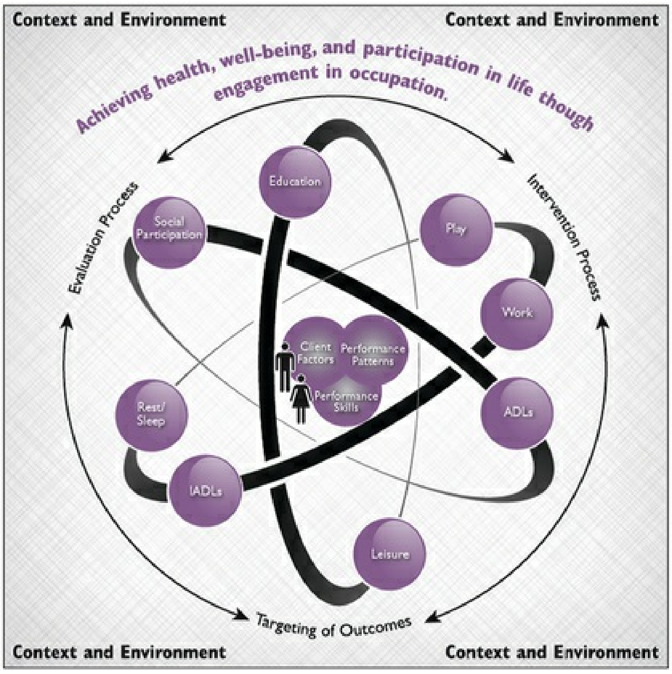

FIG 1.2 Occupational therapy process. (From the American Occupational Therapy Association: Occupational therapy practice framework: domain and process, *Am J Occup Ther* March/April[Suppl]:S10, 2014.)

Interventions also vary, depending on the client, whether person, organization, or population. In the practice of occupational therapy with adults with physical disabilities, the term *client,* at the person or individual level, may vary, depending on the treatment setting or environment. In a hospital or rehabilitation center, the person might be referred to as a *patient,* whereas in a community college post-stroke program, the person receiving occupational therapy may be referred to as a *student.* The term *client* or *consumer* might best describe the person who receives OT intervention at a center for independent living, where the individual typically lives in the community and seeks intervention for a specific, self-identified problem or issue.

Skills That Inform and Guide the Occupational Therapy Process

As mentioned previously, the therapist is guided in the OT process by the knowledge and skills acquired during his or her career; these skills include clinical reasoning, therapeutic use of self, activity analysis, and activity demands.

Clinical reasoning is described as the "process used by practitioners to plan, direct, perform and reflect on client care"—all necessary steps throughout the OT process.[3,7] OT therapists rely on the expertise and knowledge they have developed throughout their careers, including understanding of theory, research interpretation, and clinical skills.

The OTPF-3 describes the therapeutic use of self as "allowing occupational therapy practitioners to develop and manage their therapeutic relationship with clients by using narrative and clinical reasoning; empathy; and a client-centered, collaborative approach to service delivery."[3,25] The OT literature describes an occupational therapist who is successful in the therapeutic use of self as having the qualities or attributes of showing empathy (including sensitivity to the client's disability, age, gender, religion, socioeconomic status, education, and cultural background); being self-reflective and self-aware; being able to communicate effectively using active listening; and consistently keeping a client-centered perspective, which in turn engenders an atmosphere of trust.[8,11,20,25]

The very focus of the OT process provides a context that supports the therapeutic use of self by the occupational therapist. When the therapist uses a client-centered approach and begins the process with an evaluation that seeks information about the client's occupational history and occupational preferences, the client sees the therapist as being interested in what the client does (occupational performance), who the client is (contexts and environments, and client factors such as values, beliefs, and spirituality), and what occupations give meaning to the client's life. (Part 4 of the Kent and Karen case study, presented later in the chapter, describes how Kent demonstrates therapeutic use of self in each step of the therapeutic process.)

Activity analysis is recognized as an "important process occupational therapy practitioners use to understand the demands a specific activity places on a client"[3] (OTPF-3, p. S12). The analysis considers the importance of the occupation or activity to the client as paramount, bearing in mind the client's goals, interests, and abilities and the demands of the activity itself on body structures, body functions, performance skills, and performance patterns. Activity analysis and activity demands are inextricably linked; activity demands focus on what is required to engage in the activity or occupation. For the occupational therapist, this skill requires a knowledge of several aspects that must be addressed for a client to perform a specific activity, including the activity's relevance and importance to the client, the objects used and their properties, space demands, social demands, sequencing and timing, required actions and performance skills, required body functions, and required body structures. Table 7 of the OTPF-3 document provides a comprehensive list of definitions and examples for a clearer understanding of each of these categories.[3]

Consider Karen's keen interest in resuming the occupation of shopping in the "real world" instead of making clothing purchases online (ie, in a virtual context). The materials or tools needed are a purse or credit card holder. The space demands are the accessibility of the store or shopping mall and the dressing room for Karen to try on the clothes before making a purchase. The social demands include paying for the items before leaving the store. The sequence and timing process includes being able to make a selection, go to the register, potentially wait in line, place the clothing on the counter, pay for the item, and then leave the store. The required actions refer to the performance skills necessary to engage in this activity, such as the coordination needed to try on clothing, the process skills needed to select one sweater or blouse from a large array of possible choices, and the social interaction skills needed to ask for assistance or directions if needed.

These performance skills are not viewed in isolation, but rather are seen as Karen engages in the occupation of clothes shopping. The required body functions and structures refer to the basic client factors necessary to perform the activity of shopping. The act of shopping requires a level of cognition or judgment because inherent in the activity of shopping is having the opportunity to make a choice between available items. Karen's ability to engage in the activity demand of making a choice of purchases indicates that she has an adequate level of cognition for shopping.

Using his skills of clinical reasoning, therapeutic use of self, and expert knowledge of activity analysis and activity demands, Kent continually assesses the interplay of Karen's strengths and abilities and her occupational goals to select the interventions that will most effectively achieve these goals. These interventions are described next.

Types of Occupational Therapy Intervention

Table 1.1 shows the types of OT intervention typically used in physical disability practice and their relationship to the domain of occupational therapy. Five general categories of intervention are presented in the OTPF-3: Occupations and Activities, Preparatory Methods and Tasks, Education and Training, Advocacy, and Group Intervention.[3]

TABLE 1.1

Types of OT Intervention Typically Used in Physical Disability Practices

Intervention	Description
Occupations and Activities	Selected interventions for specific clients, designed to meet therapeutic goals; address underlying needs of the mind, body, and spirit of the client.
Occupations	Client-directed daily life activities that match and support identified participation goals.
Activities	Selected to enhance ultimate engagement in occupational goal—client learns and practices portions of desired occupations.
Preparatory Methods and Tasks	Prepare client for occupational performance.
Preparatory methods	Modalities, devices, and techniques to prepare the client for occupational performance—often done to the client without the client's active participation. Includes splints, assistive technology and environmental modification, wheeled mobility,
Preparatory tasks	Actions to target specific client factors or performance skills
Education and Training	
Education	Occupational therapy (OT) imparts knowledge and information about occupation, health, well-being, and participation that enables the client to acquire helpful behaviors, habits, and routines that may or may not require application at the time of the intervention session.
Training	Facilitation of acquisition of concrete skills for meeting specific goals in a real-life, applied situation. Differentiated from education by its goal of enhanced performance as opposed to enhanced understanding.
Advocacy	Efforts directed toward promoting occupational justice and empowering clients to seek and obtain resources to fully participate in their daily life occupations. Can be advocacy efforts by the practitioner on behalf of the client or self-advocacy efforts undertaken by the client.
Group Intervention	Use of distinct knowledge and leadership techniques to facilitate learning and skill acquisition across the life span through the dynamics of group and social interaction. Groups may also be used as a method of service delivery.

Because occupation is the primary focus of the OTPF-3, it is wrong to think of the types of intervention as following in a linear or stepwise order. Instead, the occupational therapist reflects on the client's goal of engagement in his or her preferred, self-selected occupations and then collaborates with the client in selecting the type or types of intervention that the therapist believes would best help the client achieve each occupational goal.

Since the inception of the OTPF (continued in the OTPF-2 and OTPF-3), the traditional concept of “intervention levels” has been dismissed in favor of viewing interventions as types, with no one type considered more important than another; rather, each type has a potential contribution to make in facilitating the ultimate goal of achieving health, well-being, and participation in life through engagement in occupation.

OT Practice Notes

Throughout the OT process, the therapist should make sure the client understands that they will select the outcomes together, based on the client's choice, and they will collaborate in planning the intervention. This lays the foundation for a relationship based on caring and trust.

Threaded Case Study

Kent and Karen, Part 4

Kent did not previously regard therapeutic use of self as an integral, identified component of the OT process. However, through his study of the OTPF-3, he has come to value it highly and use it in his practice. Clients respond well to Kent's caring and gentle approach. He enjoys the personal and interactive aspects of the therapeutic relationship, shows genuine interest in his clients' histories, and actively listens to their responses. He makes it a practice to introduce himself and explain his role to his clients as the first step in the OT process. This practice allows Kent to assert the primacy of the client and to associate and integrate the information he is learning about the client with the image of the person he has just met.

Kent practiced therapeutic use of self throughout the OT process with Karen. He brought to the process his 25 years of experience, continued education, and knowledge of SCI, in addition to his well-developed clinical reasoning skills and his experiences in providing successful—and not-so-successful—OT intervention for numerous clients. Kent's college roommate and subsequent best friend has a physical disability, and this has served to increase Kent's understanding of, and inform his attitudes and beliefs about, the experience of having a disability. His close and loving relationships with his sisters, wife, and teenage daughters have provided him with an increased awareness of women's concerns and issues and have caused him to consider how disability might be experienced differently by his women clients than by his men clients. All of these aspects of Kent's personal and professional repertoire supported his ability to use therapeutic use of self, activity analysis, and clinical reasoning as effective therapeutic skills that continually informed his actions throughout Karen's OT process.

Occupations and Activities

In the first version of the OTPF (2002), the occupations and activities category of OT intervention was adapted from the section "Treatment Continuum in the Context of Occupational Performance" (Chapter 1) in the fifth edition of this book. In the OTPF-3, the category is defined as "selected interventions for specific clients, designed to meet therapeutic goals and address the underlying needs of the mind, body and spirit of the client. To use occupations/activities therapeutically, the practitioner considers activity demands and client factors in relation to the client's therapeutic goals, contexts, and environments"[3] (OTPF-3, p. S29). Specific activities considered to be representative of the occupations and activities category are further separated into two types including occupation and activity that will each be discussed here.

The OTPF-3 describes occupations (as interventions) as "client-directed daily life activities that match and support or address identified participation goals"[3] (OTPF-3, p. S29). An example in Table 6 of the OTPF-3 is: purchases groceries and prepares a meal. For Karen, an example might entail a clothes shopping trip using public transportation or completing a typical morning of office skills independently.

Activities (as interventions) are described as "actions designed and selected to support the development of performance skills and performance patterns to enhance occupational engagement. Activities often are components of occupations and always hold meaning, relevance and perceived utility for clients at their level of interest and motivation"[3] (OTPF-3, p. S29). Examples from Table 6 of the OTPF-3 include practicing safe ways of getting into and out of the bathtub and writing answers on an application form.

After reading the descriptions of occupations and activities as interventions, Kent now believes that occupation-based intervention would promote engagement in all areas of occupation, including ADLs, IADLs, rest and sleep, education, work, play, leisure, and social participation. Most of the OT intervention for Karen was occupation based. To reach her targeted goal of resuming her favorite leisure occupation of clothes shopping, Kent and Karen took a trip to a nearby department store, where Karen looked for a blouse with three-quarter sleeves that buttoned up the front. Karen perused the racks, inspecting the blouses on display; asked for help from a salesperson; tried on blouses in the dressing room; made her selection; and paid for her purchase—all parts of a typical shopping excursion in a customary shopping environment. When necessary, Kent demonstrated or suggested ways Karen could perform some of the more difficult shopping activities, such as accessing the crowded racks, negotiating her wheelchair into the dressing room from a narrow hallway, and transporting the hangers with blouses on her lap without having them slide to the ground.

The description of the purpose of activity as intervention in the OPTF-3 and the examples provided caused Kent to reframe or slightly reconfigure his view of what activity entails in relation to occupation. Given the OTPF-3 categorization, he considered that he was providing activity intervention when he had Karen practice activities that she would encounter as part of the occupation of clothes shopping. In the OT clinic, before the shopping trip, Karen and Kent collaborated on developing her ability to perform the activities of tearing checks out of her checkbook, accessing her credit card from her wallet, using a button hook to button her sweater, and lifting clothes on hangers out of a closet. Some of the shopping activities she performed while buying her blouse were learned as part of other occupation-based interventions, such as wheelchair mobility, writing, and dressing. When using activity as intervention, the OT practitioner is concerned primarily with assessing and remediating deficits in performance skills and performance patterns.

Preparatory Methods and Preparatory Tasks

When using intervention that is preparatory in nature, the practitioner selects directed "methods and techniques that prepare the client for occupational performance, used as part of a treatment session, in preparation for or concurrently with occupations and activities or provided to a client as a home-based engagement to support daily occupational performance"[3] (OTPF-3, p. S29).

Preparatory methods used in occupational therapy may include exercise, facilitation and inhibition techniques, positioning, sensory stimulation, selected physical agent modalities, and provision of orthotic devices, such as braces and splints. **Preparatory tasks** are described as "actions selected and provided to the client to target specific client factors or performance skills. Tasks involve active participation of the client and sometimes comprise engagements that use various materials to simulate activities or components of occupations. Preparatory tasks themselves may not hold inherent meaning, relevance, or perceived utility as stand alone entities"[3] (OTPF-3, p. S30).

OT services for persons with physical disabilities often introduce these preparatory methods, devices, and tasks during the acute stages of illness or injury. When using these methods, the occupational therapist is likely to be most concerned with assessing and remediating problems with client factors such as body structures and body functions. It is important for the therapist to plan the progression of this type of intervention so that the selected methods are used as preparation for occupation or activity and are directed toward the overarching goal of achieving health, well-being, and participation in life through engagement in occupation.

Kent reflected that in preparing for Karen's occupation intervention of clothes shopping, he used several other interventions that would be considered preparatory methods. For example, he and Karen looked at her options for grasping items and decided on a tenodesis hand splint, using orthotics as an intervention. To use the splint more effectively, she had to have stronger wrist extensors, and to push her wheelchair or to reach for and lift hangers with clothes, she needed stronger shoulder muscles; therefore, the preparatory intervention of exercise was chosen to facilitate Karen's ultimate engagement in purposeful occupations and activities.

Education and Training

The OTPF-3 describes **education** as a "type of intervention process that involves imparting knowledge and information about occupation, health, well-being and participation that enables the client to acquire helpful behaviors, habits and routines that may or may not require application at the time of the intervention session"[3] (OTPF-3, p. S30).

Kent considered this definition, thinking of instances when he provided education as intervention. Most recently, with Karen, he responded to her concerns about returning to her job as an administrative assistant. She was having misgivings about the amount of physical work and energy involved; the modest salary she received, which barely covered her preinjury expenses; and the additional expenses she would have for personal and household assistance. Using his years of knowledge and experience, Kent provided intervention in the form of educating Karen about her options. He informed her of the services offered by vocational rehabilitation and educated her about the possibilities and opportunities for further education to support her work goal of becoming an attorney—a job position, he pointed out, that held the potential for higher pay and one that could be less physically demanding than her administrative assistant position. Kent also educated Karen about her rights to employment accommodations under the Americans with Disabilities Act (ADA) (see Chapter 15). He informed her about the similar circumstances of some of his former clients, describing the various scenarios and outcomes of each (being mindful to preserve the former clients' anonymity and privacy). He also drew on his wealth of experience to discuss the many resources available to facilitate such options. Karen was already preparing to resume her job (an occupational goal she prioritized) and was actively participating in OT by engaging in occupations and activities that involved her actual work occupations and supporting activities. The education intervention made her aware of her options but did not involve any actual performance of an activity. Kent could use the same intervention process to educate Karen's vocational counselor and the law firm for which Karen works.

In the OTPF-3, **training** is distinguished from education; it is described as "facilitation of the acquisition of concrete skills for meeting specific goals in a real-life, applied situation. In this case skills refers to measurable components of function that enable mastery. Training is further differentiated from education by its goal of enhanced performance as opposed to enhanced understanding, although these goals often go hand in hand"[3] (OTPF-3, p. S30). Examples of training include interventions such as teaching a personal care attendant ways to help a client with ADLs.

Kent considered that he provided training when he taught Karen how to complete her administrative assistant duties by showing her how to access files, operate her environmental controls system, and dictate notes using voice recognition software. Kent anticipates training Karen in how to manage her bladder (empty her leg bag), perform regular weight shifts, and access the cafeteria at work—all skills that are part of Karen's personal care in the work setting that she wants to master before returning to full-time employment.

Advocacy

The intervention type identified as advocacy is provided when efforts are directed toward promoting occupational justice (access to occupation) and empowering clients to seek and obtain resources to fully participate in their daily life occupations[3] (OTPF-3, p. S41). Kent worked with Karen and her work supervisor to advocate to the law firm partners for reasonable accommodations to support Karen's continued employment. After a year of Karen's successful job performance and her newly learned abilities to continually self-advocate, Kent and Karen were invited to the state bar association conference to advocate for similar collaborations on behalf of other employees with disabilities.

Group Intervention

The intervention type labeled group intervention is described as functional groups, activity groups, task groups, social groups, and other groups used in inpatient units, in the community, or in schools. These group interventions allow clients to explore and develop skills for participation, including basic social interaction skills and tools for self-regulation, goal setting, and positive choice making[3] (OTPF-3, p. S31).

In reflecting on Karen's OT process, Kent concluded that perhaps one of the most important interventions for Karen was the Home and Community Skills classes offered by the OT department during her rehabilitation stay. This eight-session experiential group class, taught by Kent and several of his OT colleagues, introduced topics such as managing friendships, negotiating occupations in the environment (eg, going to movie theaters, hair salons, grocery stores, and so on), asking for assistance, dating, childrearing, and using public transportation, to name but a few. Former clients who had achieved their goal of health, well-being, and participation in life through engagement in occupation were invited as peer experts to provide the lived experience for the discussions facilitated by the therapists. In addition to talking about issues (as an OT intervention), Kent made sure that each client had follow-up opportunities for “doing” the occupations and activities.

A year or so after her discharge, Karen was invited to share her experiences of returning to work, seeking accessible housing, and beginning a relationship with her new boyfriend. Kent facilitated the discussion. He used his clinical reasoning skills and knowledge of these topics, along with activity analysis and activity demands, to ask Karen strategic questions, to make sure the discussion included specific details, and to point out alternative solutions that others in the class might have found more applicable.

Kent has carefully studied the OTPF-3 domain, process, and types of interventions, and he has reinforced his learning by applying this knowledge to his own circumstances and those of his client, Karen. However, Kent still feels the need for additional suggestions or strategies for learning the Framework more thoroughly. The next section explores these strategies.

Strategies for Learning the OTPF-3

The most effective first step in learning the OTPF-3 may be to obtain and thoroughly read the original document, making notations as points arise, drawing diagrams for increased understanding, writing questions or observations in the margins, and consulting tables, figures, and the glossary, when directed to do so, to reinforce or clarify information. The OTPF-3 is a comprehensive conceptualization of the profession, and it requires a substantial investment of time and commitment to study and integrate it into practice before a therapist will feel comfortable using it. Box 1.1 provides an abbreviated list of the core terminology and concepts of the OTPF-3; this can serve as a quick reference or can be used to jog the reader's memory as he or she learns to use the Framework.

Box 1.1

Quick Guide to the Occupational Therapy Practice Framework

Achieving Health, Well-being and Participation in Life through Engagement in Occupation: OT's unique contribution, the overarching theme of the domain, and the overarching outcome of the process

Occupational therapists (OTs) use their knowledge and expertise in the therapeutic use of self and in activity analysis and activity demands (space demands, social demands, sequencing and timing), in addition to critical thinking skills, to guide their actions throughout each step of the OT process. Clients contribute their life experiences, knowledge, and expertise to the process in collaboration with the OT.[10]

The practice framework is composed of two primary interrelated parts: domain and process. These major elements are enhanced and supported by additional parts of the framework.

Domain: What (OTs) do—no single aspect is considered more critical than another.

- *Performance of occupations* (activities of daily living [ADLs], instrumental activities of daily living [IADLs], rest and sleep, education, work, play, leisure, and social participation)
- *Client factors* (values, beliefs and spirituality, body functions, and body structures)
- *Performance skills* (motor skills, process skills, and social interaction skills)
- *Performance patterns* (habits, routines, roles, and rituals)
- *Context and environment* (cultural, personal, temporal, and virtual)

Process: How OTs provide their services—collaborative process between client and OT

- *Evaluation* (occupational profile and analysis of occupational performance)
- *Intervention* (preferred term rather than *treatment*—includes

intervention plan, intervention implementation, and intervention review)

- *Targeted outcomes* (all goals aimed at the overarching goal of achieving health, well-being, and participation in life through engagement in occupation)

Client: Recipient of OT services (*client* is the preferred term, but the term used varies by practice setting—could be *patient, student, consumer, employee, employer,* and so on)

- *Individual* (broad view of client—could be the actual person with a disability or an individual providing support for the client, such as a family member, caregiver, teacher, or employer, who also may help or be served indirectly)

- *Organizations* (eg, businesses, industries, and agencies)

- *Populations* (within a community)

- *Client-centered approach*—an approach to the evaluation of the need for and provision of an intervention with emphasis on the client and his or her goals

- *Occupation versus activity*—*Activities* are characterized as meaningful and goal directed but not of central importance to the life of the individual. *Occupations* are viewed as activities that give meaning to the person's life and contribute to his or her identity; they are also the activities the individual looks forward to engaging in. In the *Occupational Therapy Practice Framework: Domain and Process,* Third Edition (OTPF-3), the term *occupation* encompasses *activities.*

Engagement: Includes both the subjective (emotional or psychological) and objective (physically observable) aspects of performance

Types of Intervention

Occupations and Activities

- *Occupations*—client-directed daily life activities that match and support or address identified participation goals

- *Activities*—actions that support the development of performance skills and patterns to enhance occupational engagement; client learns and practices parts or portions of occupations

Preparatory Methods and Tasks

- *Preparatory methods*—modalities, devices, and techniques to prepare client for occupational performance; includes splints, assistive technology and environmental modifications, and wheelchair mobility

- *Preparatory tasks*—actions to target specific client factors or performance skills

Education and Training

- *Education*—OT imparts knowledge and information about occupation, health, well-being, and participation that enable the client to acquire helpful behaviors, habits, and routines, which may or may not require application at the time of the intervention session.

- *Training*—facilitation of acquisition of concrete skills for meeting specific goals in a real-life, applied situation. Differentiated from education by its goal of enhanced performance as opposed to enhanced understanding.

- *Advocacy*—promotes occupational justice and empowers clients to obtain resources for full participation in occupation. Can be advocacy efforts by the practitioner on behalf of the client or self-advocacy efforts undertaken by the client

- *Group interventions*—use of distinct knowledge and leadership techniques to facilitate learning and skill acquisition across the lifespan through the dynamics of group and social-interaction. Groups may also be used as a method of service delivery.

More experienced occupational therapists, who are accustomed to using the OTPF (2002) and OTPF-2, will find it helpful to consult the Preface in the OTPF-3 (pp. S1–S2), where changes and major revisions to the Framework are listed and discussed.[3]

Several pioneering authors have written helpful articles demonstrating application of the Framework for the AJOT's various Special Interest Section (SIS) quarterlies. Writing for the *Home and Community Health SIS Quarterly,* Siebert encouraged practitioners to realize that it is "not as important to learn the OTPF as to use it as a tool to communicate practice, to support practice patterns that facilitate engagement in occupation, and to reflect on and refine our practice."[24] She also pointed out the dominant role that context plays in home and community practice by providing continuity to the client, noting how firmly the Framework supports this concept. She expressed her belief that the Framework's focus on occupation, in addition to beginning the process with the client's occupational profile, ensures that the results of OT intervention will matter to the client.[24]

Coppola, writing for the *Gerontology SIS Quarterly,* described how the framework can be applied to geriatric practice and explained that the evaluation is one of occupational therapy's most powerful means of informing others (including clients and colleagues) what OT is and what OT does. She provided a working draft of an Occupational Therapy Evaluation Summary form, which was developed to be incorporated into the Framework and to highlight occupation in a visual way into her practice in a geriatric clinic. This summary form is unconstrained by the more traditional documentation forms that seem to bury occupation under diagnostic and clinical terminology.[9]

Similarly, Boss offered readers of the *Technology SIS Quarterly* his reflections on how the Framework can be operationalized in an assistive technology setting. Addressing each of the categories of the domain, he offered examples of how assistive technology supports engagement in occupation (allowing completion of an activity or occupation) and how the use of assistive technology (personal device care and device use) can be an occupation in and of itself. He concluded his article by pointing out that "assistive technologies are all about supporting the client's participation in the contexts of their choice and are therefore part of the core of occupational therapy."[6]

Although the previously cited articles refer to use of the original OTPF, they thoroughly demonstrate how creatively the Framework can be applied to the array of OT practice settings. Another strategy for facilitating the reader's education in the Framework is the format of the chapters in this book, as described next.

The OTPF-3: Its Use in This Book

In keeping with the OTPF-3's central focus on the client and the importance of contexts and participation in occupation, each chapter begins with a case study and then integrates the information presented into the consideration of that client and those circumstances, similar to Kent's and Karen's experiences as described and threaded throughout this chapter. As the particular content information is presented, the reader frequently is asked to refer back to the case study and consider how the information applies to the specifics of the client portrayed. The probative questions asked at the conclusion of Part 1 of the case study are answered throughout the text or addressed at the end of the chapter.

Summary

“Occupational Therapy Practice Framework: Domain and Process,” the first article on this model, was published in 2002 by the AOTA. The subsequent edition, OTPF-2, and the current version, OPTF-3, were developed by the OT profession for two purposes: (1) to reassert occupational therapy's focus on occupation, and (2) to clearly articulate and enhance understanding of the domain of occupational therapy (what OT practitioners do) and the process of occupational therapy (how they do it) for both internal audiences (members of the profession) and external audiences (clients, healthcare professionals, and interested others). The overarching goal of OTPF-3 is “achieving health, well-being, and participation in life through engagement in occupation”[3]—this emphasizes the primacy of occupation, regarding it as both the theme of the domain and the outcome of the process.

The domain comprises five categories that constitute the scope of occupational therapy: occupations, client factors, performance skills, performance patterns, and contexts and environments. The OT process involves three interactive phases of OT services—evaluation, intervention, and outcomes—that develop in a collaborative and nonlinear manner. The types of OT intervention included in the OTPF-3 and typically used in physical disabilities practice settings include therapeutic use of occupations and activities (including occupation-based activity and purposeful activity); preparatory methods and tasks (including techniques to prepare the client for occupational performance; splints and orthotics; assistive technology and environmental modifications; and wheeled mobility); education and training; advocacy (by the practitioner and also by the client as self-advocacy); and group intervention.[3]

In addition to studying the chapter, readers are encouraged to explore the OTPF-3 in its entirety and to reinforce their learning by applying it to their own life experiences and those of their clients, meaning both the clients in the case studies presented throughout this book and those they encounter in real life in the clinic.

Review Questions

1. Briefly describe the evolution of the Occupational Therapy Practice Framework, including the OTPF-3.
2. Describe the need for the OTPF-3 in the practice of OT for persons with physical disabilities.
3. Describe the fit between the OTPF-3 and the ICF and explain how they inform and enhance the occupational therapist's understanding of physical disability.
4. List and describe the components that make up the OT domain, and give examples of each.
5. List and describe the components that make up the OT process, and give examples of each.
6. Briefly describe the OT intervention levels, and give an example of each as it might be used in a physical disability practice setting.

History and Practice Trends in Physical Dysfunction Intervention

Kathleen Barker Schwartz

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Trace the ideas, values, and beliefs that have influenced the development of occupational therapy as a profession.
2. Analyze the development of occupational therapy within the larger context of cultural, social, political, and legislative forces.
3. Explain how some of the opportunities and challenges that physical disabilities practitioners face today are a result of the way the history of occupational therapy evolved.

KEY TERMS

Arts and crafts movement
Disability rights movement
Independent living movement
Medical model

Moral treatment movement
Rehabilitation model
Social model

Roots of Occupational Therapy

Even into the early 20th century, individuals with physical disabilities "were kept at home, out of sight, in back bedrooms, by families who felt a mixture of embarrassment and shame about their presence."[19] This detrimental and pervasive reaction to physical disability began to change with the introduction of the medical model. From a medical perspective, disability was seen as a biological deficit that could be ameliorated with professional treatment. In fact, in the early 20th century, "progressive reformers" were looking to medical professionals to assist individuals with disability to reclaim their place in the community and the workplace.[53] It was against this backdrop that the profession of occupational therapy was founded in 1917.

The founders of occupational therapy believed that they could help rehabilitate individuals with disability through engagement in occupation. They chose the term *occupational therapy* to reflect this goal because in 1917 *occupation* was commonly used to mean "being occupied or employed with, or engaged in something."[37] The founders were aware that such broad terminology could be confusing.[15] However, they valued the breadth of the term for the freedom it would give occupational therapists to use a wide range of modalities and approaches, individually tailored to meet each person's desires and needs.

The founders of occupational therapy included William Rush Dunton, a psychiatrist; Herbert J. Hall, a physician; Eleanor Clarke Slagle, a social welfare worker; Susan Johnson, a former arts and crafts teacher; Thomas Kidner and George Barton, both former architects; and Susan Tracey, who was a nurse. They were influenced in their views of occupational therapy by ideas and beliefs prevalent during the latter part of the 19th century and the early years of the 20th century. The ideas that seemed to have most shaped the profession's early development were reflected in three movements: moral treatment, arts and crafts, and scientific management.

Moral Treatment Movement

The **moral treatment movement** grew out of a humanistic philosophy that originated in 19th century Europe and was promoted by physicians such as Philippe Pinel of France and Samuel Tuke of England. It represented a shift in thinking from a pessimistic viewpoint that labeled the mentally ill as subhuman and incurable to an optimistic one that viewed the mentally ill as capable of reason and able to respond to humane treatment. The main features of moral treatment included a respect for human individuality, an acceptance of the unity of mind and body, and a belief that a humane approach using daily routine and occupation could lead to recovery.[9] Occupations included music, physical exercise, and art,[41] in addition to agriculture, carpentry, painting, and manual crafts.[14]

Building on these ideas half a century later, the famous neuropsychiatrist Adolf Meyer proposed that many illnesses were "problems of adaptation" that could be remedied through involvement in curative occupations.[33] Dunton and Slagle enthusiastically supported this view, and Meyer's philosophy of "occupation therapy" was published in the first issue of the profession's journal. Slagle, who worked with Meyer at Phipps Clinics, developed habit training programs in mental hospitals to reestablish healthy habits of self-care and social behavior.[45]

Arts and Crafts Movement

The rise of the **arts and crafts movement** in the 1890s occurred in reaction to the perceived social ills created by the Industrial Revolution.[11] The economy was changing from an agrarian to a manufacturing society, so that what had previously been made by hand was now produced in factories. Proponents of the arts and crafts movement asserted that this resulted in a society of dissatisfied workers who were bored by monotonous and repetitive working conditions.

The use of arts and crafts as a therapeutic medium in occupational therapy (OT) arose from this trend. The arts and crafts approach was based on the belief that craftwork improved physical and mental health through exercise and the satisfaction gained from creating a useful or decorative article with one's own hands. According to Johnson, the therapeutic value of handicrafts lay in their ability to provide occupation that stimulated "mental activity and muscular exercise at the same time."[26] Different handicrafts could also be graded for the desired physical and mental effects. During World War I, OT reconstruction aides successfully used crafts for the physical and mental restoration of disabled servicemen.[43] For treating tuberculosis, Kidner advocated a graduated approach that began with bedside crafts and habit training and proceeded to occupations related to shop work and ultimately actual work within the institution.[28]

Thus, the ideas from the moral treatment and arts and crafts movements became intertwined as a definition of OT evolved to include treatment of individuals with physical and mental disabilities. In the early years of the profession, occupational therapists worked with patients throughout three stages of recovery.[28] During convalescence, patients would engage in bedside occupations that primarily consisted of handicrafts, such as embroidery and basket weaving. Once patients were able to get out of bed, they would engage in occupations designed to strengthen both body and mind, such as weaving or gardening, and occupations designed to reestablish basic habits of self-care and communication. When they were almost ready to return to the community, patients would engage in occupations that would prepare them for vocational success, such as carpentry, painting, or manual crafts.

Scientific Management

Frederick Taylor, a prominent engineer, introduced his theory of scientific management in 1911.[48] He proposed that rationality, efficiency, and systematic observation could be applied to industrial management and to all other areas of life, including teaching, preaching, and medicine. Progressive reformers of the period advocated that the ideology of scientific management address societal problems such as poverty and illness. These reformers criticized the noisy, dirty asylum of the 19th century and urged that the image of medical care be transformed into the clean, efficient hospital.[25] The idea that knowledge could be developed through research and observation and applied to patient care became an underlying tenet of the science of medicine and ultimately resulted in the development of reliable protocols for surgical and medical interventions.[53]

The founders of OT were attracted to the idea of a scientific approach to treatment. Barton was particularly taken with Taylor's time and motion studies and thought they might provide a model for OT research.[8] Dunton advocated that those who entered the profession be capable of engaging in systematic inquiry in order to further the profession's goals.[16] Similarly, Slagle urged research in OT to validate its efficacy.[45] By 1920 the profession was promoting the notion of the “science” of occupation by calling for “the advancement of occupation as a therapeutic measure, the study of the effects of occupation upon the human being, and the dissemination of scientific knowledge on this subject.”[12]

However, there is little in the OT literature of the early 20th century to suggest that OT practice was informed by systematic observation. One exception was the Department of Occupational Therapy at Walter Reed Hospital in Washington, D.C., under the direction of psychologist Bird T. Baldwin.[7] OT reconstruction aides were assigned to the orthopedic ward, where methods of systematically recording range of motion and muscle strength were established. Activities were selected based on an analysis of the motions involved, including joint position, muscle action, and muscle strengthening. Methods of adapting tools were suggested, and splints were fabricated to provide support during the recovery process. Treatment with this systematic approach was more narrowly focused at times but was applied within the context of what Baldwin called “functional restoration,” in which OT's purpose was to “help each patient find himself and function again as a complete man [sic] physically, socially, educationally, and economically.”[6]

Besides advocating a scientific approach to practice, the scientific management ideology emphasized efficiency and a mechanistic approach to medical care. Using the factory analogy, patients were the product, and nurses and therapists were the factory workers. It was assumed that doctors had the most scientific knowledge and therefore should be positioned at the top of the medical hierarchy. Dunton, a physician himself, seemed to support this arrangement, saying, “The occupational therapist, therefore, has the same relation to the physician as the nurse, that is, she is a technical assistant.”[13] As the profession evolved, the emphasis on efficiency and deference to medical authority became problematic for the profession. The focus on science and the resulting growth of the medical model were both beneficial and detrimental to OT practice.

Expansion and Specialization

The Rehabilitation Model

The growth of the **rehabilitation model** began after World War II and peaked with the healthcare industry boom in the 1970s, following the passage of bills establishing Medicare and Medicaid.

World War II revived the need for the United States to provide medical care for its wounded soldiers. Many more soldiers survived than in World War I because of recent scientific discoveries such as sulfa and penicillin. World War II also highlighted the value of OT services: "Although occupational therapy started during the last World War, it developed slowly [until] now when doctors are finding this aid to the sick and wounded invaluable."[35] A major effort was launched to reorganize and revitalize the Veterans Administration (VA) hospital system. Departments of physical medicine and rehabilitation were created to bring together all the services needed to care for the large number of war injured:

The theory that handicapped persons can be aided by persons who understand their special needs originated during World War II. The armed services established … hospitals for disabled veterans [that] helped the morale and physical condition of the patients so much that others were built for civilians.[35]

The interdisciplinary approach to care was emulated in the private sector. Demand for medical services increased in the civilian population as the treatment of chronic disability became a priority. Howard Rusk, a prominent voice in the development of rehabilitation medicine, asserted that the critical shortage of trained personnel would impede the country's ability to deliver services to the "5,300,000 persons in the nation who suffer from chronic disability."[27] He cited OT as one of the essential rehabilitation services. In response to the growing demand for rehabilitation services, Congress passed the Hill-Burton Act in 1946 to provide federal aid for the construction of rehabilitation centers. A proviso of the legislation was that rehabilitation centers must "offer integrated services in four areas: medical, including occupational and physical therapy, psychological, social, and vocational."[54] The passage of legislation establishing Medicare and Medicaid in 1965 put further demands on rehabilitation services to serve the chronically ill and elderly in healthcare institutions and also in the community.

Physical Dysfunction as a Specialty

The creation of a specialty in physical dysfunction within occupational therapy came about as a response to the changing demands of the marketplace and its requirement that specialists possess particular kinds of medical knowledge and technologic skills.[22] This new specialty began with an increasing focus on occupations that would promote physical strength and endurance:

The Army is death on the old-time invalid occupations of basket weaving, chair caning, pottery and weaving. These are "not believed to be interesting occupation for the present condition of men in military service," says an officer from the Surgeon General's office. The stress now is on carpentry, repair work at the hospital, war-related jobs like knitting camouflage nets, and printing.[51]

The scientific approach of joint measurement and muscle strengthening that Baldwin pioneered at the end of World War I was adopted and improved upon. Claire Spackman, who along with Helen Willard wrote the profession's first textbook on occupational therapy, argued that therapists must become skilled in carrying out new treatments based on improved techniques. According to Spackman, the occupational therapists serving people with physical disability needed to be skilled in teaching activities of daily living (ADLs), work simplification, and training in the use of upper extremity prostheses. But first and foremost, she asserted, "Occupational therapy treats the patient by the use of constructive activity in a simulated, normal living and/or working situation. Constructive activity is the keynote of occupational therapy."[46]

As the rehabilitation movement helped to establish the importance of OT, it further positioned the profession within the **medical model**. OT was urged to specialize and separate into two distinct fields, physical dysfunction and mental illness. The head orthopedist at Rancho Los Amigos Hospital in Downey, California, argued that the separation would result in “strengthened treatment techniques” and thus more credibility within the medical profession, which “does not recognize your field as an established necessary specialty.”[24] The American Occupational Therapy Association (AOTA) sought closer ties with the American Medical Association in order to increase occupational therapy's visibility and reputation as a profession dedicated to rehabilitation of the individual through engagement in occupation.

The closer relationship with medicine probably helped the profession gain credibility, at least within the medical model. The positive aspect of the medical model is that it emphasized the importance of the rehabilitation of those with disabilities, and it helped stimulate the development of new scientific techniques. The negative aspect of the medical model is that it presumed that the individual is a passive participant in the process. In response to this view, a new social model was proposed that placed the individual at the center of the rehabilitation process.

A New Paradigm of Disability: the Disability Rights and Independent Living Movements

The advocacy for disability rights that took hold in the 1970s had its roots in the social and political activism of the 1960s. During the 1960s, disabled people were profoundly influenced by the social and political upheaval they witnessed. They identified with the struggles of other disenfranchised groups to achieve integration and meaningful equality of opportunity. They learned the tactics of litigation and the art of civil disobedience from other civil rights activists. They absorbed reform ideas from many sources: consumerism, demedicalization, and deinstitutionalization.[18]

Like the civil rights and women's movements, the **disability rights movement** was rooted in self-advocacy. That is, individuals with disability were themselves promoting their own cause. Their activism took many forms, including lawsuits, demonstrations, founding of a plethora of organizations dedicated to achieving disability rights, and political lobbying for legislation to address inequality and protect rights.

The ideas underlying the disability rights movement were based on a social rather than a medical model. The medical model had provided the predominant view of individuals with disability for much of the 20th century. It placed the medical professional at the center of the rehabilitation process and the patient on the periphery as the person who was being helped by the experts. It categorized individuals according to their medical disability (eg, the paraplegic or the quadriplegic), and it saw the remediation of that medical condition as the way to eradicate disability. Disability rights advocates rejected this view as too paternalistic, passive, and reductionistic. Instead, they advocated a paradigm that put the individual with disability at the center of the model as the expert in knowing what it was like to have a disability.

The **social model** proposed that disability was created because of environmental factors that prevented individuals from being fully functioning members of society. Physical boundaries prevented individuals from having access to schools, the workplace, and the home. Social views of individuals as pathetic cripples blocked full participation in life activities. Political and legal interpretations advocated "separate but equal" participation rather than inclusion. The social model argued that disability must be viewed from a cultural, political, and social lens rather than a biomedical one:

This [biomedical] model makes us aware that a complex system of mutually supporting beliefs and practices can impact those with disability by: stigmatizing them as less than full humans, isolating them by policies of confinement or the built environment, making them overly dependent on professionals rather than helping them develop responsible behaviors, robbing them of independent decision making that others enjoy, undermining their self-confidence in their many capabilities, over-generalizing the significance of some impairment, and defining them as tax-eaters rather than tax-contributors.[47]

Aligning itself with the social model, the **independent living movement** got its start when Edward Roberts was admitted to the University of California, Berkeley, in the fall of 1963.[47] The polio that Roberts had contracted at the age of 14 left him paralyzed from the neck down and in need of a respirator during the day and an iron lung at night. It was arranged that Roberts would stay in Cowell Hospital on the Berkeley campus with his brother Ron providing him personal assistance. Although Roberts was the first, in the following years Berkeley admitted other students with severe disabilities. They formed the "Rolling Quads" and were dedicated to making the campus and environs physically accessible.

Having completed his master's degree, Roberts, and his fellow Rolling Quads, were invited in 1969 to Washington to help develop a program aimed at retention of students with disability on college campuses. They created the Physically Disabled Students' Program (PDSP), which included provision for personal assistants, wheelchair repair, and financial aid. In 1972 Roberts became the first executive director of the first Center for Independent Living (CIL), located in Berkeley. Roberts based the CIL on the principles underlying the PDSP,[1] "that the experts on disability are the people with the disabilities[4]; that the needs of the people with disabilities can best be met by a comprehensive, or holistic program, rather than by fragmented programs at different agencies and offices[4]; that people with disabilities should be integrated into the community."[39] Since the founding of the first CIL, hundreds of other centers have been developed throughout the country.

Providing Humanistic and Scientific Care: an Ongoing Discussion Within the Profession

Moral Treatment and the Medical Model

As previously discussed, occupational therapy was founded on two paradigms: a humanistic framework and a scientific framework. In the 1960s and 1970s, the tension between paradigms within occupational therapy was expressed in terms of moral treatment versus the medical model. A cry arose from some of the profession's leaders to return to its roots in moral treatment and to forego what Shannon referred to as the "technique philosophy."[44] In his article on what he called "the derailment of occupational therapy," Shannon described two philosophies at odds with each other. One, he asserted, viewed the individual "as a mechanistic creature susceptible to manipulation and control via the application of techniques"; the other, based on the profession's early philosophy of moral treatment, emphasized a holistic and humanistic view of the individual.

Kielhofner and Burke described the situation as a conflict between the humanistic and scientific paradigms.[29] Early OT practice, they asserted, was based on the model of occupation that had moral treatment as its foundation. This paradigm provided a "holistic orientation to Man [sic] and health in the context of the culture of daily living and its activities." Post–World War II practice, they asserted, was based on the scientific paradigm of reductionism, a mode of thinking characteristic of the medical model. This view emphasized the individual's "internal states" and represented a shift in focus to "internal muscular, intrapsychic balance and sensorimotor problems." The authors acknowledged that practice based on the scientific paradigm "would pave the way for the development of more exact technologies for the treatment of internal deficits"; however, they were concerned that it "necessitate[d] a narrowing of the conceptual scope of occupational therapy."[29]

The claims that early OT practice was based on the humanistic and holistic philosophy of moral treatment are accurate, but they do not tell the full story. As this chapter describes, the founders also valued the medical model and the important role that "science" could play in establishing the profession's credibility. For example, the Committee on Installations and Advice, directed by Dunton, was formed to scientifically analyze the most commonly used crafts and to match the therapeutic value of each craft to a particular disability.[42]

How could the founders have supported what came to be viewed in the 1970s as the two opposing views of moral treatment and the medical model? The answer may be that in 1917, when the profession was founded, the models were not considered to be incompatible because the scientific medical model had not fully taken hold. It appears that in the founding years, occupational therapists primarily *practiced* moral treatment and *talked about* how practice should also be medical and scientific. When early practitioners were asked to treat patients in order to "restore the functions of nerves and muscles" or to make use of "the affected arm or leg,"[46] they based their treatment on their belief in the importance of occupation, habit training, and their knowledge of crafts. Once knowledge and technologic advances were sufficient and occupational therapists could actually practice using a scientific, medical perspective, it became apparent that the values underlying these two paradigms might be in conflict.

The physical disabilities therapist was faced with the problem of how to give treatment that was, on the one hand, holistic and humanistic and, on the other, medical and scientific. Baldwin's answer in 1919 was to see activities such as muscle strengthening and splint fabrication as techniques that contributed to the larger goal of "functional restoration" of the individual's social, physical, and economic well-being.[7] Spackman's answer in 1968 was that the occupational therapist should use "constructive activity in a simulated, normal living and/or working situation. This is and always has been our function."[46] She emphasized the teaching of ADLs and work simplification and was critical of treatment that consisted of having patients sand or use a bicycle saw with no "constructive activity" involved.

Another answer to the question of differing paradigms was to move outside the medical model. Bockoven urged OT practitioners to set up services in the community based on moral treatment:

It is the occupational therapist's inborn respect for the realities of life, for the real tasks of living, and for the time it takes the individual to develop his modes of coping with his tasks, that leads me to *urge haste on the profession … to assert its leadership in fashioning the design of human service programs … Don't drop dead, take over instead!*[10]

Yerxa urged therapists not to rely solely on doctor's orders:

The written prescription is no longer seen by many of us as necessary, holy or healthy. … The pseudo-security of the prescription required that we pay a high price. That price was the reduction of our potential to help clients because we often stagnated at the level of applying technical skills.[56]

However, as practice moved into the 1980s, there was much concern that if occupational therapists did as their critics suggested, they would jeopardize reimbursement and referrals. They argued that they were being asked to exclude skills and knowledge they believed were valuable in patient treatment, such as exercise, splinting, and facilitation techniques. They further argued that many patients receiving OT services were initially not at the level of motor capability that would enable them to engage in satisfying occupations. It was proposed that adjunctive techniques, such as exercise and biofeedback, should be considered legitimate when used to prepare the patient for further engagement in occupation.[52] A study conducted in 1984 by Pasquinelli showed that although therapists valued occupation, they used a wide variety of treatment techniques and approaches, including facilitation and nonactivity-oriented techniques.[38] Both Ayres[5] and Trombly[52] argued that instead of attempting to redirect the focus of OT, the profession should include current clinical practices that had proved effective on an empirical and practical basis.

The Rehabilitation Model and the Social Model

By the latter decades of the 20th century, the debate was being expressed as a conflict between the rehabilitation model and the social model. Scholars such as Gill[20] brought the perspective of the social model of the disability rights advocates to the discussion of what constituted ideal occupational therapy practice. She argued that the rehabilitation model exempted society from taking any responsibility for its role in creating the climate that restricted the rights and opportunities of the disabled. She urged occupational therapists to examine their practice and make sure that their treatment did not focus solely on the individual's physical condition:

For rehabilitation to be helpful, it must address the reality of what life is like for disabled persons. If rehabilitation professionals fail to fit their services to the patient's needs, values, and interests, they fail both the patient and their own professional aspirations. … Without a proper balance of physical treatment and realistic social information, rehabilitation cannot enable patients. … What good are increased range of motion and finger dexterity when a patient's morale can be crushed by job discrimination or social rejection?[20]

A study conducted by Pendleton in 1990 supported Gill's concerns. Pendleton found that occupational therapists were much less likely to provide training in independent living skills than physical remediation.[40] She defined independent living skills as “those specific abilities broadly associated with home management and social/community problem solving.” She argued that “Mastering such skills could contribute to the achievement of control over one's life based on the choice of acceptable options that minimize reliance on others. … The result of achieving such control is that the person can actively participate in the day-to-day life of the community.”[40] She recommended that if occupational therapists were not able to provide sufficient independent living skills training in inpatient rehabilitation centers, they should shift their treatment to community-based programs. Pendleton saw independent living skills as the essence of occupational therapy and urged therapists to make it one of their priorities.

Longmore, a well-known historian and disability rights activist, emphasized the importance of the issues raised by Gill and Pendleton. He acknowledged that disability rights activism had been responsible for numerous pieces of legislation since the 1970s aimed at giving those with disability equal access to all parts of society, including schools, work, public places, and transportation. However, he warned that there was still much to be done. The most important legislation passed during this period included the Rehabilitation Act of 1973, the Individuals with Disabilities Education Act of 1973 (IDEA), and the Americans with Disabilities Act of 1990 (ADA). Longmore argued that, despite this legislation, people with disabilities continued to experience marginalization and financial deprivation. He wrote, “Depending on age and definition of disability, poverty rates among disabled people range anywhere from 50% to 300% higher than in the population at large.”[31] He worried that most people assumed that the ADA had eradicated the major problems for those with disabilities, when in fact “to a surprising extent U.S. society continues to restrict or exclude people with disabilities.”[31]

Contemporary Practice: Addressing the Unintended Consequences of the Rehabilitation Model

As previously discussed, disability scholars such as Longmore[32] and Gill[21] criticized the main premise of the rehabilitation model—that something is abnormal or lacking in the individual with disability. The main justification for rehabilitation services is that through the intervention of professionals (eg, occupational therapists), the client can become more independent and a more useful contributor to society. The problem with this premise is that it assumes that clients want to become more "independent" (as defined by the rehabilitation specialists) and that they cannot fully contribute to society in their current condition. Thus, the rehabilitation model has the unintended consequence of devaluing individuals with disabilities and placing the focus of intervention on remediating the disability rather than the social, political, and economic barriers that contribute to it. Kielhofner discussed this problem in the *Special Issue on Disability Studies* that appeared in the *American Journal of Occupational Therapy*: "As this paper and others in this special issue illustrate, disability studies raises issues and questions to which there are no easy answers."[30] He quoted the disability scholar Paul Abberley, who noted that "OT, despite what may be the best of intentions on the part of its practitioners, serves to perpetuate the process of disablement of impaired people."[30]

One answer is to create constructs that attempt to blend the rehabilitation and social models by redefining disability. The World Health Organization (WHO) sought to do this in 2001 with the *International Classification of Functioning, Disability, and Health* (ICF).[55] The ICF provides a classification system that considers physical and mental impairments in addition to environmental and personal factors, any or all of which may result in activity limitations and participation restrictions.

Basing its work on WHO's conceptual scheme, the AOTA created the Occupational Therapy Practice Framework (OTPF) in 2002, which was revised in 2008 and 2014.[1-3] The Framework provides a construct that promotes client-centered engagement in occupation as the central focus of practice. This construct addresses issues raised by the proponents of moral treatment, in addition to problems inherent in the social and medical models. It reclaims the values of moral treatment by its focus on occupation-based treatment that is both holistic and humanistic. It integrates aspects of the medical model by advocating the reduction of functional impairments caused by physical and psychological limitations. Finally, it supports the social model of the disability rights movement by emphasizing the need for client-centered treatment within the context of the social, cultural, and political environments.

Another answer is for occupational therapists to continue to emphasize the therapeutic use of self in all relationships with clients. A focus on the importance of the therapist's interaction with clients has been an underlying tenet of occupational therapy since its founding and continues today. Indeed, as Taylor et al. found in their survey of 568 occupational therapists, "Most therapists considered therapeutic use of self as the most important skill in occupational therapy practice and a critical element of clinical reasoning."[50] By focusing on the client-therapist relationship, the practitioner is more likely to understand the client's experience as an individual with a disability and thus to work jointly with him or her to formulate an intervention plan that centers on the client's goals. When a viable therapeutic relationship is formed, practice is much more likely to be client centered.

Scholarship that focuses on the disability experience can add to the profession's body of knowledge and can help increase our understanding of how occupational therapy can address disability studies concerns. For example, research by occupational therapy scholars such as Taylor,[49] Neville-Jan,[34] and Guidetti et al.[23] examines the experiences of those with disabilities through phenomenological and narrative accounts, thereby helping occupational therapists understand disability from the individual's perspective.

Finally, a knowledge of history can provide a context from which to understand the current challenge to physical disabilities practice. As this history has demonstrated, early treatment in occupational therapy was based on belief in the importance of occupation, habit training, and knowledge of crafts. As scientific knowledge and technology advanced, OT defined a role for itself within the rehabilitation model. This resulted in the emergence of physical disabilities as a specialty within OT. The closer relationship with medicine helped the profession gain credibility. However, the scientific reductionism of the medical model put professional practice at odds with the holistic humanism of moral treatment. Today we discuss this in terms of the tensions inherent in the rehabilitation model versus the social model advocated by disability scholars.

Our current challenge is to interweave the rehabilitation and social models wherever possible. Occupational therapy is uniquely qualified to do this because we were founded on two potentially conflicting paradigms, the humanistic and the scientific; therefore, tension between two paradigms is not new for our profession. There have been ongoing discussions since the 1960s on how to resolve the tension between these paradigms. These discussions have led the profession full circle, back to its most enduring belief—the benefits of engagement in occupation. As Dunton emphasized in 1919, "Occupation is as necessary to life as food and drink."[17] When occupational therapists keep occupation as the central focus, it is easier to find the common ground of the rehabilitation and social models.

As new approaches and techniques are developed, OT intervention that promotes engagement in desired occupations will remain consistent with the philosophical base of the profession and help further advance occupational therapy as a valued service in physical disabilities practice.

Using History to Understand Today's Practice

In lieu of a case study, we will demonstrate how we can use our knowledge about occupational therapy's history to answer a question that is prevalent among students and therapists today: Why do occupational therapists continually have to define occupational therapy to others?

First, we should acknowledge that more people than ever do understand occupational therapy. Most of these people are individuals who have received treatment or have had personal contact with someone who received occupational therapy. So each time an occupational therapist successfully engages a client in treatment, he or she is providing a positive definition of occupational therapy. That being said, it can feel as though occupational therapists spend quite a bit of time educating others as to what we do. We can look back to the founding years to understand why this is so. The answer is complex and includes several factors.

The first relates to the profession's purpose. As noted earlier in the chapter, in naming the profession, the founders were looking for a term that was broad enough to encompass all the things occupational therapists did. In 1923 the AOTA described occupational therapy as follows:

Occupational Therapy is a method for training the sick or injured by means of instruction and employment in productive occupation. The objects sought are to arouse interest, courage, and confidence: to exercise mind and body in healthy activity; to overcome disability; and to re-establish capacity for industrial and social usefulness.[4]

This definition reflects a holistic, humanistic, and all-encompassing view of the individual, the rehabilitative process, and the role of occupational therapy within it. It addresses the mind in addition to the body, and social as well as medical goals. The founders ultimately decided that *occupational therapy* was the term that best reflected the profession's goals. This is not to say that the founders did not consider the possible negative aspects of the term. It is clear from their writings that they were aware that such a broad term might cause some misunderstanding. However, in the end, they felt that this negative would be offset by the positive of providing occupational therapists with a wide range of freedom to treat each individual in the best way possible.

Second, we must consider that the name *occupational therapy* was chosen in 1917, and meanings of terms change over time. For example, children with disabilities were placed in "asylums for the crippled" in the early 1900s. We would never use that terminology today. Fortunately, *occupation* does not carry such a negative connotation in today's lexicon, but the term has shifted in meaning. In 1917, *occupation* was most commonly used to mean an important activity in which one engages. For example, in a novel, one might read about a woman who was searching for an occupation that would satisfy her free time. As the century progressed, the term *occupation* came to be more closely aligned with the kind of paid work a person does, as in "What is your occupation?" When the profession's name is considered in this light, it is easier to understand any confusion someone today may have about the term and the continual need for the occupational therapist to educate people about the term's meaning within today's context.

Third, we must also consider that the professions that exist today did not exist at the time of occupational therapy's founding. That is one reason the definition of OT was so broad. At the time of the founding of occupational therapy, society was looking for a profession that could help remediate the wounds and illnesses of returning soldiers and enable them to become productive members of society. Occupational therapy offered that promise. Professions such as social work and physical therapy were still in their fledgling stage, and it was unclear which profession would ultimately be involved in the soldiers' rehabilitation. In addition, art, music, recreation, and vocational therapy had yet to be introduced.

Finally, as has been discussed throughout this chapter, the ideas underlying occupational therapy do not fit neatly into just one theoretical paradigm. Occupational therapy uses an occupation-based, client-centered approach that bridges both the medical and social models, as is evidenced in the Occupational Therapy Practice Framework. Although this sounds good in theory, in practice it means that if occupational therapists are working with people who use a strict medical model (including third parties), there will be misunderstandings about OT's proper role. This is where occupational therapists must be proactive in describing what we do.

History tells us that occupational therapy has always viewed its clients and its role through a humanistic, holistic lens, and it cannot be neatly confined either to the medical or the social paradigm. The blending of these paradigms, in the ICF and OTPF, finally offers occupational therapy a suitable home. However, these are new ideas, and it will take time for them to be accepted. This is one more reason occupational therapists will not be finished defining what we do any time soon. But is it not a worthy challenge? History would suggest that it is. So the next time you have to define occupational therapy, think of yourself as the latest generation to carry on the proud tradition of defining your goals by what is good for the client rather than what “fits” into the prevailing theoretical model.

Review Questions

1. Name the seven founders of occupational therapy, and list the professional background of each.
2. What ideologies shaped the development of occupational therapy in the late 19th and early 20th centuries?
3. What were the main features of the philosophy of moral treatment?
4. Describe the ideas that were the foundations of occupation as a remedy for mental and physical illness.
5. What provoked the rise of the arts and crafts movement?
6. How did the arts and crafts movement influence occupational therapy?
7. Describe scientific management. How did it influence the development of occupational therapy?
8. When did the rehabilitation model evolve? How did the world wars influence the development of the rehabilitation model?
9. How did physical dysfunction become a specialty?
10. What factors influenced occupational therapy to adopt the medical model?
11. What was the apparent conflict between moral treatment and the medical model?
12. What impact have the disability rights and independent living movements had on occupational therapy?
13. How is the apparent conflict between the medical model and the social model being resolved in occupational therapy practice?

PART II

Occupational Therapy Process and Practice

OUTLINE

Application of the Occupational Therapy Practice Framework to Physical Dysfunction

Winifred Schultz-Krohn, Heidi McHugh Pendleton

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Identify and describe the major functions of the occupational therapy (OT) process.
2. Describe how clinical reasoning adjusts to consider various factors that may be present in the intervention context.
3. Identify how theories, models of practice, and frames of reference can inform and support OT intervention.
4. Identify appropriate delegation of responsibility among the various levels of OT practitioners.
5. Discuss ways in which OT practitioners may effectively collaborate with members of other professions involved in client care.
6. Recognize ethical dilemmas that may occur frequently in OT practice, and identify ways in which these may be addressed and managed.
7. Describe the various practice settings for OT practice in the arena of physical disabilities.
8. Discuss the types of services typically provided in the various practice settings.
9. Identify ways in which different practice settings affect the occupational performance of persons receiving occupational therapy services.
10. Identify the environmental attributes that afford the most realistic projections of how the client will perform in the absence of the therapist.
11. Identify environmental and temporal aspects of at least three practice settings.
12. Describe ways in which the therapist can alter environmental and temporal features to obtain more accurate measures of performance.

Pragmatic reasoning
Procedural reasoning
Referral
Screening
Skilled nursing facility (SNF)
Subacute rehabilitation

Threaded Case Study

Serena, Part 1

Serena is an occupational therapy student who began her first fieldwork internship 2 weeks ago. She felt fortunate to be assigned a site that provides a wide array of services. Serena's site is a community hospital that provides a continuum of care, from emergency services and critical care (intensive care unit [ICU]) to outpatient rehabilitation services. Her internship includes providing occupational therapy (OT) intervention in a variety of settings. Her clinical instructor (CI) requested that Serena review the process of developing an intervention plan and be prepared to differentiate the roles of occupational therapy in the various settings.

Critical Thinking Questions

1. What process should be used to develop an intervention plan?

2. How do theories, models of practice, and frames of reference guide an intervention plan?

3. What forms of clinical reasoning are used when providing OT services?

This chapter is divided into two sections. The first section introduces the OT process, summarizing the functions of evaluation, intervention, and outcomes described in the "Occupational Therapy Practice Framework," third edition (OTPF-3).[6,7] The chapter acquaints the reader with the complexity and creativity of clinical reasoning within the context of the contemporary clinical environment. The complementary roles of different OT practitioners are described, as are the relationships between the occupational therapist and other healthcare professionals involved in the care of the client with physical dysfunction. Common ethical dilemmas are introduced, and ways to analyze these are presented.

The second section describes various practice settings in which OT services are provided for individuals who have physical disabilities. In addition, the typical services provided in each setting are discussed.

Section 1 The Occupational Therapy Process

Winifred Schultz-Krohn, Heidi McHugh Pendleton

The Steps of the Occupational Therapy Process

The OTPF-3 discusses both the domain and the process of the occupational therapy profession.[6,94] The domain is described in Chapter 1, and the reader should be familiar with the domain before reading about the process of occupational therapy.

The OT process should be conceptualized as a circular progression initiated by a referral (Fig. 3.1). The referral may be generated by another professional or by the client seeking services. The profession of occupational therapy identifies the "client" as including "persons, groups, and populations" (OTPF-3, p. S2).[7] Following the referral, an evaluation is conducted to identify the client's occupational needs. The intervention is developed based on the evaluation results. The targeted outcome of intervention is "achieving health, well-being, and participation in life through engagement in occupation" (OTPF-3, p. S2).[5,7] The steps of evaluation, intervention, and outcome should not be viewed in a linear fashion, but instead should be seen as a circular or spiraling process in which the parts are mutually influential.

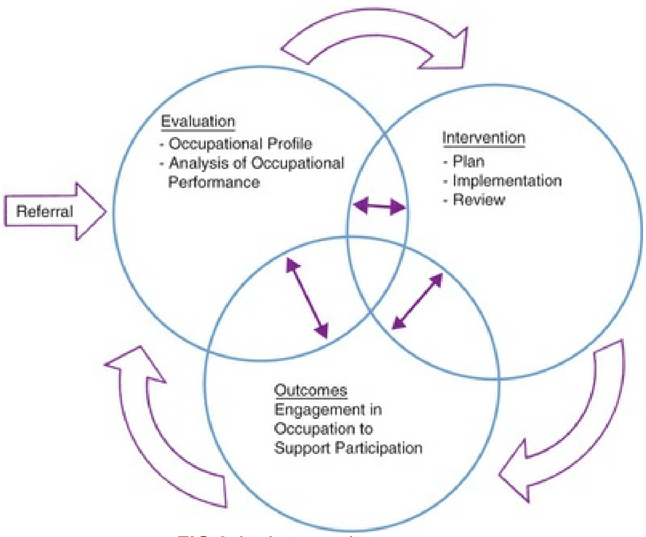

FIG 3.1 Intervention process.

Referral

The physician or another legally qualified professional often requests occupational therapy services for the client. The **referral** may be oral, but a written record is often a necessity. Individuals, groups, and/or populations may also seek occupational therapy services without a formal referral from another party. Guidelines for referral vary, and in some situations OT services may require a physician's referral before the initiation of services. The occupational therapist (OT) is responsible for responding to the referral. Although clients may seek OT services without first obtaining a referral, the occupational therapist may need a referral before the initiation of intervention services. State regulatory boards and licensing requirements should be reviewed before initiation of services to determine whether a referral for service is necessary.

Screening

The OT determines whether further evaluation is warranted and if OT services would be helpful to this client. The therapist may perform a **screening** independently or as a member of the healthcare team. Screening procedures are generally brief and do not cover all areas of occupation. A formal screening is not always conducted with the client; however, during the review of the client's record before the evaluation, the OT considers the client's diagnosis and physical condition, the referral, and information from other professionals. The therapist synthesizes this information before initiating an evaluation. In some settings, the screening process flows directly into the evaluation of the client in a seamless manner. This requires the OT to assess and view multiple influential factors through the lens of how the client would like to engage in occupations.

Evaluation

Evaluation refers to "the process of obtaining and interpreting data necessary for intervention. This includes planning for and documenting the evaluation process and its results."[1] Assessment refers to "specific tools or instruments that are used during the evaluation process."[1] Two parts of the evaluation process have been identified: the generation of an occupational profile and the analysis of occupational performance (OTPF-3, p. S10).[7] The assessments chosen, if necessary, help further develop the occupational profile. The OT then analyzes the client's occupational performance through synthesis of data collected using a variety of means.

The evaluation portion begins with the OT and client developing an occupational profile that reviews the client's occupational history and describes the client's current needs and priorities (OTPF-3, p. S10).[6,7,16] This portion of the evaluation process includes the client's previous roles and the contexts for occupational performance. For example, Serena has been assigned to develop an occupational profile for a 56-year-old man who recently had a tumor removed from his right cerebral hemisphere, resulting in dense left hemiplegia. He has been married to his wife for 27 years and reports that he never cooks. On further exploration during the development of the occupational profile, the man reports that one of his most treasured occupations is being able to grill, and he discusses the importance of grilling over charcoal versus using a gas grill. Although Serena may have initially ignored the need to work on cooking skills with this man, she now understands the occupational significance of grilling and, from the client's perspective, the difference between grilling and cooking! The occupational profile allows the OT to understand the client's occupational history, current needs, and priorities, and it also identifies which occupations or activities are successfully completed and those that are problematic for the client.

The occupational profile is most often initiated with an interview with the client and significant others in the client's life, and by a thorough review of available records.[6] Interviews may be completed using a formal instrument or informal tools. Although the occupational profile is used to focus subsequent intervention, this profile is often revised throughout the course of intervention to meet a client's needs. The purpose of the occupational profile is to answer the following questions, as posed by the American Occupational Therapy Association (AOTA) framework (OTPF-3, p. S13).[6,7] These questions provide an example of how the occupational therapist, Serena, initiates the occupational profile of one of her clients, Nora.

1. *Who is the client?* This requires consideration not only of the individual, but also of the significant others in the client's life. In some settings the client may be identified as a group and not as an individual. Serena's client, Nora, is a 28-year-old woman who sustained a traumatic brain injury (TBI), resulting in memory deficits and slight difficulties with coordination. She is a wife and the mother to two young children. During the evaluation process, Serena considers not only Nora's occupational needs, but also the needs of her family and her roles as a family member.

2. *Why is the client seeking service, and what are the client's current concerns relative to engaging in occupations and daily life activities?* This relates to the occupational needs identified by the individual and significant others. The needs not only of Nora, but also those of her husband and children, should be considered in answering this question.

3. *What occupations and activities are successful or are problematic for the client?* This requires an understanding of which occupations are successfully completed by the client. Nora has the physical ability to drive, yet she also has severe memory problems and difficulty remembering the routes for driving her children to school and various activities.

4. *What aspects of the client's environments and contexts influence engagement in occupations and desired outcomes?* Some contexts may be supportive, whereas others present challenges or prohibit occupational performance. Nora's parents expect her to be the primary caregiver for her children and when her husband attempts to support Nora, her parents interfere.

5. *What is the client's occupational history? What are the client's values and interests?* This includes the level of engagement in various occupations and activities, along with the value attributed to those occupations by the client. Although prior to her traumatic brain injury Nora was responsible for most of the housecleaning tasks, she did not highly value these duties. She was also responsible for meal preparation, and she says that she enjoys cooking. She places a much higher value on being able to drive her children to school and various after-school activities.

6. *What are the client's patterns of engagement in occupations, and how have these changed over time?* During the evaluation session, Nora explains that she has always been very active in the community and with her family. If anyone was sick, Nora was the person to provide support. Nora reveals to Serena that she has concerns about others needing to care for her; Nora has never been the one to receive care and support. Serena considers this marked change in a sense of self that Nora is experiencing after her TBI.

7. *What are the client's priorities and targeted outcomes?* These may be identified as occupational performance, role competence, adaptation to the circumstance, health and wellness, prevention, or quality-of-life issues. For Nora, the need to drive safely so as to resume responsibility for fostering community participation for her children was a primary outcome. This reflects her interest in occupational performance. She was not interested in having her parents or her husband assume these roles.

After the occupational profile has been developed, the OT identifies the necessary additional information to be collected, including areas to be evaluated and what assessment instruments should be used prior to the analysis of occupational performance. The OT may delegate some parts of the evaluation, such as the administration of selected assessment tools, to the occupational therapy assistant (OTA). The interpretation of data is the responsibility of the OT. This requires the OT to direct the evaluation by completing an occupational profile, interpreting the data collected from the profile, and then analyzing the client's occupational performance prior to proceeding to assessment of client factors. The selection of additional information beyond the occupational profile should answer the following questions:

1. What additional data are needed to understand the client's occupational needs, including contextual supports and challenges?

2. What is the best (most efficient and accurate) way to collect these data?

3. How will this information support the intervention plan?

4. How will this information influence potential outcomes?

The ability of the client to successfully plan, initiate, and complete various occupations is then evaluated. The occupations chosen are based on the occupational profile. The OT then analyzes the data to determine the client's specific strengths and weaknesses that impact occupational performance. The impact of contextual factors on occupational performance is included in the analysis of data. This can easily be seen when a client who is dependent on a wheelchair for all mobility is faced with several stairs to enter an office building to conduct business. The client has functional mobility skills but is prohibited from participating because of an environmental factor that restricts access. The analysis includes integrating data regarding the activity demands, the client's previous and current occupational patterns, and the client factors that support or prohibit occupational performance. Data about specific client factors may be helpful in developing an intervention plan but should be performed after the occupational profile is completed and an analysis of occupational performance has been initiated. The information generated from the profile and analysis will allow more careful selection of necessary assessment tools to collect further data. The OT also considers if the client would benefit from a referral to other professionals.

Threaded Case Study

Serena, Part 2

Although Serena is able to competently perform a manual muscle test and range-of-motion assessment, these assessments would not be necessary for all clients. Serena must first develop the client's occupational profile as a guide and then select the most appropriate assessment instruments to complete her evaluation of the client's occupational performance. After she has completed these steps, Serena will be able to identify more clearly what additional information is needed to plan and implement intervention services.

Intervention Planning

In collaboration with the client, the **occupational therapy practitioners** (OT and OTA) develop an **intervention plan**, using the approaches or strategies in the following list, to enhance the client's ability to participate in occupational performance.[6,7,16] Although the OT is responsible for the plan, the OTA contributes to the plan and must be "knowledgeable about the evaluation results."[3] The strategies selected should be linked to the intended outcomes of service.[6] These approaches or strategies answer the question, "What type (approach/strategy) of intervention will be provided to meet the client's goals?" Examples of each form of intervention approach or strategy are provided. with selected literature to support this form of occupational therapy intervention.[7]

1. *Create or promote healthy occupational engagement*. A disabling condition is not assumed; rather, OT services are provided to enhance and enrich occupational pursuits. This approach may be used to help clients who are transitioning in roles or to foster occupational performance across contexts. An example would be using narratives to promote a healthy transition from the role of a worker to retirement. As workers described what they anticipated in retirement, they linked "past, present, and future." This process of anticipating changes and making choices was considered to be an important factor in "understanding how people adapt to life changes."

2. *Establish or restore a skill or ability.* This strategy is aimed at improving a client's skills or abilities, thus allowing greater participation in occupations. Evidence of the effectiveness of OT services provides this form of intervention, as demonstrated by several investigators. Walker et al.[91] investigated the effectiveness of OT services in restoring skills for activities of daily living (ADLs) and instrumental activities of daily living (IADLs) in clients who had sustained a cerebrovascular accident (CVA) but who had not received inpatient rehabilitation services. Using a randomized controlled trial, these researchers demonstrated that clients who received OT services had significantly better ADL and IADL performances compared to clients who had not received these services. Rogers et al.[77] demonstrated that performance of ADLs can be significantly improved when clients are provided with systematic training by OT practitioners.

3. *Maintain current functional abilities.* This approach recognizes that many clients are faced with degenerative disorders, and OT services should actively address the need to maintain occupational engagement.[24,36] Intervention may focus on the activity demands, performance patterns, or context for occupational performance. For example, an individual in the early stage of Parkinson disease is still able to complete many self-care activities but should develop the habits that will maintain these skills as motor function continues to deteriorate. Maintenance also includes clients who have a chronic, nonprogressive disorder; these individuals need to maintain physical conditioning to meet activity and environmental demands.

4. *Modify, adapt, or compensate.* This approach focuses on modifying the environment, the activity demands, or the client's performance patterns to support health and participation in occupations. Instruction and use of energy conservation techniques for clients who have dyspnea (shortness of breath or difficulty breathing) as a result of chronic obstructive pulmonary disease (COPD) is an example of this approach.[63] The use of electronic aids to daily living (EADLs) is another example of how the activity can be modified to promote participation. In a study by Erikson et al.,[34] when clients who had acquired brain damage were provided with training in the use of EADLs, they reported a sense of mastery. Even if a client's previous abilities cannot be restored, using this adaptive or compensatory approach can promote participation in occupations.

5. *Prevention.* A prevention approach can be used for clients who have no identified disabling condition or circumstance. This approach focuses on developing the performance skills and patterns that support continued occupational performance, and it provides intervention that

anticipates potential hazards or challenges to occupational performance. Contextual issues are also addressed using this approach, and environmental barriers would be similarly considered. An example of services representing a preventive approach would be instructing a client who has compromised standing balance in fall prevention techniques and asking the family to remove loose throw rugs from the home to prevent falls.[29] Clark et al.[26] demonstrated the beneficial effects of preventive OT services in the investigation of well, elderly adults. Adults who received preventive OT displayed far fewer health and functional problems compared to adults who did not receive these services.

Through collaboration with the client and significant others, the OT can develop an intervention plan that identifies not only the specific focus of the goal, but also the explicit content of the goal. For example, Serena's client, Nora, who sustained a TBI, indicated that she wanted to be able to return to driving her children to various community-based activities. Services for Nora would focus on two approaches: restoring the skills needed to engage in this occupation of driving her children to community activities, and adapting the performance by avoiding community activities that necessitate driving during heavy traffic periods in the morning and late afternoon.

Specific driving skills would be improved using strategies to enhance reaction time, problem solving, and attention to potential safety risks. Because of Nora's diminished memory and difficulty with processing complex information, the occupation of driving her children to community activities should be modified. Nora could select community activities that are close to her children's school and home, thereby decreasing the length of time she is driving her children. Through the use of a programmable guidance system in her car, such as a global positioning system (GPS), she is able to follow the specific directions to the various community activities. If these intervention approaches are unsuccessful, the OT may explore alternatives to driving with Nora, such as bicycling or walking with her children to nearby community activities or carpooling with another parent, who assumes the actual driving role, while Nora contributes by providing snacks or gas money. Such alternatives could provide a safer solution and still meet the need for Nora to be involved in the occupation of driving or transporting her children to their community activities.

The OT is responsible for the plan and for any parts delegated to the OTA. The plan includes client-centered goals and methods for reaching them using the previously mentioned approaches or strategies. The values and goals of the client are primary; those of the therapist are secondary.[6] Cultural, social, and environmental factors are incorporated into the plan, which must identify the scope and frequency of the intervention and the anticipated date of completion. The outcomes of the intervention must be written at the time the intervention plan is developed. Discharge planning is initiated during the intervention planning process. This is accomplished by developing clear outcomes and targeted time frames for the completion of goals.

The generation of clear and measurable goals is a very important step in the planning process. Long-term goals or terminal behaviors must reflect a change in occupational performance. For a client to receive authentic OT services, the program must focus on "supporting health and participation in life through engagement in occupation."[6] This outcome may be achieved by several means, such as improved occupational performance, role competence, adaptation, prevention, and quality of life, or by fostering health and wellness.[7] Outcomes may also focus on occupational justice to afford individuals, groups, and populations the opportunity for occupational engagement. Short-term goals or behavioral objectives reflect the incremental steps that must be taken to achieve this outcome. An example would be Nora returning to driving. Several short-term steps would be necessary prior to meeting this terminal behavior or long-term goal. An intervention plan may address bilateral coordination and speed of reaction prior to having Nora return to driving. Several authors have provided detailed descriptions of the critical parts of a well-written goal.[48] Table 3.1 serves as a brief guide for the development of goals and objectives. (See Chapter 8 for additional details about goals and documentation.)

TABLE 3.1

ABCDE Format for Writing Goals

A – Actor	Begin the goal with a statement such as, "Nora will…" Name the client as the performer of the action for the goal.
B – Behavior	The occupation, activity, task, or skill to be performed by the client. If this is an outcome or terminal goal, the behavior must reflect occupational performance. Short-term goals or behavioral objectives are often steps to reaching a long-term goal or outcome. A short-term goal or objective may identify a client factor or performance skill as the targeted behavior. An outcome behavior for Nora, the client in the case study, would be the ability to drive a car, whereas a short-term behavior would be to enter the car and fasten a seat belt.
C – Condition	The situations for the performance of the stated behavior include social and physical environmental situations for the behavior. Examples of conditions included in a goal are the equipment used, social setting, and training necessary for the stated behavior. For Nora, driving a car with an automatic transmission is a far different condition than

	driving a car with a manual transmission.
D – Degree	The measure applied to the behavior and the criteria for how well the behavior is performed. These may include repetitions, duration, or the amount of the activity completed. A client may only be expected to complete a small portion of an activity as a short-term goal, but the long-term goal would address the targeted occupation. The amount of support provided serves as a measure of degree of behavioral performance. This would include whether the client required minimal assistance, verbal prompts, or performed the task independently. The criteria must be appropriate for the behavior. Safely driving 50% of the time is an inappropriate criterion; using a percentage to indicate that Nora will independently fasten her seat belt 100% of the time provides an appropriate criterion for the behavior
E – Expected Time Frame	When is the goal to be met, the time period that is anticipated to meet the goal as stated.

Adapted from Kettenbach G: *Writing SOAP notes*, ed 3, Philadelphia, 2004, FA Davis.

Intervention Implementation

The intervention plan is implemented by the OT practitioners. The OT may assign to the OTA specific responsibilities in the delivery of the intervention plan. Nonetheless, the OT retains the responsibility to direct, monitor, and supervise the intervention, and he or she must ensure that relevant and necessary interventions are provided in an appropriate and safe manner, and that documentation is accurate and complete.[3] The method used to provide interventions could include therapeutic use of self, therapeutic use of occupations and activities, preparatory methods and tasks, group interventions, education and training, or advocacy.[6,7] (See Chapter 1 for a more detailed description of these methods of providing intervention.) These methods answer the question, "How will intervention strategies be provided?" The intervention plan would identify which approach or strategy would be used in combination with the method of intervention. During the actual implementation of intervention services, a clinician may seamlessly shift between different methods, depending on the needs of the client.

OT Practice Notes

Implementation of the intervention plan does not occur in isolation; rather, it requires the OT to continuously review the effectiveness of the services delivered by monitoring the client's response to intervention. At the beginning of each intervention session, the OT should answer the following questions:

1. What is the primary focus of intervention for this session?

2. How will this service meet the client's goals and needs?

Implementation of services should also include helping the client anticipate needs and solutions. A method developed by Schultz-Krohn,[84] known as anticipatory problem solving, provides a structure for this process. This method was developed from client-centered models, such as the model of human occupation[44] and the person-environment-occupation model[55,58] (these are described later in the chapter). The method was designed to empower the client to anticipate potential challenges and develop solutions prior to encountering the challenges. The key elements of the anticipatory problem-solving process are:

1. The client and clinician identify the occupation or activity to be performed.

2. The specific features of the environment that are required for occupational/activity performance are identified. This includes contextual and environmental factors in addition to the necessary equipment to engage in the occupation/activity.

3. The OT and client identify potential safety risks or challenges to engagement in the occupation/activity that are located in the environment or with the objects required.

4. The OT and client develop a solution for these risks or challenges.

Remember that Nora would like to be able to drive her children to after-school activities. As she regains her abilities to drive, anticipatory problem-solving strategies are used to prepare her for potential environmental challenges. The process follows these steps:

1. Nora and the OT have identified the occupation of Nora driving her children to after-school music lessons as the focus for intervention.

2. Nora's car has an automatic transmission. The route she typically has taken to drive her children from school to the music lessons includes a busy street with four lanes, but no highway driving is required. She needs to make one left-hand turn on this street, but there is a left-turn light. The travel time typically is 10 minutes.

3. Nora reports that traveling on the one busy street can be a challenge because many drivers exceed the speed limit on this road and drive erratically. This is the quickest route to the music lessons, and because she is very familiar with it, it provides less challenge to her memory. Nora's husband also reports that this road often has construction, presenting an additional challenge.

4. Instead of changing her route, Nora develops a solution by allocating an additional 5 minutes to transport her children to lessons; this allows her to feel less pressure when drivers are exceeding the speed limit. Strategies to address the erratic drivers encountered on this road include frequent checks of her side mirrors and moving to the left lane two intersections before the left-hand turn light. In addition, an alternate route has been mapped out for Nora to use when road construction presents a challenge.

This process provides a brief illustration of how anticipatory problem-solving methods can be used during intervention implementation. The method can be equally applied to other activities. For example, for bathing, a client may anticipate the potential hazard of a slippery surface and make appropriate plans before getting in the bathtub. The foundation of this process is to engage the client in developing solutions for everyday challenges encountered as he or she engages in occupations/activities. The client is actively involved in identifying not only the occupation/activity, but also potential challenges or risks encountered, and in generating solutions for those challenges or risks.

Included in the intervention implementation process is ongoing monitoring of the client's response to the services provided. As services are initiated, the OT monitors the client's progression on a continuous basis and modifies the intervention methods used as needed to support the client's health and participation in life.

Intervention Review

The OT practitioner evaluates the intervention plan on a regular basis to determine whether the client's goals are being met.[6] The OT is "responsible for determining the need for continuing, modifying, or discontinuing occupational therapy services," but the OTA contributes to this process.[3] The review may include a reevaluation of the client's status to determine what changes have occurred since the previous evaluation. This measurement of the outcomes of intervention is critical in showing the effectiveness of the intervention. The intervention plan may be changed, continued, or discontinued based on the results of the re-evaluation. This re-evaluation also offers an opportunity to determine whether the intervention provided is focused on the outcomes articulated in the plan.

Outcomes

Working in collaboration with the client, the client's family, and the intervention team, the OT and OTA identify the intended outcome of the intervention. The OTPF-3 clearly states that the outcome of OT services focuses on several factors, including occupational performance, the "client's subjective impressions regarding goal attainment" (OTPF-3, p. S16),[7] and the well-being of caregivers, to name only a few potential outcomes. These outcomes can be measured in several ways. Outcomes may be written to reflect a client's improved occupational performance; a change in the client's response to an occupational challenge; effective role performance; habits and routines that foster health, wellness, or the prevention or lessening of further disability; and client satisfaction in the services provided. Client satisfaction can include overall quality of life outcomes that often incorporate several of the previously mentioned outcomes. Caregiver confidence may serve as an outcome measure, along with prevention of loss of occupational engagement for caregivers. For groups or populations, outcomes are often designed to address gains in "health promotion, occupational justice and self-advocacy" (OTPF-3, p. S16).[7]

Although the overarching outcome of OT intervention is "supporting health and participation in life through engagement in occupation,"[6] this goal can be achieved through several types of outcomes. The decision on whether the selected outcomes have been successfully met is made collaboratively with the members of the intervention team, including the client. The outcomes may require periodic revisions because of changes in the client's status. When the client has reached the established goals or achieved the maximum benefit from OT services, the OT formally discontinues service and creates a discontinuation plan that documents follow-up recommendations and arrangements. Final documentation includes a record of any change in the client's status from first evaluation through the end of services.

Fig. 3.1 shows the interrelationship of the various parts of the intervention process. This process is not completed in a linear fashion, but instead requires constant monitoring, and each section informs the other parts of the process. The outcome generated during the planning step should direct an OT to select intervention methods best suited to reach the desired client goals. During the intervention process, it may become apparent that the desired outcome is not realistic, necessitating revision of the client's goals and outcome of services.

Clinical Reasoning in the Intervention Process

Since 1986 the American Occupational Therapy Association (AOTA) has funded a series of investigations to examine how occupational therapists think and reason in their work with clients.[40] **Clinical reasoning** can be defined informally as the process used by OT practitioners to understand the client's occupational needs and make decisions about intervention services, and also as a means to think about the interactions of multiple factors that influence occupational engagement. There are several forms of clinical reasoning, and authors do not consistently use the same term for specific forms of clinical reasoning. The term “professional reasoning” has also been used by authors to capture the broad practice settings of occupational therapy because clinical reasoning is often associated with medical settings.[82] The AOTA's Standards for Continuing Competence uses the term “critical reasoning” to refer to the approach used by OT practitioners to make judgments and decisions.[5] This chapter uses the term clinical reasoning to focus on the relationship between the OT practitioner and the client.

The chapter includes information from authors discussing both professional and critical reasoning skills. Fleming[38] identified three “tracks” of clinical reasoning used by the expert clinician to organize and process data: procedural, interactive, and conditional. Yet another dimension of clinical reasoning, identified as narrative reasoning, has been discussed in the literature by Mattingly.[61] The fifth form of clinical reasoning, pragmatic reasoning, describes the practical issues and contextual factors that must be addressed.[65,81] This section describes how the five basic forms of clinical reasoning, discussed in the current literature, can be applied to practice.

Procedural reasoning is concerned with getting things done, with what “has to happen next.” This reasoning process is closely related to the medical form of problem solving. The emphasis is often placed on client factors and body functions and structures when this form of reasoning is used. A connection between the problems identified and the interventions provided is sought using this form of reasoning, and this can be seen in the “critical pathways” developed in some hospitals. A critical pathway is a form of decision-making tree that is based on a series of yes/no questions that can direct client intervention. For example, a client who had total hip replacement surgery would receive intervention that follows a predicted or anticipated trajectory of recovery.

Critical pathways are often developed to support best practice when there is substantial information about a client's course of recovery from a surgical procedure or medical treatment. Procedural reasoning would be used to develop critical pathways and is driven by the client's diagnosis and the potential outcomes anticipated for individuals with this diagnosis. This form of clinical reasoning is influenced by the current evidence regarding the client's condition and the selected intervention.[59] An OT should review the literature on an ongoing basis to provide effective and appropriate intervention services.[62] Using this knowledge to develop and implement intervention reflects procedural reasoning in practice.

This form of clinical reasoning supports evidence-based practice. Schaaf[80] describes the process of engaging in data-driven decision making, in which OT practitioners not only effectively use the current evidence to make decisions about selecting interventions, but also use the current evidence to determine appropriate outcome data. This approach connects the process of developing the occupational profile, selecting intervention methods, and determining not only the appropriate outcomes but also the data that best represent the outcomes of OT services.

Interactive reasoning is concerned with the interchanges between the client and therapist. The therapist uses this form of reasoning to engage with, to understand, and to motivate the client. Understanding the disability from the client's point of view is fundamental to this type of reasoning. This form of reasoning is used during the evaluation to detect the important information provided by the client and to further explore the client's occupational needs. During intervention, this form of reasoning is used to understand how the client is responding to the intervention selected and whether the intervention is effective in meeting the client's goals. The therapeutic use of self fits well with this form of clinical reasoning as the therapist uses personal skills and attributes to engage the client in the intervention process.

Conditional reasoning is concerned with the contexts in which interventions occur, the contexts in which the client performs occupations, and the ways in which various factors might affect the outcomes and direction of therapy. Using a "what if?" or conditional approach, the therapist imagines possible scenarios for the client. The therapist engages in conditional reasoning to integrate the client's current status with the hoped-for future. Intervention is often revised on a moment-to-moment basis to proceed to an outcome that will allow the client to participate in various contexts. Although an intervention is designed and implemented to foster occupational pursuits, conditional reasoning is not singularly focused on reaching the outcome. Conditional reasoning recognizes that the process of intervention often necessitates a reappraisal of outcomes. This reappraisal should be encouraged to help the client refine goals and outcomes.

Narrative reasoning uses story making or storytelling as a way to understand the client's experience. The client's explanation or description of life and the disability experience reveals themes that permeate the client's understanding and that will affect the enactment and outcomes of therapeutic intervention. In this sense, narrative reasoning is phenomenological. Therapists also use narrative reasoning to plan the intervention session, to create a story line of what will happen for the client as a result of therapy. Here the therapist draws on both interactive and conditional reasoning, using the client's words and metaphors to project possible futures for him or her.

The therapeutic use of self is critical when using this form of clinical reasoning. Providing an opportunity for the client to share the meaning of the disability experience helps the OT practitioners formulate plans and project future occupational performance. This is where the context and occupational performance intersect. A person may be able to engage in an activity with modifications, but those modifications may be unacceptable within the client's cultural and social context. For example, an individual who was an avid motorcyclist before a stroke now has impaired balance and is unable to operate the clutch and hand controls necessary to drive a motorcycle safely. Although automatic motorcycles are now available with three wheels, this client refuses the option, considering this to be not part of the motorcycle culture.

Pragmatic reasoning extends beyond the interaction of the client and therapist. This form of reasoning integrates several variables, including the demands of the intervention setting, the therapist's competence, the client's social and financial resources, and the client's potential discharge environment. Pragmatic reasoning recognizes the constraints faced by the therapist from forces beyond the client-therapist relationship. For example, a hospital that provides inpatient services may not have the resources for a therapist to make a home visit prior to a client's discharge. A therapist working solely through a home health agency will not have full access to clinic equipment when working in the client's home. These challenges to providing intervention would be considered when an intervention plan is developed using pragmatic reasoning.

Experienced master clinicians engage in all forms of reasoning to develop and modify their plans and actions during all phases of the OT process. Some of the questions a therapist might consider with each form of clinical reasoning are listed in Box 3.1.

Box 3.1

Questions to Engage in Clinical Reasoning

Procedural Questions

What is the diagnosis?

What prognosis, complications, and other factors are associated with this diagnosis?

What is the general protocol for assessment and intervention with this diagnosis?

What interventions (adjunctive methods, enabling activities, purposeful activities) might be employed?

What evidence supports the use of specific interventions to foster occupational performance?

Interactive Questions

Who is the client?

What are the client's goals, concerns, interests, and values?

How does the client view his or her occupational performance status?

How does the illness or disability fit into the client's performance patterns?

How might I engage this client?

How can we communicate?

Conditional Questions

What contexts has the client identified as important in his or her life?

What future(s) can be imagined for the client?

What events could or would shape the future?

How can I engage the client to imagine, believe in, and work toward a future?

Narrative Reasoning

What does the change in occupational performance mean to this client?

How is this change positioned within the client's life history?

How does the client experience the disabling condition?

What vision do I, as the client's therapist, hold for him or her in the future?

What “unfolding story” will bring this vision to fruition?

Pragmatic Reasoning

What organizational supports and constraints must be incorporated into the provision of services?

What physical environmental factors must be considered when designing an intervention plan?

What are my knowledge and skill levels as a therapist?

Clinical Reasoning in Context

Pressures for cost containment and reduction of unnecessary services require therapists to balance the needs of the client and the practical realities of healthcare reimbursement and documentation. Thus, on first meeting the client, the therapist will want to know the anticipated or required date of discharge, in addition to the scope of services that will be reimbursed and those that are likely to be denied. Simultaneously, the therapist is formulating an occupational profile with the client, evaluating the client's occupational performance, engaging the client in identifying outcomes and goals, and determining which interventions would best meet the desired outcomes. The OT also considers the contextual factors that will influence occupational performance. Further, the therapist is alert to requirements for documentation and the particular Current Procedural Terminology (CPT) codes that may apply. The OT must document services accurately and effectively so that reimbursement will not be challenged and the client's needs may be adequately addressed. (See Chapter 8 for a more detailed discussion of documentation.)

From the first meeting with the client, the therapist is guided by the client's goals and preferences. Client-centered service delivery requires client (or family) involvement and collaboration at all stages of the intervention process.[6] Effectively engaging the client and family demands cultural sensitivity and an ability to communicate with people of diverse backgrounds.[21,86,90,92] In some cultures the idea of participating equally in decision making with a health professional may be unknown. Being asked by a therapist to make decisions may feel quite unfamiliar and uncomfortable to the client. Thus, the therapist must support the client's ability to collaborate, adjust to the client's point of view, and find other ways to ensure that the intervention plan, including intended outcomes, is acceptable to the client and significant others in the client's life. Understanding the influence of culture on the client's occupational performance and performance patterns is fundamental to the provision of services.[21] The OT should ask himself or herself the following questions to foster cultural competence in the provision of services:

1. *What do I know about the client's culture and beliefs about health?* This represents the basic knowledge of cultural health practices and beliefs. Conclusions or judgments should not be formed about why these practices are present.

2. *Does the client agree with these beliefs?* Although a client may affiliate with a specific cultural group, the OT must investigate to determine whether the cultural beliefs about health and the client's beliefs about health are similar.

3. *How will these beliefs influence the intervention and outcomes of services provided?* The OT must acknowledge and respond to the influences of cultural beliefs and practices within the intervention plan. To design a plan that conflicts with cultural beliefs would not only be counterproductive to client-centered services, but also would be disrespectful of the client's belief system. If a client, in deference to the authority of the OT, follows an intervention that conflicts with cultural practices, the client may risk losing the support of and affiliation with that cultural group.

4. *How can the intervention plan support culturally endorsed occupations, roles, and responsibilities to promote the client's engagement in occupation?* The OT must consider the important occupations from a cultural perspective. Evening meals may include specific behaviors that have strong cultural symbols for one client, but another client may view an evening meal as merely taking in food with no prescribed rituals.

Client-Centered Practice

Involving clients in identifying their own goals and in making decisions about their own care and intervention is highly valued by leaders in the OT profession[37,71,83] and is endorsed by the AOTA in its policy and practice guidelines.[9] Client-centered practice begins when the therapist first meets the client. Therapists using an occupation-based assessment tool, such as the Canadian Occupational Performance Measure (COPM),[53] initiate assessment by asking clients to identify and choose goals early in the evaluation process. This process can be fostered when the therapist is aware of potential biases that could influence the development of goals.[79] Regardless of the individual's disability status or perceived limitations in cognitive functioning, every client should be invited to participate in evaluation and intervention decisions. Client-centered practice is guided by these concepts[11]:

- The language used reflects the client as a person first and the condition second.
- The client is offered choices and is supported in directing the OT process. This requires the occupational therapist to provide information about the client's condition and the evidence available about the various types of intervention.
- Intervention is provided in a flexible and accessible manner to meet the client's needs.
- Intervention is contextually appropriate and relevant.
- There is clear respect for differences and diversity in the OT process.

Although client-centered practice is most often conceptualized as the OT practitioner working with a person and those significant in that person's life, the OTPF-3 describes “clients” as persons, groups, and/or populations.[7] However, even when providing OT services to organizations or populations, the OT practitioner is expected to apply the same values of client-centered practice and enlist the client, whether an organization or population, in identifying goals and selecting outcomes.

Theories, Models of Practice, and Frames of Reference

The profession of occupational therapy acknowledges the need for theories, models of practice, and frames of reference to advance the profession, demonstrate evidence-based intervention, and more clearly view occupation.[49] Theories, models of practice, and frames of reference offer the OT practitioner a means to understand and interpret information so as to develop an effective intervention plan. These terms require definition and understanding prior to application to practice.

Theory

The term *theory* refers to the process of understanding phenomena, including articulating concepts that describe and define phenomena and the relationships between observed events across situations or settings. A theory is tested across settings for confirmation of concepts and relationships. Although a theory may be generated by one profession, it is often applied across professions if it becomes an accepted method of understanding phenomena. According to Reed,[74] theory attempts to:

- define and explain relationships between concepts or ideas related to the phenomenon of interest (eg, occupational performance and occupation).
- explain how these relationships can predict behavior or events.
- suggest ways that the phenomenon can be changed or controlled.

A clear example of a theory that meets these expectations and is well known is germ theory.[19] Widely accepted and tested, germ theory states that microorganisms produce infections. Before the relationship between these microorganisms and infections was understood, physicians would perform an autopsy and then go to an adjacent room to deliver a baby—without washing their hands between the two events. The number and severity of infections after childbirth declined dramatically when germ theory became accepted and then functionally applied to practice (a frame of reference) through the use of proper hand-washing procedures. From an OT perspective, theories provide the profession with a means to examine occupation and occupational performance and to understand the relationship between engagement in occupations and participation in context.[44] The main purpose of a theory is to understand the specific phenomenon. Mary Reilly's theory of occupational behavior was designed to explain the importance of occupation and the relationship between occupation and health.[75,76] Her theory served as a foundation for several models of practice within the profession of occupational therapy.

Model of Practice

Model of practice refers to the application of a theory to OT practice. This process is achieved through several means, such as the development of specific assessments and articulation of principles to guide intervention. Models of practice are not intervention protocols, but instead serve as a means to view occupation through the lens of theory, with the focus on the client's occupational performance. Models of practice often serve as a mechanism to engage in further testing of the theory.[44] Some authors refer to models of practice as conceptual models,[22] whereas other authors include models of practice in the discussion of professional theories.[28] In the profession of occupational therapy, several models of practice exist, but the commonality of all of them is the focus on occupation. The main purpose of a model of practice is to facilitate the analysis of the occupational profile and to consider potential outcomes with selected interventions. Models should be applicable across settings and client groups, rather than designed primarily for a specific diagnostic group. Using a very colloquial expression, a model of practice requires the practitioner to "put on the OT eyeglasses" to bring into focus the client's needs and abilities, various contextual issues, and engagement in occupation. Three of these models of practice are briefly described here. The reader is encouraged to seek additional information from the materials used in this brief description.

Model of Human Occupation

In the model of human occupation (MOHO),[49] the engagement in occupation is understood as the product of three interrelated subsystems: volitional, habituation, and performance capacity. These subsystems cannot be reduced to a linear process; they are linked to produce occupational performance.

- The *volitional subsystem* refers to the client's values, interests, and personal causation. A client may clearly identify values and interests to an OT practitioner, but then express a sense of incompetence to engage in a desired occupation. Volition is the client's thoughts and feelings, including occupational choices.
- The *habituation subsystem* refers to the habits and roles that are often critical to a sense of self. Colloquial phrases expressed by a client, such as, "I don't feel like myself," often speak of a distortion of habit or role experienced in life. A client faced with a disabling condition often experiences a severe disruption in roles and habits. The sense of self can deteriorate when roles such as driving to work, driving to go shopping, or driving friends to enjoy a picnic are eliminated because of a disabling condition.
- The *performance capacity subsystem* reflects the client's lived experience of the body. This does not refer to the muscle strength or range of motion available, but rather to the client's previous experience, changes, and expectations of performance capacity. The colloquial phrase "Once you've ridden a bicycle, you never forget" captures a portion of this concept and requires the therapist to consider the client's experience of successes or failures in using the body to engage in occupations.

Ecology of Human Performance

The ecology of human performance (EHP)[32] was not designed to be used exclusively within the profession of occupational therapy; rather, it was intended to serve as a mechanism for understanding human performance across professions. An important concept expressed in EHP is the interaction of the person, the task (activity demands), and the context. Occupational performance is intertwined with, and the product of, the interaction of these three variables. EHP is a client-centered model in which each person is viewed as unique and complex, having his or her own past experiences, skills, needs, and attributes. The task is understood as the objective and observable behaviors to accomplish a goal. The context includes the person's age, stage of life, and health status from a perspective of the cultural and societal meanings of each. Context also addresses the physical, social, and cultural factors that influence performance. EHP recognizes that these three factors influence each other and that the person and task are inextricably linked with the context. Performance is the product of the person engaged in a task within a context.

A significant contribution of this model is the equal importance placed on each variable in producing occupational performance. Instead of focusing only on improving the client's skills, intervention using this model can assume several forms. Five intervention strategies are described, reflecting a close similarity to the OTPF-3.[33]

1. *Establish/restore.* Although focused on improving the person's abilities and skills, the intervention includes the context for performance.

2. *Alter.* Intervention is designed to alter the contextual factors to foster occupational performance; an example would be home modifications to allow wheelchair access.

3. *Adapt/modify.* The task or context is adapted or modified to support performance, such as using a reacher to obtain objects or elastic shoelaces to eliminate the need to tie shoelaces.

4. *Prevent.* Intervention may address the person, the context, or the task to prevent potential problems. Examples would be teaching the client back safety techniques to prevent back injuries; removing rugs in an environment to reduce the risk of falls as a contextual prevention method; and turning down the water temperature for a client with sensory problems to reduce the risk of burns when bathing.

5. *Create.* Intervention addresses all three variables of the person, task, and context and is designed to develop or create opportunities for occupational performance.

Person-Environment-Occupation Model

The person-environment-occupation (PEO) model[54,55] shares characteristics of the EHP model; occupational performance is seen as the intersection of the person, environment, and occupation. This is a client-centered approach, but equal emphasis is placed on the environment and the occupation when the intervention is designed. PEO defines the person as a dynamic and changing being with skills and abilities to meet roles over the course of time. The environment includes the physical, social, cultural, and institutional factors that influence occupational performance. Occupations include self-care and productive and leisure pursuits. PEO further differentiates the progression from an activity, a small portion of a task, a task that is a clear step toward an occupation, and the occupation itself, which often evolves over time. An example would be the activity of safely handling a knife. This is a small portion of the task of making a peanut butter and jelly sandwich, and the task of making a sandwich is seen as a part of the occupation of meal preparation. Occupational performance is the result of the person, environment, and occupation interacting in a dynamic manner.

Frame of Reference

The purpose of a **frame of reference** (FOR) is to help the OT practitioner link theory to intervention strategies and to apply clinical reasoning to the chosen intervention methods.[51,64] An FOR tends to have a more narrow view of how to approach occupational performance compared to models of practice. The intervention strategies described within various FORs are not meant to be used as a protocol, but rather offer the practitioner a way to structure intervention and think about intervention progressions. The practitioner must always engage in the various forms of clinical reasoning to question the efficacy of the intervention in meeting the client's goals and outcomes.

A frame of reference should be well fitted to meeting the client's goals and hoped-for outcomes. The concept of "one size fits all" definitely does not apply to the use of an FOR to guide intervention; that is why there is a need for multiple FORs to meet varied client goals and outcomes. A practitioner may blend intervention strategies from several FORs to meet the client's needs effectively. As an example, a client may be able to recover precise coordination and control of both arms after a TBI if the OT practitioner combines a biomechanical FOR and a sensorimotor FOR, but the client may have persistent memory deficits, requiring the use of strategies from a rehabilitative FOR. The following brief descriptions are not meant to be an exhaustive review of all possible FORs that can be used in occupational therapy. Examples are provided to illustrate how a FOR can be used to guide the intervention process.

Biomechanical Frame of Reference

The understanding of kinematics and kinesiology serves as the foundation for the biomechanical FOR.[74] The practitioner views the limitations in occupational performance from a biomechanical perspective, analyzing the movement required to engage in the occupation. Based on principles of physics, the force, leverage, and torque required to perform a task or activity are assessed. These also serve as the basis for intervention. A client may be unable to open a jar of peanut butter or jelly because of limitations in grip strength or the range of motion available for the hands to hold the jar. A biomechanical approach would focus intervention on addressing these basic client factors to improve occupational performance. Although intervention may take the form of exercises, splinting, or other orthopedic approaches, the outcome must reflect engagement in occupation.[46]

Rehabilitation Frame of Reference

The rehabilitation FOR focuses on the client's ability to return to the fullest possible physical, mental, social, vocational, and economic functioning. The emphasis is placed on the client's abilities and using the current abilities, coupled with technology or equipment, to accomplish occupational performance. Compensatory intervention strategies are often used. An example would be teaching one-handed dressing techniques to an individual who no longer has functional use of one hand because of a CVA. The focus of intervention is often engagement in occupation through alternative means. (For additional examples of intervention strategies supported by the rehabilitation FOR, see Chapters 10, 11, and 17.) Returning to the example of making a peanut butter and jelly sandwich, instead of having the client work on strengthening the hands to finally open the jar, the OT practitioner would suggest using a device to stabilize the jar and a gripper to help accomplish the task using the client's current abilities. Regardless of the technology or equipment available, the practitioner must always link the intervention to the client's occupational performance.

Sensorimotor Frame of Reference

Several FORs are included in the sensorimotor category, such as proprioceptive neuromuscular facilitation (PNF) and neurodevelopmental treatment (NDT) (see Chapter 31 for additional information). These approaches have a common foundation: they view a client who has sustained a central nervous system (CNS) insult to the upper motor neurons as having poorly regulated control of the lower motor neurons. To recapture control of the lower motor neurons, various techniques are used to promote reorganization of the sensory and motor cortices of the brain. The specific techniques vary, but the basic premise is that when the client receives systematic sensory information, his or her brain will reorganize and motor function will return.

Meeting the Client's Needs

As mentioned previously, the occupational therapist relies on theories, models of practice, and FORs to interpret and integrate evaluation data to meet the client's identified outcomes. These elements are used in conjunction with clinical reasoning to develop an intervention plan and critically review the success of the plan. For example, the therapist would use procedural reasoning to select a theory, model, or FOR that has proven successful with clients who have a similar diagnosis. Interactive reasoning is used to assess whether the chosen model or FOR is meeting the client's needs. As a therapist applies theories, models, or FORs to meet the client's needs, a series of professional questions should be posed:

1. Does the theory, model of practice, or FOR help me understand and interpret the evaluation data as I consider the client's expressed needs?

2. Does the theory, model of practice, or FOR provide a good fit for the type of intervention that will meet the client's needs?

3. What evidence is available that the theory, model of practice, or FOR can efficiently produce the results requested by the client?

These questions should be posed throughout the intervention process as a review of the effectiveness of services provided. Although the OT is responsible for interpreting and integrating evaluation data, collaborating with the client to develop the intervention plan, and engaging in ongoing review of the effectiveness of intervention, the OTA contributes to the evaluation and intervention process.

Teamwork Within the Occupational Therapy Profession

The OT profession recognizes and certifies two levels of practitioners: the **occupational therapist (OT)** and the **occupational therapy assistant (OTA)**.[3,4] The AOTA has provided many documents to guide practice and to clarify the relationship between the two levels of practitioner.[3,9] The OT operates as an autonomous practitioner with the ability to provide OT services independently, whereas the OTA "must receive supervision from an occupational therapist to deliver occupational therapy services."[3] Even though OTs are considered able to independently provide OT services, they should seek supervision and mentoring to foster professional growth. The OT who is managing a case or providing services to clients should use the following points as a guide:

- Services are to be provided by personnel who have demonstrated service competency. Some states require advanced training and proficiency in specified arenas of practice. For example, advanced certification in dysphagia (difficulty swallowing) and physical agent modalities is required in California for an OT to provide those services.
- In the interest of rendering the best care at the least cost, the OT may delegate tasks to OTAs and, in some specific instances, to aides or other personnel, provided these individuals have the competencies to render such services. This requires the OT to establish the level of competence required and assess the ability of the OTA, aides, or other personnel to perform those duties.
- The OT retains final responsibility for all aspects of care, including documentation.

OT-OTA Relationship

To work effectively with OTAs, the OT must understand the role of the practitioner trained at the technical level.[3] It is common for OTs to alternately overestimate and underestimate the capabilities of OTAs. In overestimating the training and abilities of OTAs, OTs might assume that the OTA is trained to provide services identical to those of the OT but perhaps at a lesser pace and level and with a smaller caseload. In underestimating the OTA, the OT might assume that the OTA is capable of performing only concrete and repetitive tasks under the strictest supervision.[3]

The appropriate role of the OTA is complementary to that of the OT. Employed effectively, the OTA can provide occupational therapy services under supervision that ranges from close to general. The AOTA has identified critical factors that must be considered in the delegation of delivery of OT services.[3] These factors include the severity and complexity of the client's condition and needs, the competency of the person to whom the services would be delegated, the type of intervention selected to meet the identified outcomes, and the requirements of the practice setting. Working together with several OTAs, the OT will be able to manage a larger caseload and will have the option of introducing more advanced and specialized services because the role of the OTA is often to provide routine services. Many variations in the use of OTAs exist across settings. Some services the supervising OT may delegate to the service-competent OTA include:

1. Administering selected screening instruments or assessments, such as range-of-motion (ROM) tests, interviews, and questionnaires, ADL evaluations, and other assessments that follow a defined protocol.[9]

2. Collaborating with the OT and client to develop portions of the intervention plan (eg, planning for dressing training or for kitchen safety training).[9]

3. Implementing interventions supervised by the OT in the areas of ADLs, work, leisure, and play. With appropriate training and supervision, the OTA can implement interventions related to other areas of occupational performance.[9] As determined by the OT, an OTA can also implement interventions for which he or she has demonstrated competence. An example would be intervention related to the client factors of strength or ROM.

4. As assigned by the OT, assisting with the transition to the next service setting; for example, by making arrangements with or educating family members or contacting community providers to address the client's needs.

5. Contributing to documentation, record keeping, resource management, quality assurance, selection and procurement of supplies and equipment, and other aspects of service management.

6. Under the supervision of the OT, educating the client, family, or community about OT services.

Occupational Therapy Aides

The OT may also extend the reach of services by employing aides.[8] Under AOTA guidelines, the **occupational therapy aide** may work only under the direction and close supervision of an OT practitioner (OT or OTA) and may provide only supportive services: "Aides do not provide skilled occupational therapy services."[3] Aides may perform only specific, selected, delegated tasks. Although the OTA may direct and supervise the aide, the OT is ultimately responsible for the actions of the aide. Tasks that might be delegated to an aide include transporting clients, setting up equipment, preparing supplies, and performing simple and routine client services for which the aide has been trained. Individual jurisdictions and healthcare regulatory bodies may restrict aides from providing client care services; reimbursement may also be denied for some services provided by aides. Where permitted, the OT may delegate routine tasks to aides to increase productivity.[9]

Teamwork With Other Professionals

Many healthcare workers collaborate in the care of individuals with physical disabilities. Depending on the setting, the OT may work with physical therapists (PTs), speech and language pathologists (SLPs), activity therapists, recreational therapists, nurses, vocational counselors, psychologists, social workers, pastoral care specialists, orthotists, prosthetists, rehabilitation engineers, vendors of durable medical equipment, and physicians from many different specialties.

Relationships among and expectations of various healthcare providers are often determined by the context of care or the setting. For example, in some situations home care services are coordinated by a nurse. In a hospital or rehabilitation setting using a medical model, the physician most often directs the client care program. Some rehabilitation facilities use a team approach to assessment and intervention, which reduces duplication of services and increases communication and collaboration. Several individuals from different professions may together perform a single evaluation. For example, the OT may be the lead member of the team in some settings or may be the director of rehabilitation services. In a team, members adjust scheduling and expectations to collaborate with one another to promote effective client care.

Many factors affect relationships among professionals across disciplines: the intervention setting, reimbursement restrictions, licensure laws and other jurisdictional elements, and the training and experience of the individuals involved. Relationships develop over time, based on experience and interaction and sometimes on personality. Even when formal jurisdictional boundaries may appear to limit roles for OT, informal patterns often develop at variance with the prescribed rules. For example, although in some states a physician's referral may be required to initiate OT service, the physicians may expect the OT to initiate the referral and actually perform a cursory screening before the physician becomes involved. Some physicians rely on OT staff to identify clients who are most likely to benefit from OT service, and they generate referrals upon the recommendation of the OT.

Another example in which interdisciplinary boundaries may be at variance with actual practice is in the relationships among the rehabilitation specialists of OT, PT, and SLP. By formal definition, each discipline has a designated scope of practice, with some areas of overlap and occasional dispute. The scope of OT practice is described in the domain section of the OTPF-3 and in the AOTA document "Scope of Practice."[10] Nonetheless, it is common for practitioners to share skills and caseloads across disciplines and to train each other to provide less complex aspects of each discipline's care. Two terms used to describe this are *cross training* and *multiskilling*.

Cross training is the training of a single rehabilitation worker to provide services that would ordinarily be rendered by several different professions. Multiskilling is sometimes used synonymously with cross training but may also mean the acquisition by a single healthcare worker of many different skills.

Arguments have been made for and against cross training and multiskilling.[27,39,70,93] The consumer may benefit by having fewer healthcare providers and better integration of services, and involving fewer providers may reduce costs. Disadvantages cited include the prospect of erosion of professional identity, possible risk to consumers of harm at the hands of less skilled providers, and ceding the control of individual professions to outside parties, such as insurers and advocates of competing professions.

Ethics

Although the study of **ethics** in an OT curriculum may be addressed as a separate course or topic, practitioners encounter **ethical dilemmas** with surprising frequency. In an ethics survey conducted by Kyler for the AOTA in 1997 and 1998,[51] practitioner respondents ranked the following as the five most frequently occurring ethics issues they confront in practice:

1. Cost-containment policies that jeopardize client care
2. Inaccurate or inappropriate documentation
3. Improper or inadequate supervision
4. Provision of treatment to individuals who do not need it
5. Violation of client confidentiality by colleagues

Additional concerns were related to conflict with colleagues, lack of access to OT for some consumers, and discriminatory practice. In another finding, 21% of practitioners reported that they faced ethical dilemmas daily, 31% weekly, and 32% at least monthly.[51]

The AOTA has provided several documents to assist OT practitioners in analyzing and resolving ethical questions, including the “Occupational Therapy Code of Ethics and Ethics Standards”[4]; the “Core Values and Attitudes of Occupational Therapy Practice”[2]; the “Standards for Continuing Competence”[12]; and the “Scope of Practice.”[10] These documents provide a basis for resolving ethical issues; practitioners may find additional resources and support if they approach institutional ethics committees and review boards for guidance. Kyler[51] also suggests that OT practitioners act to formalize resolutions for recurring questions by engaging with peers and others to analyze and consider courses of action.

Ethical Considerations

One process of ethical decision making in clinical practice follows these steps:

1. Gather sufficient data about the problem.

2. Clearly articulate the problem, including the action and consequences.

3. Analyze the problem using theoretical constructs and principles.

4. Explore practical options.

5. Select and implement an action plan to address the problem.

6. Evaluate the effectiveness of the process and outcome.

Adapted from Doherty RF, Purtilo RB: *Ethical dimensions in the health professions*, ed 6, St Louis, 2016, Elsevier.

Lohman et al.[58] expanded the discussion of ethical practice to include the public policy arena. Instead of OT practitioners considering ethical practice only from the perspective of service delivery to an individual, these researchers recommended that the practitioner consider the need to influence public policy to better serve all clients.

OT practitioners should anticipate that in clinical practice, they will frequently encounter ethical distress (defined as the subjective experience of discomfort originating in a conflict between ethical principles). Many approaches for resolving this may be useful. For example, a plan of action for addressing ethical distress and resolving ethical dilemmas may involve the following:

1. Reviewing AOTA guidelines[2,4]

2. Seeking guidance from institutional ethics and review boards

3. Approaching and engaging colleagues, peers, and the community to identify and debate ethical questions and formalize resolutions

Summary: Section 1

The OT process begins with referral and ends with discontinuation of service. Although discrete stages can be named and described as evaluation, intervention, and outcomes, the process is more spiraling and circular than stepwise. The processes of evaluation, intervention, and outcomes influence and interact with one another. This may look confusing to the novice, but it is actually a hallmark of clinical reasoning.

Different types of clinical reasoning are simultaneously used to make decisions about the form and type of service provided. While logically analyzing how to proceed through the steps of therapy using procedural reasoning, the therapist also considers how best to interact with the client. Further, the therapist creates scenarios of possible future situations. The expert clinician seeks to uncover how the client understands the disability and uses a narrative or story-making approach to capture the client's imagination of how therapy will benefit him or her. This process is also influenced by the pragmatic reasoning that draws attention to the demands of the current healthcare arena.

The OT profession endorses client-centered practice, engaging the client in all stages of decision making, beginning with assessment. To achieve this ideal, clinical reality requires that the OT approach every client as a coparticipant, whom the OT assists in identifying and prioritizing goals and in considering and selecting intervention approaches.

The OT and OTA have specific responsibilities and areas of emphasis within the OT process. The OT is the manager and director of the process, who delegates specific tasks and steps to the qualified OTA. Aides may also be employed to extend the reach of OT services.

Effective practice typically involves interactions with members of other professions. This requires that the OT practitioner consider the intervention setting, the scope of practice of other professions, the applicable jurisdictions and healthcare regulations, and other factors that affect the individual situation (eg, culture, personality, and history).

Ethical questions arise with increasing frequency in modern healthcare. The AOTA provides guidelines and other resources to help resolve these. In addition, practitioners are urged to consider institutional and local resources and to take an active role in identifying and resolving ethical concerns.

Section 2 Practice Settings FOR Physical Disabilities

Winifred Schultz-Krohn

Individuals who have a physical disability receive OT services in a variety of settings. These may include acute care hospitals, acute inpatient rehabilitation, subacute rehabilitation, outpatient clinics, skilled nursing facilities, assisted living units, home health, day treatment, community care programs, and work sites. Regardless of the physical setting in which services are delivered, the OT should always focus on enhancing occupational performance to support participation across contexts. The OT practitioner needs to be mindful of the supports and constraints encountered in the various practice settings.

The term **practice setting** refers to the environment in which OT intervention occurs, an environment that includes the physical facility or structure, along with the social, economic, cultural, and political situations that encompass it. Several factors influence the delivery of OT service within a specific practice setting, including (1) government regulations, (2) the economic realities of reimbursement rules, (3) the workplace pressures of critical pathways and other clinical protocols, (4) the range of services considered customary and reasonable, and (5) the traditions and culture staff members have developed over time.

Physical aspects also play a role, such as the building itself, the temperature and humidity of the air, the colors and materials used, the layout of the space, and the furnishings and lighting. Practitioners must always be aware that context influences client performance in evaluation and intervention. The practice setting also influences the type of intervention available.[68] Limitations on the length of stay (LOS) and the number of visits require the OT practitioner to carefully examine intervention that can produce outcomes within the allotted time. Each practice setting has unique physical, social, and cultural circumstances that influence the individual's ability to engage in occupations or activities. These environmental features are important to consider when projecting how the client will perform in another setting. For example, individuals who are in control in their home environment may abdicate control for even simple decisions in an acute care hospital, giving the erroneous impression of being passive and indecisive.[20]

The following section describes the typical practice settings in which OT services are provided for individuals with physical disabilities. Table 3.2 provides a comparison of the approaches used in the various settings, the length of time services are provided, and the frequency of services. Notice that although the typical client conditions do not substantially change across settings, the approaches change to meet the client's needs. Suggestions are given for modifications of the therapeutic environment and clinical approach.

TABLE 3.2

Comparison of Practice Settings

Practice Setting	Length of Time Services Are Provided	Examples of Client Conditions Needing OT Services	Examples of Typical OT Approaches Used in the Setting	Frequency of Services
Acute care hospitalization	Days to 1 or 2 weeks	Acute injuries and illnesses, exacerbations of chronic conditions	Restore ability or skill, modify the activity or context, prevent further disability with an emphasis on discharge setting	Daily
Acute rehabilitation	Weeks	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily, 3 hours a day
Subacute rehabilitation	Weeks to months	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily to weekly
Skilled nursing facilities	Months to years	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills	Daily, weekly, monthly consultation
Home- and community-based settings	Weeks to months	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Daily to weekly
Residential care and assisted living units	Months to years	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills, promote health	Weekly, monthly consultation
Home healthcare	Weeks to months	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability	Weekly
Outpatient	Weeks to months	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Weekly
Day treatment	Months to years	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability, preserve current skills, promote health	Daily, weekly
Work site	Weeks to months	Neurological, orthopedic, cardiac, and general medical conditions	Restore ability or skill, modify the activity or context, prevent further disability with emphasis on occupational performance	Weekly, monthly consultation

Continuum of Healthcare

The variety of settings forms a continuum of care, albeit not always in a sequential fashion, for the client who has a physical disability. People with physical disabilities who are referred to OT services may enter the healthcare system at any point on the continuum and do not necessarily follow a direct progression through the various settings described here. A client in an acute care hospital might be referred for bed mobility, transfers, and self-care retraining. Depending on the severity of the condition and the potential to improve, the client may be seen in a rehabilitation or day treatment program. A home health or outpatient therapist may see the same individual to address unresolved problems and modify the home environment to maximize occupational performance.

Should the client return to the workforce, he or she may benefit from such OT services as an assessment and recommendations about modifications to the work environment or job tasks (see Chapter 14). Evidence has demonstrated the effectiveness of OT services in helping individuals return to work after they have experienced a disabling condition.[60] Some hospitals offer a range of healthcare services, from an emergency department and acute care or an intensive care unit (ICU) to inpatient and outpatient rehabilitation services. Other settings may offer only outpatient rehabilitation services.

Inpatient Settings

Settings in which the client receives nursing and other healthcare services while staying overnight are classified as **inpatient settings**.

Acute Care Inpatient Setting

Clients in an **acute care** inpatient setting typically have either a new medical condition (eg, heart attack, burn, cerebrovascular accident, or traumatic brain injury) that led to hospitalization or an exacerbation of a chronic condition (eg, multiple sclerosis). An acute decline in a chronically progressive condition abruptly confronts the client with a long-term prognosis of increasing disability. The client may require life support because of the severity of the condition. Terminally ill clients who have managed in their own home with support from a hospice program may require acute hospitalization for pain management, placement, or imminent death; in such cases, a client's hospice goals should be clearly stated and respected by the hospital staff. (For additional information on hospice care, see the section Skilled Nursing Facilities later in this chapter.)

Acute hospitalization, especially when unplanned, results in a sudden change in the client's environmental supports and context or contexts. Previous social roles may be abandoned when the person is hospitalized. External stressors (eg, financial issues or disruption of career and educational pursuits) must be considered when services are provided in an acute care setting. An individual who felt in control of his or her life becomes controlled by the circumstances requiring the hospitalization.

Threaded Case Study

Serena, Part 3

Nora, Serena's client in the case study, experienced a sudden change in her ability to control her environment and exercise her roles as wife and mother. When the TBI occurred, she was admitted through the emergency department and hospitalized in an ICU to stabilize her condition. Both a nasogastric (NG) tube and a catheter were inserted. On Nora's second day in the ICU, the OT evaluated her ability to manage oral secretions and swallow her own saliva. She would continue to receive most of her nutrition through the NG tube but was cleared to begin to eat thick liquids, such as nectar. When her vital signs stabilized on day 3, she was transferred to an acute rehabilitation setting for continued therapy services.

Three general roles have been identified for the occupational therapist working in the acute care setting: education, initiation of the rehabilitation process, and consultation.[18] Education may address safety precautions and activity analysis. Rehabilitation services may be initiated for clients who will be transferred to a rehabilitation facility. Consultation focuses on the discharge environment and the client's needs after leaving the acute care hospital. An experienced occupational therapist, equipped with a knowledge of available resources in the hospital and community, can offer a better coordinated and more efficient intervention plan to promote the client's progress toward anticipate outcomes. For example, a therapist who determines that a client living alone at discharge would be unable to prepare meals should contact the social worker, who would help arrange for the delivery of meals to the home. Another example is a therapist who evaluates a client scheduled for imminent discharge and finds that the client is impulsive, lacks insight into the consequences of his or her actions, and is confused when performing self-care tasks. In this instance, the therapist expresses these concerns to the discharge coordinator or the physician. The social worker might be consulted about available family support, or discharge may be delayed until it can be determined whether appropriate environmental supports are available for the client.

Acute hospitalization is frequently stressful and frustrating for clients. Away from home while ill and subjected to multiple tests and examinations, in addition to interrupted sleep, clients are in a socially compromised environment. They may experience sleep deprivation and overstimulation because of the frequency of procedures or interventions. Some clients, after 2 or 3 days in the ICU, may display marked difficulties with orientation, appearing confused, agitated, and disorganized.[70] This has been referred to as “ICU psychosis,” and clients may experience hallucinations in addition to anxiety and confusion. The client's history should be reviewed to determine whether he or she had had previous episodes of disorientation and confusion, or whether these conditions have been produced by the disorienting effects of hospitalization in an ICU. Concerns about whether the client will be able to return home after hospitalization, who will help with care, or who is helping care for dependent loved ones may add to a client's feelings of stress.

Acute hospitalization involves many physical environmental factors that present a challenge to clients. Often clients have several monitors in place or tubes inserted (eg, oxygen saturation monitors, cardiac monitors, arterial lines, and catheters) that may compromise engagement in occupations.[45] The arrangement of hospital room and extra equipment can further affect the client's occupational performance. The absence of carpeting and the presence of a slippery floor surface may prove challenging for clients during a transfer and when walking. The incidence of falls in the geriatric population is higher in acute care hospitals than in either the community or skilled nursing facilities.[25]

Providing OT intervention services in an acute care setting may be challenging for therapists because it is often necessary to perform assessments in a client's room rather than in more natural environments designed for ADLs. As mentioned, performance of various activities may be affected by catheters, feeding tubes, or monitors. Likewise, client performance in some self-care activities may be artificially enhanced by a lack of the extraneous stimuli found in the home and by the physical attributes of hospital equipment. For example, a client whose home includes three very active cats, several throw rugs on a slippery floor, a very soft bed several feet from the bathroom, and a tiny bathroom faces far more challenges in getting up in the middle of the night to use the toilet compared to the same activity performed in the hospital. The hospital has no throw rugs or active cats as obstacles, and often the bathroom is adapted to support safety and performance in toileting.

To partially replicate the home environment during the intervention session, the therapist might position the client's bed flat, eliminate the bed rails, and lower the bed. Most hospitals would not allow further challenges, such as bringing a cat into the room or scattering throw rugs on the floor as an obstacle for the client. Using clinical experience and judgment, along with information provided by the client about the home environment, the therapist must be able to anticipate the client's performance at home. However, referral to a home health therapist is also advisable to assess occupational performance and accessibility in the client's home.

The acute care hospital also presents the occupational therapist with unique economic, social, and physical challenges. Medical intervention is directed toward promoting medical stability and providing for safe, expedient discharge. It is not unusual for the individual in acute care to receive OT services for the first time on the day of discharge. During this single visit, the therapist must communicate the role of occupational therapy, establish an occupational profile, and assist the client in identifying problems and assets in the discharge environment. The client and the family frequently look to the therapist to identify what the client will need at home. The therapist, in collaboration with the client and family, must develop intervention priorities by identifying issues and concerns after discharge from the acute care setting. The intervention plan may include purchase of durable medical equipment and referral for further intervention to inpatient rehabilitation, a skilled nursing facility, an outpatient clinic, or home health therapy providers. By contacting other members of the healthcare team and communicating concerns, the therapist can facilitate implementation of the recommendations.

Inpatient Rehabilitation Setting

Clients may be admitted to an inpatient rehabilitation unit when they are able to tolerate several hours (usually 3) of therapy per day and are deemed capable of benefiting from rehabilitation. Rehabilitation settings may be classified as acute or subacute (discussed later). Clients are generally medically stable in this setting and require less acute medical care compared to services provided in an acute care hospital. Pain, which may be present and can affect the client's performance, should be addressed in this setting. The client's performance of ADLs will reflect his or her adaptation to pain, and the energy expended to perform self-care tasks should be considered. (See Chapter 28 for a further discussion of pain.)

During Nora's acute rehabilitation hospitalization, she received OT services twice a day, along with daily services from a speech and language pathologist and a physical therapist. These services were coordinated to support the outcomes she and her OT had selected. As is common during acute rehabilitation hospitalization, Nora was expected to dress in her typical street clothing and eat meals at a table in a dining area. This environmental feature of the acute rehabilitation setting provides a social element that is not present in the acute care hospital.

Acute Rehabilitation

When clients are medically stable and able to tolerate 3 hours of combined therapy services for 5 to 6 days a week, they may be transferred to an acute inpatient rehabilitation setting. Clients may still require some level of acute medical care in this setting. The LOS in **acute rehabilitation** settings generally ranges from 2 to 3 weeks, but it varies according to the client's needs. The usual discharge plan from acute rehabilitation is to a lesser level of care (eg, residential care or the client's home with assistance, such as a home health aide or personal care attendant).

The process of adjusting to disability has begun by the time the client enters acute rehabilitation. As the client begins to participate in areas of occupation, deficits and strengths become more defined. An improvement in the client's function from the onset of the disabling condition may have occurred. Within a rehabilitation center, many clients form new social relationships with individuals who have similar disabilities. The advantages of these relationships are emotional support and encouragement from the progress of others. In rehabilitation, interventions focus on resuming the roles and occupations deemed important to the client's life. For example, an adolescent will reestablish social roles with peers; a parent will resume childcare responsibilities.

Although bedrooms in acute inpatient rehabilitation settings are similar to those found in acute care hospitals, clients are often encouraged to personalize their room by having family and friends bring in pictures, comforters, and other items from home. In this setting, clients are expected to wear street clothes rather than pajamas. The clothing that clients most often select is easy-to-don leisure wear. However, the OT practitioner must consider the range of clothing the client will be expected to wear to resume his or her occupational roles upon discharge, and the practitioner must include training with appropriate clothing (eg, neckties, button-front shirts, and pantyhose).

Simulated living environments, family rooms, kitchens, bathrooms, and laundry facilities can be found at most rehabilitation centers. These environments may be inaccurate replicas of the client's home. For example, at home, laundry machines may be side-by-side and top-loading versions rather than coin-operated and front-loading machines. Kitchens may be wheelchair accessible in the facility but inaccessible in the home. Clutter, noise, and types of appliances encountered in the rehabilitation setting often vary from the client's natural environment.

Access to the community is not generally evaluated during the acute rehabilitation hospitalization. Some urban facilities are able to integrate community training more smoothly because stores, restaurants, and theaters are located near the hospital. Although the community surrounding the hospital may differ from the client's neighborhood, this offers an opportunity to experience a more natural environment.

The culture of rehabilitation facilities focuses on the client's performance and goal attainment. The client's own culture may be compromised in the process of rehabilitation unless the team is sensitive to and incorporates the client's perspective into the intervention plan.[21] For example, some cultures view hospital settings as a place for respite and passive client involvement. Engaging clients in ADLs can be in direct conflict with the client's and family's expectations. When cultural perspectives clash, unrealistic goals may result. As in any setting, achieving planned outcomes depends on clear communication and the identification of goals that are relevant and meaningful to the client.[79]

Upon completion of the acute inpatient rehabilitation program, some clients return home and receive home health services. Unfortunately, not all clients eligible to receive home health services are referred for these services.[66] The occupational therapist should actively participate in discharge planning for clients to ensure that they receive the necessary services when discharged from the acute rehabilitation setting. Upon discharge from the acute rehabilitation facility, some clients are referred to a subacute rehabilitation setting for continued services. There are several similarities between the acute and subacute rehabilitation settings. The primary differences found in subacute settings are discussed in the next section.

Subacute Rehabilitation

Subacute rehabilitation facilities are found in skilled nursing facilities and other facilities that do not provide acute medical care. This setting is also known as a short-term skilled nursing facility. The equipment available to the occupational therapist for intervention and evaluation in the subacute setting may be comparable to that found in the acute rehabilitation facility. The focus of intervention continues to be restoring functional abilities; however, because of the slower rate of change, the occupational therapist must also consider the need to adapt or modify the environment to promote occupational performance. LOS in the subacute setting varies; stays may last a week to several months. Clients are usually discharged to a lesser level of care when they leave a subacute rehabilitation setting.

The pace of intervention services varies, and engaging in 3 hours of therapy per day is not mandatory. The client's endurance influences the frequency and duration of therapy. A client may continue to make steady gains, but at a slower pace than was seen during the acute inpatient rehabilitation stay.

Because many subacute rehabilitation programs are located in skilled nursing facilities, the client may have roommates who are convalescing rather than actively participating in rehabilitation services. This presents as an additional variable to be considered in the intervention plan because the social context does not always support participation in the rehabilitation services provided at the setting. Staff members may be more oriented to the skilled nursing care services and may not allocate comparable effort to the rehabilitation goals of independence.

Skilled Nursing Facilities

A **skilled nursing facility (SNF)** is an institution that meets Medicare or Medicaid criteria for skilled nursing care, including rehabilitation services. Although subacute and short-term rehabilitation programs may be housed in SNFs, OT services are also provided to individuals who are not in a subacute rehabilitation program; these services are known as long-term skilled programs. Many residents (the preferred consumer label for people who live in long-term care settings) will stay in an SNF for the remainder of their lives; others will be discharged home.[17] Goals should be directed toward independence and meaningful occupational pursuits, and they may include fostering engagement in occupations through environmental modifications and adaptations. An example would be reading materials and playing cards with enlarged print to foster leisure pursuits for clients with macular degeneration.

Hospice services may be included in the SNF setting if appropriate.[90] Hospice care requires the physician to document that the client "probably has 6 months or fewer to live."[89] The services provided do not focus on rehabilitation, but instead address palliative care and environmental modifications. OT services for hospice clients should address access to the environment and participation in occupation through support and modifications. For example, OT services could address participation in leisure pursuits as a hospice client creates a memory book for significant others.

The physical and social environments in skilled nursing facilities may impede the natural performance of ADLs. Clients often receive assistance with self-care tasks to expedite task completion, but this assistance is not focused on fostering engagement in occupational performance.[78] An investigation in SNFs demonstrated that even clients who were severely cognitively impaired benefited from intervention that was focused on fostering the client's participation in ADLs. The study found that not only did clients increase participation in self-care tasks, but also that disruptive behavior declined.

Extreme variations in disability status are present in SNFs. Observing residents who are severely and permanently disabled may lead newly disabled individuals to form negative expectations of their own prognosis and performance. Younger adults placed in SNFs (where most residents are older adults) may feel isolated and abandoned, which can adversely affect performance. Friends are less likely to visit in this environment. Family and friends may expect less of the individual than they would in other settings. Maintaining connections with friends from the community may require the client to actively pursue these relationships. A therapist who facilitates identification of realistic and meaningful expectations and goals with the resident can promote a more positive outlook and outcome. A strong family commitment can support outside relationships by providing transportation to various community gatherings.

Community-Based Settings

Community-based settings often afford the therapist access to the client's natural physical, social, and cultural environments. Services provided in community settings can foster not only skill acquisition and habit formation, but also engagement in occupations in natural environments. Community-based settings may include a residential aspect, but the client is not hospitalized. Clients also reside in their homes when receiving community-based services.

Home- and Community-Based Settings

An alternative to an acute inpatient rehabilitation program for clients with traumatic injuries (eg, head or spinal cord injuries) is a home- and community-based therapy program. This type of program provides intensive rehabilitation in the client's own home and community. The client receives comprehensive rehabilitation services and acquires functional skills in daily activities in the normal environments of home, school, work site, and community. This enhances the likelihood of a successful and functional outcome. Nora, for example, may benefit more from working on tasks in her home and community than in a clinic or an acute rehabilitation setting.

In home- and community-based settings, the client is performing in her natural physical, social, and cultural environment. Scheduling is within the client's control, and intervention sessions vary in length and frequency, depending on the goals. An all-morning session to work with the client as she moves through her daily routine (eg, bathing and dressing her child, going grocery shopping, and performing various household chores) would be possible.

OT Practice Notes

The occupational therapist must be able to adapt the intervention to the natural social and cultural aspects present in the home. Attempts to alter the natural social and cultural order are ill advised because things are likely to return to their natural state after the session ends and the therapist has left.

When practice is necessary for goal attainment, a rehabilitation technician or therapy aide may be charged with carrying out specific and limited programs established by the therapist. The technician who spends many hours with the client can provide insight when the program is not succeeding because it interferes with the natural context of the client's lifestyle. Adjusting intervention strategies to adapt to these lifestyle differences will ensure better clinical outcomes.

Intermediate Care Facilities (Residential Care)

Generally, residential facilities more closely resemble home situations; clients may reside there on a permanent or transitional basis, depending on their prognosis.[63] Similarities in the age of residents, their disability status, and even diagnoses are common. Although clients do not require ongoing intensive medical care, the facilities are staffed with care providers 24 hours a day because of the clients' need for safety and supervision. OT services may not be available on a daily basis, and rehabilitation technicians may implement the unskilled portions of the intervention plans addressing ADLs, select IADLs, and leisure. Often clients require ongoing assistance for portions of these tasks, and personal care attendants or technicians complete portions of the activity or task. The therapist can identify key performance issues in this context. Difficulties with evening self-care, follow-through with safety guidelines, problem solving, schedules, and client performance are reviewed and discussed with the OT. Modifications in the intervention plan can be more easily tailored to promote independence under such close supervision.

Assisted Living Unit or Residence

An assisted living unit (ALU) provides health services in a cooperative living setting. A client may live in an apartment or a cottage where one or more meals are provided on a daily basis; medication management is provided as needed; and 24-hour support is available. These settings usually have age restrictions: commonly, residents must be over 55 years of age or, if a couple is involved, one person must be over age 55. The client generally does not plan or anticipate a move to another type of setting and is often expected to own or rent the living space in the ALU. Because of the age restriction in most ALUs, social and environmental support is present to enable a person to live in one's own space. For example, apartments or cottages may be equipped with safety railings in the bathroom and walk-in closets for ease of accessibility.

In this setting, OT services are provided to foster and enhance the habits and routines necessary to remain housed in this environment, which often includes personal care skills such as dressing, grooming, hygiene, and simple home care tasks. Some household tasks may be partially assumed by the services provided in the assisted living setting. For example, an ALU may provide a service of laundering towels and bed linen, but the individual is responsible for the care of his or her own clothing. Some ALU settings provide all meals, whereas others provide only one meal, and the individual will need simple meal preparation skills to live in that setting. It is important for the OT to determine what services are available at the ALU prior to designing an intervention plan with the client. An important occupational pursuit for those in this setting would be leisure activities. Environmental supports such as magnifiers for reading, enlarged print playing cards, and a universal remote to access the television may provide opportunities for leisure activities in this setting.

Home Health

Home healthcare provides services within the client's home and affords the most natural context for intervention.[87] The desired outcome for services provided within the home could include supported completion of ADLs or IADLs such as bathing, dressing, and meal preparation. The client, returning home from the hospital, begins to resume life roles at home. Stark et al.[87] provided guidelines to foster the decision-making process for providing home modifications; these guidelines cover both intrinsic and extrinsic factors. The intrinsic factors included the client's willingness to accept changes to the home and his or her ability to maintain any home modification, in addition to the esthetics of the proposed modifications. Extrinsic factors included financial resources, the type of home structure, and the typical weather conditions encountered. This approach allows the OT to focus intervention on supporting occupational participation in the home environment.[88]

A visiting therapist is a guest in the client's home and is subject to certain social rules associated with guests. For example, the family may practice the custom of removing street shoes within the home, and the therapist should respect and comply with this practice. The client and family establish daily schedules for meals, waking, and sleeping. Appointments should support the family's routines and not interfere with daily schedules. For example, if the client is accustomed to eating a larger meal during the middle of the day and a very small evening meal, an intervention to address meal preparation skills should be scheduled to support this routine.

Self-care, homemaking, and cooking tasks evaluated in the context of the home clearly identify the challenges that the client meets daily. The familiar clothing, furniture, appliances, and utensils used in everyday life are present and promote orientation and task performance. However, moving furniture to make things more accessible and safe for the client or modifying equipment to be used within the home may challenge the client's orientation skills and increase confusion. Caring for and feeding pets, answering the door safely, and determining a grocery list for the week are potential issues to be addressed within the home setting. Self-care tasks such as bathing can be addressed within the natural environment, and when appropriate modifications to the home are made, the client's dependence on others may decrease.[35]

Social and family support, or lack thereof, is readily evident to the home health therapist. Individuals who appeared alone and unsupported while hospitalized may have a network of friends and family members who lend support at home. Conversely, individuals who had frequent visitors in the hospital may be abandoned when the realities of disability reach the home setting.

The client who receives home health services typically requires assistance for some aspects of his or her ADLs. Nearly 20% of all family caregivers are employed full time outside the home.[15] These caregivers are available for only part of the client's day and will be concerned primarily with the safety of the client during their absence.

Stress is common among caregivers. Respite care, which temporarily places the client under the care and supervision of an alternative caregiver for a few hours and up to several days, can provide necessary relief for a caregiver.[15] Caring for a person with a disability in one's home is not an easy task. Box 3.2 identifies practical concerns that arise when a client is cared for in the home. A study by Dooley and Hinojosa[30] found that when individualized OT recommendations were provided for home modifications, caregiver approaches, and community-based resources for clients who had Alzheimer's disease, caregivers reported a decrease in a sense of burden and an improved quality of life.[30]

Box 3.2

Concerns in Caring for a Person With Disability in One's Home

Amount and Type of Care Needed

Long-term versus temporary care; intensive supervision or assistance versus minimal needs; help available to the caregiver; alternative solutions; and personal feelings about the client and the type of care required (intimate assistance versus household tasks).

Impact on the Household

Effect on spouses, children, and others living in the home; possible involvement of family in making decisions.

Environmental Concerns

Need for and possibility of adapting the home, expenses of adaptations.

Work and Finance

Options for family medical leave; ability and need to quit work; and benefits available.

Adapted from Visiting Nurses Association of America: *Caregiver's handbook: a complete guide to home medical care*, New York, 1997, DK Publishing.

When viewing the client's home environment, the therapist can make recommendations for environmental adaptations, see them implemented, and modify those changes as needed to best meet the client's needs.[44] Physical changes to the home, including moving furniture, dishes, or bathing supplies, should not be undertaken without the permission of the client and are best considered through a team approach to support the collaboration between professionals and client.[73] If the client is in the home of a family member or friend, the permission of the homeowner must also be sought.

The client and family are in control of the home environment. Clinicians who fail to ask permission before adapting the environment will rapidly alienate their clients. A throw rug, viewed by the therapist as a tripping hazard, may be a precious memoir from the client's childhood home. In seeking the permission of the client and family and providing options, the therapist opens communication. An adhesive mat placed beneath the throw rug will provide a safer surface on which to walk. Another possible solution is to hang the rug as a wall tapestry, where it will be more visually prominent and less prone to damage.

Healthcare workers in the home occasionally encounter ethical dilemmas, typically involving safety.[67] The therapist must determine the best method for resolving issues of safety hazards. Fire and health hazards must be discussed and corrected when the safety of the client or adjacent households is in jeopardy. By broaching the subject diplomatically and directly, the therapist can address most hazards and provide acceptable solutions. Inclusion of the client, family, and other team members in the process of problem identification and solution generation is strongly recommended.

When Nora returned home after her acute rehabilitation hospitalization, Serena arranged for her to receive OT services through a home health agency. Nora, Serena, and the home health OT identified concerns with meal preparation, laundry, and playing with the children as important occupations to be addressed. Serena was not able to make a home visit prior to Nora's discharge from the acute rehabilitation program, but she was able to coordinate continued services through the home health agency. The home health OT worked with Nora on strategies to improve her safety in meal preparation, helped her to simplify her laundry and cleaning routines, and provided suggestions for leisure activities in which Nora could engage with her children in the home.

Outpatient Settings

Outpatient OT service is provided in hospitals and freestanding clinics to clients who reside elsewhere. Clients receiving services in this setting are medically stable and able to tolerate a few hours of therapy and travel to an outpatient clinic. Although many clients are adjusting to a new disability, some individuals with long-standing disability may be referred for re-evaluations of functional status and equipment-related issues. The frequency of services provided in this setting varies substantially; some clients receive services several times a week, and other clients are seen once every few months. The frequency of service is determined by the client's needs and the services offered at the outpatient clinic.

Clients exert more control over outpatient therapy schedules compared to inpatient therapy schedules. Transportation issues and pressing family matters necessitate that clinics offer a variety of times from which a client may choose. Otherwise, the client may select a different clinic or choose to forgo therapy.

To evaluate a client's performance of ADLs or IADLs in an outpatient setting, the therapist must extrapolate how task performance would occur at home.[78] Engaging in self-care tasks in an outpatient clinic may be awkward for the client. Individuals who have been assisted with bathing and dressing before coming to the clinic may resist working on these same tasks during therapy. The more contrived and inappropriate a task and context seem to a client, the less likely he or she is to perform well and benefit from services addressing those needs.

The physical design and equipment in outpatient clinics vary to meet the intervention needs of specific disabilities. Clinics with hand therapy programs, for example, will have treatment tables for exercise and activities and areas for splint fabrication. A clinic designed to address industrial work is often equipped with special exercise equipment, such as Baltimore Therapeutic Equipment (BTE), which mimics work tasks. Less commonly found in the outpatient setting are complete kitchens with cooking equipment and therapeutic apartments with bathing facilities, living rooms, and bedrooms.

The social context found in outpatient programs is quite distinctive. The client has begun to resume life in the home and community and may be newly aware of problems not previously foreseen or acknowledged. If the therapist is viewed as an ally in resolving problems and promoting a smooth transition to the home, the client or family members may easily disclose concerns. However, if the client and family fear that the client will be removed from the home because of an inability to manage there, they may actively hide concerns from the therapist. In the former case, the client and family view themselves as being in control of the situation. In the latter, control and power are assumed to belong to the healthcare professional. An outpatient therapist must be skilled in empowering the client. Soliciting the client's opinion and listening for unspoken needs are two methods of increasing the client's sense of control.[44] Providing choices for intervention does much to motivate clients and improve performance in desired tasks.

Day Treatment

Day treatment programs are becoming more popular as a community-based intervention setting. Programs vary, but the underlying philosophy is to provide an intensive interdisciplinary intervention for clients who do not need to be hospitalized.[41] Clients receiving day treatment typically live at home but frequently require support and assistance for ADLs or IADLs. Most programs offer a team approach. Professionals from all disciplines are engaged cooperatively, sharing their expertise to meet the client's individual goals. Clients may seek services from a day treatment program to further recover functional skills after an acute injury or illness such as a TBI or CVA, or clients with a progressively deteriorating disorder, such as Parkinson's disease or Alzheimer's disease, may benefit from a day treatment program to foster continued participation in occupations through environmental modifications and adaptations.

Many day treatment programs are designed without the time constraints often seen in outpatient programs. Lengthy community outings and home and work site intervention sessions may be used as methods of attaining goals. In a day treatment setting, the occupational therapist may have the best opportunity to evaluate and provide intervention for clients in all their natural environments.

Work Site Therapy Settings

Industrial rehabilitation can be conducted in the context of the employee's place of work. Work site therapy programs are designed to address an employee's therapy needs related to a work injury. The injured worker receives intervention to foster the occupational performance necessary in the workplace, which may include work hardening, back safety, energy conservation, and work simplification techniques. This approach places the client back into the work role. Prevention of further injury occurs in a more natural context when employees are treated at the work site.

Providing OT services to individuals at their place of work helps them make the transition from the patient role to the role of worker. The therapist providing service at the work site must avoid compromising the worker's status.[43] The employer and peers view the employee as a worker rather than as a client. Maintaining confidentiality can be challenging because co-workers' curiosity is often aroused by the unfamiliar face of the therapist in the workplace. The therapist should remember never to answer queries that would compromise client-therapist confidentiality. Unsolicited requests from co-workers for medical advice and work site modifications are best referred to that employee's healthcare provider or manager.

In the work setting, the therapist interacts not only with the client, but also with the employer and often the insurance company. By encouraging the injured employee to communicate his or her needs for work modification and how productivity might be maintained, the therapist paves the way for a successful transition to work. The therapist strives to balance the needs of both the employee and employer while promoting resolution of work-related issues that would interfere with a smooth transition to productive work. Scheduling of therapy visits to the workplace should meet the needs of both the employee and employer. Work site visits should be scheduled in a manner that minimizes interference with the natural flow of work.

The financial impact of work modifications will concern the employer. Employers do not have unlimited resources for modifying work environments. Only reasonable and necessary work modifications should be considered. Suggestions for work modifications that have an associated cost should be discussed with the employer. The therapist can suggest work modifications but must also consider the impact of these modifications on co-workers using the same equipment. As a general rule, modifications that affect workers other than the employee must be discussed with management before they are presented to the employee as possible options.

In a traditional clinic setting, a secretary with a repetitive motion injury of her wrist may receive various modalities to control her symptoms of pain and edema and may be educated about techniques for protecting joints and tendons while performing various movements. When the secretary receives OT services in her work environment, additional benefits often occur. Joint and tendon protection techniques are applied at work while the client performs day-to-day work tasks. Because the client's injury occurred at work, this type of injury could be exacerbated or prevented at work. (See Chapters 14 and 15 for more information on the role of the OT in providing services to workers and in work settings.)

Emerging Practice: Telemedicine

Telemedicine is the use of "electronic information and communications technologies to provide and support healthcare when distance separates the participants."[42] This approach can be effectively used to meet the needs of clients who live in rural settings, where it can be difficult to receive the needed OT services.[31] The AOTA has published a document discussing the use of telemedicine for both evaluation and intervention. along with ethical considerations.[11]

Telemedicine has also been used as a method to monitor and modify a client's home exercise program.[52,57] Cason[23] clearly discussed the important role of occupational therapy in telehealth to promote access for populations. This focus allows far more individuals to receive OT services. Linder et al.[57] investigated the use of telemedicine to improve motor outcomes after a stroke, in addition to improving the quality of life and reducing depression for individuals who had had a stroke. They used a randomized controlled trial with 99 participants to compare two intervention approaches. One group received telemedicine focused on monitoring and modifying the home exercise program, and the other group received similar telemedicine coupled with robot-assisted rehabilitation to foster hand use. All participants significantly improved in motor skills, quality of life measures, and reduced depressive symptoms. This investigation demonstrated that significant improvements were made using telemedicine to modify and monitor home exercise, but it did not demonstrate any superiority of coupling robotics with telemedicine to produce better outcomes than telemedicine alone.

Asano et al.[14] investigated the use of teleconferencing to help individuals diagnosed with multiple sclerosis manage symptoms of fatigue. The occupational therapist used weekly conference calls with small groups of four to seven participants to address a variety of topics, including self-management strategies related to fatigue and energy conservation techniques. Of the 81 participants in the investigation, more than 75% indicated that they had made gains in their goals, and approximately 50% said they had achieved their goal of managing fatigue.

Summary: Section 2

Practice settings, the environment in which intervention occurs, have temporal, social, cultural, and physical contextual dimensions that affect both the therapist and the person receiving therapy services. Knowing the features of each practice setting and anticipating how the context will affect occupational performance prepares the therapist to best meet the client's needs. The continuum of care must be considered as the OT develops the intervention plan with the client in a specific intervention setting. A skilled therapist collaborates with the client to develop meaningful and attainable goals and then clearly communicates those goals from one setting to the next to foster meaningful outcomes. Evidence-based interventions and quality outcome measures should be used throughout the provision of OT services.[56] Sensitivity to the unique needs of each individual in each practice setting is critical.

Review Questions

1. What are the major functions of the OT process?
2. How are the various forms of clinical reasoning used to guide the OT process?
3. How do theories, models of practice, and frames of reference inform and support OT intervention?
4. What is the appropriate delegation of responsibility among the various levels of OT practitioners (OT and OTA)?
5. What services may be assigned to the OT aide? What are the limits, and why?
6. How should OT practitioners effectively collaborate with members of other professions involved in client care?
7. What are some of the ethical dilemmas that occur frequently in OT practice, and how can these be addressed and managed?
8. What are the various practice settings for OT services in the arena of physical disabilities?
9. What types of services are typically provided in the various practice settings?

Evidence-Based Practice for Occupational Therapy

Lynn Gitlow, Elizabeth DePoy

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:
1. Distinguish among diverse models of evidence-based practice.
2. Define systematic occupational therapy practice (SOTP).
3. List, in sequence, the five steps of SOTP and detail the content and processes of each step.
4. Compare SOTP with the OT process as articulated in the Occupational Therapy Practice Framework.

KEY TERMS

Abductive reasoning
Action processes
Deductive reasoning
Evidence
Evidence-based practice (EBP)
Goals
Inductive reasoning
Need statement
Objectives
Outcome objectives
Problem mapping
Problem statement

Process objectives

Specificity

Systematic OT practice (SOTP)

Thinking processes

In this chapter we present, discuss, and apply **systematic occupational therapy practice (SOTP)**, a model that synthesizes and builds on evidence-based approaches to professional practice. The importance of systematically grounded practice has become established within occupational therapy (OT) and the broader healthcare arena. The need for empirical analysis of the problems and needs that OT practitioners address continues to be emphasized at local, national, and international levels, as reflected by numerous initiatives from the American Occupational Therapy Association (AOTA) and the American Occupational Therapy Foundation (AOTF). Box 4.1 lists some of the current initiatives.

Box 4.1

Examples of Empirically Focused Initiatives

- Special issues of the *American Journal of Occupational Therapy*, which include systematic reviews of the literature focused on a certain area of practice; also the American Occupational Therapy Association (AOTA) Practice Guidelines, which are based on systematic reviews of the literature related to a given practice area.[8,23]
- (http://www.aota.org/Practice/Researchers/practice-guidelines.aspx).
- Evidence-based resources available on the AOTA website.
- (http://www.aota.org)[4]

Educators, scholars, and practitioners continue to discuss and encourage the use of theoretically grounded and supported OT interventions and the development of solid evidence of successful outcomes of interventions.[1,8,33] We assert that current and ongoing systematic OT practice is needed in all professional domains (persons, groups and populations) if OT is to remain a viable and valued field that will continue to flourish in the competitive environment of managed care and fiscal scarcity.

Systematic OT practice involves the integration of research-based techniques into all elements of OT practice. This chapter provides a framework that will help readers understand and learn the research-based systematic thinking and action processes necessary to conduct all or part of the sequence of SOTP. The chapter begins with a discussion and analysis of current models of **evidence-based practice (EBP)**. We then define systematic OT practice and proceed through the presentation and application of our model. As you will see, SOTP is valuable in all arenas of OT.

Threaded Case Study

Maria, Part 1

Maria, an occupational therapist, receives a referral to treat a client who has been diagnosed with carpal tunnel syndrome. The referral states, “Client needs to improve hand strength in order to increase independence in ADLs [activities of daily living].”

Critical Thinking Questions

Think about how to answer the following questions as you proceed through this chapter.

1. How do you clarify the OT problem, and what is needed to resolve it? What evidence do you need to support your decision?

2. What factors do you need to consider in examining your professional activity and interventions, and what evidence do you need?

3. How do you establish the extent to which you have determined the need and resolved the problem? What evidence do you need?

Models of Evidence-Based Practice

Many models of EBP have been presented in the literature. Practice models that integrate multiple methods of inquiry into all domains of professional practice have been called evidence-based medicine,[13,28,32] evidence-based practice,[11] evidence-based rehabilitation,[27]outcomes research,[14] and so on. Because of the expansive literature on EBP approaches, it is beyond the scope of a single chapter to review all the work in its entirety. Therefore, we have chosen to present important definitions that have been advanced in the literature and to discuss their variations. This discussion provides a rationale for systematic OT practice, our model for the critical application and use of evidence-based approaches relevant to and consistent with OT practice. At this point you may be asking, "Why create another model if there are so many?" Our approach is not entirely new. However, we developed it as a comprehensive organizational framework that sees systematic OT practice and inquiry as one and the same. In other words, following the steps of SOTP in all professional activity leads not only to sound practice, but also to the continuing creation of OT knowledge.

Table 4.1 presents diverse approaches to evidence- and inquiry-based practice. As you read these descriptions, you will notice that each approach identifies different sources as credible evidence in three categories: client generated, professionally generated, or scientifically grounded. By client generated we mean that information put forth by the client is considered as part of the evidence base for professional interaction. Professionally generated refers to the provider's education and experience as a valued source of knowledge for use. Scientifically grounded means that the evidence was developed by diverse rigorous methods of inquiry.[30,31] As Table 4.1 shows, not all models may value all three sources.

Ethical Considerations

Consistent with OT ethics, philosophy, values, and theory, we subscribe to the principle that it is our ethical obligation as professionals[6,7] to collaborate with clients regarding all aspects of their service need, provision, risk, and outcome. Therefore, we not only support the value of evidence generated by the client, the practitioner, and science, but we also encourage critical use of diverse sets of evidence as viable and purposive.

TABLE 4.1

Approaches to Evidence- and Inquiry-Based Practice

Author	Description	CREDIBLE EVIDENCE		
		Client Generated	Scientifically Grounded	Professionally Generated
Sackett et al.[31]	Evidence-based medicine is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available clinical evidence from systematic research.		X	X
Institute of Medicine[21]	Evidence-based practice (EBP) is the integration of best research evidence with clinical expertise and patient values.	X	X	X
Law[24]	Evidence-based rehabilitation is a subset of EBP that consists of four concepts: 1. *Awareness:* Being aware of the existence and strength of evidence in one's field 2. *Consultation:* Collaborating with the client and other healthcare professionals to determine the client's relevant problems and their clinical solutions 3. *Judgment:* Being able to apply best evidence to the individual with whom one is working 4. *Creativity:* Emphasizes that EBP is not a "cookie cutter" approach, but rather the combination of art and science	X	X	X
Lee and Miller[26]	The process of evidence-based clinical decision making encourages OT professionals to include the "values, knowledge, and experience" of the client and other healthcare professionals.	X	X	X
Kielhofner, Hammel, Helfrich, et al[23]	Investigation that provides evidence about the effects of services Identifying the client's need Creating the best possible services to address those needs Generating evidence about the nature of specific services and their impact Accumulating and evaluating a body of evidence about specific OT services	X	X	X

The Systematic Occupational Therapy Practice Model—SOTP

Building on and synthesizing the excellent work in EBP, we have defined systematic OT practice as the integration of critical, analytic, scientific thinking, and action processes throughout all phases and domains of OT practice. Let's look at this definition more closely.

Although thought and action are intertwined processes, for educational purposes we distinguish between them. In systematic inquiry, it is essential for the thinking sequence and its rationale to be presented clearly. Thinking processes comprise the reasoning sequence and logic that OT practitioners use to conceptualize intervention and specify desired outcomes. **Thinking processes** involve the selection of a theoretical framework on which the OT practitioner grounds and plans the steps necessary to assess problems, evaluate intervention, specify desired outcomes, and plan a strategy to determine and systematically demonstrate the degree to which client-centered outcomes were met for an individual receiving OT services. Sometimes we are not fully aware of our thought processes, but they are there nonetheless and are the foundation of systematic OT practice, as we will see later in this chapter.

Action processes are the specific behaviors involved in implementing thinking processes.[16] Action processes are behavioral steps. In systematic OT practice, these steps are founded on logical inquiry such that any claim is supported with empirically derived information from a variety of sources.

Although SOTP is not research in itself, it is the organized application of research to the conceptualization, enactment, and investigation of the process and outcome of intervention. Moreover, SOTP stimulates research and can be used as an organizing framework in which research questions are posed and answered. OT and healthcare researchers, educators, and practitioners have identified many arenas in which EBP is valuable. The AOTA's Centennial Vision statement asserts that OT will be an "evidence based profession."[2] Synonyms for evidence include terms such as data, documentation, indication, sign, proof, authentication, and confirmation. In some models of EBP, the highest evidence in the hierarchy of credibility is considered to be data generated by positivist, experimental-type inquiries, the methods most frequently used in clinical trials. This perspective is reflected in the AOTA's use of standards of evidence based on those described by Sackett et al.[32] However, other OTs and authors suggest that a broader range of methods can generate useful evidence.[20,27,36]

In this chapter and in SOTP, we define **evidence** as information used to support a claim. This expansive definition allows for the identification and acceptance of a broad scope of evidence as the basis for decision making in practice, as long as the evidence is identified and used within the systematic thinking and action processes that we discuss in detail here.

Ethical Considerations

Unsubstantiated beliefs or claims are insufficient in themselves to support professional activity in a healthcare environment that is increasingly demanding with regard to competitiveness, quality, safety, cost consciousness, and accountability. A standard established by the Accreditation Council of Occupational Therapy Education (ACOTE) attests to this professional obligation: "Be prepared to be an effective consumer of the latest research and knowledge bases that support practice and contribute to the growth and dissemination of research and knowledge."[2]

Within the OT profession, practitioners can use the information obtained from SOTP not only to improve the processes and outcomes of their practices, but also to engage in informed thinking when choosing among possible interventions, and to contribute to the overall knowledge base of our profession. Although the importance of using evidence to inform practice has been emphasized in the OT literature and scholarship, a study of practitioners' use of EBP for informing intervention revealed that only a minority of the practitioners surveyed used EBP when planning interventions.[12] SOTP systematically guides practitioners in determining which interventions will be effective at producing desired outcomes; which interventions must be improved; and what kinds of new knowledge need development. Additionally, having credible evidence to support the interventions OT practitioners use to produce desirable outcomes provides concrete feedback to the consumer.[34,35]

Furthermore, by systematically evaluating interventions, OT practitioners can develop evidence for advancing clinical practices in the profession.

Pressures and demands on health practitioners from external sources render SOTP even more critical, for three reasons:

- First, the location of service delivery and the time allowed for service delivery are in flux. Long-term hospital stays and treatments in acute care settings have been replaced by community-based treatment, and the length of time for delivery of treatment is decreasing as third-party payers demand more efficient and cost-effective healthcare. SOTP guides the practitioner in balancing the multiple factors involved in practicing within a quality-focused, fiscally driven healthcare environment.
- Second, by systematically examining the processes and outcomes of current practice, OT practitioners can provide an evidentiary basis for clinical thinking and action, which then can be presented to consumers, other professionals, insurers, and policy makers.
- Third, systematic inquiry transcends professional boundaries through shared language and theory. Within the context of physical rehabilitation, for example, the systematic foundation of the World Health Organization (WHO) *International Classification of Functioning, Disability and Health* (ICF)[36] is consistent with the current Occupational Therapy Practice Framework (OTPF-3)[7] and provides a common forum and language for cross-disciplinary communication.

As we proceed through SOTP, keep in mind that the skills and knowledge you already have are largely relevant to this conceptual approach. Let's now turn to the philosophical foundation and steps of the model.

OT Practice Note

It is no secret that OT practitioners have always had difficulty clearly describing what they do to those outside the profession. Moreover, OT practitioners have typically placed more emphasis on providing direct services than on publishing studies that document the results or that attribute successful outcomes to OT intervention. In today's increasingly complex and competitive healthcare environment, OT practitioners must clearly demonstrate their contribution to achieving clinical outcomes. It is particularly critical to do this if referral sources are to understand the benefits of OT to diverse client groups.

Theoretical and Logical Foundations of SOTP

SOTP is grounded in logic and the systematic thinking that undergirds all research thinking processes. Inductive, abductive, and deductive reasoning methods form the basis for these thinking processes. Moreover, the three major research design traditions—naturalistic, experimental, and mixed methods inquiry—are based on these logic structures.[16] Therefore, OT practitioners must understand them and use them to guide their thinking and action and to support claims about the process and outcomes of OT intervention.

Inductive reasoning is a thinking process in which a person begins with seemingly unrelated data and then links these data by discovering relationships and principles within the data set. In inductive systematic approaches, the data may take many forms. Inductive reasoning leads us to select naturalistic strategies, those in which theory is derived from gathered evidence rather than tested by scientific experimentation. Among the methods used in naturalistic design are interview, observation, and textual analysis.[16] Data are collected, and themes that emerge from repeated examination of the data are named, defined, and placed in a theoretical context.

Abduction, a term introduced by Charles Peirce[29] in 1957, currently is used by researchers and logicians to refer to an iterative process in naturalistic inquiry. This process involves the development of new theoretical propositions that can best account for a set of observations which cannot be accounted for or explained by a previous proposition or theoretical framework. The new theoretical proposition becomes validated and modified as part of the research process.

What distinguishes abduction from induction is that in inductive reasoning, an attempt is made to fit the data to a theoretical framework or to generate a set of identified and well-defined concepts that emerge from the data. In **abductive reasoning**, the data are analyzed for their own patterns and concepts, which in some cases may relate to available theories and in other cases may not.

Deductive reasoning begins with a theory and reduces the theory to its parts, which are then verified or discounted through examination. Deductive reasoning provides the foundation for experimental-type research, in which theories or parts are stated in measurable terms and standardized measurement forms the basis of all inquiry. Strategies used in deductive traditions include sampling, measurement, and statistical analysis. Because the rules of logic guide thinking, one can easily follow thinking processes and identify the basis on which guesses, claims, decisions, and pronouncements are made and verified.

Approaches that combine abduction and/or induction with deduction constitute mixed methods research, in which techniques and strategies from both the naturalistic and experimental-type traditions are used.

Complementarity With Contemporary Practice Models

Although it may seem difficult at first to engage in the formal, logical thinking processes that provide the foundation for research, we do it every day. Consider the ways the decision-making skills used in OT practice mirror the logical thinking processes that form the foundation of SOTP. Box 4.2 presents the steps of SOTP, and Table 4.2 illustrates the relationship between the OT process/clinical decision making and systematic thinking processes.

Box 4.2

Steps in SOTP

1. Identification and clarification of the problem to be addressed by the intervention

2. Understanding of need—what is needed to resolve all or part of the problem?

3. Setting of goals and objectives to address the need

4. Reflexive intervention to achieve the goals and objectives

5. Outcome assessment

TABLE 4.2

Relationship Between SOTP and the OT Process

SOTP	OT Process/Clinical Decision Making
Initial problem statement	Referral to OT
Need statement	Systematic assessment of client/occupational profile and analysis of occupational performance
Goals and objectives	Intervention goals and objectives
Reflexive intervention	Regular progress monitoring and revision of intervention in response
Outcome assessment	Final assessment of client's progress

Sequence of SOTP

Our model of SOTP has five steps (see Box 4.2). The process begins with a conceptualization of the problem to be addressed. But what exactly is a problem?

Statement of the Problem

Although we often see problems as entities existing outside ourselves, problems are contextually embedded in personal and cultural values. A problem is a value judgment about what is undesirable or in need of modification. Therefore, a **problem statement** is defined as a specific claim of what is not desired or of what should be changed. Although it seems simple to specify a problem, we often see problems stated in terms of a preferred solution; this error limits our options in analyzing problem components and solutions. Moreover, in systematic OT practice, problem statements must be derived from credible, systematically generated knowledge, including scholarly literature and inquiry, client reports and data, and other sources discussed later in the chapter.

Threaded Case Study

Maria, Part 2

Remember that the referral Maria received specified the client's problem as “needs to improve hand strength in order to increase independence in ADLs.” This problem, stated as a preferred need, suggests only one solution: to increase hand strength. However, through systematic analysis and problem solving, together with the client, Maria expands her analysis of the problem to “limited hand strength does not allow the client to participate in work or self-care occupations”; this allows Maria to generate additional potential solutions. For example, the client may take the following measures: look for alternative work, increase hand strength, work with adaptive equipment, adapt the environment, and so forth. By expanding a problem statement, the OT practitioner moves beyond the obvious primary difficulty or impairment and a singular solution and can capture the breadth of the problem, as revealed by systematically derived evidence from the literature, the client, or others.

If the OT practitioner proceeds merely from the problem statement in the referral, he or she may miss the essence of the client's problem and thus may select inappropriate interventions and outcomes. The OTPF-3 provides a guide for defining problems in OT by using a client-centered approach. Therefore, in SOTP it is critical to include the client and other diverse sources of knowledge, beyond the practitioner's guesses, to formulate the problem statement.

There are many ways to identify problems. Problem mapping is a method in which the OT practitioner expands a problem statement beyond its initial conceptualization by asking two questions repeatedly: “What caused the problem?” and “What are the consequences of the problem?”[3] As with other professionals, OTs do not address all aspects of the problem statement. **Problem mapping** helps us operationalize the OTPF in that it provides a thinking process to locate impairment and individual function (1) within several broad contexts (cultural, personal, temporal, and virtual); (2) within diverse environments; and (3) as influenced by social and physical factors.[7] As we see in the example that follows, the problem areas for OT intervention are defined by the scope of our professional activity.

In the following clinical example, we apply the problem mapping method to the statement, “Jane has impaired short-term memory resulting from a traumatic brain injury sustained in an automobile accident caused by a drunk driver.” To conduct problem mapping, we first need to conceptualize the problem as a river. Articulating the original statement of the problem is analogous to stepping into the river and picking up one rock. As we look upstream, we see what shapes (and therefore causes) the problem; as we look downstream, we see the problem's ripples, or consequences. How does this mapping technique work?

Look at the problem map in Fig. 4.1. Each box above the initial problem contains a possible answer to the question of what caused the problem. Once we have determined the first-level causes of the problem, we ask, “What caused the cause of the problem?” and so on, until we reach cultural and social value statements, both of which are specified as contexts for OT practice in the OTPF-3. Keep in mind that the evidence used to identify causes and consequences must be generated from credible, identifiable sources, including client, professional, and scientific sources.

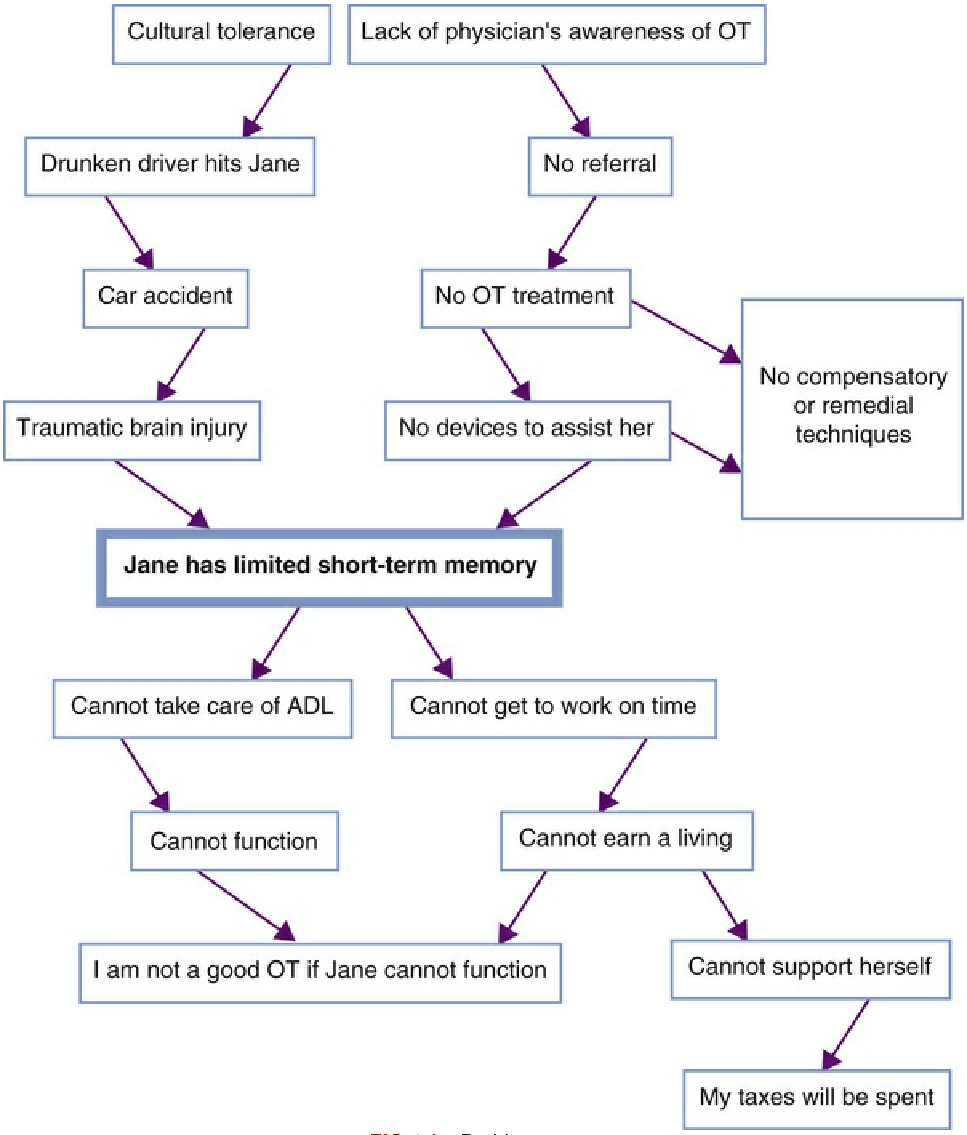

FIG 4.1 Problem map.

Below the initial problem statement, we repeatedly ask the question, "What is the consequence of the problem?" As with the upstream map, this question about the consequences of consequences is repeated until we reach the effect of the problem on ourselves. At this point, you may be asking "Why?" The reason is, problems are values and thus are in the eye of the beholder. The problem map expands the problem statement from documented cultural, social, and environmental causes to personal effect, and it suggests many different sites or targets for intervention.

As you might imagine from the clinical example of Jane's situation, many causes and consequences of problems are not within the scope of OT practice and thus cannot be resolved by OT intervention. Many OT practitioners will likely expand their efforts into political action or other areas at some point in their careers; however, others will continue primarily to look for clinical interventions that can improve the occupational performance of individuals. Given the focus of this text, the emphasis in this chapter is on clinical interventions rather than other roles OTs might assume.

Jane's problem map suggests numerous points of intervention for clinical OT; for example, in cognitive remediation, compensatory training, and provision of assistive devices and services, such as assistive technology (AT). Because our focus is on clinical practice, in Jane's case, an area of occupational performance is considered—developing vocationally related strategies that will enable Jane to return to work. The OT practitioner could also make a referral to a social service agency for Jane, who might be eligible for Social Security disability income; in this way, the OT practitioner would indirectly intervene (through referral to another professional on the team) at the level of

Jane's inability to support herself financially. In addition, as we look at the expanded problem, the OT practitioner may want to intervene on the macro level by advocating for stricter legislation and cultural "zero tolerance" of drunk driving, perhaps by educating adolescents and young adults. These areas of practice are beyond the scope of this chapter, but they allow us to see the expansiveness of problems and how mapping can assist OTs to identify diverse areas for OT to target or address through collaboration.

Consider the initial problem statement focusing on Jane's impaired short-term memory. This is not a problem that can be resolved by an OT practitioner as it is stated. Therefore, the OT, in collaboration with the client, must reconceptualize and restate the problem so that the OT can intervene using meaningful and systematic methods within the OT professional scope of practice.[5] Problem mapping or other logical, evidence-based problem identification techniques help the OT practitioner to examine and analyze problems beyond their initial presentation and to identify the strength of the evidence by which problems are analyzed. In SOTP, problem analysis and a careful statement of the part of the problem to be addressed are critical if the rest of the steps are to be implemented. Including in the process evidence from the client's perspective is essential in our model. Clarifying the problem will help the therapist ascertain what is needed to resolve the part of the problem that will be addressed. Now let's move to the next step of SOTP, ascertaining need.

Ascertaining Need

After problem mapping, the next step is ascertaining need. In this step, the practitioner must clarify exactly what is needed to resolve the part of the problem that has been targeted for change.

A distinction must be made between *problem* and *need.* As discussed earlier, a problem is a value statement about what is not desired. For a problem to be relevant to OT practitioners, it must concern improvement or maintenance of occupational performance. Thus, the problem area on the map that the OT practitioner would target for resolution would be delimited and guided by the professional and theoretical domains of OT concern. A **need statement** is a systematic, evidence-based claim, linked to all or part of a problem, that specifies what conditions and actions are necessary to resolve the part of the problem to be addressed. The identification of need involves collecting and analyzing diverse sets of information (eg, assessment data and the information from the client interview) to form an occupational profile to ascertain what is necessary to resolve a problem.

At this needs assessment stage of the SOTP sequence, the OT may already have information on which to formulate need, or he or she may collect data in a systematic fashion to clearly delimit and identify need. A need statement should include four specifics: (1) who is the target of the problem (this defines the client or recipient of OT service); (2) what changes are desired; (3) what degree of change is desired; and (4) how it will be recognized that the change has occurred. The need statement must be based on systematically derived data already contained in credible resources (eg, the relevant practice and research literature or documentation, and professional education, knowledge, and experience) or as revealed by the client in a needs assessment inquiry. Can you see that the need statement uses systematic, research-based processes to define the next steps: specifying goals and objectives, determining the intervention, and specifying the evaluative criteria to determine whether the desired outcomes of an intervention have been met?

Let's return to the example from our problem statement. As already mentioned, the problem as stated (impaired short-term memory) is not a problem an OT practitioner can resolve. Yet it is common for referrals for OT intervention to identify problems such as this one. Thus the use of a problem map or similar problem analysis strategy is not only a reasonable thinking tool, it is also essential if we are to define the nature of our interventions more clearly and thereby document the unique contributions and outcomes of OT both within and outside of our field. In Jane's case, therefore, the OT practitioner chose to reason about the causes and consequences of the problem to identify whether an area existed in which Jane would require OT intervention. By mapping the problem, the therapist found that OT did indeed have a critical role to play in Jane's treatment. The OT's problem statement then became: Jane's ability to engage in meaningful occupational performance is impaired because she is unable to manage her time and arrive at work on time as a result of her impaired short-term memory.

Given this problem statement, the therapist decided to conduct a research-based needs assessment to determine what was necessary to resolve the targeted part of the problem; to set goals and objectives to guide the selection of an intervention; and to determine what processes and outcome should be expected.

Using a systematic approach to data collection, the OT practitioner used mixed method techniques, including an interview and systematic observation of Jane, to ascertain Jane's desires and skills. The OT practitioner also administered a standardized cognitive assessment and an occupational performance assessment. In this instance the OT practitioner is integrating qualitative and quantitative inquiry strategies to document a complete understanding of need and to provide the empirical basis for clinical decisions, in addition to expected outcomes.

One of the tools the OT practitioner can use to collect data is the Canadian Occupational Performance Measure (COPM). This criterion-referenced measure is used to identify client-perceived problems in daily functioning in the areas of self-care, productivity, and leisure. By means of a semistructured interview format, the COPM may be used to assess the performance skills and patterns the client identifies as interfering with his or her ability to function in a particular area. The data from the COPM are credible, outcome based, and accepted as evidence in the research world.[25]

Systematic assessment revealed that Jane identified returning to her job as a saleswoman in a boutique as her most important goal. Additionally, the results of the COPM interview revealed that Jane was not satisfied with her ability to manage her time or her ability to be punctual and that she perceived these two issues as the greatest barriers to achieving her desired goal of returning to work. She recognized that her difficulties with short-term memory would affect her ability to do other work-related tasks, but she reported being most concerned about time management and promptness.

Standardized testing indicated that Jane's short-term memory was impaired but that her capacity to respond well to external cues remained intact. Additionally, Jane's performance on the Wisconsin Card Sorting Test (WCST) revealed that she was able to solve problems and that she demonstrated abstract reasoning. (The WCST is a standardized cognitive assessment of executive function that was developed to assess problem solving, abstract reasoning, and the ability to shift cognitive strategies.[19]) The results of standardized testing also suggested that Jane was able to learn new behaviors with specific, well-structured practice in the environment in which she would function. The WCST also provided an assessment of cognitive flexibility, and those data could be extrapolated to imply that Jane would be able to learn new skills in a structured environment, but that the number of variables and complexity of her work setting should also be considered.

With this empirically generated information, the therapist and Jane had a sound and credible basis for deciding that the OT intervention would be directed to the need to find and teach Jane compensatory strategies for time management and promptness.

In addition, Jane had indicated in her occupational profile that she was married and that her husband would be supportive in helping her get to work. Based on this information, generated from the naturalistic part of the needs assessment, the therapist and Jane decided to include Jane's husband in the intervention, and to work first in Jane's home environment and then transfer her treatment to the work environment.

Can you see from this example how SOTP both provides the guidance and the documentation for clinical decisions and suggests future steps in the intervention and outcome assessment processes? Anyone who observes the intervention process can easily see the rationale for decisions and actions. Credible, evidence-based knowledge is structured in a manner that provides a clear reasoning trail.

The desired outcomes are implicit in the need statement, which provides a basis for formulating measurable outcomes of an intervention. According to the literature on closed head injury and professional wisdom,[22] what is needed in Jane's situation is contextually based OT intervention in the home and in the workplace to assist her with time management and promptness, as a skill to facilitate her return to work. The evidence for targeting this intervention and for the goals and objectives to follow is clear and specified, as is the desired outcome.

The following case example features George, another OT practitioner, and considers a different type of need statement that illustrates why OT practice requires systematic inquiry.

Case Study

George

George, an OT practitioner, is asked by an employer to address a problem involving several computer *operators whose ability to perform their jobs has been impaired or lost as a result of neck pain. After constructing a problem map based on literature about causes and consequences of neck pain, George formulates a need statement based on two areas that he believes will address the problem: instruction in proper body mechanics and instruction in a regularly scheduled upper body stretching routine. A literature review provided him with empirical evidence on which to base his intervention. He begins his intervention by teaching proper body mechanics and upper body stretching techniques to the computer operators, but the problem is not resolved. The computer operators continue to be unable to do their jobs, and their complaints of neck pain continue. George's intervention has not successfully resolved the problem for which he was hired.*

What was missing from George's reasoning? He based his problem map on empirical literature and educated but preconceived guesses without fully assessing the situation. Had he conducted a systematic needs assessment that included interviewing, testing, and observing the workers, he might have found that the monitors were too high for the operators and the chair heights were not adjustable. Thus, the intervention of body mechanics instruction and upper body stretching that may have been viable in another situation did not address the specific needs that George failed to identify. Had he used systematic thinking and action to ascertain need, rather than guessing and then jumping from the problem to the intervention, George would quickly have identified the appropriate target areas.

In needs assessment, many systematic approaches can be useful in identifying and documenting needs, including but not limited to formal research strategies, well-conducted a priori studies, and mixed methods of information gathering and analysis. For individual clinical problems, strategies such as single case design are extremely useful for guiding and testing the efficacy of intervention decisions with a client.[16] For program development, the therapist may want to use "group" (also called nomothetic) approaches, such as survey, interview, or standardized testing strategies, to obtain needed information on which to support a needs claim. Naturalistic inquiry or mixed method thinking and action strategies may be valuable to ascertain the perspectives of client groups about whose problems and needs the therapist knows little. Many excellent research texts are available from which to build research knowledge (see the Suggested Readings at the end of this chapter).

The next step in the process of systematic OT practice is translating the needs into goals and objectives.

Goals and Objectives

Goals and objectives are two words with which OT practitioners are familiar because these concepts are used to structure treatment. In SOTP, goals and objectives emerge from the need statement and are essential not only for structuring intervention, but also for specifying how the process and outcome of intervention will be examined and supported.

Definitions of the two terms are helpful. **Goals** are statements developed by clients and relevant others identifying the client's desired outcome of the service—what would the client like to be able to do or be.[10] In other words, a goal is a vision statement about future desires that is delimited by the need that it addresses. **Objectives** are statements about how to reach a goal and how to determine whether all or part of the goal has been reached. The objective sets up the systematic approach to attaining the goal and determining its empirical measurement or assessment.[17]

There are two basic types of objectives: process and outcome. **Process objectives** define concrete steps necessary to attain a goal. Process objectives are interventions or services that will be provided or structured by the OT practitioner.[15] **Outcome objectives** define the criteria that must be met to determine that all or part of the goal has been reached; outcome objectives further specify how these criteria will be demonstrated. Ultimately, assessing the attainment of outcome objectives focuses on ascertaining whether the desired change has taken place as a result of participation in the OT process.

To develop goal and objective statements in our model, the therapist examines the need carefully, including the evidence supporting the need statement. Then, the therapist and the client formulate conceptual goal and objective statements that guide and imply how the process and outcomes of intervention will be assessed. Goals are overall conceptual statements about what is desired; objectives are statements that are operationalized (ie, stated in terms of how they will be measured or known). Both are based on systematically generated knowledge from the needs assessment.[15]

Let's now return to Jane to illustrate goals and objectives. From the problem and need statements, the OT practitioner determined that an overall goal for Jane's intervention was to develop, teach, and have Jane learn compensatory strategies for promptness and time management so she could improve her performance in these areas and return to work. Based on the evidence given in the needs assessment, the OT intervention was to be carried out at first in Jane's home, with her husband participating; after this, a transition would be made to the workplace.

A critical element of goal setting in SOTP is **specificity**. The following example uses the treatment goal discussed previously as the basis for writing specific goal and objective statements.

Goal: Jane will improve her promptness so as to be able to get to work on time (performance), to her satisfaction.

The process (P) and outcome (O) objectives to be used to attain this goal are:

1. Jane will be presented with assistive technology supports and services and repositories of assistive devices from which she can select those she thinks will be most useful for her to achieve the goal. (P)

2. Given a choice of a variety of assistive devices (eg, smart watches, notification apps, and clocks), Jane will choose one or more devices to use as an external cue provider for promptness. (P)

3. Jane will select one daily activity at home for which she needs an external promptness cue. (P)

4. With assistance from the OT practitioner, Jane and her husband will configure the device to cue Jane to attend to this daily event. (P)

5. Jane's husband will monitor her promptness and provide feedback to Jane and the therapist regarding the effectiveness of the assistive device in meeting the goal. (P)

6. Once Jane has demonstrated that she can promptly attend to her schedule at home, she will begin to use the promptness cue to arrive at work. (O)

7. Once Jane has demonstrated that she can arrive at work on time, the therapist will work with Jane at the work site so that she can use the device to attend promptly to her work schedule, to her and her employer's satisfaction. (P)

8. Using the most effective strategy and devices, Jane will improve her promptness and satisfaction with her performance at work. (O)

As you can see by reading this goal and its related objectives, in SOTP, objectives are very directive conceptual statements designed to produce broad goal statements based on an empirical understanding of need. As we will see in the following sections, Reflexive Intervention and Outcome Assessment, stating the goals and objectives as demonstrated in this chapter determines what will be formatively monitored and examined to ascertain treatment success.

Reflexive Intervention

Extrapolating from naturalistic methods of inquiry, DePoy and Gilson[15] chose the term *reflexive intervention* to highlight the fact that systematic thinking does not stop during the implementation of interventions. Therefore, we have integrated this term into our model to remind the practitioner that as practice proceeds, the OT makes decisions based on feedback from the actual intervention itself, as well as on examination of the therapeutic use of self and other influences on the intervention process. We use the term reflexive intervention to refer to the thinking and action strategies that occur during the intervention phase of OT practice. In reflexive intervention, the OT systematically monitors the client, the collaboration, the professional practice, setting-based resources, the therapeutic use of self, and other internal and external influences that affect the practice process and outcome. That is not to say that practice wisdom and intuition do not occur or are not used as evidence. They do occur, and in SOTP the OT makes it a point to be well aware of the pluralistic evidentiary basis from which he or she is making decisions, to carefully look at all practice to obtain clarity about what was done, and to consider feedback from engaging in practice.

Process assessment, the systematic monitoring of process objectives (denoted in the objective list by "P") occurs throughout the reflexive intervention phase to provide the evidence on which to describe intervention and the context in which the intervention occurs; it also yields the evidence on which decisions are made about the need for intervention or programmatic change. Knowing what outcomes occurred without knowing what was done to cause them limits our knowledge base and our ability to communicate the benefits of OT practice to those outside of the profession. Thus, reflexive intervention is critical to the growth of OT knowledge, theory, and practice strategies. Let us return to Jane to illustrate.

As we mentioned previously, the COPM is an excellent measure for documenting performance that is meaningful to the client. In process assessment, the COPM can be used to document changes in occupational performance and to illustrate the benefits of OT to Jane and other diverse audiences. Using this tool to collect data at multiple points during intervention can support the intervention "as is," or it can help the therapist reconceptualize the intervention. The OT might also have tracked and documented Jane's promptness over the course of her treatment to determine whether revisions in the intervention were necessary. Moreover, documentation is an excellent way to show Jane and others that Jane has improved through OT. Similar strategies could be used to examine and document time management and other areas that Jane and the OT were addressing. The OTPF provides excellent guidance on reflexive intervention.

Outcome Assessment

Outcome assessment is a set of thinking and action processes conducted to ascertain and document what occurs as a result of the client being voluntarily or involuntarily exposed to a purposive intervention process and to assess the worth of an intervention. (In the objective list shown earlier, outcome objectives were identified with an "O.") These objectives can be assessed by using quantitative, naturalistic techniques and mixed methods, and by applying systematic inquiry to examine whether objectives have been attained. To brush up on inquiry, we suggest that you consult one of the many excellent research method texts, some of which we list at the end of this chapter.

To perform an outcome assessment of Jane's intervention, the OT selected a pre-post test design using the COPM and the other documentation noted in the discussion on reflexive intervention. Although Jane's performance was measured multiple times, only the change from beginning to end was used for outcome assessment. As you can see, all OTs already do outcome assessment. The trick is to realize that you do it and to purposefully select methods that are credible and useful. We suggest that you choose strategies that use mixed method approaches. Box 4.3 shows how each objective was assessed in Jane's case.

OT Practice Notes

SOTP in Professional Practice

An OT should deliberately perform each of the steps of SOTP and find a personal style for using evidence in professional practice. SOTP not only serves as a valuable approach in direct intervention, it also provides the foundation for knowledge building and intervention development in all professional domains.

Box 4.3

Putting It All Together

Goal, Objectives, Evidence, and Success Criteria

Goal: *Jane will improve her promptness so as to be able to get to work on time (performance), to her satisfaction.*

1. **(P)** Jane will be supplied with repositories and assistive devices from which to select those that she thinks will be most useful for her to achieve the goal.

Criterion for success: Completion of activity

Evidence: Notes of each session documenting progress toward goal

2. **(P)** Given a variety of assistive devices (eg, smart watches, notification apps, and clocks), Jane will choose a device to use as an external cue provider for promptness.

Criterion for success: Selection of device

Evidence: Notes of each session documenting progress toward goal

3. **(P)** Jane will select one activity at home for which she needs an external promptness cue.

Criterion for success: Selection of activity

Evidence: Notes of each session documenting progress toward goal

4. **(P)** With assistance from the OT, Jane and her husband will configure the device to cue Jane to attend to this daily event.

Criterion for success: demonstration that Jane and her husband have completed the objective

Evidence: progress notes indicating mastery of task

5. **(P)** Jane's husband will monitor her promptness and provide feedback to Jane and the therapist regarding the effectiveness of the assistive device in meeting the goal.

Criterion for success: Daily record of Jane's promptness, supplied to her each evening after dinner

Evidence: Husband's recorded time charts

6. **(O)** Jane will demonstrate that she can promptly attend to her schedule at home.

Criterion for success: Daily record of Jane's promptness at home

Evidence: Husband's recorded time charts

7. **(P)** Once Jane has demonstrated that she can promptly attend to her schedule at home, she will begin to use the promptness cue to arrive at work.

Criterion for success: Daily record of Jane's use of cues

Evidence: Client self-report

8. **(O)** Jane will regularly arrive at work on time.

Criterion for success: Daily record of Jane's promptness at work

Evidence: Client's documented arrival time

9. **(P)** Once Jane has demonstrated that she can arrive at work on time, the therapist will work with Jane at the work site so that she can use the device to attend promptly to her work schedule to her and her employer's satisfaction.

Criterion for success: OT will meet Jane at work daily for 1 week to support use of device

*Eviden*ce: OT notes

. **(O)** Using the most effective strategy and devices, Jane will improve her promptness sufficient to work and sufficient for her satisfaction.

Criterion for success: Significant improvement in Jane's promptness

Evidence: COPM score on this item, compared with COPM score on pretest on this item

COPM, Canadian Occupational Performance Measure; *O*, outcome objective; *P*, process objective.

Summary

In this chapter we presented SOTP, a practice approach in which systematic thinking and action are essential tools in OT practice. Our model begins with a clear problem statement that guides all the remaining steps. Naturalistic and experimental research traditions are applied to clinical decision making to guide the subsequent steps of identifying and documenting need, positing goals and objectives, reflexive intervention, and outcome assessment.

Reexamine Table 4.2 now in light of the need statement. The links among problem, needs, goals and objectives, process, and outcome have been clearly illustrated. Each step of SOTP emerges from and is anchored in the previous step. Moreover, systematic thinking and action provide the specificity and credible evidence supporting the extent to which the intervention resolved the part of the problem that was identified as falling within the OT domain.

Review Questions

1. List three reasons OT practitioners need to use SOTP to demonstrate the efficacy of OT to external audiences.
2. Name and describe each of the steps of SOTP.
3. Compare the steps of SOTP to the steps of the OT process.
4. Using a potential OT client as a case study, select a problem and develop a problem map.
5. Suggest strategies to ascertain the need based on your problem statement.
6. Identify the need for your client based on your problem statement.
7. What is the difference between a goal and an objective, and what is their relationship?
8. How do goals and objectives relate to need?
9. How do goals and objectives relate to a problem?
10. Identify goals for your client.
11. What are the two types of objectives described in this chapter, and what are the differences between them?
12. Based on your goals for your client, identify at least two process objectives and two outcome objectives.
13. Explain how you will know that your objectives have been met.
14. Choose at least two interventions to achieve the goals and objectives you established in question 12.
15. Identify what questions you will ask and how you will answer them in reflexive intervention.
16. Discuss how you will use reflexive intervention and outcome assessment data to contribute to OT knowledge.

Health Promotion and Well-Being for People With Physical Disabilities

Michael A. Pizzi, S. Maggie Reitz, Marjorie E. Scaffa

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Discuss historical influences on occupational therapy's role in health promotion and well-being.
2. Define key health promotion and disease prevention constructs and terminology.
3. Describe the impact of Healthy People 2020 on occupational therapy practice.
4. Identify strategies for integrating health promotion into physical disability practice.
5. Develop a holistic, client- and occupation-centered health promotion perspective for physical disability practice.

KEY TERMS

Client-centered care (client-centered practice)
Empowerment

Enablement
Expert-centered
Health promotion
Health protection strategies
Moral treatment
Occupational justice
PRECEDE-PROCEED model
Prevention
Primary prevention
Quality of life
Risk factors
Secondary conditions
Secondary prevention
Tertiary prevention
Transtheoretical model (TTM)
Well-being
Wellness

The American Occupational Therapy Association (AOTA) supports and promotes involvement of occupational therapists and occupational therapy assistants in the development and provision of programs and services that promote health, well-being, and social participation of all people.

American Occupational Therapy Association[59]

In its official statement on health promotion and well-being, the AOTA describes three important roles for the profession:

To promote healthy lifestyles; to emphasize occupation as an essential element of health promotion strategies; and to provide interventions, not only with individuals but also with populations. It is important that occupational therapy practitioners promote a healthy lifestyle for all individuals and their families, including people with physical, mental, or cognitive impairments.[59]

Threaded Case Study

Jean, Part 1

Jean is a 49-year-old wife and mother with three grown children, two of whom live away from home. The one living at home has a 2-year-old child. Jean has been married for 27 years. She developed gestational diabetes with her first-born child and has been insulin dependent for most of her married life. Jean is knowledgeable about diet, the need for exercise and activity, and insulin regulation. She is active in her community, works part-time as a cashier to supplement her husband's income, and enjoys bowling, playing cards with friends every Friday night, crocheting, and maintaining her home.

Jean developed symptoms that later were confirmed to indicate a minor stroke. She lost sensation in her fingertips and in both lower extremities. As a result, she developed altered dynamic balance and grasp in both hands. She has coped with beginning glaucoma and diabetic neuropathies for several years. She has a weakened cardiac status secondary to diabetes, even though she has been active much of her life. Jean is overweight and has smoked a pack of cigarettes per day since she was 18 years old. Her husband also smokes regularly.

Critical Thinking Questions

1. How would you evaluate this client from a health promotion perspective?

2. In addition to standard occupational therapy services, what health promotion interventions might you use with this client and/or her family?

The value a society places on the health and welfare of its people can be measured by its level of commitment to policies and funding for healthcare. The wisdom of a society also can be measured by its commitment to prevention and health promotion. This chapter describes the involvement of the occupational therapy (OT) profession in health promotion and prevention activities, in addition to policy development. A new direction, which may come to be identified as a historical shift back to occupational therapy's concern with societal-level problems, is also identified.

The historical overview is followed by a review of health promotion principles and a description of health promotion–focused evaluation and intervention for individuals with physical disabilities. A case study is presented to help readers integrate the principles and practice of health promotion and impairment prevention for people with physical disabilities and impairments.

Historical Influences and Considerations

Early History and Symbolism

Humans have long appreciated the health-promoting and healing qualities of engagement in occupation.[55,58] History and anthropology,[24] in addition to archeology,[90] provide rich examples of how people through time, from cultures around the world, have used occupations not only for survival, but also as a means of healing and expressing identity and spirituality.[12,25,90] In the United States, petroglyphs (ie, rock carvings) are as important to the living as they were to those who created them centuries ago. Herman Agoyoyo, chairman of the All-Indian Pueblo Council, pointed out:

To us, these petroglyphs are not the remnants of some long lost civilization that has been dead for many years … they are part of our living culture. What is stored in the petroglyphs is not written in any book or to be found in any library. We need to return to them to remind us of who we are and where we came from, and to teach our sons and daughters of it.[84]

This pictorial evidence often depicts the human engagement in hunting or other subsistence activities, the use of symbols, or representations of the human hand or animals.[25,83] When living conditions allowed time for occupations other than for subsistence (ie, activities of daily living and instrumental activities of daily living), humans turned their energy to identifying these very occupations and the animals they shared their world with through symbols and artwork. These symbols convey feelings, identity, beliefs, and knowledge of these important occupations.

Humans currently use symbols, often subconsciously, for these same purposes.[26] The production of petroglyphs is early evidence of the importance of symbols and their influence on health. Through these symbols, early humans could communicate their essence to future generations and, according to Reilly,[57] demonstrate that "through the use of his hands, as they are energized by mind and will, [man] can influence the state of his own health."

The meanings or relevance of specific symbols can change through time, in a society and in an individual. A handprint made on the wall of the Cave of Chauvet-Pont-d'Arc[29] during the Paleolithic period could have had a symbolism that was both similar to and different from the symbolism of a small child's handprint to a parent of today. For an individual with a disability, the familiar stick person in a wheelchair symbol used to denote accessibility might have held little or no meaning before the person sustained the disability. After an individual is diagnosed with or sustains a physical disability, however, this symbol (Fig. 5.1), the International Symbol of Access (ISA), may take on new meaning and relevance both for that person and for his or her family.

FIG 5.1 International Symbol of Access (ISA).

Development of a Profession

Many descriptions of the development of occupational therapy as a profession either start with or include a discussion of moral treatment.[39,55,56,61] **Moral treatment** was defined as a "humane approach to the insane" that included occupation-based intervention that emphasized self-discipline, hard work, and learning self-control while developing "good habits."[90] (Chapter 2 provides a rich description of this time period and those who influenced the practice of occupational therapy with people with disabilities in the United States.) The values and beliefs of the founders of occupational therapy in the United States were consistent with and influenced by the values and beliefs of the mental hygiene movement, the arts and crafts movement, the settlement house movement, and the actions of other social activists and reformers in the United States at that time.[13,40] These idealistic individuals and groups worked to correct the social injustices of their time, and they are viewed as helping to promote health, well-being, and social participation.[61]

The backgrounds and contributions of the founders of occupational therapy in the United States are well documented.[a] Therefore, the rest of this discussion focuses on (1) a summary of key events for involvement in health promotion and policy development in the United States and (2) recent international developments that may influence practice in the United States in the coming decades.

Milestones in Occupational Therapy Health Promotion Interventions

Leaders in the field of occupational therapy have been encouraging the profession to focus increased attention on health promotion for many decades. As early as the 1960s, leaders articulated their vision of the role of occupational therapy in prevention and health promotion.[15,85,86,88,89] Themes have included (1) concerns about an emphasis on cure or the saving of life versus the provision of services to maximize the quality of a saved life or the prevention of the illness or injury; (2) the matching of OT values and principles with those of public health; (3) the untapped potential and responsibility for occupational therapy to contribute to the well-being of society; (4) the need to build and redefine the knowledge base of the profession; and (5) the responsibility to conduct research to determine the effectiveness of community-based initiatives for health promotion and prevention. Finn[27,28] has continued to encourage this involvement through the Eleanor Clarke Slagle Lecture[26] and subsequent work.

Through the years the AOTA has developed a series of statements and used other means to focus attention on health promotion. In 1979 the organization published its first official document related to health promotion and prevention, "Role of the Occupational Therapist in the Promotion of Health and the Prevention of Disabilities."[1] This document has been revised and republished four times since then—in 1989,[2] 2001,[14] 2008,[68] and 2013.[59] In 1986 the AOTA supported this role by devoting an entire issue of its journal, the *American Journal of Occupational Therapy (AJOT),* to health promotion.[87] In 1992 an article on the history of occupational therapy's role in preventive health appeared in the special 75th anniversary issue of the *AJOT.*[58]

Besides encouraging occupational therapy's role in health promotion within the profession, the AOTA also promoted it to external audiences. The AOTA was a participant in the Healthy People 2000 Consortium.[4] The consortium worked cooperatively with 22 expert groups and numerous state and national governmental agencies and services to set the nation's health agenda for the next decade.[80] Both this document and its current version, Healthy People 2020,[77,81,82] include targeted health goals for individuals with disabilities. Healthy People 2020[77,81,82] was released in 2010 to identify health goals for the next decade. The overarching goals of Healthy People 2020 are:

- attaining high-quality, longer lives free of preventable disease, disability, injury, and premature death
- achieving health equity, eliminating disparities, and improving the health of all groups
- creating social and physical environments that promote good health for all
- promoting quality of life, healthy development, and healthy behaviors across all life stages[81,82]

A review of Healthy People 2020 (*http://healthypeople.gov*) can assist occupational therapists in the development of new intervention strategies to address the documented unmet health needs of U.S. residents, both with and without disabilities. In 2007 the AOTA selected six focus areas for the profession to emphasize in the decade leading to its centennial in 2017. Health and wellness is one of these six areas; the others are children and youth; productive aging; mental health; work and industry; and rehabilitation, disability, and participation.[5]

Another AOTA document, "The Role of Occupational Therapy in Disaster Preparedness, Response, and Recovery,"[6] provides a prevention and action tool to help OT practitioners meet the disaster preparedness needs of individuals with disabilities and to assist employers in preparing for mass casualties resulting from extreme weather, mass transportation accidents, or terrorist activities. As will be discussed later in this chapter, prevention is part of a comprehensive health promotion strategy.

Lifestyle Redesign Programs

A significant event in health promotion OT practice was the development of the Lifestyle Redesign programs, which were created by faculty members of the Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California (USC). The outcome of the first of these programs for well elderly was published in a landmark article in the *Journal of the American Medical Association.*[20] The intervention protocol that evolved for the Well Elderly Study was eventually named "Lifestyle Redesign."[44] The results of this Lifestyle Redesign program indicated that "preventive occupational therapy greatly enhances the health and quality of life of independent-living adults."[44] Other Lifestyle Redesign programs have since been developed for individuals both with and without disabilities.[79] These include programs addressing weight, pain, headache, diabetes management, and ergonomics, among others. The USC faculty practice also has designed an interdisciplinary program with physical therapy for individuals living with multiple sclerosis (Optimal Living with MS), in addition to programs for veterans and college students, life coaching, and lifestyle risk assessment.[79]

International Trends

An international discussion started by Wilcock[90,91] and Townsend[74] has shaped the future of occupational therapy's involvement in health promotion and prevention worldwide. These researchers called attention to the potential for OTs and OTAs to combat social and occupational injustice.

The idea of occupational justice first emerged in Australia and Canada. **Occupational justice** is "the promotion of social and economic change to increase individual, community, and political awareness, resources, and equitable opportunities for diverse occupational opportunities which enable people to meet their potential and experience well-being."[90]

The World Federation of Occupational Therapists (WFOT) has actively responded to the call for the profession to become involved in promoting occupational justice; it has encouraged occupational therapists to contribute to the eradication of occupational deprivation.[70] The discussion is slowly emerging in the United States.[8,60,65,78] The WFOT continues to advocate for occupational therapy to address broad societal concerns that impact health and well-being. In 2012 the federation approved the document, "Environmental Sustainability, Sustainable Practice within Occupational Therapy,"[92] which encourages the profession "to re-evaluate practice models and expand clinical reasoning about occupational performance to include sustainable practice."

Ethical Considerations

The profession of occupational therapy has the potential to be able to conduct an assessment of societal issues that impact the daily occupational rights and function of marginalized individuals, groups, and communities. Through education, political advocacy, and activism, occupational therapists can draw attention to the inequities that exist.

As occupational therapy practitioners further gain working knowledge of the political process, they can advocate for both the prevention of disability as well as the promotion of health and prevention of secondary conditions for individuals with disabilities who have been marginalized. In preparation for this advocacy, OT practitioners should familiarize themselves with the goals of Healthy People 2020,[8] especially the second overarching goal, "Achieve health equity, eliminate disparities, and improve the health of all groups." They also should study the other data available in Healthy People 2020 regarding reducing disparities and improving the quality of life for individuals with disabilities.

One step OT practitioners can take is increasing their awareness of current history-making efforts that can be joined and supported. The independent living movement, which is working to combat disparities and social injustice for individuals with disabilities, is an example of such an effort. However, if an OT practitioner singularly embraces the rehabilitation paradigm, he or she may not feel comfortable with either the principles of the independent living movement or its political agenda. Integrating a proactive approach to health that includes health promotion, wellness, and rehabilitation can significantly impact the quality of life of people with disabilities and their loved ones.[49,52]

The rehabilitation paradigm is clearly used by OT practitioners. Wellness and health promotion strategies can easily be introduced into any practice area. An example of this can be seen when the OT works with a client post-stroke who is obese. The OT practitioner would address healthy nutrition and activity levels, identifying positive environmental supports and helping to develop routines that promote health and well-being, in addition to supporting occupational performance through remediation of persistent symptoms after the stroke. When the OT works from a client-centered perspective, rather than an **expert-centered** one, the client is given more control for positive independent living. Arbesman et al. stated:

As new approaches are developed in Medicare and in private insurance, occupational therapy's role may move from being considered a rehabilitation service to being an essential component of any well-designed, effective, and efficient healthcare system. Areas in which occupational therapy practitioners may be involved with healthy as well as frail community-dwelling older adults include several fully supported by the evidence.[7]

An important milestone in international efforts to ensure independent living and other equal rights for individuals with disabilities was the adoption in 2006 of the United Nations Convention on the Rights of Persons with Disabilities. The United States did not sign this convention until 2009, at which time 142 other countries had already signed.[75,76]

OT practitioners need to look beyond the immediate rehabilitation goals to be truly client centered in their practice.[74] This includes advocacy for equal access and rights for all people, marginalized or not, with or without physical disabilities. In a sense, this discussion has brought the OT profession full circle, giving it the opportunity to emulate its founders by becoming social activists.

Health Promotion Principles and Practice

Health is a constant interplay of a variety of factors. Important determinants of health status include biology and genetics, individual behavior, social factors, policymaking, and health services (Fig. 5.2).[59,81] Public health professionals evaluate the health status of a population by examining birth and death rates, incidence and prevalence of disease, injury and disability, use of healthcare services, life expectancy, quality of life, and other factors. Leading health indicators for the U.S. population were established during the development of Healthy People 2020 in an effort to set priorities and focus the national health promotion agenda. The leading health indicators that served as the foundation for the strategic planning process are:

- Access to health services
- Clinical preventive services
- Environmental quality
- Injury and violence
- Maternal, infant, and child health
- Mental health
- Nutrition, physical activity, and obesity
- Oral health
- Reproductive and sexual health
- Social determinants
- Substance abuse
- Tobacco[81,82]

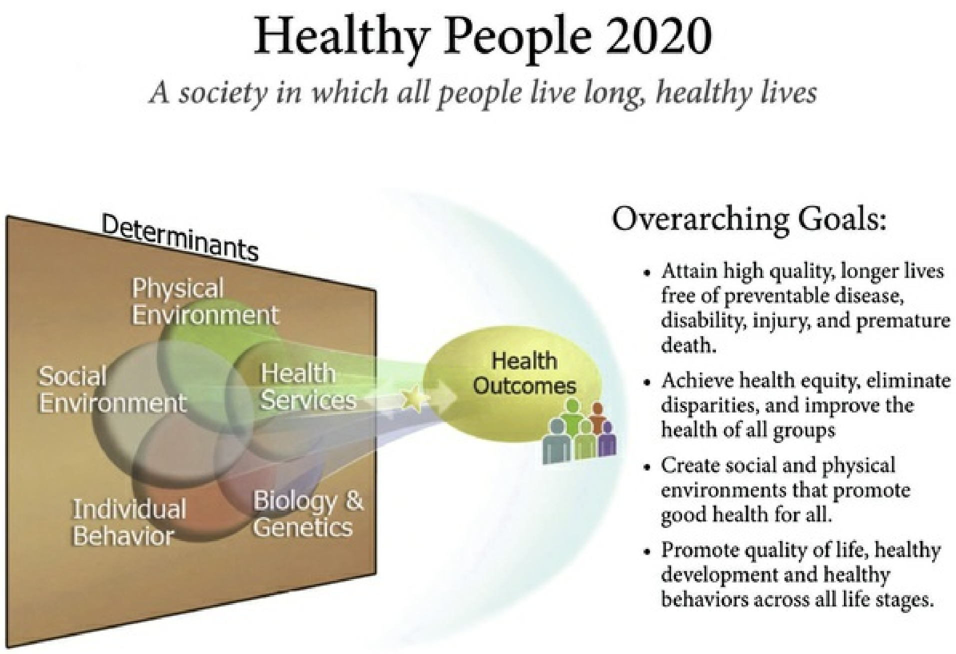

FIG 5.2 Determinants of health. (From Healthy People 2020. Washington, DC, U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion. http://www.healthypeople.gov/2020/about-healthy-people.)

The World Health Organization (WHO) has defined health promotion in this way:

[It is] the process of enabling people to increase control over, and to improve, their health. To reach a state of complete physical mental and social wellbeing, an individual or group must be able to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment.

Health is, therefore, seen as a resource for everyday life, not the objective of living.[93]

Health promotion encompasses both health protection and prevention of disease. **Health protection strategies** are targeted at populations and include control of infectious diseases, immunizations, protection from occupational hazards, and government standards for the regulation of clean air and water, sanitation, and food and drug safety, among other things.[22] According to Pickett and Hanlon,[47] **prevention** refers to "anticipatory action taken to reduce the possibility of an event or condition from occurring or developing, or to minimize the damage that may result from the event or condition if it does occur."[47] Prevention strategies can be categorized into three levels: primary, secondary, and tertiary.

- **Primary prevention** focuses on healthy individuals to decrease vulnerability or susceptibility to disease or dysfunction. Primary prevention strategies include good nutrition, regular physical activity, adequate housing, recreation and working conditions, periodic physical examinations, and seatbelt laws.
- **Secondary prevention** focuses on people at risk or in the early stages of disease, with the goal of arresting the disease progression and preventing complications and disability. Secondary prevention strategies include early detection and intervention, in addition to screening for chronic diseases such as cancer, coronary artery disease, and diabetes.
- **Tertiary prevention** focuses on individuals with disease or disability and attempts to prevent further complications, minimize the effects of the condition, and promote social opportunity. Tertiary prevention strategies include rehabilitation services and the removal of architectural and attitudinal barriers to social participation.[23,33,66]

Health promotion and prevention approaches attempt to reduce risk factors and enhance protective or resiliency factors. **Risk factors** are human characteristics or behaviors, circumstances, or conditions that increase the likelihood or predispose an individual or community to manifest certain health problems. Risk factors include not only physical conditions, such as hypertension and behaviors such as smoking, but also social, economic, and environmental conditions, such as poverty, homelessness, exposure to radiation, and pollution.[23,66] Research indicates that "it is usually the accumulation of risk rather than the presence of any single risk factor that affects outcomes, and that multiple risks usually have multiplicative rather than merely additive effects."[22] Protective or resiliency factors are human characteristics or behaviors, circumstances, or conditions that decrease susceptibility or increase an individual's or community's resistance to illness, dysfunction, or injury. Protective factors include not only an individual's genetic profile, personality, and health behaviors, but also peer and family relationships, social norms, and social support.[22,66]

Models of Health Promotion Practice

In the health promotion field there are a number of individual, interpersonal, and community models and theories of health behavior change.[62,63] Two models are presented here briefly to help the OT practitioner better conceptualize health promotion interventions. The transtheoretical model (also known as the stages of change model) was designed to facilitate individual health behavior change and is therefore extremely relevant to OT practitioners. The PRECEDE-PROCEED model is an approach to planning that facilitates the design, implementation, and evaluation of health promotion interventions.[30]

Transtheoretical Model

The **transtheoretical model (TTM)** is based on the premise that change occurs in stages. The model consists of six stages: precontemplation, contemplation, preparation, action, maintenance, and termination. *Precontemplation* is the stage in which the person has no intention of taking action to modify health behaviors. This may be due to lack of knowledge, previous failed attempts at changing health behavior, or simply a lack of motivation. The *contemplation* stage is characterized by intention to modify behaviors within the next 6 months, but with some ambivalence about the costs and benefits of doing so. The *preparation* stage is an indication that the person is ready to take action in the very near future (30 days or less) and has demonstrated some initiative to plan the change strategies, such as reading a self-help book, joining a health club, or talking to a healthcare provider. *Action* refers to specific overt manifestations of lifestyle modification. The duration of this stage is a minimum of 6 months. After 6 months of sustained health behavior change, a person is considered to be in the *maintenance* stage. The goal of this stage is to prevent relapse into previous unhealthy behaviors. *Termination* is the stage at which a person is no longer tempted and has a sense of self-efficacy that permits him or her to maintain healthy behaviors even in stressful, high-risk situations. True termination may be unrealistic for most behavioral changes, and lifelong maintenance may be the appropriate goal for the majority of people.[54]

According to the TTM, change occurs through "covert and overt activities that people use to progress through the stages."[54] These activities or processes of change include consciousness raising, dramatic relief, self-reevaluation, environmental reevaluation, self-liberation, helping relationships, counterconditioning, contingency or reinforcement management, stimulus control, and social liberation. The developers of the TTM discovered that each of these processes is more or less effective during different stages of change. For example, consciousness raising is critical in the precontemplation stage for the person to progress to the contemplation stage. Contingency management and stimulus control strategies are most useful in the maintenance stage to prevent relapse.[54]

PRECEDE-PROCEED Model

As mentioned, the **PRECEDE-PROCEED model** is used for planning interventions. It consists of nine steps. The PRECEDE portion of the model is based on the assumption that health behaviors are the result of a complex interaction of multiple factors.[31,32] In the PRECEDE framework, these factors are identified and specific objectives are developed for a population. The PROCEED portion of the model consists of policy development, intervention implementation, and evaluation.

The first five steps represent a comprehensive needs assessment that evaluates a number of social, epidemiologic, behavioral, environmental, educational, ecologic, administrative, and policy issues that might affect the development, implementation, and ultimate success of a health promotion intervention. After all these factors have been considered, the intervention is developed and implemented. The final three steps represent a comprehensive evaluation of the intervention, including process, impact, and outcome measures.[32]

PRECEDE-PROCEED has been used to plan, implement, and evaluate health promotion interventions in school, work, healthcare, and community settings. It has been used to address a number of health issues, including smoking cessation, prevention of infection with the human immunodeficiency virus (HIV), seatbelt use, driving under the influence of alcohol, nutrition, exercise and fitness, blood pressure control, and stress management,[32] in addition to depression and pain in individuals with rheumatoid arthritis.[45] Typically, interventions designed using the PRECEDE-PROCEED model address multiple risk factors and health behaviors and use multiple intervention strategies.

Occupational Therapy Involvement in Health Promotion and Disease Prevention

According to population health measures, persons with disabilities (PWDs) experience health disparities compared with individuals without disabilities. PWDs are more likely to have high blood pressure, use tobacco, be overweight, and experience psychological distress. They are also less likely to get the healthcare they need, have an annual dental visit, engage in fitness activities, or participate in health screenings.[59] The Healthy People 2020 goal in the area of disability and health is to "promote the health and well-being of people with disabilities."[59,76] Several objectives in this area are appropriate for OT intervention (Box 5.1). The objectives in Healthy People 2020 address both individuals with disabilities and the environments in which they function because it has been recognized that disability is the result of the interaction between individual limitations and barriers in the environment.[59,76]

Box 5.1

Healthy People 2020 Disability and Health Objectives

Barriers to Healthcare

DH-4 Reduce the proportion of people with disabilities who report delays in receiving primary and periodic preventive care due to specific barriers

DH-5 Increase the proportion of youth with special healthcare needs whose healthcare provider has discussed transition planning from pediatric to adult healthcare

DH-7 Reduce the proportion of older adults with disabilities who use inappropriate medications

Environment

DH-8 Reduce the proportion of people with disabilities who report physical or program barriers to local health and wellness programs

DH-9 Reduce the proportion of people with disabilities who encounter barriers to participating in home, school, work, or community activities

DH-10 Reduce the proportion of people with disabilities who report barriers to obtaining assistive devices, service animals, technology services, and accessible technologies that they need

DH-11 Increase the proportion of newly constructed and retrofitted U.S. homes and residential buildings that have visitable features

DH-12 Reduce the number of people with disabilities living in congregate care residences

Activities and Participation

DH-13 Increase the proportion of people with disabilities who participate in social, spiritual, recreational, community and civic activities to the degree that they wish

DH-14 Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs

DH-15 Reduce unemployment among people with disabilities

DH-16 Increase employment among people with disabilities

DH-17 Increase the proportion of adults with disabilities who report sufficient social and emotional support

DH-18 Reduce the proportion of people with disabilities who report serious psychological distress

DH-19 Reduce the proportion of people with disabilities who experience nonfatal unintentional injuries that require medical care

DH-20 Increase the proportion of children with disabilities, birth through age 2 years, who receive early intervention services in home or community-based settings

Modified from Healthy People 2020. http://www.healthypeople.gov/2020/topics-objectives/topic/disability-and-health/objectives

In the "Occupational Therapy Practice Framework: Domain and Process," third edition (OTPF-3),[3] the AOTA describes health promotion and prevention as appropriate intervention approaches for the profession:

Health promotion is equally and essentially concerned with creating the conditions necessary for health at individual, structural, social, and environmental levels through an understanding of the determinants of health: peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice, and equity.[59,75]

The AOTA embraces WHO's definition of well-being as a "general term encompassing the total universe of human life domains, including physical, mental and social aspects."[3]

Health promotion programming can assist individuals, families, and communities reach a state of wellness in their lives.[66] Wellness has been described as the "perception of and responsibility for psychological and physical well-being as these contribute to overall satisfaction with one's life situation."[11] OT practitioners facilitate wellness through holistic and client-centered health promotion practice.

OT involvement in health promotion and prevention can assume a variety of forms. For example, primary prevention could include providing education to workers regarding their personal risk factors for injury on the job (eg, poor body mechanics) or altering the environment to reduce the incidence of workplace accidents. Secondary prevention strategies in OT practice include joint protection, energy conservation, and work simplification techniques. Fall prevention programs and home safety evaluations for frail elderly clients are other examples of secondary prevention. OT practitioners are already experts in tertiary prevention because they provide services to maximize function and minimize barriers to occupational performance.[33,66] It is important that OT practitioners begin to engage in primary and secondary prevention to build the evidence for occupational therapy in health and wellness. One population that could benefit from all three levels of prevention is military personnel.[21] As the Affordable Care Act enables an increase in OT services, telehealth OT services in all areas of health promotion and prevention can also be enabled.[16,17]

OT practitioners who develop occupation-based health promotion and prevention programs should be cognizant of the literature in public health and use existing evidence on best practice. The American Public Health Association (APHA) developed standards for the design and implementation of health promotion programs that can guide OT health promotion efforts. These five principles include[9]:

- Addressing multiple risk factors that are measurable and clearly defined
- Focusing on the identified and expressed needs and preferences of the client or target population
- Including evidence-based interventions with demonstrated effectiveness
- Using client and community strengths and available resources
- Designing programs that can be sustained and evaluated

Health Promotion and Occupational Participation

Health promotion interventions assist in enabling people with disabilities to more fully engage and participate in society. According to Hills,[34] there are three "pillars and related assumptions" of health promotion: (1) the primacy of people, (2) empowerment, and (3) enablement.

All three of these constructs, especially the primacy of people, focus on what the profession of occupational therapy calls **client-centered care** or **client-centered practice**. The client-centered practice can be defined as "[an] approach to service that incorporates respect for and partnership with clients as active participants in the therapy process. This approach emphasizes clients' knowledge and experience, strengths, capacity for choice, and overall autonomy."[11]

It is this client-centered approach that is health promoting for individuals with physical disabilities. Respect for and involvement in decision making, particularly in occupational participation, is a foundational similarity in both health promotion and occupational therapy. Occupational therapists facilitate meaning and assist people in seeing a hopeful future through occupational engagement and **enablement** of participation. This focus helps foster optimal health and well-being for people with disabilities. There is increasing OT evidence for client-centered care and client-centered practice.[51]

Empowerment speaks to the development of autonomy and self-control. Occupational therapists are skilled at creating contexts and occupation-based interventions that support and facilitate the feeling of being empowered. Harlowe[33] stated, "To increase control over and to improve one's health, one must not only be empowered to do so but also able to do so. To be able, one must possess the requisite skills, resources and knowledge." People with impairments and disabilities and those at risk for impairment and disability can be knowledgeable about the need to change health behaviors that undermine the promotion of healthy living (eg, smoking); however, they may be lacking skills and resources to achieve optimal well-being. "The fundamental assumption underlying the notion of enablement," said Harlowe,[33] "is that people have capacity to identify their own needs, to solve their own problems and to generally know what is best for them."

To effectively promote health and well-being, occupational therapists should embrace the belief that people are capable of identifying needs and are able to problem-solve life challenges. A practitioner who implements client-centered approaches, rather than expert-centered approaches (those that come from therapists without inclusion of clients or their caregivers), empowers people with disabilities to view themselves as valued and contributing members of society.

OT Practice Notes

OT practitioners must begin to make a paradigm shift and transition from defining themselves as rehabilitation specialists, to specialists in occupation, health promotion, and well-being, using occupation to facilitate healthy living. By listening to the narratives of people with disabilities and engaging in client-centered evaluation and interventions, OTs and OTA can enable people with disabilities and chronic illnesses to maximize their quality of life and participation in society.[44]

Powers[53] has provided a glimpse into the lived experiences of people with disabilities and their perceptions of health and well-being. She believes there is a need to develop more models of health and wellness that specifically address the needs of people with disabilities. However, the models currently used, some of which were discussed earlier, do enhance the knowledge of health professionals regarding people with disabilities. Health and illness can and do coexist on a daily basis for people with physical impairments and disabilities. As Pizzi and Renwick have found:

Living healthy and well is not something new for people with disabilities. Currently, a stereotype exists that suggests people with disabilities are "sick" or are "perpetual patients" who cannot be considered "healthy" or "well." However, for years people with disabilities have used strategies to maintain health and wellness, created supportive relationships, and accessed needed resources from various service systems. It is from these resourceful people that health professionals need to be willing to continue learning about issues related to health, wellness and long-term disability.[52]

Secondary Conditions and People With Disabilities

Secondary conditions can be defined as "those physical, medical, cognitive, emotional, or psychosocial consequences to which persons with disabilities are more susceptible by virtue of an underlying impairment, including adverse outcomes in health, wellness, participation and quality of life."[34]

The term *secondary conditions* expanded the term *comorbidity*, which is often used in medical settings. However, the term secondary condition adds three dimensions that are not fully captured by the term comorbidity: (1) nonmedical events (eg, isolation); (2) conditions that affect the general population (eg, obesity, which has a higher prevalence among people with disabilities); and (3) problems that arise any time during the life span (eg, inaccessible mammography). Children and adults with disabilities can experience secondary conditions any time during their life span.[18]

OT practitioners can aid in the prevention of secondary conditions by increasing client awareness and patient education about health, healthy habits and routines, and strategies to offset increasing secondary conditions or other disability. In view of the increased rates of disability among youth, it is particularly important to target activities and services that address all aspects of health and well-being, including promoting health, preventing secondary conditions, and removing environmental barriers, in addition to providing access to medical care. For an older person with a disability, it is important to target worsening coexisting conditions that may intensify and thus threaten general well-being. For example, declining vision combined with declining hearing can greatly impair mobility, nutrition, and fitness; these impairments may intensify and thus threaten general well-being.[76]

Hough believes that a paradigm shift from disability prevention to prevention of secondary conditions is needed. After the inability to prevent primary disability, "it is within the environment that the negative effects of secondary conditions could be ameliorated and even prevented."[35] Public health agencies often focus efforts toward primary prevention, but secondary conditions need to be of equal concern. The emphasis on policy change and education of health professionals on health promotion for people with disabilities can help foster interventions toward self-management of one's disability.

Stuifbergen et al.[71] emphasized the need for health practitioners to integrate health promotion strategies into neurorehabilitation for people with stroke. Krahn[39] emphasized the need to encourage self-responsibility for health to promote health and well-being while living with a disability, whereas Rimmer[64] viewed health promotion as a means to maintain functional independence by preventing secondary conditions. Trentham and Cockburn[75] stated, "People with disabilities have increased health concerns and susceptibility to secondary conditions. Having a long-term condition increases the need for health promotion that can be medical, physical, social, emotional, or societal."

The development of secondary conditions and occupational impairments can be directly related to a person's mental health. The psychosocial aspects of physical disabilities are as important to identify and help ameliorate as the physical barriers to occupational participation.

People who have activity limitations report having had more days of pain, depression, anxiety, and sleeplessness and fewer days of vitality during the previous month than people who do not report activity limitations. Increased emotional distress, however, does not arise directly from the person's limitations. The distress is likely to stem from encounters with environmental barriers that reduce the individual's ability to participate in life activities and that undermine physical and emotional health.[75]

Exploration of a person's disability, in the context of his or her life situation, and the physical and emotional impacts of that disability on participation exemplifies OT practice committed to optimizing quality of life (QOL). QOL is an outcome of occupational therapy, as defined by the OTPF-3. QOL is "a person's dynamic appraisal of his or her life satisfactions (perceptions of progress toward one's goals), self-concept (the composite of beliefs and feelings about oneself), health and functioning (including health status, self-care capabilities, role competence), and socioeconomic factors (e.g., vocation, education, income)."[3]

Stuifbergen and Rogers[72] interviewed 20 individuals with MS who shared their stories about health promotion, QOL, and factors that affected these areas of health. They identified six life domains related to QOL, including family (most frequently identified domain), functioning to maintain independence, spirituality, work, socioeconomic security, and self-actualization. Six broad themes also emerged related to health-promoting behaviors. According to Pizzi,[48] these included exercise or physical activity, nutritional strategies, lifestyle adjustment, maintaining a positive attitude, health responsibility behaviors, and seeking and receiving interpersonal support. OT practitioners play a key role in helping people actualize QOL through interventions that include these themes. Physical disability does not translate to being unable to participate and experience a good QOL. The paradigm shift to promoting health, well-being, and wellness is necessary to optimize QOL.

Evaluation: Emphasizing the Promotion of Health and Well-Being

Evaluation of people with disabilities must include the life story or narrative of the person as elicited through careful occupational history taking. This occupational profile is coupled with physical, sensorimotor, social, psychological, and emotional assessments to create a holistic view of the person. The most important element in evaluation is incorporating the client's perspectives of health and well-being, in addition to his or her values, beliefs, and contexts of living experiences. Client-centered care promotes healthy views of living for the client and the family system, from the beginning of OT intervention through discharge.

The Pizzi Health and Wellness Assessment (PHWA)[50] is a subjective, occupation-focused, and client-centered assessment tool created for adults. It measures, both qualitatively and quantitatively, self-perceptions of a person's health and wellness in six different categories. It is an assessment that is not focused on the disability, but instead emphasizes the client's abilities and current levels of well-being. Collaboratively, the client and therapist work on strategies that the client identifies as health promoting for each area; the therapist uses clinical reasoning to problem-solve health issues related to occupational performance. A systems perspective was used during the development of this assessment. Thus, it is a useful assessment and research tool for clients and for caregivers of people with disabilities. For example, a caregiver may report additional burden achieving occupational balance of roles and occupations, in addition to the caregiving responsibilities. The caregiver could benefit from OT intervention to address identified needs, based on responses from the PHWA. (The assessment is available by contacting the chapter author Michael Pizzi at mpizzi58@gmail.com.)

Table 5.1 shows a number of assessments from a variety of disciplines that may be helpful to occupational therapists as they consider how to enhance their health promotion interventions with people with disabilities.[36] The purpose of this table is to encourage practitioners to seek resources outside the discipline that may increase options, to facilitate the end goal of enhanced participation in occupations. Inclusion of a tool in this table should not be considered an endorsement of the tool. Readers are encouraged to examine assessment tools critically in terms of reliability, validity, sensitivity, and practicability, in addition to possible training or certification requirements prior to use. Similar tables and lists of assessment tools that are more commonly used and known by OT practitioners have been developed both within and outside the field.[10,19] With all assessments and resources, the OT practitioner should review and consider the material before an assessment is selected for a specific client or client group. When chosen appropriately and used competently, assessments can be an important tool in implementing client-centered care.[41,46] Table 5.2 offers additional guidance and considerations for the selection of an assessment.[67]

Threaded Case Study

Jean, Part 2

For Jean, the PHWA could be used to evaluate the following:

- Occupational habits, routines, and patterns that may be barriers to general health (e.g., smoking, eating habits).
- Balance in daily life activity and barriers to fuller participation in occupation.
- Stress and psychosocial areas that may exacerbate cardiac insufficiency, increase smoking and eating problems, and create insulin imbalance (use stress and depression scales to help assess these areas).
- Physical versus sedentary activity levels and reasons for these activity patterns.
- Risk factors for development of secondary conditions related to her physical function and past medical history.

• Contexts for occupation including the current support system at work and at home. Caregiver assessment, especially level of support for Jean, can be crucial for health promotion programming.

TABLE 5.1

Selected Assessments for Use in Health Promotion Physical Disabilities Practice

Assessment Type	Examples
Adjustment scales	• Profile of Adaptation to Live • Social Support Questionnaire
Other well-being scales	• Perceived Well-being Scale
Arthritis	• Arthritis McMaster-Toronto Arthritis Patient Reference Disability Questionnaire (MACTAR) • Health Assessment Questionnaire (HAQ) • Arthritis Impact Measurement Scales (AIMS)
Back pain	• Disability Questionnaire
Cancer	• Karnofsky Performance Status Measure (KPS) • Functional Living Index: Cancer
COPD	• American Thoracic Society Respiratory Questionnaire and Grade of Breathlessness Scale
Depression	• Beck Depression Inventory
Diabetes	• DCCT Questionnaire
Family scales	• Caregiver Time-Tradeoff Scale • Family Hardiness Inventory
Hardiness scale	• Hardiness Scale
Health risk appraisals	• The Healthier People Network Risk Appraisal • 1999 Youth Risk Behavior Survey
HIV/AIDS	• AIDS Health Assessment Questionnaire
Heart	• New York Heart Association Functional Classification (NYHA)
Life satisfaction scales	• Kansas Family Life Satisfaction Index • Index of Life Satisfaction
Multiple sclerosis	• Expanded Disability Status Scale
Neurologic head injury	• Modified Sickness Impact Profile
Orthopedic	• Musculoskeletal Outcomes Data Evaluation and Management System (MO-DEMS)
Pain	• Medical Outcomes Study Pain Measures (MOS)
Quality of life	• Overall Life Status

AIDS, Acquired immunodeficiency syndrome; *COPD,* chronic obstructive pulmonary disease; *HIV,* human immunodeficiency virus.

TABLE 5.2

Organizing the Search for Assessment Evidence to Discuss With Different Decision Makers

Decision Maker	Decision Maker's Use of Evidence	Question Guiding Search for Evidence
Client and family members	To make informed decisions in choosing assessment procedures	Is goal attainment scaling a reliable and valid method for assessing personally meaningful goal achievement among 75-year-old men with Parkinson's disease?
Manager	To decide which assessment procedures should be supported and provided by the organization	What are the most reliable and valid methods for assessing personally meaningful goal achievement among individuals with Parkinson's disease?
Funder	To determine whether assessment procedures will effectively document important attributes of clients and their responses to rehabilitation	Same question as for manager

From Tickle-Degnen L: Communicating evidence to clients, managers, and funders. In Law M, editor: *Evidence-based rehabilitation: a guide to practice,* Thorofare, NJ, 2002, Slack, p 225.

Intervention

For people with disabilities, health promotion interventions are designed to optimize health status. One focus of these interventions is to help prevent secondary conditions from occurring and thus help people with disabilities maintain a level of well-being that allows them to engage in meaningful life roles. The Framework identifies six areas of focus for intervention: (1) areas of occupation, (2) performance skills, (3) performance patterns, (4) context(s) or physical environment, (5) activity demands, and (6) client factors.[3] All these areas affect each other, and, in turn, affect occupational performance and participation.

Interventions to promote health and well-being are implemented with consideration of all these areas. Five approaches to intervention are listed in the Framework. Although they all can relate to health promotion, the Framework specifically links the "create, promote" approach[3] to health promotion. The Framework indicates that this approach "does not assume a disability is present."[3] It can be used with people with occupational impairments and disability, as it is "designed to provide enriched contextual and activity experiences that will enhance performance for all persons in the natural contexts of life."[3]

As stated earlier, a paradigm shift in practitioners' therapeutic reasoning is needed for them to understand that health, wellness, and disability can be comingled and that interventions to promote healthy living with a disability are vital for a person with disability. Although the intervention approach of create or promote is most closely related to health promotion, the other four approaches (ie, establish/restore, maintain, modify, and prevent)[3] are all related to the creation of healthy lifestyles and well-being. They also should be considered potential approaches for the restoration and promotion of health for individuals with disabilities.

Often, such work is more successful when performed by a multidisciplinary team. An excellent example of a multidisciplinary program that uses several of the approaches discussed previously is the MS Care Center at New York University's Langone Medical Center.[37]

Threaded Case Study

Jean, Part 3

Jean's case shows how a health promotion approach for a person with disability can be implemented. In addition to standard OT services, a health promotion approach might be appropriate for this client or her family.

- If Jean's occupational habits, routines, and patterns are maladaptive and are barriers to healthy living, then patient education around developing healthy habits (including how her habits can result in further medical complications) should be implemented.

- An imbalance in occupations and occupational performance can contribute to the exacerbation of stress and to cardiac issues and can affect insulin production. Increasing Jean's awareness of the need for balance in daily life, including a balance of work, play, rest, sleep, and leisure, can assist her in creating a new structure for her daily living and optimizing her quality of life.

- Stress, depression, and other psychosocial factors can exacerbate preexisting conditions and lead to inactivity, poor self-esteem, and eventually poorer health. Client-centered care that incorporates meaningful and interesting occupation relevant to the person can help offset psychosocial conditions. Areas of concern could be feelings of worthlessness or ineffectiveness because one cannot occupationally engage in meaningful life activity. Jean may experience these issues because of her limited (and potentially limiting) medical condition. Exploring the impacts of stress, depression, and other factors on occupational performance and creating new occupational strategies for Jean can improve occupational performance and lead to Jean developing a future that includes "preventive occupations"—in this case, preventing further or future depression and managing her stress.

- After Jean's activity levels have been assessed, occupational interventions that promote a healthier heart, decrease smoking and overeating, and improve general mental and physical fitness are primary for her. Once Jean is aware of her abilities and develops a knowledge based on her real and perceived levels of activity, the OT practitioner can help her modify and adapt her lifestyle to incorporate activity that optimizes mental and physical health. It is important for Jean to optimize health for both present and future occupational performance in multiple contexts.

- Interventions must include measures to prevent the development of secondary conditions. For example, Jean has developed the warning sign (transient ischemic attack [TIA]) of potential future stroke. Preventive occupations can include increasing walks outdoors by 5 minutes each week to reach a daily target of 30 minutes maximum, working with an OT practitioner to help decrease smoking and overeating habits, or developing a stress management program. These health promotion ideas can be habituated in the acute care and home care settings and followed through by Jean and her loved ones.

- Caregiver support is critical for implementing and following through with a health promotion program. In Jean's case, she requires strong support to help her recognize and prevent future health problems (eg, reminders, environmental and verbal cues, ongoing education). She also will need support with smoking cessation, developing healthy eating (and cooking) habits, and increasing optimism for a healthy and bright future.

Summary

Readers were introduced to health promotion, well-being, and wellness terminology within the context of physical disability practice. The power of symbols was explained, and the roles of important constructs (eg, occupational justice) and the principles and practice of health promotion in helping to support best practice were demonstrated. Although practitioners have long promoted optimal health for clients of all ages, there has been little discussion about theoretical foundations for evaluation and intervention in health promotion. The OTPF-3 is a helpful guide that can assist practitioners in bridging gaps in service delivery and integrating health promotion into everyday practice. Through the Framework, the AOTA emphasizes occupational engagement and participation in life as the means to health and **wellness**, **quality of life**, and **well-being**. OT practitioners create and promote healthy living through careful attention to the physical, psychosocial, spiritual, social, and emotional abilities and challenges that support, or serve as barriers to, occupational performance. Holistic evaluation and goal planning using a client-centered approach should include health promotion goals that are codeveloped by the client and the practitioner.

Engagement in occupation to support participation in context is a key focus of the Framework. A health promotion approach enhances awareness of barriers to health and wellness, and strategies are developed to optimize health and well-being and prevent future health problems. Risk factors are considered, and interventions are implemented to support participation while a new lifestyle that is meaningful to the client is created. Client factors, although important to address to optimize occupational performance, are integrated into a top-down approach to care when a health promotion program is provided. In the case study, Jean can engage in a physical activity program designed to improve her cardiac status while she develops strategies to control her pain and discomfort (which are the secondary complications of her diabetes) as she works to decrease or cease smoking. If Jean decreases or stops smoking, this also will have a positive impact on the overall health of her family, especially her grandchildren, by decreasing or removing the health risks of secondary smoke exposure.

As practitioners learn more about health promotion, prevention, and wellness, they will be better equipped to promote healthy living within the context of a person's lifestyle. Client-centered and occupation-centered care that includes health promotion and focuses on the whole person living with disability can be occupational therapy's unique contribution to humanity.

Review Questions

1. Consider the importance of symbols. Do you think the current international symbol for accessibility is inclusive of all individuals with physical disabilities? Why or why not? Sketch an alternative symbol.
2. Describe the historical relationship between social activism and occupational justice for individuals with disabilities.
3. Identify an objective from Healthy People 2020 to support a new health promotion program you want to develop for your client group.
4. Describe the determinants of health as identified in Healthy People 2020 and discuss how occupational therapy can address these determinants.
5. Identify the levels of prevention, and give examples of potential occupational therapy interventions at each level.
6. Choose a health behavior of interest and describe the stages of change associated with that health behavior using the transtheoretical model.
7. Discuss how OTs and OTAs can facilitate resiliency for their clients with disabilities.
8. How would health promotion approaches fit within the Occupational Therapy Practice Framework?

Personal and Social Contexts of Disability

Implications for Occupational Therapists

Sandra E. Burnett *

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Describe the philosophy of the independent living movement and compare and contrast its view of the medical model and the social model of disability. Also, discuss the implications of the independent living movement philosophy in occupational therapy practice.
2. Describe the personal context of the disability experience, noting the effects of individual differences, gender, type of disability, interests, beliefs, and stage of life. Also, explain the usefulness of the stage models of disability adaptation.
3. Describe the social context of disability using the concepts of stigma, stereotypes, liminality, and spread. Also, discuss the effects on social context of person-first language, the culture of disability, and universal design principles.
4. Describe the ways the *International Classification of Functioning, Disability and Health* (ICF) challenges worldwide, mainstream ideas of health and disability.
5. Discuss various relationship issues between the occupational therapist and the person with a disability.

KEY TERMS

Devaluation

Independent living movement

Liminality

Medical model

Person-first language

Social model

Spread

Stereotype

Stigma

Threaded Case Study

Angela, Part 1

The following case study is a first-person account by Angela More, who describes her experience of living with a severe physical disability that she acquired as an infant.[63]

In Western society we live in an environment where image is valued and sought after. Acquiring spastic cerebral palsy through no fault of one's own directly challenges and contradicts this. We tend to base our judgments of other people on the way they "look" before we even speak to them or get to know them. For many centuries Western society has valued and aspired to having the "perfect" image and body shape.

The children's nursery rhyme "Humpty Dumpty" illustrates that as far back as the 1600's when something was broken people felt there was a "need" to correct the damage and fix the problem. Maybe "Humpty Dumpty" was an obese person who fell off the wall, maybe he was an intoxicated soldier, maybe it was a name of a large cannon that was sitting on the wall of Colchester … which was set up to protect the city. No matter what the situation, the reader is left with a feeling that whenever there was something wrong with Humpty Dumpty, there was a need to correct the error *and fix what was broken. Because he was "different" or "not normal" in one way or another he was not valued for his role by members of his local community. The reader is left to form his or her own opinion. Society continues to hold those views to this very day.*

I am a secondary emergency teacher, have completed a Masters in Special Needs along with having a permanent acquired physical disability, spastic cerebral palsy, affecting my four limbs. This was caused after an initial medical examination was "botched" by an unsupervised intern—the specialist left the theatre during the procedure when I was 14 weeks of age, over forty years ago. Further medical testing was arranged because there was a belief that I may have had hydrocephalus—swelling and excess fluid buildup around my brain causing it to be unnecessarily enlarged for my age. In my family's case this seems to be an hereditary trait that has passed from my father who has a large head. It's interesting to note that an obstetrician made a comment to my sister on the size of her toddler's head. Since 1970 I have had a range of both positive and negative medical experiences. As a child who wasn't able to comprehend what and why things were happening I was very frightened and often very upset. As an adult I am able to understand what and why something is going on and I ask questions when needed.

"Normal" has always been completing the same things but in a different way to other people while intending to reach the same outcome of "success." There are many ways to skin a cat and "normal" is a term that has a very broad definition which is dependent upon the individual and the situation at hand. What is "normal" for me will be "different" for someone else. What is "normal" for another person will be "different" for me. It's the differences between individuals that we come to value later on in life. That I cope in a different manner from others has clearly been aided by being able to make use of information technology—laptop, mobile phones, printers, etc.—along with a feeling that the acquired physical disability that I have is a small part of the overall person that I am. Before I became a person with an acquired disability I was a normal, happy, healthy baby and even now although I will always have a disability I have excellent health and choose not to be defined by having acquired a disability. Unlike some other people I consider myself to be a person who "acquired" a disability instead of being a "disabled" person. Having an acquired physical disability is a small part of the person I am. The manner in which I acquired a severe physical disability is what I have come to value along with the fact that I have done well in many areas of life while having such a severe condition.

Unlike people who had disabilities in the 19th century who were not given such an opportunity, I have the opportunity to participate freely in society. Traditionally people who had disabilities in Europe during early 20th century (1930's) Germany were considered along with those who were Jews, gypsies or homosexuals to be "pseudo humans" … who were considered to be the "deserving poor" who were "appropriate objects for pity, protection and charity" … who were deliberately excluded. They were seen as "victims" who were different and were segregated from their local communities because the view was held that they had nothing to offer and were feared as they were often controlled by copious amounts of medication.

The Medical Model of Disability, which operated until the mid 1970's in Australia, maintained the view that people who had a disability needed to be "cured and cared for" … which automatically disempowered and disengaged them within their own communities. The Medical Model of Disability defined an individual by his or her disability and sought to control the person's access to medical care, education, employment, housing and leisure. At no stage did this Model of Disability provide families with any notion of "hope" for their member who had the disability and usually painted a very black and bleak picture for their future outlook.

Medicine still doesn't offer a lot of hope for people with conditions as serious as spastic cerebral palsy. Traditionally on medical advice individuals with severe physical disabilities were admitted to fully serviced institutions where all of their physical needs were met within the one facility away from their families and the general community, which reinforced the "stigma" of fear and difference. Once admitted to such institutions it was uncommon for people to leave them. It wasn't until after the days of deinstitutionalization that people with disabilities formed self-help groups, started to seek and exercise their rights to equal opportunities, and commenced making a contribution to the local communities in which they lived. In Australia, this took place during the late 1960's and 1970's and was supported through the choice that my parents and others in similar situations made when they chose to keep their disabled children within the family unit even though they were advised to "leave the baby" in a hospital as it would be likely to die a natural death sooner rather than later.

As a small child I can clearly recall not a lot of "hope" offered from medical professionals for my own lifelong outcomes and now it's interesting to think that no one has ever really taken a look back to see what I have accomplished. From a medical point of view as a young child I [was] able to recall there were many appointments, a few operations, living with the label "Disability" 215 and very intense physiotherapy performed by my mother up until the time of puberty when my family was told that there was not a lot more that could be done to improve my situation. At one stage later on I did make inquiries into having my hands straightened but didn't follow it through when I was told they "would look better but wouldn't function any better." There was not much point in going through major surgery for little or no improvement. Apart from that I have never been the type of person who has sought to "doctor shop" to try and find a way of improving my physical being.

Nine months ago after walking in off the street for a mammogram one afternoon it was found that I had early stage breast cancer. As a result of this diagnosis I had a mastectomy and am about to complete my 6th and final round of optional chemotherapy as a preventive measure. I had all the necessary tests completed which included a CAT scan which came back clear, a bone scan which was clear, my heart checked, many blood tests, a port put in my arm to prevent my veins from deteriorating under a local anesthetic in addition to any other necessary treatment. Radiation therapy was very quickly ruled out as an option because I am unable to raise my left arm above my head. This rather suited me because I would not be at all comfortable being on a bed that needed to move in and out of the radiotherapy machine.

Having these tests completed reinforced to me that the disability I acquired was exactly that—acquired—through an unnecessary chain of events. My health has been excellent for over forty years and having spastic cerebral palsy hasn't affected it. With no history of cancer in my family it has been like dealing with the great "unknown" on so many levels but as an adult I am determined to exhaust all of my options in order to overcome this. At the time when the initial diagnosis was made I was extremely concerned about the effect surgery and treatment would have on my disability. Fortunately I needn't have worried because there has been no effect at all. In addition the surgery took place on the same date 42 years later. The surgery went well and I was discharged within two days of the procedure and made a good recovery before starting chemotherapy. I did smile when both the surgeon and anaesthetist were quick to inform me separately that "there was a product available now called Botox …" that may get my left arm to be able to form a fist. Quietly and confidently I reminded them both that I was there to be treated for breast cancer and although I appreciated their thoughts I had accepted my disability many years ago. The surgeon the following day commented on my "constructiveness." I smiled and thought why fix what isn't broken. It would have been different if I had gone seeking treatment to fix the disability.

While I was extremely shocked at being diagnosed with a serious health condition at a young age I *feel very fortunate that this was able to be picked up and treated quickly. While what has taken place in one sense seems extreme, as a preventive measure I feel it was the way to go. In a country like Australia I had gone from being outside the health system to front and centre within eight days. In some other parts of the world such diagnostic testing is simply not available let alone treatable. One would simply die and the cause would not become known until an autopsy was completed.*

There were many falls, many tears and major fears as a young child. However, as an adult, while there are still some occasional falls I consider myself to be in a good position because I understand what event took place on a particular date and the reason why it happened. Presently having no hair my scalp bears testament to the number and severity of falls that I had as a child by the scarring that is clearly visible. I know where the incident happened and understand that no one in their right mind would wish to inflict this type of disability onto a small and innocent baby. While it's visual and one can clearly see that there is a problem I consider it to be but a small part of the overall person that I am and how I perceive it determines how other people in turn perceive it to be.

Over forty years I really haven't had a lot to do with the healthcare system as a result of acquiring spastic cerebral palsy because I chose to accept it and not fight it. I haven't sought to be cured or fixed. I am still a daughter, sister, aunt, sister-in-law, teacher, cousin, niece, friend and neighbour regardless of what state of health my body is in. As long as I am relatively healthy I will always be happy and contented with life.

Critical Thinking Questions

1. How does Angela describe society's view of normalcy and difference in comparison with her view?

2. What impairment-based difficulties and participation restrictions are described?

3. Discuss Angela's use of language about herself.

Moore, Angela. A medical mishap. Narrative inquiry in Bioethics 3:3, 213–216, 2013, Johns Hopkins University Press. Reprinted with permission of Johns Hopkins University Press.

Throughout its existence, the profession of occupational therapy (OT) has promoted independence and self-direction for those whose lives include the experience of disability. The current Occupational Therapy Practice Framework (OTPF-3) supports this long-held value, declaring that the overarching goal of OT is “achieving health, well-being, and participation in life through engagement in occupation” (OTPF-3, p. S4).[5] Since the mid-1970s, the **independent living movement** has gained both scholarly and public support in its efforts to promote the same end goal. It has transformed both the models of disability and the ways we think about disability. Depending on how OT practitioners (as members of the healthcare and rehabilitation team) and independent living movement activists (composed primarily of leaders with disabilities) interact, the result can be a marriage of commonly held goals, or a battleground of cross-purposes. This chapter describes the ways OTs may approach a call for accord with independent living activists.

Social scientists, such as Irving Zola, who had both high academic, scholarly credentials and personal experience with physical disability, began an infusion of their work into the rehabilitation and social program literature in the early 1980s. Two of Zola's books, *Missing Pieces: A Chronicle of Living with a Disability*[102] and *Ordinary Lives: Voices of Disability and Disease,*[103] provide an insider's discovery of the unspoken-of social experience of disability that had been concealed in plain view. Zola's field notes chronicle a discovery self-framed within the social status of the researcher having a physical disability that others could easily see. For many who were also drawn to the independent living movement, it was the proverbial elephant in the room, finally acknowledged in their professional lives.

The independent living movement, which achieved public recognition in the early 1970s, is a political social justice, civil rights challenge to prior disability policy, practice, and research.[23] It is aligned with other minority groups (eg, race, gender, ethnicity) in a call for equality in the dominant society, a civil rights movement founded on the idea that the difficulties of having a disability are primarily based on the myths, fears, and stereotypes established in society today.[80] This movement seeks to modify the convention of habilitating the isolated individual with disability through social and environmental changes.[80] A major political achievement was passage of the Americans with Disabilities Act (ADA), which was signed into law in 1990, and the enactment of the ADA Amendments Act of 2008 (and subsequent partial amendments in 2010 and 2011) (see Chapters 2 and 15). The ADA's broad definition of disability emphasizes that perhaps the most significant factor people with various disabilities have in common is the experience of disability-based discrimination.[37,38] This civil rights movement has had its share of detractors, including representatives of the healthcare industry, but it has sustained an expansive momentum.[42]

The social justice movement successfully entered the international arena on May 3, 2008, with the United Nations' Convention on the Rights of Persons with Disabilities (CRPD). The CRPD treaty obligates the UN member nations that sign it to provide equal access to healthcare and related services for people with disabilities; it represents the first legally binding international instrument that specifically protects the rights of persons with disabilities. The UN has estimated that 1 billion people (residing in 1 of 4 households) have at least one disabling condition.[31] The CRPD is also the first treaty in which nongovernmental organizations were present during negotiations and could offer interventions. People with disabilities participated as members of organizations for persons with disabilities, delegations from many countries, and UN organizations. Partly because of this inclusive process, the CRPD has received wide support, and as of 2016, 157 countries had ratified it.[31]

The core principles of the CRPD are respect for human dignity, nondiscrimination, full participation, social inclusion, equality of opportunity, and accessibility.[86] The American Occupational Therapy Association (AOTA) is in full agreement with this focus. The AOTA's "Occupational Therapy Practice *Framework: Domain and Process*," third edition (OTPF-3), the current form of the Framework, emphasizes these two points:

- The relationship between occupation, justice, and client-centered practice is increasingly a focus of the OT profession.[5,15]
- Occupational therapy proclaims the necessity and power of occupation in the everyday lives of all human beings. The disruption and return of occupation for those with disability is our therapeutic focus. Health is supported and maintained when individuals are able to engage in their valued occupations. Occupation always occurs within the context of interrelated conditions that will affect client performance.[5,15]

The occupational therapist must recognize that the social environment and personal context of disability are inextricably intertwined in the lived experience of those with disability, and this must be taken into consideration when finding ways to facilitate engagement in occupation. This chapter seeks to illuminate these contexts so that valued goals are achieved.

Client-Centered Self-Report

A justified complaint by those who have found their voice in the independent living movement is that medical and rehabilitation professionals focus on an attempt to classify the individual with a disability and do not listen to the client's personal account.[48,68] The medical rehabilitation tradition of case presentation seeks to frame the individual with the disability in the professional's point of view. There can be numerous goals for a “case” description: treatment justification, entitlement to support services, legal testimony as an expert witness, reimbursement of costs, social science research, educational process, and the like. The role of the OT is to work with the client to achieve an individual desired outcome.[89] Occupational therapists are called to create a client-centered description of the individual's occupational self, one that must include the interrelated conditions of the social and personal contexts both surrounding and within the client. We must include the personal view of the client's own context to frame an accurate occupational picture that is responsive to the individual's values and goals.

Personal Context

Disability Experience

People who acquire disability share the common experience of feelings of shame and inferiority, along with avoidance of being identified as a person with disability.[98]

Neuroscience research, using state-of-the-art brain imaging, has confirmed what biological, psychological, and sociologic studies and theories have proposed; chiefly, that humans are social beings, and a neurological response at the most basic physiological level is evident when conditions of social interaction are varied.[2] In short, we are drawn toward interaction with "our kind," and isolation from others may be deemed socially abnormal.

Community psychologists note that the individual forms an identity in relation to the social environment. For those who deviate from societal-based norms, problems arise when individuals are assigned an identity and a status that is demeaning and lacks elements of personal choice and human rights.[72]

A commonly experienced effect of having a disability is the social stigma associated with all individuals with a disability, regardless of the condition.[92] The psychological effects of being labeled a "disabled individual" is considered to be the process of **devaluation**. To be continuously perceived as an individual "blemished" in form or function is psychologically demeaning, regardless of the nature of the individual condition.[92] The broadness of the term *disabled* imbues each individual with a disability with characteristics that are outside the norm.[92]

The individual with a disability must attend to an array of stimuli perceived as abnormal: some biological (eg, paralysis); some environmental (eg, inaccessible entrances); and some social (eg, the patronizing behavior of others or preferential access to an event). It is a continuous flow of perceptions, which are not experienced by those who are not disabled. In short, many of the experiences of an individual with a disability are not shared by the normative society. Isolation and a lack of accord with one's thoughts and feelings compound the list of nonnormative situations.[92]

In defining the experience of disability, social scientists[92] and psychologists have constructed what can only be described as the psychology of disability. Of interest, however, is that exploring the differences inherent in the social experiences of individuals with a disability may result in exaggerations that widen the gap in perceived differences from the social norm. Thus, devaluation of the individual with a disability may be perpetuated by those seeking to understand and even modify the conventional social perceptions. The fact is, human beings are more alike than different, regardless of variances in their physical bodies, sensory capacities, or intellectual abilities.[14]

It has been suggested that individuals with a disability shape their personal identities and social conception from their personal experiences through the modes of nonconformity and the outcomes of interactions with others in society. Specifically, if the individual considers his or her situation as nonconformative, it is due to the imposition of external societal factors and not a symptom of a condition.[84] What is actually known about the similarities and differences between people with and people without disability? Siller[84] reported that as soon as one departs from the direct fact of disability, evidence can be provided to demonstrate that people with disabilities do or do not have different developmental tracks, social skills and precepts, defensive orientations, empathetic potential, and so on. The data suggest that if people with disabilities do present themselves as different, it is often a secondary consequence of the social climate, rather than of inherent disability-specific phenomena.[84]

Another study reported that a group of people with disability showed no differences in life satisfaction, frustration, or happiness compared with a group without disability.[94] The only difference found was on ratings of the difficulty of life. People with disability judged their lives to be more difficult and more likely to remain so. For example, people with chronic but not fatal health problems may not only seem to be quite happy, they also may derive some happiness from their ability to cope with their difficulty. We may question the assumption that physical limitations are directly related to happiness. Instead, many people with disabilities may find happiness despite their disabilities, even though the able-bodied public may expect otherwise.

Individual Differences

Social scientists have observed that an individual's reactions to having a disability are influenced not only by the time of onset, type of onset, functions impaired, severity and stability of the disability, visibility of the disability, and experience of pain; they also are affected by the person's gender, interests, values and goals, inner resources, personality and temperament, self-image, the activities affected, and environmental factors.[92]

This observation is supported by Angela's first-person narrative in the case study: "'Normal' has always been completing the same things but in a different way to other people while intending to reach the same outcome of 'success.'"

Vash and Crewe[92] believed that different disabilities (eg, blindness, paralysis) generate different reactions because each creates different problems or challenges. However, the insider-outsider perspective also applies to people with disability. Thus, the person with a disability may feel that his or her condition is not as difficult as that of others. For example, a person who is blind may feel that it would be worse to be deaf. This idea has also proven to hold for the severity of the individual condition. A person with the inability to walk may have the view that this disability is not nearly as difficult as having no legs. Reactions are also tempered by the impact of the disability on the valued skills and capacities the person has lost. For example, a person who loves music more than the visual arts, such as photography, may have a stronger reaction to loss of hearing than a person who had a more dominant inclination with another sensory channel (eg, a "visual person" with the opposite pattern). Similarly, the severity of disability may not have a direct, one-to-one relationship with the person's reaction to it. (Note the use of the word *may* throughout this paragraph, indicating that reactions are individualized and unpredictable.)

The visibility or invisibility of impairment may influence a person's response to his or her disability because of social reactions. For example, invisible disabilities, such as pain, may create difficulties because other people expect the person to perform in impossible ways. One woman with arthritis indicated that it was easier for her to go grocery shopping when she wore her hand splints because then her disability was visible and people would carry her packages for her without her having to ask.[92]

The stability of the disability or the extent to which it changes over time may influence reactions both for the individual with a disability and for those surrounding him or her. In some progressive disabilities, the individual faces uncertainty as to the degree of limitation and, in some cases, the likelihood of a hastened death. Reactions to such disabilities are shaped by these realities and by what the affected people tell themselves about their projected futures.[92] When hope for neither containment nor cure is substantiated, the person may experience a new round of disappointment, fear, or anger. The prospect of a terminal condition can affect each person in individual ways. Some individuals may ignore even the experience of pain, which tends to overtake consciousness. Reactions to pain are highly influenced by culture. Particularly important for occupational therapists is the issue of finding and implementing resources to assist the client in developing effective and gratifying lifestyles. The occupations, activities and performance patterns affected by a disability become the focus of the OT. Core issues addressed by the OT must also include the individual client's spiritual or philosophical base (ie, what fulfills the individual).

Gender has also been found to elicit some of the most problematic issues for clients in their relationships with others. Gendered societal expectations dictate that individuals strive to achieve often idyllic sexual roles. For example, the ideal for women to be physically perfect specimens or to carry the major responsibility for managing the home and caring for children may be of more concern for a female client than a male client.

Temporal elements of activity are part of the impact of disablement. The ways the disability interferes with what a person is doing, with the interruption of ongoing activities, will influence the individual's reactions. Activities never done but imagined as future goals may be equally powerful influences in the person's reactions.

Interests, values, and goals influence a person's reaction to his or her disablement. The individual with a limited range of interests may react more negatively to a disability that interferes with or prevents pursuit of these interests, whereas an individual with a wide range of interests and goals may adapt more readily. Many people may not even be aware of their own interests, values, and goals and therefore may not be conscious of the ones that have the potential to lead to satisfaction after acquiring a disability. Thus, the client with multiple interests, occupations, activities, and goals has a greater probability of achieving satisfying participation in life through engagement in occupation. The resources that the individual possesses for coping with and enjoying life are assets that may counterbalance the devastation of loss of function. Some of these, such as social skills and persistence, may be developed to a level enabling paid employment, whereas others, such as artistic talent or leisure skills, may contribute to a more satisfying life.[92]

An often overlooked aspect of the individual with a disability is the importance of spiritual and philosophical beliefs in dealing with the disablement. People who acknowledge a spiritual dimension of life and who have a philosophy of life into which disablement can be integrated in a meaningful, nondestructive way may be better able to deal with having a disability.[92] Specific religious beliefs may or may not be helpful. A study of life after a stroke among African Caribbean women in the United Kingdom described a tension involving three elements: between religious beliefs and faith (resignation to "God's will") and the medical approach to stroke (following medical rules for healthy living); and the potential benefits that religion and church play in stroke recovery.[64] The person who views having a disability as punishment for past sins will respond differently from one who views the disability as a test or opportunity for spiritual development.

The OT must acknowledge the importance of the person's environment in influencing his or her reactions to having disability. Immediate environmental qualities, such as family support and acceptance, income, community resources, and loyal friends, are powerful contributors. If a client is hospitalized, the institutional environment also has a profound effect, especially the attitudes and behaviors of the staff members. The culture and its support (or lack thereof) for resolving functional problems or protecting the civil rights of people with disability are other significant influences.

Stage Models of Adjustment to Disability

The medical model generally provides the medical rehabilitation team with a four-stage process of adjustment or adaptation to the experience of disability (Box 6.1).[65]

Box 6.1

Medical Model

Four Stages of Adjustment to the Experience of Disability

Stage 1: Vigilance

Becoming engulfed at the initial point of injury or acute illness. Within the intense, immediate crisis of the event, many individuals report a separation of the subjective and objective body. They experience an internal state of calmness contrasted with outward behavior of extreme distress and screaming in response to severe pain. This stage ends when the person surrenders to the care of others, often emergency medical personnel.

Stage 2: Disruption

Taking time out, a disruption of reality, often described as feeling as if one is in a fog. Significant others do not merely provide emotional support, but also serve as an orienting force in an otherwise confusing, chaotic environment. They serve as an emotional anchor in a disordered world of the acute care medical environment.

Stage 3: Enduring the Self

Confronting and regrouping, improvement in reality orientation with the implications of the injury recognized. This is the stage in which the severity of the physical limitations is faced. Support from others is needed to control a sense of panic and fear of the diminished physical ability. At this stage even small gains witnessed in therapy sessions are interpreted as evidence that a full recovery is possible. This preserved sense of hope for reclaiming previous abilities may help the person endure the initial healing process for burns, amputation, and spinal cord injuries by allowing the individual to hold onto his or her faith in medical miracles and the ability to return to prior physical ability.

Stage 4: Striving to Regain the Self

Merging the old and new realities is a process marked by frustration in the attempts to regain previously taken-for-granted tasks (eg, walking and feeding oneself) through the use of compensatory methods. There is a feeling of exhaustion in developing new routines, frustration with the limited physical capacity to participate in a range of activities, and a need to reformulate goals.

Adapted from Morse JM, O'Brien B: Preserving self: from victim, to patient, to disabled person, *J Adv Nurs* 21:886, 1995.

Evidence exists only for emotional distress, which is commonly experienced as an initial response that tends to diminish over time; however, even that is not a universal experience. Rehabilitation researchers are turning to a far more complex process involving changes in the body, body image, and self-concept, and the interactions between the person and the environment. For example, little attention has been given to individual personality differences (ie, personal context), which are well recognized as contributors to all human endeavors (eg, work, marriage, play, education, and occupations) expressed in an environment. Rather, the disability has been seen as the sole determinant of the individual personal experience.

The terms *adaptation, adjustment,* and *acceptance* are commonly applied to the process of resolving the negative experiences of having a disability. In recent years, social scientists aligned with the social model of disability have questioned the usefulness of such terms. They point out that service professionals have become preoccupied with the psychological loss, or stages of bereavement, process to describe appropriate adjustment by those with an impairment. The studies usually cited, which involve a four-stage process of psychological adjustment and rehabilitation applied to those with a spinal cord injury, are troublesome for the social model scientists.[8,9] That process is usually thus: the initial reaction of shock and horror is followed by denial of the situation, leading to anger at others, bargaining, and finally to depression as a necessity for coming to terms with the acquired impairment. The acceptance, or adjustment, process takes 1 to 2 years to resolve.[8] The process draws from Kübler-Ross's seminal work describing the grief process, the stages of loss of those who are dying, with an implicit assumption that the former, nondisabled self is dead and must be mourned.[50]

The **social model** views the notion of adaptation, adjustment, or acceptance within an unjust society as abhorrent at the most basic level of human rights and social justice. Other minority groups have not tolerated such treatment in democratic societies, and disability rights activists believe that those with disabilities should not, either. They point to a major flaw in these stage models: what about the physical condition that is progressive in nature (eg, multiple sclerosis, rheumatoid arthritis) or limiting; physical changes as the body ages associated with lifelong disorders (eg, spina bifida); or early in life trauma (eg, spinal cord injury, or post-polio syndrome)? The stages of loss concept, common in the medical model, offers little to community-based occupational therapy, which more typically addresses the problems of chronic or progressive disability. Some might say that the stage of loss concept, at best, suits the emotional needs of clinicians to have a sense of closure and resolution as patients move out of acute medical rehabilitation.

Social Model of Disability

There has always been tension between the medical model of disability, which emphasizes an individual's physical or mental deficit, and the social model of disability, which highlights the barriers and prejudice that exclude people with disabilities from fully engaging in society and accessing appropriate healthcare (see Chapter 2). Unfortunately, one of the biggest barriers to accessing appropriate healthcare is the attitude of health professionals, which might further isolate and stigmatize people with disabilities. Despite what many health professionals might assume, people with disabilities can be healthy, do not necessarily need to be "fixed," are often independent, and might well be consulting the health professional for a reason unrelated to the disability. Conversely, people with chronic conditions, such as chronic obstructive pulmonary disease (COPD), frequently are debilitated by their condition, yet are often not perceived by health professionals as having a disability. Such perceptions matter; people with disabilities have the same health needs as other people and are entitled to specific rights, including the right to make choices about their healthcare.[99]

Healthcare in general is often inaccessible for those with disabilities. The Disability Rights Education and Defense Fund (DREDF) has produced an acclaimed video series, *Healthcare Stories,* that focuses on widespread barriers to care (*http://dredf.org/healthcarestories/*). Three short excerpts from this series feature stories about inaccessible examination tables and weight scales and healthcare provider misperceptions and stereotypes. Advocates and practitioners alike recount their personal experiences and recommend actions for improving care. These downloadable videos present an all-important human perspective and affirm the barriers to care identified in a decade of research. The OT literature documents specific prejudice toward those who are obese.[93]

Bioethicist Peter Singer[83] has proposed that healthcare rationing decisions be based on and quantified according to a quality-adjusted life-year (QALY), which might assess the relative value of life with a disability by comparing it to the value of life without a disability. This is in stark contrast to a social justice model, in which each individual has equal value.

Stages of Life and Self-Concept

Many views of the individual and of groups of people divide the human life cycle into three categories: childhood, adulthood, and old age. The stages, statuses, and transitions are defined largely by social institutions (ie, the family, economic demands, and education) and the dominant culture. One might expect that by identifying the onset of a physical impairment in the life cycle, one may know the trajectory of many factors, including self-concept. The stage of life at which disability occurs is thought to influence the person because it affects the way he or she is perceived by others and the developmental tasks that might be interrupted. In that vein, the three main trajectories commonly identified are (1) people whose impairment is diagnosed at birth or in early childhood; (2) those who acquire an impairment during adolescence or the early adult years, usually through illness or injury; and (3) older people whose impairment is most often attributed to the aging process.[8]

The person who is born with a disability or acquires one in infancy or childhood may experience isolation or separation from the mainstream in family life, play, and education. The trajectory of an early-onset disability is thought to include socialization with pervasively abnormally low expectations and a lifestyle with few positive role models to demonstrate alternative ways. Families and special-needs schools may hide children with congenital impairments to protect them from discrimination and rejection by bullying peers. A "disabled identity" results in the child with a disability who grows up in a household and community with no other disabled person, has lengthy periods of hospitalization, is provided segregated special education services, and lives in a largely inaccessible physical environment.[8]

A 2003 study of self-image of a group of Swedish young people with cerebral palsy revealed that most respondents viewed themselves in a very positive manner and rated markedly higher self-image than norm groups.[1] The influence of a generally positive or negative attitude toward oneself formed early in life and the sparse interaction with others outside the family have been proposed as explanations for these research findings. Future studies must focus on the relationship between self-image and social interaction with people outside the immediate family as the individual with an impairment begins to interact with a wider social group.

Barnes and Mercer[8] concluded that many young people with disabilities do not experience the full impact of disablement until they seek to participate in more peer-directed leisure pursuits or are expected to join the workforce. Compared to nondisabled peers, young people with disabilities report lower job aspirations, poor or nonexistent career advice, employer discrimination, and a feeling of marginalization in the job market. There is evidence that the age of key major life transition indicators (eg, leaving home, getting married, becoming a parent, and entering the job market) occurs later among those with disabilities than those without disabilities.[8]

It cannot be assumed that negative effects on self-esteem will continue in people who experience an early-onset disability. A longitudinal study found that although adolescent girls with cerebral palsy scored significantly lower on physical, social, and personal self-esteem evaluations, as adults the same individuals no longer scored significantly different from able-bodied groups.[60] The authors speculated that factors leading to their subjects' change in self-esteem may have been due to an expanded range of environments in which to interact, better social relationships, or a wider variety of experiences in education, work, and commerce than in earlier years.

A study of self-evaluations of global self-worth in adolescents with disability (eg, cerebral palsy, orofacial clefts, and spina bifida) found that the participants' self-evaluations did not differ from those of an able-bodied comparison group. The assumption that self-esteem is necessarily reduced by a disability effect needs to be reassessed in light of recent studies.[49]

A person who acquires a disability later in life may face different issues, such as the need to change vocations, find a marital partner, or remain a part of his or her culture through the routines of daily life.[11,92] Some are forced into a sudden and substantial reevaluation of their identities, a need perhaps reinforced within a short time by downward economic and social mobility. A distinction can be made between experiencing discontinuity with a sharp shift into unemployment and the drift of a more gradual process of downward mobility. Generally, a chronic illness is less drastic than an accident resulting in disability, affording the individual the opportunity to plan and adjust to threats to self-identity.[8]

It has been proposed that individuals who acquire an impairment in middle age may view the onset of a disability as an unexpected, personal tragedy more often than do those who are elderly. The elderly and those who surround them, both family and service providers, may interpret the disability experience as an inevitable fact of life and therefore more of a normal course of events.[8]

Social scientists are calling for research involving people with disabilities that includes much more descriptive factors, such as the visibility of the impairment, the distinct type of impairment, whether the impairment was preventable, the age of onset, the influence of public perception on the individual, and social interactions. Increasingly, many people with disabilities who come from various backgrounds are learning to think about disability as a social justice issue rather than as a category of individual deficiency. Some surveys have indicated that Americans with disabilities who are young enough to have been influenced by the disability rights movement are more likely than older counterparts to identify themselves as members of a minority group; namely, the disability community.[32]

Carol Gill[32] has called for “deindividualizing the problem of disability,” contrasting this view with seeing disability as a personal tragedy. Understanding the social determinants of the devalued status by challenging the disabling society reinforces the valid and whole feelings held by those who are disabled. Plainly stated, if the individual with a disability views personal experience as a problem highly influenced by factors outside herself or himself, this perspective provides a way to effectively challenge societal perceptions of a devalued status.

Individuals with disabilities often demonstrate remarkable strength and achievement in the face of environmental obstacles and social exclusion. Those seeking to truly understand the disability experience should consider the aspects of the disability identity that engender creativity and an enhanced awareness of many commonly unappreciated aspects of human experience.[32]

Understanding Individual Experience

To avoid turning a category such as disability into an inflexible framework for identity, occupational therapists must develop methods that elicit the personal experiences and opinions of those who are disabled.[1] The narrative process for discovery of the individual is a recommended method. The process relies less on observable behavior and more on how people use their own stories to gain an understanding of everyday experience and emotion. It allows us to analyze the ways that personal identity is shaped by social interaction while maintaining the individual studied as an active agent.[8] Project Muse, which captured Angela Moore's narrative, is an example of such a process in the field of bioethics.

A therapy program for clients with a disability should include client-centered exploration into the individual perspective. Initially, to help better define the client perspective, research has shown that discussing the meaning of core categories can lead to insight about the feelings and attitudes of the client.[24] Examples of core category meanings have included (but are not restricted to) illness, independence, activity, altruism, self-caring, and self-respect. Researchers demonstrated that the independence, activity, and altruism categories actively directed behavior before and during treatment and that the last two meanings (self-caring and self-respect) emerged as treatment progressed as a transformation process. Explanation of the categories identified should be a part of the rehabilitation intervention, with both therapist and client benefiting from the increased awareness and self-reflection of the client.

A study by Padilla[68] used this phenomenological approach to describe the lived experience of disability of a woman who had sustained a head injury 21 years before. The woman identified themes of nostalgia, abandonment, and hope and what the core categories meant to her. More important than simply defining these terms, she reflected on how these meanings had shaped her life experiences for those 21 years. The outcome for this individual focused on changing her perspective from that of a passive victim to an active constructor of her own identity.[8]

Revaluating these themes with the individual may allow both the therapist and the client to discover the unique disability experience.

Social Context

Social Status and Disability

The Chicago city ordinance presented in Box 6.2 is an example of the segregation and discrimination society has openly communicated to those with disabilities. A more extreme example is the extermination of 200,000 people with disabilities in the death camps of the Nazi regime in World War II. Our 21st century perspective may allow us to scoff and feel distanced from such obvious prejudice; these may seem to be events consigned to another place, another time. However, our own present-day society behaves somewhere along a continuum that still includes discrimination and injustice, and this is difficult to acknowledge. Nonetheless, this is an inquiry we must not shy away from; the cost to our professional integrity would be too high without it, and our ability to provide a useful service would be compromised without such an understanding.

Box 6.2

Chicago City Ordinance, 1911, Repealed in 1974

A city ordinance passed in Chicago in 1911, which was not repealed until 1974, read as follows:

"No person who is diseased, maimed, mutilated, or in any way deformed so as to be [an] unsightly or disgusting object or improper person to be allowed in or on the public ways or other public places in this city, shall therein or thereon expose himself to public view."

Goffman's classic work, *Stigma: Notes on the Management of Spoiled Identity,*[33] used the term **stigma** to describe the social discrediting process in strained relations between disabled and nondisabled people[32] that reduces the life chances of people with disability or other differences. In this process, an obvious impairment, or knowledge of a hidden one, signifies a moral deficiency. The individual with stigma is seen as not quite human. Society tends to impute a wide range of imperfections on the basis of the impairment.

As are individuals from other minority groups, those with disabilities are categorized with stereotypes. The standard definition of a **stereotype** is an unvarying form or pattern, a fixed notion, having no individuality, as though cast from a mold.[95] Stereotyping is part of the stigmatization process applied to those perceived to exhibit certain qualities. Stigma may be expressed as a societal reaction to fear of the unknown. One explanation for stereotypes applied to those with disabilities is that little direct experience, despite recent mainstreaming in education and the removal of some environmental barriers, produces little real knowledge of what to expect in daily life.

Individuals with visible disabilities may be discredited in social situations, without regard for their actual abilities. Segal et al.[79] stated, "The exclusion of persons with physical disabilities from educational settings and work situations regardless of their ability to participate in and perform all required activities is well recorded in the literature."

Several researchers have noted the popular media portrayals of those with disabilities, which form and reinforce the basis of our common stereotypes, even for those of us in health professions (Box 6.3).[68] For example, Fleischer and Zames[28] found that "films present people with disabilities either condescendingly as 'inspirational,' endeavoring to be as 'normal' as possible by 'overcoming' their limitations, or as disfigured monsters 'slashing and hacking their way to box office success.'" Cahill and Norden,[18] in their discussion of stereotypic characterizations of women with disabilities in the media, found the two most frequent categories of portrayal were the disabled ingénue victim and the awe-inspiring overachiever. The disabled ingénue is young and pretty but significantly helpless because of her disability. The ingénue may be victimized or terrorized by others. Usually she is cured of her malady and able to return to the mainstream by the end of the story. Her return, or "reabsorption," often produces an ability to have a new perspective on life. Similarly, the awe-inspiring overachiever is attractive and succeeds in reaching extraordinary levels of competitive acclaim, only to be taken down by an incurable disability. She eventually "overcomes" her disability with unrelenting personal fortitude and often unexplained economic resources.

Box 6.3

Media Images That Reflect "Handicapist" Stereotypes

1. *The disabled person as pitiable and pathetic*. Found in charity telethons, perpetuating the image of people with disabilities as objects of pity. Their stories are often told in terms of people who are victims of a tragic fate.

2. *The disabled person as "Supercrip."* Heartwarming stories that depict great courage, wherein someone likable either succeeds in triumphing or succumbs heroically; these are usually considered "inspirational" stories. This image leaves a lot of ordinary people with disabilities feeling like failures if they haven't done something extraordinary.

3. *The disabled person as sinister, evil, and criminal*. This stereotype plays on deeply held fears and prejudices; the disabled villain (especially one with a psychiatric illness) is almost always someone who is dangerous, unpredictable, and evil.

4. *The disabled person as better off dead*. The "better dead than disabled syndrome" is one way in which the media imply that with medical costs soaring and resources limited, a disabled person would seek suicide because life is unbearable. Society, especially the family, is thereby relieved of caring for the disabled individual, who is not whole or useful.

5. *The disabled person as maladjusted; that is, his or her own worst enemy*. "If only disabled persons were not so bitter and would accept themselves, they would have better lives" is the general statement of this stereotype. Usually it involves a nondisabled person who helps someone with a disability see the "bright side" of his or her impairment. It contains the mythology that people with disabilities need guidance because they are unable to make sound judgments.

6. *The disabled person as a burden*. Family responsibilities and duty form the core of this stereotype, which is built on the assumption that people with disabilities need someone else to take care of them. Like the stereotype of disabled people as better off dead, it engenders the belief that the burden, whether financial or emotional, is so compelling that it ruins families and their lives.

7. *The disabled person as unable to live a successful life*. The media have distorted society's view of people with disabilities by limiting their presence in the portrayal of day-to-day life. Although more disabled people are beginning to appear in cameo-like scenes or as extras, they are seldom seen in ordinary workplace situations or as happy, healthy family members.

From Switzer JV: *Disability rights: American disability policy and the fight for equality,* Washington, DC, 2003, Georgetown University Press.

The traditional approach used in telethons and other fund-raising ventures, in which people with disabilities may be portrayed as victims, reinforces negative attitudes, stereotypes, and stigma. More recently, with pressure from disability advocacy groups, some network television programs and commercials have included people with disabilities as regular participants in daily life, as workers or family members.

Increasingly, international medical and public health literature reflects a recognition that stigma, discrimination, and social exclusion of individuals with disabilities warrants direct action by diverse societies. A few examples are the current views about the rights of individuals with disabilities in Ghana[76]; discrimination against differently abled children among rural communities in India and the need for action[41]; research in Indonesia on stigma affecting those with disabilities[58]; and, in Brazil, an analysis of the sociofamilial and community inclusion and social participation of people with disabilities to improve access to healthcare.[27]

Disability as a Collective Experience

Vash and Crewe[92] recounted a rehabilitation conference a number of years ago when an address by a psychiatrist included the speaker alternatively standing up and then sitting back down in a wheelchair several times. The speaker challenged the audience to deny that their sense of his competence changed as he stood before them or sat in the wheelchair. Vash reported that when a discussion followed, most acknowledged that their perception of his competence had fluctuated;

the speaker was more credible and worth attention when he was standing. The demonstration forced them to acknowledge their own, previously denied, prejudice and was emotionally charged for much of the audience. A wheelchair can be a powerful social symbol, conveying devaluation of the person in it.

Zola[102] observed that, at its worst, society denigrates, stigmatizes, and distances itself from people with chronic conditions. He experienced little encouragement to integrate his disability identity into his life because this would be interpreted as forgoing the fight to be normal. In letting his disability surface as a real and not necessarily bad part of himself, he was able to shed his super strong "I can do it myself" attitudes and be more demanding for what he needed. Only later did he come to believe that he had the right to ask for or demand certain accommodations. He began to refuse invitations for speaking engagements unless they were held in a fully accessible facility (not only for him as the speaker, but also for the audience).

Another insider's view of disability was provided in 1990 in the book *The Body Silent*, by Robert Murphy,[66] an anthropologist who developed a progressive spinal cord tumor that ultimately led to quadriplegia. His account particularly captures the medical and rehabilitation setting from the perspective of the client. In describing his initial reaction, he wrote, "But what depressed me above all else was the realization that I had lost my freedom, that I was to be an occasional prisoner of hospitals for some time to come, that my future was under the control of the medical establishment."[66] He reported the feeling as like falling into a vast web, a trap from which he might never escape.

The hospitalized individual must conform to the routine imposed by the medical establishment. For example, Murphy spent 5 weeks on one ward where he was bathed at 5:30 every morning because the day shift nurses were too busy to do it. The chain of authority from physicians on down creates a bureaucratic structure that breeds and feeds on impersonality.[66] The totality (of social isolation) of such institutions is greater in long-term care facilities, such as mental health and rehabilitation centers. A closed-off, total institution generally attempts to erase prior identity and make the person assume a new one, imposed by authority. The hospital requires that the "inmates" think of themselves primarily as patients, a condition of conformity and subservience.

Murphy highlighted the experience of an increased social isolation as some of his friends avoided him.[66] He often encountered physical barriers in his environment, which restricted opportunities for social contact. He applied a term from anthropology, **liminality**, to the observation that people with disability have the social experience of pervasive exclusion from ordinary life, the denial of full humanity, an indeterminate limbolike state of being in the world; in other words, the marginal status of individuals who have not yet passed a test of full societal membership. Those with such social status have a kind of invisibility; just as their bodies are impaired, so is their social standing. As Goffman noted, "Caught in a transitional state between isolation and social emergence," people with disabilities "do not count as proven citizens of the culture."[32] This limbolike state affects all social interaction. "Their persons are regarded as contaminated; eyes are averted and people take care not to approach wheelchairs too closely."[32] One of his colleagues viewed wheelchairs as portable seclusion huts or isolation chambers.

Murphy was surprised to discover that in attending meetings of organizations formed by people with disability, often more attention was paid to the opinions of experts who were able bodied than to his views, in spite of his having a disability and being a professor of anthropology.[66] Those with disabilities may hold the same social attitudes from the culture about disability and behave in ways consistent with those negative views.

A major aspect of Murphy's life was his work as a professor, which he continued as long as possible. But even with his status as an internationally recognized anthropologist and researcher, hospital personnel often saw him as an anomaly (an observation shared by other professionals with disabilities in more recent times).[62] A hospital social worker asked him, "What was your occupation?" even though he was working full time and doing research in areas related to medical expertise. With their mindset, hospital workers seemed unable to place him in the mainstream of society. Murphy concluded that people with disability must make extra efforts to establish themselves as autonomous, worthy individuals.[66] Gill stated:

In certain ways, many disabled persons are forced to lead dual lives. First, they are repeatedly mistaken for something they are not: tragic, heroic, pathetic, not full humans. Persons with a wide range of impairments report extensive experience with such identity misattributions. Second, *disabled people must submerge their spontaneous reactions and authentic feelings to smooth over relations with others, from strangers to family members to the personal assistants they rely on to maneuver through each day.*[32]

Murphy's book ended with this observation:

But the essence of the well-lived life is the defiance of negativity, inertia and death. Life has a liturgy which must be constantly celebrated and renewed; it is a feast whose sacrament is consummated in the paralytic's breaking out from his prison of flesh and bone, and in his quest for autonomy.[66]

Beatrice Wright, a social psychologist, studied and wrote for many years about society's reactions to people with disability.[98] She used the term **spread** to describe how the presence of disability or an atypical physique serves as a stimulus to inferences, assumptions, or expectations about the person who has a disability. For example, a person who is blind may be shouted at, as though lack of vision also indicates impaired hearing; or a person with cerebral palsy and a speech impairment may be assumed to be mentally retarded. An extreme manifestation of spread is the belief that an individual's life must be a tragedy because he or she has a disability. This attitude may be expressed in such statements as, "I would rather be dead than have multiple sclerosis." The assumption that the presence of a disabling condition is a life sentence to a tragic existence denies that satisfaction and happiness may ever be achieved. This attitude is of particular ethical concern today, when genetic counseling and euthanasia may provide a socially acceptable means of exterminating people with disability.[90] If life is seen as tragic or not worth living, it is a fairly easy step to argue that it would be better for everyone if people with disability ceased to exist.[71]

Wright's work describing efforts to integrate disability with a positive sense of self explicitly recognizes that the devalued status of those with disability is imposed on such people collectively.[98] Gill[32] pointed out that individuals with disabilities make assessments (of asset values in comparison with comparative-status values) in terms of contributions to one's life. She used the example of the skill in using adaptive equipment; although others may judge the use of such devices as inferior (compared with "normal" functioning), people with disabilities regard them as assets because they have learned to appreciate the benefit derived from their use.

Occupational Therapy Practice and the Independent Living Philosophy

Until recently, much of the emphasis in rehabilitation has been on modifying the individual to adapt to the existing environment. Individuals have been modified by machines, surgery, physical therapy, occupational therapy, psychotherapy, vocational counseling, social work, prosthetic and orthotic devices, education, training, and so on.[92] This emphasis on modification of the person is termed the **medical model** (or biomedical model) of intervention. It is based on the belief that there must be intervention, treatment, repair or correction of pathology, of that which is a deviation from the norm. The norm may be physiological, anatomical, behavioral, or functional. The cause of the problem, in this model, is intrinsic to the person; normalization is the goal. In contrast, these normalization models are considered erroneous and dangerous by those aligned with the independent living philosophy, the social model of disability. Of particular concern is the tendency to isolate specific differences and then use those differences to determine and explain the consequences at a societal level.[29] This tendency creates a kind of logical fallacy, in which the evidence for what is normal is then used to explain the resultant problems that prevent participation in society.

In his landmark article first published in 1979, DeJong[23] described the differences between the medical rehabilitation model, and the independent living model and its sister, the social model of disability. In the medical model, the physician is the primary decision maker, and healthcare professionals are considered the experts. The problem is defined as the patient's impairment or disease; the solution lies in the services delivered by the healthcare professionals. Oftentimes, the goal of rehabilitation is for the patient to be independent in performing activities of daily living (ADLs). The client is expected to participate willingly in the program established by the healthcare professionals, and success is determined by the patient's compliance with the prescribed program and attainment of goals established by the medical rehabilitation team.[14]

Fleischer and Zames[28] pointed out that with the emergence of those with severe disabilities from secluded institutions, in combination with independent living strategies that produced participation in the community, a critical force gained momentum, creating the disability rights movement. Previously, many who became prime movers in the fledgling civil rights struggle for people with disabilities might have been hidden away in segregated institutions or become homebound. Edward Roberts, deceased father of the worldwide independent living movement, had to sleep in an iron lung. Both Roberts and Judith E. Heumann, the former U.S. assistant secretary of education, founder of Disabled in Action, and currently the special advisor for international disability rights at the U.S. Department of State, required attendant care for ADLs. In the 1990s it was reported that Fred Fay, cofounder of the Center for Independent Living and the American Coalition of Citizens with Disabilities, would lie on his back all day, every day, managing not only his home but also state and national political campaigns and international disability advocacy programs using a combination of personal assistance and three computers.[14]

Bowen pointed out that OT practitioners should not deceive themselves into believing they are using an independent living, or social, model because the professional role is to help people live independently.[3-5] This is merely a simple shift of words, not the core of the model. The independent living movement and the associated model are quite different and separate approaches to practice from the traditional medical model used by most practitioners.[14]

When the independent living model is used, the person receiving services is considered a consumer, not a patient; is the expert who knows his or her own needs; and is the one who should be the primary decision maker. In this model, the healthcare service provider describes what he or she can do with the consumer, and the consumer then decides what aspects of the service he or she wants to use. The foremost issues addressed are the inaccessible environment, negative attitudes held by others about disabilities, and the medical rehabilitation process, which tends to produce dependence on others (see the later section Client-Centered Practice: A Shift from the Medical to the Social Model).

Hammel, an occupational therapist, led a major research project that stressed that:

… across environmental factors, rehabilitation professionals also could more actively and intentionally incorporate consumer direction, empowerment, and activation strategies into rehabilitation services so people with disabilities become more informed consumers and feel empowered to navigate and manage systems, services, and resources needed to live and participate in the community long term, including the integration of peer mentoring and social learning self-efficacy, building groups into rehabilitation delivery.[37]

Occupational therapists may initiate peer support groups and encourage patients to participate in online disability support groups. These problems are best resolved through self-help and consumer control of decision making, self-advocacy, peer counseling, and removal of attitudinal and architectural barriers. The goal of independent living is full participation and integration into the entire society.[14]

Consumer-controlled and consumer-directed independent living programs offering a broad spectrum of services, including some that OT practitioners have considered hallmarks of the profession (eg, assistive device recommendation and daily living skills training), are funded through federal, state, local, and private resources. In 1993 the AOTA published a position paper outlining the role of occupational therapy in such programs. The general practice of the professional per se does not differ from other settings. The major difference is that the consumer selects which services to use, rather than receiving those chosen by the therapist. With the community-based nature of the settings (in contrast to healthcare facility–based settings), the services are directly related to the consumer's ability to function in his or her roles in the local community. The practitioner may need a higher level of creativity to address these diverse role-related functional activities.

OT Practice Notes

The independent living philosophy requires that the therapist play a supporting role in helping the consumer be the principal player as problems with the environment are solved. This role contrasts with the therapist's more common approach, in which therapeutic activities are directed to restore abilities.[14]

Bowen[14] stated that practitioners often fall short in implementation of an independent living philosophy; namely, striving to make others aware of the handicapping nature of the environment. The focused goal, using the independent living philosophy, is on problems that exist in the physical and social environment, not on a deficit in the person with a disability. Bowen's research noted that practitioners write therapeutic goals that seek to change the client 12 times more often than they do goals that focus on altering the environment.[14] Other OT researchers have reported an extreme lack of knowledge about architectural accessibility regulations among OT practitioners, which compromises their ability to promote integration into the community and empower consumers who use wheelchairs.[73]

Person-First Language

The language used to communicate ideas about people with a disability is important because it conveys images about these individuals that may diminish their status as human beings. Kailes, a disability policy consultant who has a lifelong disability, wrote:

Language is powerful. It structures our reality and influences our attitudes and behavior. Words can empower, encourage, confuse, discriminate, patronize, denigrate, inflame, start wars and bring about peace. Words can elicit love and manifest hate, and words can paint vivid and long lasting pictures.[43]

For example, in the jargon of the medical environment, disabled people may be called “quads,” “paras,” “CPs” or “that stroke down the hall.” Such categorization leads to viewing individuals as stereotypic examples, engulfed by their impairments.[13] Some individuals are of the opinion that referring to people as “the disabled” or “a disabled person” makes the disability swallow up their entire identity, leaving them outside the mainstream of humanity. How, then, might OT practitioners use language in a spirit of dignity?

In her discussion of the complexities of disability policy, Switzer noted:

[There is] virtually universal agreement that pejorative terms that objectify disabled persons (such as deformed or wheel-chair bound) diminish the importance of the individual and create the perception of people only in terms of their disability. Similarly, attempts to develop euphemisms (physically challenged, height-impaired) generally are thought to be misguided attempts that still identify persons by their disability alone.[87]

For people with disabilities (PWDs) to develop a sense of pride, culture, and community, past negative attitudes must be changed. The use of language that recognizes that the person comes first (ie, a person with a disability) acknowledges that the individual is a human being before being someone with a disability.[87] This shift in the use of language is widely known as **person-first language**.[53]

All struggles for basic human rights have included the significant issue of what labels will be used by and about a particular people. With other minority groups, examples have included “Negro,” which was replaced by “black” and then changed to “African American”; “Indian,” which was changed to “Native American” or “People of First Nations”; and “ladies” or “girls,” who are now more commonly called “women.” Kailes has reminded us that terms such as *crippled, disabled,* and *handicapped* are labels imposed from outside the community of people with disabilities, from definitions constructed by social services, medical institutions, governments, and employers.

The preferred terms continue to evolve and change. Negative attitudes, values, biases, and stereotypes can be amended by using disability-related language that is precise, objective, and neutral. Disability-related terms are often subjective and indirectly carry a feeling or bias through innuendo and tone. But the effect of these terms on those with disabilities can be very direct and disturbing; they can cause a sharp cringe, a flash of anger, or shut down interaction when the person is confronted with “ablest” and “handicapist” language. Use of such language creates social distance, establishes an inequality in the interaction, and produces demeaning expectations.[43]

What should we call the recipient of occupational therapy—*patient, client,* or *patient-client* (Box 6.4)? *Patient* conveys a sense both of ethical responsibility on the part of practitioners,[75] and of passivity and dependence on the part of those receiving care.[66] *Client,* on the other hand, conveys merely an economic relationship,[81] as does *consumer*. A product or service might be sold to a client with the "Buyer beware" ethic of a free market economy; however, our professional ethics demands the provision of service based entirely on the benefits it affords the recipients. Perhaps what is needed is a sensitive inquiry by the therapist as to what term the particular individual prefers.

Box 6.4

Use of Language

Disabled Versus Handicapped

The term *handicapped* connotes the negative image of a person on the street corner with a "handicap" in hand, begging for money. The word *disability* also is not perfect because it still implies a negative—what a person cannot do. However, it has become the word most widely used and accepted among people with disabilities. A disability is a condition, and a handicap is a barrier or obstacle that a person with a disability may encounter in the environment. People are not handicapped by their disability all the time. A wheelchair user is not handicapped in an environment where there are no steps. A disability can mean that a person may do something differently than a person without a disability, but with equal participation and equal results. The phrase *disabled people* is a shortcut to the more involved and sometimes more awkward but preferred expression *people with disabilities*. It depicts people with disabilities as people, with multidimensional characteristics in addition to their disability.

For example, a woman who has a disability as a result of polio and uses a wheelchair may also be a mother, a wife, an executive, a student, a citizen, a board member, a gifted public speaker, and more. A man who has quadriplegia as a result of an auto accident is not a "vegetable." Although he has a significant physical disability, he may also be an active, contributing, productive member of society. Disabled people can represent differentness and separateness, and we sometimes reduce a person's identity to only his or her disability; we don't refer to people with broken legs as "broken-leg people." An exception to this guideline is people who are deaf who refer to themselves as the "Deaf with a capital D." Many people who are deaf consider themselves members of a culture that has its own language. There is also emerging discussion within the disability community that supports the phrase *disabled people* as representing a sense of pride, culture, common history, and experience.

Wheelchair User Versus Wheelchair Bound or Confined to a Wheelchair

People are not bound to wheelchairs. *Wheelchair bound* or *confined to a wheelchair* conveys a stereotype that sets people with disabilities apart from others and portrays people who use wheelchairs as devalued, impotent, slow, and passive. People use wheelchairs to increase their mobility, similar to the way people use cars. Many people who use wheelchairs can walk but choose to use a wheelchair or a scooter because of such functional limitations as reduced endurance, decreased balance, or slow walking speed. Often, ability, productivity, independence, ease, and speed of movement are increased by wheelchair use. For many, a wheelchair means increased mobility and freedom; it does not mean imprisonment! People who use wheelchairs can transfer to cars and chairs. Thus they are neither confined nor bound to their wheelchairs.

Patient

Most people are patients at some point, but this does not mean that people are constant patients and always should be called patients. Patient is a noun that frequently gets paired with people with disabilities. It is common to hear expressions such as, "a multiple sclerosis patient is in my class," "he is an Alzheimer's patient," or "stroke patients walk in the mall every day." The words conjure up a vision of people walking in the mall pushing poles hung with intravenous (IV) bags, or wearing electrocardiograph (ECG) wires attached to their chests and accompanied by their doctors. Pairing people with disabilities with *patient* overmedicalizes people. It gives them a permanent status of "eternal and chronic patients" and reinforces a common misconception that people with disabilities are all sick. People with disabilities are not constant patients, and most people with disabilities are not sick.

Crippled

The term *crippled* is derived from an old English word meaning "to creep." Webster's New World

Dictionary gives a second meaning to the word *cripple,* which is "inferior." These are derogatory images that perpetuate negative stereotypes!

Overcome

People cope with, adjust to, and live with a disability. Disability is a characteristic, and just as a person does not overcome being black, a person does not overcome having a disability. People overcome social, economic, psychological, attitudinal, architectural, transportation, educational, and employment barriers.

Special

People with disabilities should not be labeled as *special*. Although the term is often used in descriptions such as *special education,* it is patronizing, inappropriate, and distancing. It is not necessary. *Special* is often viewed by the disability community as a euphemism for segregated because it implies differentness and apartness.

Suffer

An individual who has a disability does not necessarily suffer. *Suffer* conveys a stereotypical attitude of never-ending mourning. If one wants to say a particular person is suffering, this point should be developed explicitly. Mourning is one of the stages involved in adjusting to disability. It is not a chronic state.

Victim

The word *victim* is appropriate to use immediately after a diagnosis or an injury, or for someone who has experienced some form of abuse (victim of a violent crime, accident victim, or rape victim). It is inappropriate to use the word to describe an ongoing status. A person is not a lifetime multiple sclerosis victim, cerebral palsy victim, or stroke victim. Being constantly referred to as a victim reinforces the helplessness and degradation of the initial experience.

From Kailes JI: *Language is more than a trivial concern!* 2010. Self-published. http://www.jik.com.

Although all three editions of the OTPF use the word *client* to name the recipients of occupational therapy, it is clear that the developers of the Framework have struggled with this term, and they recommend that OTs adopt the terminology preferred or used by the recipients of their services.[3-5]

Culture of Disability

J. P. Shapiro,[80] a highly regarded journalist, wrote about the new group consciousness emerging through a powerful coalition of literally millions of people with disabilities, their families, and those working with them. He noted the start of a disability culture, which did not exist nationally even as recently as the late 1970s. British social scientists Barnes and Mercer[9] more recently stated that the disability culture is a sense of common identity and interests that unites disabled people and separates them from those who are non-disabled.

As Steven Brown, cofounder of the Institute on Disability Culture in Las Cruces, New Mexico, said:

People with disabilities have forged a group identity. We share a common history of oppression and a common bond of resilience. We generate art, music, literature, and other expressions of our lives and our culture, infused from our experience of disability. Most importantly, we are proud of ourselves as people with disabilities. We claim our disabilities with pride as part of our identity. We are who we are: we are people with disabilities.[28]

The notion of "disability pride," as an echo of "black pride" or "gay pride," was dismissed as unachievable even within the independent living movement during the mid-1970s. In the summer of 2004, however, the first Disability Pride Parade was held in Chicago. (Disability Pride's website is *http://www.ieccil.org/independent-living/disability-pride*.) Sarah Triano, co-chair of the 2004 parade's planning committee, said:

Disability Pride represents a rejection of the notion that our physical, sensory, mental, and cognitive *differences from the non-disabled standard are wrong or bad in any way, and is a statement of our self-acceptance, dignity and pride. It is a public expression of our belief that our disabilities are a natural part of human diversity, a celebration of our heritage and culture, and a validation of our experience. Disability Pride is an integral part of movement building, and a direct challenge to systemic ableism and stigmatizing definitions of disability. It is a militant act of self-definition, a purposive valuing of that which is socially devalued, and an attempt to untangle ourselves from the complex matrix of negative beliefs, attitudes, and feelings that grow from the dominant group's assumption that there is something inherently wrong with our disabilities and identity.*

The emergence of the disability arts movement marks a significant stage in the transition to a positive portrayal of disabled people, building on the social model of disability. From the mid-1980s, there has been a substantial increase in work by disabled poets, musicians, artists, and entertainers that articulates the experience and value of the "disabled" lifestyle.[9]Art, literature, and performance, from the time of Shakespeare to the present day physically integrated dance with Axis Dance Company and the Dancing Wheels Company and School, aspire to convey the universality of human experience. For more than 20 years, the late John Callahan, an irreverent cartoonist and self-stated "quadriplegic in a wheelchair," depicted a point of view of life, including the experience of disability, which was published in newspapers across the nation.[61] Callahan's autobiography, *Don't Worry He Won't Get Far on Foot,* made it to *The New York Times* bestseller list.

As Fleischer and Zames wrote, "Disdainful of pity, disability culture celebrates its heritage and sense of community, using various forms of expression common to other cultures such as, for example, film, literature, dance, and painting."[28]

The UCLA National Arts and Disability Center is dedicated to promoting the full inclusion of children and adults with disabilities into the visual, performing, media, and literary arts communities. *Beyond Victims and Villains: Contemporary Plays by Disabled Playwrights*[55] and *Bodies in Commotion: Disability and Performance*[77] are well-regarded examples. Josh Blue, a comedian with cerebral palsy, is another example of mainstream entertainment through the lens of the person with a disability. Sports and games, heralds of cultural pursuit, are also evident in the culture of disability. The term *disabled athlete* has been reclaimed from sports medicine and orthopedics to mean competitive athletes with disabilities. Every major city marathon includes "runners" with wheels. The international Paralympics, begun in 1960, is held every 4 years in tandem with the Olympic Games; it is now the second biggest sporting event in the world. A personal narrative by a British Paralympic competitor, a wheelchair tennis player who experienced a spinal cord injury (SCI) after a motorcycle accident in 2001 that left her paralyzed from the waist down, gives an alternative account of disability that reflects a positive, if different, social identity.[44]

The 2005 film *Murderball,* about athletes with paraplegia who play full-contact rugby in Mad Max–style wheelchairs and who competed in the Paralympic Games in Athens, Greece, was nominated for an Oscar from the Academy of Motion Pictures.[40] Professional wheelchair skaters are showcased at skate parks.[26]

The National Center on Health, Physical Activity and Disability (NCHPAD) focuses on building national leadership in the disability community that aligns with ongoing and future Healthy Communities/Community Transformation initiatives to promote community health inclusion activities in physical activity and nutrition. The center's Community Health Inclusion Sustainability Planning Guide: An Addendum to a Sustainability Planning Guide for Healthy Communities (*http://www.nchpad.org/CHISP.pdf*) can be used to help create an Inclusive Health Coalition.

James Charlton's book, *Nothing About Us without Us: Disability Oppression and Empowerment,* details the worldwide "grassroots disability activism" of those with disabilities. He stated, "A consciousness of empowerment is growing among people with disabilities … it has to do with being proud of self and having a culture that fortifies and spreads the feeling."[19]

John Hockenberry,[39] the well-known journalist and author of *Moving Violations, A Memoir: War Zones, Wheelchairs, and Declarations of Independence,* has a spinal cord injury and uses a wheelchair. He sees disability in a novel way, as a cultural resource:

Why is it that a person would not be considered educated or privileged if he went to school and never learned there was a France or a French language? But if a person went through school and knew nothing about disability, never met a disabled person, never heard of American Sign Language, he might be considered not only educated, but also lucky? Maybe we in the disability *community need to get out of the clinical realm, even out of the equity realm, into the cultural realm, and show that a strategy that leads to inclusion makes a better community for everyone.*[39]

Murphy, in *The Body Silent,* described how his degenerative disability impelled him to examine the society of people with disabilities with the same analytic tools he used to study esoteric cultures in remote geographic areas, the classic field study location of his discipline[66]:

Just as an anthropologist gets a better perspective on his own culture through the long and deep study of a radically different one, my extended sojourn in disability has given me, like it or not, a measure of estrangement far beyond the yield of any trip. I now stand somewhat apart from American culture, making me in many ways a stranger. And with this estrangement has come a greater urge to penetrate the veneer of cultural differences and reach an understanding of the underlying unity of all human experience.[66]

Why should an occupational therapist know about this evolving social phenomenon—disability culture? Is our contribution so bound to a medical model that we cannot acknowledge this cultural expression? What value is our relationship with those who have disabilities if not to support participation in all aspects of occupation, including those expressing a disability cultural perspective?

Design and Disability

Bickenbach,[12] a disability rights law and policymaker, has drawn on Irving Zola's work, reminding us that the "special needs" approach to disability is inevitably shortsighted. If we see the mismatch between impairments and the social, attitudinal, architectural, medical, economic, and political environment as merely a problem facing the individual with a disability, then we are ignoring that disability is an essential feature of the human condition. It is not whether a disability will occur, but when; not so much which one, but how many and in what combination. The entire population is at risk for the impairments associated with chronic illness and disability. As people live longer, the incidence of disability increases. Viewing disability as an abnormality does not provide a realistic picture of the human experience. Bickenbach, in his discussion of disability as a human rights issue, underlined the fact that disability is a constant and fundamental part of human experience and that no individual has a perfect set of abilities for all contexts; there are no fixed boundaries dividing all the variations in human abilities. Our usual description of contrast between ability and disability is, in fact, a continuum of functionality in various settings.[12]

This perspective affects occupational therapy's role in the realm of assistive technology and modification of the environment to enhance individual performance of occupational behavior. Our literature is overflowing with discussions about assistive technology (see Chapter 17) and environmental modifications; applications with various diagnostic classifications, methods for training in the use of assistive technology, the usefulness of providing a specialized device to enhance performance, and home modifications. The concept of universal design (the way the environment may be designed to support individual differences) is not as prominent in our professional literature. This idea includes the built environment, information technology, and consumer products, in addition to a host of commercial and social transactions, usable by all people, to the greatest extent possible, without the need for adaptation or specialized design. The concept is this: if devices (eg, buildings, computers, educational services) are designed with the needs of people with disabilities in mind, they will be more usable for all users, regardless of whether they have disabilities.

Disability is just one of many characteristics that an individual might have that should influence the design of our environments. An example of universal design is ramped entries, which are required by federal law (Americans with Disabilities Act Accessibility Guidelines [ADAAG]) in public buildings (including transportation services, such as airports and train stations) and designed for those who use wheelchairs. As that design requirement has become increasingly implemented, the use of wheeled luggage by all travelers, in addition to parents pushing children in strollers and delivery staff with rolling carts, has become commonplace. Just imagine the impact on home modification if new housing construction design included the requirement for one entrance easily adaptable and a bathroom door wide enough for wheelchair access (see Chapter 15).

Activists in the independent living movement have influenced the personal computer and digital device industry to integrate a multitude of individual preferences, from the size and type of the font to the ease with which adaptive technologies such as speech recognition and alternative keyboards interact with operating systems. In another example of successful advocacy, standards were issued under the Rehabilitation Act in 2000 to address access to electronic and information technology for people with physical, sensory, or cognitive disabilities (see the website *http://www.access-board.gov/guidelines-and-standards/communications-and-it/about-the-section-508-standards*). Universal design in instruction is becoming evident as educators are increasingly trained to include multiple modalities of visual, auditory, and tactile systems to address the needs of people with wide differences in the ability to see, hear, speak, move, read, write, understand English, attend, organize, engage, and remember.[16]

Some argue that universal design principles could make assistive technology unnecessary in many situations involving an impairment. A canopener that has been designed for one-handed use by anyone busy preparing multiple steps in a recipe will also be usable by the cook who has hemiparesis caused by a cerebrovascular accident (CVA).

Universally designed devices and aids may be one remedy for the stigmatization attached to special equipment. As Daarragh et al.[22] pointed out, we know from research with older people that "[the] potential usefulness of a device is often offset in the minds of clients by concerns about social acceptability and aesthetics." There will always be a need for individually prescribed equipment because impairments and individual needs are associated with so many variations of disability.

Interactional Process: the Person With a Disability and the Environment

International Classification of Functioning, Disability, and Health

In 2001 the World Health Organization (WHO) restructured its classification of health and health-related domains (*the International Classification of Functioning, Disability and Health* [ICF]) that describes body functions and structures, activities, and participation. The domains are classified from body, individual, and societal perspectives. The ICF also includes a list of environmental factors because the individual performs within a context. The aim of the ICF classification is to provide a unified and standard language and framework to describe changes in body function and structure, what a person with a health condition can do in a standard environment (the person's level of capacity), and what the person actually does in his or her usual environment (the person's level of performance). The text produced with the language depends on the users, their creativity, and their scientific orientation. This text is a companion to WHO's *International Classification of Disease, Tenth Revision* (ICD-10).[96] For health practitioners, including occupational therapists, the ICF challenges mainstream ideas on how health and disability are understood.

The ICF stresses health and functioning, rather than disability. Abandoned is the notion that disability begins at the point where health ends. The ICF is a tool for measuring the act of functioning, without regard for the etiology of the impairment. This radical shift emphasizes the person's level of health, not the individual disability.[97]

Fougeyrollas and Beauregard[29] pointed out that the revised ICF is more aligned with social ecology's theoretical description of disability, and distances itself from reductionist social theory by emphasizing the role of environmental factors. It is also more in accord with the disability rights movement. As did the first two editions of the OTPF, the OTPF-3 continues to use ICF terminology to enhance communication with professionals in other healthcare areas.[3-5,35] Disciplines such as ergonomics and occupational therapy consider the environment to be an essential component of human behavior. To illustrate this shift in thinking, social ecologists point particularly to models of human occupation used in occupational therapy, such as the ecology of human performance,[25] the human occupation model,[46] and the person-environment-occupational model.[52] OT theory development has had significant influence in changing the paradigm used in rehabilitation by applying holistic and ecological principles to an understanding of the human condition.[29]

Historically, occupational therapy has been associated with the field of medicine and its emphasis on etiology, or causation, to explain function and disability. In contrast, our profession is presently building an understanding of occupation as a social construction. In keeping with a social model of disability, our focus on occupation produces, as Padilla[68] said, an "understanding of people for who they are, have come to be, and are in the process of becoming."

Health, as defined by WHO, is a state of physical, mental, and social well-being. It is the capacity of the individual to function optimally within his or her environment or the adaptation of the person to his or her environment or setting.[29] The ICF measures biological changes in body function or structure, but places equal emphasis on the contextual domains of personal and environmental factors. Components of health identify the constituents of health (Table 6.1), whereas consequences of health focus on what may follow as a result of disease. This is a shift from an exclusive view of disability from the medical model (ie, directly caused by disease, trauma, or other health conditions that require individual treatment by professionals) to a paradigm that allows for integration of a social model, in which disability is not an attribute of an individual but rather a complex collection of conditions, many of which are created by the social environment (Box 6.5). The social model requires social action, and it is the collective responsibility of society at large to make the environmental modifications necessary for the full participation of people with disabilities in all areas of social life.[96]

TABLE 6.1

Elements of Health and Their Components

Element	Components
Functioning and disability	Body functions and structures Activities and participation
Contextual factors	Environmental factors Personal factors

ICF, International Classification of Functioning, Disability and Health.

Box 6.5

Environmental Factors Identified by the ICF

- Products and technology
- Natural environment and human-made changes to environment
- Support and relationships
- Attitudes
- Services, systems, and policies

ICF, International Classification of Functioning, Disability and Health.

According to WHO, neither the medical model nor the social model provides a complete picture of disability, although both are partially useful. The complex phenomenon called *disability* can be viewed at the level of a person's body, and also primarily viewed at the social level. It is always a dynamic exchange between the characteristics of the person and the overall context within which the person is operating, but some aspects of disability reside within the person (eg, the cellular changes associated with a disease process), whereas other aspects are essentially external (eg, the fears and prejudice of others about the disease). Thus, application of both the medical model and the social model is appropriate. The best model of disability is one that synthesizes what is accurate in each model, without excluding the other viewpoint. WHO has proposed calling this the *bio-psychosocial model* and has based the ICF on such a synthesis. The goal is integration of the medical and social factors to produce a coherent view of health, incorporating biological, individual, and social perspectives.[97]

The ICF allows for the real-world observation that two people with the same disease can have different levels of functioning, and two people with the same level of functioning do not necessarily have the same health problem (Table 6.2). Two individuals will generally have different environmental and personal factors interacting with distinct body functions.

TABLE 6.2

Example of ICF Terminology

Condition	Impairment	Activity Limitation	Participation Restriction
Spinal injury	Paralysis	Incapable of using public transportation	Lack of accommodations in public transportation leads to no participation in religious activities.
Bipolar illness	Cognitive and emotional dysfunction	Incapable of managing finances	Lack of credit leads to homelessness.

ICF, International Classification of Functioning, Disability and Health.

In OT practice, the shift from relying on the medical model (that is, away from fixing a problem in the individual) to integrating the social model, which accounts for the interaction of the person and the environment, has led to evolving theoretical constructs.[21,47] For example, the therapeutic notion of adaptation to environment, in which individuals are expected to transform themselves through therapy, has been questioned by occupational science theorists. Rather, an interactional, dynamic, reciprocal adaptation of the person and the environment emphasizes more the social model approach. Cutchin[21] proposed the concept of place integration instead of adaptation to environment, in which "people are more a part of their environment, and environments more a part of people," with the person's "motivations and processes never fully independent from the physical, social, and cultural realms that shape the self and desires." In his conclusion, Cutchin underlined that client and practitioner are reflexive social selves, with the potential for "the therapeutic moment, one in which the client and therapist are united by place and social ties and by the collaborative effort to coordinate occupation so that person and place become once again integrated and whole."[21]

A Canadian study of women wheelchair users underscored these evolving theoretical constructs. The researchers concluded that the barriers these women experienced were a lack of space, stairs, difficult to reach spaces, poor transportation, and limited community access. The study recognized the importance of the many strategies the women used to regain control over their environment and to attain autonomy and participation in the community. The researchers called on clinicians to be sensitive to the meaning of home by including the relationship between body and environmental features that surround that meaning.[74]

Swedish researchers Lexell et al.,[57] who studied people with multiple sclerosis (MS), similarly concluded that professionals need to broaden their repertoire to address the social conditions that influence meaningful occupations. They described the way those with MS in their study claimed that they were forced to prioritize the most necessary occupations over the most desired occupations and those that could be conducted at any time over those that needed to be preplanned. Planning and addressing the balance of occupations over time is a more complex situation than previously recognized. Moreover, because planning and balance of occupations over time seems so strongly influenced by other people, interventions must be aimed not only at the client, but also at other people involved in the client's occupational engagement.

Relationship Between the OT and the Person With a Disability

Angela Moore's narrative of her experience with spastic cerebral palsy in the case study at the beginning of the chapter does not describe any current contact with rehabilitation specialists. Her account of the younger stages of life does reveal many social and personal experiences with medical professionals. Rather, her narrative describes the long and arduous journey through multiple interventions, multiple best-guessed speculations, and recommendations, and little of the immediate support seen with aspects of medical rehabilitation in trauma or a sudden, distinct condition onset.

Ethical Considerations

Professional healthcare consultation is generally not a choice; rather, the need arises from trauma or a more insidious dysfunction that affects an individual's well-being. Healthcare providers must honor the vulnerability of those who engage us in their quest for restored well-being. Care and thoughtfulness must prevail to ensure our respect, dignity, and ethical responsibility for those who seek occupational therapy.

OT values center on a humanistic concern for the individual,[68] particularly individuals who have a chronic, severe, and lifelong disability and who will never be cured.[100] Some OT practitioners may be engaged by a person with a temporary disability (eg, an injury to the hand that regains most or even all of its former function) or may work in prevention programs designed to reduce work injuries; these professionals generally do not have contact with those considered disabled. However, most people served by occupational therapists have lifelong conditions that cannot be "cured"[6]; therefore, most of those served do not escape the potential for devaluation, stigma, liminality, stereotyping, and the experience of a world designed primarily for those without their differences. Some will have differences that are not observable in casual contact (eg, autoimmune deficiencies, seizure disorders, pain, heart and pulmonary dysfunctions); yet, once discovered or disclosed by others, these differences produce similar personal and social results.

Rather than eradicating disease, occupational therapists identify and strengthen the healthy aspects or potential of the person. Self-directedness and self-responsibility of the person are emphasized rather than compliance or adherence to orders. A generalist, integrated view of the person as an individual who interacts with his or her environment guides OT practice rather than a specialist, reductive perspective. This integration requires emphasis on daily life activities and engagement in the occupations expected by the culture. The therapeutic relationships of occupational therapists should be based on mutual cooperation[82] rather than an active therapist and passive patient approach. The recipient of our service should be viewed as an agent or actor with goals, interests, and motives, and not as one whose behavior is determined by merely physical laws[56]; we have faith in potential ability, actualized by engagement in activity. The recipient's productivity and participation, rather than relief from responsibility, are emphasized.

OT Practice Notes

Occupational therapists seek to facilitate a balance of performance in areas of occupation, such as work, rest, play, sleep, and activities of daily living (ADLs), and to help restore a sense of well-being.[3] To accomplish this goal, the occupational therapist must understand the individual's experience and point of view, instead of relying on observation as the only credible source of information.

Although many occupational therapists provide services in a medical model milieu, we view the client in a way that is different from the traditional medical perspective of diagnosis, cure, and recovery and should follow a different thought process. Our concern with the capacity to engage in daily life activities means that our scope of practice must include not only the hospital setting but also home and community. Thus, occupational therapy may practice both within and outside of the medical milieu, often helping clients to become agents in their own return to health and well-being. In this sense, OT practice bridges the sometimes alien world of acute medical care with engagement in the world of home, family, and culture.

The Therapist as an Environmental Factor

OTs and other rehabilitation professionals are a distinct part of the social context for those with disabilities; OTs are an environmental factor for an individual as he or she seeks a sense of well-being. Behaviors, beliefs, and demonstrated attitudes have a bearing on the lived experience of the person OTs seek to serve. OTs bring to the environment cultural biases (eg, woman as homemaker, man as breadwinner), religious beliefs (eg, illness as a manifestation of sin or divine intervention), and attitudes toward disability and disablement (eg, the mass media stereotypes). Personal mindset may be in conflict with the desire for an authentic understanding of each individual. For example, in discussing bioethics, Asch reported that "rehabilitation specialists … dramatically underestimate life satisfaction of people with disabilities, regardless of the length of time they had been in the field or the number of people they had worked with."[7] It is reasonable to conclude that such underestimation affects the quality of the interaction between the person served and the specialist and that it must influence the social context of the relationship.

Basnett,[10] a physician with a cervical spinal cord injury, argued that the predominant influences on healthcare professionals and their attitudes are the norms of society. Often reinforced by training and practice and biased predominantly by seeing people with disabilities when they are sick, health professionals can develop a view of disability that is at substantial variance from its reality for many disabled people. This can affect vital decisions involving health professionals that affect disabled people. His research found that (1) in general, health professionals' attitudes became more negative as professional education proceeded; (2) a power imbalance existed in the relationship between the professional and the patient; and (3) the functional limitations and differences of people with disabilities were highlighted, rather than their strengths and similarities. He noted that other professionals, such as occupational therapists, who specialize more in disability and varying functional limitations, may develop a different view than physicians.

Wright observed that the goals of rehabilitation, independence, and self-directedness must be nurtured during rehabilitation.[98] She proposed that comanagement could result in improved outcomes. She observed that helping relationships might get in the way by conveying subservience and less power for the person being helped and by reinforcing the view that the expert has or should have the answers. The client might expect and want the professional to take complete charge. In some circumstances, such as acute medical care, this approach is necessary and commendable. However, shifting responsibility and power to the therapist can interfere substantially with the goals of rehabilitation and OT, especially the goal of independent living. Wright, therefore, asserted that "it is essential that the client be brought into a directorship role as soon as [is] feasible."[98] A central research finding of Guidetti et al.,[34] the "therapeutic relationship as enabling possibility,"[34] underscored this conclusion about self-care intervention.

Wright also acknowledged that rehabilitation specialists may have needs that interfere with comanagement.[98] They might need to assert themselves, display their knowledge, gain power, or achieve satisfaction in an authoritative role. Wright also cited the increasing pressure for efficiency and cost containment in the system as a stumbling block because comanagement may require more time and effort than would professional prescriptions. Her advice was, “Don't get stuck with the problem; move on to the solution” to prod constructive thinking.

Research has supported the findings about the long-term effects of comanagement. In a study by Wright,[98] a group of 100 patients with severe disability underwent rehabilitation in a hospital that encouraged their maximum involvement and participation. One year after discharge, their status was compared with that of a control group that had completed a conventional rehabilitation program at the same hospital. The experimental group showed a greater degree of sustained improvement in self-care and ambulation and a lower mortality rate. Wright concluded that, whenever feasible, comanagement on the part of the client should be promoted.[98] The therapist should support this belief by showing that he or she respects the patient, by being friendly and caring, and by showing concern about the patient's overall welfare. Basic social civilities are important, such as knocking on the door of the hospital room, introducing oneself, and addressing the recipient of services by name. The professional needs “to question at all times whether the client is at the helm” or whether the person is being “paternalistically directed.” This last test is especially important for occupational therapists who may work in an environment in which professional authoritarianism is the norm.

Therapeutic Use of Self

Gill stated that even though there are negative depictions in the literature, many people with disabilities have commendable relationships with nondisabled family members, friends, intimate partners, health professionals, and employers; relationships that, in fact, promote health.[31] She reported that many individuals with disabilities have given descriptive narratives of their lives in which key nondisabled people are themselves without disability prejudice, are aware of prejudice when it appears, and are allied in despising it. These allies appear to learn who their disabled associates are in their “full glory and their full ordinariness.”[32]

Ann Neville-Jan[67] was an occupational therapist and professor with spina bifida. In her autoethnography of the “world of pain,” she described how an authentic and respectful relationship may be created. Referring to Elizabeth Yerxa's 1967 Eleanor Clarke Slagle lecture, she reminded us that “authentic occupational therapy implies a commitment to a patient's meaning system and a relationship that is best described as ‘being there’ with our patients.”[67] Quoting Clark et al.,[20] she stated, “ ‘Techniques of collaboration, building empathy, inclusion of the ordinary, listening, and reflection’ are important for understanding patients' stories of their world of occupation, and, thereby, developing trust and hope.” She also wrote:

In my story there were two professionals who engendered trust and hope consistently whether treatment worked or not. We were partners; they listened and shared stories from their lives, their families, and their interests. They were empathetic listeners. … They were not rushed or impatient as I told them about my daily struggles with pain. They didn't try to change the topic to one that was not pain-related.[67]

Darragh et al.,[22] from their research with participants with brain injury, described similar qualities and traits necessary for the positive perception of treatment.

Neville-Jan's account of the authentic practitioners' behavior contrasts discernibly with Vash and Crewe's description of devaluation: disdain for a lesser, inferior being, seen as incapable, not useful, probably a burden, unattractive, and of a lower status.[92] The call for the authentic practitioner is for one who does not devalue the individual with a disability.

Smith,[85] a professor in the field of education who also has a disability, has called for a relationship of allies, joined for a common purpose; the OT professional must be an individual who respects, values, and supports, in a collaborative manner, the goals and aspirations of the client, knowing that that person may speak and act on his or her own behalf. This is not the same as being an advocate, who speaks for another or presumes to know what the other wants or needs. In the words of Yerxa, “Formulating wise questions requires establishing a partnership with those we wish to serve” and “we need to understand [the] relationship [of routines of daily life] to both personal goals and the environment as seen through the eyes of the individual.”[101]

Client-Centered Practice: A Shift From the Medical to the Social Model

Client-centered practice has gained importance over the past 30 years. Occupational therapists consider it essential to have a partnership with the client, one in which the client identifies issues to be addressed and collaborates in the selection and implementation of interventions. Adoption of this approach coincides with more therapists working in settings that expect a client-centered practice: schools, independent living centers, community settings, and health promotion centers.[54]

Chuck Close, a highly regarded visual artist, was interviewed several years after his successful return to the competitive world of art after extensive rehabilitation for a collapsed spinal artery, which left him almost completely paralyzed. A brace device on his partially mobile hand, a sophisticated wheelchair, and other aids allow him to paint. He rightfully criticized the attempts of therapists to engage him in housekeeping tasks when engagement in art and art creation was, and continues to be, the defining occupation of his being, despite his physical limitations. Finding a few paints and a way to make marks with paint in the basement of the rehabilitation center was the turning point of his "recovery."[30]

Occupational therapists working in rehabilitation centers frequently place much more emphasis on technical goals (eg, range of motion and muscle strengthening) than on the skills needed for independent living.[69] Independent living skills require the OT to include a client's participation in preferred occupations, which involves not only the environment in which these occupations take place, but also the socialization that supports engagement in these occupations. Occupational therapists should devote more time and energy to preparing patients for the capacity to function in their own communities.[69]

Lyons and colleagues,[59] who are OT practitioners in a major rehabilitation center, noted that the "shift from the medical model which encourages the client to take responsibility for making decisions" about the course of treatment, presents a unique opportunity for OTs to return to a more authentic, occupation-based approach to practice and to rediscover their roots in client-centered practice. These researchers also described the many benefits of their reinvention of practice to a truly client-centered and occupation-based approach within a medical model setting, thereby declaring occupational therapy's unique approach to client care and positioning their leadership in client-centered care on the rehabilitation team. Their methods for achieving such a focus include the use of a semistructured occupational performance questionnaire, the Canadian Occupational Performance Measure (COPM),[51] an occupational story-telling and story-making narrative designed to enable the OT to come to better know the client. The researchers also use occupational kits to engage clients in occupations of their choice, such as gardening, letter writing, pet care, fishing, scrapbooking, and car care. The reinvention of practice, to return to an authentic, occupation-based approach, is a win for the profession and a win for those we hope to serve.[59]

Occupational therapists can help redefine disability.[78] This redefinition would include working for changes in social attitudes and practices so that society would recognize the dignity and worth of people with disability, granting their rights to self-definition and self-direction. The occupational therapist would strive to work in (social model) as a consultant, helper, and advocate, rather than as a diagnostician or a prescriber and manager of treatment. Schlaff[78] recommended that the consumer become self-directed and that both the consumer and the occupational therapist work to remove community barriers and disincentives for economic independence.

Life Satisfaction and Quality of Life

The concepts of life satisfaction and quality of life are very important elements of the discussion of the personal and social contexts of physical disabilities.[70] Life satisfaction is considered to be the subjective component of an individual's overall quality of life.[91] How satisfied an individual is with his or her life may include such factors as satisfaction with family life, engagement in leisure activities, vocational pursuits, self-care, and sexual expression. Satisfaction does not require the same level of participation from each individual, but instead reflects how the person values his or her level of participation in various life situations. A preponderance of the literature on the psychosocial issues of physical disability for those with a variety of chronic disabling conditions (whether acute, progressive, or congenital onset) describes using an individual's perceived quality of life or life satisfaction as a measure of the person's success in adapting to or overcoming the emotional consequences of these diagnoses. Self-reported absence of depression, anxiety, and suicidal ideation are deemed evidence of mental health, which is frequently equated with a high quality of life and life satisfaction.[45,88]

Of particular relevance to occupational therapy is what clients report as contributing to their quality of life and life satisfaction. In the early 1980s, Burnett and Yerxa[17] found that individuals with a disability, while satisfied with their performance of personal ADLs after discharge from rehabilitation, felt ill prepared for functioning in the home and community. More recent studies have indicated that individuals with a disability who reported a high quality of life and life satisfaction regarded socialization (friendship), leisure, and productive occupations as most responsible for their high ratings. In fact, for the four participants in Pendleton's qualitative study on the friendships of successful women with physical disability, friendship-supported participation in occupation, and participation in occupation, in turn, facilitated their friendship.[70]

Studies in Sweden showed that among community-based people who had had strokes, life satisfaction was not correlated with the degree of physical impairment, but rather with the person's ability to achieve his or her own valued goals.[13]

Threaded Case Study

Angela, Part 2

Angela's account of the experience of living with spastic cerebral palsy was not written to form a relationship with an OT practitioner or, for that matter, any other professional. Rather, this insider's reflection was written, in the Project Muse editors' words, to explore bioethical topics and, on behalf of individuals with disabilities, to "share deeply personal accounts of how their lives are affected by their disabilities and the way society views their disabilities."

With that understanding, one should not be drawn into speculation, based on her account, about what Angela may or may not find useful from a practitioner. Instead, reflect on her use of language to describe her disability and her view of health: How has Angela's perception of herself changed over time? What has contributed to those changes? What impairment-based difficulties does she describe? What interventions have been rejected? What effect does her disability have within treatment for an unrelated disease?

In a commentary on the Project Muse narratives, Lorna Hallahan, a bioethicist, wrote:

Acknowledging that respect compromised is a doorway to oppression in which the autonomy of the person is sacrificed in the interests of social hygiene and service efficiency opens a wide sphere for solidarity building and action. In order to understand the potency of this mechanism which masquerades as care, we need to know the history of exclusion, rights denial and violence that has shaped our social responses to those labeled disabled. It is this history, alive today, that produces and reproduces affliction.[36]

Angela's story highlights the theory of profoundly negative experiences caused by societal factors. Hallahan's conclusions help reinforce the idea that respectful understanding of all the factors affecting full participation is the first step toward collaborative partnership with those who have a disability.

Summary

This chapter explored the personal and social contexts of physical disability and the implications for occupational therapists. The individual experiences of people with disabilities are necessary resources for practitioners to create a meaningful and useful approach to the problems of living with disability.

Distinctions between the medical model, and the social model and its sister, the independent living philosophy, as applied to the experience of disability, give us important lessons for creating useful relationships with those who may benefit from our professional knowledge and skills. As we explore engagement in a unique pattern of occupations, in unique environments with individuals who have specific interests, we seek to improve the potential satisfaction of that experience for that individual. Our attention must include the removal of barriers to that engagement in occupations.

Using our professional expertise, we practitioners, along with other professionals, become an integral part of a client's environment through our direct contact and construction of a rehabilitation (or health promotion) environment. We are bound by the ethical standards and the mission of our profession to foster relationships that promote quality of life and personal autonomy. The language we use conveys a powerful affective message and must reflect our values. As members of the larger society exposed to mass media images of disability, we may need to examine our own biases—namely, “handicapist” stereotypes—that create attitudinal barriers for those with disabilities.

Our commitment to improving the life opportunities of people with disabilities directs us to always strive for improvement in our practice and knowledge base. Our thoughtful desire for, and valuing of, positive change in the human condition must lead us to continual self-examination, throughout our individual careers.

Review Questions

1. How would a therapist approach a clinical situation if following an independent living movement philosophy? In what ways does the approach differ from traditional treatment?
2. What are some of the individual elements that affect the personal context of the disability experience?
3. What do we know about stage models of disability adaptation? In what ways are they useful?
4. How do stigma, stereotypes, liminality, and spread influence the social context of disability?
5. What are innovative ways of conceptualizing disability, culture, and the environment?
6. In what ways does the ICF promote a biopsychosocial model of disability? How has this model gained support from OT theorists?
7. In what ways does the occupational therapist become an environmental factor with the person who has a disability?
8. What is the therapeutic use of self and why is it important?
9. How can OT practice become occupation centered and client centered?
10. What do we know about quality of life and life satisfaction among individuals with disabilities?

She also acknowledges Dr. Elizabeth J. Yerxa, occupational therapist and Emeritus Professor, University of Southern California, whose personal encouragement and foundation work were essential to the creation of this chapter.

Teaching Activities in Occupational Therapy

Pamela Richardson, Rochelle McLaughlin

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Discuss purposes and outcome goals for teaching in occupational therapy.
2. Analyze how teaching strategies will differ, depending on the characteristics of the client, task, and context.
3. Apply to occupational therapy interventions current knowledge about factors that influence motivation and active participation.
4. Provide appropriate instruction, feedback, and practice tailored to individual tasks and client goals.
5. Promote transfer of learning to real-life situations through effective teaching strategies.
6. Implement occupational therapy interventions designed to promote self-monitoring and strategy development.
7. Define mindfulness and the therapeutic use of self.
8. Explain ways in which the therapeutic use of self can be cultivated and fostered.
9. Describe ways in which the Western medicine medical culture and Western societal and cultural norms in general can undermine our capacity to cultivate and foster the therapeutic use of self.
0. Identify ways in which mindfulness is currently embedded within the Western medical system.
1. Examine ways in which the act and practice of embodying mindfulness as an occupational therapist can enhance the cultivation and development of the therapeutic use of self.
2. Assess and justify the efficacy of mindfulness as a skillful way to develop the therapeutic use of self.
3. Differentiate between mindful occupational participation and automatic-pilot mode occupational participation.

KEY TERMS

Blocked practice
Contextual interference
Declarative learning
Extrinsic feedback
Intrinsic feedback
Metacognition
Procedural learning
Random practice
Somatosensory instruction
Strategies
Transfer of learning
Verbal instruction
Visual instruction

KEY PHRASES

The development of the therapeutic use of self
Prepared and effective interpersonal interaction
Mindfulness-based healthcare practitioners
***Quality* of the engagement and participation in occupations**

Section 1 Teaching Strategies in Occupational Therapy

Pamela Richardson

Teaching is a fundamental skill for occupational therapists. Therapists spend much of their time with clients teaching a variety of activities. Effectiveness as a teacher depends on the therapist's ability to organize the environment and the instructional methods to meet the learning needs of the individual client. This chapter discusses the process of teaching for occupational therapists working with clients who have physical disabilities. It also presents the reasons occupational therapists teach activities, the phases and types of learning, and principles of teaching and learning with this population.

Why Occupational Therapists Teach

Occupational therapists use a variety of teaching techniques in their interventions. Occupational therapists engage in teaching activities for the following reasons:

Threaded Case Study

Li, Part 1

Li is a 67-year-old retired high school science teacher who was hit by a car as he walked across a city street. Before his accident, he was active in a variety of volunteer activities that included teaching English as a second language at an adult education program, working as a docent at the local botanical gardens, and leading nature hikes in a nearby county park. He also was an amateur watercolor artist who had recently begun to receive recognition for his landscape paintings.

Upon referral to occupational therapy, he was nonambulatory because of a fracture of the pelvis and right femur. He also had fractures of his right clavicle and humerus and multiple fractures of his dominant right forearm and hand. He had a severe concussion and experienced dizziness and impaired balance, memory loss, and episodes of confusion.

In the initial occupational therapy evaluation Li stated his desire to return to his volunteer activities and his painting. He understood that the healing and rehabilitation process would take time, and his immediate concern was to regain physical capacity so that he could be more independent in his self-care. His wife attended his occupational therapy sessions and was committed to assisting him in his recovery.

Critical Thinking Questions

1. What does Li need to learn?

2. What strategies should Li's therapist use to facilitate his learning?

3. What should Li learn first?

1. *To help clients relearn skills lost as a result of illness or injury*. Clients may need to relearn how to perform daily occupations such as eating and dressing. They may also need to relearn basic performance skills, such as the ability to maintain sitting or standing balance, reaching, or grasping. In the case of Li, his head injury affected both short- and long-term memory, impairing his ability to perform self-care skills. One of the first goals of his OT program was to relearn hygiene and grooming skills so that he could regain independence in this aspect of self-care.

2. *To develop alternative or compensatory strategies for performing valued occupations*. Clients may need to be taught new ways to perform familiar activities. Alternative or compensatory strategies can also be taught to prevent injury and increase safety. These strategies may be temporary, as in the case of an individual who needs to learn hip precautions after hip replacement surgery, or permanent, as in the case of an individual who needs to learn to use a tenodesis grasp after a complete spinal cord injury at the C6 level. In some cases adaptive equipment may be needed to achieve independence, and instruction in the use of adaptive equipment must be included in the teaching of compensatory

strategies. Li's occupational therapist instructed him in adaptive dressing and bathing techniques so that he could maintain independence in these activities while his fractures healed.

3. *To develop new performance skills to support role performance in the context of a disabling condition*. In some cases clients will need to learn new skills to enable participation in daily occupations. Propelling a wheelchair, operating a prosthetic device, and managing a bowel and bladder program are examples of new skills that clients with specific disabilities must learn. Li's therapist worked with him to develop a reminder system to compensate for his memory loss. He learned to record and keep important information with him in his phone so that he could easily access phone numbers, appointments, and other needed information.

4. *To provide therapeutic challenges that will help to improve performance skills to support participation in areas of occupation*. Therapists may teach clients activities that provide physical and/or cognitive challenges to facilitate the rehabilitation process. Activities such as board games and crafts can be used to improve strength, dexterity, postural control, and problem-solving and sequencing skills, among others. Clients may need to be instructed in the rules or procedures of the activity, and also in how to position or organize themselves to engage in the activity. To improve dexterity in Li's injured right arm after the cast was removed, and also to improve his attention and task orientation, his therapist instructed him in paint-by-number activities. These activities addressed his deficits in both motor and process skills and supported his return to participation in his valued occupation of watercolor painting.

5. *To instruct family members or caregivers in activities that will enhance the client's independence and/or safety in daily occupations.* If the client is not able to learn to perform an activity using compensatory and/or adaptive strategies, it is necessary to teach family members or caregivers how to assist or supervise the client in the activity. Many self-care and home activities may require assistance or supervision to ensure safety. Environmental modifications may need to be made to ensure the safety of the client and the caregiver and to facilitate maximal independence for the client. Li's wife was instructed on how to help him with wheelchair transfers. She was also instructed on how to cue him to use his reminder notebook at home.

Phases of Learning

Learning generally proceeds through three phases. These phases are the acquisition phase, the retention phase, and the generalization, or transfer, phase. The acquisition, or learning, phase that occurs during initial instruction and practice is often characterized by numerous errors of performance as the learner develops strategies and schemata for how to successfully complete the task. The retention phase is demonstrated during subsequent sessions, when the learner demonstrates recall or retention of the task in a similar situation. **Transfer of learning**, or generalization of skill, is seen when the learner is able to spontaneously perform the task in different environments, such as the client who is able to correctly apply hip precautions at home after learning the precautions in the therapy clinic.

Learning Capacities

Not all clients are able to transfer skills learned in one environment into other contexts. Clients who cannot transfer learning will need environmental modifications, supervision, and/or cueing to engage successfully in the activity being taught. Therefore, the therapist needs to determine each client's capacity for retaining and transferring knowledge so that therapist and client can establish appropriate goals and use appropriate teaching methods.

Dynamic assessment is one approach used to determine an individual's capacity to benefit from instruction. In this assessment framework an interactive process is used whereby the therapist uses feedback, encouragement, and guidance to facilitate an individual's optimal performance using a test-teach-retest format.[111] Dynamic assessment complements more traditional assessment methods, giving therapists the opportunity to observe learning and change, which can help guide intervention. Li's therapist used this strategy to teach safe transfer skills early in his rehabilitation program. After providing initial instruction, she asked him to demonstrate a transfer. She then provided additional instruction to address unsafe techniques she observed. After the reinstruction she again had him demonstrate the transfer to determine if he was incorporating her feedback. She repeated this process in each session until she was confident that he was able to consistently use safe technique.

Transfer of knowledge can be evaluated by changing one or more attributes of the task and observing whether the client is still able to perform the task. For instance, a therapist who has been teaching upper body dressing can change the type of garment used in the task, the location or orientation of the garment relative to the client, or the client's positioning. A client who is not able to perform the task with one or more attributes changed may not be capable of transferring new skills.

OT Practice Note

Learning capacities can change dramatically in some clients because of spontaneous recovery from neurologic insults, so therapists should frequently reassess clients to determine whether teaching methods and goals need to be adjusted.

Procedural and Declarative Learning

Therapists teach tasks in which learning occurs both consciously and unconsciously. Knowledge is demonstrated in different ways for the two types of tasks. **Procedural learning** occurs for tasks that are typically performed automatically, without attention or conscious thought, such as many motor and perceptual skills. Procedural knowledge is developed through repeated practice in varying contexts. For instance, an individual learns to maneuver a wheelchair through a process of procedural learning, while gradually developing a movement schema for the activity.[84] **Verbal instruction** alone is of little value. Rather, the procedures for performing this activity are learned through opportunities to experiment with different combinations of arm or arm and leg movements to achieve propulsion in a variety of directions and speeds. Learning is expressed through performance; therefore, individuals who have limitations in cognition or language can still demonstrate procedural knowledge.

Declarative learning creates knowledge that can be cognitively recalled. Learning a multistep activity, such as tying a shoelace or performing a transfer, is often facilitated if the client can verbalize the steps of the task while completing it. Learning can also be demonstrated by verbally describing (declaring) the steps involved in completing the activity. Through repetition of an activity, declarative knowledge can become procedural, as the movement becomes more automatic and requires less cognitive attention. Mental rehearsal is an effective technique for enhancing declarative learning. During mental rehearsal the individual practices the activity sequence by reviewing it mentally or by verbalizing the process. This method can be used effectively with clients who, because of weakness or fatigue, are limited in their ability to physically practice an activity. However, because of the cognitive requirements, clients with significant cognitive or language deficits may not be able to express declarative knowledge.

Principles of Teaching and Learning in Occupational Therapy

The process of teaching involves a sequence of clinical reasoning decisions. Regardless of the characteristics of the client and the activity, basic learning principles can be applied to any teaching and learning situation.

The principles listed in Box 7.1 illustrate that before initiating a teaching activity, the occupational therapist must be aware of (1) the client's cognitive capacity, (2) occupations that have value to the client and the family, (3) the attributes of the task being taught, and (4) the context in which the client will be expected to perform the activity. The therapist needs to gather this information during the initial assessment to create an accurate knowledge base from which to develop the intervention plan, the choice of activities, and the method of teaching. Effective intervention requires appropriate, evidence-based application of these principles to each client's unique situation. Two examples of this include the framework of occupational gradation and goal-directed training. The framework of occupational gradation is a method of systematically manipulating properties of the task, the person, the object, and the environment to optimally challenge an individual's functional performance, specifically in terms of upper extremity motor skills. This framework incorporates principles of motor learning, motor control, personal factors, environmental factors, and properties of tasks and objects. Meaningfulness of the task, client goals, and ability to incorporate the task into daily life are also key considerations.[84] The goal-directed training approach uses client-selected goals to create active problem-solving opportunities for the client. Intervention is focused on the task to be achieved, rather than on impairments that may limit performance. This approach is based on the dynamic systems models of motor control and motor learning and the ecologic occupation-based models of intervention. Progress is measured through incremental steps using goal attainment scaling.[64]

Box 7.1

Principles of Teaching and Learning in Occupational Therapy

- Identify an activity that has meaning or value to the client and/or family.
- Choose an instructional mode that is compatible with the client's cognition and the characteristics of the task to be taught.
- Organize the learning environment.
- Provide reinforcement and grading of activities.
- Structure feedback and practice schedules.
- Help client develop self-awareness and self-monitoring skills.

Each of these approaches combines occupation-centered activities and active engagement of the client, with application of specific motor learning and teaching techniques tailored to the cognitive and motor abilities of the client. Procedural reasoning and narrative reasoning assist the therapist in determining the appropriate configuration of goals, activities, and teaching methods for each individual. The principles of teaching and learning in occupational therapy are further discussed in the following sections.

Identify a Meaningful Occupation, Activity, or Task

When conducting a client-centered assessment, the therapist explores which occupations have the greatest value and importance to the client. Engagement in these occupations can serve both as outcomes of intervention and as activities used in the intervention process. The client will be motivated to be an active partner in the therapy process if the activities are perceived to be meaningful.[112] If the client does not have the capability to engage in the occupation itself, performance skills and activities that contribute to participation in the occupation are often addressed in the intervention. The client needs to be informed of how developing or improving these skills will contribute to the ability to engage in the valued occupation. Doing so helps the client ascribe meaning to the activities and facilitates optimal participation.

Li's occupational therapist learned of his skill as a painter during the initial interview with Li and his wife. The therapist was able to use Li's motivation to return to this valued occupation to guide the choice of drawing and painting activities to improve function in his injured arm. The therapist also was able to explain to Li how his participation in other therapeutic activities to improve strength, range of motion, and endurance would contribute to his ability to resume his occupation of painting, in addition to independence in daily living skills. The therapist's attention to Li's interests and values created trust that led to a productive learning partnership.[30]

Choose Instructional Mode Compatible With Client's Cognition

When many people think about the act of teaching, verbal instruction is what comes to mind. Verbal instruction is an effective means of conveying information in many situations. It is an efficient method for instructing groups, such as in back-safety classes, during training in hip precautions after hip replacement surgery, and through instruction in body mechanics and ergonomic principles for employee groups. Verbal instruction can also be used effectively when instructing individual clients. Verbal cues can be used to provide reinforcement or to give information about the next step in the sequence or the quality of performance. Verbal cues can be an effective way to provide feedback in the early and middle stages of learning; however, it should be phased out as soon as possible so that the client does not become dependent on verbal cues to complete the task. Family members and caregivers can be instructed on how to provide appropriate verbal cues if the client is unable to recall a task sequence independently. Li's wife was present during instruction on transfer techniques, and the therapist taught her brief verbal cues she could use to remind Li of key steps of the transfer process.

Visual instruction is effective for clients who have cognitive and/or attention deficits and difficulty processing verbal language, and also for tasks that are too complex to describe verbally. The therapist demonstrates the activity, and the client observes the therapist and follows the therapist's example. The therapist can repeat the demonstration as many times as necessary for the client to accurately reproduce the task. The therapist can also break the task into steps, demonstrating one step at a time and continuing to the next step as the client completes the previous step. Other forms of visual instruction include drawings or photographs that can be used to remind a client and/or caregiver about the task sequence or desired performance outcome. Visual instruction can effectively be paired with verbal instruction, but therapists must avoid overwhelming the client with combined verbal and visual input.

Somatosensory instruction is a third mode of instruction. This involves the use of tactile, proprioceptive, and kinesthetic cues to help guide the speed and direction of a movement. Manual guidance is a form of somatosensory instruction that is especially effective for procedural learning, such as the process of weight shifting and postural adjustment involved in coming from sit to stand. Hand-over-hand assistance is effective in teaching activities to clients who have cognitive and/or sensory processing deficits; the therapist guides the client's hands in completion of a task.

Li's therapist used all three instructional modes. Verbal instruction was most effective for reteaching self-care skills; verbal cueing was used to orient Li to the task sequence during the acquisition phase of learning. Visual instruction was used to teach many of the therapeutic activities the therapist used to enhance upper extremity function. Somatosensory instruction was effective for balance retraining.

Structure the Learning Environment

Choosing the appropriate environment in which to instruct a client is critical to teaching success. If a client is confused or easily distracted, a quiet environment with minimal visual distraction is often needed when teaching of a task is begun. As the client becomes more proficient in the skill being taught, visual and auditory distractions need to be introduced so that the environment more closely resembles the one in which the client will eventually engage in the activity. For instance, a therapist working with a client on self-feeding may initially conduct the intervention in the client's room. As the client becomes more proficient and confident, the therapist may move the intervention to the facility's dining room, where multiple distractions are present. In addition to providing challenges to the client's attention, the dining room provides opportunities for social interaction, which may act as a motivator for the client to further improve self-feeding skills.

Similarly, clients need opportunities to practice new skills in a variety of environments so that they are proficient in meeting environmental challenges. A client who is learning how to control a wheelchair needs to practice both outdoors and indoors on a variety of surfaces. A client who is working on refining grasp and dexterity needs experience in manipulating objects of a variety of sizes, shapes, and weights while engaging in functional tasks with a variety of demands similar to those that will be encountered in the client's daily activities.

Li's therapist determined that his initial confusion necessitated a quiet, minimally stimulating environment for initiation of teaching in self-care skills. As Li's confusion cleared, he was able to work in the therapy clinic on activities to improve balance and upper extremity skills, and later he worked in the kitchen and garden areas on more demanding and varied skills.

Provide Reinforcement and Grading of Activities

The concept of reinforcement comes from operant conditioning theory, which states that behaviors that are rewarded or reinforced tend to be repeated.[50] Many types of reinforcement may be used. For some clients, social reinforcement such as a smile or verbal encouragement creates motivation to continue. Other clients may require more tangible rewards, such as rest periods, snacks, favorite activities, and so on. Still other clients are motivated by visible indications of their progress. Use of a graph or chart to demonstrate daily improvement in performance skills or client factors such as grip strength, sitting tolerance, or range of motion can help a client to engage more actively in the therapy process. These are examples of extrinsic reinforcement.

Many clients are motivated by completion of a task; for instance, preparing a snack and then eating it, or dressing themselves independently so they can visit with friends. Completion of the task provides intrinsic reinforcement, seen in the individual's satisfaction in his or her ability to participate in desirable activities as a result of completing the task. An activity that is motivating and meaningful to the client can increase active participation and improve intervention outcomes.

Several studies have shown (1) that adding purposeful or imagery-based occupations to rote exercise results in more repetitions than are used for rote exercise alone,[36] (2) that clients select occupationally embedded activities over rote exercise tasks,[121] and (3) that added-purpose occupations result in greater retention and transfer of motor learning than occur with rote exercise.[23] Sietsema et al.[106] found that better scapular abduction and efficiency of forward reach were achieved when clients with traumatic brain injury focused on reaching to control a game panel than when they focused on how far they could reach an arm forward. Similarly, Nelson et al.[77] showed that intervention to improve coordinated forearm pronation-supination was more effective in stroke rehabilitation when clients focused on turning an adapted dice thrower in the context of a game than when they focused on the movement itself. Wu et al.[120] found that intervention to improve symmetric posture in adults with hemiplegia had significantly better outcomes when subjects focused on wood sanding and bean bag toss games. These studies support the effectiveness of teaching meaningful activities and occupations in the rehabilitation process.

In addition to structuring the type of reinforcement, the therapist needs to carefully grade the challenges of the activity, so the client can experience success and mastery during the process of learning the activity. If the client has too much difficulty completing a task, social reinforcement or inherent meaningfulness of the activity will not be enough to override frustration or fatigue. Therefore, therapists must analyze the activity and determine how to grade the activity to meet the learning and reinforcement needs of the individual client. This includes deciding on the most appropriate mode of instruction (as described in the previous section), what type of reinforcement will facilitate intrinsic motivation, and how best to structure feedback and practice schedules; these decisions are discussed in the next section.

Li's therapist knew that his strong desire to return to his occupation of leading nature hikes would motivate him to improve his balance and standing tolerance. The therapist explained how a variety of activities involving challenges to Li's sitting and standing balance would help him regain his postural stability. Li participated actively in these tasks and generated ideas for additional tasks that could be incorporated into his OT program; he also practiced outside of the therapy environment. His intrinsic motivation to perform these tasks in varied contexts was evident in his improved balance skills.

Structure Feedback and Practice

Feedback is information about a response[83] that can provide knowledge about the quality of the learner's performance or the results of the performance. **Intrinsic feedback** is generated by an individual's sensory systems. An individual learning to hit a golf ball uses visual and somatosensory feedback to evaluate performance. The visual system is used to align the head of the golf club and the golfer's body in correct orientation to the ball. Kinesthetic and proprioceptive inputs inform the golfer about joint position and the location of body segments in space; this allows the golfer to make the necessary postural adjustments and upper extremity movements to bring the club head into contact with the ball while using appropriate speed and force.

Extrinsic feedback is information from an outside source. The trajectory of the golf ball, the distance of the drive, and the location of the ball on the fairway all provide extrinsic feedback about the results of the golfer's actions. An observer can provide extrinsic feedback about task performance by giving the golfer information such as, “Your stance was too open,” “You did not follow through far enough on the swing,” or “Your head position was good.” For clients whose sensory recognition or processing abilities have been impaired, extrinsic feedback from a therapist or technological device can provide useful supplementary information to facilitate learning during the acquisition phase. Technological feedback mechanisms include biofeedback systems, virtual reality and gaming technology,[53] and digital displays of kinetic or cardiovascular data on exercise equipment. These feedback systems can allow manipulation of practice conditions and often provide more immediate and consistent feedback than can be obtained from a therapist.

Although extrinsic feedback may be helpful early in the learning process, clients will achieve greater independence and efficiency in activities by developing the ability to continue learning through intrinsic rather than extrinsic feedback. In fact, extrinsic feedback may not produce optimal learning and may create dependency, with deterioration in performance if the feedback is removed.[54] Therefore, extrinsic feedback must be gradually decreased if the client's goal is independent performance in a variety of performance contexts.

Practice is a powerful component of the occupational therapy process. The ways in which a therapist structures practice conditions can influence a client's success in retention and transfer of learning. Several aspects of practice are discussed in the following paragraphs.

Li experienced mild sensory loss in his right arm as part of his injury. When his cast was removed and active rehabilitation commenced, he benefited from extrinsic verbal and somatosensory feedback provided by his therapist about the quality of his movement. As his upper extremity function improved, the therapist gradually decreased the amount of extrinsic feedback provided. Li learned to use intrinsic feedback to adjust the timing, speed, and direction of his movements while engaged in a variety of functional activities designed to improve strength, range of motion, and dexterity. Participation in practice sessions that included varied task challenges helped him to learn strategies that could be transferred to many activities.

Contextual Interference

Contextual interference refers to factors in the learning environment that increase the difficulty of initial learning. Limiting extrinsic feedback provided about the results of performance is one example of contextual interference. A therapist who is attempting to limit extrinsic feedback will minimize the amount of verbal feedback about performance and/or the amount of manual guidance provided during the task. Performance during the acquisition phase may be poorer with high contextual interference; retention and generalization are more effective. This may occur because a high level of contextual interference forces the learner to rely on intrinsic feedback and to adapt motor and cognitive strategies to complete the task, resulting in more effective learning.[41]

Blocked and Random Practice Schedules

Blocked and random practice schedules are examples of low and high contextual interference, respectively. During **blocked practice**, clients practice one task until they master it. This is followed by practice of a second task until it is also mastered. In **random practice**, clients attempt multiple tasks or variations of a task before they have mastered any one of the tasks. A random practice schedule may be used to teach wheelchair transfer skills. The client practices each of several transfers during the course of a single session. For example, the client will practice moving between the wheelchair and a therapy mat, between the wheelchair and a chair, and between a toilet and the wheelchair. A random practice schedule for improving postural stability might include having the client stand on a variety of unstable surfaces, such as an equilibrium board, a balance beam, or a foam cushion, while playing a game of catch. These types of practice schedules may slow the initial acquisition of skills but are better for long-term retention of these skills[23] and for transfer of the learning to another context or task.[31] This is because random practice engages deeper cognitive processing than blocked practice. As a result, the stronger motor memory formed facilitates retention, particularly for more complex motor tasks.[44,80]

Whole Versus Part Practice

Breaking a task into its component parts for teaching purposes is useful only if the task can naturally be divided into discrete, recognizable units.[119] This is so because continuous skills (or whole task performance) are easier to remember than discrete responses.[93] For example, once a person has learned to ride a bicycle, this motor skill will be retained even without practicing for many years. Continuous skills should be taught in their entirety rather than in segments. For example, the activity of making vegetable soup includes several discrete tasks, including chopping vegetables, measuring ingredients, assembling the ingredients in the soup pot, and cooking the ingredients. During one session, the therapist could teach a client to chop the vegetables; the other components of the task could be taught in subsequent sessions. However, for the activity of making a pot of coffee, the task components (measuring the water, pouring it into the coffeemaker, measuring the coffee, putting the coffee into the coffeemaker, turning on the coffeemaker) need to be completed in a specific order. Teaching any of these task components in isolation would not result in meaningful learning or independent activity performance. For best retention and generalization, making coffee should be taught as a complete task, rather than having the client practice a different portion of the task during each therapy session.

To facilitate the learning process, the therapist may provide demonstration, verbal cueing, or manual guidance as needed for selected aspects of the task. This way the client experiences completion of the task on each trial, and the therapist gradually gives less assistance as practice sessions continue.

Cognitive Strategies

A growing body of literature supports the efficacy of cognitive strategies in helping individuals to learn motor skills. Cognitive strategies are goal-directed, consciously controlled processes that support motor learning and include memory, problem solving, mental imagery, perception, and **metacognition**.[69] Cognitive strategies can be general or specific. General strategies are used in a variety of situations, and specific strategies are used for a particular task. Evidence from a variety of studies suggests that cognitive strategies can assist individuals with stroke to transfer skills to different environments.[55,56,69,116] Cognitive strategies can be used in conjunction with practice in variable contexts to facilitate learning of motor and functional performance skills.

Practice Contexts

Practice under variable contexts enhances transfer of learning. Optimal retention and transfer of motor skills occur when the practice context is natural rather than simulated.[60,66] This may reflect the fact that the enriched, natural environment provides more sources of feedback and information about performance than the more impoverished simulated environment. However, transfer of learning is better when the demands of the practice environment more closely resemble the demands of the environment in which the client will eventually be expected to perform.[121] Therefore, teaching kitchen skills in a client's own home or in a kitchen environment that is very similar to the client's kitchen will result in better task performance when the client engages in the task at home.

Client factors may also influence outcomes related to the practice context. A meta-analysis of the effects of context found that treatment effects were much greater for populations with neurologic impairments than for those without neurologic impairment.[54] Errorless learning, also known as systematic instruction, is an intervention paradigm based on the principle that learning will occur more quickly and efficiently if the learner does not engage in trial and error throughout the learning process. This learning strategy has been used effectively with individuals who have cognitive or memory deficits as a result of acquired brain injury or dementia,[86] but it has also been effective in facilitating learning of a practical skill (fitting a prosthetic limb) during the rehabilitation process.[16]

One aspect of the practice context that has received little research attention is the role of the social environment in task learning. The importance of the social context of occupational performance and of the occupation of social participation is endorsed by the Occupational Therapy Practice Framework: Domain and Process, third edition (OTPF-3).[2] Working with other clients in a group promotes socialization, cooperation, and competition, which can increase clients' motivation. Acquisition of skills is enhanced through observation of others who are learning a task. Additionally, group intervention can promote the development of problem-solving skills and can create a bridge between the supervised therapy environment and the unsupervised home environment.[13]

Help Client Develop Self-Awareness and Self-Monitoring Skills

To maximize the retention and transfer of learning, clients must develop the ability to self-monitor, so they are not dependent on extrinsic feedback and reinforcement. The knowledge and regulation of personal cognitive processes and capacities is known as *metacognition*.[45] It includes awareness of personal strengths and limitations and the ability to evaluate task difficulty, to plan ahead, to choose appropriate strategies, and to shift strategies in response to environmental cues. Although metacognition is typically discussed in relation to improving cognitive skills, self-awareness and monitoring of relevant performance skills may be equally important prerequisites to developing effective motor, interpersonal, and coping strategies. Specifically, an intervention directed toward helping clients develop enhanced awareness of body kinematics and alignment may be an important component of motor learning.[12] Self-review of performance and guided planning for tackling the challenges of future tasks are key factors in the therapeutic process and are critical prerequisites to a person's ability to generate and apply appropriate strategies.

Strategies are organized plans or sets of rules that guide action in a variety of situations.[90] Motor strategies include the repertoire of kinematic linkages and schemata that underlie the performance of skilled, efficient movement. The process of stepping to the side when one is abruptly jostled is a motor strategy for the maintenance of standing balance.[101] Cognitive strategies include the variety of tactics used to facilitate processing, storage, retrieval, and manipulation of information. Using a mnemonic device to remember a phone number is a cognitive strategy. Interpersonal strategies help in social interactions with other individuals. A person who uses direct eye contact and greets another by name when being introduced is using an interpersonal strategy. Coping strategies allow people to adapt constructively to stress. Coping strategies can include deep breathing, exercise, or relaxation activities.

Strategies provide individuals with foundational skills that can be adapted to the changing demands of occupational tasks within a variety of contexts. Thus, learning is more likely to be transferred to new situations when opportunities arise to develop foundational strategies.[107] Individuals develop strategies through a process of encountering problems, implementing solutions, and monitoring the effects of these solutions. Occupational therapists use activities to help clients develop useful strategies by presenting task challenges within a safe environment that provide opportunities to try out different solutions.[90]

As Li was nearing discharge from occupational therapy services, the therapist worked with him to develop strategies to facilitate his occupational performance. Although his memory was improved, recall of names and numbers was still poor, so the cognitive strategy of using a notebook for recording important information was continued. In addition, to cope with persistent mild deficits in balance, Li and his therapist developed a motor strategy of keeping a sturdy table nearby when he stood to talk to visitors at the botanical gardens. This strategy provided a support that he could lean on or hold onto if needed, and it was a strategy that also could be used in other situations.

Factors That Influence the Learning Process

The ultimate goal of learning is to create strategies and skills that individuals can apply flexibly in a variety of contexts and occupations. As this chapter has presented, occupational therapists have many methods available to them to help their clients achieve this goal. The concepts discussed in this chapter that facilitate transfer of learning to other environments are listed in Box 7.2.

Threaded Case Study

Li, Part 2

In the case of Li, the therapist used the information gathered in the initial assessment process to determine what she should teach Li and his wife, and in what order she should teach various tasks, activities, and occupations. She began with hygiene tasks because these could be accomplished in a sitting position and because of Li's stated desire to perform these tasks independently. She also taught transfer skills and adapted activity of daily living (ADL) techniques so that Li could maximize his mobility, safety, and functional independence in a wheelchair while his lower extremity fractures healed.

As Li's healing progressed, his therapist was able to begin teaching tasks to improve postural stability and upper extremity strength and coordination. Occupations taught during this phase included ADLs and instrumental ADLs (IADLs), in addition to activities designed to improve motor skills. As Li's performance skills improved, the therapist was able to introduce more complex tasks and occupations that further challenged his motor and process skills and prepared him to return to his valued occupations of painting, hiking, and teaching.

As Li's discharge from therapy neared, the therapist changed her focus to teaching cognitive and motor strategies that Li could use to help compensate for residual deficits in balance and memory. Throughout the intervention process the therapist reassessed Li's functional status so that she could adjust her teaching strategies to his current cognitive and motor skills and to the specific demands of the task and environment.

Box 7.2

Factors That Support Transfer of Learning

- Active participation
- Occupationally embedded instruction
- Intrinsic feedback
- Contextual interference
- Random practice schedules
- Naturalistic contexts
- Whole task practice
- Strategy development

Section 1 Summary

Occupational therapists teach activities for a variety of reasons. They reteach familiar activities, teach alternate or compensatory strategies of performing valued activities, teach new performance skills to support role performance, teach therapeutic challenges to improve performance skills to support occupational participation, and teach caregivers and/or family members to facilitate the client's independence and safety in the home environment.

Occupational therapists use a variety of teaching strategies to promote skill acquisition, skill retention, and transfer of learning. Procedural and declarative learning represent unconscious and conscious learning processes, respectively.

Occupational therapists maximize the learning process by (1) identifying activities that have meaning or value to the client/family, (2) providing instruction tailored to the needs of the individual and the task, (3) structuring the environment to facilitate learning, (4) providing reinforcement and grading of activities to establish intrinsic motivation, (5) structuring feedback and practice to facilitate acquisition, retention, and transfer of learning, and (6) helping clients develop self-awareness and self-monitoring skills.

Section 2 the Therapeutic Use of Self: Embodying Mindfulness in Occupational Therapy

Rochelle McLaughlin

The experience you have today will influence the molecular composition of your body for the next 80 days, because that's how long the average protein synthesized in your body today will hang around in the future,

So plan your day accordingly.

Dr. Steven Cole, Professor of Medicine and Psychiatry at UCLA

Threaded Case Study

Irene, Part 1

Irene, an experienced occupational therapist (OT), works full time in a rehabilitation hospital in her metropolitan area. In the past Irene has experienced a great deal of gratification from her work as an OT. However, over the past several years she has steadily been experiencing increasing levels of stress at home due to family complexities, such as her husband being recently laid off from his job and her 4-year-old daughter demonstrating increasing signs and symptoms of having difficulty with focusing, effectively interacting with her family, intensifying nutrient-poor food preferences, increasing sensory seeking and avoiding behaviors, sleeplessness, and lability. Irene's father was also recently diagnosed with and experiencing significant disability from Lyme disease. Irene is currently her father's primary caregiver because her mother has passed away. On top of her family responsibilities and intensities, Irene's work hours and workload are intense, and there are increasing demands for productivity standards, professionalism, technological standards, and “billability” throughout the hospital. She is finding it increasingly difficult to skillfully and effectively meet the needs of the complexity of the patient-family-care demands, the intense productivity standards at work, the caseload, the complex needs of her team, and taking care of herself.

Irene has identified personal psychophysiologic signs and symptoms of her difficulty in meeting and responding to the complex family and work demands, such as insomnia; decreased libido; frequent chest and sinus infections; shallow breathing; muscle tension; headaches; back pain; digestive issues; increasingly poor food choices; craving caffeine, sugar, and refined carbohydrates; increased media use and a frazzled sense of always being “overly busy”; decreased motivation; reduced productivity; feelings of cynicism and hopelessness; a sense of depersonalization; and disengagement from routines and activities that she might consider restorative and nourishing.

Irene wishes that she could have greater ease and well-being in her work and in her family life. She wishes she felt more effective at work and more connected to her family and community. She feels stuck and feels that there must be a healthier, more effective way to be in relationship to her life's intensities.

Critical Thinking Questions

1. How might Irene's access to valuable clinical reasoning and critical thinking skills be limited or impaired? In what specific ways might she not be able to meet the demands of our complex profession of OT and patient care? Consider her ability or inability to build or not build meaningful rapport with her clients or her capacity or incapacity to use herself in an effective and therapeutic way.

2. What are Irene's patterns of occupational engagement? How have they changed, and why have they changed? Consider her **quality of the engagement and participation in occupations**. What barriers are affecting her success in her roles as a mother, wife, and caregiver?

3. Consider Irene's priorities and desired targeted outcomes related to occupational performance, prevention, participation, role competence, health and wellness, quality of life, and well-being?

The development of the therapeutic use of self can be considered the single most important line of intervention we can provide as occupational therapists, and *the therapeutic use of self* has been added to the process overview of the OTPF-3, published in 2014.[1,2] However, there is still little focus in the literature or even in occupational therapy education on *how* to develop, access, and implement this critical yet elusive skill.

Irene's situation, our case example, is unfortunately not unique. The current medical environment in which occupational therapists work tends not to instill institutional cultural norms for fostering or supporting these skills for their employees. The modern Western medicine medical environment itself actually tends to disproportionately value productivity and self-sacrifice over employee health and well-being. The healthcare system is also being increasingly overburdened by the chronic public health disease crisis. Industry experts state that hospital admissions have been continuously rising over the past 30 years, to the point where U.S. hospitals are being stretched to their limits—placing a heavy burden of care on the staff.[3,8] It is not surprising, then, that burnout and chronic disease statistics among healthcare professionals are staggering and growing. The U.S. reports a 25% to 70% burnout rate among healthcare workers, depending upon the working conditions; the UK reports a 70% burnout rate; and Canadian oncology healthcare workers report unfortunate statistics of up to 45% burnout rate.[a]

Although these statistics demonstrate dire circumstances for healthcare workers, there is promising and emerging research demonstrating the beneficial and encompassing effects of the development of the skills and qualities of mindfulness as a sorely needed remedy, effective intervention, and healing modality to meet the mental, emotional, physical, contextual, and therapeutic needs of our world's healthcare workers and the individuals they work with.[b] The characteristics of **mindfulness-based healthcare practitioners** (MBHPs; healthcare workers who are embodied mindfulness practitioners) are aligned with the characteristics of providers who demonstrate skillful and effective therapeutic use of self.[c]

The practices, skills, characteristics, and qualities of mindfulness take time to develop in one's life and work, just as the development of the therapeutic use of self does, and yet they are incredibly portable, practical, and useful. Employing mindfulness in occupational therapy practice with the intention to develop one's capacity to use oneself in an effective and therapeutic manner is not a quick fix for any of the complex problems an OT encounters in his or her life and work. According to extensive research, however, the implications of this kind of training are profound and far-reaching.[d] In this chapter, with the assistance of Irene's case example, we'll take a look at how the embodiment of the qualities and skills of mindfulness in occupational therapy can elicit the development of the therapeutic use of self and enhance our health, well-being, effectiveness, and sense of purpose and meaning.

The Therapeutic Use of Self

The Commission on Practice of the American Occupational Therapy Association (AOTA) added "the therapeutic use of self" to the OTPF-3 process overview in 2014. This change was made to ensure that practitioners understand that use of the self as a therapeutic agent is integral to the practice of occupational therapy and is used in *all* interactions with *all* clients.[1,2] The commission states that the *therapeutic use of self* allows occupational therapy practitioners to develop and manage their therapeutic relationship with clients using skillful narrative and clinical reasoning[51,89]; empathy[110]; and a client-centered,[20,76,79] collaborative approach to service delivery. Open communication ensures that practitioners connect with clients at an emotional level to assist them with the current life situation.[33,34] The use of the self in a therapeutic way is defined as the capacity and skill to utilize oneself in such a way that one becomes an *effective* tool in the evaluation and intervention process.[1,2]

The following highlights a few qualities and characteristics of the effective use of the therapeutic use of self to help us begin to articulate the practice and skills. They can be described as being embedded within the Mindfulness Model,[99] which, as described by Shapiro et al.,[99] highlights three important aspects of the development of the therapeutic use of self: the level of attention (LOA), the attitude (A), and the intention (I) the occupational therapist brings to therapeutic relationships. As you consider the list below, identify whether the characteristic, quality, or behavior is expressed by a *level of attention, attitude,* or *intention (or all three)* on the part of the therapist. For example, for Irene to be able to recognize her own emotional responses, she must have set an *intention* to be present *(level of attention)* to her emotional experiences as they express themselves in her body; to honor her own emotional experience, she must begin to cultivate an *attitude* of openness, curiosity, kindness, and compassion toward her internal experiences. Therefore, for this example (Fig. 7.1), all three of the characteristics defined by Shapiro and colleagues are present.

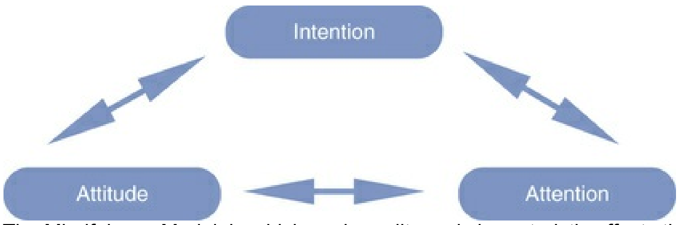

FIG 7.1 The Mindfulness Model, in which each quality and characteristic affects the others.

It is important to recognize that the skills the therapist uses in the therapeutic relationship also must be embedded within the his or her personal life. If, for example, Irene is unable to recognize her own emotional state or she tends to numb or subjugate herself to her own feelings and not process or metabolize them, her capacity to recognize and be in skillful relationship to another's pain and suffering will be limited and stunted. This would significantly affect the skillfulness and development of Irene's therapeutic use of self and would contribute to burnout and affect her therapeutic and personal relationships.

Attuning to oneself and another person with awareness of the full context of the situation with the intention to provide **prepared and effective interpersonal interaction**.[102] Prepared and effective interpersonal interaction requires a specific intention, level of attention, attitude, and skill set on the part of the therapist that can be explicitly developed via mindfulness training in the therapist's personal and work life over the course of years; it thereby becomes a "practice" and a "way of being" and includes (but is not limited to) the following list of characteristics and qualities.

These characteristics and qualities can also be related to occupational therapy's established core values and standards of conduct (Table 7.1), illustrating the relationship between characteristics and qualities of mindfulness skills, prepared and effective interpersonal interaction, and the therapeutic use of self with OT's core values, ethical principles, and standards of conduct. The profession of occupational therapy is grounded in seven longstanding core values (CVs): (1) altruism, (2) equality, (3) freedom, (4) justice, (5) dignity, (6) truth, and (7) prudence. It also follows six ethical principles and standards of conduct (PSCs) for determining the most ethical course of action: (1) beneficence, (2) nonmaleficence, (3) autonomy, (4) justice, (5) veracity, and (6) fidelity. These concepts or words are not regularly used in our modern lexicon, but each word benefits from a greater depth of inquiry and engagement so that there is a deeper understanding of its true meaning and potential impact. In-depth study of the original documents wherein these principles are fully defined and discussed is essential. It is beyond the scope of this chapter to explore the Occupational Therapy Code of Ethics (2015); however, the reader is urged to do his or her own expanded investigation into the personal, cultural, societal, and even spiritual meaning they each hold.

TABLE 7.1

Characteristics and Qualities of Mindfulness Practice in Relationship to the OT Core Values and OT Ethical Principles and Standards of Conduct

These characteristics and qualities are catalyzed by the practice of mindfulness in the development of the therapeutic use of self.

Characteristics and Qualities	OT Core Values	OT Ethical Principles and Standards of Conduct
Be able to recognize, acknowledge, validate, and honor one's emotions, feelings, and experiences, both the therapist's own and the client's.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence
Practice mindful, open, curious, embodied presence while listening. Actually hearing what another person is saying without the overlay of judgments and ruminations. This includes "listening" to one's own feelings and emotions.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Provide gentle, authentic, and kind reassurance (for oneself and the other) that may alleviate fear or anxiety.	Altruism, dignity, and prudence	Beneficence, nonmaleficence
Obtain necessary information, understanding the facts and full context of the situation to identify, provide, and prioritize	Altruism, equality, freedom,	Beneficence, nonmaleficence,

the focus of the intervention plan.	dignity, truth, and prudence	autonomy, justice, veracity, fidelity
Identify and provide appropriate and helpful support and resources.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Identify, obtain, and provide effective and skillful support and behavioral and attitudinal modeling.	Altruism, dignity, and prudence	Beneficence, nonmaleficence
Be (for oneself and the other) open to, recognize, promote, and honor growth, change, and development.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Improve the quality of engagement, function, and participation in occupations.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Foster greater capacity to skillfully manage and relate to the inevitable stresses of life. Skillfully responding, recognizing when "reacting" and making conscious choices about how to relate to inner and outer stressors or a given situation skillfully and effectively.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Develop the skills of the "conscious use of self," "reflective observation," and "situational awareness."	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Being present and open to the spontaneous, impermanent, and complex nature of life and the engagement in the profession of OT.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Recognition, inclusion, and celebration of individuality and diversity.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Respect for the integrity, dignity, and rights of each individual, including one's own.	Altruism, equality, freedom, justice, dignity, truth, and prudence	Beneficence, nonmaleficence, autonomy, justice, veracity, fidelity
Enhancing empathic drives: entering the experience of/with another individual without the loss of one's own sense of experience, practice of establishing healthy, loving boundaries, and groundedness.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
The capacity to recognize, honor, and express humility, integrity, and honesty.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Unconditional positive regard for oneself, the client, the situation.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Mental clarity and flexibility. Self-awareness, understanding, and insight.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity, fidelity
Explicitly guided by personal (intuited) values and morals that may or may not necessarily be expressed by those of modern industrialized society or Western medicine.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, justice, veracity, fidelity
Radical self-care, self-compassion, and nourishment of the parasympathetic nervous system via intentional lifestyle choices.	Altruism, dignity, truth, and prudence	Beneficence, nonmaleficence, veracity

This list of characteristics and qualities of prepared and effective interpersonal interaction can easily just become another concept or intellectual understanding that somehow one is just supposed to succumb to or "get" because it sounds nice. The key to living the qualities and characteristics with heart and authenticity is dependent upon one's ability to cultivate a new Way of Being in all aspects of one's life. This becomes a reality when the individual makes a commitment to himself or herself: to engage with the practices of mindfulness and "do the work" of integrating all aspects of oneself, of learning to turn toward one's own version of the full catastrophe, of cultivating courage to be with rather than run away from life's challenges, to nourish oneself with radical unconditional love, and to live wholeheartedly. This Way of Being comes with dedicated practice. One can build mindful awareness skills as a powerful and meaningful way to relearn what has been covered and "dis-cover" and bring this about in your life. Although it may not be a quick fix, it is a fruitful journey, one that is so sorely needed during this time of such complexity and utter distraction. Every single present moment is an opportunity to do just that, and every time you engage with and manifest these mindfulness qualities in your life, they will be deepened, until your entire life becomes one consistent stream of awake, authentic, whole-hearted, and present living. It is well worth the effort because over time and diligent effort, shift happens.

Environmental Effects on the Development of the Therapeutic Use of Self

Most would agree that the development of the therapeutic use of self is a welcome and necessary component to being and becoming an effective occupational therapist. The challenge lies in the fact that health professionals, including occupational therapists, are working in increasingly fast-paced, production-oriented, resource-driven environments in Western medicine that disproportionately value hard work and self-sacrifice over employee health and well-being. Increased productivity standards, increased client loads, and self-care discrepancy measures among health professionals demonstrate staggering and unfortunate impacts on the health professional's mental, physical, and moral health. Research has demonstrated that the resulting burnout among health professionals significantly impacts and reduces client outcomes, the development of the therapeutic use of self, and rapport building.[a]

Burnout refers to a state of emotional exhaustion in health and mental health workers that can manifest in the form of mental health problems, physical ailments, illness, and disease, and it is on the rise.[25,61,63,82] Depression, suicide, substance abuse, sexual misconduct, burnout, and relational problems can all be realistic and serious concerns for therapists who do not effectively care for themselves and do not have the skills to effectively engage with the unique and staggering personal and occupational stressors they face.[7] Burnout has been associated with suboptimal patient care.[98,99] Dr. Stephen Porges, in his book, *The Polyvagal Theory: Neurophysiological Foundations of Emotion,* *Attachment, Communication, and Self-regulation* (2011),[85] describes in great detail the very unfortunate effects of fight, flight, and freeze modes of engagement and the devastating consequences of the chronic sympathetic nervous system activation mode of operating on interpersonal relationships. In his book, *The Body Keeps the Score: Brain, Mind, and Body in the Healing of Trauma,*[115] (2014), Dr. Bessel van der Kolk explains why sympathetic nervous system activation affects concentration and memory and leads to difficulty forming trusting relationships, in addition to difficulty attending to and feeling at home in one's own body.

Irene's situation articulates these unfortunate realities; she is clearly not demonstrating skills that would enable her to be in effective and skillful relationship to the suffering in her personal or professional life. She is numbing and subjugating her own suffering in a variety of dysfunctional and misguided ways, which is deepening the level of suffering she is experiencing from external stressors. Irene's internal stressors of declining mental, emotional, and physical health are compounding the suffering even further and significantly affecting her interpersonal relationships and effectiveness as an occupational therapist.

Recognizing and acknowledging this current reality for so many health professionals can certainly make anyone feel hopeless about the situation; however, there is good news. The good news, as stated by Elizabeth Lesser, author of *Broken Open: How Difficult Times Can Help Us Grow,*[52] (2005), is this: every experience of struggle offers us what we need to be born anew. As we turn toward and deeply acknowledge the true and deep suffering occurring within the current reality of Western medicine, we can begin the work to rise out of this dark night stronger and more empowered than ever before. We can do this co-collectively and co-creatively, and there are maps to help guide us on this journey of transformation. In this chapter we will be exploring aspects of the development of mindfulness as that guiding compass.

The knowledge that therapists can do harm to their clients and themselves by not being aware of and attending to their own needs in a compassionate way and not having developed the skills to be in relationship to this degree of intensity in which they participate has driven this growing body of research. An ever-increasing number of studies demonstrate that the skills of mindfulness appear to be an effective intervention for many, if not most, of these social, emotional, physical, occupational, contextual, moral, ethical, and environmental ills.[a] Research suggests that mindfulness training for healthcare professionals can function as a viable, practical, and useful tool for promoting effective and skillful engagement in one's profession.[38] The development of body awareness in particular has been shown to be a powerful healing practice.[85,115]

Skilled and effective occupational therapists are propelled and motivated by the profession's core values, ethical standards, and principles of care. The preamble to the Occupational Therapy Code of Ethics (2015) states:

… ethical action goes beyond rote compliance with these Principles and is a manifestation of moral character and mindful reflection. It is a commitment to benefit others, to virtuous practice of artistry and science, to genuinely good behaviors, and to noble acts of courage. Recognizing and resolving ethical issues is a systematic process that includes analysis of the complex dynamics of situations, weighing of consequences, making reasoned decisions, taking action, and reflecting on outcomes.

As an example the code lists Principle 2 as "nonmaleficence," which states that "Occupational Therapy personnel shall intentionally refrain from actions that cause harm." Specifically, subprinciple 2C states that we must recognize and take appropriate action to remedy personal problems and limitations that might cause harm to recipients of service, colleagues, students, research participants, or others. Subprinciple 2D states that we must avoid any undue influences that may impair practice and compromise the ability to safely and competently provide OT services, education, or research.[1]

For Irene, participating in mindfulness training, developing awareness, getting meaningful support, and making slow, steady, and mindful lifestyle changes can remedy her personal problems that negatively affect her capacity to be guided by her core values and develop the mental clarity and intuitive intentions to implement meaningful ethical standards and principles of care. Mindfulness training that is engaged in with heartfulness will also cultivate the necessary degree of self-compassion as one begins to see the implications of one's actions and choices and intentionally directs one's actions and choices so that they are steadfastly in alignment with one's deeper (or higher self) personal and professional values and mores.

Mindfulness and the Enhancement of the Therapeutic Use of Self

Using mindfulness as the scaffolding or bedrock for enhancing the development of the therapeutic use of self in occupational therapy seems intuitively appropriate because many studies have demonstrated the potential beneficial effects of specific mindfulness training on healthcare professionals' personal self-care, in addition to improvements in interpersonal relationships. Such professionals are found to be markedly more fully present with clients and their needs, less resentful, less reactive, and less defensive. Additionally, they demonstrate increased positive affect and self-compassion, more self-awareness and acceptance, improved attention and concentration, enhanced life satisfaction and meaning, and improved morale. Furthermore, they show increased performance and decision making, improved self-regulation and impulse control, improved empathic responses, enhanced creativity, and improved senses of self-mastery, self-esteem, self-trust, and mental flexibility.[4,6,35,96] These specific qualities of attention, attitude, and intention are foundational components in the development of the therapeutic use of self and can have profound and far-reaching effects.[14,89,100,114]

Mindfulness is the skill of being deliberately attentive to one's experience; in the present, as it unfolds, without the often unacknowledged overlay of judgments and conceptualizations.[5] This does not mean that the therapist would suddenly become a perpetually unflustered and calm person. In fact, turning toward one's experience with courage can initially be more challenging than we might think. However, with steadfast practice and curiosity, the human capacity to be mindful provides a wholesome way to attend to our subjective experiences and helps us learn, grow, and overcome the unskillful habits of mind that cause us to suffer unnecessarily.[113] The practice of nonjudgmental noticing what is here for you in the moment takes courage, and over time this sense of courage can grow and instill a personal sense of strength and empowerment. It is clear that mindfulness appears to help foster states of mind that are conducive to developing and enhancing the therapeutic use of self.[38,103,104,108]

Although it may sound simple to attend to the present moment, the mind's default mode is entropy, and because we live in a society that does not typically appreciate or teach the skills of harnessing psychic energy, our modern society tends to condone the use of external stimuli—such as, in Irene's example, media and television, excessive busyness, mindless autopilot mode occupational participation, and other distractions—in a desperate attempt to focus our minds or in an attempt to avoid the discomfort of a disordered or dysfunctional mind.[11,15] We begin to recognize how familial, societal, and cultural conditioning encourages us to avoid and deny discomfort of any kind and notice and begin to appreciate ways in which the formal mindfulness practices can both deepen the awareness of life's challenges and help us recognize our capacity as human beings to be in skillful relationship to them. In her book, *A Mind of Your Own* (2016),[10] Dr. Kelly Brogan encourages us to recognize and question this kind of conditioning, so we can begin to reclaim our personal power and innate wisdom to heal our bodies and reclaim our lives. As Kabat-Zinn wrote, "If there was such a thing as a self-distraction index, in the technologically-bombarded society we live in today, it would be going through the roof."[42,43] To repeat the opening quote for this section: Dr. Steven Cole, professor of medicine and psychiatry at the University of California—Los Angeles, has stated, "The experience you have today will influence the molecular composition of your body for the next 80 days, because that's how long the average protein synthesized in your body today will hang around in the future, So plan your day accordingly."

In response, one might ask: *Okay, so how do we do this?* The key practices necessary for the cultivation of mindful awareness are the formal practices or meditations. The formal practices are a form of mental and physical exercises that are meant to strengthen and deepen the inherent human capacity to bring our awareness to the present moments of our lives.[99,102,105] Because mindfulness is the skill of leaning into the present moments of our lives without judgment, it is important that we approach the practices in this spirit, relinquishing preconceptions, as much as we can, about the practices and cultivating an open and curious state of mind. This offers us greater opportunity to benefit from them and deepen our experiences and growth. Of course, a healthy dose of skepticism is valuable; testing out the practices for each individual is important, and reflecting on and acknowledging the experiences throughout the process of developing insight, empathy, compassion, and understanding are crucial.[79] This is a true expression of "evidence-based practice"; when we can recognize the fruits of practicing these skills as "self-evident," they become personal, palpable, and incredibly healing.

Therefore, the key to using mindfulness with the intention of developing the therapeutic use of self in the context of occupational therapy is the steadfast personal work with the formal and informal mindfulness practices. Mindfulness practices are highly adaptable for any population and can be applied to participation in any occupation, such as sitting, eating, washing hands, driving, walking, shopping, taking in media, studying, reading, expressing loving kindness, and so on. Although the practices may seem simple at first, what comes up for us can actually be quite complex, offering infinite opportunities to bring the foundational qualities of compassion and kindness to our present-moment experiences.[91] Offering compassion (a desire to alleviate suffering) to ourselves throughout the journey is quite possibly the greatest practice of all. It can be challenging at times to offer ourselves compassion, and it is important to be aware of when we need it most. Mindfulness skills and techniques can help us open, lean into, and acknowledge our challenges, and through that opening deepen our potential for greater freedom, humility, and a deeper connection with humanity. We are more capable of showing up for another human being's suffering when we can trust that we can be in wise, compassionate relationship to our own.

The primary formal practices taught in mindfulness-based stress reduction curriculum are the body scan, the breath awareness practice, the sitting awareness practice, mindful lying yoga, mindful standing yoga, walking meditation, and loving kindness. Each of these practices is unique to its intended focus, yet they all share significant commonalities, such as intentionally attuning nonjudgmentally to our experience in the present moment.[67] (See the Apply it Now section of this chapter for examples of formal mindfulness practices.)

Practicing mindfulness over time reveals and develops the basic human qualities of wisdom and compassion, the main values of the skills of mindfulness. Wisdom means seeing clearly into the nature of reality. Through mindfulness practices, we can begin to recognize the impermanent nature of all phenomena and see the unsatisfactory nature of ordinary human experience that arises from the illusion that the self is an existence separate from the rest of reality.[26,76] We begin to sense our interconnectedness within the full spectrum of our shared human experience. We have a greater capacity to meet grief and loss without fear or aversion. We are more capable of behaving with wisdom and compassion while maintaining inner and outer peace, regardless of the situation.[118] We begin to recognize what is most essential for our well-being and to tune into our experience and the experience of others with greater degrees of insight and understanding (Fig. 7.2).[85,92]

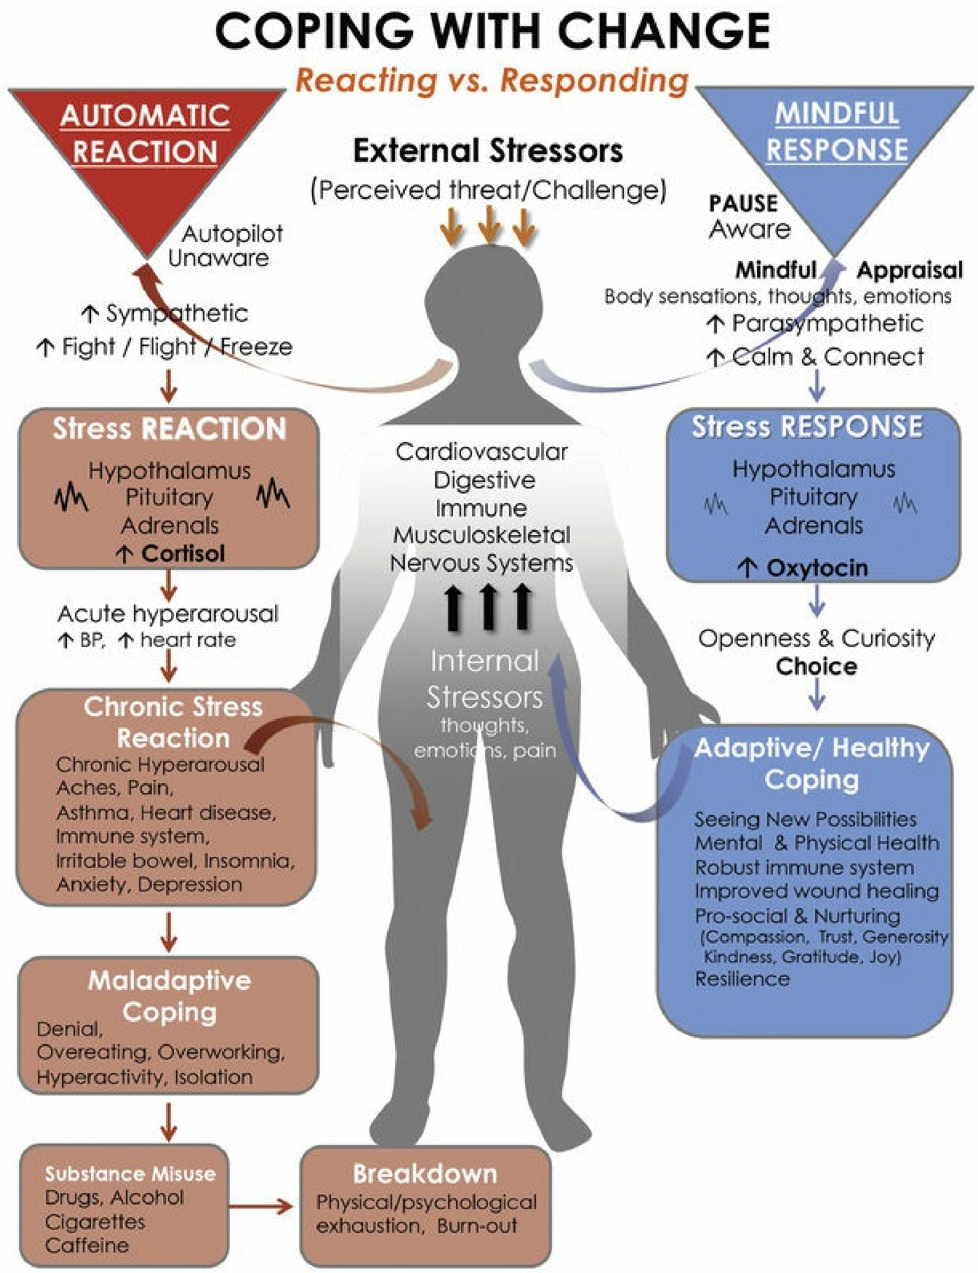

FIG 7.2 Coping with change. (©2015 Elizabeth Lin MD, MPH, ehblin@uw.edu. Adapted with permission from Kabat-Zinn J: *Full catastrophe living*, 2013; Bardacke N: *Mindful birthing*, 2012; Graphics courtesy R. Ryan.)

Mindfulness offers us an opportunity to realize the arising and passing away of all phenomena, the impermanence of all phenomena, including our thoughts and emotions, pain and discomfort, and life itself. Through this recognition, which arises out of our own subjective experiences with the practices, we are capable of learning to embrace life's transient nature and to understand the value of capturing each present moment as it arrives as fully as possible, with all our senses. This especially applies to preparing the OT self to work in the moment and value the moment, and to convey this to our clients, regardless of their loss or the severity of their circumstances. The presence of a practitioner can be a palpable anchoring presence in the midst of catastrophic life experiences. It may be imperceptible, but research has shown that these qualities are very much present and can be profoundly effective and healing.[68]

OT Practice Note

Extended Mindfulness Retreat Training

Participating in extended mindfulness training retreats are one of the best ways to deepen the skills of mindfulness in one's life and to experience the benefits more deeply and swiftly. It is necessary to cultivate a relationship to mindfulness with an attitude of nonstriving, of not needing anything to be “fixed”; to understand that we are already whole and complete just as we are as we engage with the mindfulness practices. To trust as we turn toward our own completeness and humanity while being held in the container of mindfulness that we will open to greater degrees of insight and well-being in a time frame that is unique to each individual (see resources for mindfulness-based retreat centers in the United States).

Mindfulness skills offer powerful means to work with pain and physical discomfort—by becoming aware of and experiencing for oneself the distinction between pain and suffering—as it pertains to our own perception of the experience.[43] These qualities are invaluable as we participate in the compelling and complex practice of occupational therapy, working on the front lines of incredible human suffering: our own, the world's, and that of the individuals with whom we work.

The shift for Irene was slow but palpable as she began to recognize the difference (perceptual shift) between “pain” and “suffering.” Her most valuable experiences at first were those that pertained to her own pain and experience of what it really means “to suffer.” As she built mindful awareness into her life, Irene began to recognize that the physical pain she experienced in her back fluctuated, depending on what she was doing, that it was impermanent and not present “all the time,” and that it did not spread throughout her whole body, as she had previously “thought.” Irene recognized that when she mentally resisted or ruminated about the pain in her back, it would get stronger and intensify. She recognized that the mental and emotional resistance and rumination were the root of her “suffering,” and the physical pain was something separate and was to be honored and acknowledged. The physical pain sensations were messages from her body that she could tune into, turn toward, and to which she could actually listen and skillfully respond. She recognized that steadfast personal self-care and self-compassion were particularly healing remedies for her physical pain. As she released the mental and emotional ruminations and resistance, she noticed she had much more energy to devote to her healing and she had greater mental clarity and curiosity, all of which reduced her experience of the mental and emotional “suffering” previously associated with the physical pain.

Irene sensed parallels between her reaction to her physical pain and her mental pain. She noticed that when she was ruminating about an event or situation, her thoughts would spin off and she would lose focus, become agitated, easily frustrated, and mentally unclear. She recognized rather quickly that when she did not feed into or resist the persistent and unhelpful thinking patterns, she could keep a distance, observe, not take it so personally, and actually find humor in her automatic habitual mental patterns that she could now let go of if she chose to. She sensed immediate and greater ease from this mindfulness skill, and each moment became a practice and a choice for how to respond to her physical, mental, or emotional pain. Every moment she chose, and each moment she chose ease rather than dis-ease, and this empowered her. She felt courageous and powerful. She was aligning her present moment experience with her living values of higher self, prefrontal cortex behaviors (rather than small egoic self), and her emotional and physical health.

This embodied experience of the difference between pain and suffering manifested in her work as Irene also came to recognize this in her clients. She noticed the difference between the physical pain her clients might be experiencing and the mental and emotional suffering they might be engaged in. She knew they didn't know any better, but she realized that mindfulness skills training (if the person chose to learn) could also bring reduced mental and emotional suffering, greater clarity and focus to truly heal, to move into a new normal, to freedom. She also recognized that this is a path each person must choose for himself or herself, and she was careful not to impose the skills of mindfulness on her clients. Her personal experience of pain as something separate from suffering was a powerful embodiment of the experience, which allowed Irene to meet her clients where they were and not need them to be “fixed” either. She could empathize viscerally with the experience of her clients and had a deeper and more authentic expression of compassion for her clients than she had ever had before. She described this empathic experience as one guided less by an intellectual understanding of empathy and more by an embodied, visceral experience or “knowing,” “insight,” and “understanding.” She described it with this statement: “Yes, life *is* like this.” There was a greater ease in her well-being as she met the needs of her clients as best she could. She knew her clients benefitted from her greater ease and understanding as she engaged with them in her OT practice.

Mindfulness in Western Medicine, Healthcare, and Society

Complementary and alternative medicine (CAM) and integrative medicine (IM) have been growing rapidly in the psychodynamic and humanistic traditions of psychotherapy to help meet the needs of our growing chronic public physical and mental health disease crisis. The current demand for highly qualified professionals who teach the skills of mindfulness has grown exponentially in recent years. The year 1990 was a watershed, after which "mindfulness" as a discrete term began to take hold in the discourse of academic medicine and psychology.[17] This was the year Jon Kabat-Zinn's book, *Full Catastrophe Living: Using the Wisdom of Your Body and Mind to Face Stress, Pain, and Illness,*[42] was published. In his book Kabat-Zinn describes the mindfulness-based stress reduction (MBSR) program that he developed in 1979 at the University of Massachusetts Medical Center. The curriculum started at the center has produced nearly 1000 certified MBSR instructors, who can be found in nearly every state in the United States and in more than 30 countries.[67]

Almost every major medical center in the United States currently has an IM center, and many include mindfulness and/or MBSR as an integral component of their programming. MBSR is now used as a therapeutic intervention in over 700 hospitals worldwide. Meditation and mindfulness have been featured in cover stories in the *Scientific American, New York Times, Time Magazine, The New Yorker,* and *Newsweek.* MBSR and other mindfulness-based approaches are now considered evidence-based treatment due to the extensive amount and quality of research with randomized, controlled clinical trials that has abounded over the past 10 years. In fact, 52 papers were published in 2003, rising to 477 by 2012. Nearly 100 randomized controlled trials had been published by early 2014.[67]

Clinical trials that are currently underway studying the efficacy of Mindfulness-based interventions (MBIs) include the following conditions: asthma, bone marrow transplant, breast cancer, chronic pain, chronic obstructive pulmonary disease (COPD), human immunodeficiency virus infection and acquired immunodeficiency syndrome (HIV/AIDS), hot flashes, hypertension, immune response to the human papillomavirus (HPV), irritable bowel syndrome (IBS), lupus, myocardial ischemia, obesity, cancer, arthritis, organ transplant, type 2 diabetes, and other medical conditions, including psychiatric disorders, such as anxiety disorders, eating disorders, personality disorders, post-traumatic stress disorder (PTSD), burnout, schizophrenia, and suicidality.[27,59] Grossman et al.[29] characterized the current research findings with this statement: "Thus far, the literature seems to clearly slant toward support for basic hypothesis concerning the effects of mindfulness on mental and physical well-being."[22,75]

Mindfulness and MBSR are not just in Western medicine. More than 2000 people from companies such as Google, Facebook, and Instagram showed up in San Francisco in 2016 for a mindfulness conference called Wisdom 2.0. Google now offers its 52,000 employees free lessons in mindfulness. Corporations such as General Mills have made it available to their employees and set aside rooms for meditation. In 2012, Representative Tim Ryan of Ohio published a book titled *A Mindful Nation,* and he has helped organize regular group meditation periods on Capitol Hill. An all-party parliamentary mindfulness group was developed in the UK for the House of Lords. In the UK, three universities offer master's level post-graduate professional training in mindfulness-based approaches: The University of Exeter and Oxford University Mindfulness Centre in England, and Bangor University Center for Mindfulness, Research, and Practice in Wales. The Department of Occupational Therapy at San Jose State University has offered a semester-long Mindfulness-Based Occupational Therapy (MBOT) course for their students for the past 6 years.

Mindfulness-Based Interventions (MBIs) are growing in number as well. Mindfulness-Based Cognitive Therapy (MBCT), Dialectical Behavioral Therapy (DBT), Acceptance and Commitment Therapy (ACT), Mindfulness-Based Relapse Prevention (MBRP), and Mindfulness-Based Therapeutic Community (MBTC) treatment are several MBIs that are drawing the most cultural attention at this moment.[67] The UC Berkeley Greater Good in Action (GGIA) program found at http://ggia.berkeley.edu highlights science-based practices for how to build qualities such as compassion, connection, empathy, forgiveness, appreciation, happiness, mindfulness, optimism, and resilience, to name a few. The Department of Occupational Therapy at San Jose State University is currently developing a Mindfulness-Based Healthcare Practitioner (MBHP) Post Graduate Certificate program to be offered to occupational therapists all over the world with the intention of continuing to deepen the skillfulness and effectiveness of the emerging Mindfulness-Based

Occupational Therapy (MBOT) and MBHP discourse and evidence-based interventions.[70]

Occupational therapists are currently using elements of these MBIs in a variety of ways as interventions within their practice and yet there is clearly an unmet need of applying mindfulness directly and explicitly into the complexities of occupational therapy practice, the use of self, and interventions. It is not clearly defined currently in OT literature as to how mindfulness and quality of participation in daily occupations is articulated and experienced or the impact of poor quality participation on an individual's health and well-being. This chapter is meant to begin the conversation and consider possibilities.

Threaded Case Study

Irene, Part 2

Occupational Therapists Embodying Mindfulness in Their Lives and Work

Irene began to realize that her ethical and moral duty to her work as an occupational therapist was not separate from her duty to her own mental, emotional, spiritual, and physical health, development, and self-care. She recognized that she deeply valued her ability to make sure she was not harming her clients and was not only practicing the ethical principles and standards of practice of nonmaleficence, but that she also wanted to make a meaningful contribution to her clients' lives. With this desire to improve her own well-being, quality of life, occupational participation, and therapeutic use of self, Irene pursued mindfulness practice in her own life, and this had beneficial side effects she could never have imagined. Although there was certainly “work to be done” and practices to engage in, the effects of building mindfulness into her life were so profound that her motivation to continue the path of mindfulness created palpable feedback loops that perpetuated her growth and development. Challenges became deep learning opportunities, and life's intensities became edges that actually propelled her into greater degrees of understanding and insight. She recognized that cultivating awareness, curiosity, and self-compassion during her darkest moments transformed those instances into moments of great courage, strength, growth, and learning.

Mindfulness of Self

Body Awareness

Through the cultivation of mindful awareness through the formal and informal practices of mindfulness, Irene became more aware of her body and the needs of her body. Initially Irene noticed a great deal of tension, discomfort, and pain in her body. It was surprisingly difficult to become aware of what specifically she was experiencing. She noticed how she wanted to numb and distract herself from the discomfort, and even boredom, and acknowledged this experience as a trigger for her to use all kinds of things to distract herself, as mentioned in her case example. The qualities of kindness and self-compassion were critical for her capacity to keep showing up for the discomfort in her daily formal practices, even when she succumbed to the impulse to distract herself. She simply noticed what she was choosing to numb herself to pain with, with nonjudgmental, open, curious awareness. She would come back to the formal practices and each time was more and more capable of showing up for whatever was there without needing it to go away and without needing to bolt.

As Irene developed greater degrees of body awareness, she moved through her daily routines and rounds of occupation with greater intention and ease. She slowed down her pace. As she slowed down during her ADL participation, she was able to recognize which activities exacerbated her pain, and she made adjustments over time that supported the needs of her body. Initially she took frequent mindful breaths, wherever possible, to release any unnecessary tension that she noticed. This increased blood flow, oxygenation, and healing fluids to these areas. The attention and expression of kindness toward her body that she developed over time helped her remain in a more parasympathetic nervous system response, which reduced stress hormone production and assimilation. At times she noticed herself expressing appreciation and gratitude toward her body, which felt healing and nourishing to her on all levels. She could sense even greater degrees of ease and well-being. Irene noticed that daily activities such as watching television and surfing social media sites increased ruminative thought patterns, which activated her sympathetic stress response. Fig. 7.3 is a visual representation of how Irene became empowered to choose how she was going to respond and to make empowered lifestyle choices that aligned with her intention for greater health, effectiveness, and well-being. She could sense the stress response in her body with participation in these activities, and she began to cut back on them. This, in turn, opened up more time and energy for her to be with and connect with her husband and daughter and for preparing healthy meals for her family, all of which activated her parasympathetic response and nourished her health and well-being.

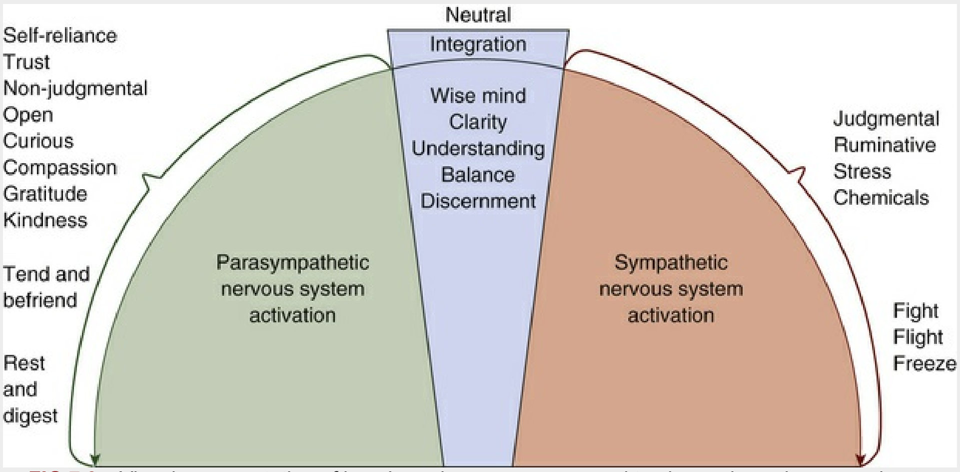

FIG 7.3 Visual representation of how Irene became empowered to choose how she was going to respond and to make empowered lifestyle choices that aligned with her intention to achieve greater health, effectiveness, and well-being.

Irene's digestion improved, allowing her to reap greater nutritional benefits from the foods she was eating. She began to eat foods that she recognized would nourish her body and noticed how her body felt after eating foods that were not nutrient dense, such as refined, processed foods. She made more dietary adjustments that supported the experience of greater health in her body. She slowly reduced her caffeine consumption until she was able to switch to herbal tea instead of drinking coffee. She significantly reduced her sugar consumption and switched to local honey as a sweetener. She was more aware of these health feedback loops, which motivated her further to continue to deepen the practices in her life and continue making healthy dietary adjustments for her family. She could physically sense the difference in her health and well-being with the body awareness practices infused with qualities of kindness and self-compassion and lifestyle adjustments. Her insomnia began to lessen, she had fewer headaches, and she felt more in control of her eating habits. She noticed that her daughter's behavior also responded positively to the dietary changes, and this continued to motivate her to make healthier choices over time by removing all manufactured foods that contained refined sugars, colorants, chemical additives, stabilizers, gums, and preservatives. Irene was ever more empowered by her and her family's healing journey at the hands of none other than herself.

Breath Awareness

Irene learned to frequently use the awareness of breath (AOB) practice to anchor her awareness in the present moment when she noticed that her mind was elsewhere. She noticed that her thoughts were often ruminating over situations that she had little control over, such as the health of her father, the overwhelming workload for which she was responsible, and her husband's lack of income. She would kindly and gently refocus her attention on the occupation at hand, and when she had time in the day, she would sit down and problem-solve with her husband about what adjustments needed to be made in their life to support greater ease, sense of control, and a sense of connectedness. They worked together over time to make necessary adjustments to their lifestyle, simplifying, reducing extraneous expenditures, getting support from community resources, and making small but meaningful problem-focused and emotion-focused adjustments that gave them a sense of self-efficacy and hope for a better situation in the future. Irene had a new and embodied sense of the true value of what occupational therapists often teach in their work, and these personal-life adjustments developed a deep sense of trust and self-efficacy in her capacity to help others make meaningful lifestyle changes that might enhance their life satisfaction and well-being.

Although Irene recognized that she could not alter the productivity, billability, or technological standards of her work environment, she now realized that she had complete control over how she responded to the work environment. She noticed that when she mentally resisted the situation in any way, this would activate her sympathetic stress response, she would get tension throughout her body, and release a storm of stress hormones and chemicals that affected every organ of her body. Over time and with practice, Irene noticed how she could allow the work environment to be as it is, come to greater degrees of acceptance over the reality of the situation, and not need to mentally or physically resist it. She could just notice it as it is, with the statement, "Yes, occupational therapy practice and Western medicine *are* this way sometimes"—with curiosity and openness—all the while acknowledging and honoring her own experience of the situation and bringing kindness and compassion toward herself, her team, and her clients, all of whom were participating in and managing the system in their own unique ways. She noticed how her usual mode of cynicism melted away over time and was replaced with wonder and awe about the complexities of a rehabilitation environment such as the one in which she worked. She was better able to recognize the simple yet deeply moving details of her workday, such as how a family dealt courageously with the suffering of their loved one. Furthermore she noted how, day in and day out, the staff members arrived and did the best they could with what they knew, or how society has developed such inspiring emergency medical care for its people. She recognized what a beautiful profession occupational therapy is, with its holistic view of each individual client and his or her situation. Irene noticed how differently her new way of being in relationship to her work environment activated her parasympathetic nervous system response; there was less tension in her body, and she sensed an overwhelming ease and equanimity even during some of the more intense moments in her day. She observed that she was more capable of responding skillfully to the complexities of patient and family care, and able to be more present and respond more rapidly and skillfully to the needs of her team. Similarly, she was less mentally and emotionally affected by the so-called "billability" and "productivity" standards and continued to do the best she could to meet them with integrity and ethical behavior without an overlay of self-condemning or system-condemning thought patterns.

Irene perceived that the deepening sense of self-compassion and appreciation for simple experiences in her life actually remotivated her to engage in occupations that she previously found nourishing and rejuvenating but had given up as life and work became more intense and less manageable. She made sure to take frequent "3-breath cycle breaks" while at work, usually while she washed her hands between clients and team meetings. She found this to be particularly grounding and restorative, and it gave her a pause to check in on how she was doing mentally, emotionally, and physically. Based upon this self-check-in she would make any necessary adjustments to gently bring herself back to the present and to a state of greater ease before she moved on to her next task of the day. She noticed that she felt more at ease and capable when she needed to have difficult conversations with her team or supervisors. She spoke with greater clarity and calm. She was able to stay on point and be an effective leader during difficult situations.

Irene reconnected with her family by planning regular activities that they all enjoyed participating in together, such as being in nature, camping, and going for walks. They incorporated more check-in time/connection during the week and ate at least one meal a day at the kitchen table together, enjoying healthy, whole, clean food and pleasant conversation. The greatest adjustment Irene made was to reduce her level of "busyness." She and her family took a fresh look at their deeply held family values and made adjustments and even removed tasks or activities that did not align with those values; this opened up more spaciousness in their lives. They all felt less hurried and harried. Over time and together, Irene's family developed a greater sense of connectedness, simplicity, ease, and well-being overall for the whole family. This experience and newly practiced behavior opened her up for more authentic and present interactions and relationships with her clients and colleagues. Irene became a source of ease for her team and was often approached for guidance about important matters and decisions that needed to be made for her team and her clients.

Awareness of Thoughts and Emotions

Over time, with her deepening experiences with the formal mindfulness practices, increased reflective observation, and open, curious, nonjudgmental active experimentation, Irene began to gradually notice how her *quality* of participation and engagement in her daily occupations affected the quality of her life and her mental, emotional, and physical well-being. She experienced how she was frequently on autopilot mode during basic self-care ADLs, often ruminating about unpleasant past events and experiences or fabricated fears about the future, which activated her sympathetic nervous system, released a storm of stress chemicals throughout her body, and increased tension in her body and affected her digestion. It was her habit to neglect her body's cues and sense of increased pain in her body when she participated in her ADLs in this unskillful way. With practice, however, Irene released her patterns of ruminative past and future thinking and was more capable of keeping her attention and awareness in the present moment. She became more capable of noticing when her mind was not in the present, and she noticed the thoughts and emotions with curiosity instead of condemnation. When she needed to plan for the future, she scheduled time in her day for this and focused her attention on the task at hand. She did her "planning" in the present moment. With the energy that previously had been spent on ruminations and stressful thinking, Irene shifted the focus of her energy on approaching her daily occupations with appreciation, awe, and wonder. Irene began recognizing things in her life that she was grateful for, such as how special it was to have running water and effective utilities. The appreciation for her ADL participation came in part due to her ability to be more and more present with the activities themselves. She no longer was stuck in the exhaustive, ruminative, unhelpful thought patterns about the past or future that used to run her moments and exhaust her energy. With practice she was developing new neural pathways in her brain that supported being present, and it became easier and easier to stay present over time.

Situational Awareness

As Irene developed a kind attunement to her present moment experience in basic ADLs, she knew that her "senses awakened." She was able to find enjoyment and appreciation for the simplest of daily life experiences, such as the warm sensations of the water while washing her hands, the smooth texture of her favorite pants as she put them on in the morning, the scent of her daughter's clean hair as she brushed it. She recognized that being present during her basic self-care in this way increased her appreciation for her ability to participate in these occupations; activated her parasympathetic nervous system, thereby releasing the healing "tend and befriend" hormones (e.g., oxytocin and endorphins), which helped her release tension; and reduced her mental, emotional, and physical pain (see Fig. 7.3).

During more instrumental daily activities, such as meal planning, preparation, and clean-up, Irene began to notice how her thoughts and emotions tended toward resentment for having "to do all this housework." She perceived anger and frustration in her body, which increased tension and pain in her body when she allowed herself to participate in this kind of dysfunctional thinking. Once again, she skillfully met these kinds of thoughts with self-compassion, recognition that "this will also pass," "this thought is impermanent," and that she could arrive in each present moment if she chose to, and she found that she actually did make that conscious choice to be present more and more. Irene consciously chose thoughts that aligned with her higher self and her core values of family and connection. She noticed that as she paid attention to the task at hand, such as preparing a healthy meal for her family, she developed appreciation for her strength and capacity to do these complex occupational tasks. Irene began to appreciate the simple yet complex sensory experiences of preparing a meal—the heaviness of the pan, the ease of turning on the burner to heat the meal, the running water, the smell of delicious aromas. She experienced how this level of attention she brought to the occupation would transform it from one of drudgery, resentment, and disconnection (from her own body and from her family) to an incredible sensory experience and an expression of love and connectedness for herself and her family. If she noticed her mind wandering into thought, she would anchor herself by becoming aware of the sensations of the breath in her body and then focus on the sensations and experience of the task at hand. She noticed that the more she did this, the easier it got. As with all the mindfulness awareness practices, she was developing new neural pathways in her brain that supported being present, and it became easier and easier to stay present over time. She expressed her appreciation to her family more, which felt to her like "a healing salve for our souls." Her family noticed it and also began to be more appreciative. The same daily occupations that were once drudgery became full of wonder and appreciation. This is the truest and most meaningful expression of alchemy in one's life (see the mindful listening exercise in Box 7.3).

Box 7.3

Mindful Listening/Mindfulness Communication Exercise

To keep the language of this guidance clear and uncomplicated, let's assume that your partner is a young woman. The process is the same, regardless of gender.

Sit about 3 to 4 feet away from your partner with nothing in between you. Lower your gaze or close your eyes. Begin by dropping your awareness into the sensations in your body, acknowledge whatever is here for you now without needing it to be any other way. Just noticing and recognizing the condition of your body in this moment. (pause) Bring awareness to what is the condition of your mind in this moment, again not trying to make any thoughts or emotions go away, just noticing them as they are in this moment with openness and curiosity. (pause)

Draw your awareness into your body. If you notice any unnecessary tension, see if you can allow those areas to release, and if not, just allow those sensations to go wherever they need to go… Now anchor your awareness into the sensation of your breath, so that as you breathe in you are aware that you are breathing in and as you breathe out you are aware that you are breathing out…

Become aware of what your intention is in communicating with your partner.

Before opening your eyes to share in this communication, see if you can keep some of your awareness anchored in your body and/or your breath sensations. Open your eyes and listen as best you can to your partner without any judgments, with openness and curiosity, without needing to have thoughts about what you are going to say next or without your own mental dialog distracting you from your partner's truth. Just listen as deeply as you are able.

When your partner is done sharing, you can ask if she has anything else to share and then pause. When she says she is done, you can both close your eyes. Drop your awareness back into your body sensations; notice any unnecessary tension and see if you can allow it to release. You can state as clearly as you can what you heard. Ask your partner if you heard her correctly.

Now take a few moments to formulate and articulate what is true for you/what it is you would like to share.

Before opening your eyes to share in this communication once again, see if you can keep some of your awareness anchored in your body and/or your breath sensations. Open your eyes and speak what is true for you. Notice any body sensations that may arise as you share. If you ever feel like you are getting off-center, just close your eyes, anchor your awareness back in your body sensations, and see if you can release tension. Connect back in with your truth and begin again when you are ready.

When you both feel that the communication is complete, thank each other for her presence and mindful listening. This is a deeply healing practice. Being deeply heard and listened to is a practice of compassion and is an incredible gift we can give to ourselves and others.

Irene also noticed how much more present she was able to stay when she was with clients. She recognized that she was much more capable of attuning to her client's mental, emotional, and physical states and responding appropriately as the moment required of her. She also experienced how she was better able to stay grounded in her own experience, not needing to be drawn into the suffering of her client and be taken away by it so readily. She was able to recognize and to be with the suffering and to stay present and honor her own experience, even when she was deeply moved by the client's suffering. She recognized when she was so moved by the suffering that she made a vow to herself to give herself space to grieve at an appropriate time, to acknowledge and validate her feelings with tenderness and gentleness, and to seek support and respite when needed.

As Irene became more aware of how she approached her clients and team members, she was also more aware of her intention, her body language, the verbal and/or tactile cues she used, her communication style, and her energy and presence and how these complexities affected others and whether they were effective. She had an embodied experience of what it truly means to be interconnected by how her response affected other people with whom she was in contact. She also recognized and honored that she was not perfect, she was still a human being with the potential to feel the full spectrum of human experiences. She was more likely to identify when she made mistakes, reflect upon the experiences, learn from them swiftly, make necessary and skillful adjustments, and move on when appropriate for the situation. She noticed how the practice of self-compassion and expression of kindness and gentleness was particularly healing during times when she felt like "she could have done better."

Interoccupational Awareness

The Quality of Engagement and Participation in Occupations (QPIO)

As occupational therapists integrate mindful awareness into their own daily personal and professional lives, they begin to become aware of their personal quality of participation in daily occupations. Through engaged participation in meaningful occupations, the therapist will gain insight into the significance of the healing nature of being more aware and present with one's unfolding experience in each given moment. Interoccupational awareness (IOA) is a state in which an individual intentionally establishes an awake, alert, nonjudgmental awareness during occupational participation. Establishing connection to our experience during daily occupations gives us the opportunity to develop deeper levels of understanding of the significance of daily occupations in our lives, of awareness of our own habitual patterns of thought and behavior, and of the effect of these patterns on our health and well-being.

As an example, Irene described that as she developed mindful awareness during her daily activities, she noticed that the occupation of washing the dishes was overlaid with her thoughts of resentment toward her family! She questioned "why she had to do the dishes, when she had other things to do that were a somehow better use of her time." She experienced how this quality of thought activated her sympathetic nervous system response, which in turn released powerful stress chemicals and hormones throughout her body, shut down her digestion, and ruined any capacity to appreciate the occupation in which she was participating. Over time, once she developed greater awareness and she made conscious choices about her relationship (in the form of thoughts, beliefs, and expectations) to washing the dishes, she was first able to cultivate a quality of neutrality, and eventually she was able to actually enjoy the activity. She noticed that it was her choice as to how she would relate to the activity. She noticed how she began to experience gratitude for having the strength to stand at the sink, to be able to use both of her arms, to have running water, hot water, to be able to afford and prepare healthy food for her family, to feel the sensory experience of washing the dishes. She noticed how her capacity to appreciate washing the dishes then became an activity that positively activated her parasympathetic "rest and digest, tend and befriend" nervous system (see Fig. 7.3). She felt at ease and almost as if the activity of washing dishes was a restorative activity, rather than her previous experience of dismay, resentment, and frustration.

Irene's example demonstrates that enhanced awareness allows us to notice our relationship to our daily occupations, and this awareness offers us information that can empower us and give us the opportunity and freedom to choose and establish deeper levels of wise relationship to the potential fullness of our occupations. Parasympathetic nervous system activation (PNSA mode) interoccupational experience can be experienced during *any* occupation we participate in. Not only those "special occupations" we choose, but *all* of our occupations hold the key to gladness and awe if we are open to the potential within the power of our choice as to how we relate to them. This is the ultimate in personal empowerment; choosing to experience all of our interoccupational relationships with a sense of awe, wonder, and gladness. Through this gained insight, the seeds of awareness are infused into all clinical interventions and also into personal and professional interactions.

"There's waking up—dragging yourself around—and then there's waking up," Kabat-Zinn said. Brushing your teeth, being in the bathroom—it's all part of developing awareness, and you can build mindful habits around those morning tasks. Kabat-Zinn's main advice is to rest in awareness, and drop in on yourself. "Drop in on yourself and rest for a stretch of time," he says. "And then as you go about your daily life, check in. Once an hour, once a minute. Once a day. You decide."[118a]

Why don't we "drop in on ourselves" during all our occupations and check in… What is the condition of my body in this moment, during this occupation?… What is the condition of my mind, during this occupation?" The implications of occupational participation within the context of our profession are addressed in the next section.

Employing Mindfulness in Occupational Therapy Practice

Occupational therapy is a beautiful and complex profession that grew up in the arms of Western medicine. The profession has a medical credibility and scientific groundedness in its value and at the same time is unique to other modern Western medical interventions in that the focus of intervention is on seeing the client and his or her situation holistically, considering mental, emotional, physical, cultural, societal, and contextual aspects. In some cases the occupational therapist may even consider spiritual aspects of an individual's functioning if he or she is so inclined and is skilled in doing so from his or her own “self-evident” experience.

Occupational therapy promotes health by enabling people to perform meaningful and purposeful occupations.[1] However, it is often the case that we (the clients, the therapist, anyone) may not be present or “conscious” while engaging in so-called meaningful and/or purposeful occupations. Not only are we not present, but we can often be lost in ruminative thoughts and unacknowledged judgments. We can often be lost in thoughts about the past or future. completely disengaged from what we are actually doing in any given moment and disconnected from the only moment in which we truly have to live in this lifetime—this one and only moment. Mental phenomena, such as plans, worries, anticipations, expectations, ruminations, imaginings, fantasies, and so on, can not only disengage us from our present-moment experience and occupational participation, but they also can often be dysfunctional or destructive to our emotional, mental, and physical health by activating our sympathetic stress response. These thoughts and ruminations are often not even our own. They have been passed on to us by family, teachers, communities, societies, religions, popular media, and other sources. We can be significantly limiting our experience of our lives by living only in the unacknowledged, often habitual, cognitive domain of experience. We can be drawn away and disconnected from our occupational experiences and our bodies for long periods of time and even life times. When we are disconnected from our lives, we are unable to fully experience our daily activities, even those that we might consider “meaningful,” and the quality of participation in occupations can suffer greatly, affecting every aspect of our lives.

Our “occupations” can even lose their “occupationess” when the participants are not engaged, not present, or are even “unconscious.” If we participate in our occupations in this way out of habit due to familial, social, cultural, or societal norms, are they really authentic occupations? Are they really meaningful or purposeful? Or do they become an end in and of the means and sheer drudgery? Can occupational participation really be considered a healing agent and skillful tool if we as therapists don't really know what it means to show up fully for our own occupations? These are questions to be lived, engaged in, embodied, and intellectualized as we explore and co-create the integration of mindfulness with the practice of occupational therapy.

It can be a profound realization to recognize that the capacity to build mindful awareness of one's body and mind can be assistive in the act of skillfully meeting many of the underlying problems of modern diseases. Mindfulness is the practice of purposefully attending to the present moment with an attitude of openness and curiosity. When we teach the heartfulness and skillfulness of mindfulness as occupational therapists, we become healing facilitators of our client's capacity to become a cohealer, using the wisdom of his or her own body and mind.[47,48,58,88] As we have coexperienced with Irene's case example, this can be incredibly empowering.

Mindfulness-based occupational therapy (MBOT) explores true healing as a journey of growing, learning, and connecting. It is not a model of fixing, correcting, or repairing. MBOT recognizes that we are already whole and complete just as we are, and our clients are whole and complete just as they are. And from that recognition, we realize that there is nothing we need to “fix.” We are in a place of meeting ourselves and our clients with radical acceptance of what is first and foremost; then we can authentically facilitate this journey of healing for ourselves and our clients if we are open to it and can hold the space for it.

The AOTA released the latest definition of occupational therapy as a practice that maximizes health, well-being, and quality of life for all people, populations, and communities through effective solutions that facilitate participation in everyday life. MBOT is an effective practice, a healing salve or “solution” steeped in a model of cultivating deeper levels of personal understanding and greater degrees of insight and freedom that can facilitate empowered participation in everyday life. This is emancipatory education because it is “really useful knowledge” that can empower people to get themselves out from under oppressive forces. These may be forces of our own mental perceptions handed to us, without our even knowing, through our industrialized cultural, societal, and familial lineage.

The skills of mindful awareness are tools that help us all engage in close connectivity in each moment with ourselves and our infinitely vast and complex human experience. The skills shed light on our present-moment experience and help us build trust in our capacity to make effective lifestyle shifts that resonate with what we each value most, to heal ourselves, our communities, and the world.

Occupational therapists work on the front lines of incredible human suffering. An occupational therapist who has his or her own personal mindfulness practice will be more able to remain present to his or her own internal mental and emotional experience and physical well-being from one moment to the next, thereby reducing potential for burnout and enhancing self-efficacy.[65] Dr. Dan Siegel, researcher, author, and director of The Mindsight Institute at UCLA, describes this process as neurologic "integration."[102–104,108] He invites us to "connect rather than correct." This process of integration involves learning to be in wise relationship to our experience in each moment, without needing it to be any other way, with a courageous degree of acceptance of what is. In this way we are capable of learning, growing, and healing ourselves and cultivating a wiser and more embodied relationship to our work as occupational therapists.

MBOT invites us to live the following questions as a journey of inquiry, healing, growth, and learning:

- What is my embodied experience of my *quality* of participation and engagement in my daily occupations?
- What is my relationship (beliefs, attitudes, expectations) to my occupations. and how can I cultivate a healthy, effective, and meaningful relationship to them?
- How might this higher quality occupation participation serve me and my higher self?
- How can I assist my client in cultivating and embodying a higher quality of participation, engagement, and relationship to his or her occupations? How might this affect the client's health and well-being?

To answer these questions the therapist must practice and develop an array of tools, skills, and practices that become a part of daily performance patterns (habits, routines, rituals, and roles). Mindful awareness tools and skills must be embodied in order to be modeled or shared authentically. If any mindfulness skills, tools, or practices do not ring true for you, don't use them. If you bring an awareness tool, practice, or skill as a therapeutic modality, bring it with the intention that you will also benefit and grow from the practice. The therapist becomes a part of the process of the authentic healing relationship. (See the Additional Resources section, at the end of the References, for suggested training pathways and a few simple mindfulness exercises with which to begin.)

Integrating Occupational Therapy and Mindfulness

Mindfulness-Based Occupational Therapy (MBOT) Competencies

When occupational therapy and mindfulness are skillfully integrated, mindfulness-based occupational therapy competencies have more fertile ground in which to grow and ultimately be embodied by the occupational therapist and be shared with the client in appropriate and profoundly meaningful ways. The following list presents the five interrelated sets of cognitive, affective, and behavioral competencies. The definitions of the five competency clusters for therapists are:

- ***Competency 1: Self-awareness.*** An occupational therapist's self-awareness deepens when it is enhanced by the mindfulness practices of focusing attention and cultivating self-compassion. It includes the capacity to recognize one's emotions, thoughts, attitudes, beliefs, and perceptions and their influence on behavior. This includes accurately assessing one's strengths and limitations and possessing a well-grounded sense of confidence and enthusiasm.
- ***Competency 2: Self-management.*** Mindfulness increases the occupational therapist's emotion, thought, and behavior regulation skills, which enhances his or her ability to meet the needs of our complex profession, resolve internal and situational conflict more creatively, recognize and honor how he or she is feeling in an emotionally balanced way, and learn and grow from his or her insights and deepening awareness. This includes managing stress responses skillfully, recognizing impulses that may be unskillful, motivating oneself, finding meaning, and setting and working toward achieving personal and professional goals that are guided by personal values.
- ***Competency 3: Social awareness.*** Mindfulness increases occupational therapists' empathic drives by helping them validate, acknowledge, and regulate their emotions rather than get emotionally

overwhelmed when faced with difficult situations. As a result, their capacity to notice and honor both their own suffering and another person's suffering and respond to it skillfully increases. In addition to this, he or she is able to take a broader contextual and anthropologic perspective and embrace others from diverse backgrounds and cultures, to understand social and ethical norms of behavior, and to recognize and offer appropriate resources and support.

- ***Competency 4: Relationship skills.*** Mindfulness increases compassion. Thus, when OTs practice mindfulness skills, such as nonstriving (*of being with things as they are and not needing them to be any other way if for no other reason than because this is the way it is in this moment*), they are doing so with more compassionate, open, curious, accepting, and nonjudgmental understanding. This manifests as communicating clearly, listening actively, and seeking and offering help when needed. This also includes recognizing the relationship therapists have with their own occupational participation, in addition to recognizing how their perceptions and thoughts about an occupation shape their experience and can make the occupational participation health enhancing or health degrading. The occupational therapist recognizes that the quality of participation is up to him or her, which is empowering, and can make effective, life-enhancing, and life-affirming adjustments over time.
- ***Competency 5: Decision making.*** Mindfulness increases cognitive flexibility and creativity, which gives occupational therapists a broader contextual perspective and a wider range of potential responses to challenging or complex situations. This includes being able to make constructive and respectful choices about personal behavior and social interactions based on consideration of ethical standards, safety concerns, social norms, the realistic evaluation of consequences of various actions, and the well-being of oneself and others.[71,117]

Ultimately, when taught and learned together, mindfulness and occupational therapy have the potential to transform our profession from one focused on what can feel more like encouraging our clients to be "occupational doers or doings" and instead foster and cultivate the qualities of what it really means to be "occupational beings." With the skills of mindfulness cultivating the tendencies for compassion and ethical ways of living and being, and MBOT teaching the skills that allow us to bypass the tendency to encourage a mode of "occupational doing," we can return to the true sense of the term "*human being*" by fostering and cultivating in our clients those qualities that mark what it truly means to be an "*occupational being.*"

As skilled mindfulness-based healthcare practitioners we will each become powerful co-creators of a new paradigm in Western medicine; one that highlights our tremendous power individually and collectively to harness newfound "self-evident" scientific knowledge and embodied clinical practice. Each of us has the opportunity to participate in this exciting stage of human evolution,[37] the development of lifestyle medicine,[10] and the movement toward a new model of care that is so deeply needed. In this way we become empowered healing agents for the bloodstream of humanity.[78]

Apply It Now: Practice Descriptions

This section describes modified versions of the core practices of mindfulness-based stress reduction. The traditional MBSR practices of body scan, sitting meditation, mindful yoga, and walking meditation have been adjusted to better fit the needs of the occupational therapist interested in integrating a practice into a treatment session. There are many ways of interpreting these practices authentically, as long as the therapist has integrated them into his or her own life first. The therapist who has had his or her own embodied experience of what it really means to participate in practices such as these will bring the practices into OT interventions in an empathic, understanding, and authentic way. It is not recommended to implant one of these practices into interventions if the therapist himself or herself is not already clear about its usefulness or effectiveness.[67]

Practice 1: Body Awareness Practice in Sitting or Lying Down

Approximate timing: introduction 3 minutes; practice 25 minutes.

Introduction. This is a body awareness practice designed for you (the occupational therapist) to use regularly to help assume an active and powerful role in your own health and well-being. It is best to use a guided body scan recording (see Additional Resources for links) and do what it says while in a comfortable place where you feel safe, secure, and free from interruption. Consider this practice time as an opportunity to be both by yourself and fully with yourself…an opportunity to nourish yourself, to open to and experience the potential of strength and insight within yourself.

This is a radical redefinition, suggesting a preference for embodiment over cognitive, verbal processes. You are choosing to show up for whatever is happening in this moment…making the choice to allow yourself to be exactly as you are in this moment. Completely as you are and complete as you are.

Our culture asks us to live so much in the cognitive and intellectual domain of experience. We often forget that the whole body feels and knows and that there is a wisdom beyond words.

The body awareness practice, as with all the others described here, provides ample opportunities to reinforce the powerful practice of cultivating nonjudgment and curiosity, in addition to kindness and compassion toward oneself.

Mindfulness Practice: The 3-Minute Breathing Space. The following instructions for the 3-minute breathing space are adapted from Segal, Williams, and Teasdale (2014).[93a] You may wish to take about 5 minutes right now to read the instructions and use them to guide you through the practice, spending about a minute practicing each step after you read it.

- **Step 1: Becoming aware of present-moment experience.** Begin by taking an intentional posture that is upright but not stiff, eyes gently closed, or holding a soft gaze on the floor or wall a few feet in front of you. Next, begin to bring your attention to your internal experience, perhaps by asking, "What is my experience right now?" "What thoughts are passing through my mind?" Acknowledge thoughts as mental events as best you can, perhaps putting thoughts into words: "What feeling tone is here?" "Is there a sense of pleasant, unpleasant, or neutral feeling present?" In particular, allow any unpleasant feelings to be known: "What body sensations or reactions are noticeable right now?" Acknowledge any sensations in your body, including any areas of tightness or tension.

- **Step 2: Gathering attention on the breath.** In this step redirect your attention to the physical sensations of the breath in your body. Focus on a particular area of the body where the breath sensations are most accessible, perhaps the abdomen rising and falling, or the air passing in and out through your nostrils. Follow the breath in your chosen area of the body from the very beginning of the in-breath, all the way to the pause when the breath turns and becomes the out-breath and follow the sensations all the way through the out-breath. Continuing in this way, allow your attention to rest on the breath sensations and gently return your attention to these sensations whenever you notice that it has wandered away.

- **Step 3: Expanding attention to whole body.** In the third step expand the spotlight of your attention once again, maintaining awareness of breathing while including a sense of whole body, perhaps a sense of the posture, and the internal sense of your facial expression.

If any sensations of discomfort, tension, or resistance are present, allow them to be acknowledged and breathe with them. Perhaps on the out-breath, see if any tension can be released.

As best you can, bring this expanded awareness to the next moments of your day.

Exploring the breath and its soothing and anchoring potential. Come to gently notice the breath. It's such a constant feature of life that we often ignore it…so take time with it now…actually feel the sensations as the breath enters the body and leaves the body of its own accord… allow it to move through its cycle of in-breath and out-breath without controlling or needing it to be any other way than it is… if it feels right to you, attend to the belly, the lower abdomen, noticing that it may be rising and falling with the cycle of the breath. If you care to, place your hands on your belly, feeling the movement of breath, the rhythm, the waves of the breath… simply ride the waves of your breath from moment to moment.

Offering a safe haven. As you listen to the body scan, if at any time sensations in the body become too uncomfortable, or emotions arrive that are too difficult, know that it is always possible to return to the breath as a safe place, as a haven, a retreat for you to rest in, until you are ready to venture again and into the body scan… wherever the recording is in its progress.

Body awareness practice—awareness of sensation and moving away from concepts toward direct experience. If you have placed your hands on your belly, allow your arms and hands to rest by your sides, and move your attention to the top of your head. Notice that sensations may arise when you bring attention to a particular part… maybe tingling, maybe pressure, maybe a feeling of breath. Or perhaps there's no sensation…that's OK, that is simply your experience at this moment. And when you're ready, move your attention to your forehead… observe sensation… perhaps sensations of tension, or tingling, or a sense of relaxation. Allow yourself to feel whatever you feel.

Now move your attention from the forehead to the eyes and eyelids… notice how you're holding them. How much or how little pressure does it take to keep them closed? Experience the eyes from the inside, from behind the eyelids. Are the eyeballs moving or still? Is there darkness? Light? Color? How does the breath affect this area?

When it feels right, begin to pay attention to the cheeks… sense the bones and the muscles coming to the skin of the cheeks… the air, sensations of coolness or warmth… note perhaps that some sensations stay for a while, whereas others pass quickly… and that intensity may change as you bring attention to them. Attend now to the nose, from the bridge to the edges of the nostrils… perhaps feeling the breath in the nostrils as it enters and leaves. Notice there is temperature, moisture, and sensations on the upper lip.

Moving the attention to the jaw… be aware of tightness or softness… allow the lower jaw to drop down slightly, and notice any changes in sensations in the muscles of the face and neck, or in other parts of the body, that that small movement may create. Expand your focus of attention to include the mouth and lips… inside the mouth, tongue against the teeth, sense the roof of the mouth, the gums… if you care to, breathe in through the nose and out through the lips, observing the sensations of dampness, dryness, warmth, or coolness.

Expanding the attention to encompass the entire face… don't just picture your face in your mind, but really feel the sensations in that area that we call the face. Where is that for you? Be aware of any thoughts and emotions as well… and if thoughts or emotions arise just allow them to simply come into awareness and then pass, like clouds in the sky.

Shifting the attention to your neck… notice how it is right now in the big muscles in the back of the neck, from the base of the skull to the shoulders… the throat… perhaps be aware of the sensation of air or the touch of clothing… be present in this experience.

Now to the shoulders; check into their condition in the moment…notice any tightness or softness, recognizing that this is the current condition…accept it, know that it does not need to be some other way. And know also that conditions change… notice if there is a sense of breath in the shoulders. How much of the body does breathing affect?

Allow attention to travel to the upper and midback… sense the muscles, tight or loose… perhaps be aware of sensations of the weight of the body here… pressure against the chair, feelings of the texture of clothing. Notice how the breath moves in this area.

Bring attention to the lower back…sense the contact or lack of contact with the chair…a sense of yielding to gravity or resisting…any tightness or softness. Notice any tendency to move away from or toward any sensations or thoughts, feelings, or judgments that may arise… remember this is simply how it is in the lower back at this moment.

Experience the whole back now, from the shoulders to the base of the spine… be aware of the subtle and not so subtle motions of the back as you breathe… dwell in the sensations in the back, not watching from your head, just knowing what the back knows.

Shift to the arms… to the upper arms and forearms… be aware of the pull of gravity, the weight of the arms… feel the muscles and joints…the touch and texture of clothing. Expand the attention to the wrists and hands… notice warmth or coolness, tingling, moisture, or dryness. How does the breath affect the arms and hands? Is it possible to feel the pulse here? Just be with what's here now.

And move, as you are ready, to the chest… to the lungs and heart in this space… maybe sensing inside, as the lungs fill and empty… perhaps noticing the heartbeat…the rhythm of the heart and the breath together. Be present to the sensations of life… what it feels like to be alive…and feel the surface, the touch of the clothing and any sense of movement.

Now extend attention to the abdomen, the belly, feeling inside first… this is the place where we have our gut feelings…there really are nerves here that sense and *know*…feel into the motion of the diaphragm, sense the breath in the belly.

When it seems right, move attention to the pelvic region, from hip to hip…be aware of the effects of gravity, the weight of the lower body… the buttocks pressed into the floor or chair, sensations in the joints… the groin, genitals… the lower abdomen… tune into the sense of the breath, or the pulse here. How far do they reach? And notice thoughts and feelings that may arise… be aware of any judgments and, as it's possible for you, let them go.

Shift the focus to the upper legs, the thighs… be aware of the sense of gravity, the pressure against the floor or chair, the feeling of clothing against the skin, and sense the quality of the muscles. Are the muscles tight or loose? Is it possible to feel the bone running through?

Extend the attention now to the lower legs, calves, and shins… notice points of contact or lack of contact with the floor or chair…be aware of gravity…be aware also that the legs are alive. How does the breath affect them? How does the pulse? Is there a sense of the blood flowing?

When you are ready, explore the feet… feel where they are…the floor…perhaps feel temperature sensations… warmth or coolness. Sense the heartbeat in the feet, perhaps?

Now, expand the attention to include the entire body, from the soles of the feet to the top of the head… be fully present to the totality of the experience of sitting or lying in this moment…sense perhaps the breath, the pulse, the heartbeat… feel a sense of gravity…a sense of being held gently, closely, without fail… dwell in what the body feels… and what it knows.

In the last moments of this body awareness practice, congratulate yourself for spending the time and energy to nourish yourself in this way… for continuing to make choices to live a more healthy, satisfying life… and know that you can carry this awareness of your body's deep wisdom beyond this practice session into each moment of your day, wherever you may find yourself.

Practice 2: Opening to and Expanding Awareness Practice

Approximate timing: introduction 3 minutes; practice 25 minutes.

Introduction. In your formal practice of sitting meditation, you are taking a seat right in the middle of your life. You are intentionally bringing yourself into a direct and intimate relationship with the present moment and what is arising in it for you—as much as possible, without judgment.

In this practice you have the opportunity to expand your attention to explore body sensations, sounds, thoughts, emotions and, when you are ready, to open to all of these—to the full range of events and phenomena, within and without as they move and change, appear and disappear in awareness. You're taking time to become more familiar—moment by moment—with who you are, beyond all the wanting and having and doing…

In a sense this practice is a perfect expression of your own unique presence in the world. It is helpful to come to this practice with a sense of kindness and care for yourself and bring a dignity and ability that resonates with your special status to the time, place, and posture of your sitting practice. Set aside a regular time when you won't be interrupted and can be in a quiet and comfortable place that can nurture your practice. When sitting, whether in a chair cushion or on the floor, maintain an attitude of confidence and stability—not leaning into or moving away from anything, simply be present with and open to what is happening now.

Opening to and expanding awareness practice. Sit in an upright position with your back straight and belly relaxed. Embody dignity and confidence… allow the sense of dignity to be both an expression and a reflection of your own innate integrity and wakefulness. Feel the floor or chair cushion beneath you, supporting you. Sense the pull of gravity holding you, receiving you. Find a point of balance where gravity is holding you comfortably upright, without strain. Allow the body to become still.

Bring your attention now to the sense of the body breathing, orient yourself to the breath entering and leaving the body… bring openness and curiosity to this moment. Notice where you feel the sensation of the breath most now… center your attention there.

Notice that there is a beginning, middle, and end of the in-breath and a beginning, middle, and end of the out-breath… (long pause).

Watch the entirety of the cycle of breath from beginning to the end. Notice the moment when the in-breath shifts to become an out-breath… and then notice the out-breath, from its beginning to when it shifts to become an in-breath… (long pause).

Realize that no matter how many times the attention leaves the breath, awareness of that does arise and there is an opportunity to choose and to bring the attention back… to this in-breath and/or the out-breath, now… (long pause).

Allow the breath to be at the center of your attention…to be center stage… allow any thoughts to come and go like clouds in the sky. If attention has wandered from the breath, gently but firmly escort it back, making the breath the focus of attention again… (long pause).

When you're ready, expand your attention beyond the breath to also include the entire body, sitting. Begin where there are distinct sensations in the body… perhaps in sensations of contact with the chair cushion… perhaps the touch of the clothes on your body or how your hands are feeling in the moment…perhaps sensations of temperature. Be present with any sensations as they rise.

Notice how sensations sometimes stay for just a short while, and how other times they linger… notice they may change in intensity, shift, and pass away as new sensations arise. Like the breath, they, too, have a beginning, middle, and end… (long pause)

Stay in touch with the sensations in the body as you sit… when attention wanders, notice you are making a choice to bring it back, with care and kindness, to the awareness of the body in the breath… (long pause)

We always have options and permission to explore our experience and notice the impermanence of all phenomena. If sensations arise in the body that are very intense, making it difficult to focus on the body or the breath, there are two ways to address this:

1. You may choose to mindfully change your posture, attending to the sensations of the movement as you shift.
2. You may choose to direct attention right into the intensity and sensation itself. Explore it with a gentle curiosity… notice nuances of sensation… perhaps notice thoughts and judgments… perhaps notice resistance or bracing… and, as much as possible, step back to observe, to open space in awareness, perhaps to soften the intensity of the sensation. Attend to duration…notice the duration and changes in sensations…notice they have a beginning, middle, and end… (long pause)

Now, allow your attention to shift from the breath and body to the sense of hearing…not seeking sound, rather, receiving whatever is available from within the body and from the environment near and far. Become particularly aware of hearing… notice how the awareness receives sounds without effort… (long pause).

Be aware of how sounds have a beginning, middle, and end… how some sounds are short and some are long… sounds are varied and textured… there is space between sounds. Notice how the mind labels sounds…has opinions about sounds…it likes and dislikes certain sounds. Notice any desire to move away from some sounds and toward others… as much as possible, make a space in which sounds can be experienced as they are… (long pause).

And when you're ready, allow your attention to shift from hearing and let it expand to thinking—the realm of thought. See thoughts not as distractions, but rather, bring your awareness to the thinking process itself. Notice how thoughts arise, stay briefly, or for a more extended period, and then dissolve… they, too, have a beginning, middle, and end. So as not to get lost in the content of the thoughts, allow thoughts to be in the foreground of awareness, with sound, body sensations, and breath in the background… (long pause).

Notice thoughts… they may be about anything—sleep, obligations, the past, the future… if you get carried away in the current of thinking, come back to observing thoughts as separate elements that come and go… thoughts moving through an open and spacious mind.

Emotions also arise in the body and mind… perhaps frustration, restlessness, peacefulness, sadness, joy, or fear…observe emotion…bring attention to emotion and to the mood state. What is here for you right now? Notice where in the body certain emotions seem to live… (long pause).

Explore emotions… notice how what is here may be wanted or unwanted… how there may be a tendency to cling to emotion judged as pleasant and to struggle with emotions judged negatively—such as sadness or fear… (long pause).

Notice whatever emotions arise in the moment… Know that they have a beginning, middle, and end… Perhaps simply observing them in the body—letting go of supporting thoughts, narratives, or stories… (long pause).

If at any time emotions or sensations become too uncomfortable, remember that you can always return to the breath… find a safe harbor and focus there until you are ready to venture out again… (long pause).

Move now, if you care to, into a choiceless awareness… not choosing to bring your attention to anything in particular. Simply sit, fully aware of whatever is presenting itself to you in each moment. If sound arises, allow sound to be the center of attention… If a body sensation arises, let that be the center of your attention until the next sensation arises, which may be another body sensation… or a thought about the body sensation… or an emotion… (long pause).

In one moment, the breath may be predominant and then, perhaps, sound might be most prominent… simply dwell with an open awareness, attending to whatever arises… (long pause).

Observe whatever presents itself to you in the moment… be spacious with whatever arises… (long pause).

Sit in stillness with whatever comes and goes… (pause) … be present with it all… (pause) … be here now… (pause) … open to the totality of your experience… (pause) … be fully human… (long pause).

Now return the attention to the body as you sit…feel the breath coming and going… stay fully present with body and breath… (long pause).

As this meditation practice comes to a close, realize that by practicing mindfulness you are intentionally deepening your ability to be fully present in your daily life. If it feels right, perhaps congratulate yourself for having taken this time and energy to nourish and care for yourself. Remember that practicing in this way helps create access to a wider, deeper, more open way of being in your life, in which you can see more clearly and make more conscious choices for health, well-being, and freedom.

Practice 3: Mindful Movement Practice During ADLs

Approximate timing: introduction 3 minutes; practice 20 minutes.

Introduction. This guiding of gentle movement during an ADL is an invitation to enter more deeply into the life of the body… experience the mind and body as one, as a unit while moving the body… to bring them together. And as with all mindfulness practices, this movement practice is about paying attention, moment to moment, to sensations, thoughts, and feelings that arise in your awareness. The movements in this guided meditation are designed to be done during a basic and routine ADL, such as washing your hands or face or folding the laundry.

As you go through this guided practice, you will be entering into the experience of the body as deeply as you can, without judgment. This is not about performing, about doing the mindful movements in some ideal way for a critical audience… rather, it's about doing them to help connect more closely to, and better understand, the body while you move and participate in ADLs. Not forcing any movement, but rather, relaxing into it… using discernment and knowledge of your own body and its limits to guide you and to override the instructions, adapting the practice in a way that works for you. Or perhaps imagining yourself doing the movements in a mindful way, feeling them in stillness as you visualize participating in the ADL in a mindful way, which is a valuable practice in itself.

Mindful Movement Practice During ADLs. For this mindful ADL practice let's begin in an alert, dignified, seated posture…notice the how the chair or other support accepts you…how gravity works so you don't have to… sense the areas of your body that touch the seat or chair…sense your feet on the floor. Bring your attention to the sensations of the breath in the body… be aware of sensations of rising and falling, expanding and contracting, on the in-breath and out-breath…

and with each breath, allow the chair or support to receive more of your weight… working less, trusting and accepting more…breathing in and out.

When you're ready, breathe in and imagine yourself preparing to wash your hands as you stand at your sink…notice your body sensations as you stand at your sink, notice any thoughts or emotions that may arise in the moment and let them be, and guide your attention, with kindness and firmness, back to sensations of your body. Then actually walk mindfully to your sink…bring a sense of curiosity and freshness to the movement… feel the pressure of the soles of the feet as you take each step…feel the lifting, swinging, placing phase of each step you take. Stand still with your arms and hands at your side as you reach the sink and just feel the sensations of standing… sense the pull of gravity and the support of the surface you are standing on. Notice any unnecessary tension in your muscles and see if you might be able to release any tension… and if not, just allow the sensations to go wherever they need to go.

Notice any thoughts or feelings that may enter your awareness, and as much as possible, allow them to simply come and go like clouds in the sky… keeping attention centered on the sensations of the body.

Now, bring your hands to the soap dispenser or bar of soap, hold the soap in your hand and experience the sensations of the force of gravity on the soap in your hand, the weight of the soap, the coolness or warmth, the texture… you may notice there is a scent to the soap, just notice it without judgment, without narrative…then slowly, aware of the sensations of movement but without anticipating the next movement, begin to wash your hands. Allow an element of freshness of experience as you move the soap around in your hands. Now sense into the body as you move your hands to turn on the faucet and feel the sensation of the water as you rinse your hands, the warmth or coolness, the weight and texture, the sounds as just sounds. Notice how much of the body is involved in this activity, how the breath may change as you move. Now mindfully reach to dry your hands off with a towel, sensing the texture of the towel on your hands and wrists, and return to standing with your hands at your sides. As you stand still, notice how you feel in your body after having experienced the ADL of washing your hands in this way—with open, curious awareness.

In your own time, mindfully walk and return to a tall, dignified seated position and become aware of how you feel… aware of thoughts and emotions, and as much as possible, let them go as you focus on bodily sensations in this moment… allowing them to pass as clouds in the sky as you focus on the sensations in the body after experiencing this ADL in this way. If it feels right, perhaps congratulate yourself for having taken this time and energy to nourish and care for yourself…remembering that practicing in this way helps create access to a wider, deeper, more open and healthy way of being and doing in your life, in which you can see more clearly and make more conscious choices for your health, well-being, and freedom.

Section 2 Summary

Over the years the AOTA's Commission on Practice has become increasingly explicit in its courageous attempts to interweave the significance of the development of the therapeutic use of self into the OTPF. Now we must be courageous in our efforts to articulate and embody what that actually means and to do more than just attend to the intellectual understanding or "concept," especially since the development of the therapeutic use of self cannot only be explained as an intellectual concept. It must be embodied and experienced individually.

How fortunate we are as a profession, in these efforts, in this time, to be able to draw upon an exquisite body of research that identifies practical and reasonable ways for us as individuals and as a profession to be able to articulate specific skills, qualities, characteristics, and practices that can, like a magic carpet, take us on a journey of compassionate self-exploration and enhanced insight and understanding, and ultimately bring us closer to an embodied experience of what it really means to use ourselves in a therapeutic way and to find for ourselves a meaningful balance between what it means to "be" and "do." Mindfulness must be embodied, just as the use of the self as a therapeutic modality must be embodied. These practices are inextricably interconnected and inseparable, with an infinite depth. Developing one does not happen without developing the other, and when working on one, we work also on deepening the other. It is a true journey of exploration and one that is just emerging for our beautiful and complex healing profession.

Acknowledgments

It cannot be overstated that the individuals in my occupational therapy and mindfulness-based stress reduction courses have had the greatest impact on my growth, depth of understanding, and education. They have taught me more than I could ever have imagined over the years, and I am deeply humbled by our shared journey, humanity, and human condition. I have also had the very good fortune of having had skilled clinical teachers and mentors, who have been especially supportive and encouraging in my journey, weaving the beautiful depths of the practice of mindfulness and the exquisite complexities of the practice of occupational therapy together in explicit, practical and, I hope, meaningful ways.

Review Questions

1. What is the difference between acquisition, retention, and transfer of learning? Apply these terms to describe the learning stages in a client you have observed.
2. When are declarative learning and procedural learning processes used? How will teaching methods differ when declarative or procedural processes are required?
3. What are the reasons therapists teach activities? Give an example of desired teaching outcomes for each of the reasons presented in the chapter.
4. In which situations is extrinsic feedback valuable to the therapeutic process? What are some advantages and disadvantages of providing extrinsic feedback to clients?
5. Why does contextual interference contribute to transfer of learning? Think of an example of how contextual interference can be incorporated into an OT session.
6. Differentiate between random and blocked practice schedules. In which situations would each of these practice schedules be chosen?
7. Provide examples of how a therapist might structure whole practice versus part practice. In which situations might each of these types of practice be appropriate?
8. In which ways can occupational therapists enhance the variability of practice contexts? Give practical examples of how occupational therapists working in inpatient settings can provide treatment in natural contexts.
9. How can occupational therapists help clients develop metacognitive skills? Why are these skills important in the learning process?
10. Define mindfulness and the therapeutic use of self.
11. Explain ways in which the therapeutic use of self can be cultivated and fostered.
12. Describe ways in which the Western medical culture and Western societal and cultural norms in general can undermine our capacity to cultivate and foster the therapeutic use of self.
13. Identify ways in which mindfulness is currently embedded within the Western medical system.
14. Describe three or four ways in which the art and practice of embodying mindfulness as an occupational therapist can enhance the cultivation and development of the therapeutic use of self.
15. What is the significance of learning to turn toward one's own present-moment experience with openness and curiosity? How might occupational therapists skilled in this particular characteristic be able to benefit their client and/or the therapist-client relationship?
16. How might an occupational therapist who takes tender care of himself or herself behave in a way that would benefit his or her professional and personal relationships? What does it mean to truly care for oneself? How might that work for you?
17. What is the potential impact of the current Western medical environment on the development of the therapeutic use of self? How might you mitigate these modern-day challenges?
18. Who is mindfulness appropriate for? What are the major practices of mindfulness? Why is self-compassion such an integral part of developing mindfulness in one's life?
19. What is the distinction between pain and suffering?
20. List a few of the mindfulness-based interventions in which an occupational therapist could be trained.
21. In what ways did developing breath and body awareness empower Irene to make meaningful and lasting lifestyle changes that enhanced her health and well-being?
22. What is the point of cultivating interoccupational awareness?
23. Can occupational participation really be considered a healing agent and skillful tool if we as occupational therapists don't really know what it means to show up fully for our own occupations?

24. What is the significance of the word “being” in the term “occupational being”? What is an MBOT's role in cultivating “being” over “doing” for one's clients?

Documentation of Occupational Therapy Services

Jerilyn (Gigi) Smith

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Identify five purposes of documentation.
2. Describe the basic technical points that should be adhered to when writing in the medical record.
3. Explain why only approved abbreviations should be used in occupational therapy (OT) documentation.
4. Describe the acceptable method of correcting an error in the medical record.
5. Explain why occupational therapy documentation should reflect the terminology outlined in the Occupational Therapy Practice Framework (OTPF).
6. Describe the components of a well-written progress note.
7. Identify the different places where documentation is required.

8. Briefly summarize the content of the initial evaluation.
9. Define assessments as they apply to the OT process.
0. Describe the purpose of the intervention plan.
1. Explain why establishment of goals should be a collaborative effort between the client and the therapist.
2. Explain the meaning of "client-centered goal."
3. Describe the purpose of progress reports.
4. Explain what is meant by a skilled intervention.
5. List the components of a SOAP note and give an example of each component of the note.
6. Identify the purpose of the discharge report.
7. List the primary reimbursement systems of OT services in the physical disabilities setting.
8. Describe two ways to ensure that confidentiality in documentation is maintained (refer to the AOTA Code of Ethics and the regulations established by the Health Insurance Portability and Accountability Act [HIPAA]).

KEY TERMS

Assessments
Checklist notes
Client record
Clinical reasoning
Confidentiality
Discharge report
Documentation
Ethical practice
Evaluation
Evaluation report
Health Insurance Portability and Accountability Act (HIPAA)
Initial evaluation report
Intervention plan
Legal document
Long-term goal
Medical record
Medicare guidelines
Narrative notes
Occupational profile
***Occupational Therapy Practice Framework*, third edition (OTPF-3)**
Privacy
Problem-oriented medical record (POMR)

Professional reasoning
Progress report
Reimbursement
Short-term goal
Skilled interventions
Skilled services
SOAP notes

Threaded Case Study

Jane, Part 1

Jane just started her first job as an occupational therapist at a skilled nursing facility. This week she completed two initial evaluations, and she has seen four clients for therapy each day. Jane knows the importance of accurate documentation, and she wants to make sure she includes data that will communicate the necessary information for reimbursement. She also knows that documentation is essential to demonstrate the value of occupational therapy. However, she has never worked in this practice setting and is worried about what terminology to use and how to document effectively to guarantee reimbursement.

Critical Thinking Questions

As you read this chapter, reflect on the following questions as they pertain to the case study.

1. What specific skills must Jane use in deciding how she will document the evaluation process?
2. What information is important to include in the SOAP note for reimbursement? Will the practice setting have an influence on what is included in the note?
3. How might federal regulations (HIPAA) and the principles put forth in the Occupational Therapy Code of Ethics influence how Jane communicates the results of the OT evaluation and the intervention program?

Documentation is an essential component of OT practice. It is the primary method of communication that is used to convey what was done with the client. Documentation supplements the practitioner's memory and creates a longitudinal record to enhance the continuity of care for the client. It demonstrates to others the value of OT intervention, and it provides validation of services to substantiate reimbursement. Documentation also serves as a means for collecting data that can later be used to support evidence-based clinical research.

Purposes of Documentation

Documentation is a permanent record of what occurred with the client. It is also a **legal document** and as such must follow the guidelines that will enable it to withstand a legal investigation. **Reimbursement** depends upon accurate, well-written documentation that provides the necessary information to justify the need for and value of OT services.

The American Occupational Therapy Association (AOTA) has identified these purposes of documentation:

- To communicate information about the client from the OT perspective
- To articulate the rationale for provision of OT services and the relationship of those services to the client's outcomes
- To reflect the OT practitioner's **clinical reasoning** and professional judgment
- To create a chronological record of the client's status, the OT services provided to the client, the client's response to OT interventions, and client outcomes[1]

Clear, concise, accurate, and objective information is essential to communicate the OT process to others. The clinical record should provide sufficient data to support the need for OT intervention.

Documentation is required whenever OT services are performed. This includes a record of what occurred during direct client care, in addition to supportive documentation required to justify the need for OT intervention.

OT Practice Notes

Examples of Documentation

Documentation is an ongoing process that continues throughout the client's therapy program. For example, the OT will document screening reports, **initial evaluation reports**, reevaluation reports, progress notes, discharge summaries, other medical record entries (eg, interdisciplinary care plans, provider telephone orders), intervention and equipment authorization requests, letters and reports to families and other healthcare professionals, and outcomes data.

Best Practices

Regardless of where documentation takes place, several basic technical points are important to adhere to when writing in a **medical record**. Box 8.1 lists the fundamental elements of documentation as set forth by the AOTA.[1] Proper grammar, correct spelling and syntax, and well-written sentences are essential components of any professional correspondence. Keeping lists of commonly used terms and using a handheld spell-check device are two strategies that can help the practitioner with spelling difficulties. Poor grammar or inaccurate spelling can lead the reader to question the skills of the therapist. Legibility is important to ensure that misinterpretation does not occur.

Box 8.1

AOTA's Fundamental Elements of Documentation

The following elements should be present in all documentation.

1. Client's full name and case number on each page.

2. Date

3. Identification of type of documentation (eg, evaluation report, progress note)

4. OT practitioner's signature with a minimum of first name or initial, last name, and professional designation.

5. When applicable on notes or reports, the signature of the recorder directly at the end of the note and the signature.

6. Countersignature by an OT on documentation written by students and OTAs as required by the payer source, state regulations, or the employer.

7. Acceptable terminology defined within the boundaries of the setting.

8. Abbreviation usage as acceptable within the boundaries of the setting.

9. All errors corrected by drawing a single line through an error and initialing the correction.

. Adherence to professional standards of technology when OT services are documented with electronic claims or records.

. Disposal of records (electronic and traditionally written) within law or agency requirements.

. Compliance with confidentiality standards.

. Compliance with agency or legal requirements of storage of records.

. Documentation should reflect the professional clinical reasoning and expertise of an OT practitioner and the nature of OT services delivered in a safe and effective manner. The client's diagnosis or prognosis should not be the sole rationale for OT services.

Modified from the American Occupational Therapy Association: Guidelines for documentation of occupational therapy, *Am J Occup Ther* 67:S32–S38, 2013.

Only approved abbreviations are to be used in the medical record. All clinical sites should have a printed list of acceptable abbreviations that can be used at the site. It is important to obtain this list and to use it as a reference when documenting. Examples of abbreviations commonly used in clinical practice are listed in Box 8.2. Misinterpretation of the intended meaning can occur when unfamiliar abbreviations or casual language unsuitable for therapeutic context is used. Language particular to a profession (slang or jargon) should never be used in the **client record**.

Box 8.2

Abbreviations Commonly Used in Clinical Documentation

abd	abduction
Add	adduction
ADLs	activities of daily living
Ⓐ	assistance
AE	above elbow
AFO	ankle-foot orthosis
AK	above knee
AM	morning
ant	anterior
A/P	anterior-posterior
AROM	active range of motion
Assist	Assistance, assistive
Ⓑ	bilateral
BE	below elbow
BM	bowel movement
BP	blood pressure
$\bar{c}$	with
CHF	congestive heart failure
CHI	closed head injury
C/O	complains of
D/C	discontinue or discharge
dept	department
DNR	do not resuscitate
DOB	date of birth
DOE	dyspnea on exertion
Dx	diagnosis
ECF	extended care facility
eval	evaluation
ext	extension
F/U	follow up
flex	flexion
FWB	full weight bearing
fx	fracture
HOB	head of bed
HOH	hand over hand
LE	lower extremity
LOS	length of stay
NWB	non–weight bearing
OOB	out of bed
po	by mouth
PMH	past medical history
PM	afternoon
prn	as needed
PWB	partial weight bearing
PMH	past medical history
post	posterior
Pt, pt	patient
PTA	prior to admission
PWB	partial weight bearing
q	every
qd	every day
qh	every hour
qid	four times a day
qn	every night
Ⓡ	right
re:	regarding
rehab	rehabilitation
reps	repetitions
R/O	rule out
ROM	range of motion
RR	respiratory rate
RROM	resistive range of motion
Rx	prescription
$\bar{s}$	without
SLR	straight leg raise
SNF	skilled nursing facility
SOB	short of breath
S/P	status post
S/S	signs and symptoms
STM	short term memory
Sx	symptoms
TDWB	touch down weight bearing
TTWB	toe touch weight bearing
t.o.	telephone order
Tx	treatment
UE	upper extremity

VC	vital capacity
v.o.	verbal orders
WBAT	weight bearing as tolerated
w/c	wheelchair
WFL	within functional limits
WNL	within normal limits
y.o.	year old
<->	to and from
->	to; progressing toward
@	at
1°	primary
2°	secondary; due to

From Gateley C, Borcherding S: *Documentation manual for occupational therapy: writing SOAP notes,* ed 4, Thorofare, NJ, 2016, Slack.

All entries made in the medical record must be signed with the therapist's legal name. Your professional credentials should follow your signature. Do not leave blank spaces at the end of an intervention note. Instead, draw a single line that extends from the last word to the signature. This prevents additional information from being added after the entry has been completed.

One of the greatest challenges for students and new therapists is writing notes that are concise yet comprehensive and include all the relevant information necessary to meet the goals of documentation as described earlier. Most third-party payers do not reimburse for time spent on documentation, so efficiency becomes essential. Although it is very important to accurately describe what occurred in the therapy session, care must be taken to keep this information to the point, relevant, and specific to established goals identified in the intervention plan. A common error is to describe each event that occurred in the intervention session in a step-by-step format. This is far too time-consuming and in fact does not meet the objectives of good documentation. Rather, short statements should be used that clearly and objectively convey necessary information to the reader. Abbreviations that have been approved by and are appropriate for the practice setting can be used to save time and space. Customized forms and checklists that include information relevant to the practice setting help streamline documentation and reduce time spent on narrative writing.

OT practitioners have an obligation to present information (verbally, in writing, or electronically) that is clear and at a level of linguistic clarity that the client can understand.[14]

Ethical Considerations

Principle 5 of the AOTA's Code of Ethics and Ethical Standards[3] addresses the OT practitioner's duty to provide comprehensive, accurate, and objective information when representing the profession. Principle 5B states that OT personnel shall "refrain from using or participating in the use of any form of communication that contains false, fraudulent, deceptive, misleading, or unfair statements or claims."[3] This pertains to OT documentation. To maintain ethical standards when documenting, therapists must be truthful and accurate in all that they report about the client.

Documentation must be written by the therapist providing the intervention. It is never acceptable to write a note for another therapist; in fact it is considered fraudulent to do so. It is best practice to complete documentation as soon after the therapy session as possible. The longer the interval between evaluation or intervention and completion of the written record, the greater the chance that details or other important information will be forgotten. Although documenting at the time of service delivery is ideal, it is not always possible. At these times, it may be beneficial for the therapist to carry a notepad or clipboard to record data that can later be included in the official write-up.

Altering, substituting, or deleting information from the client's record should never take place. Changes made to the original documentation could be used to support allegations of tampering with the medical record, even when this was not the intent of the writer. However, at times, corrections must be made. These might include errors in spelling, mistakenly writing in the wrong medical record, or inadvertently omitting information or assessment results. Several principles should be followed to avoid questioning of the validity of the corrected information. Nothing should be deleted from the record. Never use correction fluid when correcting an entry in the client's record. An acceptable method of correcting an error in the documentation is to draw a single line through the word or words, initial and date the entry, and indicate that this was an "error." Do not try to obliterate the sentence or word because this may appear to be an attempt to prevent others from knowing what was originally written. Late entries to the medical record cannot be backdated. If it is necessary to enter information that is out of sequence (eg, a note that the therapist forgot to write), it must be entered into the medical record as a "late entry" and must be identified as such. Words or sentences cannot be squeezed into existing text "after the fact." Attempts to do this may be interpreted as adding missing information to support something that occurred after the original documentation was completed. Although it is acceptable to make immediate corrections in the medical record, the medical record itself should never be altered.[8]

Corrections in an electronic medical record (EMR) are managed differently from paper-based documentation corrections. Each facility or organization has its own protocol for correcting errors in the medical record. Therapists must take the initiative to learn the site-specific guidelines for making corrections in the medical chart.

Ethical Considerations

OT notes can be the best defense against a denial of reimbursement of services or a lawsuit. Although no fraudulent intent may be present, it could be suspected if the content of a claim is ever called into question.

Do not leave blank spaces on evaluation and preprinted forms. If it is not appropriate to complete a section, N/A can be inserted to indicate that the particular area was not addressed. If sections are left blank, others reading the chart may think these areas were overlooked.

Documentation should incorporate the terminology outlined in the ***Occupational Therapy Practice Framework*, third edition (OTPF-3)**.[4] One of the purposes of the OTPF-3 is to assist therapists in communicating to other professionals, consumers of services, and third-party payers the unique focus of occupational therapy on occupation and daily life activities. Documentation should reflect the impact of occupational therapy on supporting function and performance in daily life activities and those factors that support engagement, participation, and health (performance skills, performance patterns, client factors, context and environment) during the evaluation and intervention process.[4] Many practice settings that follow the medical model, such as hospitals, use the term *patient* to describe the recipient of services. Other settings may prefer the term *resident.* Although these are acceptable, the OTPF-3 advocates use of the term *client*. *Client* encompasses not only the individual receiving therapy, but also others who are involved in the person's life (eg, a spouse, parent, child, caregiver, employer), in addition to larger groups, such as organizations or communities. The OTPF-3 provides terminology that can be used at each stage of the therapy process. This is explained in further detail when the various parts of the therapy evaluation, intervention, and discharge processes are described.

Clinical/Professional Reasoning Skills

Occupational therapists must use clinical or professional reasoning throughout the OT process. The more contemporary term **professional reasoning** is used by some authors to more closely align with language used in OT practices outside of medical settings, such as educational and community settings.[15] However, the term **clinical reasoning** is still widely used by occupational therapists, especially those working in physical disability practice settings. Clinical reasoning is also defined in the OTPF-3. For the purpose of this chapter, the term *clinical reasoning* will be used to refer to the comprehensive types of thinking and judgment used by occupational therapists in making client-related decision. Clinical reasoning also includes determining how to appropriately document information obtained during the evaluation, intervention, and discharge process. Clinical/professional reasoning is used to plan, direct, perform, and reflect upon client care.[15] Documentation must demonstrate that clinical reasoning was used in the decision-making process during all aspects of the client's therapy program.

Clinical/professional reasoning comprises many different aspects of reasoning: scientific, diagnostic, procedural, narrative, pragmatic, ethical, interactive, and conditional.[15] Scientific reasoning is used to help the therapist understand the client's impairments, disabilities, and performance contexts and to determine how these might influence occupational performance. Scientific reasoning guides the therapist's choice of interventions that will most benefit the client. Diagnostic reasoning is specifically concerned with clinical problem identification related to the client diagnosis. Procedural reasoning is used when the therapist thinks about the disability or disease and decides upon intervention to remediate identified problems. Narrative reasoning guides the therapist in evaluating the meaning that occupational performance limitations might have for the client. Pragmatic reasoning is used when the therapist addresses the practical realities associated with delivery of therapy services while looking at the context or contexts within which the client must perform his or her desired occupations. The therapist's personal situation, such as clinical competencies, preferences for particular therapy techniques, commitment to the profession, and comfort level in working with certain clients or diagnoses, is a part of the pragmatic reasoning process. Ethical reasoning is the process by which the therapist considers what should be done, taking into consideration all interested parties' needs and wishes when he or she develops the intervention plan.[15] For OT practitioners, keeping these points in mind and using clinical reasoning skills in determining what and how to document will facilitate client care and reimbursement for therapy services.

Clinical Reasoning in Documentation

Choosing appropriate assessments based on an understanding of the client's diagnosis and the occupations that might be affected involves clinical reasoning. Skilled observations, theoretical knowledge, and clinical reasoning are used to identify, analyze, interpret, and document components of occupational performance that may contribute to the client's engagement in occupation. Occupational therapists demonstrate clinical reasoning when they include information in their documentation that demonstrates synthesis of information from the occupational profile, interpretation of assessment data to identify facilitators and barriers to client performance, collaboration with the client to establish goals, and a clear understanding of the demands, skills, and meaning of the activities used in intervention.[4] Terminology used in documentation should reflect the unique **skilled services** that the occupational therapist uses to address client factors, performance skills, performance patterns, context and environment, and activity demands as they relate to the client's performance. Box 8.3 provides some examples of clinical reasoning.

OT Practice Notes

Concise, clear, accurate documentation that keeps the target audience in mind will ensure that the appropriate information is conveyed to other healthcare professionals and will meet the criteria for reimbursement.

Box 8.3

Examples of Clinical Reasoning

- Because of Mr. Page's change in affect after his total hip replacement, the Geriatric Depression Scale will be administered and his primary physician will be contacted.
- Using neurodevelopmental techniques (NDT), including facilitation at the hips, the client is now able to independently stand at the sink with good balance for 2 minutes to brush his teeth.
- A home assessment is recommended to determine what adaptive equipment is necessary to allow the client to independently and safely complete ADL tasks.
- Mr. Page's difficulty with problem solving, task initiation, and task progression impedes his ability to independently prepare a simple meal.
- A resting hand splint was fabricated for the client because of the emergence of spasticity, poor passive positioning of the upper extremity, and a high risk for development of contractures.
- Mrs. Rogers requires maximal assistance to complete upper/lower body dressing because of poor sitting balance, right neglect, and apraxia.

Legal Liability

The medical record is a legal document. All written and computerized therapy documentation must be able to pass a legal review. The medical record may be the most important document in a malpractice suit because it outlines the type and amount of care or services that were given.[8] The therapist must know what information is necessary to include in the client record to reduce the risk of malpractice in a legal proceeding. All information must be accurate and based on first-hand knowledge of care. Deductions and assumptions are to be avoided; judgmental statements do not belong in the therapy notes. The therapist instead should describe the action, behavior, or signs and symptoms that are observed. As described earlier, it is considered fraudulent to alter the medical record in any way.

Initial Evaluation

The **initial evaluation report** is a very important document in the OT process. It is the foundation upon which all other components of the client's program are based. including long- and short-term goals, the intervention plan, progress notes, and therapy recommendations. **Evaluation** is the process of obtaining and interpreting data necessary for understanding the individual, system, or situation. It includes planning for and documenting the evaluation process, results, and recommendations, including the need for intervention.[5] The OTPF-3 stresses that the evaluation process should focus on identifying what the client wants and needs to do, in addition to identifying factors that act as supports for or barriers to performance. The client's involvement in this process is essential for guiding the therapist in choosing the appropriate tools to assess these areas. The occupational therapist takes into account the performance skills, performance patterns, context and environment, activity and occupational demands, in addition to the client factors required for the client to successfully engage in occupation. This information must be articulated in the initial evaluation write-up.

A clear, accurately written account of the client's current status, in addition to a description of his or her prior status, is essential to justify the need for OT services. This initial report also provides necessary information to establish a baseline against which reevaluation data and progress notes can be compared to demonstrate the efficacy of therapy intervention. The evaluation must clearly "paint a clinical picture" of the client's current functional status, strengths, impairments, and need for occupational therapy.

The occupational profile is an important part of the evaluation. The **occupational profile** includes information about the client's occupational history and experiences, patterns of daily living, interests, values, and needs.[4] Information obtained from the occupational profile is essential in guiding the therapist to make clinically sound decisions about appropriate assessments, interventions, and goals.

Assessments are the tools, instruments, and interactions used during the evaluation process.[5] Assessments comprise standardized and nonstandardized tests and can include written tests or performance checklists. Interviews and skilled observations are examples of assessments frequently used in the evaluation process. The specific assessments used are determined by the needs of the client and the practice setting in which the client is being seen. Assessments should be chosen that evaluate the client's occupational needs, problems, and concerns. Clinical reasoning skills are used to decide which assessments are appropriate and which areas should be evaluated. It is not necessary to evaluate every occupation and all performance skills for every individual. For example, it is not appropriate to assess a client's ability to cook a meal if he or she lives in a setting in which meals are provided. Results of the assessment should be clearly identifiable and stated in measurable terminology that is standardized to the practice setting. Table 8.1 shows an example of terminology that can be used to describe the level of assistance required during the performance of a functional task.

TABLE 8.1

Levels of Assistance

Assistance Level	Description
Independent	• Client is completely independent. • No physical or verbal assistance is required to complete the task. • Task is completed safely.
Modified independence	• Client is completely independent with task but may require additional time or adaptive equipment.
Supervised	• Client requires supervision to safely complete task. • A verbal cue may be required for safety.
Contact guard/standby assistance	• Hands-on contact guard assistance is necessary for client to safely complete the task, or caregiver must be within arm's length for safety.
Minimum assistance	• Client requires up to 25% physical or verbal assistance from one person to safely complete the task.
Moderate assistance	• Client requires 26% to 50% physical or verbal assistance from one person to safely complete the task.
Maximal assistance	• Client requires 51% to 75% physical or verbal assistance from one person to safely complete the task.
Dependent	• Client requires more than 75% assistance to complete the task. **Note:** It is important to state whether the assistance provided is physical or verbal assistance.

The AOTA has outlined the recommended components of professional documentation used in occupational therapy in the text *Guidelines for Documentation of Occupational Therapy,*[1] which provides suggestions for what information should be included in screening reports, evaluation and reevaluation reports, intervention plans, progress reports, transition plans, and discharge reports.

Screening Report

The **screening report** is an initial brief assessment to determine the client's need for further OT evaluation or for referral to another service. Suggested content includes:

1. *Client information:* Name/agency; date of birth; gender; applicable medical, educational, and developmental diagnosis; precautions; and contraindications

2. *Referral information:* Date and source of referral; services requested; reason for referral; funding source; and anticipated length of service

3. *Brief occupational profile:* Client's reason for seeking OT services; current areas of occupation that are successful and areas that are problematic; contexts that support or hinder occupations; medical, educational, and work history; occupational history; client's priorities; and targeted outcomes

4. *Assessments used and results:* Types of assessments used and results (eg, interviews, record reviews, observations)

5. *Recommendations:* Professional judgments regarding appropriateness of need for complete OT evaluation

Evaluation Report

The **evaluation report** should contain the following information:

1. *Client information:* Name/agency; date of birth; gender; applicable medical, educational, and developmental diagnosis; precautions; and contraindications

2. *Referral information:* Date and source of referral; services requested; reason for referral; funding source; and anticipated length of service

3. *Occupational profile:* Client's reason for seeking OT services; current areas of occupation that are successful and areas that are problematic; contexts that support or hinder occupations; medical, educational, and work history; occupational history; client's priorities; and targeted outcomes

4. *Assessments:* Types of assessments used and results (eg, interviews, record reviews, observations, standardized or nonstandardized assessments)

5. *Analysis of occupational performance:* Description and judgment about performance skills; performance patterns; contextual or environmental aspects or features of activities; client factors that facilitate or inhibit performance; and confidence in test results

6. *Summary and analysis:* Interpretation and summary of data as they relate to the occupational profile and referring concerns

7. *Recommendation:* Judgment regarding appropriateness of OT services or other services

Intervention Plan

Upon completion of the assessment, the **intervention plan** is established. Information obtained from the occupational profile and the various tools used to assess the client is analyzed, and a problem list is generated. Problem statements should include a description of the underlying factor (performance skill, performance pattern, client factor, contextual or environmental limitation, activity demand) and its impact on the related area of occupation.[9] Based on the client's specific problems, the intervention plan is developed. The therapist must use theoretical knowledge and clinical reasoning skills to develop long- and short-term goals, to decide upon intervention approaches, and to determine the interventions to be used to achieve stated goals. Recommendations and referrals to other professionals or agencies are also included in the plan.[1] The intervention plan is formulated on the basis of selected theories, frames of reference, practice models, and best available evidence. It is directed by the client's goals, values, beliefs, and occupational needs.[4]

Establishment of the intervention plan is a collaborative effort between the therapist and the client or, if the client is unable, the client's family or caregivers. Although the occupational therapist (OT) has primary responsibility for development of the intervention plan and goal setting, the occupational therapy assistant (OTA) may contribute to the process. The OTA collaborates with the OT to select, implement, and make modifications to the interventions and provides documentation in the client's record.[2]

Intervention Goals

Intervention goals are written based on identified problems. Goals must be measurable and directly related to the client's ability to engage in desired occupations. The overarching goal of OT intervention is "achieving health, well-being, and participation in life through engagement in occupation"[4] (OTPF-3, p. S2). This must be kept in mind at all times when long- and short-term goals are developed. The OTPF-3 further identifies the outcome of OT intervention to be "the method that assists the client to reach a state of physical, mental, and social well-being; to identify and attain aspirations; to satisfy needs; and to change or cope with the environment"[4] (OTPF-3, p. S14). Documentation that uses this terminology will support the unique focus that occupational therapy contributes to the client's care plan and the rehabilitation process.

The AOTA defines intervention goals as "measurable and meaningful occupation-based long-term and short-term goals directly related to the client's ability and need to engage in desired occupations."[1] Writing goals that are clear, realistic, measurable, and appropriate for the client is an essential part of the therapeutic process that will lead to desired outcomes. Goals are written as a part of the evaluation and are critical factors in justifying the need for therapeutic intervention. As the client's status changes throughout the course of treatment, goals are upgraded or downgraded to guide further intervention. Reimbursement requirements and the setting in which the therapist works often direct the wording of the goal.

The client's intervention plan contains both short- and long-term goals. Some therapists prefer to use the term *objective* in place of *short-term goal.* **Short-term goals**, or objectives, are written for specific time periods (eg, 1 or 2 weeks) within the overall course of the client's therapy program. They are periodically updated as the client progresses or in accordance with the guidelines of the practice setting or payer requirements. Short-term goals are the steps that lead to accomplishment of the long-term goal, which is also called the *discharge goal* in some settings. The **long-term goal** is generally considered to be the overall goal of the intervention and is broader in nature than the short-term goal. For example, the client's long-term goal may be to become independent with dressing. One short-term goal to accomplish this might be that the client will be able to independently put on and take off a simple pullover shirt without fasteners. When this short-term goal has been achieved, a subsequent goal might be for the client to be able to dress independently in a shirt with buttons. Eventually, lower extremity dressing would be added as an objective, then socks, shoes, and outerwear, until the long-term goal of independent dressing is achieved.

Establishing objective, occupation-based, client-centered goals that focus on engagement in occupations and activities to support participation in life is central to the philosophy of occupational therapy.[4] Skillful goal writing requires practice and careful consideration of the desired outcome of therapy intervention. Client-centered goals are written to reflect what the client will accomplish or do, *not* what the therapist will do, and are written in collaboration with the client. The goal must reflect the outcome, not the technique or intervention used to achieve the outcome. *The client will be taught energy conservation techniques to use during dressing* is an example of a poorly written goal that focuses on the process, rather than the outcome, of therapy. The correct way to write the goal would be: *The client will independently use three energy conservation techniques during dressing.*

Goals must be objective and *measurable* and must include a *time frame.* The time frame may be written in a separate section of the evaluation form. A well-written goal clearly identifies the **expected outcome behavior** using concrete terms that describe a specific functional task, action, behavior, or activity (eg, The client will put on pants); a **measurable expectation of performance** (eg, independently); and the conditions or circumstances that support the outcome listed (eg, using a dressing stick). Examples of measurable expectations of performance include levels of assistance, degrees of motion, number of repetitions, and length of time. Examples of conditions include use of assistive devices, adaptive aids, the location where performance takes place (eg, edge of the bed), and additional time necessary to complete the activity. The following goal has all the necessary components: *Mr. B will feed himself* (expected outcome behavior) *with moderate verbal cues* (measurable expectation of performance) *while sitting in a quiet environment* (condition). Table 8.2 shows examples of short- and long-term goals.

TABLE 8.2

Examples of Short- and Long-Term Goals

Short-Term Goal[a]	Long-Term Goal[b]
Client will transfer w/c <-> (from wheelchair onto and off of) toilet with a raised seat and handrails with minimal physical assistance.	Client will independently transfer to a nonmodified toilet using a walker.
Client will brush teeth with moderate physical and verbal assistance while seated at the sink.	Client will complete morning hygiene and grooming independently after task setup using assistive devices while seated at the sink.
Client will put on socks with minimal assistance using a sock aid while seated in a wheelchair.	Client will independently complete lower body dressing without assistive devices while seated at the edge of the bed.

[a]Short-term goals are to be completed in 2 weeks.

[b]Long-term goals are to be completed in 4 weeks.

RUMBA

According to Perinchief,[12] a tool such as the RUMBA (also called RHUMBA) can be beneficial in organizing the therapist's thought processes for writing goals. RUMBA and RHUMBA are acronyms; each letter identifies something that the therapist should keep in mind when writing goals and documenting the therapeutic process. The therapist should review documentation to determine whether these questions have been answered, all the while keeping the target audience in mind.[13]

- Is the information **r**elevant (the outcome must be relevant)? *The goal/outcome must relate to an area of occupation (keep it functional). The long- and short-term goals must relate to each other and to what was identified in the evaluation as being in need of intervention.*
- **H**ow long will it take? *Indicate when the goal/outcome will be met.*
- Is the information **u**nderstandable? *Anyone reading it must know what it means. Avoid jargon, use correct grammar and acceptable abbreviations. Use an active voice rather than a passive voice (eg,* The client will brush her teeth, *rather than* Teeth will be brushed by the client*).*
- Is the information **m**easurable? *There must be a way to know when the goal has been met. This is written as a quantitative statement.*
- Is the information **b**ehavioral (describe behaviors)? *The goal/outcome must be something that is seen or heard and is described using an action verb.*
- Is the outcome **a**chievable (realistic*)? The goal/outcome must be doable and realistically able to be met in the established time frame.*

SMART

Another method that may assist the therapist in writing goals is the SMART goals system. SMART stands for **s**ignificant (and **s**imple), **m**easurable, **a**chievable, **r**elated, and **t**ime limited.[13]

- Achieving this goal will make a **s**ignificant difference in the client's life.
- You have a clear, **m**easurable target to aim for, and you will know when the client has reached the goal.
- It is reasonable that the client could **a**chieve this goal in the time allotted.
- Long- and short-term goals **r**elate to each other, and the goal has a clear connection to the client's occupational needs.
- The goal is **t**ime limited: short- and long-term goals have a designated chronological end point.[7]

Once the short- and long-term goals have been established, the therapist, in collaboration with the client, chooses appropriate interventions that will lead to goal attainment. The plan consists of **skilled interventions** that the therapist will provide throughout the client's therapy program. Interventions are chosen that involve the therapeutic use of occupations or activities (occupation-based activity, purposeful activity, preparatory methods); and consultation and client/caregiver education and advocacy.[4] Examples of OT interventions are activities of daily living (ADL) training; instrumental activities of daily living (IADL) training; therapeutic activities; therapeutic exercises; splint/orthotic fabrication, modification, and application; neuromuscular retraining; cognitive-perceptual training, community reintegration training, client/caregiver training; and discharge planning. The OTPF-3 outlines various approaches that may guide the intervention process (Table 8.3). These approaches are based on theory and best practice evidence. It is expected that the intervention plan will be modified according to the client's needs, priorities, and responses to the interventions. Modifications to the intervention plan must be documented in the client's record in the weekly or monthly progress reports.

TABLE 8.3

OT Intervention Approaches

Intervention Approach	Designed to …
Create, promote (health promotion)	Provide enriched contextual and activity experiences to enhance performance for persons in the natural contexts of life. It does not assume that a disability is present or that there is anything specific that would interfere with performance.
Establish, restore (remediation, restoration)	Change client variables to develop a skill or ability that has not yet been developed or to restore a skill or ability that has been impaired.
Maintain	Provide the supports that will allow the client to maintain performance capabilities. Without continued maintenance intervention, client performance would decline and/or occupational needs would not be met, affecting the individual's health and quality of life.
Modify (compensation, adaptation)	Find ways to revise the current context or activity demands to support performance. This includes using compensatory techniques, enhancing some features to provide cues, or reducing features to reduce distractibility.
Prevent (disability prevention)	Prevent the occurrence or development of barriers to performance in context. This approach is directed toward clients with or without a disability who are at risk for occupational performance problems.

Adapted from the American Occupational Therapy Association: Occupational therapy practice framework: domain and process, third edition, *Am J Occup Ther* 68(Suppl 1):S1–S51, 2014.

Progress Reports

Progress toward goal attainment is an expected criterion for reimbursement of OT services in most practice settings. Documentation that demonstrates progression toward goal achievement is critical to support the need for ongoing therapy. The purposes of the **progress report** are to document the client's improvement, describe the skilled interventions provided, and update goals. Progress reports may be written daily or weekly, depending on the requirements of the work site and the payer source. Various reporting formats are used to document client progress. The most prevalent formats used in physical disabilities settings are SOAP notes, **checklist notes**, and narrative notes.

Regardless of the format used, progress reports should identify the following key elements of the intervention session: the client outcome (using measurable terminology from the OTPF-3); the skilled interventions provided by the occupational therapist; and progress that resulted from the OT intervention. Skilled interventions are those that require the expertise, knowledge, clinical judgment, decision making, and abilities of an occupational therapist. Skilled therapy services have a level of inherent complexity such that they can be performed safely and/or effectively only by or under the general supervision of a qualified therapist.[11] Skilled services include evaluation; determination of effective goals and services in collaboration with the client and the client's caregivers and other medical professionals; analysis and modification of functional activities and tasks; determination that the modified task obtains optimum performance through tests and measurements; client/caregiver training; and periodic reevaluation of the client's status, with corresponding adjustment of the OT program. Box 8.4 shows examples of terminology that reflects the provision of skilled services.

Monitor

Documentation of skilled services includes a description of the type and complexity of the skilled intervention and reflects the therapeutic rationale underlying the choice of the intervention. Reimbursement for clinical services provided depends on documentation that demonstrates the clinical reasoning that underlies the intervention. The progress note must identify the skilled intervention provided and indicate the progress made toward established goals. Comparison statements are an excellent way to convey this information. Current status information is compared with baseline evaluation findings to clearly identify progress: *Client now requires minimal assistance to regain sitting posture during lower body dressing (last week required moderate assistance)*. Documentation that includes functional assessment scores from validated tests and measurements to demonstrate client progress provides strong justification for reimbursement of therapy services. A statement explaining why additional therapy services are needed substantiates the need for ongoing therapy: *Occupational therapy services are required for facilitation of balance and postural corrections to improve independence and safety with lower body dressing.* Goals are modified and updated on the basis of the client's progress: *Client will put on pants independently, without loss of balance, while seated on the edge of the bed.* Upgrading of the client's goals can consist of reducing the amount of assistance required to complete the task, increasing the complexity of the task, or introducing a new component to the activity. This is an ongoing process, and meticulous documentation is necessary to demonstrate the need for continued OT services. If a client is not making progress toward stated goals, a clear explanation of the reasons for this must be included in the progress note, with a modification of the existing goal and intervention approach.

SOAP Progress Note

The format for the **SOAP note** was introduced by Dr. Lawrence Weed in 1970 as a method of charting in the **problem-oriented medical record (POMR)**.[16] In the POMR, which focuses on a client's problems instead of on his or her diagnosis, a numbered problem list is developed that becomes an important part of the medical record. Each member of the healthcare team writes a SOAP note to address problems on the list that are specific to his or her area of expertise. The POMR is constantly modified and updated throughout the client's stay. The SOAP progress note is one of the most frequently used formats for documenting a patient's status. Each letter in the acronym SOAP stands for the name of a section of the note:

S—Subjective

O—Objective

A—Assessment

P—Plan

- The *Subjective* **(S)** part of the note is the section in which the therapist includes information reported by the client. Information provided by the family or caregivers can also be included here. Many different types of statements can be included in the subjective section of the SOAP note. Any information the client gives the therapist about his or her current condition that is relevant to treatment (eg, complaints of pain or fatigue; statements about feelings, attitudes, or concerns; and goals or plans) is appropriate to include in this section.[9] A client's subjective response to treatment is recorded in this section. Direct quotes can be used when appropriate. Family, caregivers, and others involved in the client's care can also provide valuable information. For example, nursing may report that the client was unable to feed himself or herself at breakfast, or a family member may supply information on the client's normal routine before hospitalization. If the client is nonverbal, gestures, facial expressions, and other types of nonverbal responses are appropriate to include. This information can be used to demonstrate improvement, support the benefit of chosen interventions, document the client's response, and show client compliance. However, discretion must be used when deciding what information to include. Using careful, effective communication skills during client treatment sessions will enhance the therapist's ability to gather relevant subjective information about the client's attitudes and concerns that can be used to ensure proper intervention and appropriate documentation.[9]
  The *Subjective* section should include only relevant information that will support the therapist's decision regarding which assessments should be used and which goals are appropriate for this client. The therapist should avoid statements that can be misinterpreted or that can jeopardize reimbursement. Subjective statements that do not relate to information in the other parts of the note are not useful. Negative quotes from the client that do not relate to the intervention session are not necessary or beneficial to include. If there is nothing relevant to report in the *Subjective* section, it is permissible to not include a statement. In this case, write a circle with a line through it (∅) to indicate that you have intentionally left the section blank.
- In the *Objective* **(O)** section of the SOAP note, the therapist documents the results of assessments, tests, and measurements performed, in addition to objective observations.[6] Data that are recorded in the *Objective* section are measurable, quantifiable, or observable. Only factual information may be included. Results of standardized and nonstandardized tests are documented in this part of the note. Measurable performance of functional tasks (ADLs, IADLs), range-of-motion (ROM) measurements, muscle grades, results of sensory evaluations, and tone assessments are examples of appropriate information for this section of the SOAP note. It is important that the therapist not interpret or analyze data in the *Objective* section. Rather, statements should include only concise, specific, objective recordings of the client's performance. Simply listing the activities that the client engaged in is not sufficient. The emphasis is on the results of the interventions, not on the interventions themselves. Information in the *Objective* section can be organized chronologically, discussing the results of each treatment event in the order it occurred during the session, or categorically.[6,9] Information that is organized categorically should follow the categories outlined in the OTPF-3: performance skills, performance patterns, context, and client factors.[4] Table 8.4 presents examples of documentation that can be used in the *Objective* section.

TABLE 8.4

Examples of Categories and Documentation for Objective Section of SOAP Note

Category	Objective Documentation
Activities of daily living (ADL) task performance	Note how each of the performance skills and client factors affects completion of ADL tasks. Include assist levels and setup needed, adaptive equipment required, or techniques used. Include client response to treatment.
Posture and balance	Note whether balance was static or dynamic. Note whether the client leans in one direction, has rotated posture, or has even or uneven weight distribution. Note the position of the head and what cues or feedback was necessary to maintain or restore balance.
Coordination	Include hand dominance, type of prehension used, ability to grasp and maintain grasp, reach and purposeful release, object manipulation, and gross versus fine motor ability.
Swelling or edema	Give volumetric measurements if possible, pitting or nonpitting type.
Movement patterns in affected upper extremities	Note tone, tremors, synergy pattern, facilitation required, and stabilization.
Ability to follow directions	Note type and amount of instruction required and ability to follow one-, two-, or three-step directions.
Cognitive status	Report on initiation of task, verbal responses, approach to the task, ability to stay on task, sequencing, orientation, and judgment.
Neurological factors	Note perseveration, sensory losses (specific), motor deficits, praxis, spasticity, flaccidity, rigidity, neglect, bilateral integration, and tremors.
Functional mobility	Note type of assistance required for the client to complete all types of mobility.
Psychosocial factors	Note client's overall mood, affect, and ability to engage with others. Also note family support, response to changes in body image, and ability to make realistic discharge decisions.

From Borcherding S: *Documentation manual for writing SOAP notes in occupational therapy*, ed 2, Thorofare, NJ, 2005, Slack.

- In the *Assessment* **(A)** section of the SOAP note, the therapist draws from the subjective and objective findings and interprets the data to establish the most appropriate therapy program. In this section, impairments and functional deficits are analyzed and prioritized to determine what impact they have on the client's occupational performance and ability to engage in meaningful occupation. Only information that was included in the *Subjective* or *Objective* section is discussed in the *Assessment* section. Clinical reasoning is required to analyze the information and develop the intervention plan. The *Assessment* portion of the SOAP note is where the therapist demonstrates his or her ability to summarize relevant assessment findings, synthesize the information, analyze its impact on occupational performance, and use it to formulate the intervention plan. It requires keen observation, clinical reasoning, and judgment skills, in addition to an ability to identify relevant factors that inhibit or facilitate performance. The *Assessment* section should end with a statement justifying the need for continued therapy services: *Client would benefit from activities that encourage trunk rotation and forward lean to facilitate transfers and lower body dressing.*[9] Insight and skill in completing the *Assessment* section improve with clinical experience.
- In the *Plan* **(P)** section of the SOAP note, the OT practitioner outlines the intervention plan. As the client achieves the short-term goals, the plan is revised and new short-term goals are established. Documentation reflects the client's updated goals, in addition to any modifications to the frequency of therapy. Suggestions for additional interventions are also included in this section. This information will guide subsequent treatment sessions. Fig. 8.1 shows an example of a progress note using the SOAP format.

S: Client states that "it takes too much energy to dress each day and my hands are too stiff to manage buttons and ties anyways." Client's family reports that client no longer seems interested in self-care activities.

O: Client became SOB with seated self-care task (dressing) after 5 minutes of activity. Client required minimal assistance for upper body dressing, moderate assistance to don pants and maximal assistance to don shoes (last week she required maximal assistance with all tasks). Client had moderate difficulty with buttons (last week she was unable to button blouse). Client was unable to tie shoes. BUE shoulder strength is 3+/5 (was 3/5).

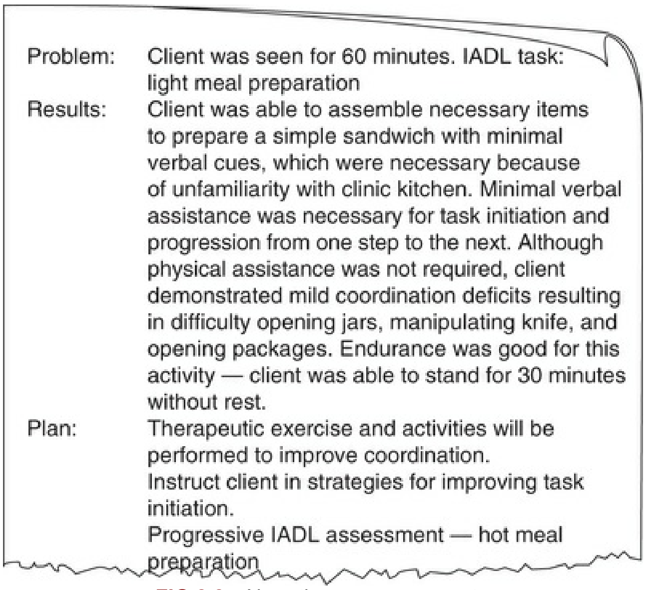
A: Client is improving in her ability to complete her self-care tasks. COPD still interferes with ADL independence. She may benefit from adaptive equipment for lower body dressing.

P: Continue ADL training: assess for independence with adaptive equipment (dressing stick, long-handled shoe horn, and elastic shoe laces). Instruct client in energy-conservation techniques during ADL task completion. Instruct client in AROM exercises before beginning morning ADL tasks.

FIG 8.1 SOAP (**s**ubjective, **o**bjective, **a**ssessment, **p**lan) note.

Narrative Notes

The **narrative note** is another format used to document daily client performance. One way to organize the narrative note is to categorize the information into the following subsections: problem, program, results/progress, and plan. The *problem* being addressed in the treatment intervention should be clearly identified. The impact on occupational performance and the underlying impairment are stated (eg, *Unable to put on socks due to poor sitting balance and postural instability)*. The intervention or intervention modality is identified in the *program* section. The *results,* including progress, are documented in measurable, objective terminology. Barriers to progress are included in this section. The plan for future intervention is outlined in the *plan* section. The need to modify goals and the rationale for this would be included here. In some practice settings, the narrative note is written directly in the medical chart. Occupational therapy may have a designated area in the medical chart in which the therapist can write notes, or all clinicians involved with the client may document in a single comprehensive interdisciplinary note. The date and often the beginning and ending times of the therapy session must be included in the note. The therapist's signature follows the last word of the note. Fig. 8.2 shows an example of a narrative note using this format.



Problem: Client was seen for 60 minutes. IADL task: light meal preparation

Results: Client was able to assemble necessary items to prepare a simple sandwich with minimal verbal cues, which were necessary because of unfamiliarity with clinic kitchen. Minimal verbal assistance was necessary for task initiation and progression from one step to the next. Although physical assistance was not required, client demonstrated mild coordination deficits resulting in difficulty opening jars, manipulating knife, and opening packages. Endurance was good for this activity — client was able to stand for 30 minutes without rest.

Plan: Therapeutic exercise and activities will be performed to improve coordination.
Instruct client in strategies for improving task initiation.
Progressive IADL assessment — hot meal preparation

FIG 8.2 Narrative progress report.

A narrative format may also be used to write any type of information the therapist wishes to convey to the other team members. For example, the therapist may document that the evaluation was initiated or that the client was unable to attend therapy because of illness. Documentation of communication between team members regarding the client's program may be expressed in a narrative format.

Descriptive Notes

At times a short descriptive note is useful to relay important information about the client. Although it is preferable to keep notes as objective as possible, it is sometimes appropriate to include subjective information. Judgmental comments, negative statements, comments about other staff members, and information not directly related to the client's intervention program do not belong in the official medical record. Unobserved behaviors that are included in the client record should be recorded as such and a clear explanation provided as to who provided the information to the therapist.

Progress Checklists or Flow Sheets

Checklists or flow sheets can be used to document daily performance in a concise, efficient manner. High productivity demands in many settings, in addition to lack of reimbursement for documentation, have made this type of documentation a useful option. Flow sheets typically have a table or graph format, which the therapist uses to record measurements at regular intervals, usually after each session. Advantages of using a flow sheet or a checklist to document daily performance on specific tasks include improved clarity and organization of data; reduction in the quantity of data that need to be recorded after each session; improved focus on interventions that are specific to the client's goals; and ease in clearly identifying the client's functional status and progress.[13] A disadvantage of using this format for documentation is that often there is not sufficient space for the therapist to include subjective statements to explain client performance, document the therapist's interpretation of the objective information, or describe the client's response to the intervention. The checklist provides a description of what the client did based on a level of assistance or an objective measurement, but it does not provide information on the quality of how the task was accomplished or modifications that were made to facilitate successful completion of the task. Whenever possible, this information should be included in a narrative format on a separate note sheet. Information from the daily checklist or flow sheet is used to write a weekly progress note.

Discharge Reports

Discharge reports are written at the conclusion of the therapy program. A comparison statement of occupational performance from initial evaluation to discharge is documented to demonstrate progress. Emphasis should be placed on the progress the client has made in engaging in occupations. A summary of the skilled interventions provided to the client is also included. Discharge recommendations (eg, home programs, therapy follow-up, and referral to other programs) are made to facilitate a smooth transition from therapy. Clients are discharged from therapy when they have achieved established goals, have received maximal benefit from OT services, do not desire to continue services,[5] or have exceeded reimbursement allowances. The discharge summary should clearly demonstrate the efficacy of OT services; it is often used to obtain information for outcome studies.

Electronic and Paper-Based Documentation

Documentation can be paper based (written record) or computer generated. Many healthcare facilities and other healthcare providers have adopted EMRs to standardize the collection of client data, improve coordination of care, improve productivity, and facilitate reporting of quality measures. Computerized documentation can be used to record all aspects of the OT process, from the evaluation report to the discharge report. Reporting forms can be accessed on the computer, and the results of the initial evaluation and the discharge report can be typed directly onto the forms. This guarantees legibility and ensures that no areas are left uncompleted.

Electronic evaluation forms and progress notes are formatted to meet the needs of the facility and include information required for reimbursement (Fig. 8.3). Therapists often are able to choose responses from a pull-down menu, thereby reducing the time spent in deciding on the appropriate terminology to use (Table 8.5). Space also is usually available to include narrative information. Because all healthcare providers enter information on a common database, members of the team are able to quickly access information about the patient by reviewing relevant sections on the computerized medical chart. One of the problems or inconveniences that may occur with electronic documentation is the accessibility of computers. Therapists must allow time to locate a computer that is not in use so that they can enter data. However, many clinical sites are now using handheld devices, which alleviates this obstacle. Additionally, some electronic forms are very restrictive in terms of what information the therapist may enter. This may make it difficult for the therapist to adequately document the session. Information entered solely from a pull-down menu may not give a clear picture of what occurred with the client. The use of electronic clinical documentation should not compromise the quality of the content in documentation. Software that allows for ease of use, ability to customize the documentation record to meet the individual needs of the practice setting, and the ability to allow for custom entries in narrative form to clarify information enhances the quality of electronic documentation.[10] In general, electronic documentation and billing can be an asset in the therapy setting.

TABLE 8.5
Definitions of Level of Assistance Based on the Functional Independence Measure (FIM)[a]

	FIM Levels
No Helper	
7	Complete independence (timely, safety)
6	Modified independence (device)
Helper—Modified Dependence	
5	Supervision (subject = 100%)
4	Minimal assistance (subject = 75% or more)
3	Moderate assistance (subject = 50% or more)
Helper—Complete Dependence	
2	Maximal assistance (subject = 25% or more)
1	Total assistance or not testable (subject less than 25%)

[a]The FIM measures level of assistance in various domains on a 7-point scale.

Many different written formats can be used to document OT services. The content of the form used is usually determined by the requirements of the third-party payer reimbursing the service and the unique needs of the practice setting. As stated before, documentation must contain the information necessary to justify the need for OT services, must demonstrate the provision of skilled therapeutic interventions, and must show client progress toward identified goals. OT documentation should address all these components to ensure reimbursement and to convey accurate information about the client's performance.

Primary reimbursement systems for OT services in the physical disabilities setting include Medicare, Medicaid, various health maintenance organizations (HMOs), and preferred provider organizations (PPOs). Each of these organizations requires specific information that must be included in the documentation for reimbursement to occur. Individual facilities (eg, hospitals, clinics, home health agencies, skilled nursing facilities) design documentation forms to meet their specific needs and to ensure that the information necessary for reimbursement is included. Billing systems may also influence the type of documentation format that is used in a particular setting.

Medicare is a major payer source in the geriatric physical disability setting. Medicare is a national insurance program and as such has set national standards for documentation. This government agency has put forth detailed guidelines stating expectations for what information must be included in the medical record to justify the need for OT services. Intermediaries will reimburse OT services only if all of the requirements established by the **Medicare guidelines** and regulations have been met. The 2016 Medicare Benefit Policy Manual[11] describes the key words and phrases medical reviewers are looking for when they review a claim for payment. Medicare requires that specific information be clearly documented for each part of the therapy process for therapy services to be reimbursed. Many other payers of therapy services in adult rehabilitation follow Medicare's guidelines when establishing documentation policies for reimbursement.[13] A thorough and up-to-date understanding of these requirements is critical for ensuring reimbursement for services provided. The therapist working with Medicare clients must become familiar with these guidelines and regulations to prevent denial of services. Detailed information can be found at the Medicare website. It is important to keep up to date on current Medicare regulations to ensure that documentation is sufficient and includes all the components required for reimbursement. The AOTA (*http://www.aota.org*) maintains current information on Medicare reimbursement coverage on its website.

The Centers for Medicare and Medicaid Services (CMS) has designed a specific form for outpatient evaluations: CMS-700, Plan of Treatment for Outpatient Rehabilitation (commonly known as the Medicare 700 form). Although Medicare no longer requires its exclusive use, the form specifies the information that must be supplied for reimbursement. Documentation on the initial evaluation must demonstrate that it is reasonable and necessary for the therapist to complete the evaluation to determine whether restorative or maintenance services are appropriate. It is important to fill in all spaces on the Medicare 700 form (Fig. 8.4). Failure to complete a section of the form could result in a technical denial. It also is important to include a statement of the client's prior level of function and the change in function that precipitated the OT referral. Results from assessments that support the need for therapeutic intervention are recorded in this section. Objective tests and measurements are used to establish baseline data. This information serves as the basis for short- and long-term goals.

	22. SERVICE DATES FROM THROUGH

Form CMS-700-(11-91)

INSTRUCTIONS FOR COMPLETION OF FORM CMS-700

(Enter dates as 6 digits, month, day, year)

1. **Patient's Name** - Enter the patient's last name, first name and middle initial as shown on the health insurance Medicare card.

2. **Provider Number** - Enter the number issued by Medicare to the billing provider *(i.e., 00–7000)*.

3. **HICN** - Enter the patient's health insurance number as shown on the health insurance Medicare card, certification award, utilization notice, temporary eligibility notice, or as reported by SSO.

4. **Provider Name** - Enter the name of the Medicare billing provider.

5. **Medical Record No.** - *(optional)* Enter the patient's medical/clinical record number used by the billing provider.

6. **Onset Date** - Enter the date of onset for the patient's primary medical diagnosis, if it is a new diagnosis, or the date of the most recent exacerbation of a previous diagnosis. If the exact date is not known enter 01 for the day *(i.e., 120191)*. The date matches occurrence code 11 on the UB-92.

7. **SOC *(start of care)* Date** - Enter the date services began at the billing provider (the date of the first Medicare billable visit which **remains the same on subsequent claims** until discharge or denial corresponds to occurrence code 35 for PT, 44 for OT, 45 for SLP and 46 for CR on the UB-92).

8. **Type** - Check the type therapy billed; i.e., physical therapy (PT), occupational therapy (OT), speech-language pathology (SLP), cardiac rehabilitation (CR), respiratory therapy (RT), psychological services (PS), skilled nursing services (SN), or social services (SW).

9. **Primary Diagnosis** - Enter the pertinent written medical diagnosis resulting in the therapy disorder and relating to 50% or more of effort in the plan of treatment.

10. **Treatment Diagnosis** - Enter the written treatment diagnosis for which services are rendered. For example, for PT the primary medical diagnosis might be Degeneration of Cervical Intervertebral Disc while the PT treatment DX might be Frozen R Shoulder or, for SLP, while CVA might be the primary medical DX, the treatment DX might be Aphasia. If the same as the primary DX enter SAME.

11. **Visits From Start of Care** - Enter the **cumulative total** visits *(sessions)* completed since services were started at the billing provider for the diagnosis treated, through the last visit on this bill. *(Corresponds to UB-92 value code 50 for PT, 51 for OT, 52 for SLP, or 53 for cardiac rehab.)*

12. **Plan of Treatment/Functional Goals** - Enter brief current plan of treatment goals for the patient for this billing period. Enter the major short-term goals to reach overall long-term outcome. Enter the major plan of treatment to reach stated goals and outcome. Estimate time-frames to reach goals, when possible.

13. **Signature** - Enter the signature *(or name)* and the professional designation of the professional establishing the plan of treatment.

14. **Frequency/Duration** - Enter the current frequency and duration of your treatment; e.g., 3 times per week for 4 weeks is entered 3/Wk x 4Wk.

15. **Physician's Signature** - If the form CMS-700 is used for certification, the physician enters his/her signature. **If certification is required and the form is not being used for certification, check the ON FILE box in item 18.** If the certification is not required for the type service rendered, check the N/A box.

16. **Date** - Enter the date of the physician's signature only if the form is used for certification.

17. **Certification** - Enter the inclusive dates of the certification, **even if the ON FILE box is checked in item 18.** Check the N/A box if certification is not required.

18. **ON FILE** (Means certification signature and date) - Enter the **typed/printed name of the physician** who certified the plan of treatment that is on file at the billing provider. If certification is not required for the type of service checked in item 8, type/print the name of the physician who referred or ordered the service, **but do not check the ON FILE box.**

19. **Prior Hospitalization** - Enter the inclusive dates of recent hospitalization *(1st to DC day)* **pertinent** to the patient's current plan of treatment. Enter N/A if the hospital stay does not relate to the rehabilitation being rendered.

20. **Initial Assessment** - Enter only **current relevant history** from records or patient interview. Enter the major functional limitations stated, if possible, in objective measurable terms. Include only relevant surgical procedures, prior hospitalization and/or therapy for the same condition. Include only pertinent baseline tests and measurements from which to judge future progress or lack of progress.

21. **Functional Level** (end of billing period) - Enter the pertinent progress made and functional levels obtained at the end of the billing period compared to levels shown on initial assessment. Use objective terminology. Date progress when function can be consistently performed. When only a few visits have been made, enter a note indicating the training/treatment rendered and the patient's response if there is no change in function.

22. **Service Dates** - Enter the From and Through dates which represent this billing period *(should be monthly)*. Match the From and Through dates in field 6 on the UB-92. DO NOT use 00 in the date. Example: 01 08 91 for January 8, 1991.

FIG 8.4 Medicare evaluation form and instructions. (Courtesy Medicare, http://www.medicare.org.)

Many rehabilitation companies and hospitals have modified the Medicare 700 form with headings and checklists to assist the therapist in providing the type of information that will support the need for therapy services (Fig. 8.5). Space on the form is limited, and the therapist must be able to concisely present data that will clearly demonstrate the need for occupational therapy. A recent change in function (a decline or an improvement) is required to justify therapy. The plan of treatment (Section 12) includes functional, measurable goals based on assessment results as described in Section 18 of the Modified Medicare 700 form (sections may differ on Fig. 8.4 of the Medicare evaluation form). Goals cannot address issues that do not have supporting baseline data in the Assessment (Section 18) section. Goals cannot address issues that do not have supporting baseline data in the Assessment section (Section 18). The plan of treatment is the skilled intervention that the therapist will provide. The Medicare 700 form also functions as the end-of-month progress report and/or as the discharge form. Section 20 is completed at the end of the billing period. Progress, current functional status, and skilled interventions provided during the previous month are included in this section.

Confidentiality and Documentation

Maintaining **confidentiality** in documentation is the responsibility of the occupational therapist. Confidentiality, which is principle 3H of the AOTA Code of Ethics, addresses the issue of **privacy** and confidentiality in all forms of communication, including documentation:

Occupational therapy personnel shall maintain the confidentiality of all verbal, written, electronic, augmentative, and nonverbal communications, in compliance with applicable laws, including all aspects of privacy laws and exceptions thereto (eg, HIPAA and the Family Educational Rights and Privacy Act).[3]

Similarly, Fremgen,[8] addressing the rules of medical law and ethics, explained that patients "have the right to have their personal privacy respected and their medical records handled with confidentiality. No information, test results, patient histories, or even the fact that the person is a patient, can be transmitted to another person without the patient's consent."

The AOTA's "Guidelines to the Code of Ethics" provides additional guidance regarding confidentiality issues[2]:

Information that is confidential must remain confidential. This information cannot be shared verbally, electronically, or in writing without appropriate consent. Information must be shared on a need-to-know basis only with those having primary responsibilities for decision making.

5.1 All occupational therapy personnel shall respect the confidential nature of information gained in any occupational therapy interaction.

5.2 Occupational therapy personnel shall respect the individual's right to privacy.

5.3 Occupational therapy personnel shall take all due precautions to maintain the confidentiality of all verbal, written, and electronic, augmentative, and nonverbal communications (as required by HIPAA.)[3] **Ethical practice** demands that the therapist understand what is meant by confidential information and is knowledgeable about how to maintain client confidentiality. Information about clients, including their names, diagnoses, and intervention programs, cannot be discussed outside of the treatment environment. Client charts should not be removed from the facility. Reports containing personal information (name, Social Security number, medical diagnosis) cannot be left out in plain view, where others can read the information. Therapists, students, and staff cannot discuss clients in public areas where others may overhear the conversation.

Federal laws have been enacted to protect the consumer against breaches of confidentiality. The privacy sections of the **Health Insurance Portability and Accountability Act (HIPAA)** clearly outline the expectations of healthcare professionals in issues of confidentiality. HIPAA was enacted in 1996 and consisted of a series of provisions that required the Department of Health and Human Services to adhere to national standards for electronic transmission of healthcare information. The law also required that healthcare providers adopt privacy and security standards by which to protect confidential medical information of patients. Beginning in April, 2003, healthcare providers were required to adhere to the privacy standards mandated by HIPAA**.** Individually identifiable health information, also known as protected health information (PHI), is federally protected under HIPAA regulations. PHI is health information that relates to a past, present, or future physical or mental health condition. The HIPAA rule limits the use and disclosure of PHI to the minimum necessary to carry out the intended purpose. It also gives patients the right to access their medical records. This regulation protects the medical records of clients, whether the information is written or electronic (computer) or is verbally communicated. Violations of the HIPAA rules are subject to criminal or civil sanctions.[8]

The law requires that all staff members be trained in HIPAA policies and procedures and that they understand the implications specific to their work setting. In addition to the client confidentiality procedures explained earlier, safeguards must now be adhered to for compliance with HIPAA regulations. The therapist has a responsibility to protect confidential information from unauthorized access, use, or disclosure. This includes information documented in the medical record. Papers, reports, and forms containing PHI should not be disposed of in the regular trash. Instead they must be shredded. Never leave medical records or portions of records (ie, therapy notes) unattended in public view. Information (written, verbal, or electronic) cannot be shared with the client's family members unless permission has been provided in writing by the client.

If documentation is done electronically, special care must be taken to prevent unauthorized individuals from accessing client information. Log-in pass codes cannot be shared among staff members, and therapists must take care to ensure privacy when entering information.

Ethical Considerations

Special safety measures, such as personal identification and user verification codes for access to records, should be established to prevent unauthorized individuals from accessing clients' records.[8]

Threaded Case Study

Jane, Part 2

Reflect on the questions posed in Part 1 of this case study. Jane, the OT beginning her first job at the skilled nursing facility, must use clinical reasoning skills at all stages of the therapy process, including the documentation of services delivered. The evaluation, the intervention plan, and short-term and long-term goals are written using sound clinical reasoning to decide which assessments are appropriate to administer, how to use best practice evidence to develop interventions, and how to best collaborate with the client (taking into account the client's goals, priorities, and desires) throughout the process. Evidence of this comprehensive approach must be reflected in the documentation provided by Jane. It is essential that OT notes also indicate the skilled service or skilled intervention that was provided for reimbursement purposes. The format used for recording this information, and also the terminology used, may be specific to the practice setting. Federal (ie, HIPAA) privacy mandates and the Occupational Therapy Code of Ethics must be adhered to at all times during all methods of documentation, whether written, verbal, or electronically generated.

Summary

Documentation is a necessary part of the OT process. The occupational therapist has a responsibility to the client, to the employer, and to the profession to develop the skills that will allow him or her to accurately document the therapy process. Well-written documentation promotes the profession by providing proof of the value of OT intervention. It can provide valuable information for outcome research and evidence-based practice. It is a professional expectation that the OT will keep current on documentation requirements for his or her practice area and will acquire the skills necessary to accurately document the OT process.

Infection Control and Safety Issues in the Clinic

Alison Hewitt George

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:
1. Recognize the role of occupational therapy personnel in preventing accidents.
2. Identify recommendations for safety in the clinic.
3. Describe the purposes of special medical equipment.
4. Identify precautions that should be taken when treating clients who require special equipment.
5. Identify Standard Precautions for infection control and explain the importance of following them with all clients.
6. Describe proper techniques of hand hygiene.
7. Recognize the importance for all healthcare workers of understanding and following standard procedures used in client care to prevent the transmission of infectious agents.
8. Identify proper procedures for handling client injuries.

9. Describe the guidelines for handling various emergency situations.

KEY TERMS

Antiseptic
Arterial monitoring line
Autoclave
Cardiopulmonary resuscitation (CPR)
Catheter
Centers for Disease Control and Prevention (CDC)
Dyspnea control postures
Endotracheal tube (ET)
Feeding pump
Fowler's position
Healthcare-associated infection (HIA)
Hyperalimentation
Intravenous (IV) feeding
Intravenous (IV) lines
Isolation systems
Nasogastric (NG) tube
Nosocomial infection
Occupational Safety and Health Administration (OSHA)
Pathogens
Standard Precautions
Total parenteral nutrition (TPN)
Transmission-Based Precautions
Universal Precautions (UP)

Threaded Case Study

Donna, Part 1

Donna is a registered occupational therapist hired as director of Occupational Therapy (OT) Services in a recently opened community hospital. This 300-bed general acute care hospital provides inpatient and outpatient services for individuals with a wide range of medical needs, including cardiac problems, brain injury, neurological and orthopedic problems, and needs in oncology, obstetrics, and gynecology. OT services are provided in acute care, skilled nursing, acute rehabilitation, and outpatient units.

As director of OT Services, Donna must establish policies and procedures pertaining to client safety, infection control, medical emergencies, and precautions with special equipment. Donna must develop written guidelines and must identify and/or develop training requirements to ensure adequate orientation and preparation of OT personnel.

Critical Thinking Questions

In preparing these policies and procedures, Donna must consider the following:

1. What general safety procedures and infection control standards should be followed to maintain a safe clinic environment?

2. What items of specialized medical equipment are OT personnel likely to encounter in their interventions with clients, and what precautions should be taken when treating a client who requires special equipment?

3. What are the basic guidelines and/or procedures to be applied in emergency situations?

4. What resources are available to healthcare providers that offer up-to-date information pertaining to safety procedures and infection control?

As you read through the chapter, keep in mind these questions and any other concerns confronting Donna in developing protocols, policies, and procedures for the safety of clients and OT personnel.

Ethical Considerations

Occupational therapists have an ethical obligation to refrain from actions that cause harm (p. 3) to recipients of OT services. To meet these ethical obligations to clients and to provide a physical context that supports clients' engagement in meaningful occupations, occupational therapists need to be educated in proper safety procedures, infection control standards, and emergency interventions.

The current (2014) version of the OT Framework, the "Occupational Therapy Practice Framework: Domain and Process," third edition[2] (OTPF-3), describes OT service delivery as a collaborative process between the client and the OT practitioner. This collaboration can occur in a variety of settings (eg, hospitals, schools, community settings, and home). The physical environment is an aspect of the domain of occupational therapy that can influence a client's engagement in occupations. The physical environment refers to the "natural (eg, geographic terrain, plants) and built (eg, buildings, furniture) surroundings in which daily life occupations occur"[2] (OTPF-3, p. S8). Therefore, the setting, or physical context, in which OT intervention occurs plays a significant role in the delivery of services in terms of supporting or inhibiting the client's performance.

Medical technology and cost control pressures have made it necessary for rehabilitation professionals to treat seriously ill clients early in their illness and for shorter periods. In the hospital setting it is not unusual for occupational therapists to work with clients using interventions that include specialized medical equipment, such as **catheters**, intravenous (IV) lines, monitoring devices, and ventilators. These circumstances increase the potential for injuries to clients. In addition to ethical obligations to provide safe and proper intervention, OT personnel can be held legally liable for negligence if a client is injured because staff failed to follow proper procedures or standards of care.

This chapter reviews specific safety precautions for use with a variety of clients. It identifies precautions to consider when encountering equipment commonly used with clients. Guidelines for handling various emergency situations are reviewed. It is important to note that the chapter is only an overview and cannot substitute for training in specific procedures used in many facilities. In addition to following these procedures, it is incumbent upon the occupational therapist to teach clients and their families applicable techniques that can be followed at home.

Safety Recommendations for the Clinic

Prevention of accidents and subsequent injuries begins with consistent application of basic safety precautions for the clinic:

1. Hand hygiene (hand washing or the use of alcohol-based hand rubs) should be performed before and after treating each client to reduce cross-contamination.

2. Make sure space is adequate to maneuver equipment. Avoid placing clients where equipment or passing personnel may bump them. Keep the area free from clutter.

3. Do not attempt to transfer clients in congested areas or in areas where your view or movement is blocked.

4. Routinely check equipment to ensure that it is working properly.

5. Make sure that the furniture and equipment in the clinic are stable. When not using items, store them out of the way of the treatment area.

6. Keep the floor free of cords, scatter rugs, litter, and spills. Ensure that the floors are not highly polished because polished floors may be very slippery.

7. Do not leave clients unattended. Follow federal guidelines for the proper use of restraint equipment (eg, bed rails, belts, vests) to protect clients when they are not closely observed.

8. Have the treatment area and supplies ready before the client arrives.

9. Allow only properly trained personnel to provide client care.

10. Follow the manufacturer's and the facility's procedures for handling and storing potentially hazardous material. Make sure that such materials are marked and stored in a place that is in clear view. Do not store such items above shoulder height.

11. Clearly label emergency exits and evacuation routes.

12. Have emergency equipment, such as fire extinguishers and first aid kits, readily available.

Precautions With Special Equipment

Newly hired OT personnel need orientation and education regarding the types of medical equipment they are likely to encounter when treating clients. Before providing any intervention to a client at bedside, the OT should carefully review the medical chart to determine whether any specific instructions regarding movement precautions, positioning, or handling should be followed. For example, a client may need to follow a turning schedule and may be limited in the length of time allowed to remain in one position. Certain joint movements may be contraindicated, or special bed and wheelchair positioning requirements may need to be followed, such as with clients recovering from a burn injury, spinal cord injury, stroke, hip replacement surgery, and so forth. Special handling techniques may be required when working with clients who have catheters, feeding tubes, IV lines, or special monitors. The various chapters throughout this book that address specific diagnoses will identify necessary precautions and handling recommendations.

Hospital Beds

OT personnel must be educated in the proper use of hospital beds to ensure client safety. The most commonly used hospital bed is electrically powered, but some are adjusted manually (cranked) or by hydraulic methods. All hospital beds are designed to make it easier to support the client and to change a client's position. Other, more specialized beds are needed for management of more complicated or more traumatic cases. Whatever type is used, the bed should be positioned so that the client is easily accessed and the therapist can use good body mechanics during mobility activities (see Chapter 11).

Most standard electrically adjustable beds are adjusted by means of electrical controls attached to the head or the foot of the bed or to a special cord that allows the client to operate the controls. The controls are marked according to their function and can be operated with the hand or foot. The entire bed can be raised and lowered, or upper and lower sections of the bed can be elevated or lowered to meet the client's needs. When the upper portion is raised 45 to 60 degrees, the client's position is referred to as **Fowler's position**. This commonly used position facilitates lung expansion, improves breathing, and decreases cardiac workload (as compared with supine lying). However, an important precaution for the OT to observe and address is that in this position, the client may slide down in the bed, which increases shearing forces on tissues of the back.

Side rails are attached to most beds as a protective measure. Some rails are lifted upward to engage the locking mechanism, whereas others are moved toward the upper portion of the bed until the locking mechanism is engaged. If a side rail is used for client security, the OT should be sure the rail is locked securely before leaving the client. The rail should be checked to ensure that it does not compress, stretch, or otherwise interfere with any IV or other tubing.

Ventilators

Ventilators (respirators) move gas or air into the client's lungs and are used to maintain adequate air exchange when normal respiration is decreased. Two frequently used types of ventilators are volume-cycled ventilators and pressure-cycled ventilators. Both ventilators deliver a predetermined volume of gas (air) during inspiration and allow for passive expiration. The gas delivered by the ventilator usually will be introduced into the client through an **endotracheal tube (ET)**, which is a catheter inserted through the nose or mouth into the trachea. When the tube is in place, the client is intubated. Insertion of the ET will prevent the client from talking. When the ET is removed, the client may complain of a sore throat and may have a distorted voice for a short period. It is important to avoid disturbing, bending, kinking, or occluding the tubing or accidentally disconnecting the ventilator tube from the ET. The client who uses a ventilator may participate in various bedside activities, including sitting and ambulation. Make sure the tubing is sufficiently long to allow the activity to be performed. Because the client will have difficulty talking, ask questions that can be answered with head nods or by other nonverbal means. A client using a ventilator may have a lower tolerance for activities and should be monitored for signs of respiratory distress, such as a change in the respiration pattern, fainting, or blue lips.

Monitors

Various monitors are used to observe the physiological state of clients who need special care. Therapeutic activities can be performed by clients who are being monitored, provided that care is taken to prevent disruption of the equipment. Many of the units have auditory and visual signals that are activated by a change in the client's condition or position or by a change in the function of the equipment. It may be necessary for a nurse to evaluate and correct the cause of the alarm unless the OT has received special instruction.

The cardiac monitor provides a continuous check on the function of the client's heart, including electrical activity (electrocardiogram [ECG]), heart rate, blood pressure, and respiration rate. Acceptable or safe ranges for the three physiological indicators can be set in the unit. An alarm is activated when the upper or lower limits of the ranges are exceeded or if the unit malfunctions. A monitoring screen provides a graphic and digital display of the values so that healthcare staff can observe the client's responses to treatment.

The pulmonary artery catheter (PAC) (eg, Swan-Ganz catheter) is a long, plastic IV tube that is inserted into a large vein (eg, subclavian, femoral, or jugular) and then threaded through the right side of the heart into the pulmonary artery. It provides accurate and continuous measurements of pulmonary artery pressures and will detect subtle changes in the client's cardiovascular system, including responses to medications, stress, and activity. Activities, including OT interventions, can be performed with the PAC in place, providing they do not interfere with the location of insertion of the catheter. For example, if the catheter was inserted into the subclavian vein, elbow flexion should be avoided and shoulder motions restricted.

The intracranial pressure (ICP) monitor measures pressure exerted against the skull by brain tissue, blood, or cerebrospinal fluid (CSF). It is used to monitor ICP in clients with a closed head injury, cerebral hemorrhage, brain tumor, or overproduction of CSF. Some of the complications associated with this device are infection, hemorrhage, and seizures. Two of the more commonly used ICP monitoring devices are the ventricular catheter and the subarachnoid screw. Both are inserted in a hole drilled in the skull. Physical activities should be limited when these devices are in place. Activities that would cause a rapid increase in ICP, such as isometric exercises, should be avoided. Positions to avoid include neck flexion, hip flexion greater than 90 degrees, and the prone position. The client's head should not be lowered more than 15 degrees below horizontal. Care must be taken to avoid disturbing the plastic tube.

The **arterial monitoring line** (A line) is a catheter that is inserted into an artery to continuously and accurately measure blood pressure or to obtain blood samples without repeated needle punctures. OT intervention can be provided with an A line in place, but care should be taken to avoid disturbing the catheter and inserted needle.

Feeding Devices

Special feeding devices may be necessary to provide nutrition for clients who are unable to ingest, chew, or swallow food. Some of the more commonly seen devices are the **nasogastric (NG) tube**, the gastric tube, and **intravenous (IV) feedings**.

The NG tube is a plastic tube that is inserted through a nostril and terminates in the client's stomach. The tube may cause the client to have a sore throat or an increased gag reflex. Feeding training can be initiated while the NG tube is in place. However, care should be taken because the tube may desensitize the swallow mechanism. Caution should be used when moving the client's head and neck, especially in forward flexion, to avoid dislodging the tube.

The gastric tube (G tube) is a plastic tube inserted through an incision in the client's abdomen directly into the stomach. Care should be taken so that the tube is not disturbed or removed during intervention activities.

Intravenous feeding, **total parenteral nutrition (TPN)**, or **hyperalimentation**, devices permit infusion of the large amounts of nutrients needed to promote tissue growth. A hyperalimentation device is used when a client is unable to eat or absorb nutrients through the gastrointestinal tract. A catheter is passed into a large vein (typically the subclavian vein) that empties directly into the heart. The catheter may be connected to a semipermanently fixed cannula or sutured at the point of insertion. The OT should carefully observe the various connections to be certain they are secure before and after intervention. A disrupted or loose connection may result in the development of an air embolus, which could be life-threatening.

The system usually includes a specialized **feeding pump**, which will administer fluids and nutrients at a preselected, constant flow rate. An audible alarm will be activated if the system becomes imbalanced or when the fluid source is empty. Intervention activities can be performed as long as the tubing is not disrupted, disconnected, or occluded and as long as undue stress to the infusion site is prevented. Motions of the shoulder on the side of the infusion site may be restricted, especially abduction and flexion.

Most **intravenous (IV) lines** are inserted into superficial veins. Various sizes and types of needles or catheters are used, depending on the purpose of the IV therapy, the infusion site, the need for prolonged therapy, and site availability. Care should be taken during intervention to prevent any disruption, disconnection, or occlusion of the tubing. The infusion site should remain dry, the needle should remain secure and immobile in the vein, and no restraint should be placed above the infusion site. For example, a blood pressure cuff should not be applied above the infusion site. The total system should be observed to ensure that it is functioning properly when intervention begins and ends. If the infusion site is in the antecubital area, the elbow should not be flexed. The client who ambulates with an IV line in place should be instructed to grasp the IV support pole so that the infusion site will be at heart level. If the infusion site is allowed to hang lower, blood flow may be affected. Similar procedures to maintain the infusion site in proper position should be followed when the client is treated while in bed or at a treatment table. Activities involving elevation of the infusion site above the level of the heart for a prolonged period should be avoided. Problems related to the IV system should be reported to nursing personnel. Simple procedures, such as straightening the tubing or removing an object that is occluding the tubing, may be performed by the properly trained therapist.

Catheters

A urinary catheter is used to remove urine from the bladder when the client is unable to satisfactorily control retention or release. Urine is drained through plastic tubing into a collection bag, bottle, or urinal. Any form of trauma, disease, condition, or disorder affecting neuromuscular control of the bladder sphincter may necessitate the use of a urinary catheter. The catheter may be used temporarily or for the remainder of the client's life.

A urinary catheter can be applied internally (indwelling catheter) or externally. Female clients require an indwelling catheter inserted through the urethra and into the bladder. Males may use an external catheter. A condom catheter is applied over the shaft of the penis and is held in place by an adhesive applied to the skin or by a padded strap or tape encircling the proximal shaft of the penis. The condom is connected to a drainage tube and a urine collection bag.

When clients with urinary catheters are receiving OT intervention, several precautions are important. Disruption or stretching of the drainage tube should be prevented, and no tension should be placed on the tubing or the catheter. The urine collection bag must not be placed above the level of the bladder for longer than a few minutes to avoid backflow of urine into the bladder or kidneys (with an indwelling catheter) or soiling of the client (with an external catheter). The bag should not be placed in the client's lap when the client is being transported. The production, color, and odor of the urine should be observed. The following observations should be reported to a physician or nurse: foul-smelling, cloudy, dark, or bloody urine or a reduction in the flow or production of urine. The collection bag must be emptied when it is full.

Infection is a major complication for persons using catheters, especially for those using indwelling catheters. Everyone involved with the client should maintain cleanliness during treatment. The tubing should be replaced or reconnected only by those properly trained. Treatment settings in which clients with catheters are routinely treated have specific protocols for catheter care.

Two types of internal catheters that are frequently used are the Foley catheter and the suprapubic catheter. The Foley catheter is a type of indwelling catheter that is held in place in the bladder by a small balloon inflated with air, water, or sterile saline solution. For removal of the catheter, the balloon is deflated and the catheter is withdrawn. The suprapubic catheter is inserted directly into the bladder through incisions in the lower abdomen and the bladder. The catheter may be held in place by adhesive tape, but care should be taken to avoid its removal, especially during self-care activities. Catheter application and bladder management are activities of daily living (ADLs) that are frequently taught to clients as part of a comprehensive OT intervention program (see Chapters 10 and 36 for examples).

Infection Control

Infection control procedures are used to prevent the spread of disease and infection among clients, healthcare workers, and others. They are designed to interrupt or establish barriers to the infection cycle. In 1996 the **Centers for Disease Control and Prevention (CDC)** published "Guidelines for Isolation Precautions in Hospitals." This document described **Universal Precautions (UP)**, which were established to protect healthcare workers and the clients they served from infectious agents, such as the human immunodeficiency virus (HIV), and diseases, such as acquired immunodeficiency syndrome (AIDS), hepatitis B, and hepatitis C. UP placed an emphasis on preventing the transmission of **pathogens** (infectious microorganisms) through contact with blood and bodily fluids. The CDC revised and developed additional guidelines for a system of isolation, called body substance isolation (BSI), which focused on isolating moist and potentially infectious body substances (blood, feces, urine, sputum, saliva, wound drainage, and other body fluids) from all patients. These guidelines recommended the use of **Standard Precautions**, which synthesized the primary features of BSI and UP. Standard Precautions apply to blood, all bodily secretions and fluids, mucous membranes, and nonintact skin (Box 9.1 and Fig. 9.1).

Box 9.1

Summary of Standard Precautions

1. Use extreme care to prevent injuries caused by sharp instruments.
2. Cover minor, nondraining, noninfected skin lesions with an adhesive bandage.
3. Report infected or draining lesions and weeping dermatitis to your supervisor.
4. Avoid personal habits (eg, nail biting) that increase the potential for oral mucous membrane contact with body surfaces.
5. Perform procedures involving body substances carefully to minimize splatters.
6. Cover environmental surfaces with moisture-proof barriers whenever splattering with body substances is possible.
7. Wash hands regularly, whether or not gloves are worn.
8. Avoid unnecessary use of protective clothing. Use alternate barriers whenever possible.
9. Wear gloves to touch the mucous membranes or the nonintact skin of any client, and whenever direct contact with body substances is anticipated.

. Wear protective clothing (eg, gown, mask, and goggles) when splashing of body substances is anticipated.

. Ensure that the hospital has procedures for care, cleaning, and disinfection of environmental surfaces and equipment.

. Handle and process soiled linens in a manner that minimizes the transfer of microorganisms to other patients and environments.

. Handle used patient care equipment appropriately to prevent transfer of infectious microorganisms. Ensure that reusable equipment is thoroughly and appropriately cleaned.

FIG 9.1 Universal blood and body fluid precautions. (Courtesy Brevis, Salt Lake City, UT.)

The most recent revision by the CDC, the "2007 Guideline for Isolation Precautions Preventing Transmission of Infectious Agents in Healthcare Settings,"[16] recommends the use of two tiers of precautions to prevent transmission of infectious agents: Standard Precautions and **Transmission-Based Precautions**. The document states:

Standard Precautions are intended to be applied to the care of all patients in all healthcare settings, regardless of the suspected or confirmed presence of an infectious agent. Implementation of Standard Precautions constitutes the primary strategy for the prevention of healthcare-associated transmission of infectious agents among patients and healthcare personnel.

Standard Precautions include hand hygiene, use of protective clothing (eg, gloves, gowns, masks, or eye protection, depending on anticipated exposure), and safe injection practices. Specific recommendations for each area of the Standard Precautions are detailed in the CDC guidelines. Key features of these recommendations are summarized in Box 9.1 and Table 9.1. Transmission-Based Precautions are additional standards that are implemented with clients who are known to be infected with infectious agents and require additional control measures to effectively prevent transmission. The most recent standards of the CDC also reflect current trends in the transition of healthcare delivery from primarily acute hospital settings to other settings (eg, long-term care, home care). These recommendations "can be applied in all healthcare settings using common principles of infection control practice, yet can be modified to reflect setting-specific needs."[16] Additionally, the term **nosocomial infection** (ie, hospital-acquired infection) has been replaced by **healthcare-associated infection (HIA)** "to reflect the changing patterns in healthcare delivery and difficulty in determining the geographic site of exposure to an infectious agent and/or acquisition of infection."[16]

TABLE 9.1

Recommendations for Application of Standard Precautions in All Healthcare Settings

Component	Recommendations
Hand hygiene	After touching blood, body fluids, secretions, excretions, contaminated items; immediately after removing gloves; between patient contacts
Personal Protective Equipment (PPE)	

Gloves	For touching blood, body fluids, secretions, excretions, contaminated items; for touching mucous membranes and nonintact skin
Gown	During procedures and patient care activities when contact of clothing/exposed skin with blood/body fluids, secretions, and excretions is anticipated
Mask, eye protection (goggles), face shield	During procedures and patient care activities likely to generate splashes or sprays of blood, body fluids, secretions, especially suctioning, endotracheal intubation
Soiled patient care equipment	Handle in a manner that prevents transfer of microorganisms to others and to the environment; wear gloves if visibly contaminated; perform hand hygiene
Environmental control	Develop procedures for routine care, cleaning, and disinfection of environmental surfaces, especially frequently touched surfaces in patient care areas
Textiles and laundry	Handle in a manner that prevents transfer of microorganisms to others and to the environment
Needles and other sharps	Do not recap, bend, break, or hand-manipulate used needles; if recapping is required, use a one-handed scoop technique only; use safety features when available; place used sharps in puncture-resistant container
Patient resuscitation	Use mouthpiece, resuscitation bag, or other ventilation devices to prevent contact with mouth and oral secretions
Patient placement	Prioritize for single-patient room if patient is at increased risk of transmission, is likely to contaminate the environment, does not maintain appropriate hygiene, or is at increased risk for acquiring infection or developing adverse outcomes following infection
Respiratory hygiene/cough etiquette (source containment of infectious respiratory secretions in symptomatic patients, beginning at initial point of encounter [eg, triage and reception areas in emergency departments and physician offices])	Instruct symptomatic persons to cover mouth/nose when sneezing/coughing; use tissues and dispose of in no-touch receptacle; perform hand hygiene after soiling of hands with respiratory secretions; wear surgical mask if tolerated or maintain spatial separation greater than 3 feet if possible

From Healthcare Infection Control Practices Advisory Committee: 2007 guideline for isolation precautions: preventing transmission of infectious agents in healthcare settings. http://www.cdc.gov/hicpac/pdf/isolation2007.pdf.

The **Occupational Safety and Health Administration (OSHA)** issues regulations to protect the employees of healthcare facilities. All healthcare settings must do the following to comply with federal regulations:

1. Educate employees on methods of transmission and on prevention of hepatitis B, HIV, and other infections.

2. Provide safe and adequate protective equipment and teach employees where the equipment is located and how to use it.

3. Teach employees about work practices used to prevent occupational transmission of disease, including, but not limited to, Standard Precautions, proper handling of client specimens and linens, proper cleaning of body fluid spills (Fig. 9.2), and proper waste disposal.

FIG 9.2 Spills of body fluids must be cleaned up by a gloved employee using paper towels, which should then be placed in an infectious waste container. Afterward a solution of 5.25% sodium hypochlorite (household bleach) diluted 1 : 10 should be used to disinfect the area. (From Young AP: *Kinn's the medical assistant*, ed 12, St Louis, 2013, Elsevier.)

4. Provide proper containers for the disposal of waste and sharp items and teach employees the color-coding system used to distinguish infectious waste.

5. Post warning labels and biohazard signs (Fig. 9.3).

FIG 9.3 Biohazard label. (From Young AP: *Kinn's the medical assistant,* ed 12, St Louis, 2013, Elsevier.)

6. Offer the hepatitis B vaccine to employees who are at substantial risk of occupational exposure to the hepatitis B virus.

7. Provide education and follow-up care to employees who are exposed to communicable disease.

OSHA has also outlined the responsibilities of healthcare employees. These responsibilities include the following:

1. Use protective equipment and clothing provided by the facility whenever the employee contacts or anticipates contact with body fluids.

2. Dispose of waste in proper containers, applying knowledge and understanding of the handling of infectious waste and using color-coded bags or containers.

3. Dispose of sharp instruments and needles in proper containers without attempting to recap, bend, break, or otherwise manipulate them before disposal.

4. Keep the work environment and the client care area clean.

5. Wash hands immediately after removing gloves and at any other times mandated by the hospital or agency policy.

6. Immediately report any exposures, such as needle sticks or blood splashes, or any personal illnesses to the immediate supervisor and receive instruction about any further follow-up action.

Although it is impossible to eliminate all pathogens from an area or object, the likelihood of infection can be greatly reduced. The largest source of preventable client infection is contamination from the hands of healthcare workers. Hand hygiene (Fig. 9.4) and the use of gloves are the most effective barriers to the infection cycle. The use of gloves does not eliminate the need for hand hygiene, and vice versa. Latex gloves provide the best protection from infectious materials. However, many individuals have latex allergies, so nonlatex gloves can be used as an alternative. The World Health Organization (WHO) also recommends the use of alcohol-based hand rubs as an acceptable alternative to hand washing.[19] Alcohol-based hand rubs are fast acting, cause minimal skin irritation, and significantly reduce the presence of microorganisms on the skin.

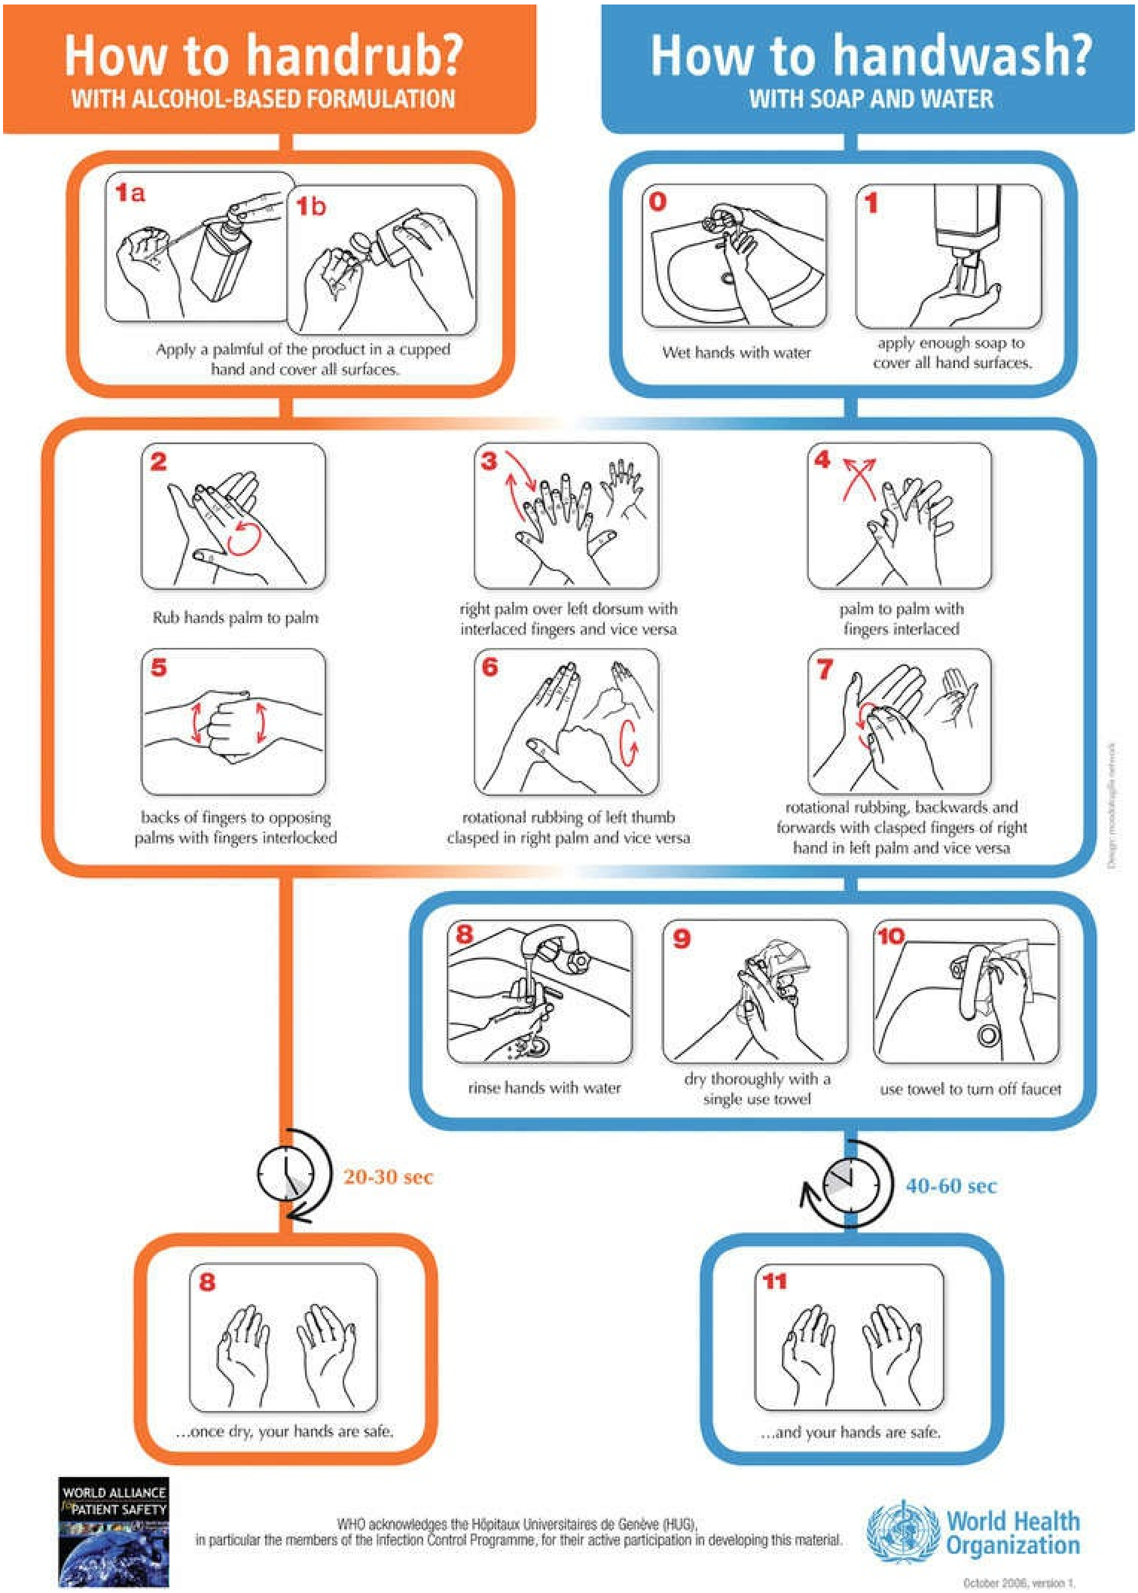

FIG 9.4 Guidelines on hand hygiene with hand rubs or hand washing. (From the World Health Organization (WHO), 2006.)

In the clinic, general cleanliness and proper control of heat, light, and air are important for infection control. Spills should be cleaned up promptly. Work areas and equipment should be kept free from contamination.

To decontaminate is to "remove, inactivate, or destroy blood-borne pathogens on a surface or item to the point where they are no longer capable of transmitting infectious particles and the surface or item is rendered safe for handling, use, or disposal."[15] Items to be sterilized or decontaminated should first be cleaned thoroughly to remove any residual matter. Sterilization is used to destroy all forms of microbial life, including highly resistant bacterial spores. An **autoclave** is used to sterilize items by steam under pressure. Ethylene oxide, dry heat, and immersion in chemical disinfectants are other methods of sterilization.

A variety of disinfectants may be used to clean environmental surfaces and reusable instruments. When liquid disinfectants and cleaning agents are used, gloves should be worn to protect the skin from repeated or prolonged contact. The CDC, local Health Department, or hospital infection control department can provide information about the best product and method to use.

Instruments and equipment used to treat a client should be cleaned or disposed of according to institutional or agency policies and procedures. Contaminated reusable equipment should be placed carefully in a container, labeled, and returned to the appropriate department for sterilization. Contaminated disposable items should be placed carefully in a container, labeled, and discarded.

Contaminated or soiled linen should be disposed of with minimal handling, sorting, and movement. It can be bagged in an appropriate bag and labeled before transport to the laundry, or the bag can be color coded to indicate the type or condition of linen it contains. Other contaminated items, such as toys, magazines, personal hygiene articles, dishes, and eating utensils, should be disposed of or disinfected. They should not be used by others until they have been disinfected.

OT Practice Notes

Therapists should routinely clean and disinfect personal items such as pens, keys, and clipboards because these objects are touched frequently and may become contaminated. If white coats or scrubs are worn, these should be cleaned regularly as well.

Isolation Systems

Isolation systems are designed to protect a person or an object from becoming contaminated or infected by transmissible pathogens. Various isolation procedures are used in different institutions. It is important for all healthcare workers to understand and follow the isolation approach used in their facilities so protection can be ensured. As mentioned, the CDC established Transmission-Based Precautions to be used for patients documented to have or suspected of being infected with highly transmissible or epidemiologically important pathogens: "Transmission-Based Precautions are used when the route(s) of transmission is (are) not completely interrupted using Standard Precautions alone." Three types of Transmission-Based Precautions may be used, singly or in combination, to control infectious transmission: contact precautions, droplet precautions, and airborne precautions. The CDC provides specific recommendations for each infection control measure. In addition, Appendix A of the 2007 guidelines provides a comprehensive list of the types of precautions (eg, standard, contact, airborne, droplet) recommended for selected infections and conditions.[16]

When Transmission-Based Precautions are needed, a client is usually isolated from other clients and the hospital environment because he or she has a transmissible disease. Isolation involves placing the client in a room alone or with one or more clients with the same disease to reduce the possibility of transmitting the disease to others. Specific infection control techniques must be followed by all who enter the client's room. These requirements are based on the type of infectious organism and common routes of transmission (ie, airborne, direct or indirect physical contact, and droplets). Specific instructions are listed on a color-coded card and are placed on or next to the door of the client's room. Strict isolation and respiratory isolation procedures are shown in Fig. 9.5. Protective clothing, including gown, mask, cap, and gloves, may be needed. When leaving the client, the caregiver must dispose of the protective clothing before leaving the room and must dispose of it in an appropriately designated area or container for storage, washing, decontamination, or disposal. Examples of diseases that require Transmission-Based Precautions are tuberculosis, severe acute respiratory syndrome (SARS), *Clostridium difficile* infection, chickenpox, measles, and meningitis.

STRICT ISOLATION

VISITORS: REPORT TO NURSES' STATION BEFORE ENTERING ROOM

1. Masks are indicated for all persons entering the room.
2. Gowns are indicated for all persons entering the room.
3. Gloves are indicated for all persons entering the room.
4. HANDS MUST BE WASHED AFTER TOUCHING THE PATIENT OR POTENTIALLY CONTAMINATED ARTICLES AND BEFORE TAKING CARE OF ANOTHER PATIENT.
5. Articles contaminated with infective material should be discarded or bagged and labeled before being sent for decontamination and reprocessing.

A

RESPIRATORY ISOLATION

VISITORS: REPORT TO NURSES' STATION BEFORE ENTERING ROOM

1. Masks are indicated for those who come close to the patient.
2. Gowns are not indicated.
3. Gloves are not indicated.
4. HANDS MUST BE WASHED AFTER TOUCHING THE PATIENT OR POTENTIALLY CONTAMINATED ARTICLES AND BEFORE TAKING CARE OF ANOTHER PATIENT.
5. Articles contaminated with infective material should be discarded or bagged and labeled before being sent for decontamination and reprocessing.

B

FIG 9.5 A, Strict isolation procedures sign. The card will be color-coded yellow and will be placed on or next to the door of the client's room. B, Respiratory isolation procedures sign. The card will be color-coded blue and will be placed on or next to the door of the client's room.

Occasionally a client's condition (eg, burns, systemic infection) makes him or her more susceptible to infection. This client may be placed in protective isolation. In this approach persons entering the client's room may have to wear protective clothing to prevent the transmission of pathogens to the client. The sequence and method of donning the protective garments are more important than the sequence used to remove them.

Healthcare-associated infections continue to be a significant problem in a variety of healthcare delivery settings. It is critical that OT personnel be given proper education and training in infection control standards to prevent the spread of unnecessary infections.

Incidents and Emergencies

Occupational therapists should be able to respond to a variety of medical emergencies and to recognize when it is better to get assistance from the most qualified individual available, such as a physician, emergency medical technician, or nurse. Securing such assistance should be relatively easy in a hospital but may require an extended period before response if the OT intervention is conducted in a client's home or an outpatient clinic. It is a good idea to keep emergency telephone numbers readily available.

Ethical Considerations

In most cases it is best to call for assistance before initiating emergency care unless delay is life-threatening to the client.

All OTs should be certified in **cardiopulmonary resuscitation (CPR)** and should have received basic first aid training. Training and certification can be obtained through organizations such as the American Heart Association (*http://www.americanheart.org*) and the American Red Cross (*http://www.redcross.org*).

Consistently following safety measures will prevent many accidents. However, the therapist should always be alert to the possibility of an injury and should expect the unexpected to happen. Most institutions have specific policies and procedures to follow. In general, the therapist should do the following when an injury to a client occurs:

1. Ask for help. Do not leave the client alone. Prevent further injury to the client and provide emergency care.

2. When the emergency is over, document the incident according to the institution's policy. Do not discuss the incident with the client or significant others or express information to anyone that might indicate negligence.

3. Notify the supervisor of the incident and file the incident report with the appropriate person within the organization.

Falls

The risk of falling is always present when functional mobility is addressed with clients. The OT can reduce the risk of falling by carefully preparing the environment before initiating intervention. This includes use of a gait belt, as needed, during mobility activities; clearing the environment of potential hazards; and having a wheelchair or chair nearby to pull into position for clients who might be prone to falling. The therapist can prevent injuries from falls by remaining alert and reacting quickly when clients lose their balance. Proper guarding techniques must be practiced. In many instances it is wise to resist the natural impulse to keep the client upright. Instead, the therapist can carefully assist the client to the floor or onto a firm object.

If a client begins to fall forward, the following procedure should be used: Restrain the client by firmly holding the gait belt. Push forward against the pelvis and pull back on the shoulder or anterior chest. Help the client stand erect once it is determined that no injury has occurred. The client may briefly lean against you for support. If the client is falling too far forward to be kept upright, guide the client to reach for the floor slowly. Slow the momentum by gently pulling back on the gait belt and the client's shoulder. Step forward as the client moves toward the floor. Tell the client to bend the elbows when the hands contact the floor to help cushion the fall. The client's head should be turned to one side to avoid injury to the face.

If the client begins to fall backward, the following procedure should be used: Rotate your body so one side is turned toward the client's back and widen your stance. Push forward on the client's pelvis and allow the client to lean against your body. Then, assist the client to stand erect. If the client falls too far backward, to stay upright, continue to rotate your body until it is turned toward the client's back and widen your stance. Instruct the client to briefly lean against your body or to sit on your thigh. You may need to lower the client into a sitting position on the floor using the gait belt and good body mechanics.

Burns

Generally only minor, first-degree burns are likely to accidentally occur in occupational therapy. These can be treated with basic first aid procedures. Skilled personnel should be contacted for immediate care if the burn has any charred or missing skin or shows blistering. The following steps should be taken for first-degree burns in which the skin is only reddened:

1. Rinse or soak the burned area in cold (not iced) water.

2. Cover with a clean or sterile dressing.

3. Do not apply any cream, ointment, or butter to the burn because this will mask the appearance and may lead to infection or a delay in healing.

4. Report the incident so that the injury can be evaluated by a physician.

Bleeding

A laceration may result in minor or serious bleeding. The objectives of first aid treatment are to prevent contamination of the wound and to control bleeding. The following steps should be taken to stop the bleeding.

1. Wash your hands and put on protective gloves. Continue to wear protective gloves while treating the wound.

2. Place a clean towel or a sterile dressing over the wound and apply direct pressure to the wound. If no dressing is available, use your gloved hand.

3. Elevate the wound above the level of the client's heart to reduce blood flow to the area.

4. Encourage the client to remain quiet and to avoid using the extremity.

5. Do not apply a tourniquet unless you have been trained to do so.

Shock

Clients may experience shock as a result of excessive bleeding, sepsis, and respiratory distress; as a reaction to the change from a supine to an upright position; or as a response to excessive heat or anaphylaxis (severe allergic reaction). Shock causes a drop in blood pressure and inefficient cardiac output, resulting in inadequate perfusion of organs and tissues. Signs and symptoms of shock include pale, moist, and cool skin; shallow and irregular breathing; dilated pupils; a weak or rapid pulse; dizziness or nausea; and an altered level of consciousness. Shock should not be confused with fainting, which would result in a slower pulse, paleness, and perspiration. Clients who faint generally will recover promptly if allowed to lie flat. If a client exhibits symptoms of shock, the following actions should be taken:

1. Get medical assistance as soon as possible because shock can be life-threatening.

2. Try to determine the cause of shock and correct it if possible. Monitor the client's blood pressure, breathing, and pulse rate.

3. Place the person in a supine position, with the head slightly lower than the legs. If head and chest injuries are present or if respiration is impaired, it may be necessary to keep the head and chest slightly elevated.

4. Do not add heat, but prevent loss of body heat if necessary by applying a cool compress to the client's forehead and covering the client with a light blanket.

5. Do not allow exertion. Keep the client quiet until emergency medical help arrives.

Seizures

Seizures may be caused by a specific disorder, brain injury, or medication. The OT should be able to recognize a seizure and should take appropriate action to keep the client from getting hurt. A client having a seizure will usually become rigid for a few seconds and then will begin to convulse with an all-over jerking motion. The client may turn blue and may stop breathing for up to 50 to 70 seconds. A client's sphincter control may be lost during or at the conclusion of the seizure, so the client may void urine or feces involuntarily. When a client shows signs of entering a seizure, the following steps should be taken:

1. Place the person in a safe location and position him or her away from anything that might cause injury. Do not attempt to restrain or restrict the convulsions.

2. Loosen clothing around the person's neck to assist in keeping the client's airway open.

3. Do not insert any objects into the person's mouth; this can cause injury.

4. Remove sharp objects (glasses, furniture, and other objects) from around the person to prevent injury.

5. When the convulsions subside, roll the person onto his or her side to maintain an open airway and to prevent the person from aspirating any secretions.

6. After the convulsions cease, have the client rest. He or she may experience confusion for a period of time. It may be helpful to cover the client with a blanket or screen to provide privacy.

7. Get medical help.

Insulin-Related Illnesses

Many clients seen in OT have insulin-related episodes. These episodes can occur as the result of severely inadequate insulin levels (hyperglycemia, or a high blood glucose level) or from excessive insulin (hypoglycemia, or a low blood glucose level). It is very important for the OT to be able to differentiate between the conditions of hypoglycemia (insulin reaction) and hyperglycemia (ketoacidosis), which can lead to diabetic coma (Table 9.2). Both conditions can result in loss of consciousness, but medical intervention for each condition is very different.

TABLE 9.2

Warning Signs and Symptoms of Insulin-Related Illnesses

	Insulin Reaction (Insulin Shock)	Ketoacidosis (Diabetic Coma)
Onset	Sudden	Gradual
Skin	Moist, pale	Dry, flushed
Behavior	Excited, agitated	Drowsy
Breath odor	Normal	Fruity
Breathing	Normal to shallow	Deep, labored
Tongue	Moist	Dry
Vomiting	Absent	Present
Hunger	Present	Absent
Thirst	Absent	Present

An insulin reaction (also called insulin shock) can be caused by too much systemic insulin, the intake of too little food or sugar, or too much physical activity. If the client is conscious, some form of sugar (eg, candy, orange juice) should be provided. If the client is unconscious, glucose may have to be provided intravenously. The client should rest, and all physical activity should be stopped. This condition is not as serious as ketoacidosis, but the client should be given the opportunity to return to a normal state as soon as possible.

Hyperglycemia can develop when a person with diabetes fails to take enough insulin or deviates significantly from a prescribed diet. Ketoacidosis and dehydration occur and can lead to a diabetic coma and eventual death if not treated. This should be considered a medical emergency requiring prompt action, including assistance from qualified personnel. The client should not be given any form of sugar. Usually, an injection of insulin is needed, followed by IV fluids and salt. A nurse or physician should provide care as quickly as possible. Table 9.2 explains how to differentiate the symptoms of hyperglycemia and hypoglycemia.

Respiratory Distress

Dyspnea control postures may be used to reduce breathlessness in clients in respiratory distress. The client must be responsive and must have an unobstructed airway. The high Fowler's position (Fig. 9.6A) may be used for clients in bed. The head of the bed should be in an upright position at a 90-degree angle. If available, a footboard should be used to support the client's feet. The orthopneic position (Fig. 9.6B) may be used for clients who are sitting or standing. In either case the client bends forward slightly at the waist and supports the upper body by leaning the forearms on a table or counter. Pursed-lip breathing (ie, a breathing pattern of inhaling through the nose and slowly exhaling through pursed lips) can help decrease dyspnea and the respiratory rate (see Chapter 44 for additional suggestions).

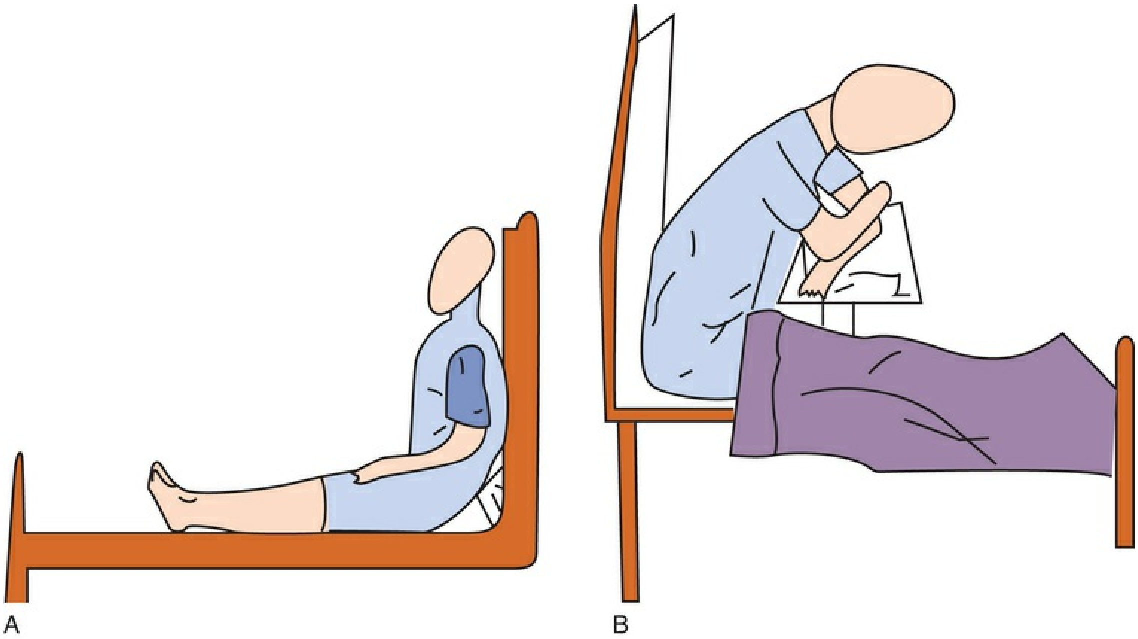

FIG 9.6 A, High Fowler's position. B, Orthopneic position.

Choking and Cardiac Arrest

All healthcare practitioners should be trained to treat clients who are choking or suffering from cardiac arrest. CPR is a series of potentially lifesaving actions that increase an individual's chance of surviving cardiac arrest. CPR certification involves instruction in recognizing a cardiac arrest, activating the emergency response system, performing specific CPR techniques, and using an automatic external defibrillator (AED). In addition, training in recognizing and providing intervention when an individual is choking is provided. In 2010 the American Heart Association introduced new standards for the performance of CPR and emergency cardiovascular care.[3] Previous guidelines comprised three basic steps to CPR: establish the airway; provide mouth-to-mouth resuscitation (breathing); and provide chest compressions—this process became known as the A-B-Cs of emergency treatment. The new guidelines[10] advise initiating chest compressions first, followed by establishing the airway, and then breathing (or C-A-B). Specific certification training courses are offered by both the American Heart Association and the American Red Cross. The following information is presented as a reminder of the basic techniques and is not meant to be substituted for training.

The urgency of choking cannot be overemphasized. Immediate recognition and proper action are essential (Fig. 9.7). When assisting a conscious adult or a child who is older than 1 year, the following steps should be taken:

1. Ask the client, “Are you choking?” If the client can speak or cough effectively, do not interfere with the client's own attempts to expel the object.

2. If the client is unable to speak, cough, or breathe, check the mouth and remove any visible foreign object.

3. If the client is unable to speak or cough, position yourself behind the client. Clasp your hands over the client's abdomen, slightly above the umbilicus but below the diaphragm.

4. Use the closed fist of one hand, covered by your other hand, to give 3 or 4 abrupt thrusts against the person's abdomen by compressing the abdomen in and up forcefully (this technique is also known as the Heimlich maneuver). Continue to apply the thrusts until the obstruction becomes dislodged or is relieved, or the person becomes unconscious. It is no longer recommended that a rescuer perform a finger sweep to remove the object.

5. Seek medical assistance.

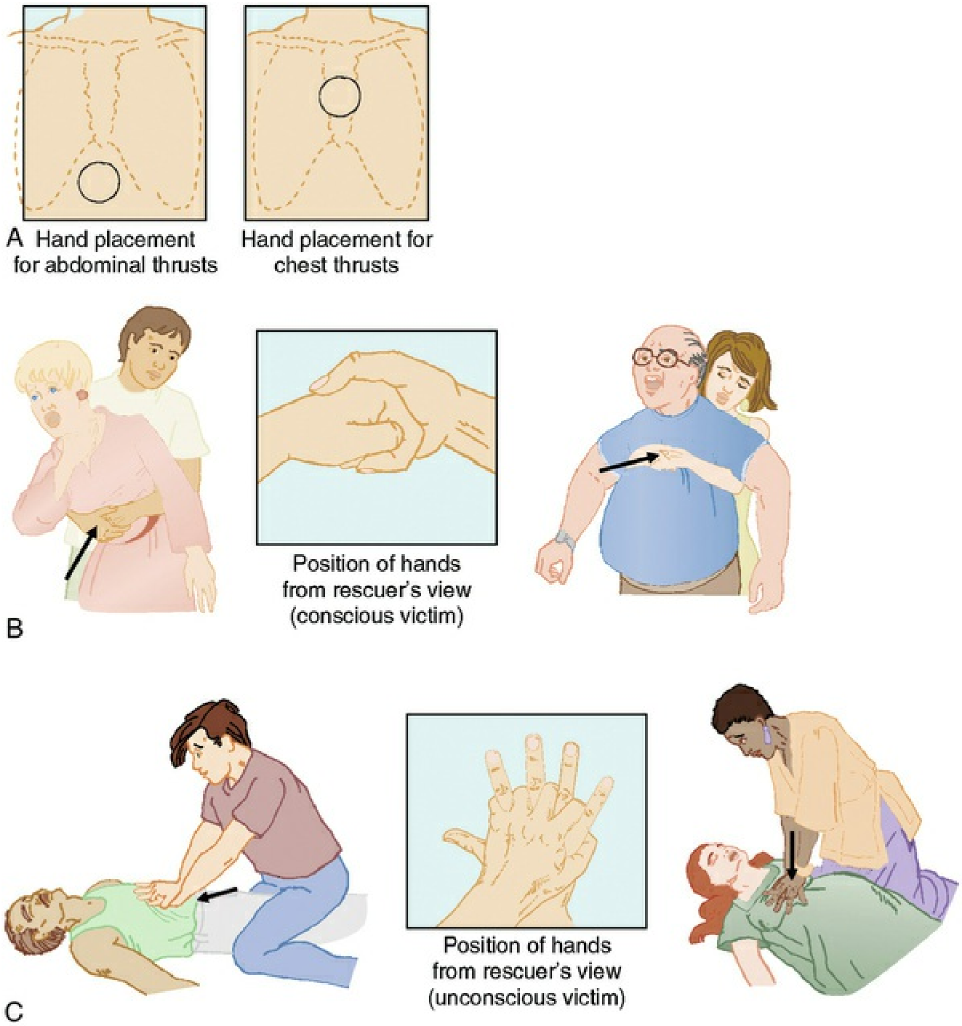

FIG 9.7 Abdominal thrust maneuver (also known as the Heimlich maneuver) used for removal of foreign bodies blocking the upper airway. A, Hand placement. B, Maneuver for conscious victims. C, Maneuver for unconscious victims. (From Black JM, Hawks JH: *Medical-surgical nursing: clinical management for positive outcomes,* ed 8, St Louis, 2009, Saunders.)

When assisting an adult or a child who is older than 1 year who appears to be unconscious, the following steps should be taken:

1. Ensure that it is safe for you to intervene (no hazards or risky environmental conditions).

2. Activate the emergency response system (call for help, or call 911). Get an AED (defibrillator), if available. If two persons are available, one should call for help and get the AED while the other individual initiates CPR.

3. Attempt to awaken or rouse the individual.

4. If the individual is unresponsive, place the person in a supine position on a firm surface. Check for a pulse, limiting the time to do this to no more than 10 seconds.

5. Initiate chest compressions. Kneel next to the client and place the heel of one hand on the inferior portion of the sternum superior to the xiphoid process (approximately in line with the nipples). Put your other hand over your first hand with the fingers interlaced. Position your shoulders directly over the client's sternum, keep your elbows extended, and press down firmly, depressing the sternum at least 2 inches with each compression; avoid excessive depths (greater than 2.4 inches). Relax after each compression, allowing the chest to fully recoil after each compression, but do not remove your hands from the sternum. The relaxation and compression phases should be equal in duration. Compressions should be applied at a rate of 100 to 120 per minute.

6. If you are not trained in CPR, continue to perform only chest compressions until help arrives or the victim awakens (“hands only” CPR).

7. If you are trained in CPR, perform 30 chest compressions, then open the victim's airway using the head-tilt, chin-lift method.

8. Check for respiration by observing the chest or abdomen for movement, listen for sounds of breathing, and feel for breath by placing your cheek close to the person's mouth. If no sign of breath is present, the client is not breathing and you should initiate breathing techniques.

9. Pinch the client's nose closed and maintain the head tilt to open the airway. Place your mouth over the client's mouth and form a seal with your lips. Perform two full breaths. Your breaths should be strong enough to make the victim's chest rise. Some persons prefer to place a clean cloth over the client's lips before initiating mouth-to-mouth respirations. If available, a plastic CPR device can be used to decrease contact between the caregiver's mouth and the client's mouth and any saliva or vomitus.

10. Evaluate for circulation by palpating the carotid artery for a pulse. Sometimes it can be difficult to locate a pulse, so also observe the client for signs of life—breathing, movement, consciousness. If no pulse or signs of consciousness are noted, you must return to performing external chest compressions.

11. If you are performing CPR procedures without assistance, you should repeat 30 chest compressions, followed by 2 breaths. Continue this sequence (30 compressions/2 rescue breaths) until qualified help arrives, the victim shows obvious signs of life (eg, moving or breathing), or you are physically unable to continue. Limit the interruption of chest compressions to less than 10 seconds. In all instances the client will require hospitalization and evaluation by a physician.

12. If you have access to an AED, continue to perform CPR until you can attach the chest pads and turn on the machine. If you are alone and you observed the victim collapse, put the AED on immediately. If you did not observe the collapse, attach the AED after approximately 1 minute of CPR. The AED will analyze the victim's heart for rhythm and will provide a shock if necessary. The AED provides auditory instructions for operation. After placement of the chest pads, it will analyze the victim's heart for rhythm and will direct the rescuer to provide a shock or to continue CPR.

Note: Extreme care must be taken when attempting to open the airway of a person who may have experienced a cervical spine injury. In such cases use the chin lift, but avoid the head tilt. If the technique does not open the airway, the head should be tilted slowly and gently until the airway is open.

As mentioned, these procedures are appropriate to use for adults and for children 1 year of age or older. CPR is contraindicated if clients have clearly expressed their desire for “do not resuscitate” (DNR). This information should be clearly documented in the medical chart. A pamphlet or booklet containing diagrams and instructions for CPR techniques can be obtained from most local offices of the American Heart Association or from a variety of websites.

Summary

All OT personnel have a legal and professional obligation to promote safety for self, the client, visitors, and others. The OT should be prepared to react to emergency situations quickly, decisively, and calmly. The consistent use of safe practices helps reduce accidents for both clients and workers and reduces the length and cost of treatment.

Threaded Case Study

Donna, Part 2

To adequately prepare the OT clinic as a safe environment for clients and staff, clear policies and procedures pertaining to client safety, medical emergencies, infection control, and precautions with special equipment need to be developed and implemented. In the case study presented at the beginning of this chapter, Donna, the director of OT Services, is responsible for developing such policies and procedures. It should be mandatory for all OT personnel to become certified in CPR and first aid. Employee manuals can be produced that orient staff to general safety procedures and infection control standards. Furthermore, in-service education should be developed for newly hired personnel that familiarizes them with the types of specialized medical equipment that OT personnel are likely to encounter in their interventions with clients.

Many resources are available that can assist Donna in establishing these policies and procedures. The Centers for Disease Control and Prevention (*http://www.cdc.gov*), the Occupational Safety and Health Administration (*http://www.OSHA.gov*), and the National Institutes of Health (*http://www.NIH.gov*) are government organizations that provide up-to-date information pertaining to health standards, infection control, medical research, and workplace safety. Information on first aid, choking, and CPR can be obtained from most local offices of the American Heart Association and from the American National Red Cross. In addition, information on emergency procedures may be found on a variety of websites.

Review Questions

1. Why is it important to teach the client and significant others guidelines for handling various emergency situations?
2. Describe at least four behaviors that you can adopt to improve client safety.
3. Why is it important to review a client's chart before initiating an intervention?
4. What types of activities are appropriate when providing an intervention to a client who is ventilator dependent? What precautions must be taken during such activities?
5. Define the following: IV line, A line, NG tube, TPN or hyperalimentation, and catheter.
6. Describe Standard Precautions.
7. Why is it important to follow Standard Precautions with all clients?
8. Demonstrate the proper technique for hand washing.
9. How should you respond to a client emergency?
10. Distinguish between an insulin reaction and ketoacidosis (diabetic coma). What is the appropriate medical intervention for each condition?
11. Describe how you would help a client who is falling forward and one who is falling backward.
12. Which emergency situations might require getting advanced medical assistance, and which situations could a therapist handle alone?

PART III

Occupational Performance and the Performance Areas: Evaluation and Intervention

OUTLINE

10

Activities of Daily Living

Jean S. Koketsu [a]

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Describe activities of daily living (ADLs) and instrumental activities of daily living (IADLs), and explain how ADLs and IADLs relate to the current Occupational Therapy Practice Framework (OTPF-3).
2. Explain why it is important to consider the cultural, personal, temporal, and virtual contexts when performing ADL and IADL assessments and training. Give examples of specific cultural, personal, temporal, and virtual contexts that an individual, a community, or a population may have that can affect ADLs and IADLs.
3. Describe a client-centered approach to evaluation, and explain why it is an important consideration in ADL and IADL training.
4. Explain the general procedures for ADL and IADL assessments.
5. Explain how to record levels of independence and summarize the results of an ADL/IADL evaluation.
6. Explain the purpose of performing a home evaluation and when it may be indicated.
7. Give at least five examples of client factors that may have limitations that can affect performance in occupations and how each can affect an ADL and IADL (eg, if someone has shoulder range of motion limitations, he or she may have difficulty putting on a shirt [ADL] and reaching for object on a shelf when cooking a meal [IADL]).
8. Give examples of how difficulties in performance skills (motor and praxis skills, sensory-perceptual skills, emotional regulation skills, cognitive skills, and communication and social skills) can affect specific ADL and IADL abilities.
9. Discuss considerations for selecting adaptive equipment for performance of ADLs and IADLs. Describe at least five pieces of adaptive equipment that may be used to increase independence and the conditions for which each device may be indicated.
10. Describe, perform, and teach specific ADL techniques for individuals with limited range of motion (ROM) and strength, incoordination, paraplegia, tetraplegia, low vision, and for the exceptionally large client.

KEY TERMS

Activities of daily living (ADLs)
Adaptive equipment and techniques
Client-centered approach

Home evaluation

Instrumental activities of daily living (IADLs)

Threaded Case Study

Anna, Part 1

Anna is a 29-year-old woman who has been diagnosed with a T4 spinal cord injury (SCI) from a car accident. She has complete sensory and motor loss below the level of injury. She is currently in an inpatient rehabilitation program. Prior to her injury, Anna lived in a recently purchased house with two bedrooms and one bathroom with her husband and 2-year-old daughter. In addition to caring for her daughter, Anna spent much of her time performing household chores, such as cooking, laundry, and grocery shopping. Anna also took care of her family's finances and enjoyed leading a Bible study group with her friends. Anna dropped their daughter off at a daycare center while she worked part-time as a bookkeeper at her church. Her husband picked up their daughter after spending a full day at his job as an auto mechanic. The family depended on Anna's part-time income to pay some of the bills. Anna's mother, Martha, has been caring for her granddaughter since Anna's accident. Martha agreed to temporarily live with Anna and her husband and granddaughter after Anna's discharge home until Anna can independently take care of her child.

Anna currently requires minimal assistance with basic transfers, bed mobility, and lower body dressing because of decreased endurance, pain in her back, and decreased trunk control. She requires minimal assistance with verbal cues for proper techniques for weight shifts in her wheelchair and skin checks to ensure skin integrity. Anna reports that she has been overwhelmed with all the new things she has had to learn. She requires moderate assistance with bowel and bladder care and showering/bathing tasks. She is independent with wheelchair mobility on indoor flat surfaces but requires standby assistance to propel in tight areas and corners and while propelling up ramps because of fatigue, decreased trunk control, and reduced upper body strength. She is independent with seated-level activities, such as hygiene and grooming at the sink and light kitchen tasks in the rehabilitation unit's kitchen.

Anna and her husband are concerned about the amount of assistance she may require when Anna is discharged from the rehabilitation program. They want to eventually grow their family and have concerns about sexual functioning, intimacy, and fertility. Their home is also not wheelchair accessible. Although they appreciate Martha and her offer to live with them after Anna's discharge home from the hospital, they hope that Martha does not have to live with them long term.

Anna wants to be independent in taking care of herself, her daughter, her household, and her husband. She wants to drive again, return to her Bible study classes, and resume her part-time job. She is not sure how she can resume the occupations she considers important to fulfilling her roles as a wife, mother, homemaker, worker, and active community member.

Critical Thinking Questions

1. What ADL and IADL tasks will Anna need to master in order to be more independent and to return home safely with her family?

2. What is the role of occupational therapy in helping Anna to return home safely and to eventually reach her goals of independence?

3. With all the occupational performance areas that need to be addressed, how can an occupational therapist prioritize which areas to address?

The American Occupational Therapy Association (AOTA), the U.S. national professional organization for occupational therapy practitioners, presents its current intervention guidelines in the "Occupational Therapy Practice Framework: Domain and Process," third edition (OTPF-3), an official document intended for both internal and external audiences.[6] This chapter describes both the aspects of the domain and the process of occupational therapy (OT) in regard to activities of daily living (ADLs) and instrumental activities of daily living (IADLs). It also focuses on specific intervention strategies for assisting clients to optimize occupational functioning.

According to the OTPF-3, ADLs and IADLs are considered two of eight broad categories of occupation in which clients engage.[6] ADLs and IADLs include, but are not limited to, routine tasks of personal care, functional mobility, communication, home management, and community mobility.[6,24] Evaluation and training in the performance of these important life tasks have long been important aspects of OT programs in virtually every type of health and wellness practice area. Loss of ability to care for personal needs and to manage the environment can result in loss of self-esteem and a deep sense of dependence. Family roles are also disrupted because partners are frequently required to assume the function of caregiver when one loses the ability to perform ADLs or IADLs independently.

In the broadest sense, service delivery in the areas of occupation begins with the occupational therapist (OT) receiving a referral for service, performing an evaluation, forming and instituting an intervention plan, and assessing the outcome of the process. The OT practitioner and client collaborate to identify which areas of occupation, such as ADLs and IADLs, the client wants or needs to participate in to optimize health and wellness. The need to learn new methods, use assistive devices to perform daily tasks, or modify the environment may be temporary or permanent, depending on the particular dysfunction, the environment, the prognosis for recovery, and a multitude of other factors.

Definitions of Activities of Daily Living (ADLs) and Instrumental Activities of Daily Living (IADLs)

Daily living activities can be separated into two areas: **activities of daily living (ADLs)** (also called personal activities of daily living [PADLs] and basic activities of daily living [BADLs]) and **instrumental activities of daily living (IADLs)**. ADLs require basic skills and focus on activities involved in taking care of one's own body. ADLs include self-care tasks such as bathing and showering, toileting and toilet hygiene, dressing, eating (or swallowing), feeding, functional mobility (eg, transfers and bed mobility), sexual activity, and care of personal devices such as hearing aids, orthotics, glasses, and **adaptive equipment**.[6]

IADLs require a more advanced level of skills in all performance areas. IADLs generally require use of executive functions,[41] social skills, and more complex environmental interactions than ADLs. IADL tasks include care of others and of pets, childrearing, communication management, community mobility (eg, driving and use of public transportation), and financial management; Anna, the client in our case study, has reported most of these as areas to be addressed. Other IADLs include the category of health management and maintenance, such as Anna performing regular weight shifts to maintain good skin integrity while up in the wheelchair and remembering her therapy appointments. Home establishment and management, a category that includes housecleaning and meal preparation and cleanup, are two other IADLs that Anna was responsible for in her home. Religious observance occupations (eg, Anna's ability to lead and participate in her Bible study), safety and emergency maintenance (eg, Anna's ability to appropriately notify authorities in case of emergencies), and shopping are other important IADLs (Box 10.1).

Box 10.1

OTPF-3 Categories for ADLs and IADLs

Activities of Daily Living (ADLs)

- Bathing and showering
- Toileting and toilet hygiene
- Dressing
- Swallowing/eating
- Feeding
- Functional mobility
- Personal device care
- Personal hygiene and grooming
- Sexual activity

Instrumental Activities of Daily Living (IADLs)

- Care of others (including choosing and selecting caregivers)
- Care of pets
- Childrearing
- Communication management
- Driving and community mobility

- Financial management
- Health management and maintenance
- Home establishment and management
- Meal preparation and cleanup
- Religious and spiritual activities and expression
- Safety and emergency maintenance
- Shopping

For a more detailed list, please refer to the OTPF-3.

Considerations in ADL and IADL Occupational Analysis and Training

The overall goal of any ADL and IADL training program is for the client and family to learn to adapt to life changes or situations and to participate as fully as possible in occupations that are meaningful. The following sections present important areas the OT must consider when analyzing ADLs and IADLs. Each area is defined in relation to an ADL or IADL evaluation and intervention plan.

Definition of "Client"

According to the OTPF-3, the term *clients* refers to persons, groups, and populations who receive OT services.[6] "Persons" include the actual person receiving services (eg, Anna) and those involved in the client's care (eg, Anna's husband and immediate family). "Groups" refers to collectives of individuals (eg, Anna's church community) who may receive general consultation or referral by an OT on accessibility. "Populations" refers to larger collectives of people who live in similar locales, such as cities or states, or who share similar concerns; for example, refugees, survivors of particular natural or manmade disasters, or people with paraplegia who live in the United States, such as Anna. Most of the intervention strategies in this chapter relate to providing such intervention to persons or individuals as clients (eg, Anna), although it is acknowledged that OTs also provide services to groups and populations in the areas of ADLs and IADLs.

Client Factors

Client factors are specific abilities, characteristics, or beliefs that reside within the client to influence performance in occupations.[6] One general category of client factors is values, beliefs, and spirituality. Does Anna's belief in her potential to improve or her ideas about her purpose in life influence her performance? OT practitioners' comfort level with the topic and self-reflection in the area may help them be more client centered and may enhance their therapeutic use of self with a client such as Anna.[92] Other general categories include body functions and structures (Box 10.2). Does Anna have the strength, range of motion (ROM), coordination, sensation, balance, and cognitive functions to participate in occupations? How is Anna coping emotionally?

Box 10.2

Client Factors

Examples of Values, Beliefs, and Spirituality

Values: Honesty, fairness, equality, and commitment

Beliefs (thoughts held as true): "Practice makes perfect"; trials are punishment for previous wrongs

Spirituality: Purpose and meaning of life

Examples of Body Functions

- *Specific mental functions (affective, cognitive, perceptual):* Emotional regulation, anxiety, executive functions (eg, organization and time management), attention, memory, and discrimination of sensation
- *Global mental functions:* Alertness, orientation to person, temperament/personality, energy, and quality of sleep
- *Sensory functions:* Vision, hearing, vestibular (perception of body position and movement), taste, smell, proprioception, touch, pain, temperature, pressure

- *Neuromusculoskeletal and movement-related functions:* Joint mobility and stability, muscle strength/tone/endurance, reflexes, involuntary/voluntary control (eg, coordination, fine motor control, and eye movement), gait patterns
- *Cardiovascular, hematological, immunological, and respiratory functions:* Blood pressure, heart rate, respiratory rate/rhythm/depth, physical endurance, stamina, wound healing capacity, bruising tendencies[a]
- *Voice and speech functions:* Fluency of speech, rate of speech, volume-audibility[a]
- *Digestive, metabolic, and endocrine functions:* Effect on bowel movements, continence, rate of healing, hormonal imbalance[a]
- *Genitourinary and reproductive functions:* Continence, ability to have intercourse or children[a]
- *Skin and related structures functions:* Wound healing, protection of the skin, nail care, and awareness of abnormalities[a]

Body Structures[a]

- Includes structures of the nervous system, eyes, ears, voice/speech/swallow structures, cardiovascular, immunological, endocrine, genitourinary, reproductive, movement, skin and related structures

[a]OT practitioners must be knowledgeable about these functions and structures as they relate to occupations, which include ADLs and IADLs, the focus of this chapter.

For a more detailed list, please refer to the OTPF-3.

Client factors can be assessed to determine the potential for remediation and restoration or the possible need for adaptive equipment or other modifications. In Anna's case, it would be important to know whether the spinal cord injury is complete and whether she has potential for muscle return to determine an appropriate approach to treatment. Cardiovascular system functioning is another area of pertinence. Is Anna's blood pressure stable enough for her to perform ADLs, or does she have orthostatic hypotension? Anna's cognitive functions (eg, memory, attention, and problem solving) are also important to assess in relation to ADLs and IADLs. Performance of ADLs and IADLs are occupations in which clients are directly confronted with what they can and cannot do as they had done previously; therefore, it is important to be alert to emotional functioning. The OT questions, “Is Anna requiring cues to perform her weight shifts and skin checks because she has a memory deficit? Or is she having difficulty learning new techniques and strategies because of issues surrounding coping with the disability?” Specific assessments to identify and measure client factors contribute information that influences ADL and IADL performance.

Sleep and Rest

Adequate sleep and rest are essential to optimal functioning in occupations for all people but particularly for clients in the hospital setting or those who are medically or otherwise compromised (see Chapter 13). Individuals who are hospitalized are particularly at risk of poor sleep, which can affect how a client (eg, Anna) may function while in an inpatient rehabilitation unit. As cited in Young et al.,[100] research has shown that approximately 50% of individuals admitted to general medical units complain of sleep disruption.[35,57] Young et al.[100] found that 50% to 70% of people with chronic pain complained of poor sleep, which suggested poorer pain tolerance. A prospective study on sleep-related breathing disorder (SRBD) and rehabilitation outcomes of stroke patients showed poorer functional recovery rates during a hospital rehabilitation stay.[26] Research has shown that electronic alerting sounds, staff conversations, and voice paging can be particularly disruptive to sleep while a client is in the hospital.[19] Researchers posit that sleep disturbance may be a modifiable predictor of rehabilitation outcomes and suggest that improving sleep/wake patterns during rehabilitation may result in better functional recovery among older adults.[1] Education in good sleep hygiene, optimal sleep/wake patterns, and advocacy for optimal sleep environments in hospital settings can go far to help clients such as Anna, who are treated by OTs in that setting. An OT working with Anna can expect better outcomes from interventions for ADLs and IADLs if she gets adequate sleep and rest.

Performance Skills

The OTPF-3 describes performance skills as "goal directed actions that are observable as small units of engagement in daily life occupations."[6] These skills include motor-praxis, sensory-perceptual, emotional regulation, cognitive, communication, and social skills. Whereas client factors reside within a person, performance skills are observable and demonstrable. Examples of a motor-praxis skill for IADLs may be Anna's ability to reach and bend down to retrieve a pot from a low cupboard or to maintain balance while performing the ADL of transferring to a low, soft surface. A client with difficulty in sensory-perceptual skills may have difficulty with the ADL of dressing to properly orient his T-shirt. A client who has difficulty with the cognitive skill of sequencing the steps of a task may have difficulty taking a shower. Should he turn on the water first or transfer into the shower first? Should he start drying himself off first or rinse the soap off first?

Performance Patterns

Habits, routines, roles, and rituals are all performance patterns according to the OTPF-3.[6] All can be helpful or detrimental to occupational performance. The OTPF-3 describes habits as "specific, automatic behaviors that can be useful, dominating, or impoverished" (OTPF-3, p. S8).[6] An example of an ADL habit may be automatically placing a napkin on one's lap before starting to eat or placing the right leg into pant legs first, then the left leg.

Routines are "established sequences of occupations or activities that provide a structure for daily life" (OTPF-3, p. S8).[6] An example of a routine ADL may be Anna's routine of waking up at the same time every day and completing the sequence of toileting, showering, dressing, hygiene and grooming, and eating breakfast on a regular basis. Her ADL routine may have to be drastically altered for her to accommodate additional ADL tasks that she previously never had to perform, such as skin checks and weight shifts to accommodate her diagnosis of C6 quadriplegia/tetraplegia and the resulting high risk for pressure ulcers.[37] Anna's IADL routine may have been to help her daughter get ready for the day by completing such activities as changing her diaper, getting her dressed and cleaned, making her breakfast, packing her lunch, and driving her to daycare.

Roles are "expected by society, shaped by culture and context; they may be further conceptualized and defined by a client" (OTPF-3, p. S8).[6] Examples of roles might include the husband of a wife with severe rheumatoid arthritis or a college student who lives independently in an apartment with a roommate. Important roles for Anna are those of wife, mother, daughter, worker, and Bible study leader.

Rituals are "symbolic actions with spiritual, cultural, or social meaning."[6] The rituals may reinforce values and beliefs.[6] Examples of rituals that are in the realm of ADLs and IADLs include praying or saying grace before every meal or celebrating particular holidays with foods served only on that date that have special cultural meanings.

Understanding performance patterns, including habits, routines, roles, and rituals, allows the OT practitioner to identify performance deficits, determine priorities in goal setting, and help the client reestablish continuity in daily living. For example, with her new functional status, Anna may not be able to perform all the previous morning IADL routines with her daughter. She may have to establish new routines with her daughter and learn to perform those activities differently. Or others, at least in the early stages, may have to assume responsibility for those tasks. Anna may need to redefine her own expectations to perform activities that she currently sees as her role in the family, an important undertaking for an OT to help facilitate.

Environment and Context

The OTPF-3 explains that occupations occur in social and physical environments within a context and that the terms *environment* and *context* may be used interchangeably in the literature (OTPF-3, p. S8).[6] A physical environment includes the natural and the built environment and the objects in them. A few of the external environments for Anna are her home and its contents, her place of work, and her church. The social environment includes the client's relationships with persons, groups, and populations. Anna's social environment includes her husband, daughter, parents, coworkers, and friends. Given Anna's circumstances, questions abound, such as who will be her primary caregiver when she goes home, her mother or her husband? How long will Anna's mother live with her family? How will Anna return to work and community activities? Can Anna's family home be modified? Will Anna be alone at home at times? Will she continue to maintain her current social network of friends, or will she also need to develop others? The answers to the questions about the physical and social environments strongly influence the treatment priorities.

Cultural, Personal, Temporal, and Virtual Contexts

Although the terms *context* and *environment* have been used interchangeably in the literature they are defined separately in the OTPF-3, which considers them to be interrelated (OTPF-3, p. S9).[6] Context can refer to situations or conditions within and around the client. The OTPF-3 describes context as cultural, personal, temporal, and virtual.

A cultural context includes "customs, beliefs, activity patterns, behavioral standards, and expectations accepted by the society" (p. 59) in which one is a member.[6] Cultures can differ vastly in terms of ADLs and IADLs. For example, one culture may view bathing as a private event, whereas another may consider it a communal event.

Cultural context is also important to consider in understanding differences in how independence is defined and valued. The AOTA position paper on the construct of independence supports the view that independence is "defined by the individual's culture, values, support systems, and ability to direct his or her life."[44] A thorough evaluation allows the OT practitioner to understand what activities are critical to each client; this aids the OT in reestablishing the client's sense of directing his or her own life. An example of differing cultural values frequently occurs when an OT raised in a more Westernized culture considers it important to foster independence in ADLs and IADLs, but a client from a different cultural view may not see independence in ADL tasks as highly valued. The OT practitioner may unfairly label the client as unmotivated. For the individual whose culture does not value ADL or IADL independence, the OT may focus primarily on teaching the client and family to adapt. The focus would be on family training and identifying the activities of highest value to the client and family.

Personal context includes a person's demographic features, such as age, gender, and educational level, which also need to be considered in ADLs and IADLs. The ADL and IADL tasks and routines may differ based on any one of many demographic factors. For example, a young adult woman may consider it important to regain the ability to shave her legs, whereas an elderly woman may not. *Temporal context* includes contexts that refer to time, such as time of year, time of day, or stages of life. An example of how temporal context can be important in ADLs is determining when certain tasks, such as dressing and eating a meal, occur during the day. *Virtual context* refers to interactions in "simulated, real-time, or near-time situations absent of physical contact" (OTPF-3, p. S9).[6] An example of virtual context for Anna is her ability to use technology, such as an alarm on her smart phone, to cue her to do her weight shifts to protect her skin or to perform other occupations, such as staying connected with friends. Others who have no use of their hands may use voice-activated features on devices to cue them to carry out daily routines.

A multitude of software applications ("apps") are now available and downloadable on mobile devices that can help people fulfill a particular purpose, such as keeping track of exercise regimens. The AOTA has a frequently updated list of apps that OTs may find useful in their practice or that can be used by clients (eg, Apps for Rehabilitation, Disability, Participation).[9] The pervasive use of technology requires OTs to be aware of the significance of virtual context for clients.

Finances

Financial resources available for potential expenses, such as assistant care, special equipment, and home modifications, are another important consideration for ADL and IADL performance. For example, consider a client who is a new full-time wheelchair user and who can no longer stand to take showers, thus requiring significant assistance from a caregiver to perform the task. If the client has unlimited financial resources; owns his or her home; has an able-bodied, committed caregiver; wants to take showers daily; and is eager to fully remodel the home for accessibility, an OT experienced in home modifications may recommend a fully remodeled bathroom by a licensed contractor. Anna has fewer financial resources, but she has reliable caregivers, and she and her husband own their home. She also wants to shower regularly. In Anna's case, an OT may make recommendations for less costly modifications, such as removing the sliding glass door from the bathtub/shower and replacing it with a shower curtain, and obtaining a bath bench and other equipment.

Occupational Justice

The term *occupational justice* was coined by Townsend in 2003 (OTPF-2, p. 630).[3] According to the OTPF-3, the term describes the OT profession's concerns with the ability of all people, “regardless of age, ability, gender, social class or other differences,”[62] to be given the opportunity to engage in occupations, including the ADLs and IADLs that are important to them. Many times occupational therapists are the first to recognize the disparity in abilities to meet occupational needs because of social, economic, and other factors. Occupational therapists can assist in supporting social policies, actions, and laws that allow all people to engage in occupations that are important to them.[6]

An example of applying this principle of occupational justice to the most basic of ADLs involves Anna's roommate in the inpatient rehabilitation unit, who does not have the resources to bring in clothes to practice dressing skills. The only clothes Anna's roommate had were destroyed in the accident that brought her into the hospital. Anna's roommate has only her hospital-issued gown and pants to practice dressing skills. On a small scale the OT can help equalize this disparity by working with social services to allow Anna's roommate access to clothes she can use so as to increase her independence in this important ADL. A common situation for an OT is a client who needs a piece of adaptive equipment, such as a transfer bath bench, that is neither covered by insurance nor within the client's ability to purchase. Creative, compassionate, and resourceful OTs can help bridge this disparity and thus help all clients participate in ADLs and IADLs that are important to them.

Evaluation of ADLs and IADLs

According to the OTPF-3, occupational therapy's overarching goal for both the domain and the process is "achieving health, well-being, and participation in life through engagement in occupation."[6] A comprehensive evaluation of occupational performance involves collaborating with the client to determine what he or she wants and needs to do to support health and participation.[6] According to the OTPF-3, occupations include ADLs, IADLs, rest and sleep, education, work, play, leisure, and social participation. A comprehensive evaluation includes a thorough occupational profile and an analysis of occupational performance, including assessing client factors, performance skills, performance patterns, the physical and social environment, and the client's contextual framework.[6]

As outlined by the OTPF-3, the process of delivering OT services to a client occurs by means of evaluation, intervention, and targeted outcomes. The process may seem linear but is actually dynamic, allowing the OT practitioner to continually assess the progress toward reaching goals.[6]

In a **client-centered approach**, the therapist collaborates with the client or the family/caregivers, centering the OT process on the client's priorities and fostering an active participation in moving toward the outcome. Evaluation consists of initially creating an occupational profile and analyzing occupational performance. An occupational profile describes the client's occupational history, patterns of daily living, interests, values, and needs.[6]

General Procedure

The focus of the OT evaluation is to discover what occupations are important for the client, to determine what a client can do, and to identify barriers, problems, and supports that affect the client's participation in those occupations.[6] The type of client information and data collected differs, based on the client's needs, the practice setting, and the frame of reference or practice models of the OT.[6] This textbook focuses on OTs who treat adults with physical dysfunction; therefore, the general procedure described highlight areas that may be targeted in assessing that group.

The initial interview may serve as a screening device to help determine the need for further assessment or treatment. The therapist makes a determination of further need for assessment and OT intervention based on knowledge of the client, the dysfunction, and previous assessments. Not all clients who receive an OT referral will need intervention. However, the interview alone can lead to inaccurate assumptions about actual performance. Clients may overestimate or underestimate their abilities or may not understand the timelines for which they are being asked. Instead of just an interview, observation of actual performance of ADLs is invaluable in assessing the client's status.

Clinical assessment of relevant client factors, such as ROM, strength, sensation, and cognition, may occur prior to the actual observations of ADLs or IADLs. In any physical disabilities settings, particularly in the hospital setting, or after any new surgery or procedure, it is essential that OTs educate themselves about any medical precautions or contraindications by reading the medical chart or consulting with the medical staff. For example, the physician may still have bed-rest orders in place; a neck brace may be required before any out-of-bed activities; an extremity may have non-weight-bearing precautions; active range of motion to a joint may not be allowed; or a person may not be allowed to shower.

When the OT first met Anna shortly after her admission, she may have been seen in the intensive care unit (ICU), or she may have been on bed rest and awaiting surgery or some type of stabilization of her spine. The OT at that point may have interviewed Anna, gotten some background and her occupational history, and assessed her upper body ROM and also sensation. The OT would have gleaned information about Anna's cognition and emotional status based on those brief assessments: Is she alert, oriented (person, place, time)? Can she follow directions? Can she recall what she had for breakfast that morning? Does she initiate asking for help?

Ideally, the OT assesses the performance of activities in the environment and context in which they usually take place.[10] For example, a dressing assessment could be arranged early in the morning in the treatment facility, when the client is dressed by nursing personnel, or in the client's home. A self-feeding assessment should occur at regular meal hours. If this timing is not possible, the assessment may be conducted during regular treatment sessions in the OT clinic under simulated conditions. Requiring the client to perform routine self-maintenance tasks at irregular times in an artificial environment may contribute to a lack of carryover, especially for clients who have difficulty generalizing learning, or it may cause confusion in clients with cognitive impairment.

The therapist should initially select relatively simple and safe tasks from the ADL and IADL checklist/assessment form and then progress to more difficult and complex items. For example, with Anna, transfer training would likely start with transfers from her wheelchair to her bed and then progress to commode transfers, which are more difficult. Tasks that would be unsafe or that obviously cannot be performed should be omitted and the appropriate notation made on the assessment form.

During the performance analysis, the therapist should observe the methods the client uses or attempts to use to accomplish the task and try to determine the causes of performance problems. Common causes include weakness, spasticity, involuntary motion, perceptual deficits, cognitive deficits, and low endurance. If problems and their causes can be identified, the therapist has a good foundation for establishing training objectives, priorities, methods, and the need for assistive devices.

Other important aspects of this analysis that should not be overlooked are the client's need for privacy and dignity in the performance of personal ADLs and the OT's questions about them. The client's feelings and cultural attitudes about having his or her body viewed, discussed, and touched should be respected. With safety in mind, privacy should be maintained for performance of basic ADLs such as toileting, grooming, bathing, and dressing tasks. For example, even if the OT needs to be an arm's length away (or closer) for safety while assessing a private ADL, dignity and a semblance of “privacy” could be provided by the therapist turning his or her gaze away, by closing the curtains, by making sure nobody else can see or hear the discussion, or by placing a small towel in a strategic location. Attempts by the therapist to honor a client's privacy as best able are usually highly appreciated and can go far to build trust in the development of the therapeutic relationship. Even if the therapeutic relationship between the primary occupational therapist and client may be good, situations may arise in which it may be necessary to change therapists when more private ADLs are practiced. For example, Anna may be fine with working with a male OT during cooking tasks but may prefer a female OT when performing showering and dressing tasks or when questions arise about sexual function or fertility. As the therapist interacts with the client during the performance of daily living tasks, it may be possible to elicit the client's attitudes and feelings about the particular tasks, priorities in training, dependence and independence, and cultural, family, and personal values and customs regarding performance of ADLs.

Performance of ADLs and IADLs

An occupational performance analysis of ADLs and IADLs may include using a checklist as a guide for questioning and selecting specific activities to perform, as identified during the interview for the occupational profile. For example, in Anna's case the OT may select lower extremity dressing and basic transfers as two key activities to have Anna perform. The OT can then determine strategies to promote independence and provide caregiver instruction regarding how to provide Anna with the appropriate level of assistance.

Many types of ADL and IADL checklists and standardized tests are available. They cover similar categories and performance tasks. The use of a standardized test ensures a more objective assessment and provides a standard means of measurement. A standardized assessment tool can be used at a later time for reevaluation, and some assessments allow for comparison to a norm group. Both Asher[12] and Letts et al.[51] have developed resources on assessments that can be used for selecting appropriate tools for evaluation. The OT should review the literature periodically to learn about new assessments developed by occupational therapists and about those that have been developed as interdisciplinary assessments. One example is the internationally recognized Assessment of Motor and Process Skills (AMPS), an OT-focused assessment of the quality of a person's ADL performance.[29-32,58] Another interdisciplinary assessment is the Functional Independence Measure (FIM).[29,84]

Recording the Results of the ADL Assessment

During the interview and performance analysis, the therapist makes appropriate notations on the checklists. If a standardized assessment is used, the standard terminology identified for that assessment is used to describe or measure performance. Nonstandardized tests may include separate checklists for self-care, home management, mobility, and home environment assessments. When describing levels of independence, OTs often use terms such as *maximum, moderate,* and *minimal assistance.* These quantitative terms have little meaning to healthcare professionals unless they are clearly defined. It also should be specified whether the level of independence refers to a single activity, a category of activities (eg, dressing), or all ADLs. The following general categories and their definitions are suggested.

1. **Independent.** Client can independently perform the activity without cueing, supervision, or assistance, with or without assistive devices, at normal or near normal speeds. Task is completed safely. If the client requires assistive devices or performs the activity at a slower than customary speed, the term *modified independence* may be used.

2. **Supervised.** Client requires general supervision (not hands on) and may require a verbal cue for safety. The OT feels comfortable being greater than an arm's length away at all times.

3. **Standby assistance (SBA)/contact guard assistance (CGA).** Client requires caregiver or someone to provide hands-on guarding to perform a task safely. *Note:* OTs may tend to use the term standby assistance, whereas other disciplines may use contact guard assistance.

4. **Minimal assistance.** Client requires 25% physical or verbal assistance of one person to complete a task safely. (Client performs 75% or more of the task.)

5. **Moderate assistance.** Client requires 50% physical or verbal assistance of one person to complete a task safely. (Client performs 50% to 74% of the task.)

6. **Maximal assistance.** Client requires physical or verbal assistance for 51% to 75% of an activity by one person. (Client performs 25% to 49% of the task.) The helper is doing more than half the work or task, while client is performing less than half.

7. **Dependent.** Client requires more than 75% physical or verbal assistance. Client does less than 25% of the task. For example, she or he can perform only one or two steps of the activity or very few steps of the activity.

These definitions are broad and general, and they can be modified to suit the approach of the particular treatment setting.

As stated previously, the AOTA published a position paper on a definition of *independence* that differs from the relatively narrow definition noted earlier. Hinojosa stated, "Independence is a self-directed state of being characterized by an individual's ability to participate in necessary and preferred occupations in a satisfying manner, *irrespective of the amount or kind of external assistance desired or required.*"[44] This means that an individual's independence is not related to whether an individual performs the activity or not or in a modified fashion or with assistance. Information from the ADL assessment is summarized succinctly for inclusion in the client's permanent record so that other professionals involved in the care of the client can refer to it. Fig. 10.1 presents two forms related to the sample case study for Mrs. Hayes, a 79-year-old woman who had had a cerebrovascular accident (CVA). Two evaluation forms are provided to illustrate Mrs. Hayes's progress: a detailed ADL assessment form (Fig. 10.1A), and an abbreviated ADL form (Fig. 10.1B). The detailed form with Mrs. Hayes's information incorporated into it will help the novice OT practitioner appreciate the details of many ADLs and IADLs that may be taken for granted. An abbreviated form is more likely to be used in actual practice.

OCCUPATIONAL THERAPY DEPARTMENT
Activities of Daily Living Evaluation/Progress Form

Name: Mrs. Hayes Age: 72 Onset Date: 2/3 Today's Date: 4/3

Medical Diagnosis: Lt. CVA Treatment Diagnosis: dysphagia, mild right hemiparesis; ↓'d independence ADL/IADL

Past Medical History: Unremarkable per pt. report and chart

Precautions: Soft foods, thick liquids

Mode of Ambulation: Mod A 20' with FWW, primarily uses w/c Hand Dominance: Right

Social / Home environment: Married 45 years, was primary caregiver to husband, lives in one-story house which they own; four adult children live out of area; has 24 hour caregivers to assist in home since CVA

Occupational Profile/Previous Level of Function: Prior to the CVA, pt. was I with ADL, IADL, volunteering at thrift store, going for walks with friends, paying bills, driving and caring for husband who has ↓'d vision and diabetes but who is otherwise ambulatory and cognitively intact. Pt. was a homemaker while she raised her four children and highly values her independence, community involvement and volunteering. Pt. enjoyed spending time with friends, potted gardening and entertaining her family including many grandchildren when they visit from out of town. Her goals are to be as independent as possible in her ADL/IADL, to be able to help her husband and to be able to enjoy previous leisure activities.

Suggestions for home modification: ______________________

FIG 10.2 Home management checklist. (Courtesy Lorraine Pedretti, MS, OTR.)

When reviewing the forms just discussed, the reader should keep in mind that the assessment and progress summaries relate only to the ADL and IADL portions of the intervention program.

It must be noted that computerized documentation has become the standard for medical records.[50] The term *electronic health record* (EHR) is widely used in the United States. The EHR is a digitized/electronic version of a client's medical chart and is kept by the provider.[21] OT documentation is included in the EHR.

Instrumental Activities of Daily Living

Home Management Assessment

Home management tasks are assessed similarly to self-care tasks. First, the client should be interviewed to elicit a description of the home and of previous and current home management responsibilities. Tasks the client needs to perform when returning home, in addition to those that he or she would like to perform, should be determined during the interview. If the client has communication or cognitive deficits, reliable friends or family members may be enlisted to obtain relevant information. The client may also be questioned about his or her ability to perform relevant tasks on the activities list. The assessment is more meaningful and accurate if the interview is followed by a performance assessment in the ADL kitchen or apartment of the treatment facility or, if possible, in the client's home. An example of a standardized assessment to evaluate the executive skills required to perform IADLs is the Executive Function Performance Test (EFPT).[16,41] Examples of specific IADL tasks to evaluate for home management can be found in the home management checklist (see Fig. 10.2).

The therapist should select tasks and exercise safety precautions consistent with the client's capabilities and limitations. The initial tasks should be simple one- or two-step procedures that are not hazardous, such as wiping a dish, sponging a tabletop, and turning the water on and off. As the assessment progresses, tasks graded in complexity and involving safety precautions should be performed, such as making a sandwich and a cup of coffee and vacuuming the carpet. For example, with Anna, initial tasks may include making a sandwich and using the microwave because using a manual wheelchair in her own home is new for her and requires working from a seated versus a standing position. As Anna performs these simple tasks using her wheelchair, the OT will be able to observe and make suggestions about modification to her kitchen, reorganization, safety techniques, or methods to transport items and simplify tasks.

Home management skills apply to women, men, and sometimes adolescents and children. Individuals may live independently or share home management responsibilities with others. In some homes, it is necessary for a role reversal to occur after the onset of a physical disability. In Anna's case, she has stated she would like to participate in previous home management activities and eventually return to work. Anna's occupational therapist will collaborate with her on home tasks to be completed by her so that interventions can be prioritized. Until Anna can perform the tasks more independently, Anna's mother or husband may be available to perform some of these tasks with direction from Anna.

If a client will be home alone, several basic ADL and IADL skills are needed for safety and independence. Lysack et al.[54] studied 122 African American women from urban areas who previously had lived alone who had a primary rehabilitation condition, such as a CVA or hip replacement. The researchers looked at FIM scores 3 and 6 months after discharge from a hospital. In telephone interviews they found that independence in five ADLs (eating, grooming, toileting, dressing, and bathing) was significantly related to live-alone status. In the same study, 9 of 10 IADLs were significantly related to live-alone status at 6 months after discharge, and four items (phone use, taking medications, managing finances, and food preparation) were highly significant.

The data suggest that investment in improved functional outcome is worthwhile, and higher functional performance is related to live-alone status. Findings such as these underscore the importance of OT intervention as it is in the domain of practice to focus on occupations and areas such as ADLs and IADLs.[6] The occupational therapist can assess the potential for remaining at home alone through the activities of the home management assessment. An evaluation such as the EFPT can be used to assist in determining whether a person is safe to remain at home or to help determine how much assistance is required for some IADL tasks.[16,41] A child with a permanent disability also needs to be considered for assessment and training for IADL skills because he or she will develop and mature, and have a growing need for independence.

Case Study

Mrs. Hayes

Mrs. Hayes is a 79-year-old woman who incurred a cerebral thrombosis, which resulted in a left cerebrovascular accident 2 months ago. She lives in a modest home with her husband of 45 years. Mrs. Hayes was active before the CVA, volunteering 10 hours a week at a local charity thrift store with her friends and caring for her husband, who has diabetes and poor vision. Mr. Hayes needs help with his medications and with cooking, but he is ambulatory, cognitively intact, and independent with ADLs. Mrs. Hayes was independent with all of the indoor home management activities and paid the bills for herself and her husband. She and her husband have a gardener, but Mrs. Hayes enjoyed gardening with potted plants.

After the CVA, Mrs. Hayes spent 3 weeks in the acute inpatient rehabilitation unit. While she was in the rehabilitation facility, the OT performed a home evaluation (see the following section, Home Assessment). Following through with the OT's recommendations, Mrs. Hayes's family made simple home modifications that would increase her safety and independence when she came home.

The CVA had resulted in an ataxic gait, mild dysarthria (slurred speech), dysphagia (swallowing deficit), and mild right hemiparesis (weakness). Mrs. Hayes was referred to outpatient OT for evaluation and training in ADLs and IADLs and for treatment of dysphagia.

The initial evaluation involved an interview with the client and her husband to create an occupational profile. Mrs. Hayes expressed concern about how she and her husband would manage because her four adult children lived 5 hours away. Her children have hired caregivers through an agency who are with the couple in shifts for 24 hours a day. Mrs. Hayes and her husband are anxious to be on their own again and do not want to be a financial burden on their children.

Based on the priorities and problems identified by the client and her husband, the occupational performance analysis included the use of the EFPT[41] and an ADL performance evaluation. The initial performance evaluation was completed during the first 1-hour session, and the EFPT was completed during the second visit.

During the initial evaluation, Mrs. Hayes became restless after 15 minutes, but with minimal redirection she continued to attend to the tasks. She also demonstrated decreased frustration tolerance during the assessment and required minimal encouragement to continue with fine motor tasks, which were difficult for her. Mrs. Hayes is independent with eating (as long as she is in compliance with a soft diet for swallowing problems), basic hygiene, and grooming while seated and with toileting tasks. Mrs. Hayes requires supervision with transfers from her wheelchair to the bed and the toilet but requires minimal assistance to transfer onto the bath bench because of occasional loss of balance, setup, and cues for safety. She requires minimal assistance with upper body dressing and bathing and moderate assistance for lower body dressing. She has difficulty with handwriting, use of the telephone, and handling keys. She requires moderate assistance to walk 20 feet using a quad cane but is independent with manual wheelchair mobility on indoor flat surfaces. Her visual fields are intact and she has no visual-spatial deficit. Her left upper extremity (UE) strength and active range of motion (AROM) are within normal limits (WNL). Her right UE strength is WNL proximally, but testing by use of a dynamometer demonstrates mild weakness in her hand. Right UE AROM is WNL. Her muscle tone in her bilateral UEs is WNL. Her right hand coordination is mildly impaired, as demonstrated with moderate difficulty pushing buttons on the phone and tying her shoes. She is able to stand while holding on to a stable surface but cannot use her hands for a task while standing because of mild balance impairments.

Results of the EFPT demonstrated significant deficits in organization of cooking and bill-paying tasks, requiring moderate assistance to complete both. The EFPT results indicated that Mrs. Hayes required minimal assistance with medication management and phone management.

A swallow assessment demonstrated moderately impaired tongue coordination and minimal delay with a swallow. Mrs. Hayes has already modified her diet by selecting very soft foods and slightly thickened liquids.

Mrs. Hayes tolerated the full OT evaluation but reported, “I'm tired,” at the end of the session. She reported that her endurance is diminished since the CVA, especially toward the end of the day. She admitted that in the later afternoon hours, “I have hard time remembering things and concentrating.” When queried about her sleep, Mrs. Hayes reported that she has difficulty falling asleep and that she wakes up in the middle of the night and cannot fall back asleep because of “too much on my mind” and discomfort in her legs. She reported having sleep difficulties prior to the CVA.

Mrs. Hayes is highly motivated and has the potential to prepare simple hot meals and perform basic self-care independently, except for showering, for which she may require supervision. Mrs. Hayes would like to be as independent as possible in her ADLs and IADLs and would like to resume caring for her husband. She acknowledges that her right hand has gotten stronger, but she reports frustration that it is taking longer than she expected. She would like to eventually resume her leisure activities.

Progress Report

Mrs. Hayes has attended OT two times a week for 6 weeks. She is generally cooperative and motivated, although periodically becomes discouraged as she continues to have an ataxic gait and requires the use of the manual wheelchair for independent mobility. Treatment has focused on lower extremity (LE) dressing, tub transfers, oral-motor exercises to improve swallowing, instruction in sleep hygiene techniques, and simple meal preparation. Because the caregiver drives Mrs. Hayes and her husband to the OT appointments, the OT has also trained the caregiver in how to assist the client to be more independent in her ADLs.

Mrs. Hayes has made significant progress in the treatment program, progressing from requiring moderate assistance with lower extremity dressing to being independent while seated. She has improved from chair-level grooming to standing with one-hand stabilization while using the other hand to brush her hair and teeth. Progress has been made from requiring minimal assistance with bathing to requiring supervision only with bathing on a shower bench. Initially requiring supervision with bed to wheelchair transfers, she is now independent. From requiring minimal assistance with transfers onto the shower bench, she now requires supervision, mainly for setup of the environment. From moderate difficulty with use of the phone, she has progressed to using the phone independently; from requiring moderate assistance with bill-paying activities and medication management, she has progressed to the supervised level. From being dependent with oral-motor exercises, she has progressed to supervised. Mrs. Hayes is now independent in cold meal preparation after initially requiring moderate assistance. Mrs. Hayes reports some improvement in her sleep at night and states that she is following through with two sleep hygiene strategies, but she says that she still has difficulties and does not wake up refreshed.

Mrs. Hayes continues to require a soft diet and slightly thickened liquids because of swallowing difficulties. She consistently follows through with the use of safety techniques for swallowing and is safe and independent to do so. She continues to have impaired hand function but is learning compensatory techniques to adapt her method of performing various ADLs. She is also strengthening her right hand with exercises provided by the occupational therapist to restore as much function as possible to that hand.

The occupational therapist, in consultation with Mrs. Hayes, has coordinated treatment and goals with the physical therapist and social worker. The therapist has recommended that the social worker refer the client's husband to a low-vision center for evaluation because he was dependent on his wife and never received instruction in low-vision training. His independence will relieve some of Mrs. Hayes's burden of caregiving. Mrs. Hayes has also been referred to the National Sleep Foundation for more information and to her primary physician, who referred her to a physician specializing in sleep medicine. The sleep specialist evaluated Mrs. Hayes and scheduled her for an overnight sleep study in 4 weeks. (See Chapter 13 for more information on the occupation of sleep and rest.)

Mrs. Hayes and her husband are pleased with her increased independence. With input provided by the occupational therapist, the family will reduce the hours needed for a hired caregiver to 16. For 8 hours a day during the day, the hired caregiver will assist Mrs. Hayes with bathing, meals, driving to appointments, shopping, and housekeeping. Occupational therapy will now focus on hot meal preparation, bed making, and exploring leisure interests, along with continuing to work toward improvement of oral-motor and hand function and improving sleep hygiene techniques.

Critical Thinking Questions

1. What deficits is Mrs. Hayes experiencing, and what compensatory strategies can she be taught to improve her ADLs and IADLs?

2. What role does the occupational therapist have in helping Mrs. Hayes meet her goals for ADLs and IADLs?

3. With all the areas that Mrs. Hayes needs to work on with the occupational therapist, how can the

OT prioritize the goals that are most important for Mrs. Hayes to accomplish so that she can continue to live in her home safely with her husband?

Home Assessment

The AOTA Representative Assembly's position paper on complex environmental modifications asserts that evaluation and provision of complex adaptations to environments where people complete daily occupations is within the scope of practice of OT practitioners.[66] One of the most important places where people complete many life occupations is the home.[24] To help with the transition from a treatment facility to home, or to optimize performance in a dwelling in which a client already lives, a home evaluation may be performed. A **home evaluation** can serve several purposes; it allows the OT to assess the home for safety and accessibility, and it also provides a way for the OT to assess client functioning at home and to perform some caregiver training.

From the initial meeting with a client or caregivers, the occupational therapist must have an idea about the home environment to which the client will return. For example, the OT treating Anna or Mrs. Hayes should know from early on whether the client lives in a second story apartment without an elevator or in a one story house. When the client's discharge from the treatment facility is imminent, a home assessment may be carried out to facilitate the client's maximal independence in the living environment. Other professionals also make home modification recommendations, but they are often provided by occupational therapists.[73] Stark et al.[77] found that home modification interventions by occupational therapists have demonstrated greater efficacy in reducing falls and improving function in older adults than interventions delivered by other professionals.

The AOTA document "Research Opportunities Tables on Home Modifications" points future researchers toward areas that can be studied further, and it acknowledges the strong evidence that OTs make important contributions in this area.[7]

Generalist OTs who work with clients with physical dysfunction regularly provide recommendations, but OTs can also specialize in this practice area and obtain advanced training.[66] OT practitioners who want to make recommendations must make sure that they have the training to do so. For example, an OT who has not had advanced training or experience in home modification should not recommend that Anna's family knock down walls or make structural changes. The OT Code of Ethics and Ethics Standards must be followed.[5]

Before performing a home assessment, occupational therapists must recognize that they will be assessing someone else's space. Chase and Christianson[22] pointed out that the "choices regarding the home belong to clients and may be highly significant to them." In addition, these researchers noted that the home is not just the sum of its physical characteristics; emotional components also are a part of it.[22] It is important that the therapist be mindful of this throughout the home assessment process and that he or she uses a client-centered approach; studies have shown greater adherence to recommendations with this method.[90]

Not all clients seen by an occupational therapist in a facility need or receive a home evaluation (this point is discussed later). The home assessment provides the family with a list of modifications and durable medical equipment (DME) needed to maximize safety and independence in the home (Box 10.3). It also helps the therapist understand the physical, cultural, and social environment the client will be returning to, so that realistic treatment methods and goals related to mobility, ADLs, and IADLs are established. Insufficient or incorrect information about accessibility can lead to costly mistakes in ordering equipment, and this ultimately may impair the client's safety and potential for greater independence.

Box 10.3

Durable Medical Equipment (DME)

- Equipment that can withstand repeated use ("durable" and long-lasting)
- Primarily and customarily used to serve a medical purpose
- Generally not useful to a person in the absence of an illness or injury
- Appropriate for use in the home

DME that OTs in the United States customarily recommend includes hospital beds, commodes, bath equipment, and client lifts (for transfers). Other professionals may recommend DME in the realm of their expertise, such as walkers, medication infusion pumps, and blood glucose monitors

From the US Social Security Administration website:[89] *https://secure.ssa.gov/poms.nsf/lnx/0600610200* and the Medicare website:[86] *http://www.medicare.gov/coverage/durable-medical-equipment-coverage.html.*

The home evaluation should be performed when the client's mobility status has been stabilized and is close to what it is expected to be at discharge. Collaboration with the physical therapist about a client's ambulatory status and potential is essential to determine the necessity and timing of home evaluation. For example, if the physical therapist reports that a client will be primarily walking at discharge, recommendations for home modifications may be very different from those for a client whose primary mode of mobility will be a wheelchair.

Ideally, the occupational and physical therapists perform the home assessment together. During the home visit, the client and essential caregivers and family members should be present. However, if it is not feasible to take the client, a wheelchair and other necessary equipment may be taken. Budget, time factors, and reimbursement issues may not allow two professionals to go to the client's home or may prohibit a home visit altogether.

If a home evaluation is not possible prior to discharge, an environmental audit, which consists of checklists with potential hazards, can be performed.[77,78] The rehabilitation team along with the client and family members should identify the most serious concerns and develop a plan to address them. Stark et al.[78] give an example of a frequently used housing audit, the Home Falls and Accidents Screening Tool (Home FAST[55]). Fig. 10.3 shows a home safety checklist that can be completed by the client or the client's family. Family members or caregivers could take pictures and measurements of the home or draw floor plans. Fig. 10.4 shows an OT home evaluation checklist, which is completed by the OT practitioner.

Home Safety Checklist

Help prevent falls: *Use this list to prioritize work tasks. Leave a copy of this list with the family so they can make further improvements. Note: 32 inch doorway recommendations are for average size person. If overall width of wheelchair or equipment is greater than 28" need 34 to 36" wide door*

1. Exterior entrances and exits

- Increase lighting at entry area
- Install stair rails on both sides
- Install door lever handles; double-bolt lock
- Install bevelled, no step, no trip threshold
- Remove screen or storm door if needed
- Create surface to place packages when opening door
- Install peephole on exterior door at level needed for mobility device
- Repair holes, uneven joints on walkway
- Provide non-slip finish to walkway surface/ramps
- Add ramp
  - Length ________________
  - Width ________________
  - Rails ________________
  - Platform size ___________

2. Interior doors, halls, stairs

- Create clear pathways between rooms
- Apply color contrast or texture change at top and bottom stair edges
- Install door lever handle
- Install swing-clear/off set hinges to widen doorway. Minimum width: 32 inches
- Install bevelled thresholds (max ½ inch)
- Replace or add non-slip surface on steps
- Repair or install stair handrails on both sides
- Clear clutter

3. Bathroom

- Install swing-clear/off set hinges to widen doorway. Minimum width: 32 inches
- Install secure wall reinforcement and place grab bars at toilet, bath and shower
- Install adjustable-height shower head
- Install non-slip strips in bath/shower
- Secure floor bathmat with non-slip, double-sided rug tape
- Elevate toilet height by adding portable seat or raising toilet base on a pedestal
- Adapt flush handle or install flush sensor
- Adapt or relocate toilet paper dispenser
- Round counter corners to provide safety
- Insulate hot water pipes if exposed
- Create sitting knee clearance at basin by removing vanity door and shelves underneath
- Install mirror for sitting or standing view
- Install good-quality non-glare lighting
- Install shower with no threshold if bathing abilities are severely limited
- Install bidet

Recommend :	• shower seat	• transfer tub bench	• 3 in1 commode
	• shower/commode tub slider system	• power tub lift	• other

4. Kitchen

- Increase task lighting at sink, stove, etc.
- Install D-type cupboard door handles
- Install adjustable shelving to increase access to upper cabinets
- Increase access to under counter storage space by installing pull-out units
- Insulate hot water pipes if exposed
- Install hot-proof surface near oven
- Install switches and outlets at front of counter
- Install pressure-balanced, temperature-regulated, lever faucets
- Create sitting knee clearance under work sites by removing doors or shelves
- Improve color contrast of cabinet and counters surface edges for those with low vision
- Add tactile and color-contrasted controls for those with low vision
- Move microwave to reachable work surface
- Arrange frequently stored items within easy reach given current mobility device and function

5. Living, dining, bedroom

- Widen or clear pathways within each room by rearranging furniture
- Secure area rug edges with double-sided tape
- Remove throw rugs
- Improve access to and from chairs and beds by inserting risers under furniture legs
- Use side bed rail or chairs with armrests
- Install telephone jack near chair or bed
- Enlarge lamp switch or install touch-control lamp at bedside
- Install adjustable closet rods, shelving and light source for better storage access
- Install vertical pole adjacent to chair and sofa
- Raise furniture to appropriate height using leg extender products
- Install uniform level floor surfaces using wood, tile or low-pile rugs

6. Laundry

- Build a counter for sorting and folding clothes
- Adjust clothesline to convenient height
- Relocate laundry appliances
- Use reacher

7. Telephone and door

- Install phone jacks near bed, sofa, and chair
- Install flashing light or sound amplifier to indicate ringing doorbell for those with visual or hearing problems
- Install mailbox at accessible height

8. Storage space

- Install lights inside closet
- Install adjustable closet rods and shelves
- Install bi-fold or pocket doors

9. Windows

- Install handles and locks that are easy to grip, placed at appropriate heights

10. Electrical outlets and controls

- Install light fixtures or outlet for lamps
- Install switches at top and bottom of stairs

11. Heat, air, light, security, water temp, carbon monoxide controls

- Install smoke/CO detectors, fire extinguishers
- Increase residents' access to environmental control systems
- Ensure water temperature is set at safe temperature (120 degrees Fahrenheit, 49 degrees Celsius) to prevent burns (U.S. Consumer Product Safety Commission, Tap water scalds, Document # 5098 retrieved from http://www.cpsc.gov/cpscpub/pubs/5098.html on August, 26, 2010)

FIG 10.3 Home safety checklist. (Adapted from Rebuilding Together: *www.rebuildingtogether.org/downloads/home-safety-checklist.pdf*; from Ralph K Davies Medical Center: Occupational/physical therapy home evaluation form, San Francisco, 1993; and Alta Bates Hospital: Occupational therapy home evaluation form, Albany, CA, 1993.)

Home Evaluation Checklist

Name ______________________________ Date ____________

Address ______________________________

Roles ______________________________

Diagnosis ______________________________

Number of people who live in the home ______________________________

Current mobility status	☐ Independent	☐ needs assist	☐ dependent
Mobility Device used in home:	☐ ambulatory, no device	☐ walker	☐ cane
	☐ power wheelchair	☐ manual wheelchair	

Exterior

Home located on: ______________________________

Type of house	☐ owns home	☐ mobile home	
	☐ apartment	☐ board and care	
Number of floors	☐ one story	☐ split level	☐ two story
Driveway surface	☐ inclined	☐ smooth	
	☐ level	☐ rough	
Is the DRIVEWAY negotiable with current mobility device?	☐ yes	☐ no	
Is the GARAGE accessible?	☐ yes	☐ no	

Entrance

Accessible entrances	☐ front	☐ side	☐ back
Steps	Number ____________		
	Height of each ____________		
	Width ____________		
	Depth ____________		
Are there HANDRAILS?	☐ yes	☐ no	
If yes, where are they located?	☐ left	☐ right	

HANDRAIL height from step surface? ____________

If no, how much room is available for HANDRAILS? ____________

Are landings negotiable?	☐ yes	☐ no

Briefly describe any problems with LANDINGS:

____

____

____

Ramps	☐ yes	☐ no	
	☐ front	☐ back	
	Height ____________		
	Width ____________		
	Length ____________		
Are there HANDRAILS?	☐ yes	☐ no	
If yes, where are they located?	☐ left	☐ right	Height ____________

Condition of current ramp ____________

If no ramp, how much room is available for one? ____________

Given 1" rise:12" length ratio for ramp, how long should the ramp be? ____________

Porch		
	Width ____________	
	Length ____________	
Level at threshold?	☐ yes	☐ no
Lighting available at porch?	☐ yes	☐ no
Door		
Width ____________		
Threshold height ____________		
Negotiable?	☐ yes	☐ no
	☐ swing in	
	☐ swing out	
	☐ sliding	
Do door locks work?	☐ yes	☐ no
Can door lock be reached with use of current mobility device and can it be safely locked and unlocked considering current status?	☐ yes	☐ no
Type of door knob?	☐ lever	☐ round

Interior

Living Room Is furniture arranged for safe maneuverability with current mobility status?	☐ yes	☐ no

Height of frequently used furniture/chair? ____________

Type of floor covering: ____________

Able to control TV, phone, lights from seat in living room?	☐ yes	☐ no

Comments ____________

Hallways

Can current mobility device be maneuvered in hallway? ☐ yes ☐ no

Hall width ______________________

Is it adequate for current mobility status? ☐ yes ☐ no

Door width ______________________

Is it adequate for current mobility status? ☐ yes ☐ no

Sharp turns? ☐ yes ☐ no

Steps? ☐ yes ☐ no Number __________

Are there HANDRAILS? ☐ yes ☐ no

If yes, where are they located? ☐ left ☐ right Height __________

Lighting: Is switch within reach with current mobility status? ☐ yes ☐ no

Bedroom

☐ single ☐ shared

Is there room for current mobility device? ☐ yes ☐ no

Type of floor covering? ______________________

Door:

Width ______________

Threshold height ______________

Negotiable? ☐ yes ☐ no

☐ swing in ☐ swing out

Bed:

☐ twin ☐ double ☐ queen

☐ king ☐ hospital bed

Overall height ______________

Safe and accessible with current mobility status? ☐ yes ☐ no

Would hospital bed fit into room if needed? ☐ yes ☐ no

Able to control TV, phone, lights from bed? ☐ yes ☐ no

Clothing:

Are drawers accessible with current mobility status? ☐ yes ☐ no

Able to reach all items in closet (higher and lower)? ☐ yes ☐ no

Is there adequate lighting in closet? ☐ yes ☐ no

Comments: ____

____

Bathroom	☐ private	☐ shared	
Door:			
Width ____________			
Swings	☐ in	☐ out	
Will door close with current mobility device inside?	☐ yes	☐ no	
Threshold height ____________			
Negotiable?	☐ yes	☐ no	
Tub/Shower	☐ tub/shower combination	☐ shower stall	☐ tub only
Height, floor to rim ____________			
Height, inside bottom to rim ____________			
Width and length inside	Width ____________	Depth ____________	
Glass doors?	☐ yes	☐ no	
	☐ sliding	☐ swing	☐ in ☐ out
Width of doors ____________			
Handheld shower?	☐ yes	☐ no	
Type of faucet controls	☐ 2 levers	☐ single lever	☐ round
If seated, will user be able to reach faucets?	☐ yes	☐ no	
Is tub/shower accessible safely with current mobility status?	☐ yes	☐ no	
The following equipment is currently being used for bathing in the home	☐ shower seat	☐ transfer tub bench	☐ 3 in1 commode
	☐ shower/commode tub slider system		☐ power tub lift
	☐ shower commode chair		
Is there room for the caregiver to assist?	☐ yes	☐ no	
Sink:			
Height ____________		☐ open (no cabinets)	
Faucet type ____________		☐ closed (cabinets below)	
Able to reach and use faucet and sink with current mobility status?	☐ yes	☐ no	
Height of mirror ____________			
Appropriate height to sit?	☐ yes	☐ no	
Can shelf be reached with current mobility status?	☐ yes	☐ no	
Are hot water pipes insulated?	☐ yes	☐ no	
Type of faucet controls	☐ 2 levers	☐ single lever	☐ round
Electrical outlets within reach from seated or standing position	☐ yes	☐ no	

Comments on clutter/organization? ____

Toilet:

Height from floor____________________

Location of toilet paper____________________

Distance from toilet to side wall L ____________________ R ____________________

Grab bars: ☐ yes ☐ no

Location ____________________

Comments: ____

The following equipment is currently being used for toileting ☐ raised toilet seat ☐ toilet safety rails ☐ 3 in1 commode ☐ grab bars ☐ bidet

FIG 10.4 Home evaluation checklist. (Adapted from Ralph K Davies Medical Center: Occupational/physical therapy home evaluation form, San Francisco, 1993; and Alta Bates Hospital: Occupational therapy home evaluation form, Albany, CA, 1993.)

Much of the information can also be obtained by interviewing the client and family members after a client's trial home visit (a visit that must be approved by the insurance company). The family member or caregiver may be instructed to complete the home visit checklist during the trial home visit and provide photographs or sketches of the rooms and their arrangements. Problems encountered by the client during a trial home visit should be discussed and the necessary recommendations for their solution made. If a home evaluation is not possible while the client is in the hospital, the home assessment may also be referred to the home health agency that will provide home care services to the client.

The client and a family member should be interviewed prior to the home evaluation to determine the client's and family's expectations and the roles the client will assume in the home and community. The family's values or those of their culture regarding people with disabilities may influence role expectations and whether independence will be encouraged. Willingness to make modifications in the home can also be determined. The purposes and procedure of the home assessment should also be clearly explained to the client and caregivers prior to the actual visit.

Understandably, the first time home (which may be at the home evaluation) after an illness or injury can be emotion filled for everyone concerned, especially for the client. Before the OT performs a home evaluation, especially with the client present, it is important that he or she know whether the home being evaluated is new for the client or whether drastic home changes have already had to be made. For example, if Anna had lived in a second story apartment prior to her accident, her family may have had to move to a first story home. Or if Anna's mother was going to move into her home to help care for her daughter and granddaughter, rooms may have been switched, furniture moved, belongings displaced. Knowing this ahead of time can help the occupational therapist and other rehabilitation team members be ready to provide emotional support to the client as needed.

If the client is present during the home visit, sufficient time should be scheduled so that he or she can demonstrate required functional mobility skills, such as selected self-care and home management tasks in the dwelling. During the assessment, the client should use the mobility aid and any assistive devices that he or she is accustomed to using or expected to use. For example, Anna and Mrs. Hayes would be asked to propel their manual wheelchairs throughout the home to determine what access issues they will encounter. The therapist should bring a sturdy tape measure to measure the width of doorways, the height of stairs, the height of the bed, and other dimensions. With permission, the OT can take photos during the assessment and refer to them later to assist with problem-solving placement of safety equipment, adaptive devices, and home modifications.

The therapist can take the required measurements while surveying the general arrangement of rooms, furniture, and appliances. Fig. 10.4 provides a format for documenting critical measurements. It may be helpful to sketch the size and arrangement of rooms for later reference and to attach these sketches to the home assessment checklist. (For more information on standardized assessments, see Letts et al.,[51] Anemaet et al.,[8] and Stark et al.[78]) Three commonly used standardized home safety assessments are the Safety Assessment of Function and the Environment for Rehabilitation (SAFER),[63] the Westmead Home Safety Assessment (WeHSA),[26] and the Housing Enabler.[46] However, researchers found that those three commonly used assessments do not address environmental features specific to individuals with vision loss.[14]

Next, the client demonstrates functional mobility skills and essential self-care and home management tasks. The client's ability to use the entrance to the home and to transfer to and from an automobile, if it is to be used, should be included in the home assessment.

During the performance assessment, the therapist should observe safety factors, ease of mobility and performance, and limitations imposed by the environment. If the client needs assistance for transfers and other activities, the caregiver should be instructed in the methods that are appropriate. The client may also be instructed in methods to improve maneuverability and to simplify the performance of tasks in a small space.

Access to the bathroom and maneuvering with a wheelchair or walker are common problems. Frequently, a bedside commode is recommended until a bathroom can be made accessible or modified to allow independence with toileting (Fig. 10.5). Shower seats can be used in the tub if a client can transfer over the edge of the tub and also may be used in a shower. A transfer tub bench (Fig. 10.6) is recommended for individuals who cannot safely or independently step over the edge of the tub. Installation of a handheld shower hose increases access to the water and also eliminates risky turns and standing while bathing.

FIG 10.5 Three-in-one commode. (Courtesy North Coast Medical, Gilroy, CA.)

FIG 10.6 Transfer tub bench. (Courtesy North Coast Medical, Gilroy, CA.)

The Americans with Disabilities Act (ADA) established standards for accessible design, which can be used as general guidelines and are available at the ADA's website (*www.ada.gov*).[88] Not all modifications recommended should necessarily meet the ADA guidelines because the home will be modified to suit the individual and to compensate for that specific disability. The ADA guidelines are meant to apply to public areas and to meet the needs of people with a variety of disabilities (see Chapter 15). The ADA standards may serve as a resource, but they should not be the only guidelines the OT uses when making recommendations.[24] The OT should recommend that the family use only licensed contractors who are aware of building code requirements in their area.

Christenson and Lorentzen[24] suggested the optimal reach zone (OZR) as a more realistic criterion for recommendations.[97] According to the OZR method, items should be placed in a zone that is 20 to 44 inches above the floor and a maximum depth of 20 inches. Christenson and Lorentzen[24] pointed out that no specific rule can accommodate every person, but ideal heights have been determined for some items that require vision, reach, or grasp; for example, clothing rods, thermostats, electric switches, and door handles should be placed between 27.3 and 45.5 inches from the ground.[64]

In a study by Cummings et al.,[27] the most common home safety recommendations were to remove mats and throw rugs (48%), to change footwear (24%), and to use a nonslip bathmat (21%). Other recommendations included changing behaviors, such as using a commode or keeping a light on at night.[27] In their small study of older adults in an independent living community, Van Oss et al.[90] found that items rated most useful included nonslip bath strips, a suction-bottom foot scrubber, a tub seat, a bath mat for outside the tub, a reacher, a magnified mirror, a pill bottle magnifier, a raised toilet seat, and a jar gripper. Box 10.4 presents additional common recommendations for home safety and access, and Box 10.5 shows a list of supplies to take on a home evaluation.

Box 10.4

Common Home Recommendations

1. Installation of a ramp or railings at the entrance to the home

2. Removal of throw rugs, clutter, and exposed electrical wires

3. Removal of door thresholds (if not level) and doorjambs

4. Installation of safety grab bars around the toilet and bathtub

5. Rearrangement or removal of furniture to accommodate a wheelchair or other assistive devices

6. Rearrangement of kitchen and other storage for access

7. Lowering of clothes rods in closets

Box 10.5

Supplies to Take on a Home Evaluation

- Measuring tape—use heavy duty (at least 30 feet long) or infrared distance measurer[13]
- Paper, pen, or laptop for notations
- Home evaluation checklist
- Digital camera, video
- Light meter[13]
- Maps or GPS
- All important emergency phone numbers (eg, nursing station, your supervisor, and healthcare provider)
- Any durable medical equipment you think the client may need (eg, wheelchair, walker, commode, and bath bench)
- Tool kit for quick fixes
- Cell/mobile phone

If taking client on the home evaluation:

- Urinal, as appropriate
- Blood pressure cuff, stethoscope, gloves

When the home assessment is completed, the therapist must write a report summarizing the information on the form and describe the client's performance in the home. The report should conclude with a summary of the environmental barriers and the functional limitations the client encountered. Recommendations should include additional safety equipment and assistive devices needed. Modification recommendations should include specific details about size, building specifications, costs, and sources. Recommendations may also include further functional goals to improve independence in the individual's home environment. Team members should be notified about the client's performance in the home and accessibility problems so that they can practice skills or be made aware of issues prior to discharge. For example, the OT may report to the physical therapist that a client such as Mrs. Hayes will eventually need to negotiate a step down into the living room to be more independent. The OT may report to the psychologist that Anna had a difficult time emotionally handling her visit home with her new functional status.

The therapist should carefully review all recommendations with the client and family. The family should receive a written report with the recommendations clearly written. This review should be done with tact and diplomacy in a way that gives the client and family options and the freedom to decline them or consider alternative possibilities. Family finances may limit the implementation of needed changes. The social worker, case manager, and/or insurance company may be involved in working out funding for needed equipment and alterations, and the client should be made aware of this service when cost is discussed. Sprague[75] noted that determination of a household's available resources and obtaining further funding, if needed, are among the most important activities in the home modification process. The OT may assist in helping to justify and prioritize projects for funding. Sprague provided ideas and a detailed list of possible funding sources in the United States for home modifications.[75] The therapist should include recommendations regarding the feasibility of the client's discharge to the home environment or of the client remaining in or managing the home alone. If there is a question regarding the client's ability to return home safely and independently, the home assessment summary should include the additional functional skills the client needs to return home. If the OT feels that the home is not safe to live in or if there is imminent danger, appropriate parties should be notified immediately and steps taken to ensure the safety of the client.

Financial Management

If the client is to resume management of money and financial matters independently, a cognitive and perceptual assessment that accurately tests these skills should be implemented. Because some persons with physical disabilities have concurrent involvement of cognition and perception, the level of impairment should be determined. The OT evaluates the methods and routines the client typically implements for financial management. For example, one client may pay each bill as it arrives by writing a check, whereas another client may pay bills once a month online. The skills needed for each are different and require different levels of organization. As with any other performance area, the OT will break down the activity into small tasks and focus treatment on building skills for each component of the task. Caregivers may require training if the role of financial manager is new and must be assumed. In the case of Mrs. Hayes, she is having cognitive deficits and handwriting difficulties. She may need to teach her husband how to manage bill paying, or they may choose to work together. The client may be capable of handling only small amounts of money or may need retraining in activities that require money management, such as shopping, balancing a checkbook, or making a budget. If a physical limitation is involved, the therapist may introduce adaptive writing devices or practice skills, such as handling coins or bills, taking a wallet out of the pocket, and calculating appropriate tips for service provided. A social worker should also be notified if a client is cognitively unable to manage finances and has no reliable support, and therefore is at risk of financial abuse.

Community Mobility

The OTPF-3[6] classifies community mobility as an IADL and includes the use of public or private transportation such as walking, driving, riding the bus, taking a taxi, riding a train, and traveling by airplane or any number of other transportation systems. Occupational therapists with advanced training and experience can specialize in the area of adaptive driving (see Chapter 11), but OTs in all areas of practice need to address community mobility. The ability to maneuver in the community opens up doors for access to many other occupations.[79,80] Lack of access can close the door, preventing many people from participating in all the other occupations, such as work, education, play, leisure, and social participation. A study by Metz[59] found that mobility in the community can contribute to positive health outcomes physically, psychologically, socially, and with overall life satisfaction.

The OT evaluates the client's potential to participate in the community under circumstances in which some type of community mobility is required. Zahoransky[101] categorized community mobility in these ways:

- Walking with or without the use of an ambulation aid, such as a cane or walker. A study by Lynott and Figueiredo[53] found that walking is second to driving a private automobile as the preferred way for older adults to be mobile in the community.
- Using wheeled mobility devices (eg, bicycle, motorcycle)
- Using a powered device (eg, power wheelchair or scooter)
- Riding as a passenger, with a family member, friend, or caregiver as primary transport
- Driving oneself in a vehicle that may or may not be adapted (see Chapter 11)
- Using public transportation (eg, taxi, bus, van, subway, airplane, or other transit system)

The OT must assess the client's physical, perceptual, cognitive, functional, and social capabilities to be independent and safe with community mobility. The OT should be familiar with the environment in which the client lives and accesses the community, and the therapist also should be aware of available resources, such as special parking placards and how to obtain them, adaptive driving programs, and types of transportation available.

Examples of physical capabilities to be considered are whether the client has the endurance to be safely mobile in the community and whether he or she can safely use assistive devices (eg, a walker, cane, crutch, or wheelchair) and perform transfers needed to go beyond the home environment. Wheelchair mobility skills include managing uneven pavement, curbs, and inclines and crossing the street. Other functional skills the OT must evaluate that influence community mobility are handling money, carrying objects in a wheelchair or with other assistive devices, and managing toileting in a public restroom.

Cognitive skills include geographical and topographical orientation, reading a schedule and a map or knowing how to get directions, and problem-solving or obtaining help if an issue should arise.

If the disability is new, the client may need to develop new social skills or relearn old skills with new modifications. Assertive or confident behaviors, such as requesting an accessible table at a restaurant, obtaining assistance with unreachable items in the grocery store, becoming comfortable with a new body image in the able-bodied community, and asking for help when needed, can be daunting for a person who is newly disabled.

Visual-spatial skills are critical to safety in judging distance stepping down from a curb, driving a car, and maneuvering a wheelchair on a narrow sidewalk. The visual-spatial skills are identified during an evaluation and considered in relation to the cognitive, physical, and functional deficits the client exhibits. Some individuals have awareness of their deficits and compensate well. Others are not aware of the deficits or have difficulty with devising or remembering compensatory strategies and therefore will require greater supervision with community mobility than others.

The OT should also assess the client's community environment, such as security, terrain, availability of curb cutouts, travel distance, location of bus and train stations, duration of traffic lights, and availability of help if needed. For Anna, her place of worship is important, so this could be an area that should be assessed. Accessibility of worship space is not mandatory according to the ADA, but inclusion is a basic part of worship in synagogues, temples, mosques, churches.[72] Shamberg and Kidd[72] provided a useful checklist in their article for basic worship space accessibility that would be helpful for Anna and others in her church.

Accessibility of public transportation should also be considered. Some communities have door-to-door cab and van services, which have certain restrictions or set protocols. Some of these restrictions include the need to arrange transportation a week in advance, the ability to get out the front door and to the curb independently, and the ability to transfer independently into the vehicle. If the client is to use a public bus, he or she must learn how to use the electric lifts and how to lock a wheelchair into place. Because not all bus stops are wheelchair accessible, the neighboring bus stops should be surveyed.

Community mobility requires preplanning by the occupational therapist and the client; accurate assessment of the client's abilities; and knowledge of potential physical, cognitive, visual-perceptual, and social or emotional barriers the client may encounter. Armstrong and Lauzen's Community Integration Program[11] is a valuable resource that provides practical treatment protocols to establish a community-living skills program. Attaining independence in community mobility allows the client to expand his or her life occupations beyond those in the home and allows full participation in the community.

Health Management and Maintenance

Health management and maintenance include the client's ability to develop, manage, and maintain routines to promote health and wellness.[6] The client's abilities in the practical aspects of health management must be assessed, including the ability to maintain fitness and an adequate nutrition and fluid intake, avoid unhealthy behaviors, obtain adequate sleep, handle medications, and know when to call a healthcare provider and how to make a medical appointment. The evaluation of the client's ability to perform these activities may be completed solely by the occupational therapist but will probably include other team members, such as a nurse, nurse practitioner, or the physician. Caregivers and family members may also need to be involved in this area. Sanders and Van Oss[69] found in their study of 149 community-living older adults that 51% of the sample required some type of social support to take medications. Most of the help involved verbal reminders and assistance with picking up or arranging for refills. The information provided by the OT's evaluation of the client's cognition, visual perception, and physical abilities can greatly enhance the skilled nurse's ability to use appropriate interventions and strategies when teaching medication management to the client.

The OT assessment can be helpful in determining which aspects of the task need to be modified for the client to be independent. For example, the occupational therapist can work jointly with a nurse to ensure that a client with hemiplegia and diabetes can manage insulin shots. The OT evaluation considers the client's cognitive and perceptual abilities to make judgments about drawing the insulin out of the bottle, measuring the insulin, and injecting the insulin. Physical concerns include how to stabilize the insulin bottle, accurately see the measurement, and handle the syringe with one hand. Another example might involve determining the best strategies for a client using eye drops to open the container and measure and dispense the correct amount of medication into the eye. Sanders and Van Oss[69] found that 91% in their study of older adults used timing of activities to remember to take medications. Seventy-one percent of the participants planned medications around mealtimes and 52% around wake or bedtimes. Because the OT usually questions clients about their ADL and IADL routines, the connection of commonly performed activities with timing of the taking of medication can be a valuable strategy for some clients.

Sanders and Van Oss[69] also found that 64% of the older adults in their study embedded medication use around breakfast, 40% around morning hygiene, and 33% around evening hygiene. Weekly routines (eg, loading pillboxes on Sundays) and monthly routines were also used to help with medications. Interestingly, the researchers noted that although physicians recommended that their clients use charts to track medication usage, fewer than 10% did so.[69]

The OT may also evaluate and train the client in other skills that affect health management. Examples include using the phone, finding the appropriate phone numbers, and providing the needed information to make a medical appointment.

Because she has paraplegia, Anna's new health management and maintenance routine may include performing regular skin checks and weight shifts to prevent decubiti (pressure sores) from developing. An occupational therapist can help Anna obtain necessary adaptive aids and devise strategies to ensure good skin health. Considering that many lifestyle factors can affect skin integrity, OT practitioners are well suited to assist clients such as Anna in this area.[37]

Health maintenance is an issue for the client and the entire healthcare team. The occupational therapist plays an important role because of the scope of the ADL and IADL assessments, which may identify and help resolve problems related to health maintenance.

ADL and IADL Training

If it is determined after an assessment that ADL and IADL training are to be initiated, it is important to establish appropriate short- and long-term goals, based on the assessment and on the client's priorities and potential for independence.

The OT should estimate which ADL and IADL tasks are possible and which are not within the client's potential to achieve. The therapist should explore with the client the use of alternative methods of performing the activities, environmental modifications to support safety and independence, and the use of any assistive devices that may be helpful.

The ADL and IADL training program may begin with simple tasks and gradually increase in complexity.

Methods of Teaching ADLs

The therapist must tailor methods of teaching the client to perform daily living tasks to suit each client's learning style and ability. The client who is alert and grasps instructions quickly may be able to perform an entire process after a brief demonstration and oral instruction. Clients who have perceptual problems, poor memory, and difficulty following instructions of any kind need a more concrete, step-by-step approach in which the amount of assistance is gradually reduced as success is achieved. For these clients it may be important to break down the activity into small steps and progress through them slowly. A demonstration of the task or step by the therapist in the same plane and in the same manner in which the client is expected to perform can be helpful. Accompanying the demonstration with oral instructions may or may not be helpful, depending on the client's receptive language skills and ability to process and integrate two modes of sensory information simultaneously.

Evidence suggests that a variety of interventions may be effective in helping people with cognitive deficits after a CVA and that a focus on use of "authentic occupations" in the clinic were more effective than contrived cognitive activities.[39] A review of the literature by Gillen et al.[39] showed some correlation in the use of "gesture training" on measures of functional independence in ADLs for people with apraxia as described by Smania et al.[74]; cognitive strategy training, such as internal rehearsal, verbalizing actions while executing ADLs, and external cueing, may also help. In general Gillen et al.[39] suggested that the literature supports a performance focus and use of strategy training techniques and compensatory techniques as being effective in treating clients with CVA-related cognitive impairment.

Physical cueing, such as passive movement of the part through the desired pattern to achieve a step or a task, and gentle manual guidance through the task are helpful tactile and kinesthetic modes of instruction. These techniques can augment or replace demonstration and oral instruction, depending on the client's best avenues of learning. It is necessary to perform a step or complete a task repeatedly to achieve skill and speed and to have a task that is currently declarative learning (consciously knowing what to do) become automatic/procedural learning (unconsciously knowing how to do it). Tasks may be repeated several times during the same training session if time and the client's physical and emotional tolerance allow, or they may be repeated daily until the desired retention or level of skill is achieved.

Other methods of teaching include forward and backward chaining. As Batra and Batra[15] pointed out, forward chaining is a concept first described by B. F. Skinner in relation to operant conditioning (reinforcement or punishment to change behavior). In this technique, tasks ("chains") are broken down into serial steps and then taught from first step to last step. In backward chaining, the task is taught in reverse chronological order. Forward or backward chaining can be used to teach ADL skills. An example of forward chaining for the ADL of putting on a sock may be having a client practicing holding a sock open, then the OT finishing the rest of the task if the client gets stuck. After that step has been mastered, the client may place the sock over the toes, and, eventually pull up the whole sock. In backward chaining, the therapist assists the client until the last step of the process is reached. The client then performs this last step independently. In the sock example, when training starts, the therapist helps the client perform the early steps of keeping the sock open, putting the toes, and then the foot, and then the heel of the sock on. The client then pulls up the sock past the ankle and masters that step. The process continues, with the therapist offering less and less assistance and the client performing successive steps of the task, from last to first ("backward"), until the client can perform the whole task from start to finish. In their small study of children in India with mental retardation, Batra and Batra[15] found that forward and backward chaining techniques were equally effective for ADL training (putting on socks or tying shoelaces). Most likely, OTs use both methods, sometimes in the same session.

Before beginning training in any ADL, the OT must prepare by providing adequate space and arranging equipment, materials, and furniture for maximal safety and convenience; this serves as an example to the client of using work simplification and energy conservation techniques. The OT practitioner should be familiar with the task to be performed and any special methods or assistive devices that will be used in its performance. The OT should be able to perform (or should know how to perform) the task as skillfully as he or she expects the client to perform it. After preparation, the activity is presented to the client, usually in one or more of the modes of guidance, demonstration, and oral instruction described earlier. The OT ensures the appropriate environmental setup for success and safety. For example, a chair with arms or a safely locked wheelchair may be provided to start. The client's feet are placed flat on the floor (or, if a wheelchair is used, on the footplates). Personal care items are located within safe reaching distance when the client is initially learning an activity. The client then performs the activity either along with the occupational therapist or immediately after being shown, with the required amount of supervision and assistance. Performance is modified and corrected as needed, and the process is repeated to ensure learning.

Because other staff or family members are frequently reinforcing the newly learned skills, staff and family training is critical to reinforce learning and ensure that the client carries over the skills from previous treatment sessions. The therapist should check performance in progress and later arrange to check on the adequacy of performance and carryover of learning with the client, the nursing personnel, the caregiver, or the supervising family members.

Recording Progress in ADL Performance

The ADL checklists used to record performance on the initial assessment usually have one or more spaces for recording changes in abilities and the results of reassessment during the training process. The sample checklist shown earlier in this chapter (see Fig. 10.1) is designed and completed for illustration purposes using Mrs. Hayes's information. If a standardized assessment is used during the initial evaluation, it should be used in the reevaluation process to objectively measure the level of progress the client has attained.

Progress is usually summarized for inclusion in the medical record. The progress record should summarize changes in the client's abilities and current level of independence and should also estimate the client's potential for further independence, attitude, motivation for ADL training, and future goals for the ADL program. The information about the client's level of assistance needed for ADLs and IADLs will help with the discharge planning. For example, if a client continues to require moderate assistance with self-care, he or she may need to hire a personal care attendant, or the occupational therapist may justify ongoing treatment if the client has potential for further independence.

Assistive Technology and Adaptive Equipment

An assistive technology (AT) device is defined in the Assistive Technology Act of 2004 as "any item, piece of equipment, or product system whether acquired commercially off the shelf, modified, or customized that is used to increase, maintain, or improve functional capabilities of individuals with disabilities."[85] AT surveys administered between 1994 and 1997 showed that 16.6 million Americans with disabilities used special equipment aids or ATs.[93] Using the same survey, Carlson et al.[20] found that 8.3 million of those using ATs indicated that the equipment was used for basic ADLs. The terms *assistive technology, adaptive equipment,* and *assistive devices* are generally used interchangeably throughout the profession. Adaptive equipment is used to compensate for a physical limitation, to promote safety, and to prevent injury. Electronic aids to daily living (EADLs) provide a bridge between an individual with limited function and an electrical device such as a telephone or door operator.[81] Physical limitations necessitating the use of these aids may include a loss of muscle strength, loss of ROM, incoordination, or sensory loss. An example of using adaptive equipment to improve safety is the use of a bed or door alarm to alert a caregiver that a client with impaired cognition and poor balance is getting out of bed or wandering. The use of adaptive equipment to prevent joint injury is indicated for the person with rheumatoid arthritis (eg, an eating utensil with a built-up handle). Occupational therapists in general practice assess the need for and recommend adaptive equipment and technology on a regular basis. OTs can also specialize in this area and obtain further education and certifications, such as Assistive Technology Professional (ATP), a credential granted by the Rehab Engineering and Assistive Technology Society of North America (RESNA) (*http://www.resna.org*).[65]

Before recommending a piece of adaptive equipment, the OT practitioner must complete a thorough assessment to determine the client's functional problems and the causes of the problems. The OT practitioner may also consider other solutions first, before settling on adaptive equipment as the solution. Some practical solutions would be to avoid the cause of the problem, use a compensatory technique or alternative method, get assistance from another person, or modify the environment. Typical of these considerations is the case of Mr. Rojas (discussed in the case study that follows). The environment was adapted, wheelchair positioning and setup were adapted, and compensatory strategies were used, instead of adaptive equipment.

Other factors to consider in the selection of adaptive equipment are whether the disability is short or long term, the client's tolerance for gadgets, the client's feelings about the device, and the cost and upkeep of the equipment

Offering good suggestions and sound advice on improving engagement in occupations is within the domain of OT and is an important responsibility; however, these good qualities, in and of themselves, may not actually mean use of the strategies provided by the therapist. In a study of 154 community-dwelling, functionally vulnerable adults over 70 years old, Chee[23] looked at modifiable factors that can influence the use of adaptive strategies. These adaptive strategies, offered mainly by occupational therapists and physical therapists, comprised environmental strategies (assistive technology, home modifications) or behavioral strategies (energy conservation, performance techniques). The researcher looked at sociodemographic information, functional status, perceived importance of learning new strategies, and degree of readiness to change or adapt to functional decline. “Readiness” was defined as the extent to which a study participant acknowledged a functional deficit and demonstrated or showed a willingness to change or modify the environment. The study's findings concurred with those of other studies; that is, that individuals with a higher stage of “readiness” are more likely to use home environmental adaptations than those who are not ready. Chee suggested that environmental strategy adherence could be improved by enhancing the readiness of older adults through education, problem solving, and more opportunities to practice. The study targeted older adults, but Chee suggested that an intervention process–related variable (eg, readiness) may affect the acceptability of therapeutic strategies offered by therapists to other clinical populations. Another finding was that living arrangements of the participants significantly predicted adherence to behavioral strategies offered. Participants who lived alone demonstrated higher use of prescribed behavioral strategies than those who lived with others.[23]

Case Study

Mr. Rojas

Mr. Rojas is 75 years old and lives in a nursing home. The occupational therapist received a referral for a self-feeding assessment because he has recently lost weight, and the nursing aides have reported that he needs assistance with eating. The nurse mentioned that he thought Mr. Rojas needed a utensil with a built-up handle to feed himself.

The OT assessment included an interview with Mr. Rojas, observation of him eating lunch in his usual location (in his room with the use of an over-bed table), physical assessment (including strength, ROM, sensation, coordination), and gross cognitive and perceptual assessments. Mr. Rojas stated that he would like to be able to feed himself because he likes to eat his food when it is hot, and he likes to be as independent as possible. The results indicated that Mr. Rojas had problems with sitting properly in his wheelchair. The over-bed table was too high and limited his ability to reach the plate. His strength, ROM, coordination, and sensation were within normal limits, except that bilateral shoulder flexors and abductors were F− (3−/5). Mr. Rojas' cognition and perception were adequate to relearn simple self-care tasks.

Treatment involved working on wheelchair positioning, lowering the over-bed table, and then teaching the client how to use a compensatory technique of elbow propping to bring his hand to his mouth during eating. The OT assessment did not indicate a need for adaptive equipment at this time; instead, the environment was adapted, wheelchair positioning modified, and a compensatory method taught.

If the results of the assessment had indicated that Mr. Rojas had a weak grasp or hand incoordination, a utensil with a built-up handle and plate guard might have been used to promote independence with self-feeding.

Specific ADL and IADL Techniques

In many instances specific techniques to solve specific ADL problems are not possible. Sometimes the occupational therapist has to explore a variety of methods or assistive devices to reach a solution. It is occasionally necessary for the therapist to design a special device, method, orthotic, or piece of equipment to make a particular activity possible for the client to perform. Many of the assistive devices available today were first conceived of and made by occupational therapists and clients. Special methods used to perform specific activities also evolved through the trial-and-error approaches of therapists and their clients. Clients often have good suggestions for therapists because they live with the limitation and are confronted regularly with the need to adapt the performance of daily tasks.

The purpose of the following summary of techniques is to give the reader some ideas about how to solve ADL and IADL problems for specific classifications of dysfunction. The focus is on compensatory strategies involving changing the method in which an activity is performed, changing the environment, or using an assistive device. If the client has the potential for improvement of specific deficits, treatment that includes remediation and restoration should be considered. For example, if a client has hand weakness as a result of a fracture of his hand, the therapist may offer alternative methods and adaptive equipment to manage until strength improves, but hand strengthening should also be a component of the treatment program, assuming there are no contraindications. Ideally, every suggestion provided should be actually tried with a client before recommendations are made.

In the following chapter sections, recommended techniques are summarized for individuals with these physical deficits:

- Limited ROM or strength
- Incoordination
- Hemiplegia or use of only one upper extremity
- Paraplegia
- Quadriplegia
- Low vision
- Exceptionally large size body (bariatric population)

These ADLs and IADLs are addressed for each of the physical deficits previously listed:

- Dressing activities
- Feeding activities (eating and swallowing are addressed in Chapter 27)
- Personal hygiene and grooming activities
- Communication management and environmental adaptations
- Functional mobility (transfers and wheelchair mobility are addressed in Chapter 11)
- Home management, meal preparation, and cleanup activities

ADLs for the Person With Limited Range of Motion or Strength

The major problem for persons with limited joint ROM is compensating for the lack of reach and joint excursion through such means as environmental adaptation and assistive devices. Individuals who lack muscle strength may require some of the same devices or techniques to compensate and to conserve energy. Some adaptations and devices are outlined here.[4,68]

Lower Extremity Dressing Activities

1. Use one of many commercially available dressing sticks with a plastic-coated coat hook on one end and a small hook on the other (Fig. 10.7) for pushing and pulling garments (eg, underwear, pants) off and on the feet and legs.

FIG 10.7 Collapsible dressing stick. (Courtesy North Coast Medical, Gilroy, CA.)

2. To put on socks, use one of many different commercially available models of sock aides (Fig. 10.8). To take off socks, use a reacher (Fig. 10.9) or dressing stick (see Fig. 10.7).

FIG 10.8 Easy-Pull Sock Aid. (Courtesy North Coast Medical, Gilroy, CA.)

FIG 10.9 Extended-handle reacher. (Courtesy North Coast Medical, Gilroy, CA.)

3. Eliminate the need to bend to tie shoelaces or to use finger joints in this fine motor activity by using elastic shoelaces or other adapted shoe fasteners (eg, Velcro-fastened shoes or secure slip-on shoes).

4. Use reachers (see Fig. 10.9) to pick up socks and shoes, arrange clothes, remove clothes from hangers, pick up objects on the floor, and put on and take off pants.

Upper Extremity Dressing Activities

1. Use front-opening garments that are one size larger than needed and made of fabrics that have some stretch.

2. Use dressing sticks (see Fig. 10.7) to push a shirt or blouse over the head.

3. Use larger buttons or zippers with a loop on the pull-tab.

4. Replace buttons, snaps, and hooks and eyes with Velcro or zippers (clients who cannot manage traditional fastenings).

5. Use one of several types of commercially available buttonhooks (Fig. 10.10) if finger ROM or strength is limited or unavailable.

FIG 10.10 Buttonhook with built-up handle. (Courtesy North Coast Medical, Gilroy, CA.)

6. A front opening or Velcro replacements for the usual hook-and-eye fasteners may make it easier to put on and remove a bra. Slipover, stretchable bras (which may be called sleep bras or comfort bras) or a bra-slip combination also may eliminate the need to manage fastenings. Regular bras may be fastened in front at waist level, then slipped around to the back and the arms put into the straps, which are then worked up over the shoulders. Bra band extenders may also be suggested. An

ambulatory person with narrow hips, good balance, and leg ROM but poor upper extremity ROM may find it easier to put on a bra by clasping the bra, putting the bra on the floor, stepping into it, and pulling it up over the hips onto the chest.

7. Quilted vests with armhole openings that are large (but not so large they get caught on things) are easier to put on and take off than jackets for those with shoulder ROM limitations.

Feeding Activities

1. Use built-up handles on eating utensils that can accommodate limited grasp or prehension (grip or pinch pattern) (Fig. 10.11).

FIG 10.11 Fork with built-up handle and swivel. (Courtesy North Coast Medical, Gilroy, CA.)

2. Elongated or specially curved handles on spoons and forks may be needed to reach the mouth. A swivel spoon or spoon-fork combination can compensate for limited forearm supination (see Fig. 10.11).

3. Long plastic straws and straw clips on glasses or cups can be used if neck, elbow, or shoulder ROM limits hand-to-mouth motion or if grasp is inadequate to hold the cup or glass.

4. Universal cuffs (Fig. 10.12) or utensil holders can be used if grasp is very limited and built-up handles are not sufficient. Notice that the utensil sleeve is placed so that the tool to be used is put in the palm of the hand, not on the top of the hand.

FIG 10.12 Universal cuff. (Courtesy North Coast Medical, Gilroy, CA.)

5. Plate guards or scoop dishes may be useful to prevent food from slipping off the plate (see Fig. 10.11).

6. Cups with nose cutouts may be useful to persons who have limited neck ROM or who may be wearing a neck brace (Fig. 10.13).

FIG 10.13 Nose cutout tumbler. (Courtesy North Coast Medical, Gilroy, CA.)

Personal Hygiene and Grooming Activities

1. A handheld flexible shower hose for bathing and shampooing hair can eliminate the need to stand in the shower and offers the user control of the direction of the spray. The handle can be built up or adapted for limited grasp.

2. A long-handled bath brush or sponge with a soap holder (Fig. 10.14) or a long cloth scrubber can allow the user to reach the legs, feet, and back. A wash mitt (Fig. 10.15) and soap on a rope can aid limited grasp. For the economically minded, bar soap can be placed in a cutoff leg of light-colored pantyhose and tied to the bath chair to eliminate the need to bend to pick up soap. If reach is limited to wash the hair, a soft rubber brush with extended handle or specially designed long-handled adaptive aid can be used to shampoo the hair.

FIG 10.14 Long-handled brush. (Courtesy Patterson Medical, Warrenville, IL.)

FIG 10.15 Bath mitt. (Courtesy North Coast Medical, Gilroy, CA.)

3. A wall-mounted hair dryer may be helpful. This device is useful for clients with limited ROM, upper extremity weakness, incoordination, or hemiplegia. The dryer is mounted (wall or stand) to allow the user to manage the hair with one arm or to position himself or herself to compensate for limited ROM.[28]

4. Long handles on a comb, brush, toothbrush, lipstick, mascara brush, and safety or electric razor may be useful for clients with limited hand-to-head or hand-to-face movements. Extensions may be constructed from inexpensive wooden dowels or lengths of various diameter polyvinyl chloride (PVC) pipe found in hardware stores. The handles can be built up or adapted for limited grasp.

5. Pump deodorant, hair spray, and spray powder or perfume can extend the reach by the distance the material sprays.

6. Electric toothbrushes and a Water-Pik may be easier to manage than a standard toothbrush; each may need to be adapted for limited grasp.

7. A short reacher (or kitchen tongs) can extend reach for using toilet paper. Several types of toilet aids are available in catalogs that sell assistive devices. Bidets can be used to help with perineal cleansing; more expensive products, such as the Toto Washlet, can help wash (variable temperature settings) and dry the area while providing a warm seat. Squeeze bottles with water may be sufficient for some who have limited ROM to reach the backside to wipe. Products such as the One-Drop Powerful Deodorizer can be a portable way for those with weak pinch strength to get rid of offensive odors.

8. If the shoulder cannot be raised enough to allow removal of hair from the underarms with a razor or wax, an epilator hair removal system (eg, Epilady rechargeable hair remover) can help perform this task.

9. Dressing sticks can be used to pull garments up after the client has used the toilet. An alternative is to use a long piece of elastic or webbing with clips on each end that can be hung around the neck and fastened to pants or panties, preventing them from slipping to the floor during use of the toilet.

10. Safety rails (Fig. 10.16) can be used for bathtub transfers, and safety mats or strips can be placed on the bathtub bottom to prevent slipping.

FIG 10.16 Tub safety rail. (Courtesy North Coast Medical, Gilroy, CA.)

11. A transfer tub bench (see Fig. 10.6), shower stool, or chair set in the bathtub or shower stall can eliminate the need to sit on the bathtub bottom or stand to shower, thus increasing safety.

12. Grab bars can be installed to prevent falls and to ease transfers.

13. Pump dispensers for shampoo, conditioners, and lotions are easier to manage than containers that require lifting and pouring of contents. If containers that require lifting and pouring are used, the contents should be transferred from larger containers to smaller ones, and objects should be placed in an accessible location in the shower.

Communication Management and Environmental Adaptations

1. Extended built-up or lever handles on faucets can accommodate limited grasp.

2. Telephones should be placed within easy reach, or portable phones can be used and kept with the client. A speakerphone or headset may be necessary. Phones with large push buttons or voice-activated phones may be helpful if individual finger movements are difficult or not possible. Cell phones with Bluetooth devices can be used for hands-free, voice-activated answering and calling.

3. Built-up pens and pencils can be used to accommodate limited grasp and prehension. A Wanchik writer (Fig. 10.17) and several other commercially available or custom-fabricated writing aids also can be used.

FIG 10.17 Wanchik writer. (Courtesy North Coast Medical, Gilroy, CA.)

4. Personal computers, word processors, voice recognition computer software, book holders, and electronic books can facilitate communication for those with limited or painful joints.

5. Lever-type doorknob extensions (Fig. 10.18), commercially available lever-style doorknobs, adapted car door openers, doors with push-button combination locks, and adapted key holders can compensate for hand ROM and strength limitations.

FIG 10.18 Doorknob extension. (Courtesy North Coast Medical, Gilroy, CA.)

Functional Mobility

The individual who has limited ROM and may have some generalized weakness, but no significant muscle weakness, may benefit from the following assistive devices.

1. A glider chair that is operated by the feet can facilitate transportation if hip, hand, and arm motion is limited.

2. Platform crutches can prevent stress on hand or finger joints and can accommodate limited grasp. Confer with the physical therapist about this option because platform crutches may increase the weight and size of the walking aid and may actually be a detriment to the client's gait or may increase pressure on the shoulder.

3. Enlarged grips on crutches, canes, and walkers can accommodate limited grasp. Confer with the physical therapist about this option.

4. A raised toilet seat can be used if hip and knee motion is limited.

5. A walker with padded grips and forearm troughs can be used if marked hand, forearm, or elbow joint limitations are present. Confer with the physical therapist about this option.

6. A walker or crutch bag, tray, or basket can facilitate the carrying of objects.

Home Management, Meal Preparation, and Cleanup Activities

Home management activities can be facilitated by a wide variety of environmental adaptations, assistive devices, management, energy conservation methods, and work simplification techniques.[25,99] The principles of joint protection are essential for those with rheumatoid arthritis and other inflammatory joint conditions (see Chapter 38). The following are suggestions to facilitate home management for persons with limited ROM.[49]

1. Store frequently used items on the first shelves of cabinets, just above and below counters or on counters where possible. Eliminate unnecessary items.

2. Use a high, stable stool to work comfortably at counter height, with the feet firmly placed on the ground; or, if a wheelchair is used, attach a drop-leaf table to the wall to create a planning and meal preparation area. Pullout breadboards can also serve as a wheelchair-accessible countertop workspace.

3. Use a utility cart of comfortable height to transport several items at once.

4. Use reachers to get lightweight items (eg, a cereal box) from high shelves. Place frequently used items in the refrigerator and on shelves in cabinets where items are easily accessible and reachable.

5. Stabilize mixing bowls and dishes with nonslip mats.

6. Use lightweight utensils, such as plastic or aluminum bowls and aluminum pots. Use lightweight plates, cups, and other serving containers.

7. Use an electric can opener and an electric mixer.

8. Use electric scissors or adapted loop scissors to open packages (Fig. 10.19B). Avoid using the teeth to rip open packages because this may wear down, weaken, or break the teeth.

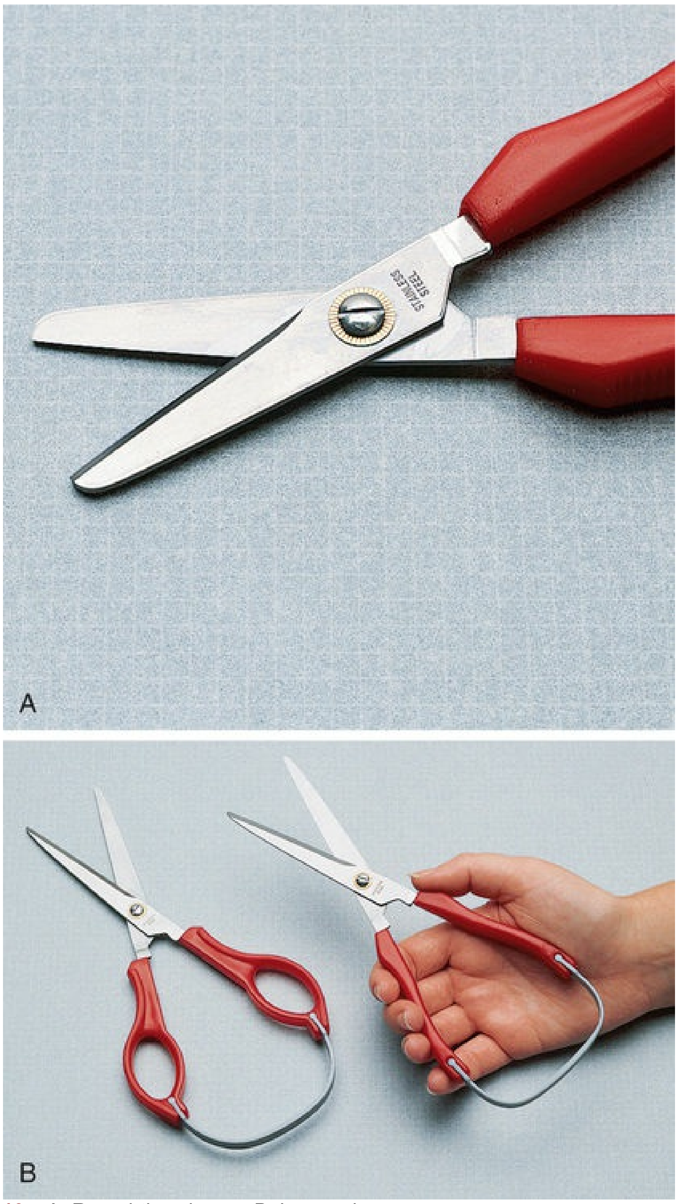

FIG 10.19 A, Round-tip scissors. B, Loop scissors. (Courtesy North Coast Medical, Gilroy, CA.)

9. Eliminate bending by using extended and flexible plastic handles on dust mops, brooms, and dustpans.

10. Use adapted knives for cutting (Fig. 10.20), or consider using precut vegetables and meat for cooking.

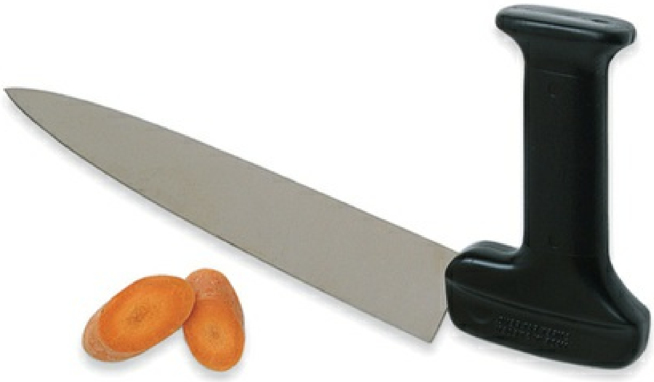

FIG 10.20 Swedish steak knife. (Courtesy North Coast Medical, Gilroy, CA.)

11. Use pullout shelves or lazy Susans to organize cupboards or the refrigerator to eliminate bending and to ease access to items.

12. Eliminate bending by using a wall oven or a countertop toaster oven or microwave oven. When remodeling the kitchen, consider elevating the dishwasher to a convenient height for wheelchair use or for those who have difficulty bending.

13. Use pump dispensers for dish soap instead of dish soap containers with pour spouts, which require lifting and pouring of contents. Ensure that the pump dispenser is not too tall to reach and that the base is stable. Single-use, premeasured, water-soluble dishwasher detergent packets eliminate numerous steps.

14. Use a piece of Dycem or other nonslip material (eg, a piece of puffy shelf liner, a thick rubber band around a jar lid, or jar openers) to open containers. Keep these handy in multiple locations.

15. Eliminate leaning and bending by using a top-loading automatic washer and elevated dryer. Alternatively, mount front-loading washers and dryers on an elevated platform. Wheelchair users or people of shorter stature can benefit from front-loading appliances. Use a reacher or other extended tool (eg, tongs or even a small bamboo rake) to remove clothes from the washer or dryer. Place smaller items in net bags for ease of retrieval from the machines.

16. Use an adjustable ironing board to make it possible to sit while ironing, or eliminate ironing by choosing permanent press clothing or wrinkle-free material.

17. For child care, elevate the playpen and diaper table and use a bathinette (portable folding baby bathtub) or a plastic tub on the kitchen counter for bathing to reduce the amount of bending and reaching by the ambulatory parent. The crib mattress can be in a raised position until the child is 3 or 4 months of age.

18. Use slightly larger and looser fitting garments with Velcro fastenings on children.

19. Use a reacher to pick up items from the floor. For individuals without hand function, investigate the Cripper, a reaching device designed for people with quadriplegia who have use of wrist extensors, elbow flexors, and shoulder musculature (Fig. 10.21).

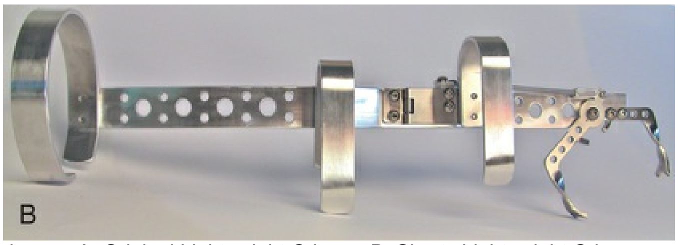

FIG 10.21 Crippers. A, Original Lightweight Cripper. B, Shorty Lightweight Cripper. (Courtesy Quadtools, Camino, CA.)

20. Use a lightweight comforter instead of a top sheet and blanket to increase the ease of making the bed.

ADLs for the Person With Incoordination

Incoordination in the form of tremors, ataxia, and athetoid or choreiform movements can be caused by a variety of central nervous system (CNS) disorders, such as Parkinson's disease, multiple sclerosis, cerebral palsy, Friedreich's ataxia, Huntington's disease, and head injuries. The major problems encountered in ADL performance are safety and adequate stability of gait, body parts, and objects to complete the tasks.[43]

Fatigue, stress, emotional factors, and fear may influence the severity of incoordinated movement. The client must be taught appropriate fatigue management techniques, along with appropriate work pacing and safety methods to prevent the fatigue and apprehension that could increase incoordination and affect performance (see Chapter 35, Section 3).[49]

Stabilizing the trunk and arm reduces some of the incoordination and may allow the individual to improve occupational performance.[38] Propping the elbow on a counter or tabletop, pivoting from the elbow, and moving only the forearm, wrist, and hand in the activity can help provide some stability to the arm when in use. When muscle weakness is not a major deficit for the individual with incoordination, the use of weighted devices can help with stabilization of objects. Use of weights on the wrists by those with intention tremors due to static brain lesions has been found to provide some functional improvement in self-feeding.[56] A Velcro-fastened weight can be attached to the client's arm or to the back of the client's hand to reduce ataxia, or the device being used (eg, eating utensils, pens, and cups) can be weighted.

Dressing Activities

To prevent falls, the client should attempt to dress while sitting on a sturdy surface (eg, a chair with arms and a back) with the feet planted firmly on floor, or in a wheelchair with the wheels locked. The following adaptations can reduce dressing difficulties.

1. Front-opening garments that fit loosely can facilitate the process of putting on and removing garments.

2. Large buttons, Velcro closures, and zippers with loops on the tab are fasteners that are easier to open and close. A buttonhook with a large, weighted handle may be helpful.

3. Elastic shoelaces, Velcro fasteners, other adapted shoe closures, and slip-on shoes eliminate the need for bow tying.

4. Slacks with elastic tops for women or Velcro closures for men are easier to manage than slacks with hooks, buttons, and zippers.

5. Bras with a front opening or Velcro replacements for the usual hook-and-eye fasteners may be easier to put on and take off. A slipover, stretch bra or bra-slip combination also may eliminate the need to manage bra fastenings. Regular bras may be fastened in front at waist level, then slipped around to the back and the arms put into the straps, which are then worked up over the shoulders.

6. When hand function or dexterity is impaired or absent, clip-on ties can be used, as can claspless necklaces that slip over the head and stretchable beaded bracelets.

Feeding Activities

Feeding can be a challenge for clients with problems of incoordination. Lack of control during eating is not only frustrating, it can also cause embarrassment and social rejection. As mentioned previously, some evidence indicates that the use of weights on the wrist may increase functional ability in feeding.[56] It is important to make eating safe, pleasurable, and as neat as possible. Here are some suggestions for achieving this goal.

1. Use plate stabilizers, such as nonskid mats (Dycem), suction bases, or even damp dishtowels.

2. Use a plate guard or scoop dish to prevent food from being pushed off the plate. The plate guard can be clipped to any ordinary dinner plate, so the client can use it when away from home (Fig. 10.22).

FIG 10.22 Plate guard. (Courtesy Patterson Medical, Warrenville, IL.)

3. Prevent spills during the plate-to-mouth excursion by using weighted or swivel utensils for stability. Weighted cuffs may be placed on the forearm, or a glove with weights can be placed on the back of the hand, to reduce involuntary movement.

4. Use long plastic straws with a straw clip on a glass, or use a cup with a weighted bottom to eliminate the need to carry the glass or cup to the mouth, thus avoiding spills. Plastic cups with covers, one or two handles, and spouts may be used for the same purpose (Fig. 10.23). Having more than one cup designed for different drinks at a meal promotes independence and saves time and effort for the individual and caregivers.

FIG 10.23 Cup adaptors. (Courtesy Patterson Medical, Warrenville, IL.)

5. Use a resistance or friction feeder similar to a mobile arm support to help control patterns of involuntary movement during the feeding activities of adults with cerebral palsy and athetosis. These devices may help many clients with severe incoordination to achieve some degree of independence in feeding. The device is available in adaptive equipment catalogs and is listed as a Friction Feeder MAS (Mobile Arm Support) Kit (see Chapter 30, Section 2).

6. Use a mechanical self-feeding device that turns the plate, scoops the food, and brings it to the mouth. Several models are available.

Personal Hygiene and Grooming Activities

Stabilization and handling of toilet articles may be achieved by having the client use the following measures.

1. Articles such as a razor, lipstick, or toothbrush may be attached to a cord if frequent dropping is a problem. An electric toothbrush may be more easily managed than a manual one. It is important to check the weight, operating mechanisms, and other properties of recommended devices to determine whether the client can manage safely.

2. Weighted wrist cuffs may be helpful during the finer hygiene activities, such as hair care, shaving, and applying makeup.

3. A wall-mounted (or stand-mounted) hair dryer (described earlier for clients with limited ROM) can also be useful for clients with incoordination.[28]

4. An electric razor offers more stability and safety than a blade razor. A strap around the razor and hand can prevent dropping.

5. A suction brush attached to the sink or counter can be used for nail or denture care (Fig. 10.24).

FIG 10.24 Suction denture brush. (Courtesy North Coast Medical, Gilroy, CA.)

6. Bar soap could be on a rope. It can be worn around the neck or hung over a bathtub or shower fixture during bathing to keep it within easy reach. A bath mitt with a pocket to hold the soap can be used for washing to eliminate the need for frequent soaping and rinsing and wringing a washcloth. A leg from a pair of light-colored panty hose (which can stretch for use) with a bar of soap in the toe may be tied over a faucet or on a bath chair to keep soap within reach. Liquid soap with a soft nylon scrubber may be used to minimize the handling of soap. Bath gloves can be worn, and liquid soap that is not too slippery can be applied to eliminate the dropping of soap bars and washcloths.

7. An emery board or small piece of wood with fine sandpaper glued to it can be fastened to the tabletop for filing nails. A nail clipper can be stabilized in the same manner.

8. Large solid deodorants are preferable to sprays.

9. Sanitary pads that stick to undergarments may be easier to manage than tampons.

10. Nonskid mats should be used inside and outside the bathtub during bathing. Their suction bases should be fastened securely to the floor and bathtub before use. Safety grab bars should be installed on the wall next to the bathtub, or one could also be fastened to the edge of the bathtub. A bathtub seat or shower chair or bench with backrest could be used. Sponge bathing while seated at a bathroom sink may be substituted for bathing or showering several times a week.

Communication Management and Environmental Adaptations

1. Doorknobs may be managed more easily if replaced or adapted with lever-type handles or covered with rubber or friction tape (see Fig. 10.18).

2. Large-button phones, speakerphones, or using a headset as a telephone receiver may be helpful.

Operator assistance services for dialing may be implemented.

3. Mobile phones or smart phones should be selected based on need for larger key pads and voice dialing capabilities.

4. Writing may be managed by using a weighted, enlarged pencil or pen. A personal computer with a keyboard guard is a helpful aid to communication. A computer mouse may frequently be substituted for the keyboard. A voice recognition program may be used with a personal computer to minimize use of the keyboard or mouse. Most computers have “accessibility” features as a choice on the control panels. These features allow for adjustments such as reducing the sensitivity of the keys to eliminate redundancy of keystrokes and reducing the sensitivity of the mouse.

5. Keys may be managed by placing them on an adapted key holder that is rigid and offers more leverage for turning the key. Inserting the key into the keyhole may be difficult, however, unless the incoordination is relatively mild. Locks for cars and homes can be modified with keypads or electronic door openers.

6. Extended lever-type faucets are easier to manage than knobs that turn and push-pull spigots. To prevent burns during bathing and kitchen activities, the person with incoordination should turn the cold water on first and add hot water gradually. The thermostat on the water heater can be turned down to a safe level or shower heads and tub spigots replaced with models that have a built-in shutoff valve to prevent scalding.

7. Lamps that can be turned on and off with a wall switch, a signal-type device, by motion, or by touch can eliminate the need to turn a small switch. Lights can also be programmed to turn on at specific times of the day if a timer is attached.

Functional Mobility

Clients with problems of incoordination may use a variety of adaptive aids, depending on the type and severity of incoordination. Clients with degenerative diseases sometimes need help recognizing the need for and accepting mobility and ambulation aids; the OT must consult with the physical therapist about devices for gait. The following suggestions can improve stability and mobility for clients with incoordination.

1. Instead of lifting objects, slide them on floors or counters.

2. Use suitable ambulation aids (eg, cane, crutches, or walker) based on suggestions by a physical therapist.

3. Use a utility cart, preferably a heavy, sturdy cart that has some friction on the wheels.

4. Remove doorsills or thresholds, throw rugs, and thick carpeting.

5. Install railings on indoor and outdoor staircases.

6. Substitute ramps for stairs wherever possible.

7. Use a bed transfer handle (or railing) to assist with bed mobility and transfers.

8. Use a wheelchair for indoors or outdoors if upright ambulation is deemed unsafe. Either the OT or the physical therapist may assist in accurate selection, depending on the facility.

Home Management, Meal Preparation, and Cleanup Activities

It is important for the occupational therapist to carefully assess performance of homemaking activities to determine which activities can be done safely, which can be done safely if modified or adapted, and which cannot be done adequately or safely and should be assigned to someone else. Major areas to consider are stabilization, handling and moving of objects and hot items, and use of tools, especially sharp ones. Potential problems need to be addressed to prevent spills, accidents, and injuries such as cuts, burns, bruises, electric shock, and falls. The following are suggestions for performing home management tasks safely.[49]

1. Use a wheelchair and wheelchair lapboard, even if ambulation is possible with devices. The wheelchair saves energy and increases stability if balance and gait are unsteady. Some people with upper extremity incoordination who do not want a lap tray find it safer to place a plastic tray on their laps (when stationary) while performing tasks with their hands.

2. If possible, use convenience and prepared foods to eliminate as many processes as possible (eg, peeling, chopping, slicing, and mixing). Prewashed salads are also now available.

3. Use easy-open containers, or store foods in plastic containers once the original container has been opened. A jar opener is also useful.

4. Use heavy utensils, mixing bowls, and pots and pans to increase stability.

5. Use nonskid mats on work surfaces.

6. Consider using electrical appliances such as crock pots, indoor plate grills, electric fry pans, an electric water heater, toaster ovens, and microwave or countertop convection ovens because they can be safer than using a range-top stove. Safe cleanup of the appliances needs to be strongly considered because appliances such as crock pots are very heavy. Automatic shutoff devices would be safer.

7. Use a blender and stand mixer because they are safer than handheld mixers and easier than mixing with a spoon or whisk. Cleanup needs to be considered because blenders and stand mixers may be heavy or difficult to clean or may have sharp parts.

8. If possible, adjust the work heights of counters, the sink, and the range to minimize leaning, bending, reaching, and lifting, whether the client is standing or using a wheelchair.

9. Use long oven mitts, which are safer than potholders.

10. Use pots, pans, casserole dishes, and appliances with two handles because they may be easier to manage than those with one handle.

11. Use an adapted cutting board with side rails (Fig. 10.25) to stabilize meats and vegetables while cutting. The bottom of the board should have suction cups or should be covered with stair tread, or the board should be placed on a nonskid mat to prevent slipping during use.

FIG 10.25 Cutting board. (Courtesy Patterson Medical, Warrenville, IL.)

12. Use heavy dinnerware, which may be easier to handle because it offers stability and control to the distal part of the upper extremity. On the other hand, unbreakable dinnerware may be more practical if dropping and breakage are problems.

13. Cover the sink, utility cart, and countertops with protective rubber mats or mesh matting to stabilize items.

14. Use a serrated knife for cutting and chopping because it can be easier to control.

15. Use a steamer basket or deep-fry basket for preparing boiled or fried foods to eliminate the need to carry and drain pots containing hot liquids.

16. Use tongs to turn foods during cooking and to serve foods because tongs may offer more control and stability than a fork, spatula, chopsticks, or serving spoon.

17. Use blunt-ended loop scissors to open packages.

18. Vacuum with a heavy, upright cleaner, which may be easier for the ambulatory client. The wheelchair user may be able to manage a lightweight tank-type vacuum cleaner or electric broom.

19. Use dust mitts for dusting. Consider eliminating breakable knickknacks, unstable lamps, and other objects to minimize the dusting required.

20. Eliminate ironing by using permanent press fabrics or a timed dryer or by assigning this task to other members of the household. Lower the ironing board so that the task can be accomplished from a seated position.

21. Use a front-loading washer, a laundry cart on wheels, and premeasured detergents, bleaches, and fabric softeners.

22. Sit when working with an infant and use foam rubber bath aids, an infant bath seat, and a wide, padded dressing table with Velcro safety straps to achieve enough stability for bathing, dressing, and diapering an infant. Some childcare tasks may not be possible if the incoordination is severe.

23. Use disposable diapers with tape or Velcro fasteners because they are easier to manage than cloth diapers and pins and also require less frequent changing.

24. Do not feed the infant with a spoon or fork unless the incoordination is very mild or does not affect the upper extremities. This task may need to be performed by another household member.

25. Children's clothing should be large, loose, and made of nonslippery stretch fabrics and have Velcro fastenings.

26. Use front infant carriers or strollers for carrying.

ADLs for the Person With Hemiplegia or Use of Only One Upper Extremity

Suggestions for performing daily living skills apply to persons with hemiplegia due to brain injury and also to those with conditions such as unilateral upper extremity amputation, fractures, rotator cuff injuries, adhesive capsulitis, burns, and peripheral neuropathic conditions that can result in the dysfunction of one upper extremity.

The client with hemiplegia due to conditions such as CVA, brain injury, or other conditions that affect the brain may have greater difficulty learning and performing one-handed skills than do those with orthopedic or lower motor neuron dysfunction and may need specialized methods of teaching. The client with normal perception and cognition and the use of only one upper extremity may learn the techniques quickly and easily.

In a client with hemiplegia due to brain injury, the trunk and leg may be involved, and static or dynamic balance difficulties may exist in both seated and standing positions. Sensory, visual, perceptual, cognitive, and speech disorders may be present in a mild to severe degree. These disorders may profoundly affect the ability to learn and retain information and to carry over techniques into functional tasks, especially if inattention or neglect of one side of the body is present. Any type of apraxia (eg, difficulty with motor planning, using objects), which is sometimes seen in this group of clients, can also have a profound effect on the potential for relearning different ways to perform once familiar tasks. These clients need to be assessed for sensory, perceptual, and cognitive deficits to determine the potential for ADL performance and to establish appropriate teaching methods to facilitate learning.

The following sections present primarily adaptive techniques rather than restorative techniques. However, it is important to incorporate the upper extremity with hemiplegia to assist in returning function to the extremity. Waddell et al.[94] conducted a study of 15 clients in an inpatient rehabilitation facility who had had a CVA and consequently had UE paresis. These individuals were provided high-repetition, task-specific training in the affected extremity. The researchers found that the clients' UE function had improved enough to allow an OT to devise a treatment plan that provided both adaptive strategies and an intensive focus on restorative strategies.

Research also has shown promise of improved function in the affected extremity with constraint-induced movement therapy (CIMT); the unaffected UE is purposefully constrained to force the client to use the affected UE, when applied in original and modified forms. Hayner et al.[42] found that constraint of the unaffected extremity, in combination with "intrusive cueing" of bilateral use of UEs, may lead to improvement in motor function of the affected extremity.

Major problems for the individual who is newly one-handed, either permanently or temporarily, include reduction of work speed and dexterity, difficulty stabilizing objects in tasks that require both hands, and learning to use the normally nondominant hand to perform tasks that the dominant hand had previously performed. Occupational therapists have an important role in helping such individuals use adaptive strategies to perform occupations in ways that maximize safety and independence.

Dressing Activities

General setup.

If balance is a problem, the client should dress while seated in a locked wheelchair or sturdy armchair. Clothing should be within easy reach. Assistive devices should be used minimally for dressing and other ADLs. Compensatory techniques are preferable to using unnecessary devices. That said, a reacher may be helpful for securing articles and assisting in some dressing activities.

The following one-handed dressing techniques can facilitate dressing for persons who can use only one upper extremity. A general rule for putting on clothing is to begin with the affected arm or leg; start with the unaffected extremity when removing clothing. The following list summarizes the general setup.

- Begin by using a sturdy chair or wheelchair and progress to more difficult surfaces (eg, higher, lower, softer, or more unstable—yet safe—surfaces).
- Keep clothing within easy reach, and keep adaptive equipment set up and within reach.
- Support the feet (or foot) on floor or some other sturdy surface.
- Usually, maintain the body in the upright and midline positions, depending on the task.
- The therapist usually is positioned on the affected side or in the midline or front.

Shirts.

Any of the three following methods can be used to manage front-opening shirts. The first method can also be used for jackets, robes, sweaters, and front-opening dresses.

Method 1.

This method also works well with individuals who have decreased shoulder ROM or pain in the shoulders.

Donning a shirt

1. Grasp the shirt collar with the stronger hand and shake out any twists (Fig. 10.26A).

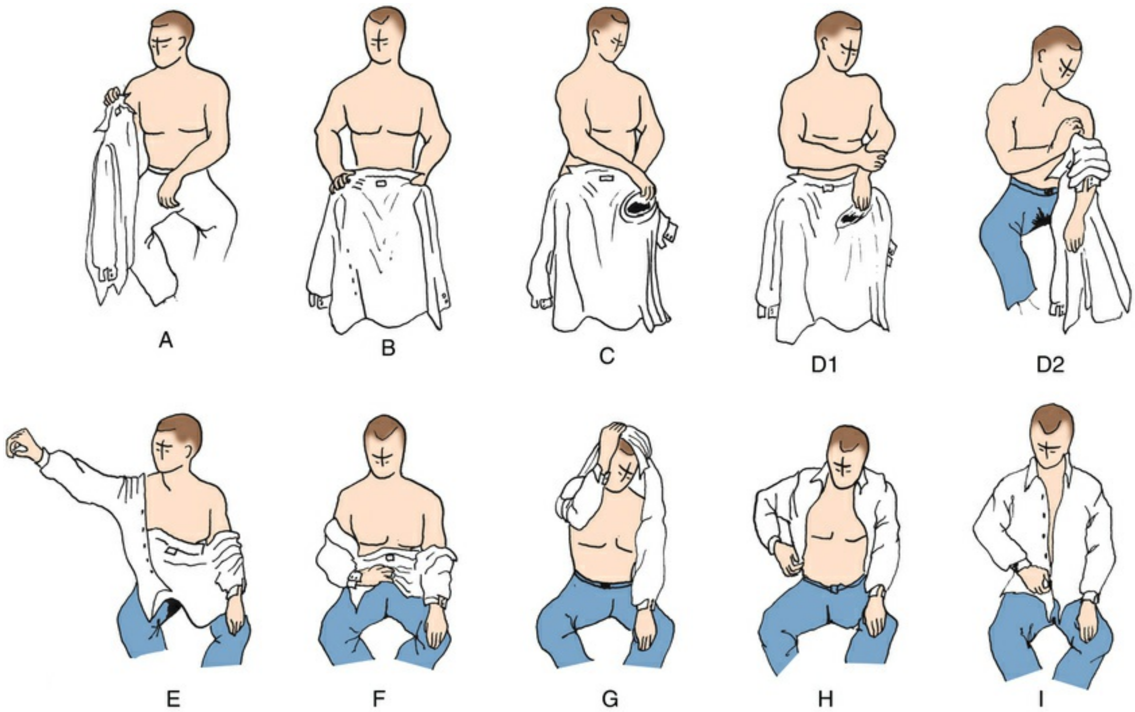

FIG 10.26 Steps in donning a shirt—method 1. (Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, OH.)

2. Position the shirt on the lap with the inside up and the collar toward the chest (Fig. 10.26B).

3. Position the sleeve opening on the affected side so that the opening is as large as possible and close to the affected hand, which is resting on the lap (Fig. 10.26C).

4. Using the stronger hand, place the affected hand in the sleeve opening and work the sleeve over the elbow by pulling on the garment. Make sure the affected hand is visible through the sleeve before proceeding to the next step (Fig. 10.26D1–D2).

5. Put the stronger arm into its sleeve and raise the arm to slide or shake the sleeve into position past the elbow (Fig. 10.26E).

6. With the stronger hand, gather the shirt up the middle of the back from hem to collar and raise the shirt over the head (Fig. 10.26F).

7. Lean forward, duck the head, and pass the shirt over the head (Fig. 10.26G).

8. With the stronger hand, adjust the shirt by leaning forward and working the shirt down past both shoulders. Reach in back and pull the shirttail down (Fig. 10.26H). Adjust the shirt so that it is smooth, any wrinkles have been removed, and the sleeve is properly positioned on the shoulders and arms. (A person with hemiplegia may not have the sensation, cognition, or vision to realize that a shirt needs adjustment.)

9. Line up the two sides of the shirt front for buttoning and begin with the bottom button (Fig. 10.26I). Button the sleeve cuff of the affected arm. The sleeve cuff of the stronger arm may be prebuttoned if the cuff opening is large. A button may be sewn on with elastic thread or sewn onto a small tab of elastic and fastened inside the shirt cuff (commercially available button extenders can be found in the adaptive equipment catalogs). A small button attached to a crocheted loop of elastic thread is another option. Slip the button on the loop through the buttonhole in the garment so that

the elastic loop is inside. Stretch the elastic loop to fit around the original cuff button. This simple device can be transferred to each garment and positioned before the shirt is put on. The loop stretches to accommodate the width of the hand as it is pushed through the end of the sleeve.

Removing a shirt

1. Unbutton the shirt.

2. Lean forward.

3. With the stronger hand, grasp the collar, or gather up the material in back from collar to hem.

4. Lean forward, duck the head, and pull the shirt over the head.

5. Remove the sleeve from the stronger arm first, then from the affected arm.

Method 2

Donning a shirt

1. Clients who get their shirts twisted or have trouble sliding the sleeve down onto the stronger arm can use method 2. Position the shirt as described in method 1, steps 1 to 3.

2. With the stronger hand, place the involved hand into the sleeve opening and work the sleeve onto the hand and forearm, but do not pull it all the way up over the elbow.

3. With the stronger arm, reach for the shirt from behind and wrap the shirt around the back. Put the stronger arm into the sleeve, and bring the arm out to the side (about 180 degrees of abduction) to get the shirt on. Tension on the fabric from the stronger arm to the wrist of the affected arm will bring the sleeve into position.

4. Lower the arm and work the sleeve on the affected arm up over the elbow.

5. Continue as in steps 6 through 9 of method 1.

Removing a shirt (one sleeve off at a time)

1. Unbutton the shirt.

2. With the stronger hand, push the shirt off the shoulders, first on the affected side and then on the stronger side.

3. Pull off the cuff of the stronger side with the stronger hand.

4. Work the sleeve off by alternately shrugging the shoulder, shaking the arm, and working the sleeve off the stronger arm.

5. Lean forward, bring the shirt around the back, and pull the sleeve off the affected arm.

Method 3

Donning a shirt

1. Position the shirt and work it onto the arm as described in method 1, steps 1 to 4.

2. Pull the sleeve on the affected arm up to the shoulder (Fig. 10.27A). The affected hand should be visible through the sleeve before the next step is done.

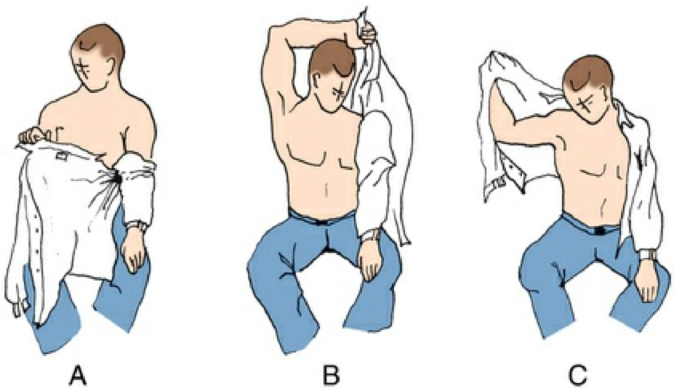

FIG 10.27 Steps in putting on a shirt—method 3. (Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, OH.)

3. With the stronger hand, grasp the tip of the collar on the stronger side, lean forward, and bring the arm over and behind the head, to wrap the shirt around to the stronger side (Fig. 10.27B).

4. Put the stronger arm into the sleeve opening, directing the arm up and out (Fig. 10.27C).

5. Adjust the shirt and button it as described in method 1, steps 8 and 9.

Removing a shirt.

The shirt may be removed using the procedure described for method 2.

Variation—donning a pullover shirt

1. Position the shirt on the lap, with the bottom of the shirt toward the chest and the label and front of the shirt facing down.

2. With the stronger hand, roll the bottom edge of the back of the shirt up to the sleeve on the affected side.

3. Position the sleeve opening so that it is as large as possible, and use the stronger hand to place the affected hand into the sleeve opening. While sitting upright, pull the shirt sleeve up onto the weaker arm past the elbow. Or, bend forward at the hips so that gravity can assist in placing the arm into the sleeve until the hand emerges from the cuff. Then, sit up and pull the sleeve onto the weaker arm past the elbow.

4. Insert the stronger arm into the sleeve.

5. Adjust shirt on the affected side up and onto the shoulder.

6. Gather the shirt back with the stronger hand, lean forward, duck the head, and pass the shirt over the head.

7. Adjust the shirt. Make sure it is adjusted properly on the shoulders and in the front and back.

Variation—removing a pullover shirt

1. Gather up the shirt with the stronger hand, starting at the top back.

2. Lean forward, duck the head, and pull the gathered back fabric over the head.

3. Remove the shirt from the stronger arm and then from the affected arm.

Trousers.

Trousers may be managed by one of the following methods, which may be adapted for shorts and women's panties. For some people, a well-constructed button fly front opening may be easier to manage than a zipper. Velcro may be used to replace buttons and zippers. Trousers should be worn in a size slightly larger than that worn previously and should have a wide opening at the ankles. They should be put on after the socks have been put on, but before the shoes are put on. If the client is dressing in a wheelchair, the feet should be placed flat on the floor, not on the footrests of the wheelchair.

Method 1

Donning trousers

1. Sit in a sturdy armchair or in a locked wheelchair (Fig. 10.28A).

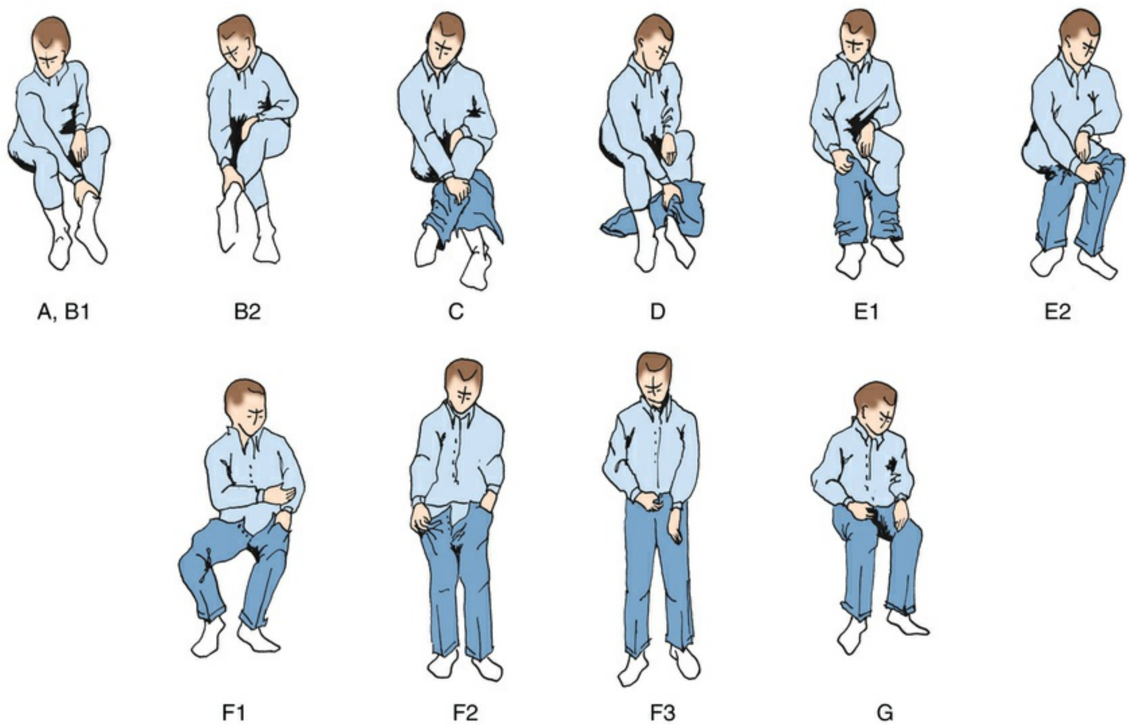

FIG 10.28 Steps in putting on trousers—method 1. (Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, OH.)

2. Position the stronger leg in front of the midline of the body with the knee flexed to 90 degrees. Using the stronger hand, reach forward and grasp ankle of affected leg or sock around ankle (Fig. 10.28B1). Lift the affected leg over the stronger leg to crossed position (Fig. 10.28B2).

3. Slip the trousers up the affected leg to a point where the foot is completely inside the trouser leg (Fig. 10.28C). Do not pull the trousers above the knee, or it will be difficult to insert the stronger leg.

4. Uncross the affected leg by grasping the ankle (or the portion of sock around the ankle) (Fig. 10.28D). Do not allow the affected leg to just drop because this can cause injury.

5. Insert the stronger leg and work the trousers up onto the hips as far as possible (Fig. 10.28E1–E2).

6. To prevent the trousers from dropping while pulling them over the hips, place the affected hand in the pocket or place one finger of the affected hand into a belt loop (this is an optional technique). If able to do so safely, stand and pull the trousers over the hips (Fig. 10.28F1–F2). This step may take more time and effort, but it is a tip that may prove useful for some.

7. If standing balance is good, remain standing to pull up zipper or to button (Fig. 10.28F3). Sit down to button front (Fig. 10.28G).

Removing trousers

1. Unfasten trousers and work them down the hips as far as possible while seated.

2. Stand, letting the trousers drop past the hips, or work them down past the hips.

3. Remove the trousers from the stronger leg first.

4. Sit and cross the affected leg over the stronger leg, remove the trousers, and uncross the leg.

Method 2

Donning trousers.

Method 2 is used in three situations: (1) for a client sitting in a wheelchair with the brakes locked, the footrests swung away, the feet on the ground, and the wheelchair anti-tips in place; (2) for a client sitting in a sturdy, straight-backed armchair that is positioned with the chair back against the wall; and (3) for a client who cannot stand independently. This method is not recommended for clients who cannot safely extend (bridge) the hips up; those who have severe sensory or perceptual deficits in the affected extremity; those with poor safety judgment and impulsivity control; or those who have a tendency to tip the wheelchair backward.

1. Position the trousers on the legs as in method 1, steps 1 through 5.

2. Elevate the hips by leaning back against the chair and pushing down against the floor with the stronger leg. As the hips are raised, work the trousers over them with the stronger hand.

3. Lower the hips back into the chair and fasten the trousers.

Removing trousers

1. Unfasten the trousers and work them down on the hips as far as possible while sitting.

2. Lean back against the chair, push down against the floor with the stronger leg to elevate the hips, and use the stronger arm to work the trousers down past the hips.

3. Proceed as in method 1, steps 3 and 4.

Method 3

Donning trousers.

Method 3 is used for clients in a recumbent position. It is more difficult to perform than the seated methods. If possible, the head of the bed should be raised to a semireclining position for partial sitting.

1. Using the stronger hand, place the affected leg in a bent position and cross it over the stronger leg, which may be partially bent to prevent the affected leg from slipping.

2. Position the trousers and work them onto the affected leg first, up to the knee. Then uncross the leg.

3. Insert the stronger leg and work the trousers up onto the hips as far as possible.

4. This step may be easier if the bed is flat. With the stronger leg bent, press down with the foot and shoulder to elevate the hips from the bed. With the stronger arm, pull the trousers over the hips, or work the trousers up over the hips by rolling from side to side. If bridging (hips off the bed) is difficult or not possible, the bed should be positioned flat, both knees can be bent, and the client can roll from side to side to hike the pants up over the hips.

5. Fasten the trousers.

Removing trousers

1. In bed, hike the hips by bridging (see Putting on trousers, method 3, step 4). Or, if bridging is not possible or is difficult, position the bed flat, bend the knees, and roll side to side to remove the pants from the hips.

2. Work the trousers down past the hips by bending the knees and rolling side to side; remove the pants first from the stronger leg and then from the affected leg.

Bra

Donning a bra

1. Tuck one end of the bra into the pants, girdle, or skirt waistband and wrap the other end around the waist (wrapping toward the affected side may be easiest). Hook the bra in front at waist level and slip the fastener section around to the back (at waistline level).

2. Place the affected arm through its shoulder strap; then place the stronger arm through the other strap.

3. Work the straps up over the shoulders. Pull the strap on the affected side up over the shoulder with the stronger arm. Put the stronger arm through its strap and work the strap up over the shoulder by directing the arm up and out and pulling with the hand.

4. Use the stronger hand to adjust the breasts in the bra cups.

Note: It is helpful if the bra has elastic straps and is made of stretch fabric. If there is some function in the affected hand, a fabric loop may be sewn to the back of the bra near the fasteners. The affected thumb may be slipped through the loop to stabilize the bra while the stronger hand fastens it. All-stretch bras, prefastened or without fasteners, may be put on by adapting method 1 for pullover shirts, described previously. For clients with some gross arm function, front-opening bras may be adapted with a loop for the affected hand.

Removing a bra

1. Slip the straps down off the shoulders, stronger side first.

2. Work the straps down over the arms and off the hands.

3. Slip the bra around to the front with the stronger arm.

4. Unfasten the bra and remove it.

Necktie

Putting on a necktie.

Clip-on neckties are convenient. If a conventional tie is used, the following method is recommended.

1. Place the collar of the shirt in the “up” position. Bring the necktie around the neck and adjust it so that the smaller end is at the desired length when the tie is completed.

2. Fasten the small end to the shirt front with a tie clasp or spring-clip clothespin.

3. Loop the long end of the tie around the short end (one complete loop) and bring it up the middle of the **V** at the neck. Then bring the tip down through the loop at the front and adjust the tie, using the ring and little fingers to hold the tie end, and the thumb and forefingers to slide the knot up tightly.

Removing a necktie

1. Pull the knot at the front of the neck until the small end slips up enough for the tie to be slipped over the head.

2. The tie may be hung up in this state. To put it on again, slip it over the head, position it around the upturned collar, and tighten the knot as described in step 3 of the preceding section.

Socks or stockings

Donning socks or stockings

1. Sit in a straight-backed armchair or in a wheelchair with the brakes locked, the feet on the floor, and the footrests swung away.

2. With the stronger leg directly in front of the midline of the body, cross the affected leg over the stronger leg.

3. Open the top of the stocking by inserting the thumb and first two fingers near the cuff and spreading the fingers apart.

4. Work the stocking onto the foot before pulling it over the heel. Care should be taken to eliminate wrinkles.

5. Work the stocking up over the leg. Shift the weight from side to side to adjust the stocking around the thigh.

6. Thigh-high stockings with an elastic band at the top are often an acceptable substitute for pantyhose, especially for the nonambulatory individual.

7. Pantyhose may be put on and taken off as for a pair of slacks, except that the legs are gathered up one at a time before the feet are placed into the leg holes.

Removing socks or stockings

1. Work the socks or stockings down as far as possible with the stronger arm.

2. Cross the affected leg over the stronger one as described in step 2 of the preceding section.

3. Remove the sock or stocking from the affected leg. A dressing stick may be required by some clients to push the sock or stocking off the heel and off the foot.

4. Lift the stronger leg to a comfortable height or to seat level and remove the sock or stocking from the foot.

Shoes.

If possible, select supportive slip-on shoes to eliminate lacing and tying. If an individual uses an ankle-foot orthosis (AFO) or short leg brace, shoes with fasteners are usually needed.

1. Use elastic laces and leave the shoes tied.

2. Use adapted shoe fasteners.

3. Use one-handed shoe-tying techniques (Fig. 10.29).

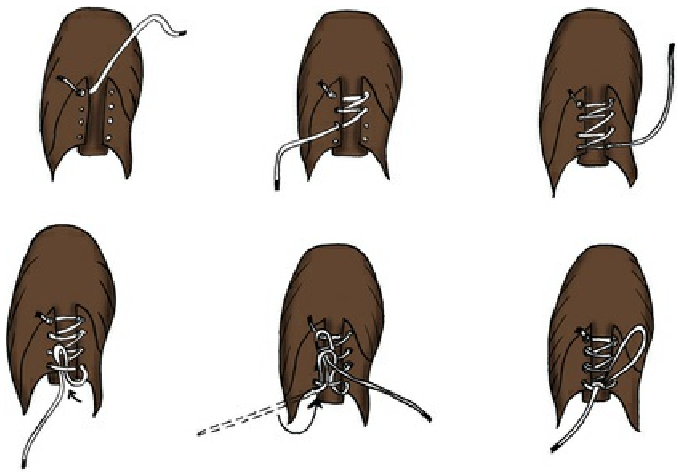

FIG 10.29 Method for tying shoelaces with one hand. (Courtesy Christine Shaw, Metro Health Center for Rehabilitation, Metro Health Medical Center, Cleveland, OH.)

4. It is possible to learn to tie a standard bow with one hand, but this requires excellent visual, perceptual, and motor planning skills, along with much practice.

Ankle-foot orthosis.

The individual with hemiplegia who lacks adequate ankle dorsiflexion to walk safely and efficiently frequently uses an AFO, which may be recommended by a physical therapist, prescribed by a physician, and made by an orthotist. The following methods are two techniques that may be used. The shoe needs to be half to one size bigger than usual.

Donning an ankle-foot orthosis

Method 1

1. Sit in a straight-backed armchair or in a wheelchair with the brakes locked and the feet on the floor. Loosen the fasteners on the shoe, and pull back the tongue to allow the AFO to fit into the shoe. Place the AFO into the shoe (Fig. 10.30A).

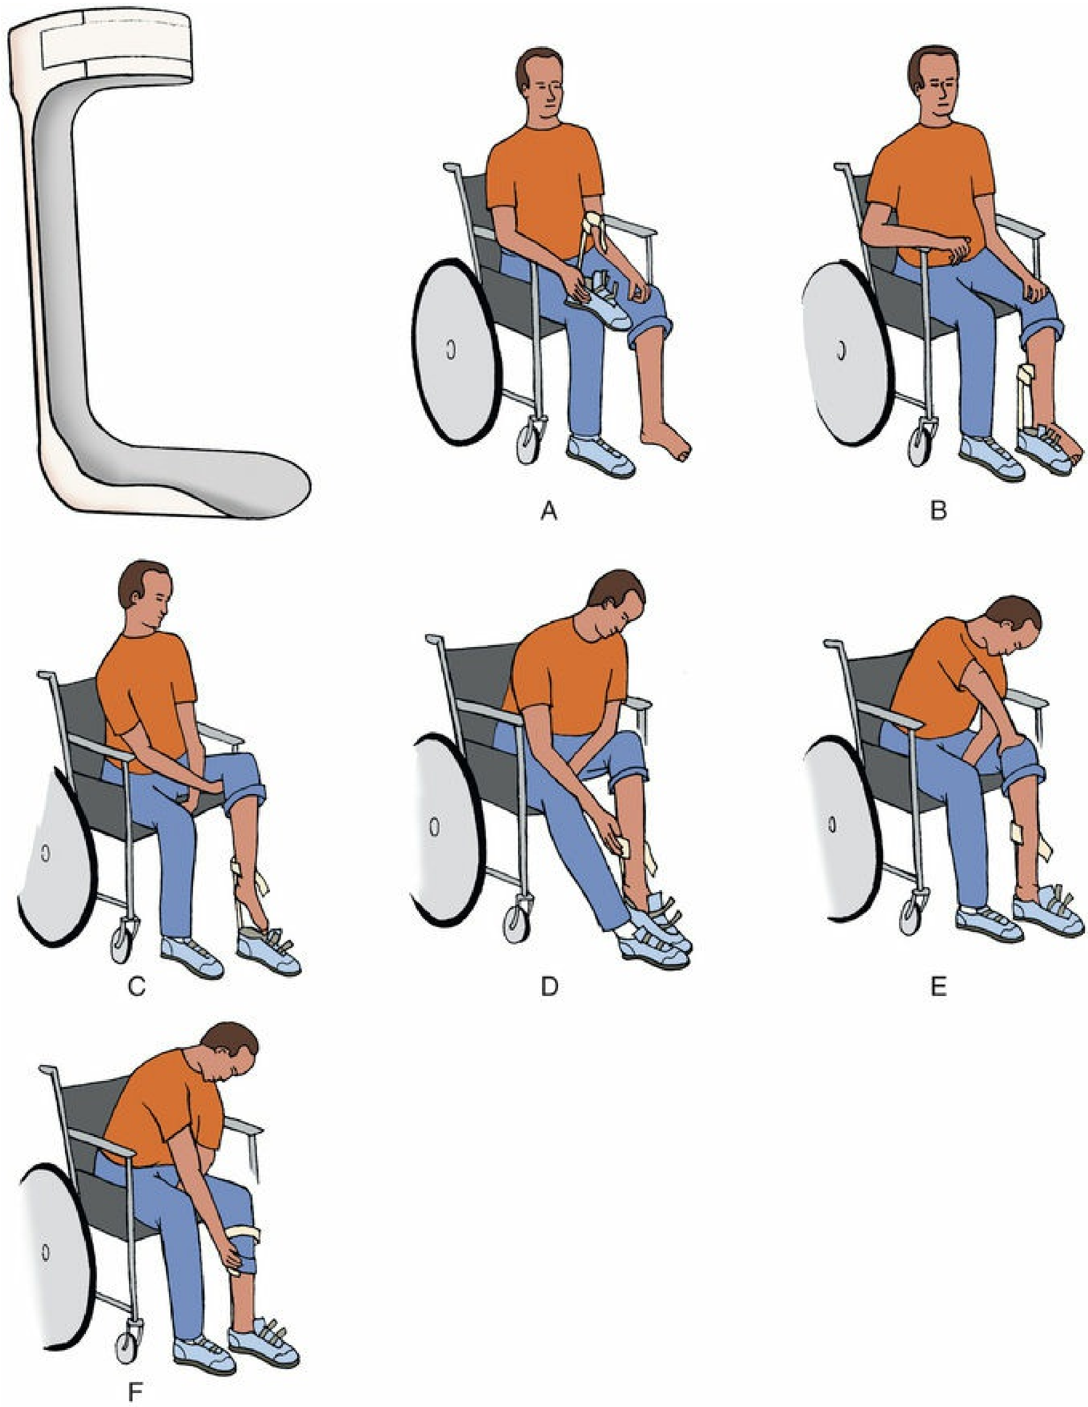

FIG 10.30 Steps in donning an ankle-foot orthosis (AFO).

2. Place the AFO and the shoe on the floor between the legs (but closer to the affected leg), facing up (Fig. 10.30B).

3. With the stronger hand, lift the affected leg behind the knee and place the toes into the shoe (Fig. 10.30C).

4. Reach down with the stronger hand and lift the AFO by the calf piece. Simultaneously, use the unaffected foot against the affected heel to keep the shoe and AFO together. The heel will not be pushed into the shoe at this point (Fig. 10.30D).

5. If leg strength is not sufficient, use the stronger hand to apply pressure directly downward on the

affected knee, pushing the heel into the shoe (Fig. 10.30E). To prevent injury, especially with clients who have poor sensation, make sure the client does not jam the heel into the AFO.

6. Fasten the Velcro calf strap, and then fasten the shoes (Fig. 10.30F). The affected leg may be placed on a footstool to assist with reaching shoe fasteners.

7. To fasten the shoes, the client may use one-handed bow-tying techniques, elastic shoelaces, or other commercially available shoe fasteners; alternatively, Velcro-fastened shoes may be used.

Method 2.

Steps 1 and 2 are the same as the positioning required for putting on trousers.

1. Sit in a sturdy armchair or in a locked wheelchair.

2. Position the stronger leg in front of the midline of the body with knee flexed to 90 degrees. Using the stronger hand, reach forward and grasp the ankle of the affected leg (or the sock around the ankle). Lift the affected leg over the stronger leg to crossed position.

3. Loosen the fasteners of the shoe and pull back the tongue to allow the AFO to fit into the shoe; unfasten the Velcro fastener on the AFO. Place the AFO in the shoe.

4. Using the stronger hand, hold the heel of the shoe and work the shoe over the toes of the affected foot and leg. Once the toes are in the shoe, work the top part of the AFO around the calf.

5. Pull the heel of the shoe onto the foot with the stronger hand, or place the foot on the floor, put pressure on the knee, and push the heel down into the shoe.

6. Fasten the Velcro calf strap on the AFO and then fasten the shoes.

Removing an ankle-foot orthosis

Variation 1

1. While seated as for putting on an AFO, cross the affected leg over the stronger leg.

2. Unfasten the straps of the AFO and the fasteners of the shoe with the stronger hand.

3. Push down on the calf part of the AFO until the shoe is off the foot.

Variation 2

1. Unfasten the straps of the AFO and the fasteners of the shoe with the stronger hand.

2. Straighten the affected leg by putting the stronger foot behind the heel of the shoe on the affected leg and pushing the affected leg forward.

3. Push down on the AFO upright with the stronger hand, and at the same time, push forward on the heel of the AFO shoe with the stronger foot.

Feeding Activities

A primary problem for individuals with only one functional hand is inability or difficulty using one hand to stabilize an object while using that same hand to perform another task. An example in feeding is a person with one functional hand trying to cut food, such as meat, using a knife while stabilizing the food at the same time. This problem can be resolved by the use of a rocker knife (Fig. 10.31) for cutting meat and other foods. This knife cuts with a rocking motion rather than a back-and-forth slicing action. Use of a rocking motion with a standard table knife or a sharp paring knife may be adequate to cut tender meats and soft foods. If such a knife is used, the client is taught to hold the knife handle between the thumb and the third, fourth, and fifth fingers, and the index finger is extended along the top of the knife blade. The knife point is placed in the food in a vertical position, and then the blade is brought down to cut the food. The rocking motion, using wrist flexion and extension, is continued until the food is cut. To stabilize a plate or bowl, a product such as foam-padded shelf liner or Dycem can be placed under it. There are many other adaptive devices, such as a plate guard (see Fig. 10.22), that the person who eats with only one fully functional hand can use.

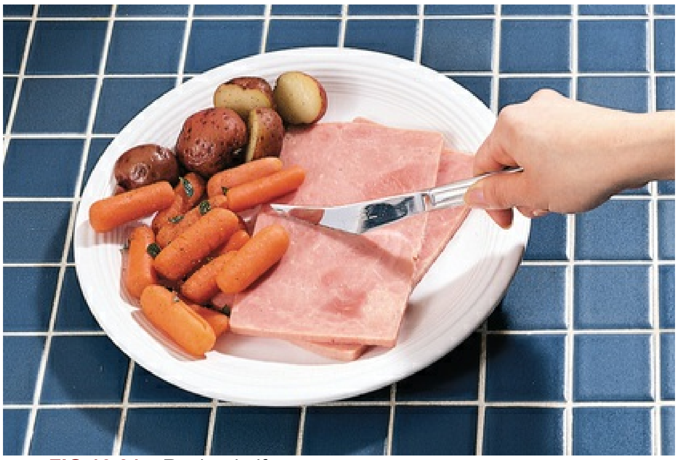

FIG 10.31 Rocker knife. (Courtesy Patterson Medical, Warrenville, IL.)

Another feeding issue that may arise is opening packages such as yogurt containers, drink bottles, and milk cartons, in addition to containers such as margarine tubs and ketchup holders. These tasks require practice, and the less functional hand should be incorporated into the task, if appropriate.

Personal Hygiene and Grooming Activities

Clients with the use of one hand or one side of the body can accomplish personal hygiene and grooming activities by using assistive devices and alternative methods. The following are suggestions for achieving hygiene and grooming with one hand.

1. Use an electric razor rather than a razor with a blade.

2. Use a shower seat in the shower stall or a transfer tub bench in a bathtub-shower combination. Other helpful devices include a bath mat, wash mitt, long-handled bath sponge, safety rails on the bathtub or wall, soap on a rope or a suction soap holder, and a suction brush for fingernail care.

3. Take a sponge bath while sitting at the lavatory using the wash mitt, suction brush, and suction soap holder. The stronger forearm and hand may be washed by placing a soaped washcloth on the thigh and rubbing the hand and forearm on the cloth.

4. Consider an easily accomplished hairstyle. Or, use a wall-mounted hair dryer, which frees the stronger upper extremity to hold a brush or comb to style the hair during blow-drying.[28]

5. As described previously for clients with incoordination, an emery board or small piece of wood with fine sandpaper glued to it can be fastened to the tabletop for filing nails, and a nail clipper can be stabilized in the same manner. For toenails, a large nail file can be used. If circulatory issues or diminished sensation is a problem, a podiatrist may need to be consulted or should perform this important but often neglected ADL.

6. Use a suction denture brush (see Fig. 10.24) for care of dentures. The suction fingernail brush may also serve this purpose.

Toileting

Clients with the use of one hand or one side of the body can accomplish toileting activities by using assistive devices and alternative methods. The following are suggestions for achieving independent and safe toileting with one hand.

1. Use a bedside commode with or without drop arms if unable to get to the bathroom quickly or safely (Fig. 10.32). Commodes can be placed over the toilet, with use of a splash guard (looks like a bucket without the bottom). Toilet safety frames and raised toilet seats can also facilitate safe transfers for toileting.

FIG 10.32 Drop-arm commode. (Courtesy North Coast Medical, Gilroy, CA.)

2. Use a urinal instead of transferring to the toilet. Female- and male-designed urinals are available, but female urinals are not always effective, depending on the client's body size. Spill-proof urinals are also available.

3. Grab bars can be strategically placed to assist with sit-to-stand or stand-to-sit movements.

4. Place toilet paper on the unaffected side.

5. Bidets or specialty toilets with wash, dry, and other features can be useful to optimize and facilitate cleansing.

6. Incontinence supplies may need to be considered, especially for community outings.

Communication Management and Environmental Adaptations

1. The primary problem with writing is stabilization of the paper or tablet. This problem can be overcome by using a clipboard, paperweight, or nonskid surface (eg, Dycem) or by taping the paper to the writing surface. In some instances, the affected arm may be positioned on the tabletop to stabilize the paper.

2. If dominance must be shifted to the nondominant extremity, writing practice may be necessary to improve speed and coordination. One-handed writing and keyboarding instruction manuals are available.

3. Book holders may be used to stabilize a book while reading or holding copy for typing and writing practice. A soft pillow placed on the lap easily stabilizes a book while the client is seated in a chair. Clients who enjoy reading may want to consider an electronic book reader (eg, Kindle), which allows touch page turning and options to increase the font size to the reader's preference.

4. Dialing numbers on a telephone with one hand requires several motions, including lifting the receiver to listen for the dial tone, setting it down, pressing the keys, and lifting the receiver to the ear. A speakerphone or headset can also leave the hands free to take messages. For writing while using the telephone, a stand or shoulder telephone receiver holder can be used for classic older model receivers. One-touch or voice-activated dialing using preprogrammed phone numbers eliminates or reduces the need to press as many keys, simplifies sequencing, and may help compensate for memory deficits.

Functional Mobility

Principles of transfer techniques for clients with hemiplegia are described in Chapter 11.

Home Management, Meal Preparation, and Cleanup Activities

Many assistive devices are available to facilitate home management and meal activities. Various factors determine how many home management and meal activities can realistically be performed, which methods can be used, and how many assistive devices can be managed. These factors include whether the client is disabled by the loss of function of one arm and hand, as in amputation or a peripheral neuropathic condition, or whether both arm and leg are affected, along with possible sensory, visual, perceptual, and cognitive dysfunctions, as in hemiplegia. The following are some suggestions for home management and meal activities for the client with the use of one hand.[49]

1. Stabilizing items is a major problem for the one-handed homemaker. Stabilize foods for cutting and peeling by using a cutting board with two stainless steel or aluminum nails in it. A raised corner on the board stabilizes bread for making sandwiches or spreading butter. Suction cups or a rubber mat under the board will keep it from slipping. A nonskid surface or rubber feet may be glued to the bottom of the board.

2. Use nonskid mats or pads, wet dishcloths, or suction devices to keep pots, bowls, and dishes from turning or sliding during food preparation.

3. To open a jar, stabilize it between the knees or in a partially opened drawer while leaning against the drawer. Break the air seal by sliding a pop bottle opener under the lid until the air is released, then use a Zim jar opener (Fig. 10.33).

FIG 10.33 Zim jar opener. (Courtesy ZIM Manufacturing, Chicago, IL.)

4. Open boxes, sealed paper, and plastic bags by stabilizing between the knees or in a drawer as just described and cut open with household shears. Special box and bag openers are also available from ADL equipment vendors.

5. Crack an egg by holding it firmly in the palm of the hand. Hit it in the center against the edge of the bowl. Then, using the thumb and index finger, push the top half of the shell up and use the ring and little fingers to push the lower half down. Separate whites from yolks by using an egg separator, funnel, or large slotted spoon.

6. Eliminate the need to stabilize the standard grater by using a grater with suction feet, or use an electric countertop food processor instead.

7. Stabilize pots on the counter or range for mixing or stirring by using a pan holder with suction feet (Fig. 10.34).

FIG 10.34 Pan stabilizer. (Courtesy SP Ableware–Maddak, Inc., Wayne, NJ.)

8. Eliminate the need to use hand-cranked or electric can openers, which necessitate the use of two hands, by using a one-handed electric can opener.

9. Use a utility cart to transfer items from one place to another. For some clients, a cart that is weighted or constructed of wood may be used as a minimal support during ambulation.

10. Transfer clothes to and from the washer or dryer by using a clothes carrier on wheels.

11. Use electrical appliances (eg, lightweight electrical hand mixer, immersion blender, traditional blender, and food processor) that can be managed with one hand and that save time and energy. Safety factors and judgment need to be evaluated carefully when electrical appliances are considered.

12. Floor care becomes a greater problem if, in addition to one arm, ambulation and balance are affected. For clients with involvement of only one arm, a standard dust mop, carpet sweeper, or upright vacuum cleaner should present no problem. A self-wringing mop may be used if the mop handle is stabilized under the arm and the wringing lever operated with the stronger arm. Clients with balance and ambulation problems may manage some floor care from a sitting position. Dust mopping or using a carpet sweeper may be possible if gait and balance are fairly good without the aid of a cane. Some people may benefit from a programmable robotic vacuum cleaner (Roomba) or floor scrubber (Scooba) from iRobot[45] (*http://store.irobot.com/home/index.jsp*). However, careful consideration must be used for these devices because they can also be a safety or tripping hazard if they do not return to the docking station.

These are just a few of the possibilities for solving homemaking problems for one-handed individuals. The occupational therapist must evaluate each client to determine how the dysfunction affects the performance of homemaking activities. One-handed techniques take more time and may be difficult for some clients to master. Activities should be paced to accommodate the client's physical endurance and tolerance for one-handed performance and use of special devices. Fatigue management techniques should be used. New techniques and devices should be introduced on a graded basis as the client masters first one technique and device and then another. Family members need to be oriented to the client's skills, special methods used, and schedule. The therapist, with the family and client, may facilitate the planning of homemaking responsibilities to be shared by other family members, in addition to the supervision of the client, if that is needed. If special equipment and assistive devices are needed for IADLs, it is advisable for the client to practice using the devices in the clinic if possible. The therapist can then train the client and demonstrate use of the equipment to a family member before these items are purchased and used at home. After training, the occupational therapist should provide the client with sources for replacing items independently, such as a consumer catalog of adaptive equipment or websites.

ADLs for the Person With Paraplegia

Clients who must use a wheelchair for mobility need to find ways to perform ADLs from a seated position, to transport objects, and to adapt to an environment designed for standing and walking. Given normal function in the upper extremities and otherwise good health, the wheelchair user can probably perform ADLs independently. The client should have a stable spine or use an appropriate orthotic or stabilization device, and the healthcare provider should clearly identify mobility precautions.

Dressing Activities

It is recommended that clients who must use wheelchairs put on clothing in this order: stockings or socks, undergarments, braces (if worn), slacks, shoes, and then shirt or dress. Underwear may be eliminated because it is an extra step, has the potential to contribute to skin breakdown, and results in greater difficulty for toileting. During the initial rehabilitation, the client with paraplegia will likely begin dressing training in bed; as his or her strength, endurance, and balance improve, the client will progress to dressing in the wheelchair. The ability to dress in the wheelchair simplifies toileting by eliminating the need to go back to bed to manage clothing.

Slacks

Putting on slacks.

Slacks are easier to fasten if they button or zip in front. If braces are worn, zippers in side seams may be helpful. Wide-bottom slacks of stretch fabric are recommended. The following steps comprise the procedure for putting on shorts, slacks, and underwear.

1. Use side rails, a trapeze, or other adaptive technique to pull up to a sitting position, with the back supported by pillows or the headboard of the bed. If side rails or a trapeze is not required, the client props up on the elbows in a semireclined position and generates momentum by alternately pushing with one elbow and then the other until the elbow comes up high enough for the client to prop the hands on the bed.[48]

2. Sit on the bed and reach forward to the feet, or sit on the bed and pull the knees into flexed position.

3. Holding the top of the slacks, flip the pant legs down to the feet.

4. Work the pant legs over the feet, and pull the slacks up to the hips. Crossing the ankles may help get the slacks over the heels.

5. In a semireclining position, using rotation and momentum by typically transferring momentum from the arms to the trunk, to the pelvis, and then to the lower extremities,[48] roll to one side, hike up the slacks, and then roll to the other side and pull up the pant leg.

6. A long-handled reacher may be helpful for pulling the slacks up or positioning them on the feet if the client has impaired balance or ROM in the lower extremities or trunk.

Removing slacks.

Remove slacks and underwear by reversing the procedure for putting them on. Dressing sticks may be helpful for pushing slacks off the feet.

Socks or stockings.

Soft stretch socks or stockings are recommended. Pantyhose that are slightly larger may be useful. Elastic garters or stockings with elastic tops should be avoided because of potential skin breakdown. Dressing sticks or a stocking device may be helpful to some clients.

Donning socks or stockings

1. Put on socks or stockings while sitting up in bed with the legs extended (long-sitting).

2. While propped up when long-sitting with the legs initially extended, pull one leg into flexion with one hand and cross the leg over onto the other extended leg.

3. Use the other hand to slip the sock or stocking over the foot, and pull on the sock or stocking. To prevent pressure skin breakdown, make sure there are no wrinkles or creases in the socks.

Removing socks or stockings.

Remove socks or stockings by flexing the leg as described for putting them on, and then push the sock or stocking down over the heel. A dressing stick may be needed to push the sock or stocking off the heel and toe and to retrieve the sock. This is a good time to perform a skin check on the feet and lower legs to detect any skin breakdown or red areas.

Slips and skirts.

Slips and skirts slightly larger than usually worn are recommended. **A**-line, wraparound, and full skirts are easier to manage and may drape better on a person seated in a wheelchair than narrow skirts, which can ride up.

Putting on slips and skirts

1. Sit on the bed, slip the garment over the head, and let it drop to the waist.

2. In a semireclining position, roll from hip to hip and pull the garment down over the hips and thighs.

Removing slips and skirts

1. In a sitting or semireclining position, unfasten the garment.

2. Roll from hip to hip, pulling the garment up to waist level.

3. Pull the garment off over the head.

Shirts.

Fabrics should be wrinkle resistant, smooth, and durable. Roomy sleeves and backs and full shirts may make this clothing easier to put on and take off than closely fitted garments.

Donning a shirt.

Shirts, pajamas, jackets, robes, and dresses that open completely down the front may be put on while the client is seated in a wheelchair. If it is necessary to dress while in bed, the following procedure can be used.

1. Balance the body by putting the palms of the hands on the mattress on either side of the body. If the client's balance is poor, assistance may be needed, or the backboard or head of the bed may need to be elevated. (If the backboard cannot be elevated, one or two pillows may be used to support the back.) With the backboard or head of the bed elevated, both hands are available.

2. If difficulty occurs with the customary methods of putting on the garment, open it on the lap with the collar toward the chest. Put the arms into the sleeves and pull them up over the elbows. Then, holding on to the shirttail or back of the dress, pull the garment over the head, adjust it, and button it.

Removing a shirt

1. Sitting in a wheelchair or on the bed, open the fasteners.

2. Remove the garment in the usual manner.

3. If the usual manner is not feasible, grasp the collar with one hand while balancing with the other hand. Gather up the material from collar to hem.

4. Lean forward, duck the head, and pull the shirt over the head.

5. Remove the arms from the sleeves, first the supporting arm and then the working arm.

Shoes

Donning shoes.

If an individual has sensory loss and is at risk for injury during transfers, shoes should be put on in bed.

Variation 1

1. Sit on the bed, on the edge of the bed (requires good balance, high skill), or in a wheelchair for back support. Pull one knee at a time into the flexed position with the hands.

2. While supporting the leg in the flexed position with one hand, use the free hand to put on the shoe.

Variation 2

1. Sit on the edge of the bed or in a wheelchair for back support.

2. Cross one leg over the other and slip the shoe onto the foot.

3. If sitting in a wheelchair, put the foot on the floor or footrest and press down on the knee to push the foot into the shoe.

Removing shoes

1. Flex or cross the leg as described for the appropriate variation.

2. For variation 1: Remove the shoe with one hand while supporting the flexed leg with the other hand.

3. For variation 2: Remove the shoe from the crossed leg with one hand while maintaining balance with the other hand, if necessary.

Feeding Activities

Eating activities should present no problem for the person who uses a wheelchair but has good to normal arm function. Wheelchairs with desk-style armrests and footrests that fit under tabletops are recommended so that the client can sit close to the table. Footrests on the wheelchair may be detachable or fixed but need to function within the client's environment for maximum independence.

Personal Hygiene and Grooming Activities

Facial and oral hygiene and arm and upper body care should present no problem. Reachers may be helpful for getting towels, washcloths, makeup, deodorant, and shaving supplies from storage areas. Special equipment is needed for tub baths and showers. (Transfer techniques for the toilet and bathtub are discussed in Chapter 11.) The following are suggestions for facilitating safety and independence during bathing activities.

1. Use a handheld shower hose and keep a finger over the spray to determine sudden temperature changes in the water. Make sure the water heater is set at a safe temperature (120°F [49°C]) to prevent scald burns.[87]

2. Use a long-handled bath brush with a soap insert for ease in reaching all parts of the body.

3. Use soap bars attached to a cord around the neck, or use liquid soap.

4. Use a padded shower chair or padded transfer tub bench. Consider a commode cutout if the bowel program is performed in the shower.

5. Increase safety during transfers by installing grab bars on the wall near the bathtub or shower and on the bathtub to provide a balance point during transfers and when bending to wash the legs and buttocks.

6. Fit a bathtub or shower floor with a nonskid mat or adhesive material.

7. Remove doors on the bathtub and replace with a shower curtain to increase safety and ease of transfers.

Skin integrity and hygiene.

Because sensory loss increases the risk of skin breakdown, regular skin checks and weight shifts should be considered a normal part of the ADL routine. Clients should be instructed in the following procedures.

1. Checking for potential areas of skin breakdown and signs of developing skin problems, and

practicing methods to maintain good skin integrity.

2. How and when to perform proper weight shifts while up in the wheelchair and how to position oneself in bed to prevent skin breakdown.

3. Performing skin checks and complying with the recommended frequency. The client can use a long-handled mirror (Fig. 10.35) to see areas that are otherwise difficult to observe.

FIG 10.35 Long-handled mirrors. (Courtesy North Coast Medical, Gilroy, CA.)

4. Maintaining all equipment to ensure that disrepair is not contributing to skin breakdown. For example, a tear in a padded tub bench could tear the skin on the buttocks, resulting in skin breakdown.

Bowel and bladder management.

The physician customarily is responsible for prescribing the bowel and bladder program, but the OT and other team members can provide valuable insight into adaptations and routines that may be ideal or most suitable.[76] For example, an occupational therapist, along with nursing staff members, may be involved in instructing the client about digital stimulation or the use of intermittent catheterization for elimination. Helping the client establish a routine for this ADL is important because ineffective bowel and bladder management may lead to significant limitations in other activities, if the client is experiencing accidents or infections. Significant time and close monitoring may be required to perform this crucial ADL, which can affect many aspects of life. An interdisciplinary approach is critical for health maintenance in bowel and bladder care. The following are some areas in which an occupational therapist may be helpful.

1. Determining the optimal DME for performing a task (eg, a padded commode, padded raised toilet seat, or padded roll-in-shower chair) and practicing transfers on and off toileting surfaces.

2. Assisting the interdisciplinary team in determining a client's readiness and cognitive/physical/emotional capacity to learn and perform the required skills.[76]

3. Determining the appropriate adaptive equipment and/or techniques for performing tasks such as inserting a suppository or an adaptive digital stimulator for bowel management, and emptying leg bags and inserting catheters for bladder management. Clothing management and perineal hygiene tasks may also be determined and practiced,[76] and the OT may make recommendations for adaptive equipment such as pants holders and electric bag openers.

4. Developing strategies to manage intermittent catheterization in public bathrooms, homes of friends, and the workplace; determining conveniences, such as using a waist pack to hold items; and establishing methods to sanitize the hands.[47,76]

5. Considering the importance of how the prescribed bowel and bladder programs can be integrated into a client's and family's life, and helping to figure out a routine.[76]

6. Educating the client and family on the health risks that arise with poor follow-through or noncompliance, such as constipation, urinary tract infections, and accidents and autonomic dysreflexia for a client with quadriplegia/tetraplegia or a higher thoracic spinal cord injury (SCI).[76]

Communication Management and Environmental Adaptations

With the exception of reaching difficulties in some situations, use of the telephone should present no problem. Short-handled reachers may be used to grasp the receiver from the cradle. A cordless telephone can eliminate reaching, except when the phone needs recharging. A mobile phone or smart phones can also be used. The use of writing implements and a personal computer should be possible. Managing doors may present some difficulties. If the door opens toward the person, it can be opened using the following procedure (Fig. 10.36).

1. If the doorknob or handle is on the right, approach the door from the right and turn the doorknob or pull the handle with the left hand.

2. Open the door as far as possible and move the wheelchair close enough so that it helps keep the door open.

3. Holding the door open with the left hand, turn the wheelchair with the right hand and wheel through the door.

4. Start closing the door when halfway through.

FIG 10.36 Independent navigation through an open door with the door opening toward the client. A, As the door is pulled open, the wheelchair is angled and ready to pivot. B, The client turns and begins to move the wheelchair through the doorway. C, The client pulls on the door frame with one hand and pushes the door farther open with the other. D, The client then quickly propels the wheelchair through the doorway. If the door closes before the client is all the way through, the client allows the door to bump against the wheelchair (first moving his or her hand out of the way) and then applies an additional push to the door. (From Fairchild SL: *Pierson and Fairchild's principles and techniques of patient care,* ed 5, St Louis, 2013, Saunders.)

If the door is very heavy and opens out or away from the person, the following procedure is recommended.

1. Back up to the door so that the knob can be turned or the handle operated with the right hand.
2. Open the door and back through it so that the large drive (rear) wheels keep it open.
3. Also use the left elbow to keep the door open.
4. Propel backward with the right hand.

Functional Mobility

Principles of transfer techniques are discussed in Chapter 11.

Home Management, Meal Preparation, and Cleanup Activities

When homemaking activities are performed from a wheelchair, the major problems are work heights, adequate space for maneuverability, access to storage areas, and transport of supplies, equipment, and materials from place to place. If funds are available for kitchen remodeling, recommendations include lowering the counters to a comfortable height for wheelchair use and opening the space under the counters and the range. Such extensive adaptation is often not feasible, however. The following are some suggestions for homemaking activities.[49]

1. Remove cabinet doors to eliminate the need to maneuver around them for opening and closing. Frequently used items should be stored toward the front of easy to reach cabinets above and below the counter surfaces.

2. If entrance and inside doors are not wide enough, make doors slightly wider by removing the strips along the doorjambs. Offset hinges can replace standard door hinges and increase the doorjamb width by 2 inches (Fig. 10.37).

FIG 10.37 A, Offset door hinges allow for a wider doorway for wheelchair users. B, Close-up of offset hinges. (**A** courtesy How to Adapt: *www.howtoadapt.com*; **B** courtesy Brigs Healthcare, West Des Moines, IA.)

3. Use a wheelchair cushion to increase the user's height so that standard-height counters may be used. This recommendation may or may not work for some because changing cushions takes energy and/or may have consequences for skin care or safety.

4. Detachable, desk-style armrests allow wheelchair users to get closer to counters and tables than is possible with detachable (or fixed) full-length armrests. Swing-away detachable footrests should be removed to allow the client to get closer to counters and tables, and also to stand at counters if possible.

5. Transport items safely and easily with a wheelchair lapboard. The lapboard may also serve as a work surface for writing, preparing food, or drying dishes (Fig. 10.38). It protects the lap from injury from hot pans and prevents utensils from falling into the lap. Use silicone pads as nonslip surfaces and to prevent burning.

FIG 10.38 Wheelchair with lapboard. (Courtesy North Coast Medical, Gilroy, CA.)

6. Fasten a drop-leaf board to a bare wall, or install a slide-out board under a counter to provide a work surface that is a comfortable height in a kitchen that is otherwise standard. When not in use, the drop-leaf board can be securely fastened to the wall to increase accessibility to the kitchen space.

7. Place a cutting board on an open drawer to set up a workstation. The drawer should be stable when pulled out and should be at a height that allows the wheelchair user to roll under it and reach with a comfortable arm position.

8. Fit cabinets with custom or prefabricated pullout shelves for ease in reaching back spaces.

9. Pull-down cupboards can be installed for reaching stored items.[24]

10. A commercially available wooden or plastic round turntable, commonly known as a lazy Susan, can be used to store items for easy access by just rotating the device.

11. Cook tops that are open underneath to accommodate wheelchairs and front-panel stove controls are easier to access.[24]

12. Tilted or angled mirrors over the range can allow cooks to see the contents of pots.

13. A small electric toaster oven with a microwave oven or a microwave convection oven can be substituted for the range if the range is not safely manageable.

14. Ovens that have doors that swing sideways (instead of the standard doors that open down) can make it safer to put items into an oven and take them out.[24]

15. Use front-loading washers and dryers. Use a reacher for items that are difficult to access in the washer and dryer.

16. Vacuum carpets with a carpet sweeper or tank-type cleaner that rolls easily and is lightweight or self-propelled. A retractable cord may prevent the cord from tangling in the wheels.

17. Sweep and mop floors with lightweight swivel head cleaners that allow easier reach.

ADLs for the Person With Quadriplegia/Tetraplegia

For an overview of expected functional outcomes for ADLs and IADLs for each level of SCI, refer to the detailed tables in Chapter 36. Expected outcomes depend in part on whether a complete or incomplete injury occurred. Persons with C1-4 injuries will require assistance for all ADLs except communication and mobility, if appropriate equipment is available. A person with a C5 injury will require considerable special equipment and assistance. (Externally powered orthotics and arm braces or mobile arm supports are recommended for C3, C4, and C5 levels of muscle function; see Chapter 30, Section 2, and Chapter 36.) Individuals with muscle function from C6 can be relatively independent with adaptations and assistive devices and may benefit from the use of a wrist-driven flexor hinge hand splint (also known as a tenodesis hand splint).

It is important to consider that some people, such as those with high-level quadriplegia/tetraplegia (eg, C1-4 injury), may be physically dependent in performing an ADL or IADL but independent in directing others to assist in those areas. It is within the purview of the OT to ensure that such clients can independently direct others, such as personal care attendants, in ADLs and IADLs as needed.[6]

Dressing Activities

Training in dressing can be commenced when the spine is stable and precautions, if present, are followed. The minimum criteria for upper extremity dressing are:

1. Fair to good muscle strength in the deltoids, upper and middle trapezii, shoulder rotators, rhomboids, biceps, supinators, and radial wrist extensors.

2. ROM of 0 degrees to 90 degrees in shoulder flexion and abduction, 0 degrees to 80 degrees in shoulder internal rotation, 0 degrees to 30 degrees in external rotation, and 15 degrees to 140 degrees in elbow flexion.

3. Sitting balance in bed or wheelchair, which may be achieved with the assistance of bed rails, an electric hospital bed, or a wheelchair safety belt.

4. Finger prehension achieved with adequate tenodesis grasp or wrist-driven flexor hinge orthosis.

Additional criteria for dressing the lower extremities are:

1. Fair to good muscle strength in the pectoralis major and minor, serratus anterior, and rhomboid major and minor.

2. ROM of 0 degrees to 120 degrees in knee flexion, 0 degrees to 110 degrees in hip flexion, and 0 degrees to 80 degrees in hip external rotation.

3. Body control for transfer from bed to wheelchair with minimal assistance.

4. Ability to roll from side to side, turn from supine position to prone position and back, and balance in side-lying.

5. Vital capacity must be greater than 50%.

Dressing is contraindicated if any of the following factors are present[17,68]:

1. Unstable spine at the site of injury

2. Pressure sores or a tendency for skin breakdown during rolling, scooting, and transferring

3. Uncontrollable muscle spasms in the legs

4. Less than 50% vital capacity

Sequence of dressing.

The recommended sequence for training to dress is to put on slacks while still in bed, then transfer to a wheelchair and put on shirt, socks, and shoes.[68] Some clients may want to put on their socks before their pants because socks may help the feet slip through the pant legs more easily. They may also want to put on their shoes in bed, after putting on their slacks, to prevent injury during the transfer.

Expected proficiency.

Clients with spinal cord lesions at C7 and below can achieve independence with dressing for both the upper and lower extremities. Clients with lesions at C6 can also achieve independence with dressing, but lower extremity dressing may be difficult or impractical in terms of time and energy for these clients. Clients with lesions at C5 to C6 can achieve independence in upper extremity dressing, with some exceptions. It is difficult or impossible for these clients to put on a bra, tuck a shirt or blouse into a waistband, or fasten buttons on shirt fronts and cuffs. Factors such as age, physical proportions, coordination, secondary medical conditions, and motivation affect the degree of proficiency in dressing skills that any client can achieve.[17] Many people with various injuries, including quadriplegia/tetraplegia, now post educational videos on sites such as YouTube to share how they perform ADLs such as dressing. Others post on websites such as the SCI Video Blog (*http://www.scivideoblog.com*) to demonstrate techniques and share them with others who have similar injuries. However, it is important for the information to be vetted by more experienced therapists and sources to ensure that the techniques are appropriate.

Types of clothing.

Clothing should be loose and have front openings. Slacks need to be a size larger than usually worn to accommodate the urine collection device or leg braces if worn. Wraparound skirts and incontinence pads are helpful for women. The fasteners that are easiest to manage are zippers and Velcro closures. Because the client with quadriplegia often uses the thumb as a hook to manage clothing, loops attached to zipper pulls, undershorts, and even the back of the shoes can be helpful. Belt loops sewn onto the waistbands of slacks with reinforced stitching are used for pulling. Bras should have stretch straps and no wires. Front-opening bra styles can be adapted by fastening loops and adding Velcro closures; back-opening styles can have loops added at each side of the fastening. Underwear may be eliminated because it is an extra step, has the potential to contribute to skin breakdown, and results in greater difficulty in toileting.

Shoes can be one-half to one size larger than normally worn to accommodate edema and spasticity and to prevent pressure sores and even autonomic dysreflexia. Shoe fasteners can be adapted with Velcro, elastic shoelaces, large buckles, or flip-back tongue closures. Some people use shoes with zippers and looped draw cords with adjustable stoppers. Loose woolen or cotton socks without elastic cuffs should be used initially. Nylon socks, which tend to stick to the skin, may be used as skill is gained. If neckties are used, the clip-on type or a regular tie that has been preknotted and can be slipped over the head may be manageable for some clients.

Slacks

Donning slacks (SCI level C6-7).

Setup—pants, socks, shoes, and adaptive devices (if needed) can be placed in the wheelchair, which is placed next to the bed the night before for easier access when the client gets dressed in the morning.

Method 1 (no assistive device)

1. Long-sit on the bed with the bed rails up and, if needed, the head of the bed elevated (if using a full electric bed). Position the slacks at the foot of the bed with the pant legs over the end of the bed and front side up.[68] Sit up and lift one knee at a time by hooking the right hand under the right knee to pull the leg into flexion; put pants over the right foot. Return the right leg to extension or semiextended position and repeat the procedure with the left hand and left knee. Work the slacks up the legs, using patting and sliding motions with the palms of the hands. While still long-sitting, with the pants to midcalf height, insert a dressing stick into a front belt loop. Grip the stick by

slipping its loop over the wrist. Pull on the dressing stick while extending the trunk, returning to the supine position. Return to the sitting position and repeat this procedure, pulling on the dressing sticks and maneuvering the slacks up to thigh level. Remain long-sitting, lean on the left elbow, and pull the slacks over the right buttock; reverse the process for the other side.

Alternatively, remain in the supine position and roll to one side; place the opposite arm behind the back; hook the thumb in the waistband, belt loop, or pocket, and pull the slacks up over the hips. These maneuvers can be repeated as often as necessary to get the slacks over the buttock. (YouTube videos demonstrating this technique have been posted by individuals who have been injured, such as Beau Vernon.[91]) Using the palms of the hands in pushing and smoothing motions, straighten the slack legs.

2. In the supine position, fasten the slacks by hooking the thumb in the loop on zipper pull, patting the Velcro closed, or using hand splints and buttonhooks for buttons or a zipper pull.[17,64]

Method 2—assistive device

1. Follow steps 1 and 2 in method 1.

2. If unable to maintain the leg in flexion by holding it with one arm or through advantageous use of spasticity, use a dressing band. This device is a piece of elasticized webbing that has been sewn into a figure-eight pattern, with a small loop and a large loop. The small loop is hooked around the foot, and the large loop is anchored over the knee. The band is measured for the individual client so that its length is appropriate to maintain the desired amount of knee flexion. Once the slacks are in place, the knee loop is pushed off the knee and the dressing band is removed from the foot with a dressing stick.

3. Work the slacks up the legs, using patting and sliding motions with the palms of the hands. While still long-sitting, with the pants to midcalf height, insert the dressing stick into a front belt loop. Grip the dressing stick by slipping its loop over the wrist. Pull on the dressing stick while extending the trunk, returning to the supine position. Return to the sitting position and repeat this procedure, pulling on the dressing sticks and maneuvering the slacks up to thigh level.

4. Follow steps 5 and 6 in method 1.

Variation.

Substitute the following for step 2: Sit up and lift one knee at a time by hooking the right hand under the right knee to pull the leg into flexion, then cross the foot over the opposite leg (which is extended) above the knee. This position frees the foot so that the slacks can be placed more easily, and it requires less trunk balance. Continue with all other steps.

Removing slacks (SCI level C6-7)

1. Lying supine in the bed (a flat bed is easier than if the head of the bed is up) with the bed rails up, unfasten the belt and fasteners.

2. Placing the thumbs in the belt loops, waistband, or pockets, work the slacks past the hips by stabilizing the arms in shoulder extension and scooting the body toward the head of the bed.

3. Use the arms as described in step 2 and roll from side to side to get the slacks past the buttocks.

4. Coming to a sitting position and alternately pulling the legs into flexion, push the slacks down the legs.

5. Slacks can be pushed off over the feet with a dressing stick or by hooking the thumbs in the waistband.

Front-opening and pullover garments (SCI level C5-7).

Front-opening and pullover garments include blouses, jackets, vests, sweaters, skirts, and front-opening dresses.[17,64] Upper extremity dressing is frequently performed in the wheelchair for greater trunk stability.

Donning front-opening or pullover garments (SCI level C5-7)

1. Position the garment across the thighs with the back facing up and the neck toward the knees.

2. Place both arms under the back of the garment and in the armholes.

3. Push the sleeves up onto the arms, past the elbows.

4. Using a wrist extension grip, hook the thumbs under the garment back and gather up the material from the neck to the hem.

5. To pass the garment over the head, adduct and externally rotate the shoulders and flex the elbows while flexing the head forward.

6. When the garment is over the head, relax the shoulders and wrists and remove the hands from the back of the garment. Most of the material will be gathered up at the neck, across the shoulders, and under the arms.

7. To work the garment down over the body, shrug the shoulders, lean forward, and use elbow flexion and wrist extension. Use the wheelchair arms for balance if necessary. Additional maneuvers to accomplish this task are to hook the wrists into the sleeves and pull the material free from the underarms, or lean forward, reach back, and slide the hand against the material to help pull the garment down.

8. If hand function is inadequate, the garment can be buttoned from bottom to top with the aid of a buttonhook and a wrist-driven flexor hinge splint.

Removing front-opening or pullover garments (SCI level C5-7)

1. Sit in the wheelchair and wear wrist-driven flexor hinge splints. Unfasten the buttons (if any) while wearing orthotics and using a buttonhook. Remove the splints for the remaining steps.

2. For pullover garments, hook the thumb in back of the neckline, extend the wrist, and pull the garment over the head while turning the head toward the side of the raised arm. Maintain balance by resting against the opposite wheelchair armrest or pushing on the thigh with an extended arm.[91]

3. For stretchy front-opening clothing, hook the thumb in the opposite armhole and push the sleeve down the arm. Elevation and depression of the shoulders with trunk rotation can be used to get the garment to slip down the arms as far as possible.

4. Hold one cuff with the opposite thumb while the elbow is flexed to pull the arm out of the sleeve.

Bra (back opening)

Putting on a bra (SCI level C5-7).

A back-opening bra fastens at the back with a hook and eye. The bra is adapted and has loop extenders attached on both the right and left sides of the fasteners. The bra is fastened around the body in the front first and then twisted around into position. The arms are placed in the straps last.

1. Place the bra across the lap with the straps toward the knees and the inside facing up.

2. Using a right-to-left procedure, hold the end of the bra closest to the right side with the hand or a reacher and pass the bra around the back from right to left side. Lean against the bra at the back to hold it in place while hooking the thumb of the left hand in a loop attached near the bra fastener. Hook the right thumb in a similar loop on the right side, and fasten the bra in front at waist level.

3. Hook the right thumb in the edge of the bra. Using wrist extension, elbow flexion, shoulder

adduction, and internal rotation, rotate the bra around the body so that the front of the bra is in the front of the body.

4. While leaning on one forearm, hook the opposite thumb in the front end of the strap and pull the strap over the shoulder; repeat procedure on the other side.[17,64]

Removing a bra

1. Hook the thumb under the opposite bra strap, and push the strap down over the shoulder while elevating shoulder.

2. Pull the arm out of the strap and repeat the procedure for other arm.

3. Push the bra down to waist level and turn it around as described previously to bring the fasteners to the front.

4. Unfasten the bra by hooking the thumbs into the adapted loops near the fasteners.

Alternatives for a back-opening bra are (1) a front-opening bra with loops for using a wrist extension grip or (2) a stretchable bra that has no fasteners (eg, sports bra), which can be put on like a pullover sweater.

Socks

Putting on socks (SCI level C6-7)

Method 1

1. Sit in a wheelchair (or on the bed if balance is adequate) in cross-legged position with one ankle crossed over the opposite knee.

2. Pull the sock over the foot using wrist extension and patting movements with the palm of the hand.[17,64] To prevent pressure areas, check to make sure there are no creases or thickened areas on the socks.

Method 2

1. Sitting in a wheelchair with the seat belt fastened, hook one arm at the elbow around the wheelchair push handle. This allows for improved stability while reaching.

2. Position the foot on a stool, chair, or stable open drawer to elevate it enough to reach easily. Unhook the arm from the push handle once stable.

3. Pull the sock over the foot using wrist extension and patting movements with the palm of the hand.[17,64] To prevent pressure areas, check to make sure there are no creases or thickened areas on the socks.

Method 3 (using an adaptive device)

1. Use a sock aid or sock cone (see Fig. 10.8) to assist in putting on socks while seated in a wheelchair. Powder sock cone (to reduce friction) and put the sock on the cone, using the thumbs and the palms of the hands to smooth out the sock on the cone.

2. With the cord loops of the sock cone around the wrist or thumb, throw the cone beyond the foot.

3. Maneuver the cone over the toes by pulling the cords, using elbow flexion. Insert the foot as far as possible into the cone.

4. To remove the cone from the sock after the foot has been inserted, move the heel forward off the wheelchair's footrest. Use wrist extension (of the free hand) behind the knee and continue pulling the cords of the cone until it is removed and the sock is in place on the foot. Use the palms to

smooth the sock with patting and stroking motions.[17] Two loops can be sewn on either side of the top of the sock so that the thumbs can be hooked into the loops and the socks pulled on.

Removing socks (SCI level C6-7)

Method 1 (no adaptive device)

1. While long-sitting in the bed and with the hips flexed forward, slide the hands into the sock with the wrist extended, gradually working the sock off the feet and toes.

2. If seated in a wheelchair, hook the thumb in the sock and use wrist extension to slide it off.

Method 2 (using an adaptive device).

While sitting in a wheelchair or long-sitting in the bed with the hips flexed forward, use a dressing stick with a coated end or a long-handled shoehorn to push the sock down over the heel. Cross the legs if needed.

Shoes

Putting on shoes (SCI level C6-7)

1. Use the same position as for putting on socks.

2. Use the thumbs, or if needed a long-handled dressing stick, and insert the aid into the tongue of the shoe. Place the shoe opening over the toes. Remove the dressing aid from the shoe and dangle the shoe on the toes.

3. Place the palm of the hand on the sole of the shoe and pull the shoe toward the heel of the foot. One hand is used to stabilize the leg while the other hand pushes against the sole of the shoe to work the shoe onto the foot. Use the palms and sides of the hand to push the shoe on.

4. With the feet flat on the floor or on a wheelchair footrest and the knees flexed 90 degrees, place a long-handled shoehorn in the heel of the shoe and press down on the flexed knee until the heel is in the shoe. Fasten the shoe.

Removing shoes (SCI level C6-7)

1. Sitting in a wheelchair with the legs crossed as described previously, unfasten the shoes.

2. Use a shoehorn or dressing stick, if needed, to push on the heel counter of the shoe, dislodging it from the heel. The shoe will drop, or it can be pushed to the floor with the dressing stick.

Feeding Activities

Feeding may be assisted by a variety of devices, depending on the level of the client's muscle function. Someone with a C1-4 injury will likely need assistance to eat unless an electrical self-feeding device is used. These devices allow independence because the client uses head movement to hit a switch that turns the plate and then brings the spoon down to the plate and back up to mouth level.

An injury at C5 may require mobile arm supports or externally powered splints and braces. A wrist splint and a universal cuff (see Fig. 10.12) may be used together if a wrist-driven flexor hinge splint is not used. The universal cuff holds the eating utensil, and the splint stabilizes the wrist. A nonskid mat and a plate with a plate guard may adequately stabilize the plate for pushing and picking up food (C5-7).

A regular or swivel spoon-fork combination with a universal cuff can be used when there is minimal muscle function (C5). A long plastic straw with a straw clip to stabilize it in the cup or glass eliminates the need for picking up cups. A bilateral or unilateral clip-type holder on a glass or cup makes it possible for many individuals with hand and arm weakness to manage liquids without a straw.

Built-up utensils may be useful for those with some functional grasp or tenodesis grasp. Food may be cut with an adapted knife if arm strength is adequate to manage the device. Food may also be cut with a sharp knife if a wrist-driven flexor hinge splint is used.

Personal Hygiene and Grooming

1. Use a padded shower seat or padded transfer tub bench and transfer board for transfers (SCI level C1-7).

2. Extend reach by using a long-handled bath sponge with a loop handle or a built-up handle (SCI level C6-7).

3. Eliminate the need to grasp a washcloth by using bath mitts or bath gloves (SCI level C5-7).

4. Hold a toothbrush with a universal cuff[1] (SCI level C5-7).

5. Use a wall-mounted hair dryer. Use a universal cuff to hold a brush or comb for hair styling while using the mounted hair dryer[28] (SCI level C5-7) (Fig. 10.39).

FIG 10.39 Hair dryer holder. (Courtesy Patterson Medical, Warrenville, IL.)

6. Use a clip-type holder for an electric razor (SCI level C5-7).

7. Individuals with quadriplegia can use suppository inserters to manage bowel care independently (SCI level C6-7).

8. Use a skin inspection mirror with a long stem and looped handle (see Fig. 10.35) for independent skin inspection. Devices and methods selected must be adapted to the degree of weakness of each client (SCI level C6-7).

9. Adapted leg bag clamps for emptying catheter leg bags are also available for individuals with limited hand function. Elastic leg bag straps may be replaced with Velcro straps (SCI level C5-7).

10. If the client is unable to reach the leg bag clamp, a commercially available electric leg bag clamp allows the individual to drive up to a urinal or bathroom drain and empty the leg bag with the switch of a button (Richardson Products) (SCI level C1-7).

Communication Management and Environmental Adaptations

1. Turn pages with an electric page turner, mouth stick (Fig. 10.40), or head wand if hand and arm function is inadequate (SCI level C4-5).

FIG 10.40 Mouth wand. (Courtesy Patterson Medical, Warrenville, IL.)

2. For keyboarding, writing, and painting, insert a pen, pencil, typing stick, or paintbrush into a universal cuff that has been positioned with the opening on the ulnar side of the palm (Fig. 10.41) (SCI level C5-7).

FIG 10.41 Typing with a keyboard aid. (Courtesy Patterson Medical, Warrenville, IL.)

3. Touch telephone keys with the universal cuff and a pencil positioned with the eraser down (SCI level C5-7). The receiver may need to be positioned for listening. For clients with no arm function, a speakerphone can be used, along with a mouth stick to push the button to initiate a call. Set any frequently used numbers for speed-dial. An operator can also assist with dialing (SCI level C1-5).

4. Mobile phones allow many functions with voice activation including calling out, automatic answering that goes to an earpiece, music functions, Web searches, calendar programs, contact directories, and global positioning systems (GPSs). A touch-screen phone with multiple functions can eliminate the need for multiple devices to organize information (SCI level C1-7).

5. Use personal computers or smart phones. A computer mouse or voice recognition program may be substituted for use of the keyboard. A variety of different mouse and keyboard designs and sizes are available (SCI level C1-7).

6. Clients with hand weakness can use built-up pencils and pens or special pencil holders. The Wanchik writer (see Fig. 10.17) is an effective adaptive writing device (SCI level C5-7).

7. Sophisticated electronic communication devices operated by mouth, pneumatic controls, and head controls are available for clients with no function in the upper extremities. Other communication devices are available that rely on eye blinks and gazes (SCI level C1-5).

8. MP3 (a digital audio recording format) players are capable of playing digitally available music and podcasts and can be used with a universal cuff and a pencil positioned with the eraser down or other adapted pointer to press buttons (SCI level C5-7).

9. Environmental controls allow easy operation from a panel designed to run multiple devices, such as televisions, radios, lights, telephones, intercoms, and hospital beds (see Chapter 17) (SCI level C1-7).

Functional Mobility

The principles of wheelchair transfer techniques for the individual with quadriplegia are discussed in Chapter 11. Mobility depends on the degree of weakness. Electric wheelchairs operated by hand, chin, head, or pneumatic controls have greatly increased the mobility of individuals with severe upper and lower extremity weakness. Vans fitted with wheelchair lifts and stabilizing devices provide transportation for these clients, allowing them to pursue community, vocational, educational, and leisure activities with the help of an assistant. In addition, adaptations for hand controls have made it possible for many clients with function of at least the C6 level to drive independently.

Home Management, Meal Preparation, and Cleanup Activities

Clients with muscle function of C6 or better may be independent for light homemaking with appropriate devices, adaptations, and safety awareness. Many of the suggestions for wheelchair maneuverability and environmental adaptation for a person with paraplegia also apply here. In addition, clients with upper extremity weakness need to use lightweight equipment and special devices. A classic book that is still available, *The Mealtime Manual for People with Disability and the Aging*, compiled by Klinger,[49] contains many excellent specific suggestions that apply to homemakers with weak upper extremities. Specialty suppliers for cooking devices to make meal preparation and cooking easier and more efficient are an excellent source for new ideas. The kitchen and home sections of general national and international stores are other good resources for ideas and products. As mentioned, in this age of digital information sharing, many people with various disabilities post themselves online performing ADLs and IADLs.

1. Use extended lever-type faucets for easier reach and control or motion sensor faucets (SCI level C5-7).

2. To eliminate the need for grasp and release, use pump bottles for cleaners and soaps or motion sensor dispensers (SCI level C5-7).

3. For cooking utensils, use universal cuff adaptations, a tenodesis splint, or adapted long-handled utensils (SCI level C5-7).

4. For opening cans, use one-touch can openers.

5. For opening jars, use electric jar openers.

6. To wash dishes, use a combination soap dispenser/sponge.

7. To wash and rinse lettuce, use a salad spinner with a push-button center.

ADLs for the Person With Low Vision

Many people with or without physical disabilities also have low vision as a result of advancing age or age-related eye diseases, or as a complication of diabetes.[52] Occupational therapists specialize in the area of vision rehabilitation itself. However, OTs who work with clients with physical disabilities frequently see individuals with visual impairment; therefore, it is important for OTs to be knowledgeable about this condition so they can help promote independence in occupations.[70,95]

Low vision is defined as a visual impairment that cannot be corrected by regular eyeglasses or other corrective lenses, or by surgery or medication, and that negatively affects the performance of daily occupations.[52,60,61] Research indicates that for older people, low vision is a greater threat to independence than hearing loss.[18,52]

Visual changes are considered part of a comprehensive OT evaluation. Evaluation of the person with low vision should initially involve understanding the specific condition that has caused the low vision, such as whether visual acuity is affected or whether a specific field of vision is impaired. (For more information on visual loss in the aging, see Chapter 46.) The type of visual loss, along with any other physical or cognitive deficits, influences treatment and adaptive equipment choices. Providing low vision devices is not sufficient in itself to optimize performance in ADLs and IADLs. A review of the OT literature in older adults with low vision has shown that multiple components are crucial, such as education, use of low vision devices, problem-solving strategies, and community resources.[52]

In addition to assistive technology, adaptive equipment, and environmental modifications, reorganization and task restructuring may be needed. Weisser-Pike and Kaldenberg[96] provided a framework of intervention strategies that the OT can consider when addressing functional activities for the person with low vision. Box 10.6 presents the modified version of this framework, which has nine categories, and provides some examples for each category. The OT may use this model in combination with interventions under the specific functional activity.

Box 10.6

Framework for Low Vision Interventions

Use of Corrective Lenses

Have client wear glasses for activities as needed. Some people use multiple pairs of glasses, depending on the task performed (eg, writing, reading, use of the computer, or driving). Ask about the client's most recent eye examination to make sure he or she has the most recent prescription.

Adequate Lighting

Examples include adding light that shines from behind the client onto the work area, avoiding glare and shadows on writing areas, and using natural light behind work area.

Good Ergonomic Positioning

Examples include raising reading material within field of vision and moving closer to an object, such as the television or a person. Ideal positions include upright, midline, comfortable postures.

Increase Contrast Enhancement

Examples include using black ink on white or yellow paper in an easy-to-read font (eg, Times New Roman or Arial) if providing printed materials. Mark edges of doorways or stairs with contrasting strip.

Simplification of Environment

An example is using a pill organizer, which can eliminate many pill bottles that create clutter and require numerous steps to manage.

Resize Written Materials

Examples include larger print, larger television, and larger label on pill bottles. For people with peripheral vision loss, enlargement of print may be contraindicated. Provide resources for large print materials.

Provide Sensory Substitutes

Use tactile or auditory cues, such as rubber bands on doorknobs and on frozen meals, to indicate how many minutes an item should be cooked; also, talking books and TV ears.

Restructure Routines

Use the time of day when vision is the best to perform difficult activities; use pill organizer.

Visual Skills/Referrals

Refer to vision specialist or low-vision rehab specialist.

Data from Weisser-Pike O, Kaldenberg J: Occupational therapy approaches to facilitate productive aging for individuals with low vision, *OT Practice* 15:CE1–CE8, 2010.

Adequate training and choosing the appropriate intervention and adaptive equipment are essential. Allow the client to touch and explore the piece of adaptive equipment before beginning practical teaching; break the steps down into small chunks of information; have the client practice a few days before doing the functional activity with the adaptive equipment; and request a return demonstration after the client has practiced.[43]

The modifications described in the following sections are appropriate for all people with low vision for performing ADLs.

Dressing Activities

1. Light the closet to improve acuity. Hang matching outfits together on the same hanger.

2. Place a safety pin on the label of the backs of shirts, pants, and dresses so that clothing is oriented correctly when worn.

3. Pin socks together before placing them in the washer and dryer so they stay matched.

Feeding Activities

1. Provide high contrast. Ensure that plates contrast with the table surface or place mats. Avoid patterned tablecloths.

2. Arrange food on the plate in a clockwise fashion and orient the person with low vision to the arrangement.

Personal Hygiene and Grooming Activities

1. Reduce clutter in bathroom drawers and cabinets.

2. Use an electric razor.

3. Use magnified mirrors.

4. Use a high-contrast bath mat in the bathtub.

5. Install high-contrast grab bars in the shower.

6. Use a high-contrast bath chair in the bathtub.

7. Train the client and other caregivers to keep supplies organized by replacing and storing them in the same location.

Communication Management and Environmental Adaptations

1. Use talking watches or clocks to tell time.

2. Use a talking scale to determine weight.

3. Use a large-print magnification screen on the computer.

4. Use large-print books, menus, and pharmacy labels.[82]

5. Use high-contrast doorknobs. Paint the doorframe a color that contrasts highly with the door to improve ease of identifying the door.

6. Use speakerphones, preprogrammed phone numbers, or a phone with large print and high-contrast numbers. Identify phone buttons with contrasting tape or a Velcro dot to teach the client how to turn the phone on and the correct buttons to push. Use a mobile phone with voice recognition commands.

7. Use writing guides to write letters, checks, or signatures.

8. To read, use books on tape, talking books, electronic books, and digital books (eg, Kindle) or an iPad. Screens can be magnified, and some of the devices have "reading" capability so the reader can listen to a story or newspaper article. Software is available, such as the JAWS screen reader, which reads aloud information on a computer screen.

9. To promote verbal communication, provide specific information when giving directions, avoid gestures, and offer to read educational materials out loud.[82]

10. When ending a conversation or leaving the room, notify the client and offer to help guide him or her out of a room because novel environments may be difficult.[82]

11. Do not have clients with low vision "guess" your identity by your voice (eg, "Do you remember me?"). Clearly introduce yourself.

Lighting and magnifiers

1. Improve lighting by aiming light at the work area, not into the eyes.

2. Reduce glare by having adjustable blinds, sheer curtains, or tinted windows. Wearing dark glasses indoors may also reduce glare.[82]

3. Maximize contrast by providing a work surface that is in contrast to the task. For example, serve a meal on a white plate if the table is dark. Paint a white edge on a dark step. Replace white wall switches with black to contrast with the wall.

4. Simplify figure-ground perception by clearing pathways and eliminating clutter.

5. Work in natural light by placing a chair by a window with the back toward the window.

6. Use magnifiers with lights. These come in a variety of sizes and degrees of magnification. Specialists in low vision can determine the appropriate degree of magnification needed. Some magnifiers are portable, others are attached to stands to do needlework or fine work, and others are sheets of plastic used to magnify an entire page of print.[40]

Functional Mobility

1. Mobility is eased with the clearing of pathways and the minimizing of clutter and furniture. Furniture can be used as guides for going from one place to another.

2. Lighting in hallways and entryways is also needed.

3. The person with low vision needs to optimize visual scanning abilities by learning to turn and position the head frequently when mobile or participating in an activity.[98]

4. Use scan courses (paths), which consist of letters and numbers that are placed systematically along a hallway to encourage those with peripheral vision loss to use visual search and scanning patterns[82] (also see Chapter 24).

5. The OT practitioner may need to refer a client with severe vision loss to an orientation and mobility specialist who is specifically trained in teaching mobility in the community, such as human guide techniques, use of a white cane, and use of service animals by people with low vision or those who are legally blind.

Home Management, Meal Preparation, and Cleanup Activities

Various devices are available to compensate for low vision while managing the home. Organization and consistency are critical to the safe and efficient performance of home management tasks. Family members need to remember to replace items where they were found and to refrain from reorganizing them without the assistance of the person with low vision. Suggestions include the following.[49]

1. For safety, cleaning supplies should be kept in a separate location from the food supplies.

2. Eliminate extra hazardous cleaning supplies and replace them with one multipurpose cleanser. Place this cleaning agent in a uniquely shaped bottle or in a specific location.

3. Mark appliance controls with high-contrast tape or paint to identify start and stop buttons or positions. Place Velcro tabs to mark frequently used positions on dials (eg, on the 350°F position for the stove or for the wash-and-wear cycle on the washer or dryer).

4. Label cans by using rubber bands to attach index cards with bold, dark print to each can. When the can is used, the card may be placed into a stack to create a shopping list.

5. Indicate the number of minutes needed for microwave cooking by placing rubber bands on the items. Two rubber bands would indicate that the item should be cooked for 2 minutes. Assistance will be needed for the initial setup.

6. Use a liquid level indicator to determine when hot liquid reaches 1 inch from top of a cup or container.

7. Use cutting guides or specially designed knives to cut meat or bread.[40]

8. Audio-record reminder lists or grocery lists.

9. Discourage the wearing of long, flowing gowns with flowing sleeves (eg, kimono style) while performing cooking tasks at the stove.

Medication management

1. Use a medication organizer to organize pills.

2. For diabetic management, many products are available for individualized evaluation of the client (eg, syringe magnifiers, talking or large-print glucometers, and a device to count the insulin dosages).

3. Use talking scales to evaluate weight.

Money management

1. Use a consistent method of folding money to identify denominations, as in the following example:

$1	Keep flat
$5	Fold in square half
$10	Fold lengthwise
$20	Fold in half and then lengthwise

2. Keep different denominations in different sections of the wallet. Learn to recognize coins by size and type of edge (smooth or rough).[98]

Leisure

1. Use low vision playing cards with large letters and symbols.

2. Search for resources in the community for activities aimed at people with low vision[71] (see Chapters 16 and 46).

ADLs for the Person of Large Size/Body Mass

The terms *morbidly obese* and *bariatrics* both are used to describe the population that is exceptionally large. Morbidly obese is defined as a body mass index (BMI) of 40 or greater. This population is to be separated from individuals who fall into the overweight or obese category because overweight and obese individuals most likely do not have functional deficits because of body size. *Bariatrics* is defined as the medical investigation, prevention, and treatment of obesity with interventions such as diet, nutrition, exercise, behavior modification, lifestyle changes, surgical alternatives, and appropriate medications. It is an area of practice that is continuing to expand.[4,33,34]

Individuals who are exceptionally large experience difficulty performing ADLs and IADLs.[2,67,83] They may have difficulty with ADLs and IADLs because of limitations in reach, strength, pain, and endurance. They may also experience neuropathies that require increased safety awareness to prevent skin breakdown. As with all clients, a comprehensive evaluation of the exceptionally large individual should include primary and secondary medical problems that result in additional functional deficits.

Adaptive techniques, adaptive equipment, and home modifications may allow for increased independence and safety. When recommending adaptive equipment and DME, the OT must consider the size and durability of equipment. For example, the standard molded sock aid may not fit around the exceptionally large client's calf, whereas softer fabric or flexible plastic sock aids likely will accommodate larger calf sizes.[33,34]

The standard DME issued may have maximal weight limits for safe use. For example, a bath chair or even a transfer (sliding) board may accommodate only individuals up to 250 pounds. Issuing adaptive equipment and DME that are inadequate for a client's weight may put the client at risk of injury.

Dressing Activities

Provide resources for clothing available in larger sizes that may help the client feel more comfortable in the community and help with self-esteem. Some manufacturers have designed exercise clothing, swimsuits, and work attire in larger sizes. Many resources can be found on the Internet that offer sizes up to at least 7X.

Lower extremity dressing activities

1. Use dressing sticks with a neoprene-covered coat hook on one end and a small hook on the other (see Fig. 10.7) for pushing and pulling garments off and on the feet and legs.

2. For socks, use a large, flexible, commercially available sock aid (see Fig. 10.8). The rigid sock aids available may not fit around larger calves.

3. Compensate for the need to bend to tie shoelaces by using elastic shoelaces or other adapted shoe fasteners, such as Velcro-fastened shoes or secure slip-on shoes. Edema is frequently a problem with this population and should be taken into account when shoes are selected.

4. Use reachers (see Fig. 10.9) for picking up socks and shoes, arranging clothes, removing clothes from hangers, picking up objects on the floor, and putting on pants, to avoid bending or unsafe reaching.

Upper extremity dressing activities

1. Use front-opening or pullover garments that are one size larger than needed and are made of fabrics that have some stretch.

2. Use dressing sticks (see Fig. 10.7) to push a shirt or blouse over the head and reach around shoulders. Some exceptionally large individuals are not able to touch the shoulder with the opposite hand because of the girth of the trunk.

Personal Hygiene and Grooming Activities

Bathing

1. A handheld flexible shower hose for bathing and shampooing the hair can eliminate the need to stand in the shower and offers the user control of the direction of the spray.

2. A long-handled bath brush or sponge with a soap holder (see Fig. 10.14) or long cloth scrubber can allow the user to reach the legs, feet, and back. If the standard long-handled bath brush/sponge is not long enough, add an extension with PVC pipe and a bend about one third of the distance from the handle to improve reach.

3. Safety rails that can accommodate the larger individual's weight (see Fig. 10.16) can be used for bathtub transfers, and safety mats or strips can be placed on the bathtub bottom to prevent slipping.

4. A bariatric transfer tub bench (similar to the transfer tub bench in Fig. 10.6) or a shower stool set in the bathtub or shower stall can eliminate the need to stand to shower, thus increasing safety and conserving energy. The bench should be built to accommodate the user's weight. The larger equipment may not be easily obtainable and may need to be special ordered. It is usually more functional to remove the back on the shower equipment to allow for increased sitting surface and room for the posterior buttocks to shift back on the seat and allow the user to lean back as legs are lifted into the shower or over the edge of the tub. The user must have adequate sitting balance before removing the back of the bench or stool.

5. Evaluate issues with water spillage from the tub or shower when using a transfer tub bench. A large person using a transfer tub bench that fits into the standard tub may need to plan ahead to manage water overflow because the width of the hips may cover the area on the bench originally designed for placement of the shower curtain. Water on the floor can lead to a fall and create extra cleanup. Extra towels may be required when setting up the shower.

6. Grab bars can be installed to prevent falls and ease transfers. A licensed contractor must securely mount these into the studs of the wall. The suction grab bars commercially available would not be safe for this population because the amount of pull and weight would cause the suction to release from the wall.

7. Use a hair dryer to thoroughly dry the skin in hard-to-reach areas (eg, buttocks, crotch, and abdominal folds) to prevent rashes and fungal infections in the folds.

Grooming

1. Use a long-handled mirror for regular skin checks of the feet to detect skin breakdown.

2. Over-the-counter spray products, such as deodorant, hair spray, and spray powder, can compensate for limited reach because the user does not need to make direct skin contact with the product. The spray can be aimed in the general direction (eg, the underarms) to provide adequate coverage.

Toileting

1. Use toilet paper holders/extenders for toilet hygiene because reach is often difficult for optimal hygiene. Several types of toilet aids are available in catalogs that sell assistive devices.

2. Use a bidet mounted on the toilet for toilet hygiene. Select one on which the controls are not mounted to the seat and likely to be covered by the user's wide hips. Many options are available, ranging from one as simple as a pump with a handheld spray to deluxe models that include front

and rear wash, warm-air drying, and water pressure control.

3. Dressing sticks can be used to pull garments up after using the toilet.

4. Bariatric bedside commodes can be used over the toilet, if there is enough room, or at the bedside. The commode should be built to accommodate the user's weight. The sitting surfaces should be smooth to prevent skin tears or pressure areas. Because body size may push the large person forward, the standard hole size is not in the correct location for toileting. The commode hole should be larger than that for a standard commode to allow space to reach for toilet hygiene and proper alignment for elimination. If the user is not able to stand and pivot to the commode, drop-arm commodes are available for the bariatric population (Fig. 10.42).

FIG 10.42 Bariatric commode. (Courtesy North Coast Medical, Gilroy, CA.)

5. Adapt male urinals with a PVC pipe handle to allow for independent use. This allows the client to use one hand to hold the urinal and the other hand to lift abdominal folds to place the urinal.

Functional Mobility

1. Set up furniture at an appropriate height by raising it on blocks to elevate it or by shortening leg rests to lower it. Multiple sitting surfaces allow the large individual to alter sitting pressures during the day; elevate lower extremities, which may be prone to edema; and provide alternatives to staying in bed. Several manufacturers make electrical lifts for furniture or chairs that accommodate individuals weighing up to 1000 pounds.

2. A glider/office chair that is operated by the feet can facilitate transportation if lower extremity endurance is limited. It should be built to accommodate the user's weight, and the user should be able to demonstrate a safe sit-to-stand technique because the chair is mobile, without brakes to secure it during transfers.

3. Encourage the use of mobility aids for safety. A physical therapist can assess whether a four-wheeled walker with a seat may improve mobility and function because the seat can be used as an energy-conservation method to carry items when moving from room to room. The user can sit on the four-wheeled walker seat to conserve energy while cooking, brushing teeth, shaving, and washing.

4. For the exceptionally large individual with limited functional mobility, a manual wheelchair is generally not functional because it is too wide for most doorways in the home. If the client is discharged home with a wheelchair that has a seat width greater than 24 inches, the user is likely to use it in only one room because doorways in most homes are too narrow to accommodate such a

large wheelchair. The OT and team should consider alternatives if a bariatric wheelchair is needed but access is limited.

Home Management, Meal Preparation, and Cleanup Activities

The exceptionally large person may be unable to reach faucet handles, reach into lower cabinets or a clothes dryer, be safe on step stools, or carry heavy items with proper body mechanics because of obstructions caused by abdomen size, limited endurance, and limited reaching and bending.[33] Home management activities can be facilitated by a wide variety of environmental adaptations, assistive devices, and fatigue management techniques.[33] The following are suggestions to facilitate home management for the exceptionally large individual.[33,34]

1. Store frequently used items on the first shelves of cabinets, just above and below counters, or on counters where possible. Eliminate unnecessary items.

2. If the individual is unable to reach faucet handles, add an extension onto the handle.

3. Use a high, stable stool to work comfortably at counter height, with the feet firmly placed on the ground; or, if a wheelchair is used, attach a drop-leaf table to the wall for a planning and meal preparation area.

4. Use a utility cart of comfortable height or a four-wheeled walker to transport several items at once.

5. Use reachers to get lightweight items (eg, a cereal box) from high shelves. Place frequently used items on shelves in cabinets and in the refrigerator where the items are easily accessible and reachable.

6. Eliminate bending by using extended and flexible plastic handles on dust mops, brooms, and dustpans. Sit to do cleaning and move the chair as needed.

7. Use pullout shelves or lazy Susans to organize cupboards to eliminate bending and to ease access to items.

8. Eliminate bending by using a wall oven, countertop broiler, microwave oven, and convection oven.

9. Use a metal kitchen spatula to pull out and push in oven racks. There also are commercially available tools for this purpose.

10. Eliminate leaning and bending by using a top-loading automatic washer and elevated dryer. Wheelchair users or people of shorter stature can benefit from front-loading appliances. Use a reacher or other extended tool to obtain clothes from the washer or dryer.

11. Use an adjustable ironing board to make it possible to sit while ironing, or eliminate ironing with the use of permanently pressed clothing.[2,33,34,83]

Threaded Case Study

Anna, Part 2

At the beginning of this chapter, Anna's case introduced questions regarding ADL and IADL participation. Anna identified many ADLs and IADLs that she wanted to engage in as independently as possible, such as self-care, childrearing, spiritual activities, sexual function and fertility, community mobility, financial management, home management, meal preparation and cleanup, and shopping. All of these areas are in the domain of occupational therapy and can be addressed while Anna is in the inpatient setting and further along in the continuum of care. The topic of sexual function and fertility were not addressed in this chapter. However, it is an important ADL that OTs can and should discuss with clients such as Anna[36] (also see Chapter 12, Sexuality and Physical Dysfunction). With the many areas that must be addressed, an occupational therapist, along with the client, family, and rehabilitation team, must prioritize which areas to address at each stage. Prior to discharge home, a home evaluation is indicated for safety and accessibility, as is an assessment for appropriate DME such as a wheelchair and padded bath bench. Other equipment and adaptive techniques in ADLs and IADLs may also be recommended to foster Anna's independence and return to her roles as wife, mother, worker, and active community member.

Summary

ADLs and IADLs are areas of occupation that include activities that enable a person to function independently and assume important occupational roles. ADLs include self-care tasks such as bathing and showering; bowel and bladder management; dressing and undressing; eating (or swallowing), feeding; functional mobility (eg, transfers and bed mobility); sexual activity; toilet hygiene; and the care of personal devices (eg. hearing aids, orthotics, and splints). IADL tasks include care of others and of pets; childrearing; communication management (eg, use of telephones, smart phones, and computers); community mobility (eg, driving and use of public transportation); financial management (eg, use of cash and check writing); and health management and maintenance.

Occupational therapists routinely assess performance in ADLs and IADLs to determine a client's level of functional independence. Interviews and performance analysis are used to carry out the assessment. OTs also assess and take into consideration the client's performance skills, performance patterns, environment, and cultural, personal, temporal, and virtual contexts when they evaluate and establish the treatment goals.

The results of the assessment and ongoing progress are recorded on one of the many available ADL checklists or with a standardized assessment, the content of which is summarized for the permanent medical record (see Chapter 8 for further information on documentation). Intervention is client centered and directed at training in independent living skills or at teaching a caregiver to assist the client with ADLs and IADLs. The OT can include in the intervention plan compensatory strategies, home modification, adaptive equipment, DME, work simplification, and energy conservation techniques to improve ADL and IADL performance.

Review Questions

1. Define ADLs and IADLs. List three classifications of tasks that may be considered in each category.
2. What is the role of OT in restoring ADL and IADL independence?
3. List at least three activities considered self-care skills, three functional mobility skills, three functional communication skills, and three home management or meal preparation and cleanup skills.
4. List three factors the occupational therapist must consider before commencing ADL performance assessment and training. Describe how each could limit or affect ADL performance.
5. What is the ultimate goal of the ADL and IADL training program?
6. Discuss the concept of maximal independence as defined in the text.
7. List the general steps in the procedure for ADL assessment.
8. Describe how the occupational therapist can use the ADL checklist.
9. List the steps in the activities of IADL assessment.
10. What is the purpose of the home evaluation?
11. List the steps in the home evaluation.
12. What kinds of things are observed in a home assessment?
13. How does the therapist record and report the results of the home evaluation and make the necessary recommendations?
14. How does the occupational therapist, with the client, select ADL and IADL training objectives after an assessment?
15. Describe three approaches to teaching ADL skills to a client with perception or memory deficits.
16. List the important factors to include in an ADL or IADL progress report.
17. Describe the levels of independence as defined in the text.
18. Give an example of a health management and maintenance issue.
19. Give three examples of adaptations that may be helpful for the person with low vision.

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Define functional ambulation.
2. Discuss the roles of physical and occupational therapists and other caregivers in functional ambulation.
3. Identify safety issues in functional ambulation.
4. Recognize basic lower extremity orthotics and ambulation aids.
5. Develop goals and plans that can help ambulatory clients resume occupational roles.
6. Identify the components necessary to perform a wheelchair evaluation.
7. Explain the process of wheelchair measurement and prescription completion.
8. Identify wheelchair safety considerations.
9. Follow guidelines for proper body mechanics.

). Apply principles of proper body positioning.

1. Identify the steps necessary for performing various transfer techniques.
2. Identify considerations necessary to determine the appropriate transfer method based on the client's clinical presentation.
3. Identify different transportation systems and contexts and the treatment implications each system presents.
4. Discuss the multilevel role of the therapist in the occupation of community mobility.
5. List performance skills and client factors that should be assessed in a comprehensive driver evaluation.
6. Discuss the value of driving within this society and how loss of license or mobility affects participation in occupation.
7. Develop awareness of the complexities involved in a driver referral and evaluation.
8. Define primary and secondary controls.
9. Discuss why driver competency assessment is a specialty practice area requiring advanced training.

KEY TERMS

Ambulation aids
Americans with Disabilities Act (ADA)
Body mechanics
Community mobility
Driver competence
Driver training
Driving
Driving retirement
Durable medical equipment (DME)
Fixed-route system
Follow-up services
Functional ambulation
Gait training
Medical necessity
Older drivers
On-road assessment
Paratransit
Pelvic tilt
Positioning mass
Primary controls
Private transportation
Rehabilitation technology supplier

Secondary controls

Skin breakdown

Vital capacity

Walking, climbing stairs, traveling within one's neighborhood, and **driving** a car are so universal and customary that most people would not consider these to be complex activities. The basic capacities to move within the environment, to reach objects of interest, to explore one's surroundings, and to come and go at will appear natural and easy. For persons with disabilities, however, mobility is rarely taken for granted or thought of as automatic. A disability may prevent a person from using the legs to walk or using the hands to operate controls of motor vehicles. Cardiopulmonary and medical conditions may limit aerobic capacity or endurance, requiring the person to take frequent rests and to curtail walking to cover only the most basic of needs, such as toileting. Deficits in motor coordination, flexibility, and strength may seriously compromise movement and may make difficult any activities that require a combination of mobility (eg, walking or moving in the environment) and stability (eg, holding the hands steady when carrying a cup of coffee or a watering can).

Occupational therapy (OT) practitioners assist persons with mobility restrictions to achieve maximum access to environments and objects of interest to them. Typically, OT practitioners provide remediation and compensatory training. In so doing, therapists must analyze the activities most valued and the environments most often used by their clients and must consider any future changes that can be predicted from an individual's medical history, prognosis, and developmental status.

This chapter guides the practitioner in evaluation and intervention for persons with mobility restrictions. Three main topics are explored. The first section addresses functional ambulation, which combines the act of walking within one's immediate environment (eg, home, workplace) with other activities chosen by the individual. Feeding pets, preparing a meal and carrying it to a table, and doing simple housework are tasks that may involve functional ambulation. Functional ambulation may be conducted with aids such as walkers, canes, or crutches.

The second section is focused on wheelchairs and their selection, measurement, fitting, and use. For many persons with disabilities, mobility becomes possible only with a wheelchair and specific positioning devices. Consequently, individual evaluation is needed to select and fit this essential piece of personal medical equipment. Proper training in ergonomic use allows the person who is dependent on the use of a wheelchair many years of safe and comfortable mobility. Safe and efficient transfer techniques based on the individual's clinical status are introduced in this chapter. Attention also is given to the **body mechanics** required to safely assist an individual.

The third section covers **community mobility**, which for many in the United States is synonymous with driving. Increased advocacy by and for persons with disabilities has improved access and has yielded an increasing range of options for adapting motor vehicles to meet individual needs. Public transportation also has become increasingly accessible. Driving is a complex activity that requires multiple cognitive and perceptual skills. Evaluation of individuals with medical conditions and physical limitations is thus important for the safety of the disabled person and the public at large.

Mobility is an area of OT practice that requires close coordination with other healthcare providers, particularly physical therapists (PTs) and providers of **durable medical equipment (DME)**. Improving and maintaining the functional and community mobility of persons with disabilities can be one of the most gratifying practice areas. Clients experience tremendous energy and empowerment when they are able to access and explore wider and more interesting environments.

Section 1 Functional Ambulation

Deborah Bolding

Section 1 Threaded Case Study

Pyia, Part 1

Pyia is a 75-year-old woman who was treated for breast cancer 8 years earlier. She developed spinal metastases, with an onset of acute, bilateral lower extremity weakness and loss of sensation. For 2 days she felt “unsteady” when she was walking, and she had one fall. By the time she was admitted to the hospital, she was unable to walk. She underwent a laminectomy and decompression of the spinal cord, with debulking of the tumor, followed by CyberKnife treatment.

Pyia was hospitalized for 1 day before her surgery and for 4 days after the surgery. Postoperatively she learned to ambulate 50 feet with a front-wheeled walker and minimal assistance and to get on and off a commode chair. She required an ankle-foot orthosis (AFO) for her left foot. Pyia was discharged from the hospital to stay with her daughter and had a rental wheelchair for community mobility. A referral for home-based occupational and physical therapy was made through a home care agency.

An occupational profile provided the following information about Pyia. Pyia was widowed and lived alone in a three-bedroom house with three steps by which to enter the home. She retired from retail sales when she was 62. She was independent in driving, was active in her church, and attended occasional programs at the local senior citizens' center. She volunteered 3 hours per week at a thrift shop that benefits the local children's hospital. Pyia has two close friends with whom she would go to lunch each Tuesday. Pyia has three children, two sons who live in other states and the daughter who lives in the same town. She has two grandchildren, ages 10 and 13, who live nearby. Two or three times per year she would fly to visit her sons.

An important part of Pyia's life for the past few years has been going to her daughter's home one or two afternoons per week. She would help watch the grandchildren after school or drive them to activities while their parents worked. She would also help her daughter with laundry and dinner preparation.

After 3 weeks at her daughter's home, Pyia was asked to identify what areas of occupational performance were still problematic for her, what she could do well, and what her goals were. She replied that she was happy to be walking better but felt endurance was still a problem. She used the walker independently in the home but still needed assistance to get up and down stairs. The PT felt that she soon would be independent with stairs and may be able to transition to a cane because her lower extremity strength, especially in her right leg, had improved. Pyia was able to walk to the bathroom and to use a toilet independently and was independent in dressing. Her daughter helped her into and out of the tub for safety reasons, and she used a stool in the tub for bathing. She was able to prepare a simple breakfast and lunch but needed a rest period each morning and afternoon.

Pyia felt like a burden to her daughter and son-in-law. She felt guilty that her daughter had taken a week off work after her hospitalization to be with her at home and that her son had to visit to help her for the second week. She was happy that she could now take care of herself during the day but would like to be able to help with household chores. She had to rely on her family and friends to drive her to doctors' appointments, and she will need them to drive her to therapy appointments the following week as she transitions to outpatient care. Pyia wished that she could return to her home but recognized that she was not yet ready. Her old friends brought lunch to her daughter's home the previous Tuesday, and she was grateful for their support and the support she received from her pastor and church.

Critical Thinking Questions

1. How did Pyia's needs, goals, and occupational roles change during the course of her illness and recuperation?

2. Where would you start your intervention plan, considering her current goals?

3. What are safety issues, and how would you address them?

Occupational therapists (OTs) work with many types of clients who may have impaired ambulation due to congenital conditions, disease, or trauma. These impairments may be temporary or long term. For example, an elderly person with a hip fracture may require the use of a walker for several weeks or months until the bone is healed and strength is regained. Persons with a spinal cord injury may have permanent motor and sensory losses that require lower extremity bracing and the use of crutches for walking, or they may require a wheelchair for mobility. They may be ambulatory only part of the time and may use a wheelchair part of the time. The ability to ambulate involves many factors, including the condition or type of disability, the amount of energy required for ambulation, balance, and the person's occupational roles.

Functional ambulation, a component of functional mobility, is the term used to describe how a person walks while achieving a goal, such as carrying a plate to the table or carrying groceries from the car to the house. Functional ambulation training is applicable for all individuals with safety or functional impairments and for a variety of diagnoses, such as lower extremity amputation, cerebrovascular accident, brain trauma or tumor, neurological disease, spinal cord injury, orthopedic injury, and total hip or knee replacement. Older adults and persons with neurological diagnoses are at higher risk for falls, and training may be important to prevent injuries as a result of falls. Intervention goals should focus on the ability of individuals to engage in occupations and to promote wellness and safety during those occupations.

Ambulation evaluation, **gait training** (treatments used to improve walking and ameliorate deviations from normal gait), and recommendations for bracing and **ambulation aids** are included in the professional role of the physical therapist. The PT makes recommendations that can be followed by the client, families, hospital staff, or other caregivers. The OT works closely with colleagues in physical therapy to determine when clients may be ready to advance to the next levels of functional performance. For example, the OT may begin having a client walk to the bathroom for toileting instead of using a bedside commode. The PT may recommend techniques, equipment, or cueing to improve safety. Mutual respect and good communication between all professionals help coordinate care and maximize client outcomes. For example, a client with Parkinson's disease may walk well with the PT immediately after taking his medication in the morning but may have difficulty walking to the refrigerator to select items to prepare lunch a few hours later when the effects of medication are waning. Client-centered care, with strong interprofessional communication, will help with meeting the client's identified goals.

The following section is meant to provide an introduction to the OT about the basics of ambulation and aids (eg, crutches, canes, walkers, and braces) to assist with the teaching of activities of daily living (ADLs). It is not meant as a substitute for close collaboration with a physical therapist. A basic introduction will also be provided to fall prevention and safety.

Basics of Ambulation

Normal walking is a method of using two legs, alternately, to provide support and propulsion. The terms gait and walking are often used interchangeably, but gait more accurately describes the style of walking. The “normal” pattern of walking includes components of body support on each leg alternately (stance phase), advancement of the swinging leg to allow it to take over a supporting role (swing phase), balance, and power to move the legs and trunk. Normal walking is achieved without difficulty and with minimal energy consumption. During normal walking the person has more time in the stance phase compared to the swing phase.

Descriptors of the events of walking include loading response, midstance, terminal stance and preswing, and midswing and terminal swing; the duration of the complete cycle is called cycle time. Cadence is the average step rate. Stride length is the distance between two placements of the same foot. It may be shortened in people with a variety of diseases. Walking base is the distance between the line of the two feet. It may be wider than normal for people with balance deficits.[212]

Abnormal gait is caused by disorders of the complex interaction between neuromuscular and structural elements of the body. It may result from problems with the brain, spinal cord, nerves, muscles, joints, or skeleton, or from pain. Problems may include weakness, paralysis, ataxia, spasticity, loss of sensation, and inability to bear weight through the limb or pelvis. Deficits may include decreased velocity, decreased weight bearing, increased swing time of the affected leg, an abnormal base of support, and balance problems. Functional deficits may include loss of mobility, decreased safety (increased fall risk), and insufficient endurance. The OT should reinforce gait training by following the recommendations of the PT.

Orthotics

As the PT evaluates the causes of gait problems, orthotics and ambulatory aids may be recommended. The OT should be familiar with basic lower extremity (LE) orthotics, including the reason for bracing. The OT may teach clients to put on the orthotics as part of dressing training.

Orthotics, or braces, are used to provide support and stability for a joint, to prevent deformity, or to replace lost function. They should be comfortable, easy to apply, and lightweight, if possible. The more joints of the lower extremity require bracing, the higher is the energy cost of ambulation.

Orthotics are named by the part of the body that is supported. A supramalleolar orthosis (SMO), or supramalleolar ankle-foot orthosis (SMAFO), is made of plastic and fits into a shoe. It provides medial-lateral stability at the ankle, provides rear foot alignment during gait, supports midfoot laxity, and can control pronation/supination positions of the forefoot. It is not useful in cases of high tone or limited dorsiflexion. An ankle-foot orthosis (AFO) is usually made of plastic; it inserts into a shoe and extends up the back of the lower leg. It is sometimes called a foot drop splint because it is used in cases of central or peripheral nerve lesions, which cause weakness of ankle dorsiflexors. An AFO may consist of one piece or may be hinged to permit ankle dorsiflexion. A knee-ankle-foot orthosis (KAFO) may be recommended for clients with knee weakness or hyperextension, or with foot problems. The KAFO might be used with diagnoses such as paraplegia, cerebral palsy, or spina bifida. For clients with spinal cord lesions or spina bifida involving the hip muscles, a hip-knee-ankle-foot orthosis (HKAFO) might be used. A reciprocating gait orthosis (RGO) is a type of HKAFO that may be used to help advance the hip in the presence of hip flexor weakness. High energy costs are associated with use of HKAFOs, and clients' upper extremities are used for support on walkers and crutches. This makes functional ambulation tasks extremely challenging for these clients, and it may be more energy efficient and safer to perform some tasks while seated in a chair or wheelchair.

Walking Aids

Ambulation aids may be used to compensate for deficits in balance and strength, to decrease pain, and to decrease weight bearing on involved joints and help with fracture healing, or in the absence of a lower extremity. Walking aids are generally classified as canes, crutches, and walkers. All three help support part of the body weight through the arm or arms during gait. They may also be sensory cues for balance and may enhance stability by increasing the size of the base of support.

A single-point cane may be used with clients who have minor balance problems to widen the base of support or provide sensory feedback through the upper extremity about position. For clients with a painful hip or knee, a cane is most commonly used on the contralateral side to reduce loading on the painful joint. The cane is advanced during the swing phase of the leg it is protecting. Variations of cane designs include quad canes and hemiwalkers, which are heavier and bulkier than single-point canes but provide greater stability.

Crutches are able to transmit forces in a horizontal plane because two points of attachment exist —one at the hand and the other higher on the arm. Clients should be cautioned not to lean on crutches at the axilla because this may cause damage to blood vessels or nerves. The lever between the axilla and the hand is long, and enough horizontal force can be generated to permit walking when one leg has restricted weight-bearing capacity or when both legs are straight and have limited or no weight-bearing capacity. Crutches are suitable for short-term use, such as for a fractured leg.

Forearm crutches may also be called Lofstrand or Canadian crutches. The points of contact are on the hand and forearm. Forearm crutches are lighter than the axillary type, and the lever arm is shorter. For most people mobility is easier with forearm crutches than with the axillary type, and forearm crutches are useful for active people with severe leg weakness. All crutches require good upper body strength.

Walkers are more stable than canes or crutches. With a pick-up–style walker, the walker is moved first; the client takes a short step with each foot and then moves the walker again. This type of walking can be slow. Most clients who need a walker are able to use a front-wheeled walker, which has two wheels on the front, making it lighter and easier to advance. Another variation is to have four wheels, along with a braking system. Some walkers have seats so that clients can rest when they become fatigued. Walkers require the use of both arms but do not require as much upper body strength or balance as crutches. Forearm platforms can be added to forearm crutches or walkers when clients are unable to bear weight through their hands or wrists, perhaps because of fracture or arthritis. For example, the client in the case study, Pyia, is currently using a walker that supplies substantial support during ambulation but requires additional energy to use compared with a cane. The PT may recommend a cane as Pyia progresses, but a walker may still be necessary in some situations within the home environment.

Ambulation Techniques

Basic ambulation techniques recommended by the PT vary from client to client, depending on the individual's goals, strengths, and weaknesses, and may be more complex than the descriptions provided previously. The OT reinforces the PT's recommendations and incorporates them into functional ambulation activities.

During functional ambulation on a level surface, the OT is positioned slightly behind and to one side of the client. The therapist may be on the client's stronger or weaker side, based on the recommendations and preference of the PT or the goals of the activity. The OT moves in tandem with the client when providing support during ambulation. The OT's outermost lower extremity moves with the ambulation aid, and the OT's inside foot moves forward with the client's lower extremity. Of course, some clients may be independent with basic ambulation and may need guarding or assistance only when practicing new activities, such as transporting hot foods, mopping a floor, or reaching into a dryer.

Safety

OT Practice Notes

Safety for Functional Ambulation

1. Know the client (eg, status, orthotics and aids, precautions).

2. Use appropriate footwear.

3. Monitor physiological responses.

4. Use a gait belt to guide the client. Do not use the client's clothes or upper extremity to guide the client.

5. Think ahead for the unexpected.

6. Do not leave the client unattended.

7. Clear potential hazards.

Safety is the number one priority for clients during functional ambulation. Before beginning an evaluation of ADLs, the OT should know basic client information. The therapist reviews the medical record, especially the current status and precautions. Does the client use oxygen? Does it need to be increased during activity? In the hospital setting it may be useful to be aware of the client's hematocrit level, if available, to help predict how much activity the client may be able to tolerate. The therapist should review PT reports and confer with the PT as needed about gait techniques, aids, orthotics, and ambulatory status. To prepare the client for functional ambulation, the therapist and the client should have safe and appropriate footwear. Soft-soled shoes or shoes with a slippery sole should be avoided, and slippers or shoes without a heel support can compromise safety and stability for the client.

Another key to safe and successful ADLs is awareness of the client's endurance level, including the distance the client is able to ambulate. It is very important to plan ahead for the activity. The therapist should have a wheelchair, a chair, or a stool readily available for use at appropriate intervals or in case of need caused by client fatigue. The area should be free of potential safety hazards, such as throw rugs or other objects on the floor. In certain cases, however, as with a client with unilateral neglect, hemianopsia, or visual or perceptual deficits, the therapist may want to challenge the client to manage in a complex environment.

The client's physiological responses should be monitored during the activity. The therapist should be aware of the client's precautions and should respond appropriately. Physiological responses may include a change in breathing patterns, perspiration, reddened or pale skin, a change in mental status, and decreased responsiveness. These changes may require termination of the activity to allow the client a period of rest. Recall that Pyia continues to experience limited endurance and easily fatigues. Activities that require sustained standing or walking may be too challenging at this time.

Elderly clients who use assistive devices for ambulation before hospitalization are particularly at risk for loss of ADL and instrumental activities of daily living (IADLs) function after hospitalization. A history of use of assistive devices may be a marker for decreased ability to recover.[120] It may be important to target these elderly individuals for intensive therapy to maintain function.

Falls represent a major problem in the elderly. Studies suggest that one-fourth of persons aged 65 to 79 and half of those older than 80 fall every year.[60] Falls result from many factors, including both intrinsic (eg, health, existence of balance disorders) and external, or environmental, factors. Home hazards include poor lighting, inadequate bathroom grab rails, inadequate stair rails, exposed electrical cords, items on the floors, and throw rugs. Elderly people with health problems such as cardiac disease, stroke, and degenerative neurological conditions have an even greater risk of falling.[110,171] OTs may visit the client's home while the client is hospitalized or may work through home health agencies, fall prevention programs, or senior citizen centers to help evaluate homes for potential hazards.[148] All reasonable efforts should be made to decrease the risk of falls.

If a client loses his or her balance or stumbles, the therapist will have better control of the client if he or she is holding onto the client's trunk. Therapists may be less prone to injure their own backs if they use their legs to support or lower the client to the floor instead of pulling or twisting with the upper body. For a client who feels faint or develops sudden leg weakness, the therapist lowers the client onto the therapist's flexed leg, as if onto a chair, and then down to the floor.

OT Practice Notes

All clients who are at risk for falling and who are alone for significant periods of time should be connected to a lifeline-type phone system by which help can be summoned in the event of a fall or other emergency. Local hospitals or senior citizen centers will have further information about lifeline services.

Functional Ambulation Activities

OT Practice Notes

The therapist must develop a good working relationship with the equipment supplier and reimbursement sources to facilitate payment of the most appropriate mobility system for the client. The therapist must have the oral and written documentation skills needed to clearly communicate the medical necessity, appropriateness, and cost-effectiveness of each item throughout the assessment and recommendation process.

Functional ambulation integrates ambulation into ADLs and IADLs. By using an occupationally based approach, the OT assesses the client's abilities within the performance context and with an understanding of the client's habits, routines, and roles. What role or roles does the client have or want to have? What tasks does this role require? The OT plans for functional mobility activities with the goal of helping the client achieve valued roles and activities. Several typical functional ambulation activities follow. These activities must be individualized for clients. Functional ambulation may be incorporated during ADLs, IADLs, work, play, or leisure activities.

Kitchen Ambulation

Meal preparation and cleanup involve many different tasks, such as opening and reaching into a refrigerator, dishwasher, stove, microwave, and cupboards. This often involves transporting items within the kitchen and to a table. If something is dropped, the item will need to be retrieved from the floor. The task may be relatively quick and easy, such as heating food in a microwave, or may require someone to stand while chopping, stirring, or cooking food. The OT can help the client engage in problem-solving strategies on how to safely accomplish these tasks. For example, clients with left hemiplegia who ambulate with a quad cane may be guided to the left of the oven so that they can open the oven door by using the unaffected right upper extremity. The same concept should be kept in mind for opening cabinet doors or drawers or refrigerator doors. The therapist can help assess the client's safety during these tasks and can recommend alternatives as needed. If the client is unable to successfully balance and reach into the oven, a toaster oven on the counter may be a safer alternative. Clients can place frequently needed items in convenient locations, or equipment such as a reacher may be needed. If the reacher is applied to a walker with Velcro, it is usually available when the client needs it. Clients may be able to pick up items from the floor by kicking or pushing the item close to a counter, where they can hold on to the counter while bending to pick up the item. If they have had a total hip replacement and have hip flexion precautions, they can position the affected leg behind them, being careful to not internally rotate the hip, while they reach down to the floor.

Transporting items such as food, plates, and eating utensils during functional ambulation invites creative problem solving on the part of the OT, particularly when the client is using an ambulation aid (Figs. 11.1 and 11.2). Baskets attached to a walker, rolling carts, or countertops on which to slide the item may be appropriate in these situations. Clients must clearly desire the equipment or adaptations, and care should be taken not to provide unwanted or unnecessary equipment. A client who does not live alone may prefer to share jobs with other family members; that is, the client may do the cooking while a family member sets and clears the table. Although Pyia was able to prepare a simple meal, she still experiences fatigue after doing so and is unable to assist her daughter in meal preparation. Suggestions regarding adaptations and energy conservation techniques may support Pyia's goal of being able to help with this activity while still living with her daughter.

FIG 11.1 Functional ambulation with an active walker and serving tray. (©2016 Problem Solvers.)

FIG 11.2 Functional ambulation with a straight cane.

Bathroom Ambulation

Functional ambulation to the sink, toilet, bathtub, or shower is an important concern for the client. Care should be taken during activities in the bathroom because of the many risks associated with water and hard surfaces. Spills on the floor are slipping hazards, and loose bath mats are tripping hazards. Clients must be educated about these dangers. Nonslip surfaces or mats should be used on tub and shower floors.

Functional ambulation to the sink using a walker may be performed by having the client approach the sink as closely as possible. If the walker has a walker basket, the client can position the walker at the side of the sink; then, while holding on to the walker with one hand and the sink or countertop with the other, the patient can turn to face the sink.

The importance of helping the client become as independent as possible in toileting cannot be overemphasized. People who are unsure about their abilities to safely use a toilet in friends' or families' homes, in restaurants, in the mall, or at gas stations may become homebound as a result. When safe to do so, practice toileting in a variety of settings and with and without equipment such as commodes or elevating toilet seats and grab bars. One limiting factor may be postoperative precautions; a tall client who has had a total hip replacement may not be able to sit safely on a regular toilet while observing the postsurgical precaution of no hip flexion greater than 90 degrees. A shorter client may be able to sit successfully on a toilet of regular height without difficulty. If a client is unable to get up and down from the toilet without assistance or if he or she does so with difficulty, consult the PT, who can provide the client with lower extremity strengthening exercises.

When the client is ambulating to a tub or shower, make sure the equipment and supplies are in position for the client to use. While stepping into a shower stall with a low rim, clients use the same technique that they would use to go up a curb or step, using their walking aid if it fits into the door of the shower. If the walking aid does not fit, the therapist can evaluate the client's ability to safely step in without the equipment. A client who has non–weight-bearing precautions on a leg will not be able to step into a shower without walking aids and will not step into a tub. A tub bench must be used for non–weight-bearing clients who have access only to tubs. Pyia is able to negotiate her daughter's home and to use the toilet but still requires assistance to transfer into and out of the tub. These skills will have to be addressed before Pyia can return to her own home.

Grab bars are important safety items for clients in the shower and tub. The therapist may want to practice shower or tub transfers under trial conditions before practicing an actual shower or bath. Some older persons have become accustomed to taking sponge baths because of a fear of falling in the bathroom. The therapist should determine whether the client is satisfied with this system or would like to work toward independent showering.

Home Management Ambulation

The ability to live alone is closely tied to the ability to perform IADLs.[118] Home management activities include cleaning, laundry, and household maintenance. Cleaning includes tidying, vacuuming, sweeping and mopping floors, dusting, and making beds. Clients may balance with one hand and hold onto a counter or a sturdy piece of furniture while cleaning floors if they are not stable independently or are using a walking aid. Lightweight duster-style sweepers, which come with dry or wet replaceable pads, are easy to handle and use. When making the bed, the client can stabilize himself or herself on the bed or walking aid while straightening and pulling up sheets and bedcovers. The client then moves around the bed to the other side to repeat the process. Some clients find that carrying items in a small fanny pack or shoulder bag slung over the neck is an easy way to transport small items such as cordless phones, bottled water, and books. Moving clothes to or from a laundry room may present a challenge for people with mobility impairments, particularly if they use a walking aid. Rolling carts may be useful to transport items to the laundry and in the kitchen. Some clients carry items over the front of their walkers, in a bag attached to the walker, or in a bag that they hold while walking with crutches or a cane. Whichever method is safe for the client is acceptable. Watch to make sure that the clothes do not shift while clients carry them; this may throw them off balance.

Other home management activities may include maintenance of the yard, garden, appliances, and vehicles. The client should be consulted to determine the home management activity most valued by him or her before the functional activity is begun. Sometimes the client has goals that the therapist does not believe are safe for the client to perform. For example, the client who has had a mild stroke who wants to climb a ladder and trim tree branches with his power saw may need to be persuaded to wait until his balance and strength are improved. Although this is a valued activity, it may be incompatible with the client's functional abilities at the time. Gardening is an area in which the PT and the OT may wish to collaborate. The PT helps the client learn to maneuver over uneven surfaces and get up and down from the ground, whereas the OT helps the client learn how to carry tools and other equipment and how to dispose of clippings and weeds.

In case of falls clients should learn how to get up and down from the floor or ground during physical therapy sessions. It may be a functional activity with the OT when clients want to be able to get to the bottom of a tub, reach objects stored under a bed, or sit on the floor to play with their grandchildren.

Therapists should listen to clients about the techniques that clients have developed to be independent and safe. Some clients with fall risks manage to walk to the bathroom from their bed every night without putting on braces and/or using equipment. They will say things such as, “I lean against the wall as I walk,” or “There is a couch there, and I brace myself on the back.” If the technique is safe and if the client has not had falls, the routine may not need modification.

Section 1 Summary

Functional ambulation may be incorporated during ADLs, IADLs, work and productive activities, and play or leisure. OTs and PTs have an opportunity to collaborate, with the PT providing gait training, exercises, and ambulation aid recommendations, and the OT reinforcing training and integrating it during purposeful activities.

Section 1: Threaded Case Study

Pyia, Part 2

Pyia's roles as homemaker, caregiver, grandmother, mother, and volunteer changed with her illness. Her role became more passive as others became her caregivers. Initially, she was very concerned about her disease, whether and how long she would live, and if she would ever be able to walk again. After surgery, her goals were to be able to walk and to go to her daughter's home. Once this was achieved, she began to experience loss about her change in roles and to plan for the future: taking care of herself during the day, resuming homemaking activities, planning a return to her own home, visiting with her friends, and becoming more independent in the community.

Pyia is home alone during the day. She would like to be more active with homemaking, both to help her daughter and to prepare for the return to her own home. The therapist could begin practice on laundry and cleaning. Pyia is already able to do basic meal preparation. The therapist could help assess safety in Pyia's home, make recommendations for equipment or modifications, and refer the family for lifeline services. Pyia might arrange transportation services for the disabled through her county, or she could have a driver's evaluation to determine whether she could start to drive again. She would need to be able to get into and out of the car safely and to put her walker and other items in the car.

Section 2 Wheelchair Assessment and Transfers

Michelle Tipton-Burton, with contributions from Carol Adler

Wheelchairs

Section 2: Threaded Case Study

William, Part 1

William is a 17-year-old male who sustained a C6 spinal cord injury after a diving accident approximately 2 weeks ago. Sensation and motor function are absent below the level of the lesion. He is medically stable, receiving rehabilitation services, and has been referred for a wheelchair assessment. William has a halo vest for stabilization and is able to tolerate sitting upright for 1 hour before he complains of getting dizzy. He still asks the rehabilitation therapists, nurses, and his physician when he will be able to move his legs. He has been told that because he has had no return of function during the past 2 weeks, it is unlikely that he will have significant changes in his current level of motor and sensory function.

Upon discharge from the inpatient rehabilitation unit, William will be returning to his home, where he lives with his parents and younger brother. The home is two stories high, and William's bedroom is located on the second floor. A bathroom is located on the first floor.

Before his injury William was very physically active and was on the track and field team at his high school. He was also an avid hiker and often would go camping with his family and friends. William is a high school senior and received early acceptance to a university located within 2 hours of his home. He was very excited about attending this university because of the track and field program, in addition to his interest in becoming a marine biologist. Although William's friends have come to visit him, his girlfriend of 2 years has not visited.

Critical Thinking Questions

1. How would you anticipate that William would respond to being fitted for a wheelchair? What emotional responses may be evoked in William by this experience? How could you minimize his potential distress?
2. What decisions could William make regarding selection of the wheelchair?
3. Considering William's needs across several contexts, what type of wheelchair would you recommend?
4. What client factors must be considered when a wheelchair is selected for William?

A wheelchair can be the primary means of mobility for someone with a permanent or progressive disability, such as cerebral palsy, brain injury, spinal cord injury, multiple sclerosis, or muscular dystrophy. Someone with a short-term illness or orthopedic problem may need it as a temporary means of mobility. In addition to mobility, the wheelchair can substantially influence total body positioning, skin integrity, overall function, and the general well-being of the client. Regardless of the diagnosis of the client's condition, the OT must understand the complexity of wheelchair technology; available options and modifications; the evaluation and measuring process; the use, care, and cost of the wheelchair; and the process by which this equipment is funded.

Wheelchairs have evolved considerably in recent years, and significant advances have been made in powered and manual wheelchair technology by manufacturers and service providers. Products are constantly changing. Many improvements are the result of user and therapist recommendations. Durable medical equipment reimbursement (DME benefit) has also changed, and clients' benefits should be explored prior to initiating a wheelchair assessment.

OTs and PTs, depending on their respective roles at their treatment facilities, are usually responsible for evaluation, measurement, and selection of a wheelchair and seating system for the client. They also teach wheelchair safety and mobility skills to clients and their caregivers. The constant evolution of technology and the variety of manufacturers' products make it advisable to include an experienced, knowledgeable, and certified assistive technology professional (ATP) on the ordering team. The ATP is a supplier of DME who is proficient in ordering custom items and can offer an objective and a broad mechanical perspective on the availability and appropriateness of the options being considered. The ATP will serve as the client's resource for insurance billing, repairs, and reordering upon returning to the community.

Whether the client requires a noncustom rental wheelchair for temporary use or a custom wheelchair for use over many years, an individualized prescription clearly outlining the specific features of the wheelchair is needed to ensure optimal performance, safety, mobility, and enhancement of function. A wheelchair that has been prescribed by an inexperienced or nonclinical person is potentially hazardous and can cause undue financial harm to the client. Once a wheelchair has been purchased, the DME benefit has been used, and therefore another wheelchair may not be purchased. Typically payer sources do not authorize another wheelchair for at least 5 years unless there has been a significant change in physical status. An ill-fitting wheelchair can, in fact, contribute to unnecessary fatigue, **skin breakdown**, and trunk or extremity deformity, and it can inhibit function.[62] A wheelchair is an extension of the client's body and should facilitate rather than inhibit good alignment, mobility, and, most importantly, function.

Wheelchair Assessment

The therapist has considerable responsibility in recommending the wheelchair appropriate to meet immediate and long-term needs. When evaluating for a wheelchair, the therapist must know the client and have a broad perspective on the client's clinical, functional, and environmental needs. Careful assessment of physical status must include the specific diagnosis, the prognosis, and current and future problems (eg, age, spasticity, loss of range of motion [ROM], muscle weakness, reduced endurance) that may affect wheelchair use. Additional client factors to be considered in assessment of wheelchair use are sensation, cognitive function, and visual and perceptual skills. Functional use of the wheelchair in a variety of environments must be considered, along with how the wheelchair will be transported. For instance, if a power wheelchair is being considered, there must be a means of transporting the patient and the wheelchair safely. Collaboration with representatives of other disciplines treating the client is important. Box 11.1 lists questions to consider before making specific recommendations.

Box 11.1

Questions to Ask Before Making Specific Recommendations for a Wheelchair

- Who will pay for the wheelchair?
- Who will determine the preferred durable medical equipment (DME) provider: the insurance company, the client, or the therapist?
- What is the specific disability?
- What is the prognosis?
- Is range of motion limited?
- Is strength or endurance limited?
- How will the client propel the chair?
- How old is the client?
- How long is the client expected to use the wheelchair?

- What was the client's lifestyle, and how has it changed?
- Is the client active or sedentary?
- How will the dimensions of the chair affect the client's ability to transfer to various surfaces?
- What is the maneuverability of the wheelchair in the client's home or in the community (eg, entrances and egress, door width, turning radius in bathroom and hallways, floor surfaces)?
- What is the ratio of indoor to outdoor activities?
- Where will the wheelchair be primarily used—in the home, at school, at work, or in the community?
- Which mode of transportation will be used? Will the client be driving a van from the wheelchair? How will it be loaded and unloaded from the car?
- Which special needs (eg, work heights, available assistance, accessibility of toilet facilities, parking facilities) are recognized in the work or school environment?
- Does the client participate in indoor or outdoor sports activities?
- How will the wheelchair affect the client psychologically?
- Can accessories and custom modifications be medically justified, or are they luxury items?
- What resources does the client have for equipment maintenance (eg, self, family, caregivers)?

Before the final prescription is prepared, collected information must be analyzed for an understanding of advantages and disadvantages of recommendations based on the client's condition and how all specifics will integrate to provide an optimally effective mobility system.

To ensure that payment for the wheelchair is authorized, therapists should have an in-depth awareness of the client's insurance DME benefits and should provide documentation with thorough justification of the **medical necessity** of the wheelchair and any additional modifications. Therapists must explain clearly why particular features of a wheelchair are being recommended. They must be aware of standard versus “up charge” items, the cost of each item, and the effects of these items on the end product.

Wheelchair Ordering Considerations

Before selecting a specific manufacturer and the wheelchair's specifications, the therapist should carefully analyze the following sequence of evaluation considerations.[6,152,210]

Propelling the Wheelchair

The wheelchair may be propelled in a variety of ways, depending on the physical capacities of the user. If the client is capable of self-propulsion by using his or her arms on the rear wheels of the wheelchair, sufficient and symmetric grasp, arm strength, and physical endurance may be assumed to be present to maneuver the chair independently over varied terrain throughout the day.[210] An assortment of push rims are available to facilitate self-propelling, depending on the user's arm and grip strength. A client with hemiplegia may propel a wheelchair using the extremities on the unaffected side for maneuvering. A client with tetraplegia may have functional use of only one arm and may be able to propel a one-arm drive wheelchair, or a power chair may be more appropriate. Although William, the 17-year-old in the case study who has a C6 spinal cord injury, has functional strength in both biceps, energy and potential injury in the future must be considered if he is to use only a manual wheelchair.

If independence in mobility is desired, a power wheelchair should be considered for those who have minimal or no use of the upper extremities, limited endurance, or shoulder dysfunction. Power chairs are also preferred in situations involving inaccessible outdoor terrain.[210] Power wheelchairs have a wide variety of features and can be programmed; driven by foot, arm, head, or neck; or pneumatically controlled (sip and puff), or even controlled by eye gaze or tongue driven. Given current sophisticated technology, assuming intact cognition and perception, even a person with the most severe physical limitations is capable of independently driving a power wheelchair.

If the chair is to be propelled by the caregiver, consideration must be given to ease of maneuverability, lifting, and handling, in addition to the positioning and mobility needs of the client.

Regardless of the method of propulsion, serious consideration must be given to the effect the chair has on the client's current and future mobility and positioning needs. In addition, lifestyle and the home environment; available resources, such as the ability to maintain the chair; transportation options; and available reimbursement sources are major determining factors.

Although William is physically fit, his upper body strength has been compromised by the spinal cord injury. If he is interested in engaging in outdoor activities, he may lack the physical strength to propel a manual wheelchair on varied terrains. A powered wheelchair seemed an appropriate option for William, but the therapist also considered his previous occupations of camping and hiking when selecting a wheelchair that could potentially be used in outdoor terrain.

Rental vs. Purchase

The therapist should estimate how long the client will need the chair and whether the chair should be rented or purchased; this will affect the type of chair being considered. This decision is based on several clinical and functional issues. A rental chair is appropriate for short-term or temporary use, such as when the client's clinical picture, functional status, or body size is changing. Rental chairs may be necessary when the permanent wheelchair is being repaired. A rental wheelchair also may be useful when the prognosis and expected outcome are unclear or when the client has difficulty accepting the idea of using a wheelchair and needs to experience it initially as a temporary piece of equipment. Often the eventual functional outcome is unknown. In this case a chair can be rented for several months until a reevaluation determines whether a permanent chair will be necessary.[6]

A permanent wheelchair is indicated for the full-time user and for the client with a progressive need for a wheelchair over a long period. It may be indicated when custom features are required or when body size is changing, such as in the growing child.[6]

Frame Style

Once the method of propulsion and the permanence of the chair have been determined, several wheelchair frame styles are available for consideration. The frame style must be selected before specific dimensions and brand names can be determined. The therapist needs to be aware of the various features, the advantages and disadvantages of each, and the effects of these features on the client in every aspect of his of her life, from a short-term and a long-term perspective.

William is still in emotional shock that he no longer has motor control of his legs and hands. These variables must be considered when William is approached about wheelchair selection. Although a power wheelchair seemed the most appropriate choice for William, the therapist was concerned about the appearance of the wheelchair. The therapist actively engaged William in making choices regarding the type, model, and options available on various wheelchairs.

Wheelchair Selection

The questions in the following sections regarding client needs should be considered carefully before the specific type of chair is determined.[6]

Manual vs. Electric/Power Wheelchairs

Manual Wheelchair (Fig. 11.3A)

- Does the user have sufficient strength and endurance to propel the chair at home and in the community over varied terrain?
- Does manual mobility enhance functional independence and cardiovascular conditioning of the wheelchair user?
- Will the caregiver be propelling the chair at any time?
- What will be the long-term effects of the propulsion choice?

A

B

FIG 11.3 Manual vs. electric wheelchair. A, Rigid-frame chair with swing-away footrests. B, Power-driven wheelchair with hand control. (A, Courtesy Quickie Designs, Phoenix, AZ; B, Courtesy Invacare, Elyria, OH.)

Power Chairs

Power chair controls come in a number of designs and allow for varying degrees of customization and programming. Most power chair users drive using a joystick control mounted on the armrest. For those without upper extremity function, several other types of controls are available, such as head controls, chin drives, and breath controls (sip and puff). New technology even accommodates a client with only eye or tongue movement that can be used to operate a power wheelchair (Fig. 11.3B).

- Does the user demonstrate insufficient endurance and functional ability to propel a manual wheelchair independently?
- Does the user demonstrate progressive functional loss, making powered mobility an energy-conserving option?
- Is powered mobility needed to enhance independence at school, at work, and in the community?
- Does the user demonstrate cognitive, visual, and perceptual ability to safely operate a power-driven system?

- Does the user or caregiver demonstrate responsibility for care and maintenance of equipment?
- Is a van available for transportation?
- Is the user's home accessible for use of a power wheelchair?
- Has the user been educated regarding rear, mid, and front wheel drive systems, and has he or she been guided objectively in making the appropriate selection?

Manual Recline vs. Power Recline vs. Tilt-in-Space Wheelchairs

Manual Recline Wheelchair (Fig. 11.4A)

- Is the client unable to sit upright because of hip contractures, poor balance, or fatigue?
- Is a caregiver available to assist with weight shifts and position changes?
- Is relative ease of maintenance a concern?
- Is cost a consideration?

FIG 11.4 Manual recline vs. power recline wheelchair. A, Reclining back on folding frame. B, Low-shear power recline with collar mount chin control on electric wheelchair. C, Tilt system with head control on electric wheelchair. (A, Courtesy Medline Industries, Inc., 2016; B and C, Courtesy Luis Gonzalez.)

Power Recline vs. Tilt (Fig. 11.4B–C)

- Does the client have the potential to operate independently?
- Are independent weight shifts and position changes indicated for skin care and increased sitting

tolerance?
- Does the user demonstrate safe and independent use of controls?
- Are resources available for care and maintenance of the equipment?
- Does the user have significant spasticity that is facilitated by hip and knee extension during the recline phase?
- Does the user have hip or knee contractures that prohibit his or her ability to recline fully?
- Will a power recline or tilt-in-space decrease or make more efficient use of caregiver time?
- Will a power recline or tilt-in-space feature on the wheelchair reduce the need for transfers to the bed for catheterizations and rest periods throughout the day?
- Will the client require quick position changes in the event of hypotension and/or dysreflexia?
- Has a reimbursement source been identified for this add-on feature?

Folding vs. Rigid Manual Wheelchairs

Folding Wheelchairs (Fig. 11.5A)

- Is the folding frame needed for transport, storage, or home accessibility?
- Which footrest style is necessary for transfers, desk clearance, and other daily living skills? (Elevating footrests are available only on folding frames.)
- Is the client or caregiver able to lift, load, and fit the chair into necessary vehicles?

A

FIG 11.5 Folding vs. rigid wheelchair. A, Lightweight folding frame with swing-away footrests. B, Rigid aluminum frame with tapered front end and solid foot cradle. (A, Courtesy Quickie Designs, Phoenix, AZ; B, Courtesy Invacare, Elyria, OH.)

Equipment suppliers should have a variety of brands available and be knowledgeable about each. Frame weight can range approximately from 28 to 50 pounds (lb), depending on size and accessories. Frame adjustments and custom options vary with the model.

Rigid Wheelchairs (Fig. 11.5B)

- Does the user or caregiver have the upper extremity function and balance needed to load and unload the nonfolding frame from a vehicle if driving independently?
- Will the user benefit from the improved energy efficiency and performance of a rigid frame?

Footrest options are limited, and the frame is lighter (20 to 35 lb). Features include an adjustable seat angle, rear axle, caster mount, and back height. Efficient frame design maximizes performance. Options are available for frame material composition, frame colors, and aesthetics. These chairs are usually custom ordered; availability and expertise are generally limited to custom **rehabilitation technology suppliers**.

Lightweight (Folding or Nonfolding) vs. Standard-Weight (Folding) Wheelchairs

Lightweight Wheelchairs: Under 35 Pounds (See Fig. 11.5A)

- Does the user have the trunk balance and equilibrium necessary to handle a lighter frame weight?
- Does the lighter weight enhance mobility by reducing the user's fatigue?
- Will the user's ability to propel the chair or handle parts be enhanced by a lighter weight frame?
- Are custom features (eg, adjustable height back, seat angle, axle mount) necessary?

Standard-Weight Wheelchairs: More Than 35 Pounds (Fig. 11.6)

- Does the user need the stability of a standard-weight chair?
- Does the user have the ability to propel a standard-weight chair?
- Can the caregiver manage the increased weight when loading the wheelchair and fitting into a vehicle?
- Will the increased weight of parts be unimportant during daily living skills?

FIG 11.6 Standard folding frame (>35 lb) with swing-away footrests. (Courtesy iStock.com.)

Custom options are limited, and these wheelchairs are usually less expensive (except for the heavy-duty models required for users weighing more than 250 lb).

Standard Available Features vs. Custom, Top-of-the-Line Models

The price range, durability, and warranty within a specific manufacturer's model line must be considered.

Standard Available Features

- Is the chair required only for part-time use?
- Does the user have a limited life expectancy?
- Is the chair needed as a second or transportation chair, used only 10% to 20% of the time?
- Will the chair be primarily for indoor or sedentary use?
- Is the user dependent on caregivers for propulsion?
- Will the chair be propelled only by the caregiver?
- Are custom features or specifications not necessary?
- Is substantial durability unimportant?

For standard wheelchairs, a limited warranty is available on the frame. These chairs may be indicated because of reimbursement limitations. Limited sizes and options and adjustability are available. These cost considerably less than custom wheelchairs.

Custom and Top-of-the-Line Models

- Will the client be a full-time user?
- Is long-term use of the wheelchair a likely prognosis?
- Will this be the primary wheelchair?
- Is the user active indoors and outdoors?
- Will this frame style improve the prognosis for independent mobility?
- Is the user a growing adolescent, or does he or she have a progressive disorder requiring later modification of the chair?
- Are custom features, specifications, or positioning devices required?

Top-of-the-line wheelchair frames usually have a lifelong warranty on the frame. A variety of specifications, options, and adjustments are available. Many manufacturers will work with therapists and providers to solve a specific fitting problem. Experience is essential in ordering top-of-the-line and custom equipment.

Wheelchair Measurement Procedures

The client is measured in the style of chair and with the seat cushion that most closely resembles those being ordered. If the client will wear a brace or body jacket or will need any additional devices in the chair, these should be in place during the measurement. Observation skills are important during this process. Measurements alone should not be used. The therapist should visually assess and monitor the client's entire body position throughout the measurement process.[6,209]

Seat Width (Fig. 11.7A)

Objectives

1. To distribute the client's weight over the widest possible surface.

2. To keep the overall width of the chair as narrow as possible.

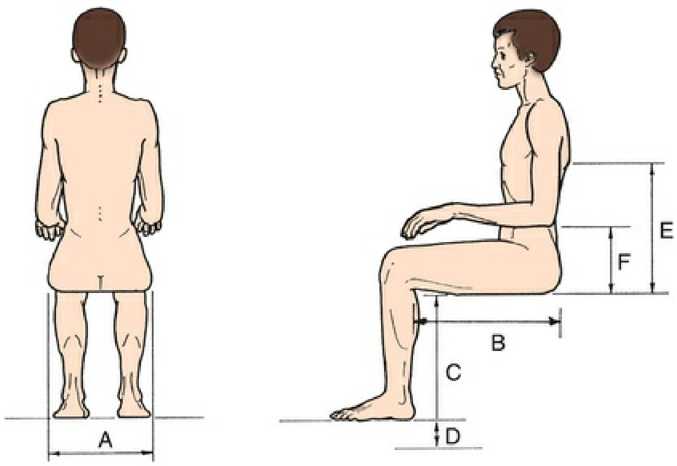

FIG 11.7 Measurements for wheelchairs. A, Seat width. B, Seat depth. C, Seat height from floor. D, Footrest clearance. E, Back height. F, Armrest height. (Adapted from Wilson A, McFarland SR: *Wheelchairs: a prescription guide,* Charlottesville, VA, 1986, Rehabilitation Press.)

Measurements

Measure the individual across the widest part of the thighs or hips while the client is sitting in a chair comparable to the anticipated wheelchair.

Wheelchair Clearance

Add ½ to 1 inch on each side of the hip or thigh measurement taken. Consider how an increase in the overall width of the chair will affect accessibility.

Checking clearance.

Place the flat palm of the hand between the client's hip or thigh and the wheelchair skirt and armrest. The wheelchair skirt is attached to the armrests in many models, and clearance should be sufficient between the user's thigh and the skirt to avoid rubbing or pressure.

Considerations

- User's potential weight gain or loss (ie, gender tendencies—male [abdominal weight gain] and female [hips and buttocks])
- Accessibility of varied environments

- Overall width of wheelchair. Camber, axle mounting position, rim style, and wheel style can also affect overall wheelchair width.

Seat Depth (Fig. 11.7B)

Objective

The objective is to distribute the body weight along the sitting surface by bearing weight along the entire length of the thigh to just behind the knee. This approach is necessary to help prevent pressure sores on the buttocks and the lower back and to attain optimal muscle tone normalization to assist in prevention of pressure sores throughout the body.

Measurements

Measure from the base of the back (the posterior buttocks region touching the chair back) to the inside of the bent knee; the seat edge clearance needs to be 1 to 2 inches less than this measurement.

Checking clearance.

Check clearance behind the knees to prevent contact of the front edge of the seat upholstery with the popliteal space. (Consider front angle of leg rest or foot cradle.)

Considerations

- Braces or back inserts may push the client forward.
- Postural changes may occur throughout the day from fatigue or spasticity.
- Thigh length discrepancy: the depth of the seat may be different for each leg.
- If considering a power recliner, assume that the client will slide forward slightly throughout the day and make depth adjustments accordingly.
- Seat depth may need to be shortened to allow independent propulsion with the lower extremities.

Seat Height From Floor and Foot Adjustment

Objectives

1. To support the client's body while maintaining the thighs parallel to the floor (Fig. 11.7C).

2. To elevate the foot plates to provide ground clearance over varied surfaces and curb cuts (Fig. 11.7D).

Measurements

The seat height is determined by measuring from the top of the wheelchair frame supporting the seat (the post supporting the seat) to the floor, and from the client's popliteal fossa to the bottom of the heel.

Wheelchair Clearance

The client's thighs are kept parallel to the floor, so the body weight is distributed evenly along the entire depth of the seat. The lowest point of the foot plates must clear the floor by at least 2 inches.

Checking clearance.

Slip fingers under the client's thighs at the front edge of the seat upholstery. *Note:* A custom seat height may be needed to obtain footrest clearance. One inch of increased seat height raises the foot plate 1 inch.

Considerations

If the knees are too high, increased pressure at the ischial tuberosities puts the client at risk for skin breakdown and pelvic deformity. This position also impedes the client's ability to maneuver the wheelchair using the lower extremities.

Posterior **pelvic tilt** makes it difficult to shift weight forward as needed to propel the wheelchair, especially with uphill grades.

Sitting too high off the ground can impair the client's center of gravity, seat height for transfers, and visibility if he or she is driving a van from the wheelchair.

Back Height (Fig. 11.7E)

Objective

Back support consistent with physical and functional needs must be provided. The chair back should be low enough for maximal function and high enough for maximal support.

Measurements

For full trunk support for the client, the back must be of sufficient height. Full support height is obtained by measuring from the top of the seat frame on the wheelchair (seat post) to the top of the user's shoulders. For minimum trunk support, the top of the back upholstery is below the inferior angle of the client's scapulae; this should permit free arm movement, should not irritate the skin or scapulae, and should provide good total body alignment.

Checking back height.

Ensure that the client is not being pushed forward because the back of the chair is too high or is not leaning backward over the top of the upholstery because the back is too low.

Considerations

- Adjustable-height backs (usually offer a 4-inch range)
- Adjustable upholstery
- Lumbar support or another commercially available or custom back insert to prevent kyphosis, scoliosis, or other long-term trunk deformity

Armrest Height (Fig. 11.7F)

Objectives

1. To maintain posture and balance.

2. To provide support and alignment for upper extremities.

3. To allow change in position by pushing down on armrests.

Measurements

With the client in a comfortable position, measure from the wheelchair seat frame (seat post) to the bottom of the user's bent elbow.

Wheelchair Clearance

The height of the top of the armrest should be 1 inch higher than the height from the seat post to the user's elbow.

Checking armrest height.

The client's posture should look appropriately aligned. The shoulders should not slouch forward or be subluxed or forced into elevation when the client is in a relaxed sitting posture, with flexed elbows resting slightly forward on armrests.

Considerations

- Armrests may have other uses, such as increasing functional reach or holding a cushion in place.
- Certain styles of armrests can increase the overall width of the chair.
- Are armrests necessary?
- Is the client able to remove and replace the armrest from the chair independently?

- Review all measurements against standards for a particular model of chair.
- Manufacturers have lists of the standard dimensions available and the costs of custom modifications.

Pediatric Wheelchairs

The goals of pediatric wheelchair ordering, as with all wheelchair ordering, should be to obtain a proper fit and to facilitate optimal function. Rarely does a standard wheelchair meet the fitting requirements of a child. The selection of size is variable; therefore, custom seating systems specific to the pediatric population are available. A secondary goal is to consider a chair that will accommodate the child's growth.

For children younger than 5 years of age, a decision must be made about whether to use a stroller base or a standard wheelchair base. Considerations include the child's ability to propel the chair relative to his or her developmental level and the parents' preference for a stroller or a wheelchair.

Many variables must be considered when a wheelchair frame is customized. An experienced ATP or the wheelchair manufacturer should be consulted to ensure that a custom request will be filled successfully.

Bariatric Wheelchairs

According to the latest data from the National Center for Health Statistics, more than 30% of American adults 20 years of age or older (more than 60 million people) and more than 16% of children and adolescents aged 2 to 19 years are obese.[53] The average wheelchair is rated to hold up to 250 pounds, and most bariatric wheelchairs can accommodate 500 pounds. It is imperative that the therapist order a wheelchair that not only meets the client's functional needs, but also will safely accommodate his or her weight. Using a wheelchair for patients who exceed the weight limit has potential safety issues, such as skin breakdown and the risk of the wheelchair bending or buckling, which may cause injury to the client. Bariatric wheelchairs feature heavy-duty frames, reinforced padded upholstery, and heavy-duty wheels. An experienced DME supplier should be able to guide the therapist and the client to the most appropriate and safe wheelchair.

Additional Seating and Positioning Considerations

A wheelchair evaluation is not complete until the seat cushion, the back support, and any other positioning devices—in addition to the integration of those parts—have been carefully thought out, regardless of the diagnosis. The therapist must appreciate the effect that optimal body alignment has on skin integrity, tone normalization, overall functional ability, and general well-being (Fig. 11.8).[6]

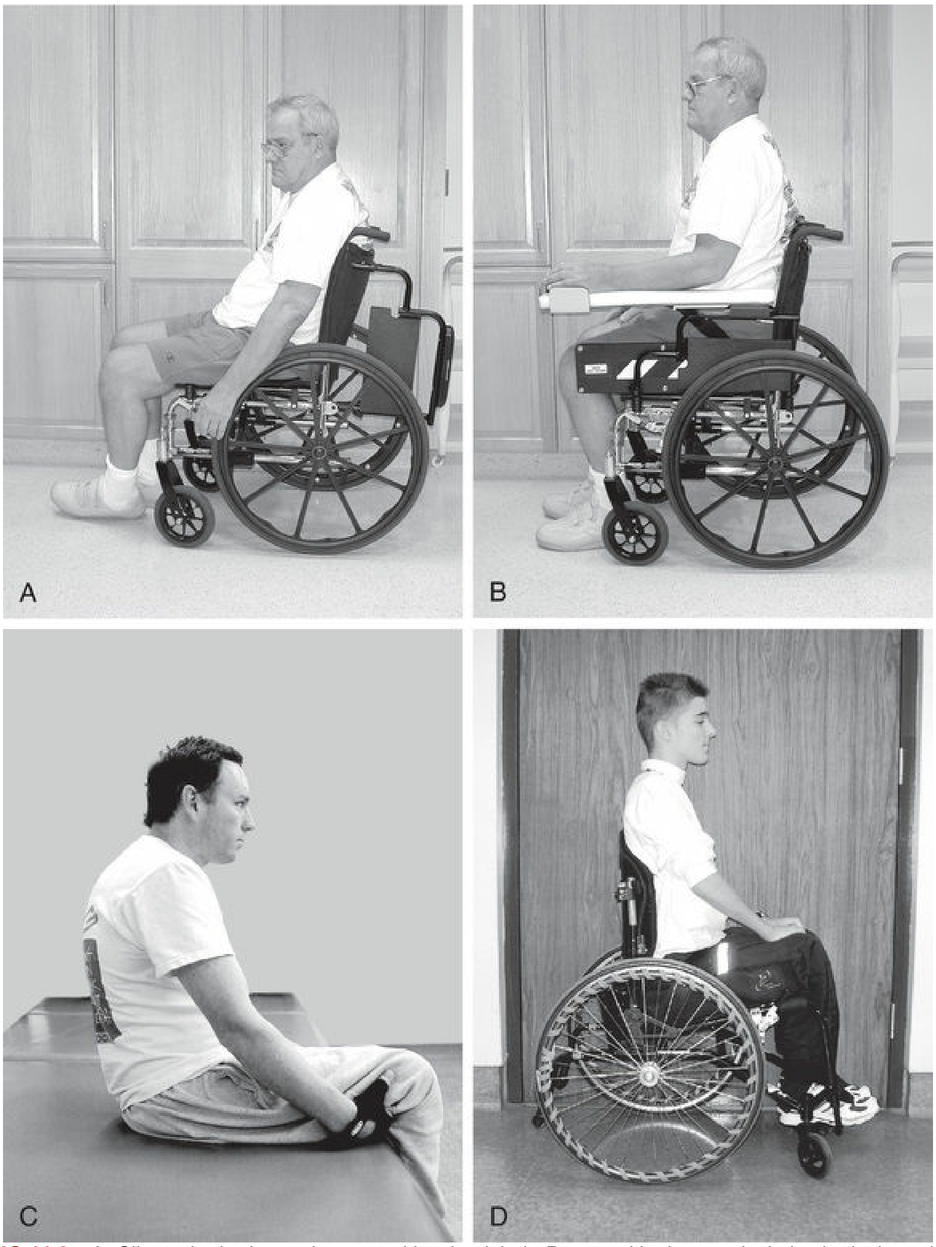

FIG 11.8 A, Client who had a stroke, seated in wheelchair. Poor positioning results in kyphotic thoracic spine, posterior pelvic tilt, and unsupported affected side. B, Same client now seated in wheelchair with appropriate positioning devices. Seat and back inserts facilitate upright midline position with neutral pelvic tilt and equal weight bearing throughout. C, Client who sustained a spinal cord injury, sitting with back poorly supported; this results in posterior pelvic tilt, kyphotic thoracic spine, and absence of lumbar curve. D, Client seated with rigid back support and pressure-relief seat cushion, resulting in erect thoracic spine, lumbar curve, and anterior tilted pelvis.

Consider William's potential need for a wheelchair seat cushion that will distribute weight evenly and avoid excessive pressure on his ischial tuberosities while sitting. He lacks sensory awareness in the buttocks region, and that places him at risk for developing decubitus ulcers. He should develop sitting tolerance that extends beyond the current 1-hour time period to help him pursue his educational goals of attending college. An appropriate seat cushion that distributes weight evenly will help William remain seated for a longer period of time. He will also need to develop the habit of shifting his weight while seated. This can be done by having William position his arm around the upright posts of the wheelchair back and pulling his body slightly to one side and then repeating the process on the other side. This shifting of the body from side to side reduces the risk of developing decubitus ulcers.

The following seven sections present the goals of a comprehensive seating and positioning assessment.

Prevention of Deformity

Providing a symmetric base of support preserves proper skeletal alignment and discourages spinal curvature and other body deformities.

Tone Normalization

With proper body alignment, in addition to bilateral weight bearing and adaptive devices as needed, tone normalization can be maximized.

Pressure Management

Pressure sores can be caused by improper alignment and an inappropriate sitting surface. The proper seat cushion can provide comfort, assist in trunk and pelvic alignment, and create a surface that minimizes pressure, heat, moisture, and shearing—the primary causes of skin breakdown.

Promotion of Function

Pelvic and trunk stability is necessary to free the upper extremities for participation in all functional activities, including wheelchair mobility and daily living skills.

Maximum Sitting Tolerance

Wheelchair sitting tolerance will increase as support, comfort, and symmetric weight bearing are provided.

Optimal Respiratory Function

Support in an erect, well-aligned position can decrease compression of the diaphragm, thus increasing **vital capacity**.

Provision for Proper Body Alignment

Good body alignment is necessary for prevention of deformity, normalization of tone, and promotion of movement. The client should be able to propel the wheelchair and to move around within the wheelchair. Positioning starts with the pelvis, then progresses to the trunk and finally to the head. If the pelvis isn't properly positioned, the trunk and head will not be aligned in a neutral and midline position. Spending time addressing the trunk and head positions, rather than starting at the pelvis, will often address the symptoms, but not the root problem.

A wide variety of seating and positioning equipment is available for all levels of disability. Custom modifications are continually being designed to meet a variety of client needs. In addition, technology in this area is ever growing, as is interest in wheelchair technology as a professional specialty. However, the skill of clinicians in this field ranges from extensive to negligible. Although it is an integral aspect of any wheelchair evaluation, the scope of seating and positioning equipment is much greater than can be addressed in this chapter. The Suggested Readings list at the end of this chapter provides additional resources.

Accessories

Once the measurements and the need for additional positioning devices have been determined, a wide variety of accessories are available to meet a client's individual needs. It is extremely important for the therapist to understand the function of each accessory and how an accessory interacts with the complete design and function of the chair and with seating and positioning equipment.[6,210]

Armrests come in fixed, flip-back, detachable, desk, standard, reclining, adjustable height, and tubular styles. The fixed armrest is a continuous part of the frame and is not detachable. It limits proximity to table, counter, and desk surfaces and prohibits side transfers. Flip-back, detachable desk, and standard-length arms are removable and allow side-approach transfers. Reclining arms are attached to the back post and recline with the back of the chair. Tubular arms are available on lightweight frames.

Footrests may be fixed, swing-away detachable, solid cradle, and elevating. Fixed footrests are attached to the wheelchair frame and are not removable. These footrests prevent the person from getting close to counters and may make some types of transfers more difficult. Swing-away detachable footrests can be moved to the side of the chair or removed entirely. This allows a closer approach to bed, bathtub, and counters, and, when the footrests are removed, reduces the overall wheelchair length and weight for easy loading into a car. Detachable footrests lock into place on the chair with a locking device.[210] A solid cradle footrest is found on rigid, lightweight chairs and is not removable. Elevating leg rests are available for clients with such conditions as lower extremity edema, blood pressure changes, and orthopedic problems.

Foot plates may have heel loops and toe straps to aid in securing the foot to the foot plate.[210] The angle of the foot plate itself can be fixed or adjustable, raising or lowering toes relative to heels. A calf strap can be used on a solid cradle, or when additional support behind the calf is necessary. Other accessories can include seat belts, various brake styles, brake extensions, anti-tip devices, caster locks, arm supports, and head supports.

Preparing the Justification/Prescription

Once specific measurements and the need for modifications and accessories have been determined, the wheelchair prescription must be completed. It should be concise and specific so that everything requested can be accurately interpreted by the DME supplier, who will be submitting a sales contract for payment authorization. Before-and-after pictures can be helpful to illustrate medical necessity. The requirements for payment authorization from a particular reimbursement source must be known, so that medical necessity can be demonstrated. The therapist must be aware of the cost of every item being requested and must provide a reason and justification for each item. Payment may be denied if clear reasons are not given to substantiate the necessity for every item and modification requested.

Before the wheelchair is delivered to the client, the therapist should check the chair against the specific prescription and should ensure that all specifications and accessories are correct. When a custom chair has been ordered, the client should be fitted by the ordering therapist to ensure that the chair fits and that it provides all the elements expected when the prescription was generated.

Often there are many adjustments that need to be made to ensure that the patient is properly positioned, supported, and most importantly, symmetrically aligned in order to participate in wheelchair propulsion and functional activities. Even the smallest misalignment of the body can affect the client's ability to operate his or her wheelchair or, most importantly, could cause future skin breakdown.

Wheelchair Safety

Wheelchair parts tend to loosen over time and should be inspected and tightened on a regular basis. Elements of safety for the wheelchair user and the caregiver are as follows:

1. Brakes should be locked during all transfers.

2. The client should never weight bear or stand on the foot plates, which are placed in the “up” position during most transfers.

3. In most transfers it is an advantage to have footrests removed or swung away if possible.

4. If a caregiver is pushing the chair, he or she should be sure that the client's elbows are not protruding from the armrests and that the client's hands are not on the hand rims. If approaching from behind to assist in moving the wheelchair, the caregiver should inform the client of this intent and should check the position of the client's feet and arms before proceeding.

- To push the client up a ramp, the caregiver should move in a normal, forward direction.

- If the ramp is negotiated independently, the client should lean slightly forward while propelling the wheelchair up the incline.[211]

- To push the client down a ramp, the caretaker should tilt the wheelchair backward by pushing his or her foot down on the anti-tippers to its balance position, which is a tilt of approximately 30 degrees. Then the caregiver should ease the wheelchair down the ramp in a forward direction, while maintaining the chair in its balance position. The caregiver should keep his or her knees slightly bent and the back straight.[211] The caregiver may also move down the ramp backward while the client maintains some control of the large wheels to prevent rapid backward motion. This approach is useful if the grade is relatively steep. Ramps with only a slight grade can be managed in a forward direction if the caregiver maintains grasp and pull on the hand grips, and the client again maintains some control of the big wheels to prevent rapid forward motion.

- If the ramp is negotiated independently, the client should move down the ramp facing forward, while leaning backward slightly and maintaining control of speed by grasping the hand rims. The client can descend a steep grade by traversing the ramp slightly back and forth to slow the chair. Push gloves may be helpful to reduce the effects of friction.[211]

5. A caregiver can manage ascending curbs by approaching them forward, tipping the wheelchair back, and pushing the foot down on the anti-tipper levers, thus lifting the front casters onto the curb and pushing forward. The large wheels then are in contact with the curb and roll on with ease as the chair is lifted slightly onto the curb.

6. The curb should be descended using a backward approach. A caregiver can move himself or herself and the chair around as the curb is approached and can pull the wheelchair to the edge of the curb. Standing below the curb, the caregiver can guide the large wheels off the curb by slowly pulling the wheelchair backward until it begins to descend. After the large wheels are safely on the street surface, the assistant can tilt the chair back to clear the casters, move backward, lower the casters to the street surface, and turn around.[211]

With good strength and coordination, many clients can be trained to manage curbs independently. To mount and descend a curb, the client must have good bilateral grip, arm strength, and balance. To mount the curb, the client tilts the chair onto the rear wheels and pushes forward until the front wheels hang over the curb, then lowers them gently. The client then leans forward and forcefully pushes forward on the hand rims to bring the rear wheels up on the pavement. To descend a curb, the client should lean forward and push slowly backward until the rear and then the front wheels roll down the curb.[48]

The ability to lift the front casters off the ground and balance on the rear wheels (“pop a wheelie”) is a beneficial skill that expands the client's independence in the community with curb management and in rural settings with movement over grassy, sandy, or rough terrain. The chair will have to be properly adjusted so that the axle is not too far forward, which makes the wheelchair tip over backward too easily. Clients who have good grip, arm strength, and balance usually can master this skill and perform safely. The technique involves being able to tilt the chair on the rear wheels, balance the chair on the rear wheels, and move and turn the chair on the rear wheels. Wheelies make it possible to wheel up or down (jump) curbs. The client should not attempt to perform these maneuvers without instruction and training in the proper techniques, which are beyond the scope of this chapter. Specific instructions on teaching these skills can be found in the sources cited at the end of the chapter.[48]

Transfer Techniques

Transferring is the movement of a client from one surface to another. This process includes the sequence of events that must occur both before and after the move, such as the pretransfer sequence of bed mobility and the posttransfer phase of wheelchair positioning. If it is assumed that a client has some physical or cognitive limitations, it will be necessary for the therapist to assist in or supervise a transfer. Many therapists are unsure of the transfer type and technique to use or feel perplexed when a particular technique does not succeed with the client. Each client, therapist, and situation is different. This chapter does not include an outline of all techniques but presents the basic techniques with generalized principles. Each transfer must be adapted for the particular client and his or her needs. If there is a team involved, it is best to discuss with the physical therapist the most appropriate and safe transfer technique for the client. Discussion in this chapter includes directions for some transfer techniques that are most commonly used in practice. These techniques include the stand pivot, the bent pivot, and one person– and two person–dependent transfers.

Preliminary Concepts

The therapist must be aware of the following concepts when selecting and carrying out transfer techniques to ensure the safety of both the client and the therapist:

1. The client's status, especially his or her physical, cognitive, perceptual, and behavioral abilities and limitations

2. The therapist's own physical abilities and limitations and whether he or she can communicate clear, sequential instructions to the client (and if necessary to the long-term caregiver of the client)

3. The use of correct moving and lifting techniques

Guidelines for Using Proper Body Mechanics

The therapist should be aware of the following principles of basic body mechanics[7]:

1. Get close to the client or move the client close to you.

2. Position your body to face the client (face head on).

3. Bend the knees; use your legs, not your back.

4. Keep a neutral spine (not a bent or arched back).

5. Keep a wide base of support.

6. Keep your heels down.

7. Don't tackle more than you can handle; ask for help.

8. Don't combine movements. Avoid rotating at the same time as bending forward or backward.

The therapist should consider the following questions before performing a transfer:

1. What medical precautions affect the client's mobility or method of transfer?

2. Can the transfer be performed safely by one person or is assistance required?

3. Has enough time been allotted for safe execution of a transfer? Are you in a hurry?

4. Does the client understand what is going to happen? If not, does he or she demonstrate fear or confusion? Are you prepared for this limitation?

5. Is the equipment (wheelchair, bed) that the client is being transferred to and from in good working order and in a locked position? Is it the appropriate size and type?

6. What is the height of the bed (or surface) in relation to the wheelchair? Can the heights be adjusted so that they are similar? (Transferring downhill is easier than uphill.)

7. Has all equipment been placed in the correct position?

8. Have all unnecessary bedding and equipment (eg, footrests, armrests) been moved out of the way so that you are working without obstruction?

9. Is the client dressed properly in case you need to use a waistband to assist? If not, do you need a transfer belt or other assistance?

10. What are the other components of the transfer, such as leg management and bed mobility?

The therapist should be familiar with as many types of transfers as possible so that each situation can be resolved as it arises. It is also important to consult other team members, such as the physical therapist, to discuss the client's condition and the appropriate technique. It is best to start with basic, even-level transfers (eg, mat table to wheelchair) and then progress to more complex transfers (eg, toilet and car) because these have more variables and are more challenging.

Many classifications of transfers exist, based on the extent of the therapist's participation. Classifications range from dependent, in which the client is unable to participate and the therapist moves the client, to independent, in which the client moves independently while the therapist merely supervises, observes, or provides input for appropriate technique related to the client's disabling condition.

Before attempting to move a client, the therapist must understand the biomechanics of movement and the effect the client's center of **positioning mass** has on transfers.

Principles of Body Positioning

Pelvic Tilt

Generally, after the acute onset of a disability or prolonged time spent in bed, clients assume a posterior pelvic tilt (ie, a slouched position with lumbar flexion). In turn, this posture moves the center of mass back toward the buttocks. The therapist may need to verbally cue or manually assist the client into a neutral or slightly anterior pelvic tilt position to move the center of mass forward over the center of the client's body and over the feet in preparation for the transfer.[170]

Trunk Alignment

It may be observed that the client's trunk alignment is shifted to the right or the left side. If the therapist assists in moving the client while the client's weight is shifted to one side, this movement could throw the client and the therapist off balance. The client may need verbal cues or physical assistance to come to and maintain a midline trunk position before and during the transfer.

Weight Shifting

Transfer is initiated by shifting the client's weight forward, thus removing weight from the buttocks. This movement allows the client to stand, partially stand, or be pivoted by the therapist. This step must be performed regardless of the type of transfer.

Lower Extremity Positioning

The client's feet must be placed firmly on the floor with the ankles stabilized and with the knees aligned at 90 degrees of flexion over the feet. This position allows the weight to be shifted easily onto and over the feet. The heels should be pointing toward the surface to which the client is transferring. The client should be barefoot or should have shoes on to prevent slipping out of position. Shoes with proper ankle support are beneficial for patients who have weakness or instability in the ankles or feet. The feet can easily pivot in this position, and the risk of twisting or injuring an ankle or a knee is minimized.

Upper Extremity Positioning

The client's arms must be in a safe position or in a position in which he or she can assist in the transfer. If one or both of the upper extremities are nonfunctional, the arms should be placed in a safe position that will not be in the way during the transfer (eg, in the client's lap). If the client has partial or full movement, motor control, or strength, he or she can assist in the transfer by reaching toward the surface to be reached or by pushing off from the surface to be left. The decision to request the client to use the arms during the transfer is based on the therapist's prior knowledge of the client's motor function. The client should be encouraged to not reach or grab for the therapist during the transfer because this could throw both the therapist and the client off balance.

Preparing Equipment and Client for Transfer

The transfer process includes setting up the environment, positioning the wheelchair, and helping the client into a pretransfer position. The following four sections present a general overview of these steps.

Positioning the Wheelchair

1. Place the wheelchair at approximately a 0- to 30-degree angle to the surface to which the client is transferring. **The angle depends on the type of transfer and the client's level of assist.**

2. Lock the brakes on the wheelchair and the bed.

3. Place both of the client's feet firmly on the floor, hip width apart, with the knees over the feet.

4. Remove the wheelchair armrest closest to the bed.

5. Remove the wheelchair pelvic seat belt.

6. Remove the wheelchair chest belt and trunk or lateral supports if present.

Bed Mobility in Preparation for Transfer

Rolling the Client Who Has Hemiplegia

1. Before rolling the client, you may need to put your hand under the client's scapula on the weaker side and gently mobilize it forward (into protraction) to prevent the client from rolling onto the shoulder, potentially causing pain and injury.

2. Assist the client in clasping the strong hand around the wrist of the weak arm, and lift the upper extremities upward toward the ceiling.

3. Assist the client in flexing his or her knees.

4. You may assist the client to roll onto his or her side by moving first the arms toward the side, then the legs, and finally by placing one of your hands at the scapular area and the other hand at the hip, guiding the roll.

Side-Lying to Sit Up at the Edge of the Bed

1. Bring the client's feet off the edge of the bed.

2. Stabilize the client's lower extremities with your knees.

3. Shift the client's body to an upright sitting position.

4. Place the client's hands on the bed at the sides of his or her body to help maintain balance.

Scooting to the Edge of the Bed

When working with a client who has sustained a stroke or a traumatic brain injury, the therapist should "walk" the client's hips toward the edge of the bed. Shift the client's weight to the less affected or unaffected side, position your hand behind the opposite buttock, and guide the client forward. Then shift the client's weight to the more affected side and repeat the procedure if necessary. Move forward until the client's feet are flat on the floor.

In the case of an individual with a spinal cord injury, grasp the client's legs from behind the knees and gently pull the client forward, placing the client's feet firmly on the floor and making sure that the ankles are in a neutral position.

Stand Pivot Transfers

The standing pivot transfer requires the client to be able to come to a standing position and pivot on both feet. It is most commonly used with clients who have hemiplegia, hemiparesis, or general loss of strength or balance. If the client has significant hemiparesis, stand pivot transfers encourage the less affected or the unaffected side to accommodate most of the body weight and may put the more affected limb (ankle) at risk while pivoting.

Transfer From Wheelchair to Bed or to Mat Table

1. Facilitate the client's scoot to the edge of the surface and put his or her feet flat on the floor. The client's heels should be pointed toward the surface to which the client is transferring. The feet should not be perpendicular to the transfer surface, but the heel should be angled toward the surface.

2. Stand on the client's affected side with your hands on the client's scapulae or around the client's trunk, waist, or hips. Stabilize the client's involved foot and knee with your own foot and knee. Provide assistance by guiding the client forward as the buttocks are lifted up from the present surface and toward the transfer surface (Fig. 11.9A).

FIG 11.9 Standing pivot transfer—wheelchair to bed, assisted. A to C, Therapist stands on client's affected side and stabilizes client's foot and knee. He or she assists by guiding client forward and initiates lifting the buttocks up. D, Client reaches toward transfer surface. E and F, Therapist guides the client toward transfer surface. (Courtesy Luis Gonzalez.)

3. The client may reach toward the surface to which he or she is transferring or may push off the surface from which he or she is transferring (Fig. 11.9B).

4. Guide the client toward the transfer surface and gently help him or her down to a sitting position (Fig. 11.9C).

Variations: Stand Pivot and/or Stand/Step Transfer

A stand pivot and/or stand/step transfer is generally used when a client can take small steps toward the surface goal and not just pivot toward the transfer surface (Fig. 11.9D, 11.9E, and 11.9F). The therapist's intervention may range from physical assistance to accommodation for potential loss of balance to facilitation of near normal movement, equal weight bearing, and maintenance of appropriate posture for clients with hemiplegia or hemiparesis. If a client demonstrates impaired cognition or a behavior deficit, including impulsiveness and poor safety judgment, the therapist may need to provide verbal cues or physical guidance.

Sliding Board Transfers

Sliding board transfers are best used with those who cannot adequately bear weight on the lower extremities and who have paralysis, weakness, or poor endurance in their upper extremities. If the client is going to assist the caregiver in this transfer, the client should have good upper extremity strength. This transfer is most often used with persons who have lower extremity amputations, individuals with spinal cord injuries, and bariatric clients.

Method (Fig. 11.10)

1. Position and set up the wheelchair as previously outlined.

2. Lift the leg closer to the transfer surface and place the board under this leg, at midthigh between the buttocks and the knee, angled toward the opposite hip. The board must be firmly under the thigh and firmly on the surface to which the client is transferring.

3. Block the client's knees with your own knees.

4. Instruct the client to place one hand toward the edge of the board and the other hand on the wheelchair seat.

5. Instruct the client to lean forward and slightly away from the transferring surface.

6. The client should transfer his or her upper body weight in the direction opposite to which he or she is going. The client should use both arms to lift or slide the buttocks along the board.

7. Assist the client where needed to shift weight and support the trunk while moving to the intended surface.

FIG 11.10 Positioning sliding board. Lift leg closest to transfer surface. Place board midthigh between buttocks and knee, angled toward opposite hip. (Courtesy Luis Gonzalez.)

Bent Pivot Transfer—Bed to Wheelchair

The bent pivot transfer is used when the client cannot initiate or maintain a standing position. A therapist often prefers to keep a client in the bent knee position to maintain equal weight bearing, provide optimal trunk and lower extremity support, and perform a safer and easier therapist-assisted transfer.

Procedure

1. Assist the client to scoot to the edge of the bed until both of the client's feet are flat on the floor. Grasp the client around the waist, trunk, or hips, or even under the buttocks, if a moderate or maximal amount of assistance is required.

2. Facilitate the client's trunk into a midline position.

3. Shift the weight forward from the buttocks toward and over the client's feet (Fig. 11.11A).

FIG 11.11 Bent pivot transfer—bed to wheelchair. A, Therapist grasps client around trunk and assists in shifting client's weight forward over feet. B, Client reaches toward wheelchair. C, Therapist assists client down toward sitting position. (Courtesy Luis Gonzalez.)

4. Have the client reach toward the surface he or she is transferring to or push from the surface he or she is transferring from (Fig. 11.11B).

5. Provide assistance by guiding and pivoting the client around toward the transfer surface (Fig. 11.11C).

Depending on the amount of assistance required, the pivoting portion can be done in two or three steps, with the therapist repositioning himself or herself and the client's lower extremities between steps. The therapist has a variety of choices regarding where to hold or grasp the client during the bent pivot transfer, depending on the weight and height of the client in relation to the therapist and the client's ability to assist in the transfer. Variations include using both hands and arms at the waist or trunk, or one or both hands under the buttocks. The therapist never grasps under the client's weak arm or grasps the weak arm—such an action could cause significant injury because of weak musculature and poor stability around the shoulder girdle. The choice is made with consideration of proper body mechanics. Trial and error in technique is advised to allow for optimal facilitation of client independence and safety, and the therapist's proper body mechanics.

Dependent Transfers

The dependent transfer is designed for use with the client who has minimal to no functional ability. If this transfer is performed incorrectly, it is potentially hazardous for therapist and client. This transfer should be practiced with able-bodied persons and should be used first with the client only when another person is available to assist.[7]

The purpose of the dependent transfer is to move the client from surface to surface. The requirements are that the client must be cooperative and willing to follow instructions and the therapist must be keenly aware of correct body mechanics and his or her own physical limitations. With heavy clients it is always best to use the two-person transfer, or at least to have a second person available to spot the transfer.

One Person–Dependent Sliding Board Transfer (Fig. 11.12)

The procedure for transferring the client from wheelchair to bed is as follows:

1. Set up the wheelchair and bed as described previously.

2. Position the client's feet together on the floor, directly under the knees, and swing the outside footrest away. Grasp the client's legs from behind the knees and pull the client slightly forward in the wheelchair, so the buttocks will clear the large wheel when the transfer is made (Fig. 11.12A).

3. Place a sliding board under the client's inside thigh, midway between the buttocks and the knee, to form a bridge from the bed to the wheelchair. The sliding board is angled toward the client's opposite hip.

4. Stabilize the client's feet by placing your feet laterally around the client's feet.

5. Stabilize the client's knees by placing your own knees firmly against the anterolateral aspect of the client's knees (Fig. 11.12B).

6. Facilitate the client's lean over the knees by guiding him or her forward from the shoulders. The client's head and trunk should lean opposite the direction of the transfer. The client's hands can rest on the lap.

7. Reach under the client's outside arm and grasp the waistband of the trousers or under the buttock. On the other side, reach over the client's back and grasp the waistband or under the buttock (Fig. 11.12C).

8. After your arms are positioned correctly, lock them to stabilize the client's trunk. Keep your knees slightly bent and brace them firmly against the client's knees.

9. Gently rock with the client to gain some momentum and prepare to move after the count of three. Count to three aloud with the client. On three, holding your knees tightly against the client's knees, transfer the client's weight over his or her feet. You must keep your back straight and your knees bent to maintain good body mechanics (Fig. 11.12D).

10. Pivot with the client and move him or her onto the sliding board (Fig. 11.12E). Reposition yourself and the client's feet and repeat the pivot until the client is firmly seated on the bed surface, perpendicular to the edge of the mattress and as far back as possible. This step usually can be achieved in two or three stages (Fig. 11.12F).

11. You can secure the client onto the bed by easing him or her against the back of an elevated bed or onto the mattress in a side-lying position and then lifting the legs onto the bed.

FIG 11.12 One person–dependent sliding board transfer. A, Therapist positions wheelchair and client and pulls client forward in chair. B, Therapist stabilizes client's knees and feet after placing sliding board. C, Therapist grasps client's pants at lowest point of buttocks. D, Therapist rocks with client and shifts client's weight over client's feet, making sure client's back remains straight. E, Therapist pivots with client and moves client onto sliding board. F, Client is stabilized on the bed. (Courtesy Luis Gonzales.)

The one person–dependent sliding board transfer can be adapted to move the client to other surfaces. It should be attempted only when therapist and client feel secure with the wheelchair-to-bed transfer.

Two Person–Dependent Transfers (Fig. 11.13)

Bent Pivot: With or Without a Sliding Board, Bed to Wheelchair

A bent pivot transfer is used to allow increased therapist interaction and support. It provides the therapist with greater control of the client's trunk and buttocks during the transfer. It is often used with neurologically involved clients because trunk flexion and equal weight bearing are often desirable with this diagnosis. The steps in this two-person procedure are as follows:

1. Set up the wheelchair and bed as described previously.

2. One therapist assumes a position in front of the client and the other in back.

3. The therapist in front assists in walking the client's hips forward until the feet are flat on the floor.

4. The same therapist stabilizes the client's knees and feet by placing his or her knees and feet lateral to each of those of the client.

5. The therapist in back positions himself or herself squarely behind the client's buttocks, grasping the client's waistband, grasping the sides of the client's pants, or placing his or her hands under the buttocks. Maintain proper body mechanics (Fig. 11.13A).

FIG 11.13 Two person–dependent transfer—bed to wheelchair. A, One therapist positions self in front of client, blocking feet and knees. The therapist in back positions self behind client's buttocks and assists by lifting. B, Person in front rocks client forward and unweights buttocks as the back therapist shifts buttocks toward wheelchair. C, Both therapists position client in upright, midline position in wheelchair. Seat belt is secured, and positioning devices are added. (Courtesy Luis Gonzales.)

6. The therapist in front moves the client's trunk into a midline position, grasps the client around the back of the shoulders, waist, or hips, and guides the client to lean forward and shift his or her weight forward, over the feet and off the buttocks. The client's head and trunk should lean in the direction opposite the transfer. The client's hands can rest on the lap (Fig. 11.13B).

7. As the therapist in front shifts the client's weight forward, the therapist in back shifts the client's buttocks in the direction of the transfer. This can be done in two or three steps, making sure the client's buttocks land on a safe, solid surface. The therapists reposition themselves and the client to maintain safe and proper body mechanics (Fig. 11.13C).

8. The therapists should be sure they coordinate the time of the transfer with the client and one another by counting to three aloud and instructing the team to initiate the transfer on three.

9. Transfer or gait belts may be used to offer a place to grasp while assisting the client in a transfer. The belt is placed securely around the waist and often is used instead of the client's waistband. The belt should not be allowed to slide up the client's trunk because leverage will be compromised.

Mechanical Lift Transfers (Fig. 11.14)

Some clients, because of body size, degree of disability, or the health and well-being of the caregiver, require the use of a mechanical lift. A variety of mechanical lifting devices can be used to transfer clients of any weight (Fig. 11.14). A properly trained caregiver, even one who is considerably smaller than the client, can learn to use the mechanical lift safely and independently.[211] The client's physical size, the environment in which the lift will be used, and the uses to which the lift will be put must be considered to order the appropriate mechanical lift. The client and caregiver should demonstrate safe use of the lift for the therapist before the therapist prescribes it.

FIG 11.14 A, Traditional boom-style mechanical lift. B, Sling attachments should be exposed with the outside seams of the sling directed away from the patient. C, Position the lift perpendicularly to the patient, close to the bed, and with the spreader bar over the chest; attach the chains or web straps to the spreader bar. D and E, Fold the patient's arms over the abdomen and elevate the body. Elevate the patient until the buttocks clear the surface of the bed. F to H, The patient's knees can be allowed to flex or can be kept extended. Carefully move the lift away from the side of the bed and then turn the patient to face the support column. Transport the patient to the wheelchair and lower into the chair. (From Fairchild S: *Pierson and Fairchild's principles and techniques of patient care,* ed 5, St Louis, 2013, Saunders.)

Transfers to Household Surfaces

Sofa or Chair (Fig. 11.15)

Wheelchair to sofa and wheelchair to chair transfers are similar to wheelchair to bed transfers; however, a few unique concerns should be assessed. Transfers to surfaces that are variable are described as complex transfers. The therapist and the client need to be aware that the chair may be light and not as stable as a bed or wheelchair. When transferring to the chair, the client must be instructed to reach for the seat of the chair. The client should not reach for the armrest or the back of the chair because this action may cause the chair to tip over. When moving from a chair to the wheelchair, the client should use a hand to push off from the seat of the chair as he or she begins to stand. Standing from a chair is often more difficult if the chair is low or the seat cushions are soft. Dense cushions may be added to increase height and provide a firm surface to which to transfer.

FIG 11.15 Client who sustained a stroke in midtransfer reaches for seat of chair, pivots, and lowers body to sitting. (Courtesy Luis Gonzales.)

Toilet and Bedside Commode

In general, wheelchair to toilet and wheelchair to bedside commode transfers are difficult because of the confined space in most bathrooms, the height of the toilet, and the instability and lack of support of a toilet seat. The therapist and client should attempt to position the wheelchair next to or at an appropriate angle to the toilet or commode. The therapist should analyze the space around the toilet and wheelchair to ensure that no obstacles are present. Adaptive devices such as grab bars and raised toilet seats can be added to a regular toilet to enhance the client's independence during this transfer. (Raised toilet seats are poorly secured to toilets and may be unsafe for some clients.) The client can use these devices for support during transfers and to maintain a level surface to which to transfer.

Bathtub

The OT should be cautious when assessing or teaching bathtub transfers because the bathtub is considered one of the most hazardous areas of the home. Transfers from the wheelchair to the bottom of the bathtub are extremely difficult and are used with clients who have good bilateral strength and motor control of the upper extremities (eg, clients with paraplegia and lower extremity amputation). A commercially produced bath bench or bath chair or a well-secured straight-back chair is commonly used by therapists for seated bathing. Therefore, whether a standing pivot, bent pivot, or sliding board transfer is performed, the technique is similar to a wheelchair to chair transfer. However, the transfer may be complicated by the confined space, the slick bathtub surfaces, and the bathtub wall between the wheelchair and the bathtub seat.

If a standing pivot transfer is used, it is recommended that the locked wheelchair be placed at a 45-degree angle to the bathtub if possible. The client should stand, pivot, sit on the bathtub chair, and then place the lower extremities into the bathtub.

If a bent pivot or sliding board transfer is used, the wheelchair is placed next to the bathtub with the armrest removed. The transfer tub bench may be used and removes the need for a sliding board. This approach allows the wheelchair to be placed right next to the bench, which permits safe and easy transfer of the buttocks to the seat. Then the lower extremities can be assisted into the bathtub.

In general, the client may exit by first placing one foot securely outside the bathtub on a nonskid floor surface and then performing a standing or seated transfer back to the wheelchair. Often the client's buttocks may be bare; therefore, a pillowcase may be placed over the sliding board, or a Safetysure Transfer Sling (The Wright Stuff [*http://www.thewright-stuff.com/*]; AAA.) (Fig. 11.16) may be used for safe transfers for bathing.

FIG 11.16 Safetysure Transfer Sling fastened around the client's waist and lower back for support. (Courtesy Scan Medical, North Billerica, MA.)

Car Transfers

A car transfer is often the most challenging for therapists because it involves trial-and-error methods to develop a technique that is safe and easy for the client and caregiver to carry out. The therapist often uses the client's existing transfer technique. The client's size and degree of disability, in addition to the vehicle style (two door or four door), must be considered. These factors will affect the client's level of independence and may necessitate a change in the usual technique to allow a safe and easy transfer.

In general, it is difficult to get a wheelchair close enough to the car seat, especially with four-door vehicles. The following are some additional considerations when making wheelchair to car transfers:

1. Car seats are often much lower than the standard wheelchair seat height, which makes the uneven transfer much more difficult, especially from the car seat to the wheelchair. Sport utility vehicles (SUVs) and trucks are especially challenging due to the increased height.

2. Occasionally clients have orthopedic injuries that necessitate the use of a brace, such as a halo body jacket or a lower extremity cast or splint. The therapist often must alter the technique (eg, recline the car seat) to accommodate these devices.

3. The therapist may suggest the use of an extra-long sliding board for this transfer to compensate for the large gap between transfer surfaces.

4. Because uphill transfers are difficult and the level of assistance may increase for this transfer, the therapist may choose a two person–assist instead of a one person–assist transfer to ensure a safe and smooth technique.

5. The therapist may have to practice transfers in both the front and back seats to determine which car position would be safest for the client.

Section 2 Summary

A wheelchair that fits well and can be managed safely and easily by its user and caregiver is one of the most important factors in the client's ability to perform ADLs with maximal independence.[209] All wheelchair users must learn the capabilities and limitations of the wheelchair and safe methods of performing all self-care and mobility skills. If a caregiver is available, he or she needs to be thoroughly familiar with safe and correct techniques of handling the wheelchair, the positioning equipment, and the client.

Transfer skills are among the most important activities that must be mastered by the wheelchair user. The ability to transfer increases the possibility of mobility and travel. However, transfers can be hazardous. Safe methods must be learned and followed.[211] Several basic transfer techniques are outlined in this chapter. Additional methods and more detailed training and instructions are available, as discussed previously.

Many wheelchair users with exceptional abilities have developed unique methods of wheelchair management. Although such innovative approaches may work well for the person who has devised and mastered them, they cannot be considered basic procedures that everyone can learn.

Section 3 Transportation, Community Mobility, and Driving Assessment

Ana Verran, Sandra Okada, Gayle San Marco

Section 3: Threaded Case Study

Jacqueline, Part 1

Jacqueline is a 67-year-old retired teacher who has been referred to outpatient occupational therapy by her physician. She has had increased difficulty in her ADLs because of painful arthritis in her neck, hands, back, hips, knees, and ankles. While establishing an occupational profile for Jacqueline, her therapist, an OT in general practice, asks her if she drives. She learns that Jacqueline's husband, a retired accountant who has diabetes and peripheral neuropathies in his legs, has had to cease driving. This has brought about a major change in Jacqueline's role. Whereas she had previously been a passenger and navigator, she has now assumed the primary role for transportation and driving, including assisting her husband with his wheelchair and car transfers. Jacqueline is 5 feet, 6 inches tall and weighs 138 pounds. Her husband is 6 feet tall and weighs 220 pounds. The family vehicle is a 20-year-old sedan, which is meticulously maintained.

The OT reviews Jacqueline's chart and ascertains that she seems to be in good health other than the limitations imposed by the arthritis. During the IADL evaluation, the OT carefully observes Jacqueline's occupational performance in the kitchen and notes that she is able to plan and problem-solve easily. Her primary deficits are in motor performance areas. Larger grip kitchen utensils are recommended to facilitate meal preparation. Because Jacqueline has emphasized the importance of being the caregiver and driver for her husband, the therapist makes a plan to observe how her deficits affect her ability to transfer her husband into the car. In doing this she notes difficulties in several other driving-related areas. There is trouble loading the husband's manual wheelchair, managing the key in the car door, and opening the door. Jacqueline tells the therapist that she doesn't mind driving, but on days when she is experiencing a lot of pain or fatigue, she does not drive at all.

During therapy sessions Jacqueline reports that she feels fatigued from so much driving. She mentions that she drives herself and her husband to all doctor appointments, to the pharmacy for medicines, and to church. When the therapist asks about her preferred occupations, she states that she rarely participates in her hobby of scrapbooking anymore because of fatigue and lack of time. She is worried about what the future will bring in terms of transportation because their two adult children live out of state, 500 miles away.

Critical Thinking Questions

1. What areas of Jacqueline's community mobility are appropriate for OT intervention?
2. Upon analysis of the task of driving relative to her diagnosis, what client factors can be predicted as needing assessment and intervention?
3. What adaptations or recommendations can Jacqueline and her therapist consider to improve mobility for her and her husband?

Competence in community mobility is an important component of quality of life throughout the lifespan.[16,45] Community mobility can be accomplished in many ways, including walking, using a bicycle or a powered mobility device, riding as a passenger, driving oneself, or using public transportation.[13,215] It is an area of occupation that affects all areas of practice and is considered an IADL in the current version (2014) of the "Occupational Therapy Practice Framework: Domain and Process," third edition[23] (OTPF-3). Community mobility can be a means to an occupation (walking or driving to work) or an occupation in and of itself (a leisurely stroll or scenic drive).

The potential for engagement in areas of occupation and community mobility are closely linked.[59] OTs understand that community mobility is critical for accomplishing necessary activities and enabling individuals to maintain social connectedness.[215] In the United States, community mobility, and the subset of driving in particular, is often viewed as synonymous with independence.[87] Conversely, limitations in community mobility and loss of a driver's license can negatively impact autonomy and feelings of well-being. Lack of transportation to engage in occupations such as grocery shopping, going to medical appointments, and attending religious and/or recreational events can result in diminished social participation.[14,98] Transportation problems are often cited as a primary barrier among individuals with disabilities.[193,213] Also, older adults faced with driving cessation risk depression[156] and entry into long-term care[95] and have increased self-perceptions of disability.[108]

Role of Occupational Therapy

The OT is ideally suited to identify when community mobility occupations require assessment and intervention.[14] OTs understand the interplay between engagement in occupation, the existence or lack of mobility options, and physical and mental health. Knowledge in this area makes the profession relevant to clients, the community, and public and private entities.[13] Therapists develop treatment plans by analyzing the interplay of client factors, performance skills and patterns, and the contexts and environments involved in community mobility (Fig. 11.17).[23] Within this framework OTs are concerned with the community mobility needs of clients with varying disabilities at all stages of life. Service recipients could be as diverse as a toddler with cerebral palsy, an adolescent with Asperger's syndrome, a young adult with a spinal cord injury, and a senior citizen with dementia.[13]

FIG 11.17 OTs must take a comprehensive view of community mobility throughout the lifespan. Community mobility in this context includes pedestrian, bicycling, public transportation, and driver issues.

OT services are directly related to a client's mobility concerns and are as varied as clients and the occupations in which they engage. They can address various aspects of passenger safety, walking, biking, and use of mass transit. Interventions may also involve training in preparation to acquire a first driver's license, evaluation of experienced drivers with age-related changes that interfere with driving, and exploration of alternative transportation options for those people who must temporarily discontinue driving.[13] Although clients are often individual persons, organizations or populations may also benefit from OT services.[13,45] Examples of services that might be provided to organizations include modification of the **paratransit** eligibility evaluation for a transit company seeking to increase ridership of disabled persons and training of drivers and bus aides for a school system seeking to improve the safety of student passengers with special needs. Services to populations may include collaboration with municipal planning organizations to promote roadway design, bike lanes, and pedestrian paths to support **older drivers** and persons using other modes of transportation.[13]

Historical Context

Current driver rehabilitation practices were developed during the last half of the 20th century. A growing interest in providing professional education and support to practitioners in the various disciplines involved in driver rehabilitation led to formation of the Association for Driver Rehabilitation Specialists (ADED) in 1977.[33] The organization, which is multidisciplinary and includes OT practitioners, has developed a code of ethics and standards of practice,[30] in addition to best practice guidelines[31] for delivery of driver rehabilitation services by individuals providing services to persons with disabilities or age-related impairments. The ADED has offered a certification in driver rehabilitation to allied health professionals and individuals from other multidisciplinary backgrounds since 1995.[35]

Expansion of the driver rehabilitation field prompted trade and government agencies to address safety issues. In 1997 the National Mobility Equipment Dealers Association (NMEDA), a national organization to promote and support individual members engaged in the modification of transportation for people with disabilities, established an accreditation program to promote quality, safety, and reliability within the mobility industry.[142] The National Highway Traffic Safety Administration (NHTSA), a federal agency charged with saving lives, preventing injuries, and reducing the economic costs related to traffic accidents, also became involved in overseeing vehicle safety related to vehicle modifications for people with disabilities.[140]

As the issues of driving, driving cessation, and the need for transportation alternatives brought about by an aging American population became recognized, NHTSA developed a plan to address the needs of older drivers.[126] The agency has funded research and developed educational materials to increase awareness of older driver issues. One example is the American Medical Association's (AMA) *Physician's Guide to Assessing and Counseling Older Drivers*,[51] which was created in collaboration with the NHTSA to help physicians address the public health issue of older adult driver safety. To increase the quality and availability of service providers dealing with senior driving, the NHTSA has promoted partnerships with professional organizations serving the older population. The agency has recognized the role of OTs in driving and community mobility of older adults and acknowledges that OTs in general practice, who frequently encounter seniors with medical conditions, would be in a position to screen for problems and refer at-risk individuals for additional services. The NHTSA also realizes that OTs with a driver rehabilitation specialty have the skill set to offer driving-related services and interventions that other allied health professionals cannot.[129]

In 2003 the American Occupational Therapy Association (AOTA) received funding from the NHTSA for an Older Driver Initiative (ODI) to provide professional training in the specialty area of older adult driving and to coordinate multiple projects related to raising awareness of senior driving issues.[13] The ODI resulted in various continuing education materials, development of the AOTA's Older Driver Microsite (*http://www.aota.org/olderdriver*), the annual Older Driver Safety Week, and the Specialty Certification in Driving and Community Mobility.[13] The ODI plan has also included partnering with other providers and stakeholders in older driver safety. For example, CarFit, a national educational program to ensure that seniors fit well with their vehicles, resulted from a multiagency partnership between the American Society on Aging (ASA), the American Automobile Association (AAA), the American Association of Retired Persons (AARP), and the AOTA.[9,187] The Gaps and Pathways Project, launched by the AOTA in 2011, was funded through another cooperative agreement with the NHTSA. The intent of the Gaps and Pathways Project is to provide guidance to OTs for effectively addressing the IADLs of driving with all clients, either through direct service or through referral pathways.[174] One of the outcomes of the Gaps and Pathways Project was a special issue of *Occupational Therapy in Health Care*,[27] which presented resources and papers to guide practitioners in promoting client participation in driving and other forms of community mobility.[25]

The Centennial Vision endorsed by the AOTA board of directors in 2003 has served as a road map for the profession,[12,29] prompting practitioners to identify opportunities to expand OT practice. An initial focus on opportunities for meeting the needs of senior drivers led to recognition of community mobility and older drivers as an emerging practice niche.[26,46] The current emphasis is that OT within various practice settings must evolve to address community mobility throughout the life span in a comprehensive way that considers needs beyond driving rehabilitation.[13,14] The Centennial Vision's strategy of linking education, research, and practice has been implemented by increased scholarly research in the driving and community mobility area. Several evidence-based literature reviews related to driving and community mobility for older adults have been published in the *American Journal of Occupational Therapy*.[63,100,184] Additionally, four critical appraisals of articles focused on driving and community mobility topics have been conducted.[18-21]

Generalist and Specialist Roles

Both OT generalists and specialists have the skills and training necessary to ask basic questions about community mobility issues.[13,45] The two levels of practitioners have in common the goals of supporting participation in the community, optimizing independence in community mobility, and reducing crashes, injuries, and fatalities. In order to optimally meet driving and community mobility needs, OT services are provided along a continuum.[15] The depth at which the individual therapist addresses community mobility issues with clients depends on his or her level of experience and the specialized training that he or she has received.[153,173] A generalist OT practitioner addresses driving and community mobility as part of a larger agenda to optimize occupational engagement. OT practitioners with specialty training and advanced certification may offer a focused approach in which driving is the primary goal.[13]

All OTs should explore how impairments impact driving and set goals related to their clients' driving and community mobility needs. Generalists should incorporate questions about driving and community mobility when performing an initial IADL evaluation.[8] The observation of performance skills during the IADL assessment enables a determination of the client's strengths and whether his or her impairments have the potential to impact driving.[15] If impairments are noted, the generalist has the opportunity to initiate treatments that may improve driving capabilities.[107] Generalists may recommend temporary driving cessation for clients with acute medical conditions based on this evidence.[102] Additionally, if it is determined that a client must eliminate complex IADLs (eg, cooking or financial management) because of moderate to severe dementia, the generalist may appropriately recommend driving retirement and focus intervention efforts on exploration of transportation alternatives.[14] Generalist practitioners can assist clients in choosing simple aids that do not directly affect vehicle control (eg, a key holder or a handle that attaches to the door latch to assist with entering and exiting a vehicle), but they should consider the potential effect of any recommended piece of equipment.[14]

An OT driver rehabilitation specialist should be contacted if there are any questions about driving safety and driver competence. Driving presents a greater possibility of personal and public harm than does any other ADL or IADL; therefore, OTs offering driver evaluation services should have advance training to effectively intervene in this complex occupation. OT driving specialists administer assessments specific to the requirements involved in driving, including those for vision, cognition, motor performance, reaction time, knowledge of traffic rules, and a behind-the-wheel (BTW) assessment of skill.[13] They recommend whether to continue, modify, or cease driving, suggest vehicle modifications and adaptive devices, provide driver retraining or specialized driver education, and document all findings. In some states OT practitioners specializing in driving must also be certified driver instructors in order to perform on-road assessments and provide **driver training**.[13,14] OT specialists who are not driving instructors should consider working in collaboration with driving instructors with advanced training with medically at-risk drivers.

Specialty Training and Certification

Professional specialty designation expedites services, assures appropriate matches between the practitioner's skills and the client's need, and validates the depth and breadth of OT practice.[182]

There are two ways by which OT practitioners can designate themselves as specialists in the area of driver rehabilitation (Box 11.2). The first is the Specialty Certification in Driving and Community Mobility (SCDCM), which is available to OTs and Certified Occupational Therapy Assistants (OTAs) through the AOTA. The SCDCM is awarded after a peer review of a reflective portfolio demonstrating the practitioner's relevant experience and ongoing professional development.[17] Board and specialty certifications are recognized as quality markers by accrediting and regulatory agencies and sources of reimbursement.[97] They communicate OT expertise to consumers and professionals outside the profession.

American Occupational Therapy Association (AOTA)

Specialty Certification in Driving and Community Mobility

- http://www.aota.org/Education-Careers/Advance-Career/Board-Specialty-Certifications/Driving-Community-Mobility.aspx

The second alternative is the Certified Driver Rehabilitation Specialist (CDRS) certification in driver rehabilitation, available through the ADED. The CDRS credential allows individuals from an allied health or a driver training background who meet the criteria for educational background and experience to sit for an examination covering driver education, disabilities, and vehicle modifications.[34] In some states, agencies such as the Department of Rehabilitation require the CDRS credential to provide services.

Occupational Therapy Assistants

OTAs are a valuable asset to driver rehabilitation. Completion of standardized testing, vehicle entry/exit and lift safety training, transfer training, and functioning in the role of driver instructor are just some of the ways the OTA can contribute to a driving program. The OTA must work under the supervision of and in partnership with the OT.[22] Appropriate utilization of OTA skills can be an asset to driving programs by assisting with cost containment. Expanded roles are possible when intervention protocols are developed, documented, and followed, again under the OT's supervision. For example, OTAs can be used to determine the need for progression in driver training, as long as the driving skills being observed have been defined and training has been provided to the OTA in recognizing them. Clear treatment protocols facilitate supervision by enhancing communication between colleagues.

Public Transportation

Impact of the Americans With Disabilities Act

Public transportation refers to services operated by public agencies or supported by public funds that are available to anyone for any trip purpose.[206] Public transportation involves the use of buses, trolleys and light rail, subways, commuter trains, streetcars, cable cars, van pool services, paratransit services, ferries and water taxis, and monorails and tramways.[28] Title II of the **Americans with Disabilities Act (ADA)** of 1990[3] prohibits discrimination on the basis of disability by all public entities that provide transportation at the local and state levels. Title III extends coverage to private entities that provide public transportation services.[3] The ADA has jurisdiction over most modes of transportation, including buses, trains, and ships but transportation that is specifically covered through other laws is excluded. For example, discrimination on the basis of disability in air travel is prohibited by the Air Carrier Access Act of 1986 (ACAA).[5]

The ADA's public transportation requirements for vehicles, facilities, and service were meant to create integration so that people with disabilities could travel to desired activities and do so in a nonsegregated way.[83] The law established accessibility guidelines for buses, trains, and light rail systems and specified the need for wheelchair lifts and ramps.[196] ADA guidelines also provide for priority seating, handrails to facilitate interior circulation, public address systems to announce stops, stop request controls, clearly marked destination and route signs, and various other features intended to ease navigation by persons with disabilities. Major improvements in transit systems across the United States have resulted from this legislation. As of 2006 the Federal Transit Administration (FTA) estimated that 98% of bus service was ADA accessible.[93]

Fixed-Route and Demand-Response Systems

Public transportation includes both fixed-route and demand-response systems of service delivery. **Fixed-route systems** use defined routes with predetermined stops and run on a published schedule.[206] Trains, city buses, and shuttles are types of fixed-route transportation. Demand-response transit refers to transportation service delivery in which rides are generated by calling a transit operator who then dispatches a vehicle to pick up passengers and transport them to their destination. The vehicles do not operate over a fixed route or on a fixed schedule. They may be dispatched to pick up several passengers at different points before taking them to their respective destinations.[198]

Fixed-route transportation creates links to home, work, schools, recreation areas, and other important destinations. The fixed-route system does not have a process for qualification and is open to anyone. It is an important transportation alternative for many segments of the population because it costs less and offers greater autonomy and flexibility than demand-response systems. In some locations the use of fixed-route transit by people with disabilities is two to six times higher than ADA paratransit ridership.[186] Older nondrivers also rely on public transit significantly, using it for 9% of their trips.[2] Public transit appears to be important to the Millennial generation. Some studies have also shown that young people born between 1983 and 2000 appear to be less focused on using cars for transportation than older generations and seem to use alternate transportation methods, including public transportation, more extensively.[80]

The ADA requires public transit agencies that provide fixed-route service to offer a type of demand-response service called "complementary paratransit" to people unable to use the fixed-route service because of a disability. The individuals who are entitled to the complementary service as a civil right and the service characteristics that must be provided for it to be considered complementary are defined by the law.[82] Some communities offer demand-response transit referred to as "call-a-ride services" in addition to ADA complementary paratransit. These services may be offered in place of ADA complementary paratransit in locations where there is no fixed-route service.[83] Call-a-ride systems may be open to the general public or may be limited to people who participate in specific social service programs. The services such systems offer can vary from community to community.[82]

The people entitled to use complementary ADA paratransit include those with physical or mental impairments who cannot board and ride accessible fixed-route transit systems, those in areas where the fixed-route system lacks accessible vehicles, and those who have specific impairments that prevent them from getting to and from a stop. Eligibility may be conditional if the person can use fixed-route transit for some trips and not others. Examples of situations that might prevent an individual from using a fixed-route service for some trips include weather conditions for a person with temperature sensitivity, presence of a variable medical condition, and environmental barriers at certain locations.[82,208]

Complementary paratransit service considered equivalent to the fixed route must be provided within ¾ of a mile of a bus route or rail station, at the same hours and days, for no more than twice the regular fixed-route fare. The ADA further requires that paratransit rides be provided if requested at any time during the previous day. Trip times can be negotiated but must not be more than 1 hour before or after the requested departure. Personal care attendants can ride for free.[113]

Transit authorities are required to have a process for determining paratransit eligibility.[73,114] An application is usually needed to qualify. Some transit authorities also ask for supporting documentation, an in-person interview, and/or an in-person assessment of the applicant's ability to use fixed-route service.[208] The in-person assessment is conducted either in a real setting or using a transit simulator. The focus of the in-person assessment is to determine whether the person can perform the tasks involved in using public transportation, not on the presence of a disability.[73]

Intervention Implications for Fixed-Route Transit

Trepidation about traveling alone can make an older adult or a person with a disability reluctant to use the fixed-route system, even when it is a viable transportation alternative.[45,149,206] To achieve increased ridership, OTs must match the task demands of the local fixed-transit environment with client factors and performance skills.[208] If possible, the client's proficiency and destination points, skill in boarding and exiting the bus, and the time at which he or she would travel as a fixed-transit user should be evaluated in the actual setting in which the bus or rail services will be used. Factors such as the ability to efficiently get to a bus stop, the safety of bus stops at origin and destination points, skills in boarding and exiting the bus, and whether the time at which travel will occur is optimal for the client should be addressed.

If barriers to successful use of fixed transit are identified,[149] a focused intervention plan may be necessary to remediate or compensate for limited subskills. Strengthening, balance, and endurance programs to increase ambulation or efficiency in using a mobility device[207] can be carried out in the clinic. OTs recommending a scooter or wheelchair should determine whether the device's weight and dimensions will allow it to fit and be safely transported on a bus's lift. Guidelines require buses to have lifts with a minimum design load of 600 lb and the lift platform to accommodate a wheelchair measuring 30 inches by 48 inches.[199] Lower footrests tend to make a wheelchair functionally longer. The length may make the wheelchair incompatible with some transit lifts and complicate maneuverability within the bus or light rail system. The ADA allows transit operators to adopt a policy specifying whether wheelchairs must be secured or can ride unsecured on a bus.[199] Clients should know where securement devices should be placed on their wheelchair. Bus drivers receive training to become proficient in using securement devices but in practice may not know how to work them properly.[72] Practice in verbally communicating how to secure the wheelchair is thus warranted.

Skills such as managing money and reading a schedule can also be practiced in the clinic. Trip planning tools found on transit authority websites and those available through smart phone apps from third-party developers are useful resources. Clients who do not use computers or smart phones can be shown how to obtain travel information by dialing 511 on their telephone land line or mobile phone. The Federal Communications Commission (FCC) has designated this number as the single travel information telephone number available to states and local jurisdictions across the country.[197]

The natural environment poses limitations that cannot always be anticipated or duplicated in a clinic setting. Many clients benefit from participation in real-life sessions to develop the competence and confidence to use fixed-route transit independently. Community outings provide opportunities for skill practice and discussion of problems. Some transit systems offer individualized training programs, known as travel training, to assist persons who cannot negotiate the fixed-route system to travel safely and independently to a regularly visited destination such as work or school. OTs who are part of an Individualized Educational Plan (IEP) team should consider the need for travel training when they plan for a child's postsecondary transition needs.[195] OTs have the basic academic competencies to provide travel training.[14] Additional education in this area is available through Easter Seals Project Action, a national technical assistance program for community transportation.[81] Some transit authorities offer travel instruction geared specifically to older adults. In some cases a senior is paired with an experienced bus user who will accompany them on a test ride to a destination of their choosing.[116]

Intervention Implications for Paratransit

OTs can play a critical role in helping clients determine whether paratransit service best meets their community transportation needs. To do this practitioners must become familiar with the policies of the local transit company and clearly understand their clients' passenger assistance level. The ADA allows transit companies to determine whether door-to-door or curb-to-curb service will be provided. In door-to-door service, the driver offers help from the door at the origin point of the trip and comparable assistance to the door at the destination point. In curb-to-curb service, help is not provided until the person actually reaches the curb. Guidance provided by the federal Department of Transportation (DOT) to transit agencies has clarified that transit agencies with curb-to-curb service must still provide assistance to riders who need it due to a disability; however, door-to-door service may be provided only as needed, not necessarily for all rides.[74] The activity demands of curb-to-curb service are greater than those of door-to-door service. The OT should prepare the client to advocate for door-to-door service if the person's functional limitations require it.

Because Jacqueline had reported that she was sometimes unable to drive because of arthritic flare-ups, her therapist used the opportunity to talk to her in greater depth about her transportation needs. Jacqueline had never heard of paratransit, but after the therapist explained how it operated and what the qualification process to use it would involve, Jacqueline decided it would be an option worth trying. However, because she was still concerned about her husband's blood sugar level if the ride caused them to be way from home for an extended time, the therapist recommended that she pack appropriate diabetic snacks to avoid low blood sugar problems during the trip. After Jacqueline had established paratransit eligibility for herself and her husband, she expressed relief that she had found an effective transportation safety net.

The costs of providing a paratransit trip are significantly higher than for a fixed-transit trip—often 10 times higher.[52] The high expense of providing paratransit service has caused some transit providers to implement a stringent eligibility certification process as a way to contain costs.[52] OTs have a potential role in all aspects of eligibility certification.[208] To ensure appropriate categorization of disability, assistance can be provided during the application process. Clients can be encouraged to accurately report all significant disabling conditions that interfere with using fixed-route service. Assistance during the interview process could involve educating the person to provide necessary documentation of these problems and helping him or her articulate the difficulties encountered when using fixed-route service, for example, by describing an inability to wait at a bus stop. OT services are also needed by transit authorities to determine whether a person's wheelchair conforms to the common wheelchair ADA requirements, to prescreen an applicant for balance and motor capabilities, and to conduct an assessment of the person's skills during an actual transit trip.

OT interventions may include orientation to the local system, training in making a reservation, and education related to service limitations. Paratransit ridership combines the trips of several individuals to meet the capacity of the vehicles; consequently, travel often takes longer than private transportation. In some cases it can exceed fixed-route timelines. Long trips can pose a hardship for those whose medical conditions or symptoms include urinary urgency and frequency, pain with prolonged immobility, insensate skin, or decreased endurance. OT intervention in such cases may call for cushioning and positioning devices to decrease discomfort and fatigue during the trip. Clients who are reluctant to travel alone can gain confidence in their abilities when accompanied by an OT on a trip to a destination and back.

Private Transportation

Private transportation refers to vehicles that are privately owned, either individually or by a group, and are used for the benefit of those individuals.[15,145] The primary advantages of private transportation are the on-demand, 24-hour availability of origin-to-destination travel, the flexibility to modify travel plans, and the strong sense of control over one's life. Individuals in rural areas that are not served by fixed-transit routes may have no alternative but to use private transportation. The costs of fuel and insurance, the expenses related to maintaining and replacing a vehicle, and the need for adaptive driving controls and vehicle modifications prohibit many people from using private transportation options. Nondrivers who own vehicles also face the expense of hiring drivers.

Supplemental Transportation Programs for Seniors

The aging of America has resulted in a focused effort to develop supplemental transportation programs for seniors, sometimes referred to as STPs.[41] The primary purpose of these programs is to support the gap in transportation service for older adults, particularly those over age 85, who most likely do not drive. There are thousands of STPs throughout the country, sponsored by a wide variety of private organizations, places of worship, government agencies, and even public transportation authorities. Some STPs have their own vehicles, purchased through public funding. Others, such as volunteer driver programs, rely on the vehicles of their volunteer drivers. Eligibility criteria are established by the sponsor organization, and the services provided can vary significantly. Depending on the program, door-to-door, door-through-door, escort, and assistance at the destination services might be offered. Service destinations may be affected by who sponsors a program. In some cases an organization may only offer transportation for a specific purpose, such as to attend religious services or to participate in a hot lunch program. Some STPs do not restrict the types of trips that can be taken and provide very flexible service, allowing for multiple stops during a single outing and crossing jurisdictional boundaries.

Intervention Implications for Supplemental Transportation Programs for Seniors

OTs should be aware of the factors (availability, accessibility, acceptability, affordability, and adaptability) that have been identified as facilitating senior-friendly transportation services.[42] Knowledge of the resources available for locating programs in a particular community is helpful in matching services to a client's particular needs (Box 11.3). The Eldercare locator is a public service of the federal Administration on Aging that connects users to information and assistance resources, including transportation services, for older adults at the state and community level. This resource can be accessed by telephone or through its website. The interactive maps on the AAA's Senior Driving website and the website for the Beverly Foundation are additional resources for finding

STPs. The nonprofit Independent Transportation Network of America (ITNAmerica), offers a searchable national database and toll-free telephone number where callers can obtain information about the transportation alternatives available in their particular areas.[105]

Box 11.3

Resources for Driving Safety Programs

AAA Foundation for Traffic Safety

- http://lpp.seniordrivers.org/lpp/

Contains a database of state driver licensing policies and practices affecting older and medically at-risk drivers.

American Association of Retired Persons (AARP)

- http://www.aarp.org (search under Driver Safety Resources)

Contains We Need to Talk online seminar about driving retirement, information about driver safety education classes, brain games, and various tools, including interactive driving simulations and a link to the University of Florida's Fitness to Drive Screening Tool.

American Automobile Association (AAA)

- http://dev.seniordriving.aaa.com/

Contains the Roadwise Review, Roadwise Rx, videos of the 12 steps involved in CarFit, a tool for selecting vehicles with features adapted to individual considerations, and additional information about topics related to senior driving.

American Occupational Therapy Association (AOTA)

- http://www.aota.org/Practice/Productive-Aging/Driving.aspx
- http://otconnections.aota.org/

Contains a driver rehabilitation specialist database, various tip and fact sheets, continuing education offerings, evidence-based research articles, and the organization's official documents related to driving and community mobility. Provides a discussion forum for driving and driver rehabilitation issues that is available to any AOTA member via the Physical Disabilities Special Interest Section in OT Connections.

Association for Driver Rehabilitation Specialists (ADED)

- http://www.aded.net

Contains documents related to best practices, ethics and standards of practice, disability fact sheets, and a database of driver rehabilitation specialists.

Beverly Foundation

- http://www.beverlyfoundation.org/map/stps

Provides an interactive map with a city and state listing of volunteer transportation providers. The Beverly Foundation dissolved in 2014 but made arrangements for the map to be maintained by the National Volunteer Transportation Center.

ITN Rides in Sight Hotline 1-800-60-RIDES

A free service uses ITN America's database of senior transportation options to identify local availability for callers.

National Mobility Equipment Dealers Association

- http://www.nmeda.org

Trade association for manufacturers of equipment and vehicle modifiers. Has a quality assurance program (QAP).

National Highway Traffic Safety Administration (NHTSA)

- http://www.nhtsa.gov (Search under Driving Safety)

The Older Driver subsection contains a video toolkit on medical conditions, a link to the Physician's Guide to Assessing and Counseling Older Drivers, and driver fitness medical guidelines. Parents Central has information about child safety, including selecting the right car seat, a database of installation locations, and information to promote seat belt use. Information about Safe Routes to Schools programs and pedestrian safety workshops for youth and older adults is provided under the Pedestrian subsection. The Bicycles subsection has materials and videos related to bicycling safety for youth and adults.

Rehabilitation Engineering Research Center on Wheelchair Transportation Safety

- http://www.rercwts.pitt.edu/RERC_WTS2_Intro/RERC_WTS2_Intro.

Contains information and educational materials about safe transportation of people who use wheelchairs as a seat in a motor vehicle.

Safe Kids Worldwide National Child Passenger Safety Certification

- http://cert.safekids.org/

Contains information for becoming a child passenger safety technician, certified to provide one-on-one personalized instruction on how to properly install a child's safety seat.

U.S. Administration on Aging Eldercare Locator

- http://www.eldercare.gov/Eldercare.NET/Public/Index.aspx and 1-800-677-1116

The site connects users to information and assistance resources, including transportation services, for older adults at the state and community levels.

Taxis and Ride-Sharing Services

Taxi service is a significant source of transportation for people with disabilities affecting mobility, vision, and thinking and other mental processes. Easter Seals Project Action (mentioned earlier), a government-funded program to assist the disability community and transportation industry to achieve the goal of accessible community transportation, reports that as many as 10% of taxi service customers are people with disabilities.[84] Taxi services are mandated to comply with ADA requirements as private companies that provide demand-response–type services. Companies do not have to purchase accessible sedan-type automobiles; however, if a new vehicle type other than a sedan is purchased, it must meet ADA accessibility requirements for transportation vehicles. Service cannot be denied to a person who uses a service animal or to a person who is able to transfer from a wheelchair to a vehicle seat, if the wheelchair can be stowed in the cab or the trunk. Additionally, personnel have to be trained to proficiency. Dispatchers must know how to operate communications equipment, such as a Telecommunications Display Device (TDD), and have enough knowledge about various disabilities to dispatch an appropriate vehicle. Training in the correct operation of lifts and securement devices is required for drivers.

Ride-sharing services, primarily Uber, Sidecar, and Lyft, are new additions to the transportation industry.[117,179,201] These businesses use smart phone apps and the smart phone's GPS function to identify a user's location and connect the person to a ride in the personal vehicle of the nearest available driver. Payment transactions are cashless and are completed using the smart phone app. Proponents of ride-sharing services proclaim their convenience, environmental benefits, and potential savings in fuel and parking costs. However, ride-sharing services are so new that they have been largely unregulated. They face opposition from the taxi industry, which claims they are unfair competition and also pose a risk to public safety because ride-sharing companies are not subject to the same licensing rules and other regulations imposed on traditional taxis. Ride-sharing services have also faced criticism from disability rights advocates because they lack accessible vehicles to provide service to people who use wheelchairs. and they sometimes discriminate against people who use service animals.[123,162,194] In 2013 California became the first state to regulate ride-sharing services. The California Public Utilities Commission mandated that ride-sharing companies (called transportation network companies in that state) provide incentives to attract accessible vehicles to their fleets, report annually on the demand for them, and ensure accessibility accommodations for their apps and websites.[50]

Interventions for Taxi and Ride-Sharing Services

For some clients, practice in the clinic using the telephone, computer, and smart phone apps to arrange for taxi and ride-sharing services may be helpful. If the client uses a wheelchair, he or she should be trained in the procedure for correctly securing it in a vehicle and should be able to communicate the steps for doing so to another person. Clients who believe they have been denied transportation services or have been treated unfairly should know where to seek information about legal requirements. OTs can be helpful in providing general information but should know about resources that can assist with accurately answering questions. The ADA National Network, funded by the National Institute on Disability and Rehabilitation Research, provides informal guidance on the ADA to meet the needs of business, government, and individuals at local, regional, and national levels. Inquiries can be submitted to the 10 regional centers comprising the network, either online, via email, or by calling a toll-free number (1-800-949-4232). Specialists can answer most questions immediately, and, if necessary, will research complex questions. Referrals to local resources for disability issues not addressed by the ADA are also provided.[4]

Traveling as A Passenger

General Considerations

In the United States, motor vehicle crashes are a source of significant medical and work costs. They are a leading cause of death among people ages 1 to 54 years and the leading cause of death among teens. Seat belts reduce serious crash-related injuries and deaths by half, but not everyone wears them.

Seat belts are designed to be used in conjunction with air bags to provide optimal protection. Without the seat belt, occupants can be thrown into the rapidly inflating front air bag, which could result in significant injury or death. Passengers need to wear both a lap and shoulder belt to best distribute crash forces.[131] The chances of living through a collision are three to four times higher when both belts are worn. The shoulder belt should be placed across the middle of the chest and away from the neck, and the lap belt should be adjusted to fit low on the pelvis, across the hips and below the stomach. The shoulder belt should never be worn behind the back or under an arm.

Intervention for Passengers

Because of the significant role seat belts play in reducing injuries and fatalities in a car crash, seat belt use should be encouraged in all clients. OTs should be aware of the populations with lower seat belt use (ie, teens, adults aged 18 to 34, people living in rural areas, and men[57]), and they should be ready to provide factual information about seat belts' effectiveness and how to wear them properly.

Safety in entering a vehicle should be carefully assessed. Training family and personal care attendants to assist a client in transferring to the passenger seat may be warranted. OTs not primarily responsible for teaching transfers should work in conjunction with physical therapists to maximize safety during the process. Generalists can make recommendations for low-tech equipment to facilitate entering and exiting the vehicle and twisting in a seat. Motorized turning seats designed for use by elderly or disabled passengers may be a good solution for some clients but should be prescribed by driving rehabilitation specialists because their fit in a particular vehicle will vary, depending on the model. Cushions, either commercially available or custom made, can aid in positioning and maximizing comfort and should be considered when pain and joint limitations are present. Jacqueline, the client described in the case study, may need to consider specialized passenger seats designed for the elderly to help her husband transfer more easily. These motorized seats move outside the car and rotate, easing the activity demand of car transfers (Fig. 11.18).

FIG 11.18 Bruno's Valet Plus aids vehicle entry by modifying activity demands for caregiver and client. (Courtesy Bruno Independent Living Aids, Oconomowoc, WI.)

Traveling While Riding in a Wheelchair

In most cases sitting in a motor vehicle seat offers the highest level of protection for a person riding in a vehicle. Cars, vans, and SUVs are designed with seats and belt restraint systems that work in conjunction with air bags to prevent occupant ejection and minimize the potential for contact with the vehicle interior. For various reasons people who use wheelchairs may find that they have to ride in their wheelchair when seated in a motor vehicle. However, wheelchairs are not typically designed for this purpose. Protecting vehicle occupants that use a wheelchair as a seat requires attention to the position of the wheelchair in the vehicle, the structure of the wheelchair itself, and to the systems for securing the wheelchair to the vehicle and restraining the occupant in the wheelchair.

Occupied wheelchairs should face forward during transport.[159] A sideways orientation is the least safe for enduring a frontal crash, which produces the most serious injuries. Wheelchairs that meet standard WC 19 of the American National Standards Institute/Rehabilitation Engineering Society of North America (ANSI/RESNA) are recommended by safety experts. However, not every wheelchair will meet this standard. A WC 19–compliant wheelchair (also known as a wheelchair with the transit option) has a frame and transit components that have been sled-impact tested to determine how they will respond in a crash. The chair also has four securement points, specific securement point geometry, a clear path of travel for proper placement of vehicle-mounted occupant safety belts, and anchor points for an optional wheelchair-anchored pelvic safety belt.[160] Wheelchairs that meet this standard are labeled to show that they comply.

Wheelchair tiedown and occupant restraint systems (WTORS) should meet standard J2249 of the Society of Automotive Engineers (SAE), which ensures that these systems have undergone dynamic strength testing conducted on an impact sled.[161,203] The wheelchair tiedown portion of WTORS is the system for securing the wheelchair to the vehicle. It consists of two front straps and two rear straps, all four of which are needed for safe transport. If an individual is traveling in a personal vehicle, an SAE J2249 docking system can be recommended in place of the straps.[160] Adaptor hardware is attached to the wheelchair frame so it can engage with a docking device installed on the vehicle's floor. The occupant restraint part of WTORS is the system for keeping the wheelchair occupant safely in his or her seat. OTs should be aware that the postural support belts of a wheelchair cannot do this effectively. Occupant restraint can be provided either by the vehicle manufacturer's three-point restraint or by an upper and lower torso occupant restraint provided by the WTORS manufacturer.[180] All parts of the WTORS must be used to safely transport a person in a wheelchair.

Interventions for Passengers Traveling in Wheelchairs

Passenger evaluations, which can significantly improve the safety of a rider, are too often overlooked as a focus of OT intervention. Determining whether a client can safely and efficiently transfer to a vehicle seat or should ride in his or her wheelchair is an important first step in addressing passenger transportation safety. If the client cannot transfer, the OT should advocate for a WC 19 wheelchair by providing justification and documentation of need to third-party payers. Collaboration with physical therapy may be needed if the OT is not directly responsible for ordering the wheelchair. OT driver rehabilitation specialists should recommend that SAE J2249–compliant WTORS be installed by vehicle manufacturers or accredited members of NMEDA.[96] The website of the Rehabilitation and Engineering Research Center on Wheelchair Transportation Safety (*http://www.rercwts.pitt.edu*) provides valuable resource information about WC 19–compliant wheelchairs and other issues of transportation safety for occupants of motor vehicles who remain seated in their wheelchair.

OTs working in a school setting must consider that their responsibility for students who use wheelchairs extends to their safe transportation to and from school.[162] Educating transporters in the safe loading of a wheelchair onto a lift (passenger facing away from the vehicle and wheel locks applied) and in deciding whether an individual with a power wheelchair can safely drive onto a lift is warranted. Additional opportunities exist for school-based therapists to work with transporters in developing a bus evacuation plan for disabled students.[178]

Child Passengers

Children are at significant risk when traveling in a motor vehicle. The leading cause of death among those ages 3 to 14 years is car crashes.[163] Fortunately, there are several steps that can be taken to mitigate risk. Safety seats have been shown to reduce fatal injuries by 71% for infants and 54% for toddlers.[134] The safety seat should be selected according to the child's age, height, and weight and should be positioned in the back seat of a vehicle. The NHTSA recommends a four-step progression from rear-facing car seats, to forward-facing car seats, to booster seats, to seat belts.[132] Children are ready to use seat belts in the back seat when they are tall enough to sit without slouching and are able to keep their back against the vehicle seat, naturally bend their knees over the edge of the seat, and keep their feet flat on the floor. The NHTSA advises that children remain in the back seat at least until age 12.[132]

Incorrect installation of car seats can jeopardize the safe transport of a child in a motor vehicle. Most parents believe that they are putting their children in car seats correctly and installing the car seats in the right way; however, NHTSA research has shown that 7 of 10 children are actually improperly restrained.[176] Typical mistakes include using the wrong harness slot, improper harness retainer/chest clip position, loose car seat installation, loose harness strap, and improper seat belt placement.[133] The confusion is understandable because there are different installation instructions for every vehicle and car seat.

Intervention for Child Passengers

Parents may need help in selecting and installing a car seat that is appropriate for their child's needs. The NHTSA's Parent Central website (*http://www.safercar.gov/parents/index.htm*) offers information about various car seat types, in addition to tools for finding an appropriate seat based on the child's age and size. The site allows parents to register the car seat so that they can be notified if there is a safety recall.[139] OTs can also refer families to a SeatCheck program for assistance in installing the car seat. SeatCheck is a national campaign to promote proper securement of children in motor vehicles. The program's website (*http://www.seatcheck.org*) and toll-free number (1-866-SEAT-CHECK) list inspection stations where trained and certified child safety technicians provide a free installation check. The website also contains tips and tools for keeping children safe in a motor vehicle, a listing of safety seat manufacturers, and a seat recall list.

OTs may want to take a more active role in child safety seat inspection by providing this service themselves. Safe Kids Worldwide, a global organization dedicated to preventing injuries in children, offers a Child Passenger Safety Technician certification course that provides specialized training in this area.[166] The certification course combines classroom instruction, hands-on activities, and skills assessments with car seats and vehicles. It concludes with a checkup event in which new technicians teach caregivers how to properly install and use car seats and booster seats.

Safe transport of infants and children with medical needs or disabilities is another area of practice that should not be overlooked. Car seats should not be modified unless the person performing the modification is certified to do so. Inappropriate car seat adaptations recommended or made with good intentions can have life-threatening implications.[40]

Assessment for children and teenagers must take into account future physical growth. For example, a 6-year-old riding in a van seated in a wheelchair may no longer fit in the vehicle by age 15 because of increased height. Also, activity demands associated with caregiving will be greater for a 15-year-old than for a 6-year-old. Alternate mechanical or power lifts or adaptations may become necessary for children or adults when their body size becomes unmanageable (and therefore unsafe) for their caregiver. Growth and development and aging affect the choice of equipment that will meet the individual's needs at a given age.

Pedestrians and Cyclists

General Considerations for Pedestrians

Regardless of transportation preferences, the vast majority of Americans will be pedestrians at some point, either by walking or using a wheelchair or other mobility device. Although walking is an important means for getting around and has health, environmental, and economic benefits, it also involves risk. In 2012 alone, traffic crashes in the United States resulted in 4743 pedestrian deaths and 76,000 injuries.[135]Awareness of the factors that cause risk for various age groups is necessary in order to plan effective OT interventions that allow clients to fully realize the benefits of walking.

Older adults are one of the population groups most at risk for pedestrian injury. Decreased visual acuity, reduced reaction time, and slower walking speed contribute to the risk.[214] Nonfatal injuries from walking due to falls, especially while attempting to navigate curbs, are common.[56] Due to their greater physical frailty, older adult pedestrians are less likely to survive a collision with a motorized vehicle than are younger pedestrians.

Children are also at significant risk for injury when walking. In 2012, 1 of 5 children killed in a car crash was a pedestrian.[56] Young children may not have fully developed judgment of speed and distance or use of peripheral vision, which can make crossing the street by themselves unsafe. Safety experts suggest that children age 10 or younger should not cross the street without an accompanying adult.[167] A child's experiential basis for judging traffic situations is small. Emotions such as excitement may overwhelm their regard for safety. Older children have a more mature sensory processing system, but the brain areas that deal with the ability to control impulses and weigh the long-term consequences of actions may not be fully mature.[172]

Adolescents and young adults become increasingly mobile as they strive to gain independence. Teens have both the highest death rate and the highest nonfatal pedestrian injury rate of any group of children.[164] The problem appears to be connected to distractions brought about by listening to music, texting, and talking on cell phones.[164] Walking while intoxicated is connected to very significant risk because of impaired judgment and diminished appreciation of hazards. More than one-third of the pedestrians killed in crashes were intoxicated.[136]

Intervention for Pedestrian Safety

Mitigation of walking risk begins with pedestrian education. Some basic rules apply to all pedestrians and are fundamental to walking safety. These include walking on the sidewalk or facing traffic when there is no crosswalk, and crossing at intersections whenever possible, looking left, right, and left when doing so. Additional recommendations are to increase visibility by wearing light-colored or reflective clothing, avoiding alcohol and distractions such as cell phones and headsets, and carrying identification.

The NHTSA and the Federal Highway Administration (FHWA) have developed a one-stop shop website (*http://www.nhtsa.gov/pedestrians*) with tips and resources for pedestrian safety that can be incorporated into OT interventions for people at various ages and developmental levels. The site includes links to the NHTSA's *Child Pedestrian Safety Curriculum* for students in kindergarten through the 5th grade and to the *Pedestrian Safety Workshop: A Focus on Older Adults*. There are additional links to the FHWA's *Pedestrian Safer Journey* series of videos about walking safety for children ages 5 to 18, checklists for conducting environmental audits, educational materials to teach parents about walking safety, and guides for community pedestrian safety advocates.

Individual assessment of skills to determine a person's potential to move about safely and independently as a pedestrian should be conducted. Impairments in vision, cognition, and motor skills caused by medical conditions and aging can potentially affect walking speed and endurance, management of uneven terrain, stepping up and down curbs, way finding, accurately estimating the time for street crossing, and recognizing and reacting appropriately to hazards. If assessments show that walking independently would be unsafe, OTs have an obligation to advise the client and his or her family of the risks involved.

When pedestrian skill acquisition or remediation appears feasible, skills should be practiced within a natural context as much as possible.[14] Real-life settings are valuable for reviewing the basic rules of safe walking, showing clients how to effectively use vision to scan for traffic hazards, and for practice in managing mobility devices outdoors. However, in the majority of clinical settings there are many opportunities to improve pedestrian skills. For instance, OTs can take part in selecting a mobility device that matches a client's functional abilities while keeping in mind the areas where the person will be walking. Tasks such as reading a map and selecting an ideal route to a destination do not have to occur on the streets to be practiced. The clinic can also be an ideal setting for educating families with children about pedestrian risks and helping parents develop strategies for modeling safe pedestrian behaviors.

According to the Centers for Disease Control and Prevention (CDC), many Americans view walking and biking in their communities as unsafe due to the presence of environmental barriers and absence of sidewalks, crosswalks, and bicycle paths.[54] Crashes between pedestrians and motor vehicles commonly involve people attempting to navigate environments designed primarily for use by cars.[216] In contrast, "walkable" communities are those in which it is easy and safe to walk to goods and services. They encourage pedestrian activities, expand options for transportation, and have safe streets that serve people with different ranges of mobility.[169] OTs can be involved in bringing about change to improve the walkability of a neighborhood; however, intervention in this area requires a change in focus from serving individuals to serving communities. The FHWA's *A Resident's Guide for Creating Safe and Walkable Communities*[169] is a useful resource for practitioners interested in influencing neighborhood walkability. In addition to providing a section on assessing environmental problem areas, the guide discusses ways to take action, the various government agencies responsible for maintaining roads and the engineering improvements and law enforcement strategies needed to lower pedestrian risk.[169]

Safe Routes to School (SRTS) is a national and international movement to create safe, convenient, and fun opportunities for children to bicycle and walk to and from schools through its "Walking School Bus" and "Bike Train" programs.[124,168] The website for this organization offers free tools and resources for establishing SRTS programs and ideas for integrating SRTS considerations into community planning.[128] SRTS allows OTs to address issues of childhood obesity with individual pediatric clients, and it also offers a platform for OTs to serve the community by providing input for the design of roadways, bike lanes, and pedestrian paths that foster mobility for people of various ages and abilities using multiple forms of transportation.

General Considerations for Cyclists

Bicycling can be a means of exercise, recreation, conducting personal errands, or commuting to work or school. According to the National Survey of Pedestrian and Bicyclist Attitudes and Behaviors, 18% of the population age 16 or older rode a bicycle at least once during the summer of 2012.[150] Like walking, bicycling has many health benefits. Yet bicycling is not without risk. In the United States, bicyclists are at greater risk for injury and fatality from crashes than occupants of motor vehicles, even though bicycle trips represent only a small portion of all trips taken.[55] Most bicycling deaths occur at night and in urban areas.[137] In 2010 roughly half of the cyclists killed or injured in the United States were children and adolescents under the age of 20. Annually 26,000 of the bicycle-related injuries to this age group have been traumatic brain injuries.[59] Alcohol use also appears to be a significant risk factor to safe bicycle riding. One in four bicycle riders killed in a crash had an illegal blood alcohol level.[137]

Bicycles are considered vehicles, and bicyclists are considered operators of vehicles in all 50 states.[137] Bicycle riders consequently have the same rights and are subject to the same rules as other motorists when they operate in traffic. There is no federal law requiring bicycle helmets; however, close to half of the states have state laws mandating that children wear helmets. Additionally, some areas have local ordinances related to helmet use.[43] The League of American Bicyclists, an organization dedicated to creating a more bicycle-friendly America, is an excellent resource for information about the rules of the road and bike riding laws in the various states.[189,190]

Intervention for Cycling Safety

Bicycling requires clients to simultaneously pedal, balance, look around, and make decisions about whether it is safe to proceed. OTs should determine whether a client has these skills prior to recommending bicycling. Interventions to improve subskills such as strength, ROM, coordination, and balance may be needed before bicycling can become a realistic goal.

Pedestrian activities in progressively complex traffic situations may be necessary to understand traffic patterns and practice safe decision prior to introducing biking. Knowledge of a client's physical and cognitive functioning allows OTs to provide guidance in selecting the contexts in which bicycling can safely occur. Not every person will be able to bike ride in all environments. Heavy city traffic conditions may be too fast moving for some people who can ride effectively in their familiar residential neighborhood. Off-road conditions may prove too physically challenging for some clients who can ride easily on paved roads.

Most clients will benefit from classes to ensure they can ride confidently, safely, and legally. The bicycle safety education classes shown to be the most effective in preventing crashes are those that involve lectures to teach rules and include several hours of supervised riding to practice their application in dynamic situations.[90] The League of American Cyclists offers online lessons with interactive components and videos, in addition to local education classes for all experience levels taught by certified instructors.[191] The FHWA's *Bicycle Safer Journey*, a series of three free educational videos for those ages 5 to 18, can be used to introduce safe bicycling skills or augment a comprehensive biking curriculum.[91] The NHTSA's *Bike Safe–Bike Smart*[125] and *Ride Smart–It's Time to Start* [138] videos use a peer-to-peer approach to teach bicycle safety to children from elementary to high school. A safety video targeting adult bicycle riders is also available on the NHTSA website.

Use of appropriate bicycling equipment should be encouraged. Knowledge of the client's functional abilities is valuable for selecting an appropriate bicycle. OTs should familiarize themselves with the many design options available for various abilities. These range from hand-pedaled bikes to recumbent bikes to adult tricycles. Bicycle helmet use during every ride should be encouraged for clients of all ages. These helmets are the single most effective safety device to reduce head injury and death from bicycle crashes.[165] An instructional video for correctly fitting a bicycle helmet is available from the NHTSA at the following website: *http://www.nhtsa.gov/bicycles*.

OTs can make a significant impact on reducing the number and extent of bicycling injuries by advocating to increase bicycle safety on a community level. Advocacy efforts in the community could focus on bringing about engineering changes to alter the infrastructure affecting the operation and movement of traffic and pedestrians or involve education to motivate behavioral change among various groups. Advocacy might also entail efforts to enforce laws and regulations or encouragement to promote bicycling in a community.[169]

Driving

Driving is cited again and again as the basis for personal independence, employment, and aging in place (Fig. 11.19).[14,51,129] A driver's license has deep social and cultural contexts; it serves as a rite of passage for the teenager and provides the adult with an ability to pursue employment and recreational opportunities. The social impact of an aging population (20% of the U.S. population will be 65 or older in 2030)[92] has brought the issues of maintaining independence and quality of life, especially as they pertain to driving, to the forefront of public attention.

FIG 11.19 This client was experiencing difficulties driving and at work because progression of her multiple sclerosis exceeded the activity demands of pushing a manual wheelchair. Driving from a power wheelchair and using an electronic gas-brake hand control decreased the activity demands on her upper extremities, enabling her to drive safely and work full time as a teacher.

Clinical Reasoning for Driving and Community Mobility Services

An OT's ethical responsibility to investigate a client's vulnerability in driving is no less than with any other IADL that is within the profession's scope of practice. Where a client desires to go and if he or she wants or needs to drive to get there should be determined when the client's occupational profile is established. Although it is understood that driving may not be a goal for some people, for others it will be an important way to get around, in which fitness to drive can be negatively impacted by disabilities or medical conditions.

An understanding of the implications of medical conditions and disease processes, the ability to analyze ADLs and IADLs, and knowledge of adaptive devices and occupation-based interventions make OTs uniquely qualified to provide driver rehabilitation. OTs already make up the overwhelming majority of professionals providing these services for the physically disabled population.[109] The ODI has poised the profession to respond proactively to meet the needs of the growing numbers of senior drivers. However, there is a shortage of OTs that specialize in driver rehabilitation, and the need to train additional practitioners in this practice area is tremendous.[2,14] To contain costs and expedite service delivery, OT generalists must be prepared to address driving-related needs within their level of expertise. This includes accurately identifying clients requiring comprehensive assessment by a specialist, appropriately timing referrals, and understanding the spectrum of services provided by driving programs.[71]

Observation of performance during ADLs and IADLs is a fundamental part of the OT generalist's evaluation process and provides valuable data about a client's skills. OTs routinely correlate observations such as paralysis, impulsivity, and visual neglect with the client's ability to function safely and independently in the home, but they may not realize that the IADL assessment can also provide information about abilities associated with driving (eg, scanning the environment, simultaneously timing and sequencing tasks, anticipating outcomes, and modifying actions in a changing environment). Research conducted by Dickerson et al.[71] demonstrated that experienced generalist OTs can use skilled observation of complex IADLs to identify older adults who are not at risk for driving unsafely, who must stop driving until their functional performance has improved, or who would benefit from comprehensive evaluation by a driver rehabilitation specialist. These researchers developed an algorithm based on the OTPF (Fig. 11.20) to illustrate the decision-making process necessary to determine how providers and services can be effectively involved in assessment, referral, and training.[71] The referral pathway demonstrated in the algorithm can be appropriately modified for specific practice settings and used with any population.[14]

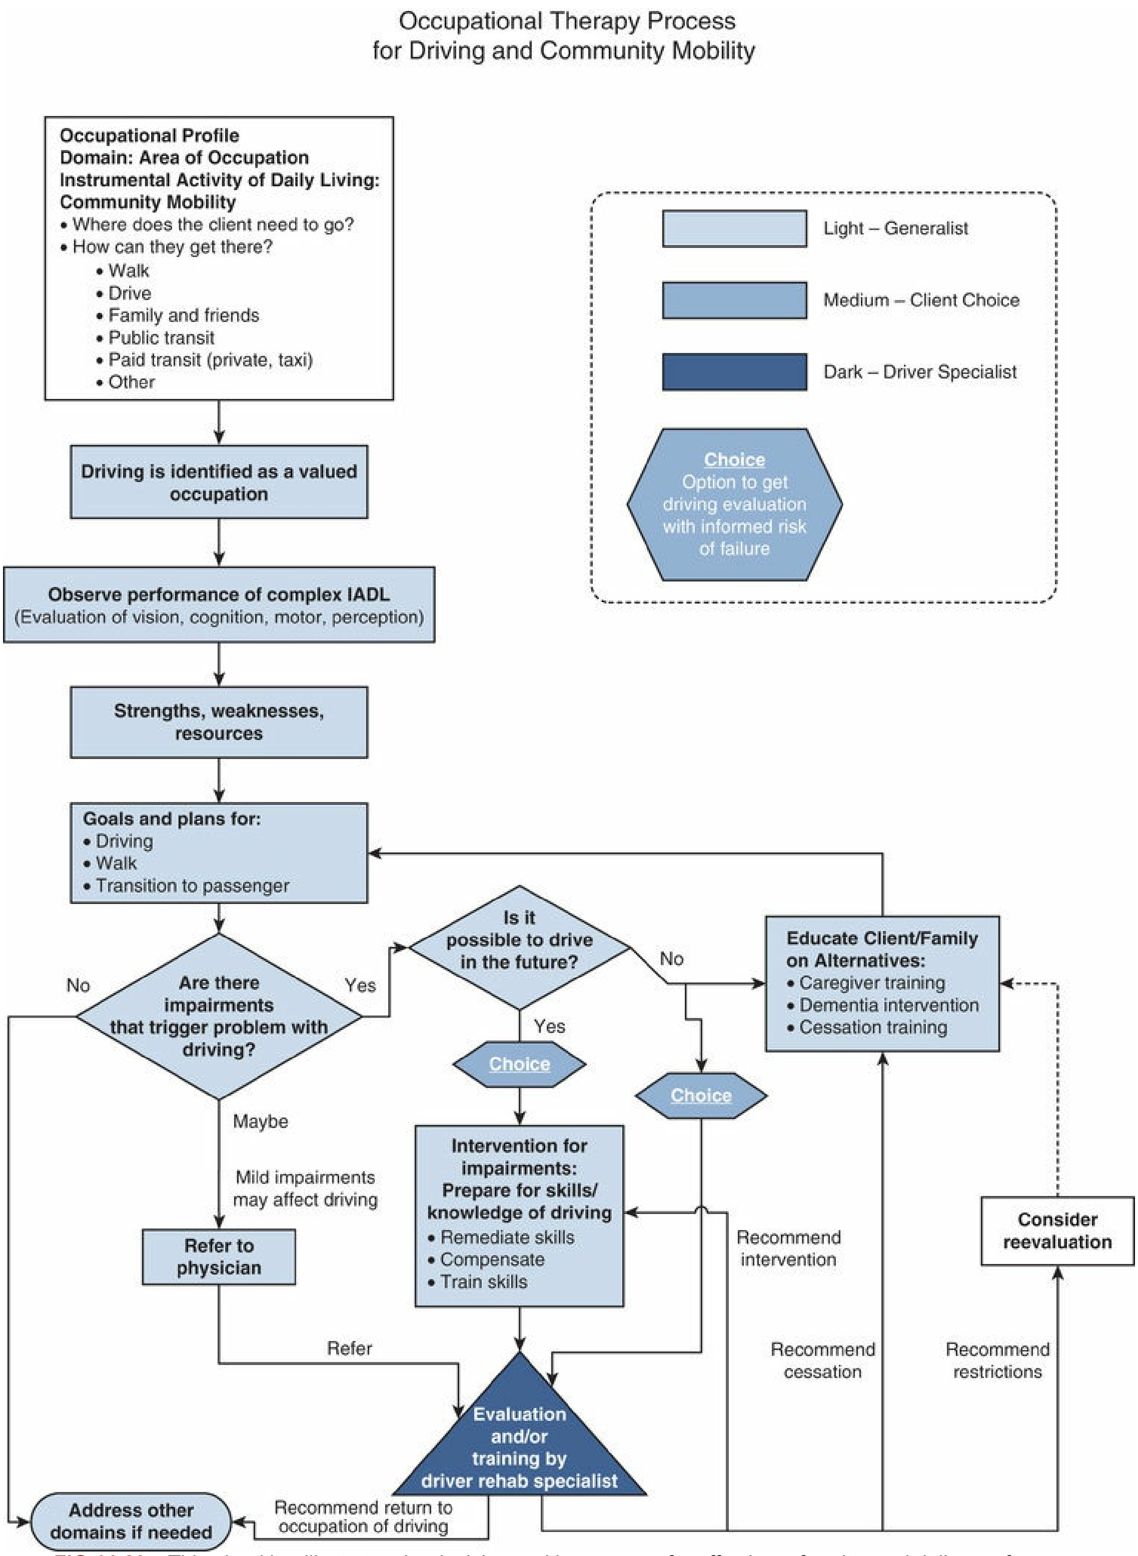

FIG 11.20 This algorithm illustrates the decision-making process for effective referral to and delivery of driving-related services. (From Dickerson AE, Reistetter T, Schold Davis E, Monahan M: Evaluating driving as a valued instrumental activity of daily living, *Am J Occup Ther* 65:64–75, 2011.)

Driving Evaluation Program Spectrum

Driver rehabilitation programs provide a wide range of services related to driving and community mobility for individuals with disabilities, medical conditions, or age-related changes. These programs offer driving skills assessment, education and training, and instruction in the use of driving adaptations and compensatory techniques. Identifying the program that is best for a particular person can be challenging for consumers and referral sources because of the variation in services. The ADED, in association with the AOTA/NHTSA Pathways Project, has developed a document to define the various program models. The *Spectrum of Driver Services/Spectrum of Driver Rehabilitation Program Services*, approved in 2013, describes three categories of driving program services: community-based education programs; medically based assessment, education, and referral programs; and specialized evaluation and training programs.[36]

Community-based education programs include driver safety programs having specific credentials (eg, AARP and AAA driver improvement programs) and driving schools. Driver safety programs offer classroom or computer-based refresher courses for licensed drivers. Driving schools employ licensed driving instructors to teach, train, and refresh driving skills for novice or relocated drivers. These schools focus on well individuals rather than people who have medical or age-related conditions that might interfere with driving. Driving schools typically provide services to enhance driving skills and to assist in acquisition of a driver's license or permit.[36]

Medically based assessment, education, and referral programs offer driver screens and clinical IADL evaluations. Programs offering driver screening are typically staffed by healthcare professionals (eg, physicians, social workers, or neuropsychologists) with knowledge of medical conditions, assessment tools, and intervention processes. They understand the limits and value of the assessment tools used as a measure of fitness to drive and are able to counsel consumers regarding the risks associated with medical conditions and make referrals when indicated.[36]

Programs offering clinical IADL evaluations employ OT practitioners (either a generalist or a driver rehabilitation specialist) or another healthcare professional with expertise in IADLs who has knowledge of medical conditions and their implications for community mobility, including driving. Clinical IADL evaluators interpret risks associated with changes in vision, cognition, or sensory motor functions caused by acute or chronic conditions; they also facilitate remediation of deficits, develop individualized transportation plans, and discuss resources for vehicle adaptations. They refer to driver rehabilitation specialists when appropriate, discuss driving cessation, and follow professional ethics on referrals to other resources or to the driver licensing authority.[36]

Specialized evaluation and training programs administer comprehensive driving evaluations that include clinical and on-road components to establish fitness to drive. These programs provide rehabilitative services specific to driving. There are three levels of this type of program, distinguished by the complexity of evaluations, types of equipment used, and expertise of the provider. Basic programs offer comprehensive driving evaluations and training for individuals who can independently transfer and drive using standard primary driving controls (eg, a standard steering wheel and standard gas and brake pedals). Low-tech programs offer comprehensive evaluation and training services with or without the use of adaptive equipment. At this level of service, the adaptations for primary control are typically mechanical (eg, a mechanical gas/brake hand control, pedal extensions, and left foot accelerator). Wireless or remote access to secondary controls (eg, turn signal, horn) may be used.[36]

High-tech driver rehabilitation programs offer all the services available through basic and low-tech programs; however, they also have high-tech equipment for primary control (eg, powered hand controls, remote steering, and joystick driving controls) and devices such as powered transmission shifters, remote panels, and switch arrays for secondary control. They have the ability to address the needs of drivers able to transfer to an unmodified vehicle seat; those who require a transfer seat base to facilitate a transfer; and those who cannot transfer and must drive while seated in a wheelchair. Service providers in this category are able to recommend vehicle structural modifications (eg, ramps or lifts) that allow people in wheelchairs access to the vehicle's interior and to the driving position.[111]

Jacqueline's OT generalist noticed that she demonstrated some difficulties with motor skills when performing kitchen tasks. Because Jacqueline planned to continue to drive as her primary way of getting around, the therapist was concerned that she might have problems gripping the steering wheel, turning her head to check traffic, and applying the brakes quickly. The OT designed a home exercise program to address these areas of limitation and recommended that Jacqueline undergo a comprehensive driving evaluation by a driving rehabilitation specialist.

Ethical Considerations

Therapists in this practice area must be able to withstand significant pressure in their decision making. A novice driver with significant cognitive and perceptual impairments, for example, may press to curtail the assessment process prematurely because of time and financial considerations. Pressure to sway the therapist's opinion before completion of an assessment may come from biased third-party payers; even family members may strongly attempt to influence the outcomes of the assessment in a direction that is not supported by performance observations.

Best Practice Standards for Driving Programs

Practice guidelines for driving and community mobility for older adults, which use an evidence-based perspective and concepts from the *Occupational Therapy Practice Framework: Domain and Process (2nd ed.),* have been developed by AOTA. The guidelines emphasize the expertise of OTs in understanding the occupations of driving and community. They are helpful for OT practitioners, program developers, administrators, legislators, third-party payers, educators, and others to understand the contribution of OT in serving the needs of the older adult population.[183] Although developed for older adults, the process they describe can be appropriately used in various practice settings with people across the lifespan.

Best Practices for the Delivery of Driver Rehabilitation Specialists was initially published by the ADED in 2004 and was updated in 2009. The document is intended for any individual providing rehabilitation services to persons with various disabilities or age-related impairments that impact driving. It is not specific to OTs. Guidelines for assessment, BTW training, and intervention are discussed, as are the recommended procedures for documentation, completion of a prescription for equipment, and conducting a final fitting.[31]

Clinical Assessments in Driving

The level of assessment related to driving will depend on the OT practitioner's expertise, the availability of assessments in his or her practice setting, and time constraints. An initial assessment of the skills that impair driving can be accomplished as part of an observation of the quality of complex IADL performance.[71] Generalists may also administer screenings of visual, motor, and cognitive function to determine the need for additional evaluation and intervention.[69] In-depth clinical evaluation of the client's driving skills and a BTW assessment are conducted by the specialist.[13] A systematic review of the research on screening and assessment tools used to determine fitness to drive revealed that while some measures were better able to discriminate the skills and abilities necessary for driving, no measure by itself was sufficient to predict fitness to drive. Currently specialists tend to use the same assessment tools with all clients instead of selecting measures for specific diagnoses.[68] The systematic review supported using specifically selected tools in combination for specific diagnoses.[70]

Ethical Considerations

Principle C-46 of the ADED's Code of Ethics states that, “Driver rehabilitation specialists use only assessment techniques that they are qualified and competent to use. They do not misuse assessment results or interpretations.”

Occupational Profile and Client-Centered Goals

A review of the available medical records and a client interview are necessary to establish an occupational profile that identifies the importance of driving and the contexts and environments in which it is performed.

The medical record will contain valuable information related to driving abilities, including whether a client's medical condition is acute, chronic, or progressive; the amount of medication taken; the presence of symptoms (eg, pain and fatigue); and the client's communication status. Clients should be asked about driving frequency; whether they drive with passengers; whether they have experienced driving problems, such as seeing clearly, turning the steering wheel, confusing the pedals, getting lost, getting tickets, or having near misses; and whether family members or friends have expressed concern about their driving ability.[102] License status and the availability of a suitable vehicle should also be established. Without this information it is very difficult to project the client's future needs for driver rehabilitation, adaptive driving equipment, or a modified vehicle.

The information-gathering process should focus on establishing what the client's goals for driving are. Is the goal to be able to conduct errands and get to medical appointments? Does the client want to be able to commute to work? Does he or she want to drive on surface streets or freeways or both? A client-centered focus is necessary to understand the client's perspective, guide assessment, and help therapists plan interventions that are contextually appropriate. The *Canadian Occupational Performance Measure* can be used to help clients identify and prioritize goals important to them and to make decisions about their care.[103] If driving is not an option at the time, addressing alternate transportation needs would be more appropriate.

Jacqueline was concerned that she was the primary driver for her husband and lacked a backup transportation plan. Based on her identified priority, the immediate intervention was for the therapist to provide information about alternative transportation options using public transportation.

Analysis of Occupational Performance

An analysis of occupational performance is conducted after the occupational profile has been established. The purpose is to more specifically identify the client's assets or problems related to driving through observation, measurement, and enquiry about supporting and limiting factors. OT generalists are not able to directly observe a client's performance behind the wheel, but they can make inferences about driving performance based on how well the client does on other complex IADLs. Emerging evidence suggests that the *Assessment of Motor and Process Skills,*[94] a standardized assessment to observe IADL performance, can be used to successfully predict whether a client will be able to pass or fail a BTW assessment or would require restrictions for driving.[71]

There are many assessments available for evaluating the contexts, environments, and client factors that influence performance skills and patterns in driving. Some of these are screenings that can be appropriately used by a generalist; others are more complex tests that are more appropriate for use by the specialist. The reader is referred to *Driving and Community Mobility: Occupational Therapy Strategies Across the Lifespan*[14] for an extensive list of various tests. This section describes a few assessments that are commonly used or are recognized for their usefulness in predicting fitness to drive.

Professionally Administered Driver Safety Screens

Driver safety screens allow OTs to obtain data about a client and identify areas of concern for additional evaluation and intervention. Generalists can use results from driver safety screenings to supplement observations of risk obtained during IADL performance and as evidence to justify the need for a BTW assessment by a specialist. The Assessment of Driving Related Skills (ADReS)[51] is a screening test battery, developed by the AMA with support from the NHTSA, to assist physicians in preventing motor vehicle crashes in older adults. It screens aspects of vision, cognition, and motor function, three areas that have been identified as necessary for safe driving. The ADReS does not predict crash risk, although some of its components have documented associations with crash risk.[102] A limitation of this test is its poor sensitivity because it tends to recommend intervention even for people who do not demonstrate a lack of fitness to drive.[122] The test is available in the Physician's Guide to Assessing and Counseling Older Drivers, which can be accessed at no cost on the NHTSA website.

The DrivingHealth Inventory is a software screening program based on research sponsored by the NHTSA and the National Institute on Aging.[192] It contains eight measures (high- and low-contrast visual acuity, leg strength and stamina, head/neck flexibility, route planning, short-term and working memory, visualization of missing information, visual search with divided attention, and visual information processing speed) that have been validated against at-fault crashes. The test procedures are standardized and provide a rating of no deficit, mild deficit, or serious deficit in the tested abilities. The software can be ordered at a cost at *www.drivinghealth.com*.

Self or Family/Caregiver–Administered Driver Screens

Some screening measures are intended for client self-administration outside of a clinical setting to increase self-awareness about fitness to drive. These measures may be less threatening for some clients than other types of assessments, but they may not be suitable for cognitively impaired persons who lack insight.[85] These types of tests may also have value when completed in conjunction with an OT for the purpose of gathering data to plan an intervention program or identify individuals who would benefit from comprehensive assessment. The AAA's Roadwise Review is based on the DrivingHealth Inventory.[61] Feedback about the level of impairment on each of the eight test items is given, and advice is provided for improving performance in each area. The test is available for free online at *www.SeniorDriving.AAA.com* and *www.aaafoundation.org* or as a CD ROM from regional AAA offices.

SAFER Driving: The Enhanced Driving Decisions Workbook is an online workbook to help clients consider health concerns that could affect safe driving. The instrument content has been validated and provides individualized feedback on potential driving problems and strategies to continue safe driving. Three health concern areas (seeing, thinking, and getting around) based on symptoms experienced from medical conditions, medications, and the general aging process that affect fitness to drive are addressed.[85] This self-assessment is free and can be completed online at *www.um-saferdriving.org/firstPage.php*.

The Fitness-to-Drive Screening Measure is a Web-based tool designed for caregivers and/or family members of older drivers and OTs to identify at-risk older drivers. Caregivers and family members who have driven with the driver in the past 3 months rate the driver's difficulties with 54 driving skills. A rating profile classifying the driver into at-risk, routine, or accomplished driver categories is generated, and recommendations based on the category are provided.[202] The recommendations can be used to begin a conversation about fitness to drive and to identify the need for referrals to other professionals for further intervention.

Tests Related to Specific Client Factors

OT driver rehabilitation specialists routinely administer tests, either individually or as part of a battery, to examine specific body functions (vision, visual perception, cognition, and motor and sensory functions)[68] with the potential to affect driving performance. Generalists may administer these tests during an overall evaluation of a client's occupational performance. The tests would supplement observations of driving risk gleaned from observations of IADL performance. Screening results would inform decisions for improving function in a specific area, to establish a basis for advising clients of the need for driving cessation, and to provide evidence of the need to refer to a specialist for a comprehensive driving evaluation.

Vision (Acuity, Eye-Motor Skills, Visual Fields, and Contrast Sensitivity)

Vision provides most of the sensory input related to driving.[177] Not surprisingly, uncorrectable vision deficits are a leading cause of driving cessation.[106] Visual conditions that are red flags for driving problems include cataracts, glaucoma, macular degeneration, diabetic retinopathy, diplopia, and strabismus. Specialists may have access to an instrument such as the Optec Functional Vision Analyzer[185] to test skills such as visual acuity, depth perception, color perception and recognition, phorias, and eye teaming. However, there are many tests that can be performed by either generalists or specialists with minimal equipment or by using mobile phone or tablet apps. Clients should be referred to a vision care practitioner to maximize visual skills before a referral to a driver rehabilitation specialist is initiated.[45] Vision care specialist interventions, such as a corrective lens prescription, prisms, and eye occlusion or surgery, can have a significant impact on safe driving potential. Because standards for licensing vary among the various states, OTs should be aware of the requirements in their particular area to appropriately educate clients. The AAA Foundation for Traffic Safety maintains a database of driver licensing policies and practices, which includes a state-by-state listing of vision requirements for driver licensing. The information can be accessed at *http://lpp.seniordrivers.org/lpp/index.cfm?selection=visionreqs*.[1]

Visual acuity, typically tested using a Snellen wall chart, is the most widely tested skill among driver licensing agencies. Acuity can impact the ability to read signage if it is worse than 20/30,[146] but it does not appear to be related to crash risk unless it is worse than 20/70.[51] Most state driver licensing agencies have established a far acuity standard of 20/40 with both eyes for initial licensing and for some renewals. Clients with acuity worse than 20/40 should be referred to a vision care specialist for further assessment.

Screening of ocular ROM and ocular alignment (pursuits, saccades, phorias, and tropias) is also valuable because these functions can impact the ability to efficiently scan the road for hazards. Visual field testing provides information about the range of the traffic environment a person is able to see. Peripheral vision is particularly important for detecting cues such as a signal light blinking on a car in the next lane. Visual field deficits have been linked to crash risk, but there is currently no conclusive evidence about the field range that is adequate for driving.[51] Eye movements can serve as a compensatory strategy to increase the amount of the visual environment that can be seen.[146]

However, the difficulty of accomplishing this successfully is increased in a fast-paced driving environment. There is evidence that educational programs improve awareness of visual deficits in people with low vision; however, they do not appear to result in lowered crash risk.[106] Training of visual skill deficits in a protected environment using a driving simulator may be appropriate prior to initiating an actual driving assessment.[106]

Contrast sensitivity, the perception of contrast between visual stimuli,[51] is an important visual function that is not currently used as a measure for driver licensing. It has been found to be a valid predictor of crash risk among older drivers.[75] Testing is accomplished using a Pelli Robson Contrast Sensitivity Chart,[154] which presents lines of letters with progressively less contrast relative to the chart's background color. Deficits in this function are common in cataracts and glaucoma. The specialist should be careful to identify the lighting conditions under which a client will drive because low-light conditions such as fog, dawn, and dusk exacerbate deficits in contrast sensitivity.

Visual Perception

Although visual skills, visual perceptual processing skills, and cognition are typically evaluated individually, in the dynamic and complex driving context, they work synergistically and must be used quickly. The Motor-Free Visual Perception Test is a widely used standardized test that measures various aspects of perception without requiring a motor response. The most recent version includes norms for ages 4 to 80 years.[49] Research results linking it (or its subcomponent of visual closure) to fitness to drive have been inconsistent, with some showing a link and others no relationship.[18] In relation to driving, visual closure, which is the ability to complete a figure when only fragments are presented, might be needed for tasks such as anticipating where lane markers would continue when they are divided by an intersection or for recognizing a stop sign that is partially occluded by a branch.

The Clock Drawing Test is widely used with geriatric populations to discriminate healthy individuals from those who have dementia.[51] There are several versions and various procedures for scoring it.[121] In the Freund Clock Drawing form that is used in the ADReS, the person is asked to draw a clock on a blank sheet of paper with the numbers and hands arranged to read 10 minutes after eleven. Scoring is based on correct completion of seven different elements, not time for completion.[51] This seemingly simple measure involves visual spatial skills, language, selective attention, long- and short-term memory, abstract thinking, and executive functioning. Its visual spatial demands appear to be significant in identifying fitness to drive, given that visual spatial skills have the highest level of prediction in the driving performance of older adults.[158]

Cognition (Attention, Processing Speed, Memory, and Executive Function)

A significant part of what is required to drive safely occurs "between the ears." Cognitive factors in driving include the ability to focus and sustain attention on single and multiple stimuli, the speed with which traffic information is perceived, and all aspects of memory. There is clear evidence that higher order cognition involving executive functioning is critical to safe BTW performance.[18] There are many tests of executive function with varying levels of ability to predict safe driving. The strongest predictive evidence for fitness to drive derives from the UFOV (useful field of view) test and the Trail Making Tests (TMTs), which are discussed in this section.

The useful field of view can be conceptualized as the spatial area from which a person can quickly extract visual information without head or eye movement.[204] It requires identification and localization of targets, and it is not the same as the visual sensory field.[65] Age-related speed of processing deficits can cause the area to decline and its size can be reduced by poor vision and difficulty in dividing attention and ignoring distraction (Fig. 11.21).[86] Driving places particular demands on processing speed and selective and divided attention. For instance, quick processing speed is necessary for a driver to recognize when a child's ball has rolled into the street. Selective attention is needed to attend to urgent stimuli (the person in the crosswalk) without being distracted by unimportant ones (eg, the puppy running on the sidewalk). Divided attention is required to focus on the multiple relevant stimuli that are encountered in a complex driving environment (eg, viewing traffic to the front and sides of the vehicle when changing lanes).[51] The UFOV test is a computerized measure of visual processing speed, divided attention, and selective attention. Test takers are assigned to five crash risk categories based on results from the assessment. The test has been widely used in research related to crash risk in older drivers. There is moderate evidence that it correlates with crash outcomes and fitness to drive.[18] Although the UFOV test is becoming more widely used, it is still not widely used by driver rehabilitation specialists[68] and may not be a test that is widely available to a generalist.

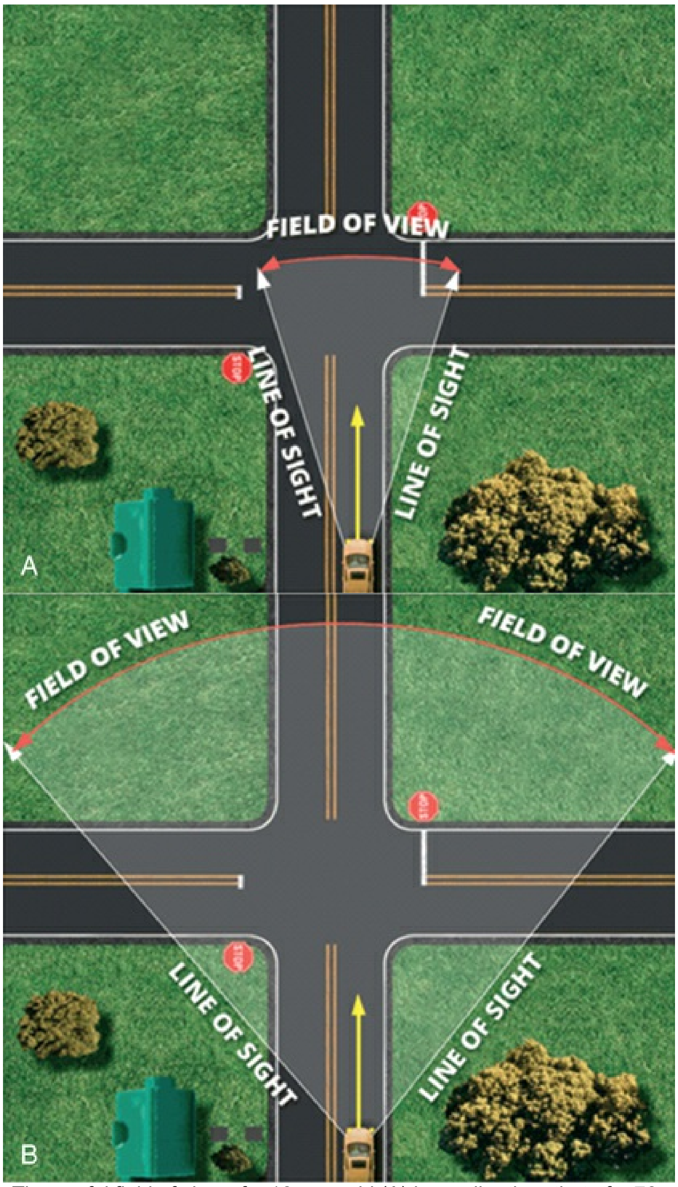

FIG 11.21 The useful field of view of a 16-year-old (A) is smaller than that of a 76-year-old (B). Reduction of the useful field of view can prevent the individual from seeing things that are a safety risk to driving. (Courtesy American Automobile Association, Heathrow, FL.)

The TMTs Parts A and B are paper-and-pencil assessments of overall cognitive function measuring selective and divided attention, mental flexibility, visual scanning, sequencing, and visual memory.[61] Part A involves connecting scattered numbers in order, and Part B requires alternately connecting numbers and letters. Poor performance on Part B has been significantly correlated with poor driving performance.[61] Part B is one of the components of the ADReS and is scored by the time needed to correctly connect the letters and numbers. A time for completion of greater than 3 minutes signals a need for intervention.[51]

There are a number of assessments borrowed from the field of neuropsychology that test memory, orientation, attention, calculation, recall, language, and visual-spatial perception. These include the various versions of the Mini-Mental State Examination, the Short Blessed Test, and the Montreal Cognitive Assessment. Lower scores on these assessments are associated with poor driving performance and warrant referral to a specialist.[14,61]

Motor Skills (Strength, Range of Motion, Sensation, and Balance)

Strength, ROM, sensation, and balance are important to many driving-related tasks. Paralysis, incoordination, tremors, amputations, limitations in static and dynamic balance, fatigue, and slowing of reaction time can impact performance of driving tasks such as loading and unloading a mobility device, entering and exiting a vehicle, turning a key in an ignition, and operating the primary and secondary controls. Both generalist and specialist OTs are trained in evaluation of client factors such as strength, ROM, and sensation using well-established testing protocols. The OT generalist can use clinical reasoning and task analysis to anticipate the impact of identified limitations on driving. For example, when a client demonstrates restriction in cervical ROM, it can be anticipated that there may be difficulty turning the head to see blind spots or check cross traffic. When deficits are identified, the generalist should determine whether it is possible to remediate skills, either through OT intervention or through treatment by professionals such as physical therapists.

The specialist will have an in-depth understanding of how motor skills relate to driving. The assessment information will be used by the specialist to determine when it is appropriate to use adaptations and vehicle modifications to compensate for deficits. Technological advances have made it possible to compensate for motor deficits in many instances. Matching client abilities with vehicle characteristics and equipment features, particularly when high-tech equipment is required, is critical to driving safety and is the purview of the specialist.

In terms of usefulness for predicting driving safety, some research has demonstrated a link between the Rapid Pace Walk (RPW) test and fitness to drive.[18,51] In this test clients are asked to walk 10 feet, turn around, and return to the starting point as fast as possible, using a mobility device if necessary. The RPW test, which is another component of the ADReS, measures lower extremity mobility, trunk stability, and balance. The Toe Tap Test simulates the lower extremity mobility for alternately pressing gas and brake pedals with a foot. To observe for deficits in proprioception, the test can be performed with the eyes closed. Scores have not been shown to be predictive of at-fault crashes in older drivers, but the test has face validity as a measure of one's ability to move the leg/foot quickly from the accelerator to the brake.[181] Diminished cervical ROM is another motor ability that some studies have linked to increased risk of a motor vehicle crash.[61] Brake reaction time is typically measured as the time of the stimulus to the time the brake pedal is depressed. It decreases with age[14] and is affected by surprise, urgency, and critical situations.[101] Although shown not to be predictive of crashes,[18] brake reaction time does have face validity and may be an effective tool for observing psychomotor performance.[14]

Driving Simulators

Interactive driving simulators use computer-based technology that provides virtual scenarios of driving situations. Ranging in cost and size, they enable assessment in a safe environment coupled with the ability to change the scenarios to reflect various traffic situations, daytime or nighttime driving, and weather (eg, sunshine, rain, fog). Driving simulators can provide an effective way to initiate a stationary assessment and to train a client in driving skills in controlled situations. Additionally, the conditions for testing can be replicated for data comparison. For these reasons, simulators' popularity is increasing among OTs working in hospital settings. Yet the question of whether they can predict driving behavior in real-life situations remains. These devices may not represent the reality of driving accurately because they do not drive like an actual car, and the depictions of driving situations may not be perceived as realistic. Currently there is a limited amount of evidence that driving simulators can be used to determine driving fitness.[18] One of their biggest limitations is simulator sickness. The problem is similar to motion sickness and is sometimes experienced when the ocular, motor, and kinesthetic systems receive sensory messages of movement in the absence of true motion.[14] Client factors such as being female and being over age 70 appear to contribute to simulator sickness.[14]

In-Vehicle Assessments

Stationary Assessment

Before the on-road assessment is initiated, the specialist typically performs a number of evaluation steps with the vehicle parked. At the most basic level, the evaluation involves a check of the driver-vehicle fit. Decisions about whether the client is sitting at an appropriate height to optimally look out the front window; his or her position relative to the steering, gas, and brake pedals; and the person's ability to reach these controls easily must be made. Additional skills that require assessment are opening and closing the door, getting into and out of the vehicle, adjusting the seat, securing the seat belt, adjusting the mirrors, turning the key in the ignition, and reaching and operating all the secondary driving controls (eg, horn, headlight switches, turn signals, windshield wipers). Generalist OTs can be involved in evaluating the driver-vehicle fit of older adults through participation in a CarFit event (Fig. 11.22).[9] All OT practitioners should be familiar with the guidelines for driver-vehicle fit established by this program.[14] Videos demonstrating the 12-point assessment used to determine the vehicle-driver fit are available on the program's website (*http://www.car-fit.org/*).

FIG 11.22 Participation in CarFit events provides the OT generalist with experience in evaluating the fit between an older adult and his or her vehicle.

After familiarizing the client with the evaluation vehicle, the next step is to start the engine and assess performance skills for turning the steering wheel and applying appropriate pressure to the gas and brake pedals. When the specialist encounters a client who requires either low-tech or high-tech driving equipment, the stationary assessment includes additional steps. The adaptive equipment is chosen based on the client's needs, but in order to minimize cost, it is important to start with the lowest-tech option that is appropriate. When low- or high-tech equipment is involved, the stationary assessment serves to verify whether the proposed equipment is the correct option or whether another option needs to be tried. At various points in this phase the client will move into the driver's seat and the engine will be turned on to assess the driver-vehicle fit and the performance skills in steering, acceleration, and braking. This process continues until the correct equipment configuration is identified. If the on-road component of the evaluation reveals that the demands of the driving activity exceed the client's performance skills, the stationary process is repeated using the next level of equipment. This trial-and-error approach is an expected and necessary step when assistive driving technology is being considered.[39]

Seating and Positioning

Primary controls are used to operate the vehicle while it is moving. The term refers to the steering, gas, and brakes. Seating and positioning issues can impact effective use of the primary controls and must be carefully assessed to ensure safety. A driver must be seated in a favorable position in front of the steering wheel so that optimal mechanical advantage is realized. When poor trunk control is present, an upper torso support or chest strap may be needed to prevent falling or leaning to the side during braking and turning. The proximal stability provided by the torso support will enhance control of the extremities, which will in turn facilitate operation of the primary controls. Seating and positioning as they relate to maintaining a functional field of view for the driver must also be considered. The sitting position goal is for the line of sight to be 3 inches above the steering wheel, whether the person is seated in the vehicle seat or a wheelchair.[14]

Steering

Either the upper or lower extremities can be appropriately used for steering. When the feet are used, a specialized wheel is mounted on the floor of the vehicle (Fig. 11.23). With either the upper or lower extremities, steering competence is demonstrated by having the client slowly turn the steering wheel to the lock position in both directions without exhibiting undue effort or pain. Rapid turning can cover substitution patterns or decreased strength and does not address performance skills adequately or allow motor performance to be analyzed.

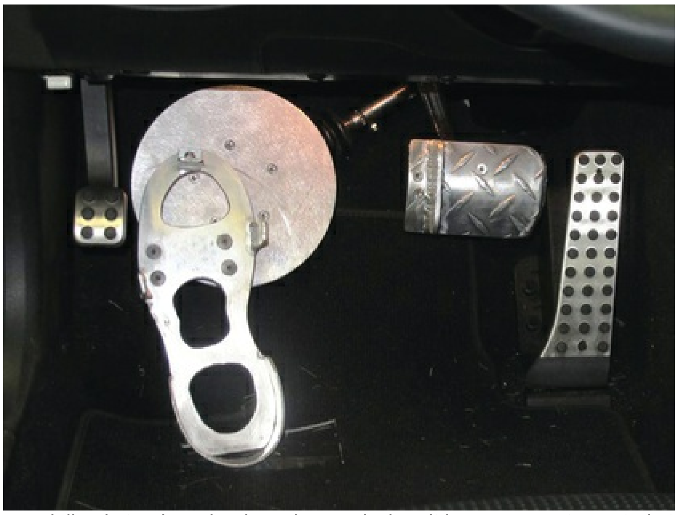

FIG 11.23 A specialized steering wheel can be used when it is necessary to control steering using a foot. (Courtesy Drive-Master, Fairfield, NJ.)

The stronger arm is typically used for steering when a driver cannot use both arms for the task. A steering device attached to the steering wheel is often recommended to improve one-handed control, especially during sharp, fast turns and evasive maneuvers. Adaptive steering devices, such as a spinner knob, **V**-grip, tri-pin, palmar cuff, or amputee ring, can accommodate a variety of hand function abilities and improve the driver's control and speed when turning the wheel.[14] After the setup has been completed, the client's competence in steering must be verified through a dynamic on-road evaluation.

All steering systems include an element of resistance. Automotive manufacturers do not have universal standards for grading resistance. As a result, one car manufacturer's power steering can be as difficult or as easy to turn as another vehicle's manual steering. Knowledge about the trends and patterns in steering system resistance among popular vehicle models is helpful in order to make appropriate recommendations and achieve desired outcomes. It is very difficult to remain current on this type of technology because it changes quickly. Rehabilitation engineers and vehicle modifiers can be a valuable information resource to OTs in this area.

Both low-tech and high-tech modifications are available for clients who lack the strength or ROM to effectively turn an original equipment manufacturer (OEM) power steering wheel. Steering column extensions can bring the steering wheel up to 6 inches closer to the wheelchair driver when there are reach limitations or when extra leg room is needed for positioning. Smaller diameter steering wheels can be used for people who have upper extremity ROM restrictions, but they require more strength and repetitions to turn than a standard wheel. When strength limitations are present, they are often coupled with steering effort reduction adjustments.[44] Effort reduction of approximately 40% is achieved with low-effort steering, whereas zero effort reduces effort by approximately 70%.[143] A mechanical horizontal steering wheel enables a gravity-eliminated horizontal placement when the arms cannot be raised to turn the wheel in a vertical position (Fig. 11.24).[76] Small electronic steering wheels that enable horizontal positioning for clients with very severe weakness are also available. In general, high-tech solutions such as electronic remote steering are only considered after all the lower tech options have been tried.

FIG 11.24 A steering wheel that can be placed in a horizontal position can enable steering for clients who lack upward range to reach a traditional wheel. (Courtesy Drive-Master, Fairfield, NJ.)

A critical final step in steering assessment developed as a result of air bags. The driver air bag is located in the steering wheel hub. Newer vehicles have advanced air bag technologies that tailor air bag deployment to the severity of the crash and thus reduce injury. Close or direct contact with an air bag module during deployment can still cause serious or fatal injury, however. The NHTSA continues to recommend that drivers sit with at least 10 inches between the center of the breastbone and the center of the steering wheel.[127] In some instances wheelchair-seated drivers are positioned very close to the steering wheel so that they can reach adaptive equipment. The NHTSA will grant permission for installation of an on/off switch to disconnect a driver air bag under certain circumstances. These include a medical condition that places the driver at specific risk or inability to adjust the driver's position to stay the recommended distance from the steering wheel.[127] The specialist should document the client's distance from the steering wheel.

Accelerator and Brake Controls

Modified accelerator and brake controls can be installed in most vehicles. Simple modifications, such as pedal extensions, which extend the OEM pedals over 12 inches, can compensate for limited lower extremity reach in short persons. Maintaining an appropriate seated distance from an air bag can often prevent the driver from fully reaching the accelerator and brake pedals and has resulted in an increased need for this type of modification.

When right hemiplegia or right lower extremity amputation is present, the right foot is unable to operate the standard pedals. Intuitively some clients cross over with the left foot to operate the brake and accelerator pedals. This can be an unsafe practice because the person is off-center for proper steering, and the awkward posture involved can cause strain on body structures over time. A left-sided accelerator pedal can be placed to the left of the standard brake pedal so that the accelerator and brake can be operated with the left foot. It is imperative to determine that the device can be operated reliably. Cognitive and visual perceptual deficits may prevent safe use of this seemingly simple device.[14] If the device is recommended, the driver must be educated about the necessity of instructing anyone who will be operating the vehicle (mechanics, parking attendants) in how to use it.

Hand controls can be used when the lower extremities are not functional for operating foot pedals. Mechanical hand controls consist of rods connected to the OEM accelerator and brake pedals. In a push/right angle type of hand control, the motion of pulling down presses the rod attached to the right foot pedal and causes acceleration. Pushing forward depresses the rod attached to the left foot pedal and activates the brake. Depending on the style, hand controls use various upper extremity movements (rotary, push-pull, push-pull down, or push-rock motions) to activate the brake and accelerator pedals. Hand controls that use a motor to move the pedals are known as powered controls. High-tech accelerator and brake controls have servomotors that are activated by vacuum, hydraulic, or electronic means.[44] Some high-tech driving systems allow a client to steer, brake, and accelerate using a single vertical column control or a joystick and can enable driving with a single limb (eg, the EMC AEVIT 2.0 gas/brake/steering system, Scott Driving

System, Joysteer Driving System, and Paravan Space Drive II).[77-79,88] A careful match between the functionality provided by these devices and the client's strength and motor control must be made. The devices are very sensitive, and postural control is absolutely critical when they are used. Inadvertent movements may result in loss of vehicle control. Longer, more complex evaluations and lengthier driver training are needed when high-tech systems such as these are recommended (Fig. 11.25).

FIG 11.25 This client with muscular dystrophy required a joystick system to operate the primary controls for driving. Evaluations and training requirements for clients using high-tech systems are more complicated and time intensive.

Secondary Controls

Secondary controls include those for interacting with the elements and other roadway users. They are operated while the vehicle is in motion but do not affect the vehicle's speed or direction. A driver must be able to activate at least four secondary controls at will when the vehicle is in motion: turn signal indicators, horn, dimmer, windshield wipers, and cruise control.[14] The switches to control these functions can either be placed on the hand control itself or in a spot where they can be controlled through elbow and sometimes lower extremity motions.

Some people lack the motor function to access multiple switches. In such cases secondary functions can be controlled by a single sequencing switch. Activation of the switch initiates a tone or word assigned to a particular function. A second touch of the switch selects the desired function. The transmission, parking brake, heater, air conditioner, hazard light, and headlights can be operated when the vehicle is parked. As the configuration and positioning of these controls vary, they may be operable by some clients without modification. If a client cannot access them, extension levers and other mechanical alternatives for operation can be investigated. Remote switches and electronic modifications can be considered if these options are not appropriate for a client's function.[14]

Section 3: Threaded Case Study

Jacqueline, Part 2

Jacqueline was initially concerned that the driving evaluation would result in her losing her license and was hesitant about participating. Her OT generalist took the time to communicate the intent of the evaluation. After Jacqueline realized that the purpose was to help her drive safely for as long as possible, she readily agreed to a referral to the low-tech driving program at the hospital.

The specialist in this program took a closer look at how Jacqueline's hand limitations affected opening the car door and gripping the steering wheel. Jacqueline received an adaptive key holder to open the car door and a recommendation to purchase a steering wheel wrap to build up the steering wheel diameter. A cartop carrier for her husband's wheelchair was recommended, but

Jacqueline decided to wait to purchase it because of financial considerations. Jacqueline told the specialist that she had had some near misses while changing lanes, nearly colliding with cars she didn't see. Many older drivers never received formal driver training and are unaware that a blind spot check is required. In Jacqueline's case the problem was caused by neck ROM limitations that prevented her from turning her head sufficiently to look over her shoulder.

A wide-angle interior rearview mirror and blind spot mirrors on the car's exterior mirrors greatly improved Jacqueline's safety and confidence in viewing traffic and conducting blind spot checks. The specialist also found that she sat too low in the driver's seat, which resulted in poor field of view out the windshield and poor mechanical advantage for turning the steering wheel. Jacqueline's seat was adjusted, and a cushion was used to raise her eye level 3 inches above the top of the steering wheel.

On-Road Assessment

Behind-the-Wheel Assessment

Once the stationary assessment has accomplished the task of setting the driver up with primary controls, the specialist applies the OT skill of IADL observation to the actual process of driving. This part of the evaluation is commonly referred to as the BTW assessment, or **on-road assessment**. It is considered the definitive measure of driving competence because it is completed in the context of the environment and has ecological validity.[18] The OT generalist should not undertake the on-road evaluation because it requires the advanced training and skills of the specialist. The specialist will conduct the on-road evaluation to determine whether the client is able to meet competency criteria (eg, passing a driver licensing test) and to identify driving deficiencies in order to develop a remediation program.[67]

The individual in the role of the driving instructor orients a driver in the use of adaptive driving equipment, maintains vehicle control by intervening for safety when necessary, and directs the route. In some settings the specialist will work alone in the role of the driving instructor to directly administer the on-road evaluation. In others he or she will collaborate with a commercial driving school instructor. OT practitioners specializing in driving should be well versed about the rules and regulations related to driving instruction in their state. Some locations will require that OT practitioners specializing in driving also be certified driver instructors in order to perform on-road assessments and provide driver training.[13,14]

Ethical Considerations

No therapist should proceed with the on-road driver evaluation without first meeting the industry standard or equivalent for driver instructors within his or her own state. Proceeding without this basic driver instructor training is not recommended; it has the potential to be unsafe and to result in the therapist teaching techniques incorrectly that must later be unlearned.[14]

Driving Routes

The on-road assessment should be no longer than 2 hours but should be a minimum of 45 minutes long. A time less than 45 minutes is inadequate to make the necessary observations, particularly those required to determine whether the client is able to sustain mental and physical effort during the drive. Driving routes used for the assessment should incorporate a sampling of road conditions, traffic patterns, and unusual settings common to the local region. The driving route should allow the driver time to become familiar with the vehicle and adaptive equipment in a low-stimulation environment. This period of learning and accommodation will be longer for the novice or apprehensive driver.

Initially the assessment will involve straight-line driving to determine the driver's ability to maintain lane position or to make accommodations to position. The route should progress through faster and more congested traffic and various dynamic traffic conditions so that information about the driver's performance in a wide variety of conditions can be gathered. A method of keeping track of driving performance, such as recording observations of driving errors, is recommended. The criteria for assessing driving performance should reflect physical management of the vehicle, ability to use the adaptive equipment, interaction with other traffic, adherence to rules of the road, and safety judgment.

Competence implies that a client can repeat a performance skill consistently; that his or her success was not based on a lack of environmental or traffic challenges. Repeated success in executing maneuvers in situations requiring the use of judgment must be demonstrated before competence can be ascertained. Specialists should always work within a window of comfort and only take clients in situations in which it is possible to provide override control.

After the on-road assessment has been completed, the driving team reviews the results with the driver. Asking the client for feedback before doing this provides a valuable perspective on his or her insight. Results cannot be shared with family without permission from the client; a verbal agreement from the client to share results should be documented.

Jacqueline was very nervous during the BTW portion of the driving evaluation and made some noncritical errors in freeway situations. She felt that the better positioning in her car decreased her shoulder pain and believed that she had performed well overall. The specialist agreed with her appraisal but recommended 4 hours of driver training focusing on defensive driving skills, use of expanded mirrors, and freeway maneuvers. The ADED best practices resources were used by the specialist to assist her in formulating the criteria used in making recommendations for the additional training.

Recommendations Resulting From Assessment

The driver evaluation culminates in a decision about driver competency, identification of the necessary adaptive equipment and vehicle, and when appropriate, a recommendation for the number of driver training hours required to raise performance skill to a safe and independent level. New driver evaluators need to be cautious not to misconstrue new driver or older driver patterns as uncorrectable errors incompatible with driving. Conversely, errors must be carefully weighed, especially with neurologically involved clients who may have inconsistent driving performance. Recommendations may include (but are not restricted to) (1) drive unrestricted; (2) drive with restrictions; (3) cessation of driving pending rehabilitation or training; (4) planned reevaluation for progressive disorders; (5) driving cessation; and (6) referral to another program.[36]

Written Report

The comprehensive driving report should contain a summary of the clinical assessment and driving performance observations and should provide a statement of the client's potential to be a safe and independent driver. It should specify the type of vehicle needed, the specific vehicle modifications required, the necessary primary and secondary controls and recommendations for their location, all equipment necessary to position and restrain the client and secure his or her mobility device, and all necessary auxiliary equipment. When high-tech or custom equipment has been recommended, the report should specify the need for follow-up fitting sessions to confirm that the equipment has been installed correctly and is functioning as intended.[31] The report should also estimate the amount (duration, frequency, and total length) of driver training needed, indicate specific areas of emphasis for training, and provide resources for where the training is available.

Driver Training

Training needs for clients vary, depending on the person's amount of driving experience and the need to use adaptive vehicle controls. A young person with a disability who has never driven may have training needs related both to being a novice driver and to the limitations imposed by the disability. Individuals with driving experience who have cognitive and perceptual impairments and older adults with age-related declines often need to relearn driving behaviors or implement compensatory skills to obtain consistent driving performance, even though they may not require adaptive equipment. Extensive training with a focus on vehicle control and recovery, especially in unexpected situations and at high speeds, is essential when high-tech equipment is recommended. Some clients will require training in their own vehicle because the unique modifications that they need for driving may not be available on any of the evaluation program vehicles. Depending on each state's requirements and on the individual client's needs, driver training may occur before or after the vehicle has been modified.

Vehicle and Equipment Prescription

A basic level of service provided by the majority of driving programs is the car evaluation. A car is generally appropriate if a person is able to enter and exit a vehicle and load mobility devices into it independently. The standard car recommendation is a midsize vehicle with power steering, power brakes, and an automatic transmission. A two-door car can be advantageous for wheelchair loading by the driver, although some find the larger and heavier vehicle door difficult to manage. Fewer two-door models are being manufactured, resulting in the more frequent use of four-door vehicles.

When loading a manual wheelchair into a car is not feasible, a mechanical device such as a cartop carrier or rear bumper loader may provide the driver with some independence. Clients with limited ambulation who use a scooter or wheelchair for long distances may be able to continue using their standard sedan, SUV, truck, or minivan with the assistance of a power hoist to lift the mobility device (Fig. 11.26).

FIG 11.26 Bruno's Curb-Sider lifts and stows a scooter or power wheelchair inside a minivan by the push of a button on a handheld pendant. (Courtesy Bruno Independent Living Aids, Oconomowoc, WI.)

Numerous variables affect equipment selection and driving performance when a person drives from a wheelchair; consequently, a more skilled evaluation is needed. Individuals who must drive from a wheelchair most often choose between minivans and full-size vans in which the floor has been lowered to provide more headroom to pass through the door while seated in a wheelchair. Another reason for the floor lowering is that the wheelchair seat is higher than the OEM seat. If the floor were not lowered, the wheelchair user would sit too high to have optimal visibility through the front window.[44] A ramp and kneeling system are used to lower the minivan height and decrease the ramp angle sufficiently for a wheelchair user to roll in. Lifts are required for entry into a full-size van because they are higher than minivans. Full-size vans have more headroom, a greater load capacity, and more ground clearance than minivans. Because of this, they are more suitable for certain environments (the rough terrain of unpaved roads, for instance). Minivans are popular because they drive like a car, fit more easily in home and public garages, and get better gas mileage than full-size vans. Their entry ramp can be positioned at the rear or the side, depending on the driver's needs and preferences.

Manufacturing changes in the automotive industry have affected the choices available to people that need to drive from their wheelchairs. The Ford E series full-size van, which was most often modified, is no longer in production. Its replacement, the Ford Transit van, is not suitable for a lowered floor conversion, although it can be used as a wheelchair passenger van. The specialist will need to keep abreast of changes in the automotive industry through attendance at NMEDA and ADED conferences to know which full-size alternatives will be available to clients in the future. SUVs and trucks, both midsize and full size, may present additional options for individuals (Fig. 11.27). However, when clients decide on vehicle options other than vans or cars, it becomes more difficult to ensure that the modifications they require to drive safely and independently will be compatible with the chosen vehicle type.

FIG 11.27 The BraunAbility MXV is a wheelchair-accessible SUV that might be an appropriate alternative to a minivan for some clients. (Courtesy Braun, Winamac, IN.)

Client factors, adaptive equipment features, and vehicle modifications must match appropriately before an expectation of safe and independent driving can be met. The OT generalist can play an important role by advising clients and their families that vehicle choices will have implications and by recommending that they consult with a specialist before making a vehicle purchase. Vehicle modifiers and funders may have requirements for the age, mileage, make, and model of a vehicle. It may not be feasible to install costly modifications in an old vehicle that will not last and might not be safe.[14]

Follow-Up Fittings

Follow-up services are another important aspect of comprehensive assistive technology service delivery. When adaptive equipment is recommended, a follow-up evaluation ensures that the equipment is positioned and adjusted to meet the client's functional needs (Fig. 11.28).[31] Follow-up services include mid-fit and final fitting sessions for quality assurance and verification of safety. When an adapted vehicle is delivered, it is the first time that the client, adaptations, and selected vehicle have interfaced. Some adjustment is almost always needed to meet functional goals and to have the adaptations perform as envisioned.[14] An on-road session is recommended to make sure adjustments are adequate for function when dynamic forces involved in driving come into play.

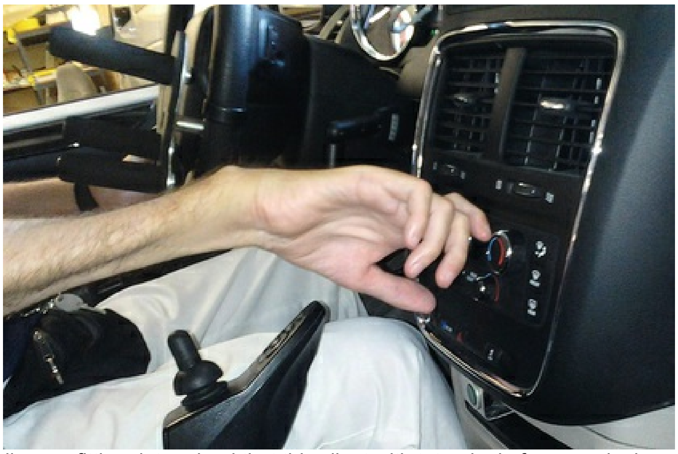

FIG 11.28 A follow-up fitting determined that this client with tetraplegia from a spinal cord injury required extension modifications to operate the dials on the dashboard.

Licensing Assistance

Dealing with the licensing situation related to a disability or medical condition can be both daunting and intimidating to a client. Some individuals may feel unjustly treated if their license has a medical suspension. OTs must be knowledgeable about the licensing procedures, requirements, and reporting laws in their state and understand how they may impact the client's ability to begin or return to driving and participation in their valued occupations.[175] To determine qualification for on-road testing, specialists should ascertain license status, eligibility for acquisition/renewal of the license or permit, the expiration date of the license/permit, and any restrictions that have been imposed. State licensing forms and related information should be made available to the client and other health professionals to hasten resolution of licensing issues.[31] Compilation of a resource file that includes links to licensing information websites, handbooks of licensing laws in culturally appropriate languages, and the medical evaluation forms required by licensing agencies is beneficial. The process of obtaining the permit or license can be expedited by early vision screening. Testing of visual acuity, visual fields, and color vision may be appropriate, depending on a particular state's requirements. Clients with deficits should be referred to an eye care specialist for treatment and correction of problems that could otherwise delay the process.

State licensing agencies are the primary entities providing the criteria for safe road users. License practices and reporting laws vary among the states.[1] Licenses must be renewed every 4 to 5 years in most states, but in some the time is longer. Arizona, for instance, has a license validation time of 12 years. Mandatory physician reporting is the policy in some states; others encourage but do not require reporting, and some have no reporting requirements at all. Immunity from liability depends on a particular state's policy. Frequent review of the state licensing laws is warranted to stay abreast of changes. An online database of state-by-state driver licensing policies and practices affecting older and medically at-risk drivers has been compiled by the AAA Foundation for Traffic Safety. The database is accessible at *http://lpp.seniordrivers.org/lpp/*. Individual agencies, facilities, and hospitals should establish policies and procedures for reporting clients who are unsafe drivers based on their state's laws. As stakeholders in public safety involved in the screening of medically at-risk drivers, OTs should provide input relevant to formulation of the policy.

Driving Retirement

Driving is the most complex IADL we perform on a day-to-day basis, requiring that visual, cognitive, and sensory-motor skills be in peak condition. As the Baby Boomer generation begins to experience functional declines brought about by medical conditions common in aging, safe driving may no longer be realistic. **Driving retirement** is the term used by the AMA to refer to the transition from driver to nondriver.[51] OTs should approach this very emotional topic with compassion. The Hartford Center for Mature Market Excellence has created several free publications related to older adult driving.[188] *We Need to Talk: Family Conversations with Older Drivers* is their guidebook of practical information to help with initiating productive and caring conversations about driving safely. It is available at *http://www.thehartford.com/mature-market-excellence/publications-on-aging*. AARP has produced a free, three-module, online seminar with videos, printable worksheets, practice activities, and an interactive review based on the Hartford materials. The seminar is available at *http://www.aarp.org/home-garden/transportation/we_need_to_talk/*.

The discussion of driving retirement should be initiated well before the need arises for driving cessation so that the client can begin exploring available resources for alternative transportation within the structure of his or her home and community. Making a "plan" for driving retirement helps to normalize the process so that it feels similar to planning for financial retirement or retirement from gainful employment. Discussions of this subject should include transportation alternatives and barriers to participation, such as finances, limited service destinations, and reluctance to rely on family and friends.[51]

Technology-based resources that can ease the transition from driver to passenger are becoming increasingly obtainable and should be discussed with the client facing driving retirement. Many goods and services can be procured via the worldwide Web. Home delivery of groceries and medications has become more common. As they gradually become more accepted by society, app-based transit services (eg, Uber, Sidecar, and Lyft) have the potential to foster independence in the community and facilitate engagement in occupations. Finally, self-driving vehicles, such as the Google car, which have been in development for over a decade, will be introduced to American roads in the near future and have the potential to have a transformative effect on community mobility.

Although the subject is sensitive, when deficits that preclude driving safely are demonstrated, it is imperative that the OT make the recommendation for the client to refrain from driving. If the client's medical condition is one with potential for functional improvement, the recommendation should be that the client refrain from driving until the area or areas of deficit have been remediated. However, if additional functional decline is anticipated, retirement from driving should be clearly recommended. If possible the client's family or another individual within his or her support system should be included in the discussion. Recommendations should be provided to the client both verbally and in writing. All aspects of the assessment and recommendations should be clearly documented in the medical report. Additionally, the client's physician should be informed in writing of the assessment results and recommendations made by the OT.

After her competency was verified and she received interventions for freeway situations, Jacqueline decided that she was not ready to retire from driving. She told the specialist that she shared the good news about her driving skills with her family. Although they were relieved she had had the evaluation, they were still concerned about her transportation needs long term. The specialist used the opportunity to discuss services available through STPs that would enable Jacqueline to augment the transportation available to her through paratransit. She encouraged Jacqueline to talk about transitioning to driving retirement with her family now, so that there would be a well-thought-out plan in place when the time actually came.

Intervention Implications for Various Disabilities

Many different types of disabilities affect driving ability. OTs can apply their knowledge of the various conditions to understand the client factors that might be affected and to anticipate how disease progression could influence the need for driving equipment over the course of time. The ADED website provides factsheets discussing driving issues and assessments for several different types of disabilities.[32] A discussion of the driving issues related to some commonly seen disabilities is presented below.

Wheelchairs and Driving

People with many different types of disabilities use wheelchairs to move about in the community. It is important to keep clients informed about how their wheelchair choices will impact their ability to drive safely and independently. Consultation with a specialist is strongly recommended when a wheelchair-using client plans to become an independent driver; otherwise, factors critical to driving may be inadvertently overlooked by professionals involved in prescribing the wheelchair. For example, independent driving for a client pushing a manual wheelchair may not be feasible if management of the ramp of a minivan cannot be accomplished.

The implication of the wheelchair's width in optimal positioning for steering may not be understood. Also, there may not be an appreciation of whether the wheelchair frame's design will be compatible with certain types of loading devices. Finally, some wheelchair evaluators may not be aware that generally desirable features (eg, independent suspension) can cause inadvertent movements that affect a driver's ability to safely use high-tech driving systems, or they may not know that wheelchairs in which the seat rests on a single post may be unsafe to use as a driving platform.

Client education about the safety risk involved in driving from a wheelchair is necessary. It is generally accepted that the hierarchy of safe seating for a driver begins with the OEM driver's seat, which is designed to withstand crash forces. The OEM seat is followed by an aftermarket powered seat base. Driving from a wheelchair is next, with a power wheelchair considered safer than a manual wheelchair, even when both are WC 19 compliant. The heavier weight of the power wheelchair allows it to withstand forces at the higher speeds typical in many driving situations. Proper securement of the wheelchair in the vehicle is critical to safety in either case. Guidelines for using a WTORS for this purpose were discussed earlier in this chapter. For safety reasons, it is not possible to drive from a scooter.

Spinal Cord Injury

Many people with a spinal cord injury (SCI) will have a goal of resuming driving or becoming independent drivers. Driving-related intervention for these clients requires critical thinking early on in a rehabilitation program. Mild or undiagnosed traumatic brain injury (TBI) is common among people with an SCI.[119] It is important to remain alert to possible signs of TBI so that intervention services addressing the future demands of driving can be planned. Because there is evidence that transfers can increase the risk for upper limb injury in people with an SCI,[147] the client's efficiency and technique during transfers into and out of a vehicle should be carefully assessed. If limiting transfers is necessary in order to preserve upper limb function, the client may need to consider driving from a wheelchair.

The functional outcomes and equipment needed for driving with an SCI depend on a number of factors. Particularly critical are which key muscle groups are functioning and whether the injury is complete or incomplete. A significant percentage of SCIs are incomplete,[144] which allows varying levels of motor and/or sensory function below the level of the lesion that can facilitate task performance. Steering devices may be needed to accommodate hand and upper extremity impairments. Upper torso supports or chest straps may be required in addition to a diagonal seat belt to maintain an upright position during a sharp or fast turn. Lower extremity spasms in some people may necessitate the use of pedal blockers to prevent accidental activation of the brake and gas pedals.

In practice, even some people with a C5 SCI can drive safely from a wheelchair in a lowered floor minivan with a ramp. A high-tech, one-arm driving system in which the steering, gas, and brakes are operated with a lever modified with a tri-pin is needed (Fig. 11.29). Individuals with C6 tetraplegia typically require a modified van and sensitized steering and hand controls for driving. Some are able to transfer into the driver's seat if it is modified with a powered seat base, which moves up/down, forward/back, and rotates to facilitate transfers. People with C7-8 injuries and paraplegia typically have sufficient upper limb function to use mechanical hand controls and can usually transfer into the driver's seat of a car. However, full hand function is not present in low tetraplegia, and there may be balance limitations due to varying degrees of trunk musculature paralysis in paraplegia. These two factors can make dismantling and loading/unloading a manual wheelchair from a car difficult and time-consuming and should be considered when evaluating the feasibility of driving from a car.

FIG 11.29 Some people with severe disabilities are able to drive if matched with the right technology. This variation of the Scott Driving system allows the steering, gas, and brake to be operated with a single arm. (Courtesy Driving Systems, Van Nuys, CA.)

Traumatic Brain Injury

Diffuse and local damage from TBI can cause physical and visual deficits; impairments in aspects of cognition such as attention, processing speed, language function, and memory; and visuospatial and visuomotor limitations. Moderate and severe TBI can result in paresis, plegia, and posttraumatic seizures that affect fitness to drive.[99] However, even mild TBI, which accounts for most TBIs,[58] can lead to concentration and attention difficulties, irritability, and executive functioning challenges that interfere with driving performance.[66] Although research studies have not consistently identified the risk for crashes after a TBI, there is evidence that even mild cognitive difficulties can lead to increased risk while driving.[47] Despite this, between 40% and 80% of people with moderate to severe injuries return to driving after injury, many without evaluations for driving competency.[66]

These findings suggest that clinicians should be concerned about fitness to drive in any client with a history of TBI, regardless of its severity. People with mild TBIs may experience a short hospitalization and may be discharged before their symptoms have fully resolved. OTs in an acute care setting may be called upon to provide advice about whether it is safe to return to driving. Based on the time for resolution of symptoms from mild TBI, some facilities have developed clinical protocols identifying the timing for safe return to driving.[38] Clinicians in a facility without such established protocols should administer a driving screen to identify whether referral to a specialist for more in-depth evaluation and BTW assessments is warranted. Generalists should be aware of their state's laws for reporting loss of consciousness or seizure disorders to the state's Department of Motor Vehicles.

Given that cognitive and perceptual impairments are common problems that can interfere with driving safety, generalists in inpatient and outpatient rehabilitation settings should be familiar with the evidence pertaining to the effect of interventions to address cognition and perception in people with TBI. Evidence-based guidelines for practice with TBI clients using key concepts from the OTPF are available.[99] Additionally, the AOTA's "Critically Appraised Topics and Papers" series reviews current evidence for interventions related to cognitive impairments and skills, vision and visual processing, and psychosocial, behavioral, and/or emotional impairments and skills.[24]

It is important to establish whether driving or a returning to driving is a goal for a client with a TBI. Family members and other caregivers often have valuable insight into a client's ability to return to driving[157] and should be included in the conversation about driving potential, provided the client agrees. The timing of consultations, predriving assessments, and referrals to on-road driving programs should be carefully considered. Clients whose functional return has stabilized require less adaptive equipment than those who are newly injured. A referral made too early can use up limited therapy visits from an insurance provider or tax the financial resources of the individual or family. Exploration of driving potential becomes appropriate when there is evidence that the client has insight about his or her physical and cognitive limitations and when improvement in factors such as the ability to demonstrate new learning, divide attention, and incorporate good judgment into decision making has been demonstrated. Consultation with the driving specialist can identify performance skill needs that can be integrated into inpatient, outpatient, day treatment, or community intervention programs prior to the actual referral. OTs can render a valuable service, even if driving is not a realistic goal, by providing information about transportation alternatives.

Cerebrovascular Accident

A cerebrovascular accident (CVA) can have varying effects on function, depending on the anatomical brain structures damaged. Deficits that can interfere with driving include hemiparesis or hemiplegia, visual limitations, problems with memory and concentration, slowed reactions, spasms, speech and reading difficulties, and other consequences.[130] Scores on the Functional Independence Measures and extremity Motoricity Index on admission to inpatient rehabilitation may be helpful in focusing treatment goals for patients who want to resume driving. Low scores on these measures have been linked to a lower likelihood of return to driving at 6 months.[37] Driving screens are a valuable service that a generalist can provide to identify people who are at risk for unsafe driving from a stroke. There is evidence that many stroke survivors do not receive professional advice or a formal evaluation on which to base a decision to resume driving.[102] The NHTSA has produced a series of short videos to show how different medical conditions can affect driving abilities.[141] The educational video about stroke, available as part of the NHTSA video tool kit on the agency's website, can be an important tool for educating stroke clients about the driving risks resulting from their functional deficits.[141]

Hemianopia is a common occurrence after a CVA.[151] Visual field loss is of concern because it has the potential to affect driving safety.[51] Visual neglect often occurs in conjunction with visual field loss and can result in lack of attention to the neglected side. In these cases driving is usually counterindicated.[14] However, there is evidence that people with hemianopia or quadrantanopia with no lateral spatial neglect can demonstrate safe driving.[89] To best advise clients, OTs will need to familiarize themselves with the DMV visual field requirements in their states because they vary substantially.[51]

Equipment used for driving after a CVA will depend on the individual's functional impairments. If the person cannot steer with both hands, a steering aid may be needed to assist with turning.

When there is paralysis of the right leg, modification of the vehicle with a left foot accelerator might be appropriate, if the person is able to operate it reliably. Extra mirrors may be necessary in order to compensate for visual deficits.

Arthritis

Arthritis is the most prevalent disease of people over 65 years of age. The pain, fatigue, ROM deficits, and diminished strength and reaction time caused by arthritic conditions can negatively impact driving performance.[205] Depending on the location of joint involvement, arthritis can limit specific driving skills. For example, involvement of the cervical spine can impair head turning and the ability to check traffic to the side and rear of a vehicle. Clients report difficulties in turning a key, operating the switches for the secondary controls, entering and exiting a vehicle, managing seat belts, and operating gas and brake pedals. Loading and unloading mobility devices can also prove to be problematic. OTs should be aware that side effects from medications used to treat pain associated with arthritis also have the potential to affect reaction time and alertness for driving.

The NHTSA video tool kit previously referenced is a helpful tool to assist generalists in educating clients and their families about the driving problems associated with arthritis. Exercise programs to improve strength and ROM and instruction in proper body mechanics and energy conservation may also be warranted. Some clients will benefit from adaptations such as key turners and simple devices to facilitate getting into and out of a car. A knowledge of resources for identifying vehicle design features that facilitate comfort and safety for drivers with arthritis may also be helpful. The website *SeniorDriving.AAA.com* includes the Smart Features for Older Drivers tool to assist with selection of vehicle features tailored to individual considerations, including those related to arthritis.[10] However, generalists need to appreciate that all levels of equipment affect how a driver interfaces with a vehicle and must be ready to refer clients to a specialist for a comprehensive evaluation when a client's needs exceed simple aids.

Medically At-Risk Older Drivers

By the year 2020 there will be 53 million seniors. Licensed drivers will account for approximately 75% of this group.[51] Driving in this age group is often viewed negatively by the public, but age by itself is not a good determinant of one's fitness to drive. The facts are that older drivers do not engage in risky behaviors such as speeding, not wearing a seat belt, and drinking and driving, and they often self-regulate their driving by using strategies such as not driving at night or forgoing left turns.[51] The real issue is that age increases the likelihood that they will experience the type of medical conditions that can impair driving abilities and increase crash risk.[14] Even with self-regulation, the rate of crashes per mile driven starts to increase after age 65.[51] Another factor is that seniors are more susceptible to injury because of fragility and do not survive crashes as well as younger people. Their risk of being involved in a fatal car crash begins to increase at ages 70 to 84 and is highest for drivers 85 or older.[104] Functional declines brought on by polypharmacy have also been shown to be associated with an increased risk of motor vehicle crashes. This is significant because more than 40% of persons age 65 or older use five or more medications per week.[115] Considered all together, these issues are the reason that older adult driving is a pressing public health concern.

Driving is the preferred transportation for older adults[41] and is the means by which many of them remain connected to goods, services, and leisure activities. Loss of driving privileges can cause social isolation and can have a very harmful effect on engagement outside of the home. Because most older adults will outlive their ability to drive (men by 6 years and women by 10 years),[51] OTs must be diligent in helping them remain drivers as long as it is safe. When driving is no longer feasible, practitioners have an important role in helping to identify transportation alternatives.

The importance of the role of the generalist practitioner in addressing older driver needs cannot be sufficiently stressed, as is evidenced by the algorithm for making driving and community mobility decisions introduced earlier. Driving status should be explored routinely when the OT is establishing these clients' occupational profiles. Medical records should be carefully reviewed to identify "red flag" health issues and medications known to have the potential to impair driving. OTs can use the AAA's RoadwiseRx tool,[11] accessible at no cost at *SeniorDriving.AAA.com*, to provide clients with individualized feedback about how medication side effects and interactions can impair their ability to drive safely. Observation of a client's performance on complex IADL tasks, a routine part of the OT generalist's intervention, provides valuable information about whether the client is likely to encounter problems in driving; it is a key factor in helping generalists identify when a client requires referral to a specialist.[14]

Generalists should keep the performance skills needed for driving in mind throughout the evaluation process so that appropriate interventions can be designed to remediate any deficits. When clients demonstrate a lack of insight into how their health issues and driving interact, many of the tools discussed earlier in this chapter (ie, RoadwiseReview, Enhanced Driving Decisions Workbook, and the Fitness to Drive Screening Measure) are useful for assisting them to gain self-awareness. CarFit events will provide an opportunity for clients to learn about how well they fit with their vehicle. They also serve to increase the public's awareness of the role of OT in older driver safety and provide a means to identify clients who would benefit from referral to a specialist. Practitioners need to introduce local transportation options to senior clients well in advance of the need to cease driving, in preparation for eventual driving retirement. To facilitate referrals for the right level of service for clients requiring comprehensive driver evaluation services, generalists should be aware of the various driver rehabilitation programs available in their particular area.

Section 3 Summary

Community mobility, whether it occurs while accessing a school bus, driving one's own vehicle, or riding in the local senior transport van, is a pivotal IADL. All forms of community mobility have the ability to enable engagement in necessary and meaningful occupations and are thus the concern of OT practitioners, regardless of whether they are generalists or specialists in the practice area. Individual evaluation, with consideration of valued occupational roles and the transportation systems available to a person, provides a foundation for determining the necessary level of intervention. Evidence-based research should be used to support practice, but without losing sight of the importance of driving and community mobility for facilitating social participation and involvement in other occupations throughout the life span. OTs are challenged to provide driving and community mobility services that will be widely recognized and valued by consumers, communities, and organizations.

Section 3: Threaded Case Study

Jacqueline, Part 3

Jacqueline's generalist OT and her OT driver rehabilitation specialist both played important roles in meeting her needs in driving and community mobility. Her generalist OT first identified problem areas in community mobility as she formulated Jacqueline's occupational profile. She assisted her in successfully applying for paratransit services, to be used as backup transportation when pain from her arthritis prevented her from driving. After evaluating Jacqueline's performance capabilities, she also designed a home exercise program to improve her limited neck ROM and grip strength. Because these deficit areas could negatively impact Jacqueline's performance behind the wheel, she discussed the benefits of a comprehensive driving evaluation with her. The generalist OT used her knowledge of local driver rehabilitation programs to determine that Jacqueline's needs could be met through the low-tech program at her hospital. The specialist at this program prescribed equipment to help Jacqueline compensate for the physical limitations to driving imposed by the arthritis. She provided Jacqueline with training in adaptive techniques for vehicle entry/exit, car transfers, wheelchair loading, and driving performance. She also helped her to begin thinking about a transportation plan for the future, when she had to retire from driving. Jacqueline's quality of life was greatly improved through therapeutic intervention in several aspects of community mobility. She is quite pleased with the outcomes achieved with the help of both therapists.

Review Questions

1. Define functional ambulation. List three ADLs or IADLs in which functional ambulation may occur.
2. Who provides gait training?
3. What is the role of the OT practitioner in functional ambulation?
4. How do OT and PT practitioners collaborate in functional ambulation?
5. List and describe safety issues for functional ambulation.
6. Name five basic ambulation aids in order of most supportive to least supportive.
7. Discuss why great care should be taken during functional ambulation within the bathroom.
8. List at least three diagnoses for which functional ambulation may be appropriate as part of OT services.
9. What purpose does a task analysis serve in preparation for functional ambulation?
10. What suggestions could be made regarding carrying items during functional ambulation when an ambulation aid is used?
11. What is the objective in measuring seat width?
12. What is the danger of having a wheelchair seat that is too deep?
13. What is the minimal distance for safety from the floor to the bottom of the wheelchair step plate?
14. List three types of wheelchair frames and the general uses of each.
15. Describe three types of wheelchair propulsion systems and tell when each would be used.
16. What are the advantages of detachable desk arms and swing-away footrests?
17. Discuss the factors for consideration before wheelchair selection.
18. Name and discuss the rationale for at least three general wheelchair safety principles.
19. Describe or demonstrate how to descend a curb in a wheelchair with the help of an assistant.
20. Describe or demonstrate how to descend a ramp in a wheelchair with the help of an assistant.
21. List four safety principles for correct moving and lifting technique during wheelchair transfers.
22. Describe or demonstrate the basic standing pivot transfer from a bed to a wheelchair.
23. Describe or demonstrate the wheelchair-to-bed transfer using a sliding board.
24. Describe the correct placement of a sliding board before a transfer.
25. In what circumstances would you use a sliding board transfer technique?
26. List the requirements for client and therapist to perform the dependent transfer safely and correctly.
27. List two potential problems and solutions that can occur with the wheelchair-to-car transfer.
28. When is the mechanical lift transfer most appropriate?
29. How is community mobility defined?
30. What unique qualifications do therapists have that enable them to address community mobility issues?
31. What are the primary advantages and disadvantages of public and private transportation?
32. What are the basic components for protecting passengers seated in a wheelchair within motor vehicles?
33. What are three resources for educating clients about safe pedestrian behavior?
34. Describe the role of the OT generalist and specialist in driving rehabilitation.

35. Name four ways the OTA may be used in a driver evaluation program.
36. Describe the decision-making process for assessment, referral, and training of clients with driving related needs.
37. What are the three categories of driving program services?
38. Explain the useful field of view and its impact on driving.
39. What is the best method to determine driver competency?
40. How long should the on-road evaluation session be?
41. Why are older driver issues of particular interest?
42. What additional credentials can therapists obtain in the field of driver rehabilitation?
43. What is the function of driver training?
44. Why is a follow-up evaluation necessary when adaptive equipment is prescribed?
45. What legal issues must be considered by a driver rehabilitation therapist?
46. Where can the interested therapist go for additional information on this area of practice?

Sexuality and Physical Dysfunction

Michelle Tipton-Burton, Richard Delmonico

With contributions from, Gordon Umphred Burton

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Justify sexuality as a concern of the occupational therapist.
2. List at least five possible reactions of the person with physical disability to her or his sexuality.
3. List some attitudes and assumptions that the able-bodied population may make about the sexuality of people with physical disability.
4. Discuss how sexuality and sensuality are related to self-esteem and a sense of attractiveness.
5. Define sexual harassment and describe how to handle a situation in which clients harass staff members.
6. Describe the effects that such items as mobility aids and splints can have on sexuality.
7. List signs of potential sexual abuse of adults.
8. List at least two intervention goals designed to improve sexual functioning.
9. Discuss ways in which the occupational therapist can provide a safe environment for discussing sexual issues.
10. Describe how sexual values can be communicated.
11. List at least five effects that physical dysfunction can have on sexual functioning, in addition to possible solutions for each.
12. Discuss the potential hazards of birth control.
13. List the potential complications of pregnancy and childbirth for a woman with disability.
14. Discuss methods of sex education.
15. Define PLISSIT.

KEY TERMS

Autonomic dysreflexia
Emasculation
Erogenous
New body
PLISSIT
Reflexogenic erection
Self-perception
Sensuality
Sexual abuse
Sexual harassment
Sexual history

Sexual values
Sexuality
Sexually transmitted diseases (STDs)
Vaginal atrophy

Threaded Case Study

Shivani, Part 1

Shivani has cerebral palsy. She is 29 years old and has been married for 2 years. She would like to have a child but has some barriers to overcome with the occupation of reproduction. To start with, as she was growing up, she was never taught by her therapists or anyone else to enjoy her body. Also, she has never had a role model who has cerebral palsy give birth to and raise a child. For 2 years she has been trying to relax and enjoy sexual activities with her spouse. This has been complicated by the fact that several people sexually molested her as she grew up, including her physician and a caretaker. Shivani has also found that sex is uncomfortable for her in the missionary position (ie, lying on her back with her husband on top of her), but this is the only position she is aware of for sexual intercourse. She feels like a failure as a partner and a woman, and in her culture, she feels that she should not discuss this topic with anyone.

Critical Thinking Questions

1. Can Shivani enjoy having sex, get pregnant, and raise a child?
2. Do issues such as sexual positioning, enjoyment of the body, and abuse have anything to do with occupational therapy?
3. How would you approach this situation with Shivani and her partner?

Sensuality and sexuality are important aspects of everyone's activities of daily living (ADLs) and directly relate to the quality of each person's life.[2] As an ADL, sexual activity is in the domain of occupational therapy (OT).[66] Occupational therapists work with clients in all areas related to sensuality and sexuality (Box 12.1). Sexuality is an integral part of the human experience and is important for self-esteem and self-concept. It includes emotions, feelings, and hopes for the future. Individuals express sexuality in different ways. Sexual expression is not only the sexual act of intercourse; it may include talking, touching, hugging, kissing, or fantasizing. Engagement in sexual activities does not always take priority when individuals are coping with so many other problems and deficits related to their disabling condition (Fig. 12.1).

Box 12.1

Factors Related to Sexuality and Sensuality

- Quality of life
- Role delineation
- Cultural aspects
- Impulse control
- Energy conservation
- Muscle weakness
- Hypertonicity and hypotonicity
- Appreciation of body

- Psychosocial issues
- Range of motion
- Joint protection
- Motor control
- Cognition
- Increased or decreased sensation

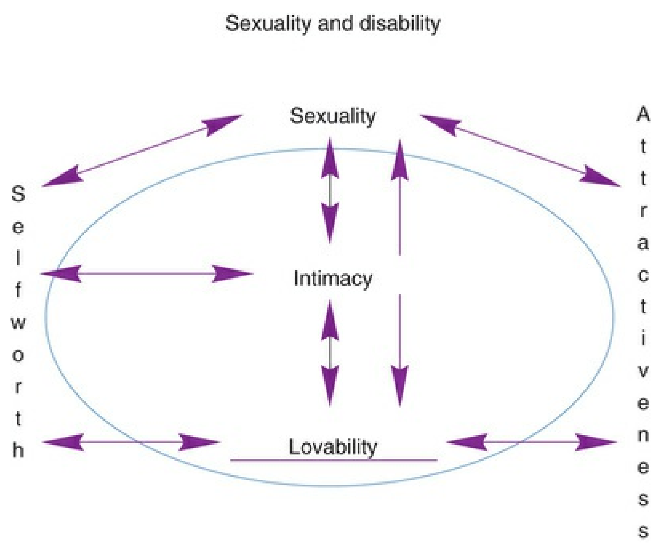

FIG 12.1 Sexuality and disability.

Physical limitations may cause the client to question his or her physical attractiveness, sexual desire, arousal, and/or general ability to experience sexual pleasure. With the onset of physical disability, the client undergoes a significant change in how he or she perceives the world and how others perceive him or her. This transformation significantly affects the client's perception of the commonly held roles and practices of the able-bodied population.[12,60,71]

Individuals with disabilities have a broad range of sexual expression and orientation, just as is the case in the population of individuals without disabilities. Healthcare providers and individuals without disabilities often incorrectly assume that individuals with disability are sexually inactive, or the healthcare provider neglects to consider the issue of sexuality. In a recent study, 94% of the subjects with physical disabilities were found to be sexually active, a rate matching that of nondisabled individuals.[13]

There is a significant paucity of information in the medical and scientific literature about sexuality in individuals with disabilities. The available literature contains biases and myths that individuals with disabilities are asexual, lack sexual desire or attractiveness, are incapable of healthy sexual function, and lack the social and/or problem-solving skills necessary for sexual functioning. In particular, women with disabilities are even more poorly understood.[24] For example, in general women are portrayed as less affected sexually than men with disabilities. These incorrect assumptions are not supported by scientific data and unfortunately often negatively influence how healthcare providers perceive and treat sexuality in individuals with disabilities.[1,53]

The result of this general lack of awareness or bias is that individuals with disabilities may not receive adequate and/or appropriate healthcare, including screening, education, and/or treatment for sexual problems or reproductive health.[1] Even more troubling is that women with physical disabilities encounter serious barriers to receiving appropriate reproductive healthcare. This includes identifying physicians and other healthcare professionals who are knowledgeable about the disability.[13]

For individuals with disabilities, the associated features of the disabling condition may significantly influence the assessment of the client's sexuality. For example, incontinence, pain, spasticity, medications, cognition, and many other associated features may have a significant impact on sexual functioning. Many healthcare professionals may not recognize the ways in which the disabling condition may affect sexuality and intimacy. Therefore, OTs must not only receive training in sexuality, they also must be educated about how disabling conditions influence sexual functioning.

The individual with a disability may be regarded by people without disabilities as asexual, or hyposexual, an object of pity, and unattractive.[5,41,45] Being perceived as unattractive and possibly unlovable can cause the client to believe that he or she can never be intimate with anyone. Holding this belief can lead the client and related others to a sense of despair. McCabe and Taleporos[48] found that “people with more severe physical impairments experienced significantly lower levels of sexual esteem and sexual satisfaction and significantly higher levels of sexual depression than people who had mild impairments or who did not report having a physical impairment.”

Low and Zubir[45] and Kettl et al.[39] found that females with acquired spinal cord injuries reported feeling less than half as attractive after they had acquired the disability, even though spinal cord injury is a disability with little observable physical change in body appearance. These studies showed a major decrease in the **self-perception** of attractiveness.[45] Another study found that with the advent of a disability, males felt a loss of their sense of masculinity and sensed a threat to the male role.[58]

These are just a few examples of the feelings and perceptions that affect the **sensuality** and **sexuality** of the person who has a physical disability. To provide comprehensive rehabilitation with the client, the OT and other health professionals must address self-perception, beliefs, and needs related to sexuality. This chapter examines issues related to sexuality and sensuality in individuals with physical disability.

Reactions to Sexuality and Disability

The many obstacles encountered by people with disability should not interfere with the expression of sensuous and sexual needs. As an informed professional, each therapist can help the adult client eliminate unnecessary obstacles, overcome anxieties, and appreciate personal uniqueness. The expression of sexuality or sensuality is a sign of self-confidence, self-validation, and a sense of being lovable. When a person acquires a disability or is born with a disability, he or she can feel less positive about him or herself and less lovable or unattractive to others.[23,57,58]

Sexuality can symbolize how a person is dealing with the world. If a person feels inadequate as a sexual, sensual, and lovable human being, the motivation to pursue other avenues of life can be affected. When people have a negative self-image, their approach to other challenges in their lives may also be negatively affected. Coping with life's problems thus becomes much more difficult. Because sexuality can be seen as a barometer of how one feels about oneself, it is productive for the therapist to help the client feel as positive as possible about her or his physical and personal qualities. A healthy attitude toward one's sexuality enhances motivation for all aspects of therapy. The therapist must try to help the client adjust self-perceptions enough to function positively in life.

Sexuality has been found to be a predictor of marital or relationship satisfaction, adjustment to physical disability, social interaction, and success of vocational training. In society, people are often judged by their physical attractiveness.[60] In Western civilization, physical intimacy is closely associated with love. Therefore, if a person perceives himself or herself as incapable of expressing sensuality or sexuality, it is possible that he or she feels incapable of loving and being loved. The majority of people who have had a stroke "reported a marked decline in all measured sexual functions."[28,40] Without the capability to love and be loved, a sense of isolation and of being valueless may ensue.[8,45,52,57] Adaptive devices such as splints, wheelchairs, and communication aids can be a detriment to a person's self-perceived attractiveness and sexuality. For example, it may be hard to perceive of oneself as sexual when an indwelling catheter is present or when splints are worn. By discussing the effects of these devices on social interaction, the client can get some ideas about how to handle difficult situations when they arise.[3,44,52,73]

OT intervention should include goals that facilitate an increase in self-esteem and enable the client to feel lovable. The therapist's role is to foster feelings of self-worth and a positive body image to help the client engage in occupations and to minimize feelings of worthlessness and hopelessness.[8,25,45,57,60] Feeling lovable engenders a sense of self-worth, attractiveness, sensuality, sexuality, and being capable of intimacy. Achieving this goal enhances the development of a healthy and realistic life balance in which the client engages in occupations.

Whether sex is still possible is a concern that arises after the onset of physical disability. This concern is often set aside in the immediacy of coping with the adjustment to hospital life and activities that make up the daily routine. However, the concern is not forgotten. A common complaint from people with disabilities about members of the healthcare team is that the staff members do not readily bring up the subject of sexuality and it's not an integral part of the rehabilitation process, treatment plan, or medical appointment.[24] Individuals with disabilities feel that if their sensuality and sexuality are often negated, a significant facet of their personhood is negated. This lack of acceptance causes the person with a disability to lose the feeling that he or she is being treated as a whole person. Currently no single healthcare profession has been designated to address issues concerning the physiological and psychosocial changes related to sexuality after an injury or illness; rather, interdisciplinary team approaches are often used. However, when a single discipline is not designated, the subject may be left unaddressed.[71]

Often men and women with disabilities have an increased dependence on an able-bodied partner, which can result in a decrease in the couple's sex life.[21] One possible explanation is that the able-bodied partner is less inclined to be aroused when he or she has just bathed the partner or assisted the partner with toileting. It is often difficult to transition from caregiver to intimate partner. The therapist must be sensitive to the possibility of these perceptions and help clients deal appropriately with the feelings they evoke.

The client's sense of masculinity or femininity may be threatened by the disability.[46,58,62] Men who have recently acquired a disability report that they feel emasculated.[58,62] Feelings of **emasculation** can be reinforced by physical limitations. For example, lifting weights may no longer be possible, sports participation may not be possible without adaptations, and the need to use a wheelchair and ask for assistance can engender feelings of dependency.

A man with a disability may react to feelings of dependency and emasculation[58] by flirting or making sexual comments to prove his masculinity. The client may attempt to flirt, making sexually inappropriate gestures or comments to a therapist.

Women experience many of the same feelings but may interpret and react to them in a different way.[5] Although many women with physical disabilities may be just as sexually active as women without disabilities,[13,24] some women with disabilities report feeling unattractive and undesirable. This can lead to despair if a woman feels that she cannot achieve some of her major goals in life. Thus, the female client may flirt to see whether she is still attractive to others.

The therapist must realize that the client may be seeking confirmation of her or his sexuality. The therapist should not be surprised by flirtations or sexual advances from clients. The OT practitioner should deal with these behaviors and set therapeutic boundaries in a positive and professional manner, but therapists should never allow themselves to be harassed. All of the therapist's interactions should be directed toward creating an environment that promotes the client's self-esteem, positive and appropriate sexuality, and adjustment to disability.

Ethical Considerations

When responding to the client, the therapist should be alert to the client's current sexuality issues to avoid doing further damage to the client's sense of self. If the therapist rejects or makes the client feel uncomfortable, the client may hesitate to attempt similar interactions in which these behaviors are more socially appropriate. If the therapist rejects the client, the client may assume that if someone who is familiar with people who have disabilities is rejecting, then a person who is unfamiliar with them would not be likely to be accepting, either.

Inappropriate sexual advances, **sexual harassment**, and exploitation of either the therapist or the client cannot be permitted.[49,65] Behavior is considered harassment when it causes the therapist to feel threatened, intimidated, or treated as a sexual object. If sexual harassment is allowed, it can be damaging to the client and to staff morale.[31] The therapist should provide direct feedback, explaining that he or she feels offended and that the behavior is inappropriate and must stop. All staff members should be informed of the situation, and they should develop and implement a plan to modify the client's behavior if it persists.

Therapeutic Communication

Conversations about sexuality can be opportunities for discussing personal feelings and perceptions. Before initiating a conversation about sexuality, the OT practitioner should ask the client for permission to discuss topics that some may find uncomfortable. Beginning with open-ended, nonthreatening questions can help the client feel more comfortable and assist the therapist in obtaining important information. One way to approach a discussion of intimate matters is to ask the female client how she will perform breast self-examination with her disability. A way to introduce the subject to a male client would be to ask if he has noticed any physical changes in his body or how he will perform self-examination of the testicles. If the treatment facility does not have information about these examinations, the client can obtain them from the American Cancer Society or the local Planned Parenthood Association. Each of these activities falls into the domain of health maintenance, and they may not have been discussed by other health team members either because of lack of knowledge or because of the team member's own discomfort in discussing sexuality with clients. This interaction can set the stage for discussion of other personal matters; it also impresses upon the client the necessity for concern about personal health and reaffirms the client's sexual identity.

Clients may feel safe asking the OT about sexual matters related to their disabilities because the therapist deals with other intimate activities, such as bathing, dressing, and toileting. It is also important to discuss sexual hygiene as an ADL. The trust built up in the relationship encourages this communication. The therapist should be prepared with accurate information and resources. The therapist does not need to know everything or be a sex expert, but he or she should ensure that the client gets the necessary information or appropriate referral.

The OT is the most appropriate professional to solve some problems, such as the motor performance needed for sexual activity.[15] For example, discussing positioning to reduce pain or hypertonicity or to enable the client to more comfortably engage in sexual relations will help the client deal with problems before they occur.[18,42,52]

In the case study, Shivani, who has hypertonicity, particularly in the hip adductors, experiences discomfort in a sexual position in which she abducts her legs during intercourse with her husband. She and her husband have not explored other positions, but instead have reduced the number of times they have intercourse during the month. Shivani's sense of failure and feelings of diminished worth as a wife may have further affected the intimacy of her marriage.

Approaches to intervention can include individual, partner, or group sessions. The format in which the information is presented can also vary and depends on the client's status physically, cognitively, and emotionally. It is important to provide the information in a way that can be best understood and when the individual is ready to assimilate it. Information can be presented in many ways and may include diverse media such as videos, pamphlets, or booklets. Varied media may be used to address the unique learning style and need of the individual.[10]

During all aspects of the rehabilitation process, the therapist, staff members, and the client's sexual partner should work on communication with the client. The therapist can facilitate this process simply by giving the client permission to discuss feelings and potential problems, especially sexual problems, and initiate the discussion through open-ended questions. The client needs to learn how to accurately communicate sexual needs, desires, and position options to a partner, either verbally or nonverbally, to have a mutually satisfactory sexual relationship.[22,39] Each client will have unique problems or issues that are related to the nature of the disability. An example is a client with Parkinson's disease in whom the lack of facial expression impedes the nonverbal communication of intimacy. The client can be taught to communicate feelings verbally that were previously conveyed with facial expressions.

OT Practice Notes

Discussion of sexuality is a way to explore feelings of dependency, identity, attractiveness, and unattractiveness.[39,43] Communication must be established about the client's feelings of sexual role changes. If a client's perceived roles are threatened, this situation should be dealt with as early as possible during intervention. If it is not, the effects could persist throughout the client's life and impinge on occupations important to the client.

Values Clarification

The **sexual values** of the client, the partner, and the therapist must be examined for the therapist to interact with the client in the most effective and positive manner.[5,20,46,52,60] Many professional schools do not train healthcare workers on the subject of sexuality and disability.[5,30,62,67] In-service training can be arranged to help staff members become aware of the sexual needs of people with disability.[27,39] Books, articles, videos, training packets, and online Internet resources are available for professional education.[11,19,20,62] Sensitivity training for staff members is imperative in creating an atmosphere of openness to discussing issues of sexuality. The Sexual Attitude Reassessment Seminar (SARS)[32] uses lectures, media, and small group discussions to help participants explore their knowledge and beliefs about sexuality. This seminar also describes sexual problems, how they develop, and how education and therapy can help with their clients. At the very least, it is helpful for therapists to participate in in-service classes and to role-play situations so as to improve their knowledge and comfort in dealing with questions about sexuality from patients and families.

Unless the staff members are educated about the significance of sexuality and related issues, they may have negative feelings about dealing with these matters.[5,11,67,72] If the therapist is not aware of the thoughts and feelings of all of the individuals involved, the therapist could make incorrect assumptions that have negative results.[18] One of the most direct ways of gaining information is by taking a sexual history.[18,62,63] The purpose of a **sexual history** is to learn how a person thinks and feels about sex and bodily functions and to discover the needs of those concerned.[18,43,62] According to some researchers, individuals with a disabling condition may have had a sexual dysfunction before they acquired the physical disability. Taking the sexual history can help identify such a problem.[44]

Sexual History

When taking a sexual history, the therapist should create an environment that ensures confidentiality and encourages comfort and self-expression. Early in the intervention process, the therapist should ask about the client's concerns regarding contraception, safe sex, sexual orientation, gender, masturbation, sexual health, aging, menopause, and physical changes.

Box 12.2 lists some questions that could be asked. All questions should not be asked at the same time, nor would all questions be asked of every client.

Threaded Case Study

Shivani, Part 2

The following questions may have been able to elicit important responses from Shivani.

1. *How important is sexuality at this time in your life?*
   Shivani's answer would reveal that she does not feel that sexuality is important to her, but that it is to her spouse and also for having a child.

2. *How would you describe your sexual activities at this time?*
   The occupational therapist would find out that sex is uncomfortable for Shivani; the OT would also learn how Shivani views sexual activities—whether sexual activity is a meaningful activity to her, or more of a responsibility.

3. *If you could change aspects of your current sexual situation, what would you change and how would you change it?*
   Shivani may say that she is uncomfortable during sex because she had been molested previously and that sex is physically uncomfortable for her now, which makes her feel like a failure. The therapist may not want to pursue the discussion about the sexual molestation and the psychological counseling aspects, but may ask for a referral to a psychiatric professional. The physical discomfort may be then addressed. Positions could be found to make intercourse more comfortable, helping Shivani to feel less like a failure as a partner.

Box 12.2

Questions to Ask in a Sexual History

- How did you first find out about sexuality?
- When and how did you first learn about heterosexuality and homosexuality?
- Who furnished you with information about sexuality when you were young?
- Were you ready for the information when you first heard about sexuality?
- How important is sexuality at this time in your life?
- How would you describe your sexual activities at this time?
- How do you feel sexuality expresses your feelings and meets your needs and those of others?
- If you could change aspects of your current sexual situation, what would you change and how would you change it?
- What concerns do you have about birth control, disease control, and sexual safety?
- What physical, medical, or drug-related concerns do you have relating to your sexuality?

- Have you ever been pressured, threatened, or forced into a sexual situation?
- Which sexual practices have you engaged in, in the past (eg, oral, anal, and genital)?
- Do you consider certain sexual activities "kinky"? How do you feel about participating in such activities?
- How important do you think sexuality will be in your future?
- What concerns do you have about your sexuality?
- Are there questions or concerns that you have regarding this interview?

After taking the sexual history, the therapist can often ascertain whether guilt or discomfort is connected with the sex act, body parts, or sexual alternatives (eg, masturbation, oral sex, sexual positions, or sexual devices). For example, some clients report feelings of guilt or fear in relation to having sex after a heart attack or a stroke—fear that sex can cause a stroke, or guilt that it may have caused the first episode. Another fear is that the partner will not accept the presence of catheters, adaptive equipment, or scars. Performance is often an issue. Able-bodied individuals and those with disabilities ask questions about the sexual ability of the person with disabilities.

The therapist can provide appropriate and accurate information by (1) directing the client to other professionals, (2) providing magazines and books that discuss the subject, (3) showing movies, or (4) suggesting role models. The therapist must be tactful and remember that the client may be questioning her or his own values and previous notions about sexuality. Personal care issues (eg, toileting, personal hygiene, menstrual hygiene, bathing, and birth control) can evoke reflection on values about sex and body image.

Self-care issues, particularly personal hygiene and sexuality, usually are not emphasized enough during acute illness and rehabilitation. Discussing such issues once or twice is not sufficient. The circumstances and environment in which these issues are discussed should also be considered. The therapist must create an environment that allows personal discussions. A personal conversation cannot take place in a crowded therapy room, during a rushed and impersonal treatment session, or with a therapist with whom a good personal rapport does not exist. Building rapport is a problem in healthcare facilities in which therapists are frequently rotated or work on a per diem basis.

A discussion of feelings will also help the client explore her or his new body, or adapt to ongoing degeneration of the body if there is a progressive disability. These conversations may take place while other therapeutic activities are in progress so that billing insurers for time is not a barrier.

Sexual Abuse

The **sexual abuse** of adults with disabilities is a significant problem.[3,64,67,72] Clients should be made aware of the possibility of exploitation, especially when they use the Internet for social networking and online dating. Others have reported that medical staff members took inappropriate liberties with them and that personal care attendants, on whom they depended, demanded sexual favors. Clients can and should report such abuse to their state's Adult Protective Services agency. The therapist also must report cases of suspected sexual abuse. The client may be reluctant to report abuse because of a concern that it will not be possible to get another aide or that, during the time it takes to hire another aide, essential assistance will not be available. These are major problems for a person who is dependent on others for care. However, therapists must discuss with clients the need for mandatory reporting, to reduce their reluctance to report. In addition, the therapist should provide emotional support throughout this reporting process and/or provide a mental health referral to assist the client once an abuse report has been made.

Therapists may not suspect caregivers, medical staff members, aides, transportation assistants, or volunteers of sexual abuse, but the therapist should be alert to signs of possible abuse even from these sources.[61] Some individuals are sexual predators who prey on adults and children with disabilities. They may be drawn to the health fields with this motive.[3] The therapist must always be alert for signs of potential abuse, such as clients usually being upset after interacting with a specific person, the client being reluctant to be left alone with a particular caregiver, caregivers taking the client off alone for no apparent reason, excessive touching in a sensual manner by caregivers, the client being agitated when around a particular individual, and the client being overly compliant with a specific individual.

Ethical Considerations

Therapists must increase their awareness of what constitutes sexual abuse. Formal training is available through continuing education courses, and therapists should update their knowledge on a regular basis to stay current with changes in laws and regulations in their particular state. Children with disabilities have long been expected to undress and be examined or treated as part of their medical care. This treatment is sometimes necessary, but the preferences and dignity of the client should be respected at all times. A person of any age should not be forced to endure humiliation.

The therapy session should help the client develop a sense of personal ownership of her or his body. However, this goal is sometimes overlooked when the OT is working with adults and children. For example, a child who believes that he or she does not have the right to say “no” to being touched, who cannot physically resist unwanted touching, and who may not be able to communicate that unwanted touching or frank abuse has taken place, is in jeopardy of being victimized.[3]

The therapist should ask permission before touching the client; he or she should touch with respect and maintain the client's sense of dignity. If the therapist does not ask permission to touch a client, the client can lose his or her sense of control over being touched by others. The therapist should guard against communicating this notion to clients and should educate clients about their personal rights regarding others touching them.

Naming body parts and body processes is a good way of helping clients take charge of their bodies. Once the body parts and processes have been named, using correct terminology rather than slang, the possibility exists for the client to communicate and to relate in an appropriate manner.[3,17,51,63] The use of the proper terms has the effect of helping the client view the body in a more positive way, whereas slang tends to communicate negative images.[63]

Effects of Physical Dysfunction

Specific physical problems that may create difficulties in sexual performance for people with disabilities and their partners and suggestions for management of the problems are outlined next and summarized in Table 12.1.

TABLE 12.1

Possible Effects of Selected Conditions on Sexual Functioning

	SYMPTOMS														
	Anxiety/Fear	Contrac-tures	Cultural Barriers	Decreased Libido	Depres-sion	Impo-tence	Incon-tinence	Limited ROM	Loss of Mobility	Low Endur-ance	Medication	Paralysis/Spasticity	Poor Body Image	Tremor	Catheter/Ostomy
Diagnosis															
Amputation	X	X	X		X				X				X		
Arthritis	X	X	X	X	X			X	X	X	X		X		
Burns	X	X	X		X			X	X	X		X	X		
Cardiac disease	X		X	X	X	X	X		X	X	X		X

Cerebrovascular accident	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X
Diabetes	X	X	X	X	X	X			X	X			X	X	
Hand injury	X	X	X		X			X	X			X	X		
Head injury	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X
Musculoskeletal injury	X	X	X		X		X	X	X	X	X	X	X	X	
Spinal cord injury	X	X	X		X	X	X	X	X	X	X	X	X	X	X

Hypertonia

Hypertonia can increase when muscles are quickly stretched. To prevent quick stretching of muscles involved in a movement pattern, motion should be performed slowly. It is advisable to incorporate rotation into the movement to break up the tone. Slow rocking can be used to inhibit hypertonic musculature. Gentle shaking or slow stroking (massage) can also be inhibitory. Heat or cold can be used to inhibit tone. Clients with hypertonia should review options for different positions in which to have sexual intercourse. Alternative ways of dealing with personal hygiene (eg, toileting, inserting tampons, gynecologic examinations, and birth control) may also need to be explored in relation to hypertonicity.

Shivani's OT discussed strategies that could be used to relax the hypertonicity in her legs, such as gently rocking her legs side to side while she was seated. Although initially presented as a means to reduce the hypertonicity affecting Shivani's sitting balance when toileting and for personal hygiene during menstruation, this technique also was suggested as a means to relax her legs before intercourse.

Hypotonia

Clients with low muscle tone (hypotonia) need physical support during sexual activity. Pillows, wedges, or bolsters may be used to support body parts, allowing for endurance and protecting the body from overstretching and fatigue. Sexual positions that allow support of the joints involved should be explored. The client and her or his partner should also explore their attitudes about the positions.

Low Endurance

Prolonged sexual activity can be intolerable because of low physical endurance. Some techniques for dealing with low endurance apply the principles of work simplification to sexual activity; for example, using timing to engage in sex when the client has the most energy, and assuming positions in which sexual performance uses less energy.

Loss of Mobility and Contractures

Limited mobility and contractures prohibit many movement patterns and limit the number of positions for sex. Activity analysis must be done to find positions that allow sexual activity. This system often requires creative problem solving on the part of the client, the partner, and the responsible professional counselor.

Joint Degeneration

Conditions such as arthritis can cause pain, damage to the joints, and contractures. Avoiding stress and repetitive weight bearing on the joints can reduce joint damage. Activity analysis is needed to reduce joint stress and excessive weight bearing on the joints. It is necessary to find a position that takes weight and stress off the knees or hips, such as the one in Fig. 12.2. This position is sometimes referred to as the missionary position. A position with substantial hip abduction may not be acceptable for the client, in which case a side-lying position may be more comfortable. If hip abduction is limited, the woman should avoid positions such as those shown in Fig. 12.2 (also see Figs. 12.5 and 12.9, presented later in the chapter).

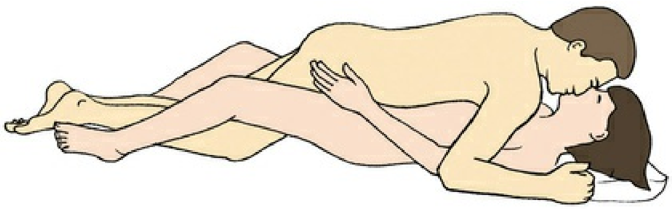

FIG 12.2 This position places pressure on a female's bladder and requires hip abduction but little energy expenditure for her. An excellent discussion of these alternatives can be found in the journal *Sexuality and Disability* 12:1, 1994.

After Shivani's OT introduced the technique of slow rocking, Shivani asked about other positions that would be more comfortable during intercourse. The OT discussed the possibility of using side-lying intercourse.

Pain

Pain limits the enjoyment of sexual activities.[35] Usually, at some time of day, pain is diminished and energy is at its highest. Sexual activities can be scheduled for such times. Many people find that sexual activity is possible after pain medication has taken effect. However, pain medications can also interfere with sexual functioning. These medications can interfere with alertness, sexual desire, and arousal. Communication between partners is especially important when pain is involved. An unaffected partner who does not understand the negative effects of pain and/or the negative effects of pain medications may believe that the affected partner is not interested in sex and/or is not considering her or his personal needs. A referral to a psychotherapist who understands the effects of pain or to a pain specialist can help address emotional and physical aspects of this problem. The OT can help the client think of acceptable ways of meeting the partner's and the client's own sexual needs without causing pain. Masturbation and mutual masturbation with sexual fantasy are possible ways of meeting sexual needs in these circumstances. In this way, the partners are interacting and neither person feels isolated.

Loss of Sensation

The loss of sensation can affect the sexual relationship in several ways. The lack of **erogenous** sensation in the affected area can block proper warning that an area is being abraded (eg, the vagina is not being sufficiently lubricated) or damaged (eg, the bladder or even bones if the partner is on top and being too forceful). A lack of sensation may be a sign of disruption of the reflex loop responsible for sensation and erections in the male and sensation and lubrication in the female.

Cognitive Impairments and Behavioral Changes

Disabilities such as traumatic brain injury (TBI), multiple sclerosis (MS), and cerebrovascular accident (CVA) may affect sexual relationships and sex drive. Clients may have difficulties with impulsivity, poor initiation, attention/concentration, multitasking, memory, social communication, decreased awareness, and executive functions, such as problem solving and reasoning, all of which can affect relationships and successful sexual interactions.[9,59]

Emotional Factors

Depression and anxiety adversely affect sexual desire and arousal, and new onset of a disability has a high incidence of depression. For example, depression is seen in 14% to 61% of those with TBI or a spinal cord injury (SCI).[14,47]

Aging and Sexuality

With aging, changes take place that can affect sexuality. In women, menopause and the resulting hormonal changes cause **vaginal atrophy**, decreased lubrication, pain, an increased need for direct stimulation, and slower reactions to sexual stimulation. In men, greater stimulation may be needed to develop and maintain an erection, and the recovery time between erections may be greater. Partners can be informed of ways to increase direct stimulation and can be helped to understand that it is the quality, not the quantity, of sexual activity that is important in the relationship. In addition, many couples over time develop maladaptive sexual patterns. One common pattern is that any type of sexual or affectionate expression always culminates in sexual intercourse. Unfortunately, any type of sexual dysfunction that arises can lead to a significant decrease in expressions of affection or any sexual touching or communication for these individuals and their partners. Clients and their partners should be educated on the importance of intimacy, sexual and nonsexual touching, and other ways of expressing affection. The client should be made aware of the maturation process and its normal effect on sexuality so that the disability is not blamed for all problems.

Isolation

The environment is composed of objects, persons, and events. All activities involve an interaction between the person and environment. Some of the objects with which people with disabilities interact are wheelchairs, braces, canes, crutches, and splints. These objects are all hard, cold, and angular. They can communicate a hard exterior and a fragile interior and can convey the notion that no softness exists, that it is not safe to hug, and that a person in a wheelchair or in braces or on crutches can get hurt or toppled if touched. As a result of these ideas, individuals with a disability may feel isolated by the appliances or equipment they need to successfully interact with the world around them.

Some people tend to withdraw from the objects around the client. This may reinforce the client's notion of a lack of sensuousness and increase the client's sense of isolation. Clients often feel isolated and different from the "normal" population.[20] This phenomenon is more common among clients who have been out of the healthcare facility for a period of time. In the early phases of the disability, the therapist and the client can role-play about how to deal with a new partner or how to explain the equipment used, such as a catheter. This approach may help ease the client's anxieties and fears and increase his or her comfort with such issues. At the same time, the therapist should be communicating that sex may be a possibility in the future. It should be pointed out to clients that at no time in human history have people with disabilities not existed in society, that they are a part of society, and that it is not "abnormal" to have a disability. All people who live long enough eventually acquire a disability, to a greater or lesser extent.

Medication

Approximately 20% of individuals experience various side effects from prescription medications. Potential side effects of medication are impotence, delayed sexual response, or other problems. Diuretics and antihypertensives can cause erectile dysfunction, decreased desire, and changes in orgasm. Tranquilizers, selective serotonin reuptake inhibitors (SSRIs), and antidepressants can contribute to changes in sexual desire, arousal, and orgasm in some individuals.[62] Side effects of medication should be discussed with the prescriber and the pharmacist to see whether medications can be altered or changed. If they cannot be, acknowledging that the problem is a side effect of a needed medication can be helpful to the client. Clients should be strongly discouraged from stopping their medications on their own, without first discussing the implications with their prescriber.

Street drugs also have sexual side effects and adversely affect sexual functioning at every level of the sexual response cycle. For example, methamphetamines and cocaine may have the sexual side effect of decreased interest in sex and difficulty reaching orgasm. Marijuana and alcohol can cause difficulty in obtaining and sustaining erections. Occupational therapists do not condone the use of street drugs, but it is important for the OT to consider that such drugs may be part of a client's life, and providing education on these side effects is critical.

Performance Anxiety

At times of emotional stress, regardless of his age, a male client may have difficulty obtaining and maintaining an erection. Even one or two instances of difficulty with an erection can lead to increased anxiety and create a cycle of erectile dysfunction and even avoidance of sex. Another problem that can arise is premature ejaculation, which can in turn lead to performance anxiety. It can be helpful for the client and his partner to take the emphasis off erection and genital intercourse and focus on sensuality and making each other feel good. A massage or nondemand touching are techniques that can be helpful with performance anxiety. More specifically, with premature ejaculation there are very useful techniques the patient and his partner can be taught to manage the issue. If these approaches do not work and it has been determined that the problem is not physical in nature or related to medications, a sex therapist or psychotherapist trained in sexuality may be needed to help the couple deal with the problem.

Skin Care

The person with a disability should be informed that positioning modifications might be needed to protect the skin, prevent skin breakdown, and increase pleasure. If a sexual position causes repeated rubbing on the skin, this friction can cause abrasions and result in skin damage. The therapist and client can discuss methods to prevent the friction, such as through an alternative position. Pressure on bony prominences or pressure exerted in a specific area by a partner can also cause problems with skin irritation and must be avoided.

Lubrication

Stimulating natural lubrication in female clients is important. It may be overlooked in a woman with paralysis because she may not be able to feel the stimulation or lack of natural lubrication. Stimulation to cause reflexive lubrication should occur even when the woman does not feel it. Without proper lubrication, damage may occur without the woman being aware of the problem. If needed, artificial water-based lubricants should be used. The individual should be warned that only water-based lubricants are appropriate because petroleum-based lubricants can cause irritation and can attack the integrity of latex condoms, causing condom failure. This is a major concern because the female partner is more likely than the male to become infected with the human immunodeficiency virus (HIV) in any given heterosexual encounter.

Erection

Many men regard the ability to achieve an erection as one of the most significant signs of masculinity.[43] If awareness of sensory stimulation to the penis is blocked by the sensory loss associated with paralysis and if the male client does not try to stimulate a **reflexogenic erection**, he may believe that he is unable to obtain an erection. This is not necessarily true, and the client may go through much needless anguish. The client should be encouraged to explore his body. Rubbing the penis, the thighs, or the anus can be effective ways to evoke a reflexogenic erection. Even rubbing the big toe has been reported by some men with quadriplegia to stimulate an erection. If the normal reflex arc is interrupted, it is usually not possible to achieve an erection, and alternative methods must be explored.

Alternative methods can be forms of sex that do not require an erect penis, such as using a vibrator, or oral or digital sex. If the client feels that penile intercourse is the only acceptable method, other possibilities exist.[16] Injections or penile suppositories that stimulate erections can be used, but this practice may have adverse reactions or lead to problems if the client does not have good judgment or lacks hand dexterity. Penile vacuum devices are available that are very easy to use and result in erections firm enough for penetration. The use of a vibrator or massager against the penis to help produce ejaculate is sometimes effective and is one of the less invasive techniques.[63] Prescription medications are readily available for men with erectile dysfunction (ie, sildenafil, vardenafil, and tadalafil).

Fertility

Some disabilities may directly affect an individual's ability to biologically become a parent. For example, women who sustain an SCI or a TBI may experience a disruption in their menstrual cycle. This pause may last as long as 6 months after an injury. However, a woman's ability to have children is not usually affected once menstruation resumes. It should be noted that depending on the disability, women may be subject to certain pregnancy-related complications, and those should be discussed with a physician prior to considering pregnancy. Men with catastrophic injuries or illnesses (eg, SCI) also experience difficulty with fertility. Typically, the reason for this is the inability to ejaculate during intercourse. Men who wish to father a child do have options, and a fertility specialist should be consulted.

Birth Control

The client should consult her or his healthcare provider when weighing the pros and cons of various methods of birth control. People with disabilities must consider a number of factors when planning birth control.[15,16,33,42,51] Because most disabling conditions do not impair fertility (especially for women), it is important for the client to be aware of birth control and potential complications of the use of birth control.

Adequate hand function is needed to successfully apply a condom. An applicator can be adapted in some cases, but someone with good hand dexterity must assemble the device beforehand. Diaphragms are not very feasible for people who have poor hand function, unless the partner does have hand function and both parties feel comfortable about inserting the diaphragm as part of foreplay. The contraceptive sponge also requires good use of the hands.

Using birth control pills can increase the risk of thrombosis, especially when the client is paralyzed or has impaired mobility. If the client has decreased sensation, the intrauterine device (IUD) can result in complications from bleeding, cramping, puncturing of the uterus, or infection. The use of spermicides requires good control of the hands or the assistance of the partner who has normal hand function. The use of nonoxynol-9 has been suspected to increase the risk of HIV transmission and should be avoided.[50] The injectable type of birth control may allow for easy use but has many of the same side effects as the pill. In using any method of birth control, the client must always be concerned with reducing the chance of infection and practicing safe sex.

Adaptive Aids

Adaptive aids may be necessary, especially if the client lacks hand function. One aid is a vibrator for foreplay or masturbation.[29] Special devices have been adapted for men and women.[18,42,51] Pillows may be used for positioning, and other equipment may be used for clients who have special needs. The therapist must prepare the client for the concept of using sexual aids before suggesting the option to the client. For example, the therapist can suggest that the client privately explore the sensation that the vibrator produces in the lower extremities. The client might discover the possible use of the vibrator for sexual stimulation or at least, when told how it can be used, may be more open to the idea of using a vibrator as a sexual aid.

Safe Sex

The importance of safe sex has increased considerably since the advent of acquired immunodeficiency syndrome (AIDS). However, safe sex is important to protect against all forms of **sexually transmitted diseases (STDs)**.[33] Clients need to be advised that this is a crucial issue. If there is sensory impairment in and around the genital area, the person might not be aware of an abrasion or infection. Any genital irritation or infection allows easy entrance of STD pathogens. The person with disability must be informed of the increased risk of HIV and STDs so that extra care can be taken.

Hygiene

Catheter care is a concern, especially when hand function is impaired. Questions may be raised about how or if a person with an indwelling catheter can have sex. Sex is possible for both men and women, but some precautions should be taken. If the catheter becomes kinked or closed off (which will definitely happen in the case of a catheterized man having vaginal intercourse), pressure should not be placed on the bladder. The bladder should be fully voided before sexual activity. Urine flow should be restricted for as short a time as possible, and no longer than 30 minutes. Damage to the bladder and kidneys could result if these precautions are not followed. The client should not drink fluids for at least 2 hours before sex to prevent the bladder from filling during this time. Sexual positions that avoid placing pressure on the bladder should be used, such as those shown in Figs. 12.3 to 12.10. Many of the same positions can be used if the client uses a stoma appliance.

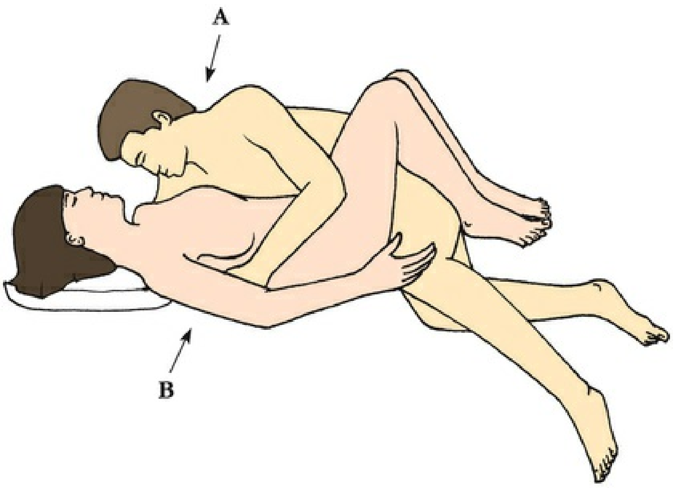

FIG 12.3 Vaginal entry of partner B requires no hip abduction, and hip flexion tightness would not impede performance. Energy requirements for both partners are minimal, and bladder pressure, catheter safety, and stoma appliance safety should not be an issue for partner B. This position may also be recommended if partner B has back pain or is paralyzed, especially if a rolled-up towel is used to support the lumbar spine.

FIG 12.4 Partner A needs little hip abduction but good strength. Partner B may feel less strain on his back. Hip, knee, or ankle joint degeneration would preclude this position for either partner.

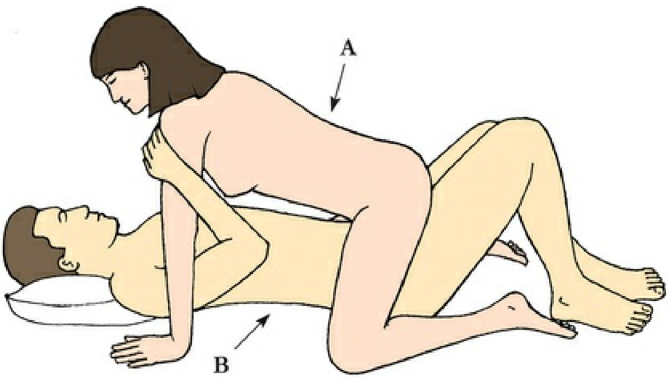

FIG 12.5 Partner A must have hip abduction, balance, and endurance in this position, but pressure is kept off the bladder and stoma. If a catheter is used, it would be unrestricted. Back pain may be avoided by keeping the trunk vertical. Partner B's hip flexors could be contracted. If low back pain is a problem, the legs should be flexed and a rolled-up towel placed under the lower back. If a stoma appliance is used, this position would prevent interference. If low endurance is a problem, this position can be used effectively for partner B.

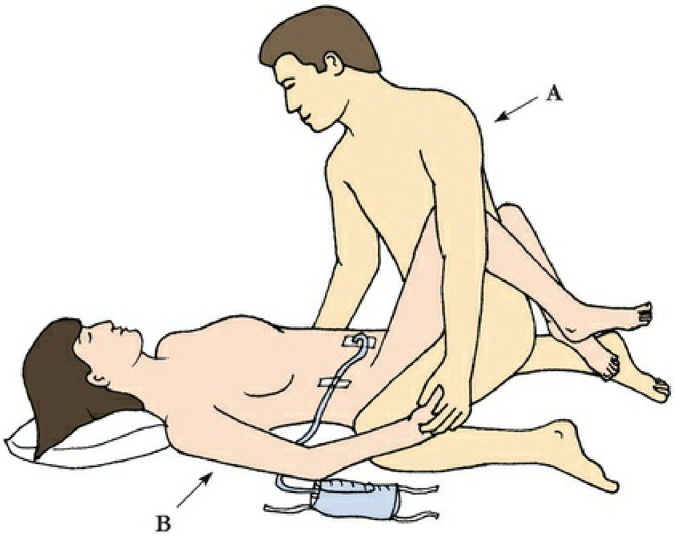

FIG 12.6 This position keeps pressure off the bladder, lessens the chance of tubing becoming bent, reduces pressure on the back (especially if a small rolled-up towel is used under the lower back), and does not require partner B to use much energy. The legs do not need to be as high as shown, but if the hip flexors are contracted, this position may be comfortable.

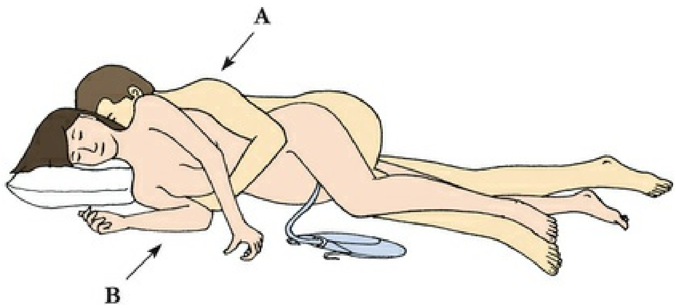

FIG 12.7 Partner B need not expend much energy in this position, and both partners may avoid swayback. Either partner may have hemiparesis. Partner B will not need hip abduction, and pressure on the stoma bag may be avoided.

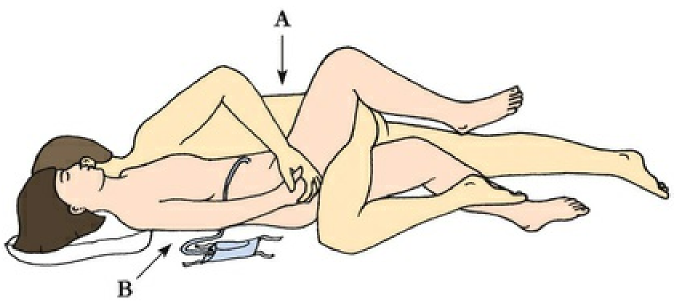

FIG 12.8 This position can be used if either partner has hemiparesis, or if low endurance is a problem. Partner A may avoid swayback in this position.

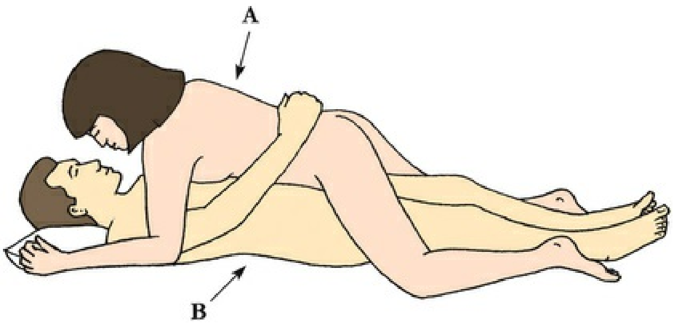

FIG 12.9 Partner B may be paralyzed or have limited range of motion. His back may need a rolled-up towel for support, and he must be concerned with pressure on his bladder.

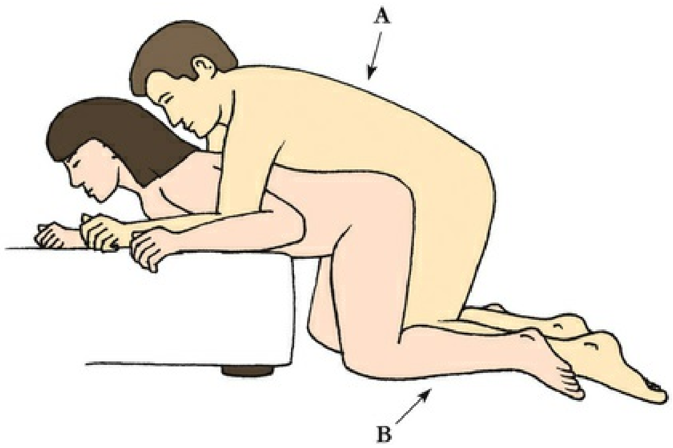

FIG 12.10 Rear vaginal entry of partner B, who does not need much energy because support is provided by a low level bed or cushioned footstool and little or no abduction of the hips is required. Flexion tightness of the hips does not affect performance. Because of the weight on partner B's knees, hips, and back, in addition to the inevitable repetitive movement at the hips, this would not be a good position for individuals with back, hip, or knee joint degeneration.

Women who have various disabling conditions have reported irregular menstrual periods and deterioration of their neurological condition during menstruation.[70] Hygiene issues may occur for several reasons. Lack of education, poor hand function, and poor sensation are conditions that may contribute to menses complications. Information about toxic shock syndrome should be given to clients who may not feel or be aware of infection. A sanitary napkin or pad requires less fine motor skill and is less dependent on intact sensation than a tampon. Although the client's preferences must be considered, the therapist is responsible for educating a woman about the pros and cons of using either a sanitary pad or a tampon during menstruation. Menopause complications may be increased, but this area may need further research.

A person with an impairment of bowel or bladder function may have an occasional episode of incontinence during sexual activities. If the client and the therapist discuss this possibility and how to deal with it, some embarrassment can be averted when the episode occurs. The client and the therapist can role-play to explore various scenarios, such as, "You are planning intimacy with a new partner. How will you explain your catheter and appliances to the person?" These may be awkward conversations for the therapist and the client, but dealing with these issues beforehand is usually easier than waiting for the situation to arise. Such topics must be approached with caution and discretion.

Pregnancy, Delivery, and Childcare

Before becoming pregnant, women must weigh the risks and benefits of pregnancy, childbirth, and childcare. Complications of pregnancy may affect the client's function and mobility. These complications include the potential for respiratory or kidney problems, the effect of the increased body weight on transfers, an increased possibility of **autonomic dysreflexia**, and the need for increased bladder and bowel care; all of these should be considered when pregnancy is contemplated.[69] Labor and delivery can present some special problems, such as a lack of awareness of the beginning of labor contractions. Induction of labor may be contraindicated if a person has a spinal cord injury at T6 or above and the medical staff members are not trained to deal with the respiratory problems or dysreflexia that can result. After delivery, the parent with disability will need to have modifications made to the wheelchair. The client may need consultations to achieve an optimal level of function in the parenting role.[33]

Using Shivani as an example, the therapist may help her find information about pregnancy. Introducing her to sites appropriate for an online search or encouraging her to contact Planned Parenthood or United Cerebral Palsy can help her locate the information she needs to make informed decisions. She could also ask these agencies for a list of healthcare providers who have experience with women who were pregnant and had cerebral palsy.

The therapist may then simulate situations during the first year after birth. These may include how to transport an infant, change diapers and dress the child at different stages, play with the child, bathe the child, and deal with parenting despite mobility impairments, just to name a few possible scenarios.

Sexual Surrogates

A sexual surrogate is someone trained to work with individuals to help them deal with sexual dysfunction or to explore their sexuality. Typically a surrogate works with a therapist and a client. A sexual surrogate engages in sexual behaviors with the client, often using specific techniques that have been shown to be effective. The goal is to allow the client to explore aspects of sexual response, sexual feelings, and sexual techniques in a safe environment with a professional who is trained to provide feedback and offer advice.[38] The main goal of the interaction is education.

Methods of Education

The following techniques or approaches have been used effectively to deal with the emotional aspects of sex education for people with disability.

Repeat Information

Mentioning sexual issues just once is not enough for anyone. Whether the individual has a disability or not, most people need to hear information more than once to fully understand the complexity of sexual function. This fact is especially true for people who are in crisis or who are in the process of adjustment to a disabling condition. Too much information, or more than is asked for, should not be offered at one time. Whenever possible, the therapist should try to say something positive in every conversation. Holding out hope for the restoration of function or alternative function is important. The therapist should not assume that the client understands all of the information. To verify that the client understands the information, the therapist should invite him or her to ask questions and to paraphrase what was said.

Help the Client Discover the "New" Body

With any disability, the client's body image and perception of the body are altered. In effect, the client has a **new body** and must find altered ways of moving, interpreting sensations, and performing ADLs. A large part of the therapeutic experience is directed toward helping the client discover how to use this new body as effectively as possible. The therapist can facilitate this discovery of the new body by creating situations that encourage awareness of the body through the input of sensation and function.[44] The client alone or with her or his sexual partner can accomplish this awareness through exercises that encourage exploration of the body. Exercises such as the gentle tapping or rubbing of a specific area can be developed to see if sensation exists or if the stimulation causes a change in muscle tone. Many people with a disability such as paralysis report that they have experienced nongenital orgasms[15] by stimulating other new erogenous areas, often in the area just above where sensation starts to appear. The therapist may suggest ways to use this sensation or change in tone in ADLs or may ask the client to think of ways this change in tone could be used, such as triggering reflex leg extension to help with putting on pants. This discussion stimulates problem solving by the client.

PLISSIT

The acronym **PLISSIT** stands for **p**ermission, **l**imited information, **s**pecific **s**uggestions, and **i**ntensive **t**herapy. PLISSIT is a progressive approach to guide the therapist in helping the client deal with sexual information.[4] *Permission* refers to allowing the client to feel new feelings and experiment with new thoughts or ideas regarding sexual functioning. *Limited information* refers to explaining what effect the disability can have on sexual functioning. An explanation with great detail is not usually necessary early in the counseling process. The next level of information is providing specific suggestions. It may be in the therapist's domain to give *specific suggestions* on dealing with specific problems that relate to the disability, such as positioning. This is the highest level of input the average occupational therapist should attempt without advanced education and training in sexual counseling. *Intensive therapy* should be reserved for the rare client who has an abnormal coping pattern in dealing with sexuality. An extensive counseling background is needed to provide intensive therapy; therefore, referral to a trained sex therapist is required in these situations.

Perform Activity Analysis

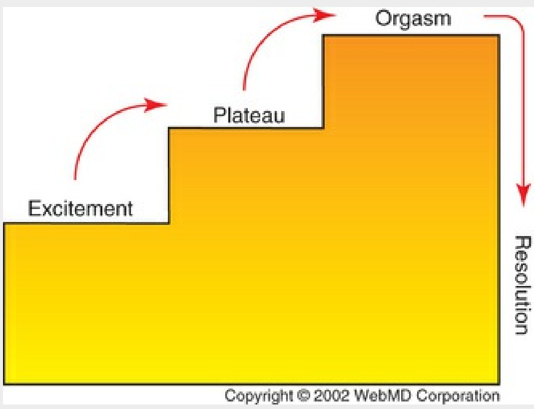
To assess the client's positioning needs, the therapist must analyze the demands of the particular activity. This analysis entails looking at the physical, psychological, social, cultural, and cognitive aspects of the client's functioning. Activity analysis should be implemented, using an objective and professional perspective. The therapist must realize that the sex act itself, if one exists, is only a small part of the act of making love and should be treated as just one more ADL that must be analyzed and with which the client needs professional assistance. The therapist must also remember that not all partners had sexual intercourse on a daily, weekly, or even yearly basis before the onset of the disability. The therapist's values and biases should not be imposed on the client. Same-sex partners, multiple partners, masturbation, or a preference for no sexual activities are some client practices that could evoke bias.

Provide Basic Sex Education

Some clients need basic sex education if they did not have the information before the onset of disability (Box 12.3). Some clients may not have been informed because of the disability, or they may be misinformed about sexual practices.[3,15,45,50] Research has shown that people with hearing impairments have substantially less information about sex than do those without hearing impairments.[68] In one study of adolescents with congenital disabilities, it was found that they were misinformed or not informed about sexual issues and that they relied on health professionals and parents to keep them informed.[6] Women who had not had sex before age 18 years may be less inclined to have sex later if they are not given sexual information.[22,29,45]

Box 12.3

The Sexual Response Cycle



The sexual response cycle has four phases: excitement, plateau, orgasm, and resolution. Both men and women experience these phases, although the timing usually is different. For example, it is unlikely that both partners will reach orgasm at the same time. In addition, the intensity of the response and the time spent in each phase varies from person to person. Understanding these differences may help partners better understand one another's bodies and responses and thus enhance the sexual experience.

Phase 1: Excitement

General characteristics of the excitement phase, which can last a few minutes to several hours, include the following:

- Muscle tension increases.
- Heart rate quickens, and breathing is accelerated.
- Skin may become flushed (blotches of redness appear on the chest and back).
- Nipples become hardened or erect.
- Blood flow to the genitals increases, resulting in swelling of the woman's clitoris and labia minora (inner lips) and erection of the man's penis.
- Vaginal lubrication begins.

• The woman's breasts become fuller, and the vaginal walls begin to swell.

• The man's testicles swell, his scrotum tightens, and he begins secreting a lubricating liquid.

Phase 2: Plateau

General characteristics of the plateau phase, which extends to the brink of orgasm, include the following:

• The changes begun in phase 1 are intensified.

• The vagina continues to swell from increased blood flow, and the vaginal walls turn a dark purple.

• The woman's clitoris becomes highly sensitive (may even be painful to touch) and retracts under the clitoral hood to avoid direct stimulation from the penis.

• The man's testicles are withdrawn up into the scrotum.

• Breathing, heart rate, and blood pressure continue to increase.

• Muscle spasms may begin in the feet, face, and hands.

• Muscle tension increases.

Phase 3: Orgasm

The orgasm is the climax of the sexual response cycle. It is the shortest of the phases and generally lasts only a few seconds. General characteristics of this phase include the following:

• Involuntary muscle contractions begin.

• Blood pressure, heart rate, and breathing are at their highest rates, with a rapid intake of oxygen.

• Muscles in the feet spasm.

• There is a sudden, forceful release of sexual tension.

• In women, the muscles of the vagina contract, and the uterus undergoes rhythmic contractions.

• In men, rhythmic contractions of the muscles at the base of the penis result in the ejaculation of semen.

• A rash, or “sex flush,” may appear over the entire body.

Phase 4: Resolution

During resolution, the body slowly returns to its normal level of functioning, and swollen and erect body parts return to their previous size and color. This phase is marked by a general sense of well-being, enhanced intimacy and, often, fatigue. Some women are capable of a rapid return to the orgasm phase with further sexual stimulation and may experience multiple orgasms. Men need recovery time after orgasm, called a *refractory period,* during which they cannot reach orgasm again. The duration of the refractory period varies among men and usually lengthens with advancing age.

Data from Kaplan HS: *The new sex therapy: active treatment of sexual dysfunctions,* New York, 1974, Routledge; and Masters WH, Johnson VE: *Human sexual response,* Boston, 1966, Little, Brown.

If the OT is not the one to educate the client or the client's partner, the therapist should anticipate the need for information and have resources available for the client to acquire the information. It is not advisable to recommend only books about sexuality and people with disabilities. Such books are useful, but their focus on the disability may be discouraging to some. Books written for the able bodied, such as *The Hite Report: A Nationwide Study of Female Sexuality,*[36] *The Hite Report on Male Sexuality,*[37] and *How to Satisfy a Woman Every Time,*[34] can be helpful. These books will not only give the client an understanding of sex, they will also show the client that he or she is normal, while minimizing the focus on the disability.

Excellent books written for individuals with disabilities also can be recommended. Some of these are *Choices: A Guide to Sexual Counseling with the Physically Disabled,*[51] *Reproductive Issues for Persons with Physical Disabilities,*[33] *The Sensuous Wheeler,*[56] *Sexuality and the Person with Traumatic Brain Injury,*[31] *Sex and Back Pain,*[35] *Sexuality and Disabilities,*[46] *Sexual Function in People with Disability and Chronic Illness,*[62] and *Enabling Romance.*[42]

Summary

This chapter began with the case of Shivani and examined some of the possible needs of people with disabilities that affect the ADLs of sexuality. This topic is a powerful one that the OT must deal with in a professional and sensitive manner. We have seen that Shivani can engage in sexual activity, become pregnant, and be a good parent. She may need assistance with finding the better positions to have sex, and she may learn to enjoy her body and sex even though she was sexually abused. All of these issues may be within the role of the OT and should be dealt with to improve the quality of life for the client.

OTs are concerned with the sexuality of their clients because sexuality is related to self-esteem, it influences the adjustment to disability, and it is an activity of daily living. As with other ADLs, a physical dysfunction can necessitate some changes in the performance of sexual activities. Education, counseling, and activity analysis can be used to solve many common sexual problems confronted by persons with physical dysfunction.

OTs can provide information and referrals to clients who are concerned with sexual issues. Trained therapists can provide counseling. Issues of sexual function, sexual abuse, and values need to be considered in providing sex education and counseling. Through activity analysis and problem solving, physical limitations that affect sexual functioning can usually be managed. Various sexual practices, modes of sexual expression, and expressions of sensuality are possible. The client needs the opportunity to explore her or his needs and acceptable options to meet those needs. The OT is one of the members of the rehabilitation team who has something to offer the client in the area of rehabilitation and sexuality and sensuality.

Review Questions

1. List at least five areas related to sensuality or sexuality that are usually the concerns of the OT.
2. What are some common attitudes of the able-bodied population about the sexuality of persons with physical dysfunction?
3. How do these attitudes affect the disabled person's perception of herself or himself and attitudes toward his or her own sexuality?
4. How is sexuality related to self-esteem and a sense of attractiveness?
5. Describe some typical questions for taking a sexual history. How can these questions be used to clarify values about sexuality?
6. How do mobility aids and assistive devices affect sexual functioning? How can this concern be managed?
7. What are some signs of potential sexual abuse of adults?
8. What are some suggestions for dealing with the following physical symptoms during sexual activity: hypertonia, low endurance, joint degeneration, and loss of sensation?
9. List some medications that may cause sexual dysfunction.
10. Discuss some issues and precautions relative to birth control for the woman with a physical disability.
11. How is a catheter managed during sexual activity?
12. What are some potential problems in pregnancy, delivery, and childcare?
13. Discuss some techniques for educating a person about sexual issues.
14. How should sexual harassment of staff members by clients be handled?

Sleep and Rest

Jean S. Koketsu

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Describe sleep architecture in the young adult population.
2. Describe how sleep architecture changes across the lifespan.
3. Describe the difference between sleep and rest.
4. Describe at least five negative consequences of poor sleep and rest in daily occupations.
5. Name at least seven techniques to promote good sleep hygiene techniques that will optimize conditions to facilitate sleep.
6. Describe the role of the occupational therapy practitioner in sleep and rest.

KEY TERMS

Circadian rhythm
Comorbid insomnia
Excessive daytime sleepiness (EDS)
Homeostasis
Hypnogram
Insomnia
Non–rapid eye movement (NREM) sleep
Polysomnograph (PSG)
Rapid eye movement (REM) sleep
Rest
Sleep
Sleep architecture
Sleep hygiene

Threaded Case Study

Mrs. Tanaka, Part 1

Mrs. Tanaka, a 63-year-old first-grade teacher born and raised in California, was diagnosed with left ischemic cerebrovascular accident (CVA), right hemiplegia. She was admitted to the in-client rehabilitation unit that specializes in clients with neurological injuries or events. She is married and lives with her husband of 40 years in a single-story house, to which she will return. Mrs. Tanaka has two adult children and three grandchildren. Her 65-year-old husband is in good health and will be her caregiver upon discharge.

Prior to the CVA, Mrs. Tanaka enjoyed working as a teacher and taking care of her grandchildren. Her status at evaluation consisted of the following: She had right hemiplegia with severe sensory and perceptual motor deficits. Her right arm was edematous, her muscles were hypotonic and dependent for movement. She was able to follow one-step verbal/gestural cues with moderate assistance. She required maximum assistance for bed mobility, dressing, hygiene, and grooming due to distractibility and impairments in trunk control, balance, awareness of her right side, and endurance. She was totally dependent for bathing, basic transfers, all instrumental activities of daily living (IADLs), and community mobility. Mrs. Tanaka tolerated 15 minutes of the team evaluation before falling asleep. The prior hospital did not note any sleep disturbance.

The occupational therapist (OT) scheduled an appointment to see Mrs. Tanaka in the morning to work on activities of daily living (ADLs), such as bed mobility, transfers, dressing, and hygiene activities. The nursing staff noted that the client had a "rough night" and slept for only 2 to 3 hours. Her hospital roommate complained to the OT that Mrs. Tanaka snores loudly and stated that she wanted to change rooms because of this. Throughout the day, Mrs. Tanaka was unable to participate in all therapies because of her sleepiness. As the first week of her rehab stay progressed, she continued to have difficulty participating in therapies because of her sleepiness.

Mrs. Tanaka, her family, and the rehab team are concerned about her inability to get restful sleep at night and to stay awake during the day, so as to fully benefit from therapies and to reach her rehab goals before returning home.

This chapter addresses sleep and rest, two occupational performance areas within the domain of OT practice.[12]

Critical Thinking Questions

1. What is the role of the occupational therapist in addressing Mrs. Tanaka's sleep disturbance?

2. What are sleep and rest, and why do OTs need to address these areas of occupation?

3. What can an OT do to help with Mrs. Tanaka's sleep difficulty?

To help guide OTs in their practice, the American Occupational Therapy Association (AOTA), the national organization representing occupational therapy in the United States, has established the Occupational Therapy Practice Framework (OTPF).[12] The OTPF is reviewed every 5 years and is considered an evolving document. The original OTPF (2002)[8] identified seven performance areas in which humans engage; in this first edition, sleep and rest were organized under the category Activities of Daily Living (ADLs). The second edition (OTPF-2 [2008]) contained several revisions,[10] and one change was reclassification of sleep and rest as its own category of occupation. In the OTPF-3, sleep and rest remains its own separate category of occupation among seven other categories. [12]

In 1922 Adolf Meyer,[113] considered one of the founders of occupational therapy, wrote that the "big four" areas in life that need to be balanced and in rhythm, even under difficult circumstances, were work, play, rest, and sleep. Many years later the OTPF-2 stated, "Unlike any other area of occupation, all people rest as a result of engaging in occupations and engage in sleep for multiple hours per day throughout their life span" (OTPF-2, p. 665).[10] Another reason cited in the OTPF-2 for categorizing sleep and rest as its own occupation was "[s]leep significantly affects all other areas of occupation."[10] (OTPF-2, p. 665). In 2007 Jonsson had suggested that providing sleep prominence in the Framework as an area of occupation promoted the consideration of lifestyle choices as an important aspect of participation and health (OTPF-2, p. 665).[10,93] As mentioned, the OTPF-3 continues to present sleep and rest prominently as an occupation.

Because sleep and rest are considered an occupation in its domain of practice, it is appropriate for an occupational therapist to address sleep and rest when treating Mrs. Tanaka.

History of Sleep and Rest in Occupational Therapy

From the earliest published writings in occupational therapy, sleep was considered to be important. In October, 1921, while presenting a paper at the Fifth Annual Meeting of the National Society for the Promotion of Occupational Therapy (now known as the American Occupational Therapy Association), Adolf Meyer stated:

There are many other rhythms which we must be attuned to: the larger rhythms of night and day, of sleep and waking hours, or hunger and its gratification, and finally the big four—work and play and rest and sleep, which our organism must be able to balance in all this actual doing, actual practice, a program of wholesome living as the basis of wholesome feeling and thinking and fancy and interests.[113]

Even though the founders of occupational therapy considered sleep and rest important for a healthy balance in life, this area seems to have been forgotten in the OT literature, and in OT practice.

Green[71] suggested that occupational therapy has paid little attention to the area of sleep because influential scholars in the field have omitted sleep definitions from classifications of occupations. Green also noted that occupational scientists are uncertain about whether sleep is considered an occupation. In his research, Green found evidence in the occupational science literature on sleep with respect to time use and of occupational therapists giving advice on sleep. However, he noted, "Coverage has been neither consistent nor comprehensive and it is unclear why sleep has been considered by so few writers."[71]

Howell and Pierce[85] suggested that Meyer's ideas about the importance of the occupations of sleep and rest were not embraced or further developed in occupational therapy because of the culture's overemphasis on productivity in industry, business, home management, and even leisure. The authors believe that the Protestant work ethic, the Industrial Revolution, and the Victorian era all played a role in shaping current Western views on restorative occupations. They pointed out that Meyer's message was ignored in Western society because "it is generally believed that valuable time is wasted while sleeping, time that could be spent more productively."[85]

In a review of OT textbooks published since 1990, Green[71] found that information on sleep was limited. He pointed out, however, that Yasuda[71,79,188] and Hammond and Jefferson[79] addressed the topic more thoroughly in chapters on fibromyalgia and rheumatoid arthritis, respectively.

More recent major textbooks used by OT students and practitioners have included chapters on the topic of sleep and rest.[101,159] Similarly, Green and Westcomb[75] edited a book on sleep in which the perspectives of various disciplines, including occupational therapy, were represented. In 2015 Green and Brown[72] edited a book focused on sleep that was intended specifically for occupational therapists.

The AOTA has produced the document "Blueprint for Entry-Level Education,"[11] which identifies key content areas that should be included in OT students' course of study. The topic of sleep and rest was included on the list of occupation-centered factors that should be included in entry-level curriculum content.

In 2013, in an opinion piece in the *British Journal of Occupational Therapy,* Fung et al.[63] proposed that "sleep (and wakefulness) should be routinely assessed and addressed as part of standard occupational therapy practice." They recommended more sleep and wakefulness education in OT curriculums; more education on sleep itself and on assessments, interventions, and tools pertaining to it, and more attendance by OTs at professional development workshops held by experts in the field. O'Donoghue and McKay[136] studied the impact of obstructive sleep apnea (OSA) on occupations in Ireland and agreed that OTs' interventions can have a significant impact on the lives of people with sleep disorders.

It should be considered that occupational therapists may be so busy helping clients in areas of occupations when the client is awake that focusing on the area of sleep may be given lower priority. For example, the areas an OT needs to address with Mrs. Tanaka are numerous and can be overwhelming for a novice practitioner, or even for an experienced OT, given the time pressures for clients to meet functional and other occupational goals. Data have shown that in-client rehabilitation stays have shortened for clients with a CVA, whereas acuity levels have risen, as evidenced by lower Functional Independence Measure (FIM) scores on admission and discharge.[70] Pressures for Mrs. Tanaka to meet her goals quickly are high.

Because sleep and rest are now identified as a category of occupation in itself; major OT textbooks cover the topic more thoroughly; and the AOTA blueprint supports sleep education and the interest of international OT researchers, it is anticipated that educational programs will cover the occupation of sleep and rest more thoroughly in their curriculums and that practicing therapists will advance their knowledge in this area.

Occupational Therapy's Definition of Sleep and Rest

Sleep

OT definitions of sleep and rest are fluid (or fluctuating), changing as more research is dedicated to this understudied occupation. For example, the OTPF-3[12] does not give a definition of **sleep** itself in the glossary, but rather describes the activities surrounding this occupation, such as preparing for sleep, tending to nighttime toileting needs, and performing nighttime caregiving for others (eg, breastfeeding). The OTPF-3 describes sleep in relation to other occupations and to its role in supporting "healthy, active engagement in other occupations"[12] (OTPF-3, p. S20).

The OTPF-2 had defined sleep as "[a] natural periodic state of rest for the mind and body, in which the eyes usually close and consciousness is completely or partially lost, so that there is a decrease in bodily movement and responsiveness to external stimuli."[10] During sleep, the brain in humans and other mammals undergoes a characteristic cycle of brain wave activity that includes intervals of dreaming.[10,167] The OTPF-2's definition of sleep included the statement that consciousness could be completely lost during sleep.[10]

The OTPF-3 alludes to sleep preparation as "preparing the physical environment for periods of unconsciousness …"[12] (OTPF-3, p. S20). However, Mahowald,[108] a sleep researcher, has stated, "There is now overwhelming evidence that the primary states of being (wakefulness, NREM sleep and REM sleep) are not mutually exclusive, but may become admixed or may oscillate rapidly, resulting in numerous clinical phenomena." Coren,[42] a psychologist and author on sleep, pointed out that at some level, our vision, hearing, and sense of touch are still functioning to some extent when we are asleep.

Human sleep is not just the opposite of wakefulness, or wakefulness the opposite of sleep.[109] It appears that consciousness is not completely lost during sleep.

Rest

In the OTPF-3, **rest** is defined as "engaging in quiet and effortless actions that interrupt physical and mental activity, resulting in a relaxed state"[12] (OTPF-3, p. S20). According to the OTPF-3, rest includes identifying a need to rest and relax, reducing involvement in taxing (physically, mentally, or socially) activities, and participating in relaxation or other activities that restore energy, calm, and renewed engagement.[12]

Nurit and Michal[134] compared how the literature of the various fields that interact with occupational therapy conceptualize rest. Psychology, they pointed out, considers rest a basic human need,[110] whereas the nursing profession differentiates between physical and mental rest. Various religions and philosophies view rest as important for restoration and focus. The researchers concluded that although the various fields may have different concepts of rest, they all concur with occupational therapy that rest is important for a healthy, balanced life.

Nurit and Michal also reviewed debates surrounding the concept of bed rest in medicine. They noted that, historically, rest was highly recommended[28,134]; however, they also pointed to research that has shown that clients on bed rest, compared to clients in ambulatory groups, may experience detrimental effects to their health.[4]

This chapter focuses on the general concept of rest, rather than the idea of physician-ordered bed rest (ie, not allowing a client out of bed for medical or safety reasons).

Sleep and Rest

The OTPF-3 explains that the concepts of both sleep and rest include "activities related to obtaining restorative rest and sleep that supports healthy active engagement in other occupations"[12] (OTPF-3, p. S20). Instead of categorizing the occupations into what she called "adopted cultural categories" of work, play, leisure, and self-care, Pierce[146] described the categories of occupation based on how the individual experiences them. She described three categories of occupation as *pleasurable,* which includes play and leisure; *productive,* which includes work; and *restorative* types of occupations, which include sleep, self-care, and quiet activities.[145,146] Among the pleasurable, productive, and restorative occupations, Howell and Pierce[85] considered restorative occupations the least recognized. In 2003 Pierce[146] stated, "In our clients, the need for improvements in the restorative quality of their occupational patterns can be critical. Without adequate restoration, productivity and pleasure also remain low."

Need to Address Sleep in Occupational Therapy

It is important to emphasize that a founding figure of the OT profession, Adolf Meyer, regarded sleep as one of the four main areas that determine whether humans can function (in addition to work, rest, and play). It is also noteworthy that the OTPF considers sleep a major human occupation.[12] Perhaps an even more compelling reason that OTs should address sleep is because it is an occupation in which every human being across the age span engages in or should engage in. Of the eight occupations listed in the OTPF-3, sleep and rest is the only one that cannot be performed by someone else or by an alternative means. The environment and actions surrounding sleep can be adapted, but the act of sleeping itself is the only occupation that cannot be adapted for an individual to function optimally, let alone survive. As Dahl[45] bluntly stated, "Sleep is not some biological luxury. Sleep is essential for basic survival, occurring in every species of living creature that has ever been studied. Animals deprived of sleep die."

As this chapter illustrates, sleep (or the lack thereof) affects almost every client population with whom OT practitioners work and within virtually every setting.

Need to Address Rest in Occupational Therapy

As mentioned previously, rest, along with sleep, is considered one of the primary occupational performance areas in the OTPF-3.[12] However, rest should not be confused with sleep. According to Dahl,[45] "Sleep is not simply rest. Mere rest does not create the restorative state of having slept." If a client such as Mrs. Tanaka "rests" during the day but does not sleep, she will still suffer the loss of sleep and therefore of all its unique restorative benefits.

Howell and Pierce[85] discussed the importance of rest in addition to sleep for physical, cognitive, and mental restoration. They noted the uniqueness of individuals in deciding which occupations are restorative, and how one person may consider a particular activity to be relaxing and calming, whereas another may not. The authors also pointed out that occupations that are highly restorative tend to have strong routines of a simple and even repetitive nature, and they are often considered pleasurable and have personal meaning to the individual based on tradition and history with the occupation.

Edlund,[57] an expert on rest, body clocks, and sleep, described four different forms of active rest that are needed in addition to sleep: physical rest, mental rest, social rest, and spiritual rest. He stated, "Rest is not useless but a major pathway to our renewal, our survival."[57] His book, *The Power of Rest: Why Sleep Alone Is Not Enough: a 30-Day Plan to Reset Your Body,* provides information on how a person can obtain those types of rest efficiently.

Sleep and Rest and Occupational Justice

Occupational justice describes the OT profession's concerns with the ability of all people, "regardless of age, ability, gender, social class or other differences"[133] to be given the opportunity to engage in occupations. Occupational justice describes concerns that OT practitioners have about the ethical, moral, and civic aspects of clients' environments and contexts.[12] Sleep is an occupation that is optimized by a safe setting and environment, especially for someone with a physical or mental disability. In a 2014 point-in-time survey of communities across the United States, 49,933 homeless veterans (8.6% of the total) were identified.[120] Significantly, 54% of these homeless veterans were found to have a mental or physical disability.

Homeless veterans tend to be male (91%), single (98%), live in a city (76%), and have a mental and/or physical disability (54%). Black veterans are substantially overrepresented among homeless veterans, comprising 39% of the total homeless veteran population, but only 11% of the total veteran population.

Sleep researchers Dement and Pelayo[52] stated, "It is a deplorable fact that in the inner portions of our large cities, we have begun to see large numbers of individuals who are homeless and who do not have a comfortable, safe place to sleep." Occupational therapists work with many people in society who may not statistically be considered homeless, but these people may live (and sleep) in substandard environments. Even other species attempt to find safe places to sleep.

History of Sleep in Society and Cultural Influences

Howell and Pierce[85] stated that one of the most significant forces to shape our current view of occupations is the Protestant work ethic, which evolved during the Protestant Reformation of the 1500s. The values of honesty, thrift, and hard work were embraced during this time in Europe. Leisure (often associated with pleasurable, "nonproductive" activities such as sleep and rest) was considered a potential temptation into sin and thus to be avoided, similar to the belief in the adage "idle hands are the devil's workshop."

In 1996 Coren[42] pointed out that the invention of the light bulb by Thomas Edison had a powerful influence over sleep and served to transform society, making shift work possible throughout the night. Prior to the introduction of the modern tungsten filament light bulb in 1913 (an inexpensive and long-lasting bulb), the average person slept 9 hours a night, as was documented by a 1910 study. The new light bulb served to "free" working people from working in darkness; but, ironically, it may have simultaneously served to reduce the hours of sleep for future generations.

The National Commission on Sleep Disorders Research, mandated by the U.S. Congress, concluded in the 1990s that the "root cause of pervasive sleep deprivation and unidentified sleep problems is the continued low level of public and professional awareness due to failure to give sleep topics adequate attention in the educational system."[52] In 2015 Dement and Pelayo[52] pointed out that international surveys conducted since the 1800s show that people in industrialized nations are sleeping less than they did a century ago. Dement and Pelayo[52] referred to studies in Japan, where surveys were conducted annually; they noted that these surveys showed an overall reduction in the daily amount of sleep of $1\frac{1}{2}$ hours since 1920.

In a poll conducted in 2009 by the U.S. National Sleep Foundation (NSF),[129] 1000 telephone interviews were conducted among a random sample of Americans in the continental United States. Respondents were at least 18 years of age and a head of the household. They were asked how many hours of sleep they needed to function at their best during the day. On average, respondents reported needing 7 hours and 24 minutes to function at their best. However, they reported getting an average of 6 hours and 40 minutes of sleep on a typical workday or weekday, almost $2\frac{1}{2}$ hours less than people had reported in 1910. The 2014 NSF poll[131] found that of 1103 adults polled who were parents of or had parental responsibility for a child aged 6 to 17 in their household, more than 90% felt that sleep was either very or extremely important for their own mood, health, and performance, in addition to the mood, health, and performance of their children. Although the parents felt that getting enough sleep was important, they acknowledged that their children were not getting enough, especially as the children got older.

These statistics point to the existence of a culture-wide "sleep debt," a point of relevance for occupational therapists, whose overarching goal, according to the OTPF-3,[12] is "achieving health, well-being, and participation in life through engagement in occupation."

Mrs. Tanaka, whose primary cultural influence is Western, has her own beliefs and values about sleep. Therefore, it is of utmost importance to identify Mrs. Tanaka's and her family's beliefs about sleep. Is sleep considered important or a waste of time?

Cultures of Sleep Practices

Sleep behavior among Western industrial societies is distinctive to that culture. In a comparative analysis of sleep among industrialized Western society and indigenous cultures, Worthman and Melby[186] pointed out several uniquely Western sleep practices, including the following:

1. Solitary sleep from early infancy, supported by cultural norms and beliefs about the risk of an overlying need for infant independence or autonomy and the need for sexual decorum

2. Consolidation of sleep into a single long bout

3. Distinct bedtimes enforced in childhood and reinforced by highly scheduled daytime hours for work or school and mechanized devices for waking

4. Housing design and construction that provide remarkably sequestered, quiet, controlled

environments for sleep in visually and acoustically isolated spaces

In contrast, non-Western sleepers habitually engage in co-sleep in shared beds or spaces.[186] In 2012 Steger[162] reported that in some cultures, it would be "simply unthinkable" to leave a baby or toddler to sleep alone in a room. Steger also pointed out that mothers in Japan are convinced that it is important to convey a sense of security and belonging to their children by sleeping with them, not firmly putting children to bed alone in a room and letting them cry themselves to sleep.

Steger[162] pointed out that in monophasic sleep cultures (one long bout of night sleep), only "marginal social groups" (eg, children or sick people) or night shift workers are allowed to sleep during the day. A "siesta culture," as described by Steger, supports biphasic sleep in which there is a predetermined time for night and midday sleep. Social life quiets down during the night and early afternoon. A "napping culture" (polyphasic sleep) occurs when there are often irregular sleep times during the day in addition to the regulated nighttime sleep. However, there are many other sleep cultures within those three basic types.

Compared to Western cultures, other cultures may have more fluid sleep schedules and more fluid sleep/wake states, and may fall asleep and remain asleep in more sensorially dynamic settings.[186] As mentioned, Western sleep areas, by design, provide minimal sensory stimulation[186] (ie, protection from the elements, minimal contact with others, climate control, and negligible noise, movement, or light). Compared to this, sleepers in other cultures may sleep exposed to the elements and co-sleep, and may be accustomed to sounds, movement, and light. For example, the Ache (Paraguay), Hiwi (southern Venezuela), Efe (Zaire), and !Kung (northwest Botswana) use fire as light, heat, and protection at night and therefore may need to tend the fire and awaken frequently to monitor it.[186]

Humans universally sleep in a recumbent position (unless ill or during infancy) but can differ widely in terms of accessories (eg, bedding).[186] For example, "foragers" (eg, Ache, Efe, !Kung) who inhabit tropical or mild climates and move regularly do not sleep on platforms but directly on the ground.[186] !Kung sleep on skin, a blanket (or nothing) over conforming sandy ground. Efe sleep on thin layers of leaves or between logs. Hiwi use hammocks. According to Worthman and Melby,[186] none of the groups listed regularly use pillowing material or coverings, whereas Westerners use an abundance of these. The minimal use of bedding by the groups listed may have to do with available technology and resources, but it may also have to do with avoidance of pests such as fleas, bedbugs, lice, or mites, which thrive in bedding material.[186]

Human beings have a tremendous diversity in sleep patterns and sleep developmental histories based on cultural background and upbringing.[186] Steger[162] suggested that four major sources of the emotional security required for relaxing and peaceful sleep shape sleep practices around the world:

1. Stability of the physical sleep environment/sleeping place

2. The presence of trusted people

3. Recurring rituals or routines

4. Social acceptance of certain sleep behavior (Fig. 13.1).

FIG 13.1 This 3½-year-old boy uses a teddy bear as a sleep aid, for comfort and a sense of security. It is considered socially acceptable at this young age, but it would not be so as he moves into the teen years and adulthood. (Courtesy Jean S. Koketsu.)

It is important for occupational therapists to be aware of a client's sleep history and culture so they can set realistic and meaningful goals for the client in the area of sleep. The OTPF-3 acknowledges that client engagement in occupations within cultural contexts influence how the occupation is organized.[12]

The occupational therapist treating Mrs. Tanaka should find out what her typical sleep habits were prior to the stroke. Did she sleep in her bed alone or with her husband? What time did she normally go to bed and wake up? Did she usually take naps? What habits or routines did she have before going to sleep or upon waking up? Did she experience interruptions during sleep, such as getting up to go to the bathroom? What kind of bed did she sleep on? What are her sheet and pillow preferences? Was there noise in the room where she slept? What are comfortable light and temperature levels for her?

Brief History of Sleep Medicine

Sleep medicine as a medical specialty is relatively new. William C. Dement, a pioneer in sleep medicine himself, considers Nathaniel Kleitman, a physiologist who started studying sleep in the 1920s, as the first to devote his professional life to the study of sleep.[49,50,52] Kleitman and Aserinsky first described **rapid eye movement (REM) sleep** in the early 1950s, and overnight electroencephalograms (EEGs) were first reported in the late 1950s by Dement and Kleitman.[51] In 1965 sleep apnea was identified in Europe, and in 1970, Dement founded the first sleep disorders center at Stanford University Hospital. The 1970s saw a proliferation of sleep disorder clinics. Since that time, sleep medicine has become a specialty in medicine; scholarly journals focusing on sleep were launched; national and international organizations that focused on sleep research and education were founded; and a congressional commission focused on sleep was mandated.

Dement and Pelayo[52] reported that there was no scholarly discipline that was the "best candidate to assume responsibility for the education of the public about sleep." They found that traditional academic organizations of colleges and universities viewed psychology and biology departments as the "obvious homes" of the topic. Fung et al.[63] argued that "occupational therapists should be equipped with a subset of skills to assess and address sleep in practice." In these researchers' view, occupational therapy seemed to be an "obvious home," or at least a good home, for this discipline.

The OTPF-3 highlights the importance of how engagement and participation in an occupation (such as sleep) occur in physical, social, cultural, and even virtual contexts, which must be considered in the process of helping people with occupational concerns. Sociologists Williams et al.[180] made note of the "medicalization" of sleep issues (ie, the "cultural framing of sleep problems as medical matters") and described how popular culture and media can play a role in defining and highlighting sleep concerns and opinions about sleep.

This chapter addresses sleep definitions and problems sometimes more from a medical perspective. However, the complex and varied dimensions of sleep must be considered; OTs cannot just "medicalize" the issue.

Definition of Sleep According to Sleep Medicine

Behavioral Definition

According to Carskadon and Dement,[36] the two defining characteristics of sleep are (1) being a reversible behavioral state and (2) demonstrating perceptual disengagement from and unresponsiveness to the environment. The perceptual disengagement is compared to the waking state in which humans are conscious or aware of various sights, sounds, smells in the world.[52] For example, Dement and Pelayo[52] pointed out that even if the eyelids are taped open, we stop seeing when we fall asleep. However, this perceptual disengagement is not unconscious and is still considered an active process. Reversibility, the other essential defining characteristic quality of sleep, means that a person could be taken out of that state relatively easily based on the stage of sleep he or she is in.[52] Other sleeplike states, such as coma, anesthesia, and hibernation, are differentiated from normal sleep because of the difference in reversibility.[52]

Dement and Pelayo[52] considered sleep a restorative process, with "sleep and wakefulness occur(ring) as complementary phases in the daily cycle of existence." Sleep is usually characterized by closed eyes, postural recumbence (lying down), and behavioral quiescence.[36] Other sleep behaviors also may occur, such as sleep talking and sleepwalking.[36]

Scientists have described several discrete stages of sleep based on brain wave patterns and eye and muscle activity. The two major types of sleep are **non–rapid eye movement (NREM) sleep** (NREM is pronounced non-rem) and REM sleep.[52] The two states (NREM and REM) exist in virtually all mammals and birds and are as distinct from each other as sleep is from the waking state.[36]

The American Academy of Sleep Medicine (AASM) characterizes the sleep stages as stage N1 (NREM 1), stage N2 (NREM 2), stage N3 (NREM 3), and stage R (REM).[88] It should be noted that from 1968 to 2007, NREM sleep was divided into four stages (stages 1 to 4); at that point, stages 3 and 4 were combined into one (N3, or slow wave sleep), according to the AASM.[52] NREM sleep accounts for 75% to 80% of total sleep time in young adults. The stages are defined by brain wave patterns from an EEG. The EEG pattern in NREM sleep is synchronous and shows wave forms called spindles and K complexes, in addition to high-voltage slow waves (Fig. 13.2). Carskadon and Dement[36] gave a shorthand definition of NREM as a relatively inactive state yet actively regulating the brain in a movable body.[36]

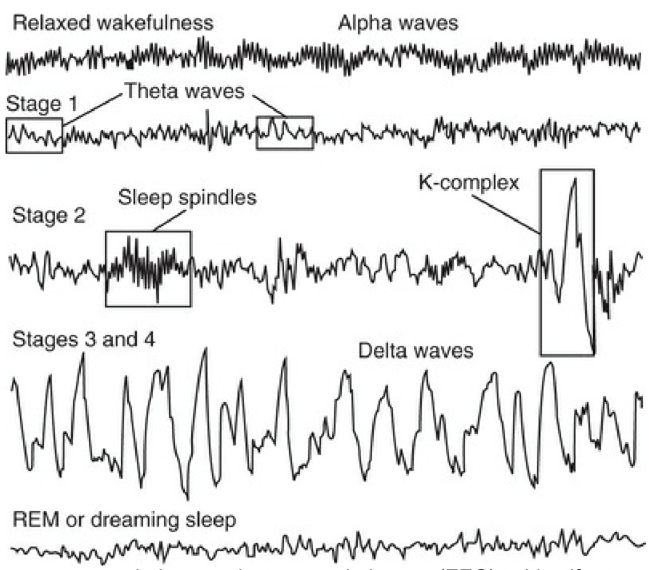

FIG 13.2 Brain waves recorded on an electroencephalogram (EEG) to identify stages of sleep. (From Epstein LJ, Mardon S: *Harvard Medical School guide to a good night's sleep*, New York, 2007, McGraw-Hill.)

REM sleep accounts for approximately 20% to 25% of total sleep time in young adults and is defined by EEG activation, muscle atonia or paralysis, and occasional bursts of rapid eye movements.[36] The eye movements are binocularly synchronous and rapid, although drifting movements may be seen.[52] REM sleep is associated with dreaming.[52] This is based on vivid dream recall reported after approximately 80% of arousals from this state of sleep.[51] Spinal motor neurons are inhibited by brainstem mechanisms that suppress postural motor tonus during REM sleep. It is believed that the body is paralyzed during REM sleep to protect dreaming individuals from physically acting out dream content and injuring themselves or others, although brief, minor position shifts or limb movements occur. Carskadon and Dement's short definition of REM sleep is an activated brain in a paralyzed body.[36]

Evidence from human beings and other species suggests that mammals have only minimal ability to thermoregulate during REM.[36] The poor ability to respond to temperature extremes during REM suggests that problems with temperature regulation may be worse later during the night, when REM sleep tends to predominate; these are important considerations for OT practitioners working with people with thermoregulation problems. Interestingly, Carskadon and Dement[36] pointed out that sweating or shivering during sleep under ambient temperature extremes occurs in NREM sleep and is limited during REM sleep.

Sleep Architecture

Polysomnography

A **polysomnograph (PSG)** is a continuous recording of specific physiological variables during sleep. It is typically performed at night during a sleep study in a sleep clinic. The PSG quantifies sleep; the AASM recommends measuring brain waves (via electroencephalogram [EEG]), eye movements (via electrooculogram [EOG]), chin and leg muscle movements (via electromyogram [EMG]), airflow, oxygen saturation, and body positions.[88] The AASM also recommends that in addition, the PSG record respiratory, arousal (wake-up), cardiac (eg, heart rate), movement, and behavioral events.[88]

The sleep stages are charted on a diagram, called a **hypnogram** (histogram, or graphical representation of sleep), made from the data collected from the PSG. The chart resembles a city skyline and is referred to as **sleep architecture** by sleep experts (Fig. 13.3). A client's sleep architecture describes the details of an individual's sleep after an overnight recording of EEG, EOG, and EMG. The histogram shows the following:

- Time needed to fall asleep (sleep latency)
- Sequence of sleep stages
- Time spent in each stage of sleep
- Total sleep time
- Number and length of nighttime wakenings[49]

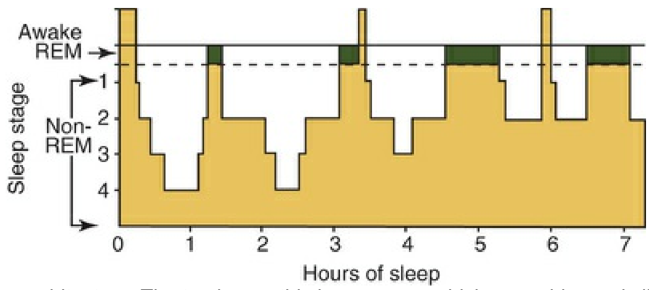

FIG 13.3 Sleep architecture. The tracing on this hypnogram, which resembles a skyline, illustrates a typical night's sleep. A hypnogram charts the sleep stages during an overnight sleep study. (From Epstein LJ, Mardon S: *Harvard Medical School guide to a good night's sleep*, New York, 2007, McGraw-Hill.)

Actigraphy

Actigraphy is another way sleep is measured. It is increasingly used in research and in the clinical care of clients with sleep issues.[117] The client wears a motion sensor on the wrist, and the sensor continuously monitors movement.[52] The data can be downloaded immediately, or the sensor can be worn for a specified period. Actigraphy is more convenient and less expensive than a PSG.[52] In recent years smart phone apps and sleep management systems have been developed to track sleep.

Progression of Normal Sleep

Normal young adults first enter sleep through NREM sleep, and REM sleep occurs 80 to 100 minutes afterward. Throughout the night, in approximately 90-minute periods, cycles of NREM and REM sleep alternate, usually with progressively increasing periods of REM sleep.[36] Box 13.1 lists the general stages of sleep and describes the bodily functions that occur during these stages.[a]

Box 13.1

Stages of NREM and REM Sleep

Non–Rapid Eye Movement (NREM) Sleep

Stage N1 (1–7 Minutes)

Stage N1 is considered transitional wakefulness to sleep onset or to rapid eye movement (REM) sleep. The body temperature begins to drop, muscles start to relax, and the eyes may move slowly from side to side. An electroencephalogram (EEG) shows brain waves slowed to 4 to 7 cycles per second *(theta waves).* A person in this phase can be easily wakened by tapping him or her or softly calling the individual's name (low arousal threshold). However, everyone experiences stage N1 differently. If awakened in this stage, one person may say he or she was asleep, whereas another may only say that he or she was drowsy. A common sign of severely disrupted sleep is an increased amount and percentage of sleep in this phase.

Stage N2 (About 10–30 Minutes)

Stage N2 follows stage N1. The eyes aren't moving much, and the heart rate and breathing are slower than when the person is awake. This is the first stage of established sleep. Brain waves are irregular; the EEG shows intermediate-sized brain waves with brief bursts of fast sleep spindles, or K-complexes, that occur about every 2 minutes. Generally, a more intense stimulus is required to arouse a person in this stage (higher arousal threshold). In the later phases of this stage, the EEG shows high-voltage slow wave activity. Overall, this stage may account for half the night.

Stage N3 (About 20–40 Minutes in the First Cycle)

Stage N3 sleep is also called *delta sleep* or *slow wave sleep* (it formerly was called stage 3 and stage 4 sleep). Breathing slows and becomes more regular, and the blood pressure and pulse fall to 20% to 30% of the waking state. The EEG shows high-amplitude slow waves. Stage N3 accounts for approximately 10% to 15% of total sleep time, but it may be undetectable in older adults, especially men.

Rapid Eye Movement (REM) Sleep

Stage R (About 1–5 Minutes in the First Cycle, Increases up to 30 Minutes)

The body temperature, blood pressure, heart rate, and respiratory rate all increase and are often irregular. The clitoris or penis may become erect. The EEG shows a dramatic decline in amplitude, which resembles the waking state. Thermoregulation is severely inhibited. Motor neurons also are inhibited, which means major muscles are paralyzed, except the diaphragm and the ocular muscles.

Note: See Fig. 13.1 for brain wave patterns during sleep. Slow wave sleep (SWS) is considered the most restorative phase for physiological repair, whereas REM sleep is believed to be necessary for memory consolidation.

Sleep Across the Age Span

Research shows that age is the strongest and most consistent factor that affects sleep stages (Fig. 13.4).[36,140] The biggest difference in sleep stages is seen in newborns, who enter from wake to sleep through the REM phase first for the first year of life (Fig. 13.5). Infants also cycle between REM and NREM, but they cycle through the phases in 50 to 60 minutes instead of the approximately 90 minutes seen in adults. At birth, active (REM) sleep accounts for approximately 50% of total sleep and declines over the first 2 years to approximately 20% to 25%.[36] Infants do not seem to have fully developed and recognizable NREM sleep until they are 2 to 6 months old.[36] Stage N3, also known as deep or slow wave sleep (SWS), is maximized in young children but decreases markedly with age in quantity and quality (Fig. 13.6). That may explain why children may be very difficult to arouse when they are in SWS in the first cycle, whereas an older adult may be easier to awaken in that phase.

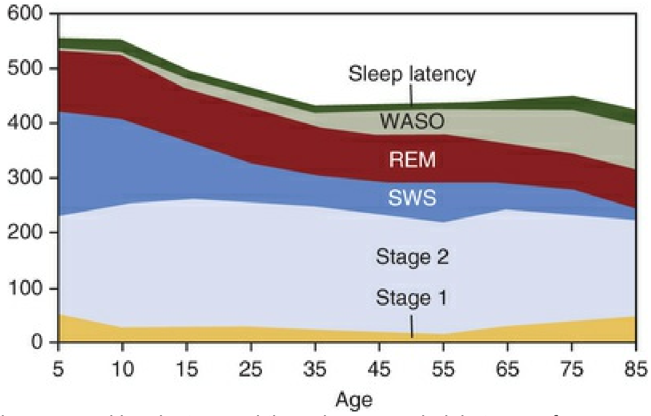

FIG 13.4 Time is measured in minutes, and the values recorded, in terms of age, are sleep latency (the time it takes to fall asleep), wake time after sleep onset (WASO), rapid eye movement (REM), slow wave sleep (SWS), and stage 1 and stage 2 sleep. Note that as we age, it takes longer to fall asleep (sleep latency increases), the time spent in deep sleep decreases, and the time spent in stages 1 and 2 increases. Also note that SWS decreases markedly during adolescence. As we age, night awakenings (WASO) also increase. (From Ohayon M, et al: Meta analysis of quantitative sleep parameters from childhood to old age in healthy individuals: developing normative sleep values across the human lifespan, *Sleep* 27:1255–1273, 2004.)

FIG 13.5 Newborns enter REM sleep first for the first year of life and cycle through REM and NREM sleep within 50–60 minutes, instead of the 90 minutes seen in adults. (Courtesy Jean S. Koketsu.)

FIG 13.6 A 22-month-old child has no social qualms about falling asleep anywhere, even on a public diaper-changing table. Young children's deep sleep is maximized, so they may be very difficult to arouse from stage N3 sleep. (Courtesy Windy Chou.)

Adolescence.

Contrary to popular belief, teenagers require more sleep than adults. As cited by Carskadon[35] and Carskadon et al.,[37] evidence shows that teenagers need at least 9 to $9\frac{1}{4}$ hours of sleep a night to maintain optimal alertness. Teenagers also have been shown to have a phase delay in the circadian timing system, which means that their biological clocks alert them to stay up late and sleep in later (eg, sleep from midnight to 9 am).[37] The quantitative change in SWS may best be seen across adolescence; SWS decreases by nearly 40% during the teen years, even while nocturnal sleep remains constant.[36] These are important considerations in OT practice in terms of clients' scheduling and optimal performance of occupations.

Adulthood and aging.

From ages 20 to 60, sleep patterns don't change as rapidly as during childhood. However, there are consistent trends that occur in sleep patterns, such as decreased sleep efficiency, decreased time in restorative deep sleep, and easier arousal during the deep sleep phase (Table 13.1). After age 60, the sleep trends of adulthood continue.[58] A hallmark of aging is an increased percentage of time in stage N1 (NREM sleep) and a decreased percentage of time in N3 (deep, SWS), particularly in men. Sleep efficiency also decreases as a person ages. Sleep efficiency is measured by dividing the actual time a person is asleep by the amount of time he or she is in bed. Sleep efficiency at approximately age 45 is 86%, and it declines to 79% for those over age 70. Brief arousals are also more common in the elderly. In addition, older adults may have an advanced sleep phase, meaning that they may get sleepy in the early evening and have a tendency to awaken early in the morning.[36]

TABLE 13.1

Sleep Changes With Aging

	Age 20	Age 40	Age 60	Age 70	Age 80
Sleep latency	16 min	17 min	18 min	18.5 min	19 min
Total sleep time	7.5 hr	7 hr	6.2 hr	6 hr	5.8 hr
Time in stage 2 sleep	47%	52%	53%	55%	57%
Time in deep sleep	20%	15%	10%	9%	7.5%
Time in REM sleep	22%	21%	20%	19%	17%
Sleep efficiency	95%	88%	84%	82%	79%

Data from Epstein LJ, Mardon S: *Harvard Medical School guide to a good night's sleep*, New York, 2007, McGraw-Hill, p 43; and Ohayan M, et al: Meta analysis of quantitative sleep parameters from childhood to old age in healthy individuals: developing normative sleep values across the human life span, *Sleep* 27:1255–1273, 2004.

Carskadon and Dement[36] reported that possibly the most notable finding about sleep in the elderly is the profound increase in interindividual variability, which precludes generalizations such as those made for young adults.

Circadian Rhythm, Homeostasis, and Allostasis

The timing of human sleep is regulated by two systems in the body: the circadian biological clock and sleep/wake homeostasis.

Circadian rhythms are approximately 24-hour cycles of behavior and physiology that are generated by biological clocks (pacemakers or oscillators).[115] The internal biological clock regulates the timing and periods of sleepiness and wakefulness, temperature, blood pressure, and the release of hormones throughout the 24-hour day without need of outside cues for the clock to persist. However, environmental stimuli known as *zeitgebers*, or "time cues," help synchronize the internal clock to the 24-hour day. Light is the most dominant zeitgeber for most species[115]; bright light has the ability to shift circadian rhythms. Blind people who may not have a conscious perception of light can still entrain to the 24-hour day because human eyes have irradiance detectors that can sense light despite the inability to produce a visual image.[143] The receptors may remain intact in many people with blindness, which allows entrainment as usual. However, people without eyes (or the receptors) often have difficulty with entrainment and may have circadian rhythm problems.[143]

The master circadian (24-hour) clock, which is located in the suprachiasmatic nucleus (SCN) in the hypothalamus of the brain, dictates when we feel sleepy and when we feel most awake. Melatonin, a naturally occurring hormone, is inhibited by light. It is secreted by the pineal gland at night, which induces sleep and has the ability to synchronize circadian rhythms (Fig. 13.7).[150]

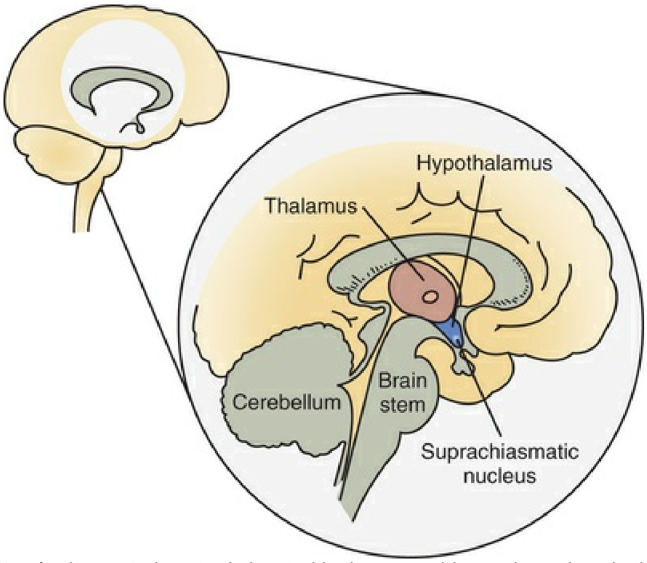

FIG 13.7 The sleep/wake control center is located in the suprachiasmatic nucleus in the hypothalamus. This "pacemaker" regulates the circadian rhythm of sleep and wakefulness. (From Epstein LJ, Mardon S: *Harvard Medical School guide to a good night's sleep*, New York, 2007, McGraw-Hill.)

The circadian rhythm for sleep and wakefulness is bimodal; the strongest desire to sleep occurs between midnight and dawn and in the midafternoon (Fig. 13.8).[58,116] This explains why people have the most difficult time staying awake between 2 and 4 in the morning and why they feel most sleepy in the afternoon after lunch. A person who is sleep deprived will feel sleepier during the afternoon dip in the circadian rhythm than if he or she had sufficient sleep. On the other hand, if a person is sleep deprived and has been awake for a long time, he or she may have difficulty falling asleep during the clock "alerting" times. This may explain the quandary of the world traveler who has flown through many time zones and wants to sleep but is unable to do so because his biological clock is telling his body to stay awake.

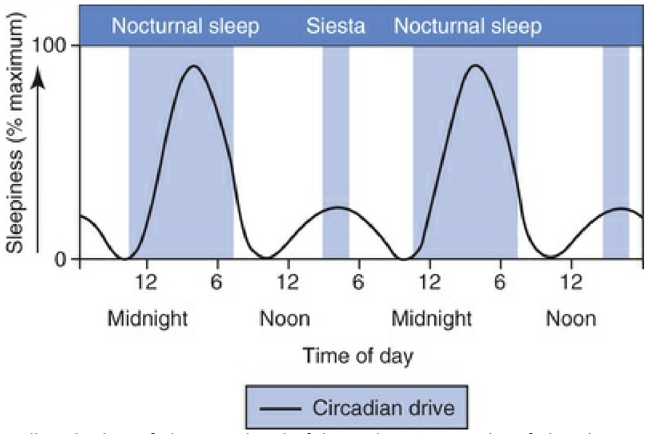

FIG 13.8 The circadian rhythm of sleep and wakefulness has two peaks of sleepiness during the 24-hour day. These peak times of sleepiness are between midnight and dawn (higher peak) and in the afternoon after the typical lunchtime. (From Epstein LJ, Mardon S: *Harvard Medical School guide to a good night's sleep*, New York, 2007, McGraw-Hill.)

All phases of normal sleep are considered to be under homeostatic control (**homeostasis**), or the tendency to maintain equilibrium. The longer a person is awake or deprived of certain sleep stages, the greater will be the drive to obtain that lost sleep or stage.[169] Stated differently, as soon as a person awakens, the sleep debt starts to accumulate. This sleep/wake homeostasis creates a drive that balances sleep and wakefulness.

A third, less understood mechanism, the allostatic process, is another factor involved in controlling the sleep/wake cycle.[143] Allostasis achieves stability of a system through many or variable physiological or behavioral changes, and it can be controlled by external forces such as social or ecological cues. Those mechanisms can override the circadian or homeostatic propensity for sleep, if necessary.[143] Social factors may include work, family, and societal structure.[143] Examples of ecological factors include habitat, light, food, warmth, shelter, and the presence of young; these are drivers that can determine the timing and duration of sleep and whether sleep actually occurs because of other pressing needs.[143] As cited by Czeisler et al.,[44] humans can override the signals of the circadian and sleep/wake system short term if they have very urgent matters to which they must attend.[44] The invention of artificial light and the alarm clock contributed to human beings' need (or desire) to override the biological clock, simply because they can or because of societal and cultural pressures to do so.

What is considered adequate sleep?

Determining what is considered adequate sleep varies widely based on age, genetics, and many other factors. Table 13.2 presents the recommendations of the National Sleep Foundation for determining how much sleep an individual needs.

TABLE 13.2
How Much Sleep Do You Need?

Age	Sleep Needs (hours)
Newborns (0–3 months)	14–17
Infants (4–11 months)	12–15
Toddlers (1–2 years)	11–14
Preschoolers (3–5 years)	10–13
School-age children (6–13 years)	9–11
Teens (14–17)	8–10
Young adults (18–25)	7–9
Adults (26–64)	7–9
Older adults (65+)	7–8

Data from the National Sleep Foundation. http://sleepfoundation.org/how-sleep-works/how-much-sleep-do-we-really-need. To view the full research report, visit SleepHealthJournal.org.

Sleep Disorders

Many sleep disorders have been researched and identified by sleep medicine researchers. Only the more common sleep disorders are reviewed here.

Insomnia

In general, **insomnia** is defined as repeated difficulty with initiating sleep or maintaining sleep, awakening earlier than desired, or having poor-quality sleep that is not restorative[56] despite adequate opportunities for sleep.[157] *The International Classification of Sleep Disorders*, third edition (ICSD-3), is the authoritative clinical text for the diagnosis of sleep disorders; the text was updated in 2014.[7] Insomnia is the most common sleep disorder and in isolation affects 30% to 50% of the general population; 9% to 15% of those report impairment in daily activities as a result.[56]

Insomnia is primarily diagnosed by clinical evaluation (by a physician) with a thorough sleep history and detailed medical, substance, and psychiatric history.[157] A diagnosis of insomnia requires an associated daytime dysfunction in addition to appropriate insomnia symptoms.[157] Because occupational therapists well understand occupations and the process of assessing function, they can provide valuable information to the treatment team on occupational performance in relation to sleep issues.[63]

Treatment for insomnia may include:

- Initially, at least one behavioral intervention is tried, such as stimulus control therapy or relaxation therapy, or a combination of cognitive therapy, stimulus control therapy, and sleep restriction therapy, with or without relaxation therapy. Cognitive behavioral therapy for insomnia (CBT-I) is a combination of cognitive therapy with behavioral treatments (eg, stimulus control, sleep restriction). Trained occupational therapists can use these therapies, but they are traditionally offered by other mental health professionals.
- Adherence to good sleep hygiene is recommended, but there is insufficient evidence to indicate that sleep hygiene alone is effective in the treatment of chronic insomnia. It is agreed that sleep hygiene education should be used in combination with other therapies. Occupational therapists can certainly provide education and training in this area.[157]

Table 13.3 presents more detailed information on possible treatments for chronic insomnia.

TABLE 13.3

Common Cognitive and Behavioral Therapies for Chronic Insomnia[a]

	Description	Instructions
Standard (generally accepted strategy that reflects a high degree of certainty based on good research)		
Stimulus control	Stimulus control is designed to extinguish the negative association between the bed and undesirable outcomes (eg, wakefulness, frustration, and worry). These negative states are frequently conditioned in response to efforts to sleep as a result of prolonged periods in bed awake. The objectives of stimulus control therapy are for the client to form a positive and clear association between the bed and sleep and to establish a stable sleep/wake schedule.	Go to bed only when sleepy; maintain a regular schedule; avoid naps; use the bed only for sleep; if unable to fall asleep (or back to sleep) within 20 minutes, remove yourself from bed and engage in a relaxing activity until drowsy, then return to bed—repeat this as necessary. *Note:* Clients should be advised to leave the bed after they have *perceived* their lack of sleeping within *approximately* 20 minutes; actual clock watching should be avoided.
Relaxation training	Relaxation training (progressive muscle relaxation, guided imagery, abdominal breathing) is designed to lower somatic and cognitive arousal states, which interfere with sleep. Relaxation training can be useful in clients displaying elevated levels of arousal and is often used with cognitive behavioral therapy (CBT).	Progressive muscle relaxation training involves methodical tensing and relaxing of different muscle groups throughout the body. Specific techniques are widely available in written and audio form.
Cognitive behavioral therapy for insomnia (CBT-I)	Cognitive therapy seeks to change the client's overvalued beliefs and unrealistic expectations about sleep. Common cognitive distortions identified and addressed in the course of treatment are "I can't sleep without medication," "I have a chemical imbalance," "If I can't sleep, I should stay in bed and rest," "My life will be ruined if I can't sleep."	A combination of cognitive therapy and behavioral treatments (eg, stimulus control, sleep restriction) is used, with or without relaxation therapy.
Guideline (moderate degree of clinical certainty and consensus)		
Multicomponent therapy (without cognitive therapy)	Multicomponent therapy is the use of various combinations of behavioral therapies (eg, stimulus control, relaxation, sleep restriction) and sleep hygiene education. Many therapists use some form of multimodal approach in treating chronic insomnia.	Determined by the healthcare provider.
Sleep restriction	Sleep restriction therapy initially limits the time in bed to the total sleep time, as derived from baseline sleep logs. This approach is intended to improve sleep continuity by using sleep restriction to enhance sleep drive. As sleep drive increases and the window of opportunity for sleep remains restricted, with daytime napping prohibited, sleep becomes more consolidated. When sleep continuity substantially improves, time in bed (TIB) is gradually increased, so as to provide sufficient sleep time for the client to feel rested during the day while preserving the newly acquired sleep consolidation. This approach is consistent with stimulus control goals in that it minimizes the amount of time spent in bed awake, which helps restore the association between bed and sleeping.	The client is instructed to do the following: • Maintain a sleep log and determine the mean total sleep time (TST) for the baseline period (eg, 1–2 weeks). • Set bedtime and wake-up times to approximate the mean TST to achieve a sleep efficiency (SE) > 85% over 7 days (to find the mean TST: Mean TST = {TST/TIB} × 100%); the goal is for the TIB (not < 5 hours) to approximate the TST. • Make weekly adjustments: • SE > 85% to 90% over 7 days: TIB can be

		increased by 15–20 minutes • SE < 80%: TIB can be further decreased by 15–20 minutes. • Repeat TIB adjustment every 7 days. *Note:* When sleep restriction is used, clients should be monitored for and cautioned about possible sleepiness.
Paradoxical intention	Paradoxical intention is a specific cognitive therapy in which the client is trained to confront the fear of staying awake and its potential effects. The objective is to eliminate a client's anxiety about sleep performance. A mental health clinician, not the occupational therapist, should address this issue.	Determined by the healthcare provider.
Biofeedback therapy	Biofeedback therapy trains the client to control some physiological variable through visual or auditory feedback. The objective is to reduce somatic arousal.	Determined by the healthcare provider.
Option (uncertain clinical use; insufficient, inconclusive, or conflicting evidence or conflicting expert opinions)		
Sleep hygiene therapy (no recommendation)	Sleep hygiene therapy involves teaching clients about healthy lifestyle practices that improve sleep. It should be used in conjunction with stimulus control, relaxation training, sleep restriction, or cognitive therapy.	Instructions include but are not limited to: keep a regular schedule; follow a healthy diet and get regular daytime exercise; create a quiet sleep environment; before bedtime, avoid napping, caffeine and other stimulants, nicotine, alcohol, excessive fluids, and stimulating activities.

[a]The American Academy of Sleep Medicine (AASM) has defined the levels *standard*, *guideline*, and *option* for recommendations on the treatment of chronic insomnia.

Adapted from Schutte-Rodin S, et al: Clinical guideline for the evaluation and management of chronic insomnia in adults, *J Clin Sleep Med* 4:487–504, 2008.

Risk factors for insomnia include advancing age; female gender; psychiatric, medical, or substance abuse problems; shift work; and possibly unemployment and lower socioeconomic status.[157] Individuals with comorbid medical and psychiatric conditions are at particularly increased risk; the insomnia rates in clients with psychiatric and chronic pain disorders are as high as 50% to 75%.[23,138,165]

The consequences of insomnia are impaired cognition, fatigue or tiredness, depressed mood or irritability, and impaired work or school performance.[102,138] Dement and Pelayo[52] described how a person with insomnia may talk about "trying" to go to sleep, whereas others say they "go" to sleep, and effort is not required.[52] People with chronic insomnia may get worse because their poor sleep leads them to think and behave negatively toward sleep. Gayle Greene, a professor of literature and women's studies, wrote a memoir about her insomnia and her lifelong search and research in this area.

The first thing to go is your sense of humor. Then goes the desire to do the things you used to do, then the desire to do anything at all. Parts of your body ache that you don't even know the names of, and your eyes forget how to focus. Words you once knew aren't there anymore, and there's less and less to say. People you once cared about fall by the way and you let them go, too.[71]

Comorbid insomnia refers to clients who have a medical or psychiatric diagnosis but also have symptoms of insomnia. Treatment begins by addressing the comorbid condition, such as treatment of major depression or pain.[157] Previously it was assumed that treating the condition would eliminate the insomnia, but it is now apparent that numerous psychological and behavioral factors develop that perpetuate the insomnia problem (Box 13.2).[157]

Box 13.2

Common Comorbid Disorders, Conditions, and Symptoms Seen With Insomnia

Neurological	Stroke, dementia, Parkinson's disease, seizure disorders, headache disorders, traumatic brain injury, peripheral neuropathy, chronic pain disorders, neuromuscular disorders
Cardiovascular	Angina, congestive heart failure, dyspnea, dysrhythmias
Pulmonary	Chronic obstructive pulmonary disease (COPD), emphysema, asthma, laryngospasm
Digestive	Reflux, peptic ulcer disease, cholelithiasis, colitis, irritable bowel syndrome
Genitourinary	Incontinence, benign prostatic hypertrophy, nocturia, enuresis, interstitial cystitis
Endocrine	Hypothyroidism, hyperthyroidism, diabetes mellitus
Musculoskeletal	Rheumatoid arthritis, osteoarthritis, fibromyalgia, Sjögren's syndrome, kyphosis
Reproductive	Pregnancy, menopause, menstrual cycle variations
Sleep disorders	Obstructive sleep apnea, central sleep apnea, restless legs syndrome, periodic limb movement disorder, circadian rhythm sleep disorders, parasomnias
Other	Allergies; rhinitis; sinusitis; bruxism; alcohol and other substance use, dependence, or withdrawal; cancer[102]; pain from any source[102]

From Schutte-Rodin S, et al: Clinical guideline for the evaluation and management of chronic insomnia in adults, *J Clin Sleep Med* 4:492, 2008.

Insomnia can be severe; it is a pervasive condition and should not be taken lightly. Most people who do not have chronic insomnia may have had the occasional sleepless night and may feel they can relate to a person whose insomnia is chronic. However, the occupational therapist working with a client with insomnia should show sensitivity and should not assume that he or she fully understands the situation; the therapist also must be able to recognize the need to refer the client to a specialist, if necessary.

Obstructive Sleep Apnea

Obstructive sleep apnea (OSA) can be a serious medical condition. It has been shown to affect 3% to 7% of men and 2% to 5% of women in the adult general population.[148] Untreated OSA impairs daytime functioning and can limit quality of life, accelerate multiple health risks, compromise public safety, and result in increased healthcare spending.[16] Despite increasing awareness by both the public and clinicians, OSA remains considerably underdiagnosed and undertreated.[16] The most common terminal events induced by OSA are heart attack, CVA, and accidents.[52] OSA is twice as common in men as in women before age 50, but the prevalence in the genders equalizes with age.[82]

OSA is one of several sleep-related breathing disorders (SRBD) that healthcare providers treat. In OSA the airway becomes blocked when a portion of the individual's airway slackens and collapses, blocking airflow. This causes the person to stop breathing and then awaken (though not usually fully wake up) throughout the night, sometimes hundreds of times. Apnea is defined as a complete cessation of airflow for a minimum of 10 seconds, regardless of whether there is oxygen desaturation or fragmented sleep. Hypopnea (shallow breathing) is defined as airflow decreased by 30% or more with oxygen desaturation of 3% to 4%.[77] The apnea/hypopnea index (AHI) is the frequency of abnormal breathing events per hour of sleep.[52] An AHI of 40 means that a person experiences complete or partial airflow blockage 40 times an hour.[52] Snoring and daytime sleepiness are prevalent symptoms of OSA (Box 13.3),[16] and recent research has shown that nocturia (waking one or more times a night to urinate) is comparable to snoring as a screening tool for OSA.[149,154] This constant awakening throughout the night can lead to severe daytime sleepiness and fatigue and higher rates of depression.[139] Furthermore, the decrease in oxygen levels throughout the night can cause an increase in blood pressure and can lead to cardiovascular disease.[52]

Box 13.3

Symptoms of Obstructive Sleep Apnea

- Snoring
- Witnessed apnea
- Excessive daytime sleepiness
- Morning headache
- Dry throat in the morning
- Depressive symptoms
- Erectile dysfunction
- Insomnia
- Impaired vigilance and memory

No treatment modalities are universally accepted or used by all clients with OSA; however, evidence indicates that several modalities can improve alertness or quality of life.[16] Currently, OSA is typically treated with a positive airway pressure (PAP) device that provides continuous positive airway pressure (CPAP, pronounced "C-pap") (Fig. 13.9), bilevel PAP (BPAP), or autotitrating PAP (APAP).[16] The client is fitted with a mask, from which a hose attaches to a generator that provides (for CPAP) a continuous flow of pressurized air through the nose to keep the airway open while the client sleeps. A variety of masks is available (Fig. 13.10), but the three general types are the nasal mask, nasal pillow, and full face mask (Fig. 13.11). CPAP has proved to be effective and is a standard for use in OSA.[103] It can be critical for reducing blood pressure in some clients[91] and has been found to eliminate apneas, improve sleep quality, reduce **excessive daytime sleepiness (EDS)**, and improve quality of life.[46] However, many people do not follow the recommendations for proper use of a CPAP; 29% to 93% of clients do not adhere to the therapeutic recommendation when adherence is defined as using the CPAP for more than 4 hours a night.[142]

FIG 13.9 Continuous positive airway pressure (CPAP) machines have dramatically decreased in size since they were first introduced. *Left,* The SleepEasy system (1985). *Right,* The DreamStation system (2016). (Courtesy Philips Respironics, Murrysville, PA.)

Internationally, adherence has also been shown to be poor. Researchers in Tianjin, China, found adherence to CPAP therapy to be about 50%[174]; many clients did not follow through, abandoned use of the device, or did not even purchase it in the first place. Swedish researchers described nonadherence as occurring for a variety of reasons, such as dry throat, difficulty adjusting the mask, mask leakage, disturbing noise, difficulty changing sleep positions with the mask on, dry eyes, and difficulty traveling with the device.[27] Other barriers to CPAP adherence include negative attitudes toward the CPAP machine, insufficient support from healthcare personnel and family, feelings of shame about the need for CPAP, reduced freedom, a desire to avoid lifelong treatment, claustrophobic thoughts, and anxiety about the technology itself.[27]

Other primary treatments for OSA include oral appliances or dental devices provided by dentists trained in this specialty, in addition to surgery to open the airway.[16,82] Oral appliance application is relatively simple and reversible and may be used for snoring and mild OSA.[52] Examples of dental appliances include molds for the teeth to move the lower jaw forward or a tongue retainer that pulls the tongue forward.[52] Surgical procedures may include removal of nasal polyps, tonsils, or redundant palatal tissue; advancement of the mandible (cutting of the bone of upper and lower jaw and pulling structures forward), and tracheostomy.[52] Weight reduction, topical nasal corticosteroid use, and positional therapies[16,118] are all within the guidelines of the AASM as possible treatments for OSA. Positional therapy, which involves sleeping in the nonsupine position and using pillows, is most useful (ie, normalizes the AHI) for clients who have less severe OSA, are less obese, and younger.[118] A pilot study showed that use of trained "peer buddies" who were successful in CPAP use increased adherence to CPAP therapy in a group of veterans newly diagnosed with OSA.[142]

If left untreated, OSA can have severe adverse effects on a client's functioning throughout the day. When a person is chronically sleep deprived, daytime function is affected by slowed thought processes, forgetfulness, slowed responses, and difficulty concentrating.[175] Clients who had sustained a CVA and had been treated in a hospital rehabilitation program were found to have a comorbid SRBD that predicted a poorer outcome in the functional recovery rate.[38] Researchers suspect that two processes contribute to decreased cognitive functioning in clients with OSA: nocturnal hypoxia (decreased oxygen to the brain) and fragmented sleep. Furthermore, as a group, OSA clients' risk of motor vehicle accidents is increased twofold. Research has also shown that sleep-disordered breathing precedes stroke and may contribute to its development.[96]

A small, qualitative study in Ireland looked at how occupations were affected in nine people diagnosed with OSA. The six men and three women participants were interviewed, and an overarching theme emerged: sleep apnea is a life-changing condition.[136] Five subthemes representing the life-altering aspects of OSA also became apparent: occupational participation, psychological well-being, relationships, executive functioning, and treatment. Participants reported inability to fully enjoy and partake in daily life, being forced into early retirement, having worries about the future, having relational/social difficulties, memory/executive function problems, and the need to use a CPAP (described as an "albatross" that must be lugged around until death) due to OSA.[136]

Considering the functional and cognitive impairments that can result from OSA, it is important for occupational therapists to ask clients about their sleep when evaluating those who may have a secondary diagnosis of OSA or symptoms that indicate an SRBD and referral to a physician. Functional-cognitive impairments may affect follow-through on home programs, safety, and ability to meet goals, and they can diminish the quality of life.

Since the mid-1990s it has been known that 60% to 70% of all stroke clients exhibit sleep-disordered breathing (SDB) as defined by an AHI of 10 episodes per hour.[22] As cited by Alessi et al.,[3] studies of older adults admitted to rehabilitation hospitals after a stroke showed that sleep apnea is commonplace,[96] is associated with lower admission functional levels, and results in poorer outcomes.[96,177]

Could it be that Mrs. Tanaka has a history of an undiagnosed SRBD? Or is the sleep disturbance the result of the CVA and location of the brain insult? Or is poor sleep hygiene in the hospital the biggest contributor to Mrs. Tanaka's sleep problems? It is critical for the occupational therapist treating Mrs. Tanaka to keep the physician informed about the client's sleepiness during treatment and her loud snoring, both of which can be indicators of OSA.

Restless Legs Syndrome and Periodic Limb Movement Disorder

Restless legs syndrome (RLS), also known as Willis-Ekborn disease,[33] is a common disease that affects a client's ability to fall asleep and stay asleep.[18] RLS affects 10% of adults in the United States, and the prevalence increases with age. The International Restless Legs Syndrome Study Group updated its guidelines for diagnosis of the disease to the following five criteria:

- An *urge to move the legs* is usually but not always accompanied by or felt to be caused by uncomfortable sensations (eg, creepy-crawly) in the legs.
- The urge to move the legs and any unpleasant sensations begin or *worsen during periods of rest or inactivity,* such as lying down or sitting.

- The urge to move the legs and any accompanying unpleasant sensations are *partially or totally relieved by movement*, such as walking, getting up, or stretching, at least as long as the activity continues.
- The urge to move the legs and any accompanying unpleasant sensations during rest or inactivity only occur or are *worse in the evening or night* rather than during the day.
- The occurrence of the previously listed features is *not due to other medical or behavior problems* (eg, muscle pain, leg edema, arthritis, leg cramps, positional problems, or foot tapping behaviors).[5]

The clinical significance of this disorder is determined by issues or impairments in social, occupational, educational or other areas of functioning and by their impact on sleep, energy and vitality, daily activities, behavior, and cognition or mood,[5] all of which are in the realm of occupational therapy.[12]

Many clients with comorbid conditions associated with RLS are treated by occupational therapists as in-clients or out-clients and in home health, nursing home, and other settings (Fig. 13.12). RLS symptoms can occur anytime in the day during prolonged immobilization (eg, a long car drive), but they typically occur in the evening, with increasing symptoms until bedtime. The urge to move the legs results in insomnia, the effects of which can be detrimental to occupational performance.

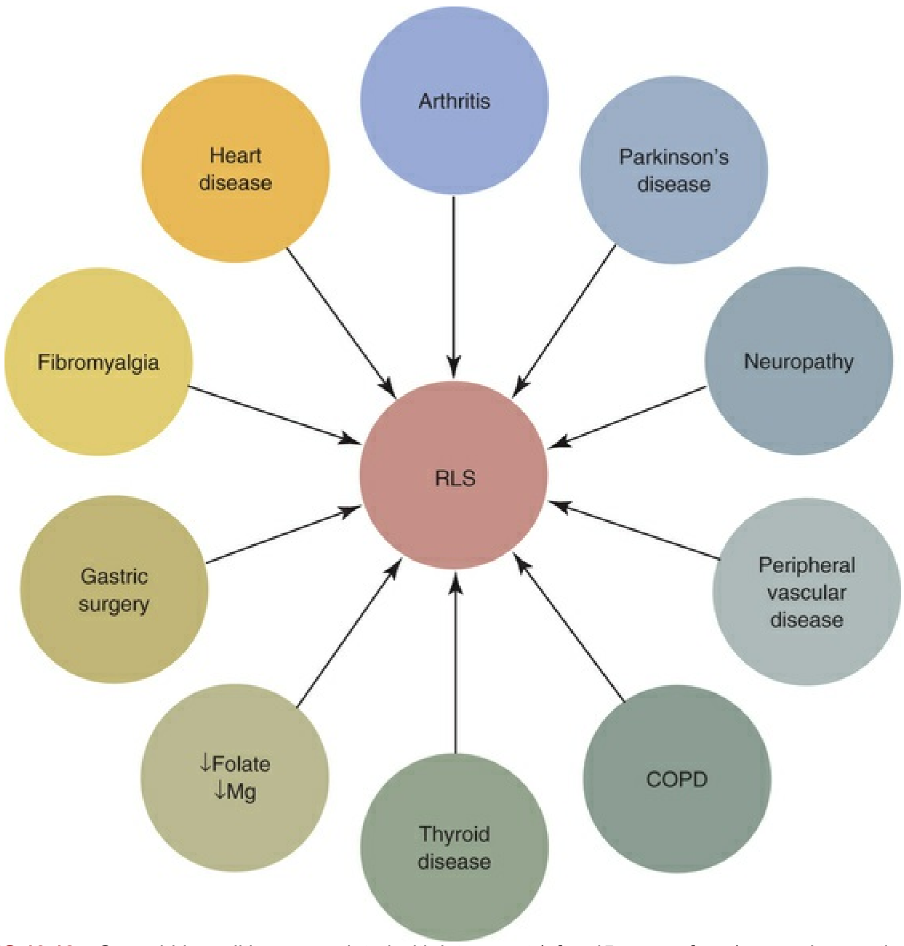

FIG 13.12 Comorbid conditions associated with late-onset (after 45 years of age) secondary restless legs syndrome (RLS). OTs treat many of these clients in their practice. *COPD*, Chronic obstructive pulmonary disease; *Mg*, magnesium. (From Avidon A: Restless legs syndrome and periodic limb movements in sleep. In Kryger MH, editor: *Atlas of clinical sleep medicine*, Philadelphia, 2010, Saunders Elsevier.)

Some believe that RLS is related to dopamine deficiency, whereas other hypotheses focus on brain iron deficiency. Current nonpharmacological treatment includes encouraging alerting (mentally challenging) activities, which have been found to relieve RLS symptoms, and avoiding caffeine, alcohol, and nicotine.[19] Because OTs focus on occupation and wellness, these are certainly areas in which practitioners can provide treatment.

Periodic limb movement disorder (PLMD) is frequently confused with RLS, but it is a different condition, although the two can coexist. PLMD affects up to 34% of clients over 60 years of age, and the prevalence increases with age. PLMD can be definitively diagnosed only with an EMG and a sleep study/PSG. In this disorder, a client has periodic episodes of repetitive and stereotyped movements of the limbs (arms or legs), which the client cannot control, during sleep. This results in client arousals or awakenings during sleep, which the client often doesn't recognize. The "creepy crawly" sensations present in RLS do not exist in PLMD. When PLMD is severe, clients experience excessive sleepiness, which can affect daytime functioning.[19]

Narcolepsy

Narcolepsy is a neurological sleep disorder characterized by EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations; it is most likely an autoimmune disease.[52] Cataplexy, sleep paralysis, and hypnagogic hallucinations are abnormal manifestations of REM sleep into wakefulness.[19] The excessive sleepiness is not relieved by adequate time sleeping.[19] Cataplexy, which affects 60% to 100% of individuals with narcolepsy,[19] manifests when a person has a sudden loss of postural and muscle tone during an emotional event such as laughter, joking, anger, excitation, startle, fear, and even sex.[19,52] The person is still conscious when the cataplexy occurs, and his or her breathing is normal.[19] People with this disorder have disturbed and fragmented nocturnal sleep. Sleep paralysis occurs at the start or end of sleep and is demonstrated by the fact that a person cannot move for a few seconds or minutes.[19,52] Hypnagogic hallucinations are characterized by vivid, dreamlike experiences that occur at the onset or end of sleep; they are generally frightful and visual but can be tactile or auditory.[19] The goal of therapeutic approaches is to control the narcoleptic symptoms, maintain wakefulness and alertness during the day, and allow the client to have full participation in life.[52] Good sleep hygiene, instruction in anticipation of attacks, behavioral treatments, and support groups may be important.[52]

Parkinson's Disease and Alzheimer's Disease

Alzheimer's disease (AD) and Parkinson's disease (PD) are not sleep disorders, but they are the two most common neurodegenerative disorders in our society.[119] Sleep disturbances are commonly reported in both PD and AD,[153] especially insomnia, hypersomnia, and excessive daytime napping.[119] The most commonly seen neurodegenerative disorder in a sleep disorders clinic is Parkinson's disease.[20]

Sleep problems are common in all forms of PD.[168] Among clients with PD, 60% to 90% have sleep complaints. A majority of clients with PD have sleep complaints that adversely affect sleep, including excessive sleepiness, insomnia, nightmares, and other sleep disorders. As the severity of the disease increases, sleep complaints also increase. Foster and Dixon et al[61] pointed out that people with PD are referred to occupational therapy when significant physical disabilities are present,[54] so clients referred to an OT may already have severe sleep complaints. Gregory et al.[76] found that the chronically disturbed sleep of a person with PD can also adversely affect the coping ability and sleep quality of the person's caregivers. Improved sleep hygiene is an important treatment that can be provided to this population, in addition to training in safe bed mobility, transfer training, and adaptive equipment (eg, bedside commode) for safety in toileting tasks.[20]

Nascimento et al.[119] studied the effects of a multimodal mild to moderate physical exercise program on 35 people diagnosed with AD and 42 subjects with PD in Brazil. Examples of exercises included calisthenics, resistive, balance. and aerobic exercises performed over a 6-month period by both PD and AD clients. The results showed a reduction in IADL deficits and attenuation of sleep disturbance in both groups.

Consequences of Poor Sleep

Sleepiness

The seemingly obvious but not so obvious consequence of sleep debt is sleepiness or drowsiness. Behavioral signs of sleepiness include yawning; ptosis (drooping of the upper eyelid); reduced activity; lapses in attention; head nodding,[152] with decreased animation; and head-drop, accompanied by sudden jerking up with a startle, which may indicate a "microsleep."[52] Dement and

Pelayo[52] suggested that the "real essence" of the onset of sleepiness is the awareness that remaining alert and attentive takes effort. Besides the embarrassment that may be caused by those behaviors in a public place, there are serious consequences to sleepiness.

The terms *sleepiness, fatigue,* and *somnolence* are sometimes used interchangeably. However, sleepiness should be distinguished from fatigue. Sleepiness is a sleep state that is characterized by the tendency to fall asleep, whereas fatigue is the exhaustion that occurs after exertion.[69] As cited by Bushnik et al.,[29] another definition of fatigue is "the awareness of a decreased capacity for physical and/or mental activity due to an imbalance in the availability, utilization and/or restoration of resources needed to perform activity."[2] Although many people, including sleep experts, use the word *somnolence* and *sleepiness* interchangeably, Gooneratne et al.[69] stated that the terms should not be considered the same. Somnolence is an impaired neurological state that can lead to lethargy or coma, whereas sleepiness is a tendency to fall asleep.

Roehr et al.[152] described sleepiness as a physiological need state, much like hunger or thirst. The body's desire to sleep cannot be met by resting, eating, taking a cold shower, or exercising. It can only be met by sleep. Researchers have quantified sleepiness by how readily subjects fall asleep, by subjects rating how likely they are to fall asleep in certain situations, and by subjects rating themselves on how they feel at the moment. The Multiple Sleep Latency Test (MSLT) is considered the standard method for quantifying sleepiness and is performed by trained sleep technologists.[52,152,161] With this test, subjects are placed in a dark room on a bed. The amount of time it takes the subject to fall asleep is measured every 2 hours during the waking hours on several occasions. Severely sleep-deprived individuals fall asleep instantly (zero sleep latency). Generally, many clinicians consider an average latency of 5 to 8 minutes to be consistent with EDS, a chronic state of inability to stay awake during the day that occurs when unintended; 10 to 12 minutes or longer is considered to be within normal limits.[39]

Research has shown that those who are the most sleep deprived, as evidenced by behavioral measures, are the least accurate in rating their sleepiness. Roehr et al.[152] speculated that adaptation to the chronic sleepiness state occurs, such that some people actually forget what complete alertness feels like. The researchers also reported that for those with mild to moderate sleepiness, subjective complaints of sleepiness and even its behavioral indicators can be masked by a number of factors, such as motivation, environment, posture, activity, light, and food intake. The researchers reported, "Heavy meals, warm rooms, boring lectures, and the monotony of long-distance automobile driving unmask physiologic sleepiness when it is present, but they do not cause it."[152] However, for those with significant and severe sleep debt, the ability to override sleepiness diminishes. Even in the most exciting environment, microsleeps (brief episode of sleep, usually NREM)[52] can occur, in addition to the likelihood of sleep onset. An example would be a person falling asleep while watching a live basketball game.

A healthy individual becoming sleepy while watching a sporting event is a relatively benign problem, if it is isolated. However, research has found that sleepiness can be a detriment to functioning. One study found that excessive sleepiness in the elderly without dementia or depression was associated with self-reports of moderate impairments in activities such as housework, sports, activities in the morning or evening, and keeping pace with others.[69] This study showed strong associations between having a number of medical conditions and reporting excessive sleepiness.

Other studies have shown that activities and positioning may affect sleepiness. One study showed that sleep latency increased by 6 minutes when the subject was sitting up rather than lying down. Sleep latency has also been shown to increase by 6 minutes when subjects went for a 5-minute walk before taking the MSLT.[24,25]

Instead of investigating behaviors (of purposefully not getting enough sleep), one group of researchers examined the clinical and PSG predictors of the natural history of EDS in a random population sample. Seven and a half years after the initial data were collected from 1741 individuals (known as the Penn State Adult Cohort), 1395 of them provided follow-up data. Obesity and weight gain were found to play a key role in the development and chronicity of EDS, and weight loss was associated with its remission.[60]

Many well-known disasters have been attributed to workers who were sleep deprived, including the Exxon *Valdez* oil spill (1989), the Three-Mile Island nuclear meltdown (1979), and the *Challenger* space shuttle explosion (1986).[42,49,192]

Countermeasures, or techniques and behaviors used to counteract the drive to fall asleep, are frequently used by sleepy drivers to try to stay awake. The National Sleep Foundation's 2012 poll found that pilots and train operators use caffeine more than controls to stay awake and alert on the job.[130] Staffan's small study in Sweden[160] used social media to find subjects to investigate the kinds of countermeasures used by people to avoid falling asleep while driving. The more common countermeasures included changing seat position, pulling off the road to get fresh air, increasing the fan speed, decreasing the temperature, turning on loud music, and opening windows, among others. Staffan suggested a mismatch between what researchers suggested (short naps) and how people actually behave when sleepy on the road. The research (sponsored by Volvo) suggested the possibility that cars of the future could be designed to include seats that automatically changed position, and systems that could change the temperature in the car or announce to the driver that he or she should get a cup of coffee.[160]

All these findings have implications for occupational therapists who work with sleepy clients in setting goals and creating treatment plans.

For Mrs. Tanaka, if medical or psychiatric conditions or medication problems are ruled out, occupational therapists can help ensure the client gets adequate sleep at night. If Mrs. Tanaka's sleep problem includes a shifted circadian rhythm, light exposure during treatment and between therapies during the day may help shift her circadian pattern so that she sleeps at night, not during the day. Treatment in an upright posture in a bright room may help keep her alert longer during treatment so that she can participate in therapy during the day.

Drowsy Driving

A March, 2011, report by the U.S. National Highway Traffic Safety Administration (NHTSA) found that drowsy driving was reportedly involved in 2.2% to 2.6% of fatal car crashes annually from 2005 to 2009.[123] However, in 2014 a study conducted by the AAA Foundation for Traffic Safety found that the numbers were much higher than reported by the NHTSA.[1] The AAA foundation study focused on the 14,268 crashes that occurred from 2009 to 2013 in which a vehicle was towed. The study found that a drowsy driver was involved in 7% of crashes in which a person received treatment for injuries sustained in a crash; 13% of crashes in which a person was hospitalized; and 21% of crashes in which a person was killed. If these proportions are applied to all reported crashes nationwide, results suggest that an average of 328,000 crashes annually, including 109,000 crashes that result in injuries and 6,400 fatal crashes, involve a drowsy driver.[1]

In another study, the NHTSA looked at data collected annually from 1991 to 2007 on fatal, single-vehicle crashes in which the car ran off the road.[122] The most influential factor in the occurrence of these fatal crashes was sleepiness. The NHTSA reported that a sleepy driver's odds of being involved in a run-off-the-road crash are more than three times higher than those for a driver who is not sleepy. In comparison, the odds of a driver with alcohol in his system (blood alcohol concentration = 0.01 + grams per deciliter) being in a similar crash are almost two times higher than those for a sober driver. Currently, of the 50 states in the United States, only New Jersey (Maggie's Law, passed in 2003) and Arkansas (SB 874, passed in 2013) consider falling asleep at the wheel and fatigued driving a criminal offense in a fatal crash if the driver is found not to have slept in 24 consecutive hours.[121] As of this writing, five other states have “Drowsy Driving Awareness Days” or weeks or have enacted laws to post road signs about the dangers of drowsy driving.[121]

Drowsy driving is a serious international concern. According to data from Australia and from England, Finland, and other European nations, all of which have more consistent crash reporting procedures than the United States, drowsy driving accounts for 10% to 30% of all crashes.[128]

The NSF has reported the following groups as most at risk of being involved in a fall-asleep crash:

- Young people, especially males under 26
- Shift workers and people with long work hours
- Commercial drivers, especially long-haul drivers
- People with undiagnosed or untreated disorders (for individuals with untreated OSA, the risk of falling asleep at the wheel is up to seven times higher)
- Business travelers who drive many hours or are jet lagged[131]

Most drowsy driving crashes happen between midnight and 6:00 am or in the midafternoon during the circadian dip. They typically occur when a driver is alone; they tend to involve a single vehicle running off the road and often hitting a stationary object; and, as opposed to alcohol-related driving, there may not be any evidence of the driver braking or taking evasive maneuvers.[125]

Shift Work

Research results suggesting that shift work can be deleterious to people's health are well documented. As previously mentioned, the invention of artificial light and the Industrial Revolution changed the work world so that people could now work around the clock. The prevalence of shift work sleep disorder that results in insomnia is estimated to be about 10% of the night and rotating shift worker population.[151]

Neuromuscular Disorders and Sleep

Individuals with neuromuscular disorders are considered in a "state of vulnerability" during sleep because normal REM-related changes, such as atonia and other changes in ventilation, are magnified as a result of muscle weakness. Sleep disturbance can also be related to spasticity, poor secretion clearance, sphincter dysfunction, inability to turn, pain, and any associated or secondary autonomic dysfunction. All these factors can impair sleep and decrease daytime functioning.[68] Individuals who rely on accessory muscles to breathe (eg, those with tetraplegia) are also in a vulnerable state during sleep. Indeed, research has shown that individuals with a spinal cord injury (SCI) have a two to five times greater prevalence of SDB than that seen in the general population.[155] Researchers suggest that all clients with SCI undergo full PSG studies to better detect sleep-disordered breathing because many such cases may go undetected with a limited sleep study recording.[155] Sleep disturbance also is a common consequence of traumatic brain injury (TBI),[141] and individuals with this condition are another group of clients that OTs treat.[55]

Other Consequences of Sleep Deprivation

Young et al.[189] noted that sleep deprivation can result in a multitude of negative physical and psychological consequences, even when the person is healthy. These negative consequences include but are not limited to hypertension,[65,137] decreased postural control,[59] possible obesity, and diabetes[67,100] and decreased insulin sensitivity (seen in a group of nondiabetic white males).[183] Inadequate sleep can also result in greater likelihood of falls.[163] In older adults the consequences of poor sleep are significant; they can include overall poorer health, physical function, and cognitive function, and increased mortality.[14]

Sleep Considerations in the Hospital Setting

As mentioned previously, inadequate sleep can have serious consequences in and of itself. Acute hospitalization combined with inadequate sleep can further hinder recovery. Studies have shown that approximately half of clients admitted to general medical wards complain of sleep disruption. Young et al.[189] found that clients who were hospitalized had difficulty initiating and maintaining sleep and complained of early awakening and nonrestorative sleep. Hospital sounds have been found to disrupt sleep even in healthy individuals.[30] Buxton et al.[30] studied the effects of typical sounds present in hospital settings on 12 healthy young subjects. They found that electronic sounds designed to alert medical staff were more arousing than other sounds and that even brief frequent noises can increase heart rates, which is especially important to consider in critical care settings. These researchers stressed that their study was conducted on young, healthy subjects, and that many hospital clients are older, have a decreased quality and quantity of deep sleep, and would be less able to tolerate the noises present in hospital settings.[30] They concluded that "protecting sleep from acoustic assault in hospital settings is a key goal in advancing the quality of care for in-client medicine."[30]

Hardin[80] reported that for more than 30 years (now 35+ years), sleep abnormalities have been documented in clients in the intensive care unit (ICU). Current research continues to show that ICU sounds and lights interrupt sleep and that earplugs, eye masks, and oral melatonin improve sleep quality in healthy subjects.[86] Environmental noises and client care activities account for about 30% of awakenings in ICU clients.[64] The noise levels in ICUs are found to be especially high.[114]

Although noise in the hospital is a concern, a study by Freedman et al.[62] suggested that nursing care activities, such as taking vital signs and giving sponge baths, may actually contribute more to client awakening than the environmental conditions. Bartick et al.[21] reported similar results in their study, which found that hospital staff was the factor most responsible for sleep disruption in clients and that behavioral interventions for hospital staff members can actually reduce the use of sedatives. A qualitative study by Hopper et al.[84] of nurses and physicians working in an ICU found multiple environmental barriers to sleep; in addition, the study found that attitudinal barriers also may contribute to sleep disruption in the ICU. Attitudinal barriers included staff uncertainty about the significance of sleep, the tensions of providing protocol-driven care versus allowing the client to sleep, and lack of consensus about interventions.[84]

The etiology of sleep disturbances in the hospital or institutional setting is multifactorial and can be related to a client's medical illness, medical treatments, and the environment.[189] Clients treated in a traditional rehabilitation setting may also have a higher likelihood of sleep disturbance. In one study[107] of 31 consecutively admitted clients, diagnosed with a closed head injury (CHI), who were admitted to a brain injury unit, 68% had sleep/wake cycle disturbance. Those with the aberrations in nighttime sleep had longer stays in both the acute and rehabilitation settings—an important consideration in an era of concern over high healthcare costs.

Taking account of these factors, it is important to consider Mrs. Tanaka's sleep patterns at the facility or unit prior to admission to the rehabilitation hospital or unit. Was Mrs. Tanaka in the ICU? How long was she there prior to admission to the rehabilitation unit? Was her sleep disturbed in that setting?

To Nap or Not to Nap?

According to the NSF, napping can be categorized in three ways:

- *Planned napping:* Also known as preparatory napping, planned napping involves taking a nap before one becomes sleepy. This type of nap is used when a person knows that a later bedtime than usual is planned for that day.
- *Emergency napping:* This type of nap occurs when a person suddenly realizes that sleep is imminent and that the activity he or she is engaged in will not be possible very shortly. This type of napping can be used to help a drowsy driver or a worker who is operating dangerous machinery.
- *Habitual napping:* This type of nap is taken at the same time every day and is frequently done by children or by adults who require an afternoon nap.[127]

The research has been mixed on whether it's a good idea for a person to nap during the day. The primary concerns are that napping fragments sleep and that consolidated nighttime sleep may be disrupted as a result. A study by Alessi et al.[3] suggested that sleep disruption is common and severe among older persons receiving in-client post-acute rehabilitation and that excessive daytime napping was associated with less functional recovery for up to 3 months after admission. As cited by Woods et al.,[184] other studies have shown that naps longer than 1½ hours in the afternoon can be associated with increased falls and hip fractures,[17] more night awakenings, and higher mortality.[164] In their study of nursing home residents with moderate to severe dementia, Woods et al.[184] found that excessive daytime naps may be linked to elevated evening cortisol levels, indicative of circadian rhythm dysregulation (phase delay).

In a large population-based study of middle- to older-aged cohorts of British citizens, associations were found between daytime napping and an increased risk of mortality from all causes and respiratory diseases.[106] Another study, conducted in China, suggested an association between frequent napping and a higher prevalence of type 2 diabetes in the older population.[104]

On the other hand, some researchers are finding benefits to napping and thus recommending short naps, and other researchers have found that daytime naps do not necessarily hinder night sleep. In their study of 100 community-dwelling older adults with typical age-related health issues, Dautovich et al.[48] found that naps do not hinder consolidated night sleep. A study by Payne et al.[144] added to a growing body of evidence suggesting that even a short daytime nap can be enough to produce marked memory advantages, and that these benefits can be selective for emotionally salient and adaptive information. A study of clients with myasthenia gravis found that naps longer than 5 minutes can mitigate symptoms of fatigue.[98] A still-limited but growing body of literature suggests that a daily afternoon nap may be a safe and effective means of increasing 24-hour sleep and improving waking functions.[32] Box 13.4 presents tips on napping.

Box 13.4

How to Take a Good Nap

- Keep the nap short. A 20- to 30-minute nap may be ideal, but even a few minutes has benefits. A longer nap may lead to post-sleep grogginess ("sleep inertia").
- Find a dark, quiet, cool place. Don't waste a lot of time getting to sleep. Dimming the light and reducing noise help most people fall asleep faster.
- Plan a nap in the afternoon instead of napping haphazardly.
- Time caffeine intake so that it does not coincide with the nap.
- Don't feel guilty about taking a nap. A good, well-timed nap can actually help increase productivity.

Modified from the Harvard Health Letter: How to take a good nap, Boston, 2009, Harvard Medical School Publications.[81]

The debate over whether naps are beneficial continues. Current research seems to indicate that shorter daytime naps (eg, 20–30 minutes) may be beneficial, but overly extended daytime naps (1½–2 hours) may actually have negative health effects. More research needs to be done in this area; the OT practitioner should keep up to date on current research and not simply rely on commonly held beliefs. For example, caregivers who work in nursing homes frequently view napping during the day as good for residents with dementia. However, they may not be aware of the potentially negative consequences of extended naps.[184]

Nocturia

Nocturia is defined as waking one or more times to void (urinate) at night. It is the most common lower urinary tract symptom.[26] Booth and McMillan[26] cited prevalence studies[89,156] indicating that nocturia increases in both genders with age. The most significant consequence of nocturia is sleep disturbance, with evidence of fatigue during the day affecting energy and activity.[15] Zeitzer et al.[191] examined the sleep and toileting patterns of 147 community-dwelling older men and women with insomnia and found that more than half of all reported awakenings were associated with nocturia. The need for more trips to the toilet was associated with decreased feelings of being rested and decreased sleep efficiency; thus, nocturia compounds the negative impact of insomnia.[191]

Obayashi et al.[135] reported similar results from their large-scale study of general community-dwelling older adults in Japan. They found an association between nocturnal voiding frequency and poor objective sleep quality (lower sleep efficiency, longer duration of wakefulness after sleep onset, and shorter duration of sleep latency). Other studies have shown an association between the risk of falls and nocturia, and that caregivers and other sleeping partners also are at risk of falls during the night and day because of fatigue due to sleep disruption.[15]

In an editorial on the study by Obayashi et al.,[135] Mehra[111] pointed out that nocturia is also highly prevalent in the nonelderly population, citing a study[43] that showed that in a U.S. sample, 31% reported voiding more than once a night, and 14% reported voiding two or more times a night. Mehra suggested that more research should be done on ways interventions could influence nocturia so as to improve sleep health.

When evaluating a client's ADL status, occupational therapists should always ask the client about his or her voiding habits at night. The frequency of voiding can alert the OT practitioner to sleep disturbances or other issues. Information on voiding habits also can help the OT determine whether the client is using safe toileting practices, and whether he or she needs durable medical equipment (eg, bedside commode), adaptive equipment, routines, splint/orthotic schedules, a safe environmental setup, or possibly referral to the client's physician to address problems in this area.

Hunjan and Twiss[87] suggested that OT practitioners embrace the practice of helping clients with urinary incontinence in general, not just nocturia. They offered behavioral strategies that can be explored, including evaluating schedules; implementing timed, scheduled, or prompted voids; seeking assistance as needed; modifying the diet (with the help of a dietitian); and managing fluids and medications (in consultation with the physician or healthcare provider)—all of which may also help with nocturia.

Occupational Therapy and Sleep

In current practice, a sleep disturbance may not be the primary reason a client seeks OT services. However, because it has been established that insufficient sleep can impair or negatively affect all occupations, this is clearly an important area to consider in OT treatment in all practice settings. Based on a 2010 survey of state OT regulatory boards,[9] the AOTA estimated that there were roughly 137,000 OT practitioners in the US workforce (102,500 OTs; 34,500 OT assistants [OTAs]). These numbers are expected to grow, especially considering the aging of the population. The Department of Labor's Bureau of Labor Statistics reported that as of May, 2014, the labor force included 142,750 OT practitioners (110,520 OTs and 32,230 OTAs).[170] These numbers could be higher because self-employed OT practitioners were not included.

Occupational therapists work in many settings, including hospitals, long-term care and skilled nursing facilities, home health, out-client rehabilitation clinics, psychiatric facilities, community health programs, schools, and academia.[13] OT practitioners in all practice settings are well educated about the occupations of sleep and rest; they therefore can have a significant positive impact on the general health of society.

Occupational Therapy Evaluation

It is important to obtain a thorough occupational profile of the client during the evaluation, including the client's history and experiences, patterns, interests, values, and needs.[12] The profile also should include questions about the client's sleep and rest patterns, routines, and habits. A thorough medical history and information on whether the client has a history of sleep disorders or difficulties are other elements of the profile. A standardized, valid measure, such as the Epworth Sleepiness Scale (ESS) (Fig. 13.13) or the Pittsburgh Sleep Quality Index (PSQI),[31] can be used to collect initial and later outcome information on sleep.

Epworth Sleepiness Scale

Using the following scale, circle the *most appropriate number* for each situation.

0 = Would doze *less than once a month*
1 = *Slight* chance of dozing
2 = *Moderate* chance of dozing
3 = *High* chance of dozing

Situation	Chance of Dozing			
Sitting and reading	0	1	2	3
Watching TV	0	1	2	3
Sitting, inactive in a public place (in a theater or in a meeting)	0	1	2	3
As a passenger in a car for an hour without a break	0	1	2	3
Lying down to rest in the afternoon (when circumstances permit)	0	1	2	3
Sitting and talking to someone	0	1	2	3
Sitting quietly after a lunch without alcohol	0	1	2	3
In a car, while stopped for a few minutes in the traffic	0	1	2	3

Add the 8 numbers you have circled **Total** _______

FIG 13.13 The Epworth Sleepiness Scale has been validated in clinical settings and can be used by occupational therapists to collect information for referring a client to a physician. A score of 10 or higher indicates excessive daytime sleepiness. A score of 6 is the norm. However, clients with insomnia can have scores in the normal range. A score of 12 to 24 may indicate a severe abnormality. (Modified from Johns MW: A new method for measuring daytime sleepiness: the Epworth Sleepiness Scale, *Sleep* 14:540–545, 1991.)

Fung et al.[63] found the Functional Outcome of Sleep Questionnaire[176] to be well suited to helping OTs understand the impact of sleep on function and daily occupational performance. They also suggested use of the Daily Cognitive-Communication and Sleep Profile,[181] another self-reporting instrument that investigates sleep/wake disturbances in terms of cognition, communication, and mood.

Occupational Therapy Intervention for Sleep and Rest

Leland et al.[105] conducted a scoping review/systematic summary of the literature on sleep interventions and identified four intervention areas in which OT practitioners can help clients with sleep: (1) cognitive behavioral therapy for insomnia, (2) physical activity, (3) multicomponent interventions, and (4) other intervention strategies that improve sleep and fall within OT's scope of practice. Physical activity included a variety of activities, such as stretching, resistance training, yoga, tai chi, Qigong, dancing, and running. Examples of multicomponent interventions included sleep restriction/compression, sleep hygiene, relaxation techniques, and bright lights. Other interventions included strategies such as earplugs, eye masks, light therapy, music, and headphones to help with sleep. With all these interventions, the emphasis was on consistent focus on modifying existing habits and routines, and participation in activity that followed adherence to sleep restriction/compression.[105] Fung et al.[63] suggested that OTs can provide education and interventions such as awareness of pain, energy levels, sleepiness, fatigue, and stress levels, in addition to environmental recommendations and strategies to pace activities (also see Chapter 7, Section 2).

According to the OTPF-3,[12] the types of OT intervention include therapeutic use of occupations and activities, preparatory methods and tasks, education and training, and advocacy and group interventions. All of these interventions can be used for treating clients in the occupations of sleep and rest. They are reviewed after the discussions of the therapeutic use of self and consultation.

Therapeutic Use of Self

The therapeutic use of self is a therapeutic agent (not necessarily an "intervention") that should be integral to the practice of occupational therapy and interwoven in all interactions with clients.[12] Therapeutic use of self allows OT practitioners to develop and manage their relationships with clients by using narrative and professional reasoning, empathy, and a client-centered and collaborative focus.[12] With therapeutic use of self, the OT practitioner can demonstrate caring and concern for the client or caregivers about the amount and quality of their rest and sleep. Sleep medicine is a relatively new discipline, so many physicians do not ask their clients about their sleep or don't recognize the signs of sleep disorders or issues.[58] Therefore, because of occupational therapy's attention to occupations, routines, and life balance, the OT practitioner may be the first to ask a client or caregiver about sleep concerns.

The OT practitioner can practice "mindful empathy," a mode of observing the client's emotions, needs, and motives while remaining objective.[166] For example, instead of judging a client for canceling appointments or not fully participating in treatment, the OT should actively listen to the client and reassess the situation; this approach could reveal a sleep-deprived client.

Therapeutic use of self also means that OT practitioners must be more knowledgeable and have competency in the areas of sleep and rest so as to help clients optimize their sleep and rest patterns. Becoming knowledgeable about sleep and sleep disorders can help the OT practitioner recognize any problems that may indicate severe sleep disturbance so the client can be referred to a physician or sleep specialist.

OT practitioners can also model good sleep practices, so that they are alert, safe, and functioning at their best when working with clients. In addition, OTs need to examine their own values about sleep and rest because attitudinal barriers on the part of the healthcare staff may affect the sleep of clients.[84] For example, do you consider sleep and rest a waste of time? Is a person lazy if he or she requires a nap during the afternoon?

Developing cultural competency is a "central skill" for using oneself therapeutically.[166] As previously mentioned, recognizing and appreciating diversity in sleep and rest are important because others' definitions, patterns, practices, and environments may completely differ from our own.

Mrs. Tanaka's views about and experiences with sleep, in addition to her sleep habits and patterns of sleep, are all important considerations in her treatment. For example, if Mrs. Tanaka's family reports that she always used a night-light to sleep and was afraid of the dark, the OT practitioner should not impose complete darkness in her room at night as a sleep hygiene technique (see Chapter 7, Section 2).

Consultation

Infused throughout the OTPF is the role of the OT providing consultation as a method of service delivery versus being considered a separate intervention.[12] Consultation takes place when practitioners provide services to clients indirectly on their behalf, such as within multidisciplinary teams or community agencies.[12] Occupational therapists can provide consultation in institutional settings where a 24-hour "on" schedule is frequently in place. Typical delivery of service addressing sleep and rest could include consulting with the treatment team and staff about providing an optimal sleep environment for clients at night. Or, the OT consultant might discuss with the team the necessity of middle of the night, nonurgent blood pressure readings, sponge baths, and blood draws, and recommend they be avoided. Providing training to night-shift aides, nurses, orderlies, and caregivers in bed mobility, bed positioning, transfer techniques, and body mechanics is another common form that OT consultation can take.

The occupational therapist also can act as a consultant in worksite settings, meeting with managers and administrators about the importance of sleep for optimal functioning and safety. The OT consultant can encourage balance in life for a more productive and safer workforce. West[178] pointed out that consultation services may be particularly useful in settings that employ shift workers (eg, hospitals, factories, airlines), providers of driver education, the military, and emergency relief programs.

Certified driver rehabilitation specialists (CDRSs), who are usually OT practitioners trained in driving and community mobility and OT generalists, can educate clients and the public about the dangers of drowsy driving. Occupational therapists who are specialists in adaptive driving and evaluation of disabled or at-risk individuals are usually the most up to date about regulations and information on driving, and they can act as consultants to other OT practitioners and healthcare professionals. The CDRS also can counsel clients on driving training or driver retirement when appropriate.

Occupational Therapy Interventions in Various Practice Settings[12]

Therapeutic Use of Occupations and Activities

Occupational therapy offers an abundance of therapeutic occupations and activities that can focus on helping the client have a healthy lifestyle balance and well-planned routines to ensure adequate rest and sleep. An activity configuration or pie chart can be used with the client to review occupations that are important to the client and to assess how time is spent and the portion of time allocated to each of the occupations.

Woods et al.[184] stated that nursing home staff or caregivers can alter daytime napping behavior to prevent prolonged napping in residents. The researchers suggested increasing physical activity and activity programs to increase engagement with the environment. Interventions that maintain a more normal sleep/wake cycle may help the person with dementia maintain a more normative cortisol diurnal rhythm. Increased daytime activities may decrease excessive daytime napping and mitigate sleep dysregulation.

Activities of Daily Living

Schedules.

Consider optimal times for ADL training; for example, if the client is a “night owl,” don't schedule training in showering and dressing for 7 am. Try to schedule certain ADLs at “customary” times, especially for clients with cognitive impairment (eg, work on dressing in the morning rather than at 1:30 pm) so that they become accustomed to a routine. Consult with other team members or family members and ensure that clients are getting sleep and rest. Keep track of sleep by using a sleep chart or diary. Schedule regular daytime naps (in bed, if possible; not in a wheelchair or recliner) or rest breaks if needed. Keep the medical team informed about the client's alertness during therapies.

Dressing.

If dressing is considered a usual habit for a client, dissuade the use of pajamas during the day and have clients dress in “street” clothes. Encourage pajamas or “usual” sleeping clothes at night while the client is on a rehabilitation unit or recovering from illness or injury at home. However, it is important to note that some clients regularly wear housecoats during the day. Some cultures may also deem it necessary to wear pajamas because the client is still considered “sick.”

Hygiene and grooming.

If a client normally shaves or wears makeup during the day, encourage this as part of the morning/daytime routine, if it is important to the client. Ensure that the client and caregiver have a routine for activities to get ready for the day and to go to sleep at night.

Bed positioning, bed mobility, the bed, and bedding

- *Bed positioning.* Train the client and caregivers in bed positioning to ensure comfort and optimal functioning. Are there enough pillows? Does the head of the bed need to be elevated? Does an extremity need to be elevated? Are there other precautions that need to be followed while the client is in bed (eg, total hip, logroll)? As previously mentioned, “positional therapy” was recommended as a practice guideline for medical professionals in the treatment of OSA. This type of positioning entails keeping clients in a nonsupine position, which has been found to be useful as a secondary therapy (to PAP therapy) for people with OSA.[118]
- *Bed mobility.* Train the client and caregivers in bed mobility techniques for safety. Assist in determining the optimal bed for the client to use to facilitate sleep, with consideration for skin protection, breathing, and mobility and transfer status at the forefront. Ensure that the client has easy access to a call light, and make or request adaptations to the call light if needed. Provide adaptive equipment for safe bed mobility, such as a transfer handle, bed rails, loops on bed rails, and a trapeze, as indicated.

- *Bed*. Consider the type of bed required for safety and independence in bed mobility, transfers and even to support relationships. Factors to consider include size; height for safe transfers; height if the client tends to fall out of bed (lower bed may be safer); whether the client co-sleeps; mattress materials (some absorb and retain heat, which can be an issue for people with thermoregulation problems, such as those with severe burns or tetraplegia, or women going through menopause); whether a mechanical bed (semielectric or full-electric) is required; whether the bed helps protect the skin, requiring fewer turns at night; and how the client with mobility problems can maneuver on a particular type of mattress. For example, some clients may find it more difficult to position themselves on a foam mattress than on a spring mattress.
- *Bedding*. If the client is going to be away from home, consider whether a special quilt or blanket from home may assist him or her to sleep, or whether particular textures for sheets may be more suitable during sleep for skin protection or comfort. The 2012 National Sleep Foundation Bedroom Poll[130] of 1500 Americans between the ages of 25 and 55 found that 92% of people said that a good mattress was important for good sleep; 91% identified pillows; and 85% mentioned bedding. Seventy-eight percent of the study subjects said that sheets with a fresh scent helped them become enthusiastic about going to sleep.

OT practitioners are well versed in bed positioning, mobility, and the use of durable medical equipment (DME), in addition to environmental setup; therefore, OTs are a natural fit when it comes to addressing these areas for sleep and rest concerns.

Transfers.

Train the client, caregivers, and family members in safe techniques for transferring onto a commode or other surfaces where transfers may occur at night.

Toileting.

Consider the most appropriate times for catheterization, voiding, and a bowel program to optimize rest and sleep. Ensure that any equipment (eg, commode, urinal) is readily available by the bedside or in the toileting area. Help the client and caregivers choose incontinence products, such as seat and bed protectors, disposable underwear ("pull-up" style), diapers, and so on. Discuss with the medical team, the client, and the caregivers the optimal toileting techniques to encourage sleep at night for all concerned and for safety. For example, if transfers are difficult for a male client, with the physician's approval a condom catheter initially can be used at night for urination rather than a commode.

Showering and bathing.

Consider the optimal time for a bath or shower to encourage sleep at night or wakefulness during the day to participate in therapies or daytime activities. Perhaps a morning shower would "wake up" a client. Or, the optimal time for a client to take a shower or bath may be at night, to help with sleep. The shower increases the core temperature, which then decreases to the optimal body temperature for sleep. Safety should be the primary consideration in determining showering and bathing times.

Eating and meals.

Work on feeding activities. Encourage the client to eat meals with the rest of the family in the family dining area, as appropriate, to ensure that daily rhythms are reinstated to help distinguish day from night. Avoid allowing the client to eat in bed, even the hospital bed, if possible. The appropriate dietary and fluid intakes and their timing should be discussed with the dietitian and physician.

Instrumental Activities of Daily Living

IADLs call for more advanced skills than basic ADLs and generally require use of executive functions.[78]

Homemaking, bed making, and laundry.

The 2012 National Sleep Foundation Bedroom Poll of 1500 Americans between the ages of 25 and 55 found that nearly 9 in 10 (88%) made their beds at least a few days a week.[130] Seven in 10 (71%)

made their beds every day or almost every day. Respondents living in the Northeast, women, older respondents and those married or partnered were more likely to make their beds every day or every other day. Those who made their beds every day or almost every day were more likely than those who did so less often, or not at all, to say that they got a good night's sleep every day or almost every day (44% vs. 37%).[130] These are interesting statistics to consider because bed making as an IADL is under the domain of OT and should not be forgotten. The same poll found that 53% of respondents rated sleeping on sheets with a fresh scent an important contributor to their sleep experience. More research is needed to determine whether fresh-smelling sheets actually help people sleep better, but it is an important consideration for an OT practitioner when working on laundry tasks with clients or when considering sleep environments in industrial or home settings.

Community mobility.

If clients are no longer deemed safe to drive because of sleep disorders, OT practitioners can train them in community mobility and alternative transit (see Chapter 11, Section 3).

Home Safety Evaluation

As appropriate, perform a home evaluation to ensure that the home is safe for transfers, toileting, and ambulation at night, and to determine any equipment needs (see Chapter 10). Suggestions can be made for bed placement, and night-lights and call bells can be set up as needed. Lighting and security are also important to facilitate sleep. Blackout curtains are frequently recommended, but sufficient lighting for safety in mobility is also important, as is a clean, uncluttered sleeping area. Confer with a physical therapist about optimal ambulation devices the client can use at night. According to Solet,[159] an OT and sleep researcher at Harvard Medical School, the optimal sleep environment is quiet, dark, cool, comfortable, and clean. She recommended that the OT help adapt and organize the sleep environment. Because the body temperature drops as part of the sleep cycle, a cooler bedroom is more conducive to sleep.[159] Solet also noted that clean environments are especially important to consider for people with allergies.[159]

Healthcare environment.

Check with the nursing staff before making changes to the environment, especially in the acute hospital setting. To encourage sleep, turn off lights, encourage a quiet room, turn off the TV, and close the door fully if needed and if safe. Consider whether the client may be overstimulated if too many items are posted on the wall. However, keep in mind that photos of loved ones and personal blankets and objects may provide comfort and a sense of security to a person in the hospital. For safety, make sure the floor is clear of clutter and obstructions. Make sure the temperature in the room is comfortable for the client to sleep. Extra blankets may be needed for clients who tend to get cold. Make sure call lights, water (if allowed), and a phone are accessible to the client before leaving the room. Bed rails should be up unless the medical team states that they may be down.

Leisure Activities, Social Participation, and Restorative Activities

Try to schedule treatments outdoors so that the client is exposed to light because it is the strongest zeitgeber (time cue) and can help to reset the biological clock if it is off kilter. Collaborate with the client and family to make sure activities selected are interesting and important for the client. Clients sometimes sleep during the day because they're bored. Encourage participation in activity groups, therapeutic recreation groups, and community events if it helps the client to sleep at night. Make suggestions for and encourage quiet restful evening activities. As mentioned previously, Howell and Pierce[85] have pointed out that occupations that are highly restorative tend to have strong routines of a simple and repetitive nature, are often considered pleasurable, and have personal meaning to the individual. West[178] has suggested relaxing activities such as reading, stretching, meditating, or praying before bedtime. Use of sleep preparatory activities such as visual imagery and massage can also be used.[178] Some evidence suggests that aromatherapy with essential oils such as lavender and chamomile may have some promise in helping to induce a state of mind that assists with sleep.[179] However, continued research is needed to find evidence of its effects on sleep architecture by polysomnography.[179]

Preparatory Methods and Tasks

Instruction and training in good sleep hygiene strategies can be considered preparatory activities to facilitate sleep.

Splint, exercise schedule, and pain.

Consider client sleep when giving splinting schedule instructions. Ensure proper fit for comfort so that the client can sleep. Make sure the splint schedule doesn't interfere with sleep or that the continuous passive motion (CPM) machine, typically used with clients who require a total knee replacement, doesn't keep the client awake all night. Collaborate with physical therapy about CPM use. Make sure exercises are performed at a time that will optimize sleep at night. Consider the client's pain levels and consult with the medical staff and physicians. Talk to the client about whether he or she is unable to sleep at night because of pain, edema, or immobility.

Sleep hygiene.

Sleep hygiene refers to activities involving lifestyle choices and environmental factors that can lead to healthy sleep. "Hygiene" does not just imply cleanliness, but generally stands for everyday habits to promote good health; "sleep hygiene" emphasizes proper habits to promote healthy sleep.[52] Sleep specialists provide sleep hygiene education with the intent of providing information about lifestyles and environments that either interfere with or promote sleep. OT practitioners can also provide sleep hygiene information to support healthy, active engagement in other areas of occupation (Box 13.5).[12]

Box 13.5

Important Considerations in Sleep Hygiene (OTPF-3)

Preparation of Oneself

- Developing routines that prepare one for comfortable sleep, such as grooming, undressing/dressing, reading, listening to music to fall asleep, saying goodnight to others, meditation or prayers
- Determining the time of day and length of time desired for sleeping or the time needed to wake
- Establishing patterns that support growth and health (patterns are personally and culturally determined)

Preparation of the Environment

- Making the bed or space in which to sleep
- Providing for warmth/coolness and protection
- Setting an alarm clock
- Securing the home (eg, locking doors, closing windows or curtains)
- Turning off electronics or lights

Participation in Actual Sleep

- Stopping all activities so as to ensure the onset of sleep, napping, and dreaming
- Sustaining a sleep state without disruption
- Ensuring nighttime care of toileting needs or hydration
- Negotiating needs of others in the social environment
- Interacting with those who share the sleeping space (eg, children or partners)

- Nighttime caregiving (eg, breastfeeding)
- Participating in activities to monitor the comfort and safety of others (eg, the family) while sleeping

Data from the American Occupational Therapy Association: Occupational therapy practice framework: domain and process, ed 3, *Am J Occup Ther* 68(Suppl 1):S1–S48, 2014. http://dx.doi.org/10.5014/ajot.2014.682006.12

According to Dement and Pelayo,[52] general guidelines for sleep hygiene are:

1. Create an optimal environment for sleep.
2. Reinforce predictability.
3. Avoid substances that negatively affect the sleep/wake cycle.
4. Follow good general health practices, which favor optimal sleep.

Box 13.6 provides more specific examples for each of these four categories.[52]

Box 13.6

General Recommendations for Sleep Hygiene

1. Create an optimal environment for sleep.

- Remember that the only activities that should occur in bed are sleep and sex (avoid reading, watching TV, texting, tweeting, or using other media or computer devices in bed).[101]
- In the hour before bedtime, turn off electronics. Research has shown that blue light from a television, personal computer, or tablet screen can interfere with sleep.[66] Culture and generational differences should be considered. Kaji and Shigeta[95] found that Japanese teenagers considered their mobile device a "teddy bear" that provided reassurance that they could connect to friends if needed.[162]
- Prepare a quiet environment for sleep or use "white noise" to foster sleep.[101]
- Ensure that the environment is dark, quiet, comfortable, cool,[66] and clean.[159]

2. Reinforce predictability (and activity).

- Develop a regular sleep/wake cycle. Use an alarm clock if needed.[52]
- Develop a relaxing routine before bedtime.
- Avoid mentally stimulating or arousing activities before bedtime.[97]
- Keep a sleep diary, which is considered the gold standard for subjective sleep assessment.[34] Sleep diaries are currently not standardized. However, insomnia experts, with feedback from potential users, have created a Consensus Sleep Diary, which is considered a living document.[34] In addition, the National Sleep Foundation (NSF) has created the NSF Official Sleep Diary.[126]
- If a person can't fall asleep within a reasonable amount of time (eg, 15 minutes) while in bed, he or she should leave the bed, go to another room, or perform another activity until the individual feels sleepy. Mindfulness-based activities (eg, mental body scanning, deep breathing) may be considered for those who cannot readily hop out of bed.[94]

3. Avoid substances that negatively affect the sleep/wake cycle.

- Do not use alcohol to fall asleep. Alcohol can make snoring and obstructive sleep apnea (OSA) worse. Evidence exists that three to five glasses of alcohol in the evening can cause arousal when the effects of the alcohol wear off.[49,52]

- Do not use caffeine prior to sleep. Caffeine has a half-life of 3.5 to 5 hours, depending on a person's age, activity level, or body chemistry; this means that it could remain in the body for many hours after ingesting it.[49,112] Keep in mind that besides coffee, some teas, soft drinks, and chocolate also contain caffeine.[49,112]

- Avoid medicines that will keep a person awake at night. Confer with a prescriber about medications taken at night, particularly those that affect sleep occupations (eg, diuretics taken at night).[189]

4. Follow good general health practices (eg, exercise, diet, timing of meals), which favor optimal sleep.

- Exercise daily, but do not do vigorous exercise in the 2 hours before bedtime.[66] Research has shown that participation in an exercise training program can have positive effects on sleep quality in middle-aged and older adults.[187]

- Avoid going to bed with a full stomach; try to finish dinner at least 2 hours before bedtime.[66]

- Avoid spicy foods and heavy eating in the evening, but do not go to bed when hungry.[52]

- Limit liquids at night. Talk to a healthcare provider about this.

Education and Training

In the healthcare setting, the occupational therapist can educate and empower the client and family to set a strict visitation schedule, if necessary, to dissuade visitors from arriving at night or during scheduled rest times, which may interrupt rest and sleep. OT practitioners can help empower caregivers to limit visits to short periods, or they can help with the enforcement of visitation rules. The occupational therapist can educate caregivers about sleep and make sure they realize how important it is for them to get their own rest and sleep.

Some institutions require doors in rooms to be open at night despite the lights and noise. Education can be provided to staff about how best to facilitate sleep in these settings. Young et al.[190] suggested several strategies, including offering earplugs and eye masks, encouraging regular nocturnal sleep time, and discouraging long daytime naps. Other suggestions included encouraging the medical staff to minimize nighttime bathing, dressing changes of wounds, or other medical procedures and to avoid discussing emotionally charged topics with the client at night.

OT practitioners can also train people in pain awareness and management, energy levels (work simplification techniques), sleepiness and fatigue, time management, and cognitive behavioral techniques.[63]

OT instructors can educate their students about the consequences of sleep deprivation; as college and graduate students, they are a group known to be at risk for erratic sleep behaviors and significant sleep debt. If afternoon classes are scheduled, more “active” class activities may be required to fend off sleepiness for instructors and students during the circadian clock's “sleepiness” times. During short breaks for longer classes, instructors can encourage students to stand up, stretch, or walk around instead of remaining in their chairs to check their mobile devices. Occupational therapy and occupational science educators can coordinate assignment due dates and spread them out to encourage balance for the instructor and students and to ensure proper sleep for both.

Green et al.[74] noted that many clients complain of lack of information about the management of insomnia. Occupational therapists can provide education to the sleep-deprived public in community practice settings.

Advocacy

OT practitioners can provide services in the form of advocacy to their clients.[12] The OTPF-3 defines clients as individuals, groups, or populations.[12] Advocacy as an OT service involves more than just education; it includes follow-up and an assertive voice and action to ensure that people's needs are met. Advocacy is defined as an “act of pleading, supporting, recommending; active espousal.”[53]

For occupational therapists, advocacy can take any of the following forms.

- *Individuals:* Simply asking clients about their rest and sleep is the first step in advocacy. If the assessment indicates problems with sleep and rest, notify the physician. If indicated, recommend to the primary care physician that a sleep specialist be consulted. Inform the treatment team of poor function due to inadequate sleep. Encourage families and friends to abide by hospital visitation rules if the client lives (temporarily or permanently) in a facility. Advocate for appropriate environments for adequate rest and sleep. Through detailed documentation or calls to vendors, advocate for timeliness for appropriate DME and adaptive equipment to maximize sleep; examples include a hospital bed, mattress with skin protection, diapers, pads, urinal, and appropriate pillows. Ensure follow-through with adequate client positioning by nursing staff and caregivers; talk to the treatment team about adequate pain control to maximize sleep.
- *Groups:* Advocate for appropriate sleep and nap environments in any number of settings. For example, in day healthcare centers for frail older adults or dementia activity centers where seniors may stay all day, promote the creation of nap or rest areas. Options for reclining and lounging should be provided, in addition to just dining-type chairs. Ensure that workers, injured or not, have appropriate sleep and rest to perform their jobs. Advocate for students in OT educational settings to have adequate sleep and rest.
- *Oneself and the role of the OT profession:* Educate others on the role of OT in sleep. Advocate for more involvement of OTs in IADL, leisure, and rest activities, not just basic ADLs, so that clients will have meaningful activity to engage in during the daytime to avoid prolonged napping due to boredom. In an evidence-based review of the literature on OT intervention for people who had had a CVA, Wolf et al.[182] found an overemphasis on ADLs, with less attention paid to other areas of occupation, such as leisure, social participation, rest and sleep, and work and productivity.[182] As the authors noted, "In general, regardless of diagnosis, occupational therapy is too focused on ADL performance, which limits practitioners' role in the other areas of occupation that are meaningful to clients."[182]
- *Populations:* The NSF has produced educational materials and fact sheets to educate the public about the dangers of drowsy driving. It also created the National Sleep Foundation 2014 Drowsy Driving Advocacy Kit, which provides ideas on resources for advocacy at a statewide level.[132] School times for high school students in metropolitan Minneapolis were shifted to match adolescent circadian rhythms (ie, later school start times), and a subsequent study[171] found statistically significant improvements in graduation rates, rates of continuous enrollment, tardiness, and attendance. OT practitioners can be involved in future research in this area or in political advocacy.

In addition to individual client treatment, the topics of sleep and rest lend themselves well to group OT sessions, as is discussed in the next section. Marilyn B. Cole's book, *Group Dynamics in Occupational Therapy: The Theoretical Basis and Practice Application of Group Intervention,* fourth edition (2012), offers the beginning OT student or novice group leader a helpful seven-step format for leading groups. Experienced group leaders can also benefit from this book.

Group Interventions

OTs should develop cognitive strategies to help manage negative, anxiety-producing thoughts and concerns.[97] These strategies can be used successfully in both group and individual interventions.[73] Examples of negative, anxiety-producing thoughts are, "I'll never sleep again," or "It's already 2 o'clock in the morning, and I have to wake up in four hours." Occupational therapists can consider training in CBT-I. CBT-I usually focuses on modifying unhealthy sleep habits, reducing autonomic and cognitive arousals, altering dysfunctional beliefs and attitudes about sleep, and educating clients about healthier sleep hygiene practices. Research has supported the use of CBT in groups as a nonpharmacological treatment for sleep disturbance.[90]

In a 2013 article in *OT Practice,* a magazine published by the AOTA, Gentry and Loveland[66] discussed how an OT and a recreational therapist co-led a 10-week sleep hygiene therapy group for military veterans. The group sessions were attended by 20 to 25 members and lasted 90 minutes. The leaders led discussions on topics such as the nature of sleep, sleep-related problems. and nightmares because many members had post-traumatic stress disorder (PTSD). The group leaders reported that participants felt healthier and more engaged in daily life after attending the group sessions.

Gentry and Loveland[66] also provided suggestions for documentation and the use of Current Procedural Terminology (CPT) codes when billing for sleep-related services in the United States. CPT codes are maintained by the American Medical Association and are important for billing purposes in the United States.[66]

Determining When to Refer a Client to a Physician or Sleep Specialist

Refer the client to a physician or sleep specialist if he or she complains of any of the following conditions[58]:

- Has trouble initiating sleep or getting restful sleep for more than a month or two
- Does not feel rested despite getting the usual amount of sleep or more sleep than he or she is accustomed to getting to feel rested
- Falls asleep at inappropriate times, even though he or she is getting $7\frac{1}{2}$ to 8 hours of sleep
- Has been told that he or she snores loudly or gasps and has periods of not breathing that disrupt a bed partner or roommate
- Has to sleep in a different room because a bed partner claims the client's snoring is too disruptive
- Follows good sleep hygiene habits but still has difficulty sleeping

Other reasons to refer a client to a physician or sleep specialist are:

- Caregivers complain that the client is awake all night and sleeps all day.
- A cognitively impaired client is not able to report clearly his or her sleep habits but has obviously declined in occupational performance areas (eg, ADLs, mobility) and you suspect poor sleep.
- The client falls asleep regularly during your treatment in the daytime.

If appropriate, have the client fill out a sleepiness scale, such as the Epworth Sleepiness Scale (see Fig. 13.13), which has been validated in clinical settings.[92] A score of 10 or higher indicates EDS; a score of 6 is the norm.[192] Present the data to the client's physician, and notify him or her of the client's deficits in occupational performance or other symptoms resulting from sleep deprivation.

Summary

Historically, occupational therapists and occupational scientists have been interested in the importance of helping clients maintain a healthy, balanced lifestyle.[40] Included in that balance should be adequate sleep and rest, two “restorative” occupations.[146] According to the OTPF-2[10] and OTPF-3, the category of sleep and rest is considered a major occupational performance area that is in the domain of OT practice; accordingly, addressing this area in all practice settings is appropriate.

Occupational therapists have not traditionally treated clients whose diagnosis or problem has been primarily a sleep disorder. However, the sleep medicine literature abounds with information about the deleterious effects of sleep deprivation, including the effects on the at-risk clients occupational therapists treat daily in physical disability and other practice settings. Although occupational therapy has not focused research or practice on rest and sleep, sleep medicine research affirms what OT practitioners have known all along: Humans need to sleep, and they need to rest. Otherwise, occupational performance declines, negatively affecting a person's quality of life and health.

However, compelling evidence suggests that occupational therapists could and should put more emphasis, research, and practice into helping clients who have sleep difficulties. A study in Scotland of 38 healthcare professionals (including 19 occupational therapists) who took a 3-day course on sleep in people with Parkinson's disease showed that cognitive behavioral sleep management can be successfully transferred to healthcare professionals who were not sleep specialists.[76] Clients who were seen by the healthcare professionals who took the course reported reduced anxiety over sleep problems, better ability to manage sleep, and more of a sense of control over sleep.[76]

Solet points out that there are ten influences on sleep: exercise activity levels, sleep schedule, bed partner/pets, caffeine/alcohol/medications, psychological state, age/gender/genetics, cultural norms/social context/“lifestyle,” light/circadian drive, sleep environment and sleep debt.[159] The only area that occupational therapists cannot influence from that list is age/gender/genetics.

An emerging body of research shows that purpose in life is linked with a variety of healthy behaviors, positive health outcomes, longevity, and a lower incidence of sleep disturbances.[99] In a nationally representative sample of U.S. adults over age 50, Kim et al.[99] found that purpose showed an independent association with sleep disturbances, even after adjusting for psychological distress such as anxiety and depression. This finding may suggest that purpose is important for good sleep above and beyond the absence of negative psychological factors. Further research is needed, but interventions to enhance purpose in life could be an approach for reducing sleep disturbances.[99]

Another important client factor, spirituality, is not considered the same as religion; the OTPF-3 describes it as “the aspect of humanity that refers to the way individuals seek and express meaning and purpose …”[12] (OTPF-3, p. S7).[147] Waite[172] offered ideas on how OT practitioners can incorporate spirituality into practice.

OT practitioners are in the front lines of those working closely with clients who must cope with life-altering events. They help people face the realities of needing to change or alter their life course. OT practice emphasizes the occupational nature of humans' drive to achieve a healthful, productive, and satisfying (meaningful) life[12]; thus, OT practitioners are primed to help people find meaning through occupation, even when their lives have been drastically altered.

Reflecting on the case of Mrs. Tanaka, it is evident that OT practitioners can help make a difference in her rehabilitation outcomes by focusing on her sleep disturbance, once medical issues have been ruled out. A multitude of reasons may explain Mrs. Tanaka's sleep disturbance. The exact location of her brain injury may help the medical team determine whether the disturbance is organic, but further study may also reveal a sleep disorder. An OT practitioner who is educated and attuned to Mrs. Tanaka's sleep and rest needs can help her reach her rehabilitation goals and improve her quality of life.

Review Questions

1. What is sleep architecture?
2. How does sleep architecture change as we age?
3. What is REM sleep, and how does it differ from NREM sleep?
4. Why should OT practitioners address sleep in their practice?
5. What is the difference between sleep and rest?
6. Where does the area of sleep and rest fit into the OTPF-3?
7. What is sleep hygiene?
8. What is the Multiple Sleep Latency Test? What is the Epworth Sleepiness Scale?
9. When is it appropriate to refer a client to a physician or sleep specialist?
10. How can an occupational therapist help improve a client's sleep hygiene in a hospital setting?
11. Name at least five consequences of inadequate sleep.
12. What is obstructive sleep apnea, and what are some signs and symptoms of the disorder?

Work Evaluation and Work Programs

Denise Haruko Ha, Jill J. Page, Christine M. Wietlisbach

CHAPTER OUTLINE

LEARNING OBJECTIVES

After studying this chapter, the student or practitioner will be able to do the following:

1. Understand the role of occupational therapy in the development of work programs.
2. Describe the different types of work evaluation and work programs that are currently being practiced.
3. Identify the components of an industrial rehabilitation program.
4. Understand the difference between work hardening and work conditioning.
5. Identify the aspects of a well-designed functional capacity evaluation.
6. Explain the importance of reliability and validity in the context of evaluation.
7. Understand the differences between job demands analysis, ergonomic evaluation/hazard identification, and worksite evaluation.
8. Discuss the application of job demands analysis.
9. Discuss basic ergonomic interventions.
10. Describe the components of injury prevention programs.
11. Describe school-to-work transition services.
12. Describe the purpose of a work readiness program.
13. Identify various community-based work programs.

KEY TERMS

Ergonomic evaluation
Ergonomics
Essential tasks
Functional capacity evaluation
General vocational evaluation
Industrial rehabilitation
Job demands analysis
Primary prevention
Secondary prevention
Specific vocational evaluation
System theory
Tertiary prevention
Vocational evaluation
Work conditioning
Work hardening

Work readiness program
Work-related musculoskeletal disorders
Worksite evaluations

Threaded Case Study

Joe, Lorna, and Henry, Part 1

Joe is a 26-year-old man who worked two jobs to support himself and his daughter, who lived with his ex-wife. He worked as a janitor during the day at a hotel and spa and cleaned offices at night. Because of a motor vehicle accident, he sustained a T11 spinal cord injury, which resulted in complete paralysis of his legs. This injury affected his mobility, strength, and effort, so he could not return to janitorial work because he would not be able to effectively carry out the essential functions of the job from a wheelchair. Fortunately, one of Joe's employers, the hotel and spa, liked him because he was a good worker and was willing to offer him an alternative job as a laundry attendant if he could meet the physical demands of the job. Joe was referred to occupational therapy by his physician.

Lorna is a 39-year-old single mother who has been working at the same job in a St. Louis upholstery factory for the past 20 years. Lorna's job is to pull heavy fabric tightly over a padded wooden frame and then staple the fabric to the frame. Once she is finished stapling, she pushes the piece of furniture over to a coworker, who checks her work and then wraps the piece of furniture in thick plastic. It is hard work, and her hands and back often ache at the end of the day from pulling the fabric tightly, using the heavy staple gun, and handling the awkward furniture. With the holidays approaching, Lorna and coworkers decided to put in extra hours to make some additional money to buy presents for their children. Lorna is now experiencing significant pain, numbness, and tingling in her hands. She can no longer just shake her hands out to make it go away. She is having trouble holding onto the fabric and often drops the staple gun. She has had to take a few days off work because of the pain in her back and hands.

Henry is a 42-year-old father and husband who has been supporting his family by working as a roofer for the past 15 years. On one of his work assignments he fell off the roof and sustained a traumatic brain injury and a couple of lower extremity fractures. As a result, his motor and praxis skills, sensory-perceptual skills, cognitive skills, emotional regulation skills, and communication and social skills have been affected. He has been receiving worker's compensation for 2 years; Henry now feels ready to return to some type of work but does not know what he can do. He has enough insight to know that he cannot return to roofing but would like to do something with his life.

Critical Thinking Questions

As you read through the following information on occupational therapy work evaluation and intervention, keep in mind the circumstances of Joe, Lorna, and Henry to determine which services they may benefit from most.

1. What type of evaluation and services could occupational therapy offer to assist Joe, his physician, and the employer?

2. What occupational therapy interventions can help Lorna and her work environment?

3. What work-related occupational therapy services can help Henry discover what type of work he can do at this point?

One of the most significant occupations in which adults engage is work. A stable job provides the means to fulfill the most basic physiological and safety requirements that humans need to survive and thrive: food and water, a safe place to sleep, and the security of knowing that these resources will continue to be available. For many, belonging and esteem needs are also met at the workplace. Anything that prevents an adult from participating in the occupation of work will have significant consequences for that individual's health and well-being. According to the Office of Disability Employment Policy of the U.S. Department of Labor, in 2014, 17.1% of the labor force consisted of people with disabilities. The unemployment rate for those with disabilities was 12.5%. Occupational therapy practitioners play a key role in helping workers maintain their employment despite the symptoms they experience; they also facilitate an individual's entry or reentry into the workforce.

History of Occupational Therapy Involvement in Work Programs

The therapeutic use of work has always been a core tenet of occupational therapy, since the inception of the profession.[32] Work programs have their roots in efforts to help those with mental illness during the moral treatment movement, which started in Europe in the late 18th and early 19th centuries.[77] In 1801 Philippe Pinel, one of the founders of moral treatment, introduced work treatment in the Bicentre Asylum for the Insane. He suggested that "prescribed physical exercises and manual occupations should be employed in all mental hospitals … Rigorously executed manual labor is the best method of securing good morale … The return of convalescent patients to their previous interests, to industriousness and perseverance have always been for me the best omen of a final recovery."[80] Later in the 1800s, several psychiatric settings instituted productive activity programs.

In 1914 George Barton, one of the founding fathers of the occupational therapy profession, who was disabled by tuberculosis and a foot amputation, established the Consolation House in New York.[89] This program enabled convalescents to use occupations to return to productive living.[89] Barton stated, "The purpose of work was to divert the mind, exercise the body, and relieve the monotony and boredom of illness."[83]

In 1915 Eleanor Clarke Slagle, another founder of the occupational therapy profession, was hired to create a program for persons with mental or physical disabilities that would enable them to work and become self-sufficient.[89] The program was located at Hull House, a settlement house in Chicago, and was funded by philanthropic contributions. The participants involved in the program produced goods such as baskets, needlework, toys, rugs, and cabinets while developing manual skills and receiving wages for their work.

The early leaders of occupational therapy identified the importance of work when defining the profession's focus and purpose. Adolph Meyer, a psychiatrist who emigrated from Germany at the time and was an early proponent of moral treatment, observed that healthy living involved a "blending of work and pleasure."[61] Dr. Herbert Hall helped establish a medical workshop at Massachusetts General Hospital in Boston, where clients were involved in "work cure."[30] In this workshop clients produced marketable goods and received a share of the profits. The focus of treatment in these curative workshops was to restore the impaired body part to as normal function as possible, with the goal of returning the client to work.

While this curative workshop movement was transpiring on the East Coast, similar programs were developing elsewhere in the United States. For example, at the Los Angeles County Poor Farm, now recognized as Rancho Los Amigos National Rehabilitation Center in Downey, California, "all inmates were requested to do an amount of work that was commensurate with their physical strength and mental capacity, which was determined by the admitting doctor."[27] Inmates used woodworking machinery to build a large amount of furniture, which was used at the farm. Commodes, bedside tables, wheelchair tables, park benches, cabinets, and other items were built in the shops. In later years, when there was a true occupational therapy department, patients made Navajo-type rugs, rag or braided rugs, brushes, shawls, pottery, pictures, baskets, and leatherwork (Fig. 14.1A). Patients took special occupational therapy classes "which were designed to enable those who are crippled, blinded, or otherwise handicapped to make themselves useful" by producing articles that could be used at the County Farm or sold to employees or the California Crafts and Industries Society in Los Angeles (Fig. 14.1B).[27]

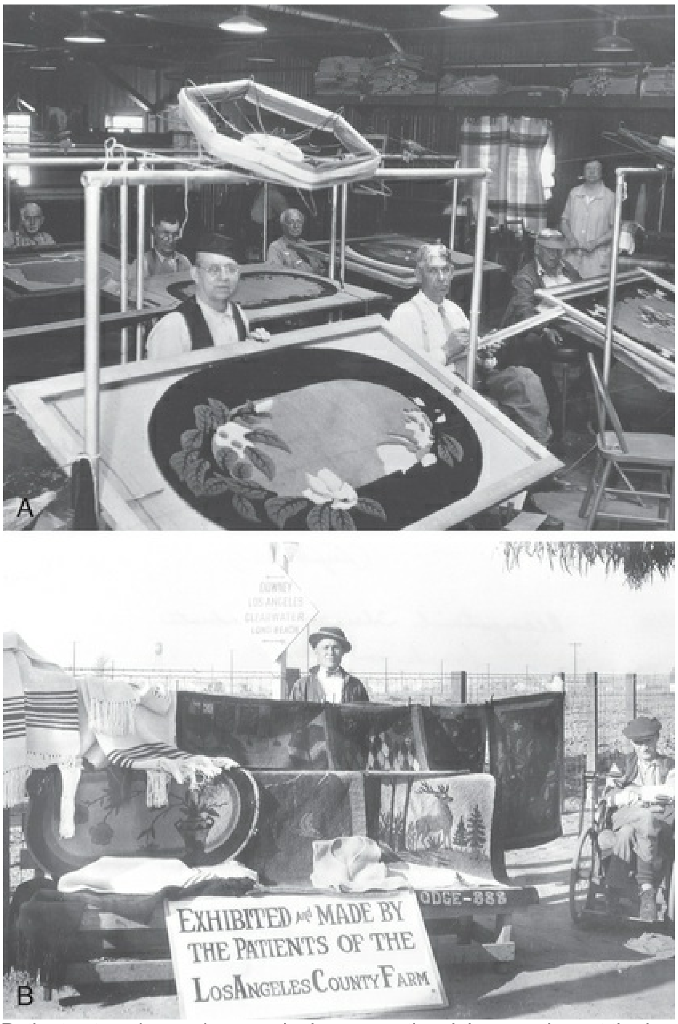

FIG 14.1 **A,** Patients at work weaving rugs in the occupational therapy shop at the Los Angeles (LA) County Poor Farm. **B,** Patients with a display of their products made at the LA County Poor Farm. (From Fliedner CA: Occupational therapy: for the body and the mind. In Rodgers GM, editor: *Centennial Rancho Los Amigos Medical Center 1888-1988,* Downey, CA, 1990, Rancho Los Amigos Medical Center.)

In the early 1900s the medical profession did not seem to consider vocational readiness programs to be important. The focus of care for persons with physical illnesses was primarily palliative and involved immobilization and bed rest. This attitude shifted after World War I, with the need to rehabilitate the large number of injured soldiers to help them become functional and gain employment.

The U.S. Federal Board for Vocational Education (FBVE) was created after adoption of the Vocational Education Act of 1917.[42] In 1918 the Division of Orthopaedic Surgery in the Medical Department of the Army organized a reconstruction program for disabled soldiers.[77] One of the founders of occupational therapy, Thomas Kidner, served as an advisor. This program led to the development of reconstruction aides, who were the precursors to occupational and physical therapists. Treatment involved both handicrafts and vocational education. The reconstruction aides used work activities to return the injured soldiers to military duty or civilian life to the highest degree possible.

In 1920 Congress passed the Civilian Rehabilitation Act of 1920 (Smith-Fess Act, Public Law 66-236). This law provided funds for vocational guidance and training, work adjustment, prostheses, and placement services.[42] If therapy was part of a medical treatment program, the law provided payment for occupational therapy services; however, it did not provide payment for physician services. Physicians either provided free services or received payment through state or volunteer contributions. This limited the use of occupational therapy services in vocational rehabilitation to the states that received supplemented federal program funds to support services such as the curative workshops.

The Social Security Act of 1935 defined rehabilitation as "the rendering of a person disabled fit to engage in a remunerative occupation."[53] This was the first attempt to provide vocational rehabilitation to the physically handicapped in the community.

In 1937 industrial therapy, called employment therapy, was born.[58] The occupational therapist used activities as treatment modalities. It was common for patients to have work assignments in the hospital that matched their experience, aptitude, and interest. Sheltered work environments within the hospital were used, including the hospital laundry, barber shop, and carpenter shop.

The term *prevocational* started appearing in the literature by the late 1930s. It referred to the use of crafts to develop skills readily transferable to industry.[101] Prevocational therapy prepared patients for the work role. Occupational therapists worked as directors, work evaluators, and prevocational therapists in work programs. In the 1940s prevocational programs and work evaluation were accepted as part of the practice of occupational therapy. Patients in acute care facilities who were physically disabled were transferred to outpatient or rehabilitation prevocational and vocational programs.

World War II brought more opportunities for occupational therapists to become involved in work programs. With the advancement of medicine and pharmacology, many injured soldiers survived their wounds. Federal funding for rehabilitating disabled veterans increased as the government discharged the disabled soldiers. This led to an increase in the development of work programs designed to evaluate and rehabilitate injured veterans.[17]

In 1943 the Barden-LaFollette Act (Public Law 78-113) modified the original provisions of the Civilian Rehabilitation Act of 1920.[42] This new law, called the Vocational Rehabilitation Act, covered many medical services, including occupational therapy and vocational guidance. Services were expanded to those with physical and mental limitations. This law also created the Office of Vocational Rehabilitation, a state and federally funded agency that is still in existence today and provides job training and placement services to people with disabilities. Industrial therapy continued in various settings as a form of vocational rehabilitation.

During the 1950s many occupational therapists believed that work evaluation belonged to a newly established profession, vocational rehabilitation, rather than to occupational therapy.[58] Occupational therapy involvement declined, and vocational counselors, vocational evaluators, and work adjusters were primarily the leaders in this field. There were, however, still a few occupational therapists who remained active in work programming.

A high point in the development of prevocational exploration and training techniques in the field of occupational therapy occurred in 1960.[42] Rosenberg and Wellerson published an article on development of the TOWER (Testing, Orientation, and Work Evaluation in Rehabilitation) system in New York.[84] The TOWER system was one of the first work sample programs to use real job samples in a simulated work environment. In 1959 Lilian S. Wegg gave the Eleanor Clarke Slagle Lecture on "Essentials of Work Evaluation," based on her experiences at the May T. Morrison Center for Rehabilitation in San Francisco. Wegg promoted the need for both sound testing procedures and training programs.[101] Florence S. Cromwell, a president of the American Occupational Therapy Association (AOTA), established norms for disabled populations on certain prevocational tests while evaluating the performance of adults with cerebral palsy at the United Cerebral Palsy Organization.[42] Cromwell continued to be an important advocate of occupational therapy–based work-related therapy in the ensuing decades.

Occupational behavioral theory, which emerged in the mid-1960s and early 1970s, offered a return to the profession's concern for occupation. Mary Reilly, an early proponent of occupational behavior theory and a 1962 Eleanor Clark Slagle lecturer, believed that productive activity as treatment was the unique contribution of occupational therapy.[42] Occupational behavior theory advocated that persons can achieve healthy living only through a balance between work, rest, and play.

The increasing number of industries in the late 1970s and early 1980s introduced a whole new arena for occupational therapists: industrial rehabilitation and work hardening.[42] Work hardening used actual work tasks in a simulated, structured work environment, generally in community-based settings.[5] Occupational therapists used their knowledge of neuromuscular characteristics, including range of motion (ROM) and endurance, along with task analysis skills and knowledge of the psychosocial aspects of work, in evaluating, planning, and implementing a work-hardening program.

In 1989 the Commission on Accreditation of Rehabilitation Facilities (CARF) developed work-hardening standards requiring an interdisciplinary approach.[15] The interdisciplinary team consisted of occupational therapists, physical therapists, psychologists, and vocational specialists.

The Americans with Disabilities Act of 1990 (ADA; Public Law 101-336) was important legislation that opened major markets for occupational therapists.[42] Occupational therapists were involved in providing both work training for persons with disabilities and assistance to employers in meeting the requirements of the ADA. This legislation continues to have important implications for work practice.[23] (See Chapter 15 for more information on the ADA.)

Also in 1990 the National AgrAbility Project (http://www.agrability.org) was established through the 1990 Farm Bill.[101] This opened up opportunities for occupational therapy practitioners to help farmers, ranchers, and other agricultural workers with disabilities safely return to work. AgrAbility funds occupational therapy practitioners' site visits to evaluate and identify what is needed for a farmer or rancher to return to work. If assistive technology or other workplace modifications are needed, various funding sources (e.g., the state's vocational rehabilitation office) usually support some or all of the recommendations that need to be implemented.

In 1992 the AOTA published a document that defined work as “all productive activities and included life roles such as homemaker, employee, volunteer, student, or hobbyist.”[4] This document was replaced in 2000 by “Occupational Therapy Services in Facilitating Work Performance.”[3] This statement asserted that “occupational therapists and occupational therapy assistants contribute to the delivery of services for the promotion and management of productive occupations as well as the prevention and treatment of work-related disability.”

In 2002 the Occupational Safety and Health Administration (OSHA) unveiled a comprehensive approach to ergonomics to reduce the incidence of musculoskeletal disorders (MSDs) in the workplace. This four-pronged, comprehensive approach includes guidelines, enforcement, outreach and assistance, and a national advisory committee on ergonomics.

Occupational therapists have traditionally consulted and continue to consult with employers and employees on making recommendations about equipment, posture, and body mechanics to prevent injuries. Ergonomic intervention continues to be an area of many opportunities for occupational therapists who have received additional training and education in the area of ergonomics.

Role of the Occupational Therapist in Work Programs

Occupational therapists (OTs) and occupational therapy assistants (OTAs) play an important role in helping individuals participate in all aspects of work. According to the "Occupational Therapy Practice Framework: Domain and Process," third edition (OTPF-3), work is an area of occupation that is defined by Christiansen and Townsend as "labor or exertion, to make, construct, manufacture, form, fashion, or shape objects, to organize, plan, or evaluate services or processes of living or governing, committed occupations that are performed with or without financial reward" (OTPF-3, p. S20).[1] Work is further described in the OTPF-3 as "employment interests and pursuits, employment seeking and acquisition, job performance, retirement preparation and adjustment, volunteer exploration, and volunteer participation" (OTPF-3, p. S20).[1] Occupational therapy practitioners provide services to those with limitations in the area of work performance. The occupational therapist focuses on identifying and analyzing the problem and selecting and/or designing appropriate assessments and interventions for solution of the problem. According to the statement "Occupational Therapy Services in Facilitating Work Performance," problems in work performance may arise from challenges related to "motor, sensory-perceptual, emotional regulation, cognitive, or communication and social performance skills or from those associated with performance patterns, the activity demands, or the context and environment."[2] Work-related services are provided by occupational therapists in a variety of settings, including, but not limited to, acute care and rehabilitation facilities, industrial and business environments, psychiatric treatment centers, schools, and community settings. The occupational therapy process involves "evaluation, treatment planning, implementation, review, and outcome monitoring."[2] This chapter describes the range of work evaluations and interventions in which occupational therapists are involved in assisting people in actively participating in meaningful work roles.

Industrial Rehabilitation

The range of services provided to injured workers and industry is often encompassed by the terms "industrial" or "occupational" rehabilitation. These terms will be used interchangeably in this chapter. **Industrial rehabilitation** includes functional capacity evaluation (FCE), vocational evaluation, job demands analysis (JDA), worksite evaluation/fitness for duty testing, preemployment screening, work hardening/conditioning, on-site rehabilitation, modified/transitional employment, education, ergonomics, wellness, health promotion, and preventive services. Occupational therapists are integral in providing these services, and this area of practice provides a tangible way for therapists to experience the tremendous reward of seeing lives changed through their efforts. The AOTA has developed a Work and Industry Special Interest Section (WISIS) for those who are involved in or wish to know more about this area of specialization.

Functional Capacity Evaluation

A **functional capacity evaluation** is an objective assessment of an individual's ability to perform work-related activity.[28,52] These functionally based tests have been used since the early 1970s to assist in making return-to-work decisions and were primarily performed by occupational and physical therapists.[38] Today, however, the results of such an evaluation can be used in many different ways, and the evaluation is performed by a multitude of disciplines. Occupational therapists are remarkably qualified to conduct FCEs because of their education and background in task analysis.[2,3] An FCE can be used to set goals for rehabilitation and readiness for return to work, assess residual work capacity, determine disability status, and screen for physical compatibility before hiring a new employee and case closure.[75]

Ethical Considerations

The FCE is a tremendous tool in the course of rehabilitation that allows a therapist to have objective findings for making thoughtful and appropriate recommendations regarding initiation, continuation, or cessation of treatment, or for referring the client to another service. Great care must be taken to ensure that the results are not derived lightly because of the enormous impact that such results can have on a person's life.[45,50]

An FCE usually consists of a review of medical records, an interview, musculoskeletal screening, evaluation of physical performance, formation of recommendations, and generation of a report.[45] Evaluation of physical performance usually takes the form of assessing the client's physiology, both cardiovascular and muscular endurance, during the course of strength, static, and dynamic tasks. The report usually contains information regarding the overall level of work, tolerance for work over the course of a day, individual task scores, job match information, level of client participation (cooperative or self-limited), and interventions for consideration.[45,50]

OT Practice Notes

The referral source for an FCE can and does vary. Physicians, attorneys, case managers, insurance carriers, and other therapists are the primary sources for FCE referrals. Some states, institutions, and insurance carriers require a physician's prescription for an FCE; therefore, it is important to be aware of each state's practice act, employer, and insurance carrier guidelines for accepting referrals. Reimbursement also varies with geographic location.

A wide variety of FCEs are currently used in practice today, both commercially available systems and evaluations developed by individual therapists or clinics (Fig. 14.2).

FIG 14.2 The EvalTech Functional Testing System, an example of a functional capacity evaluation system. (Courtesy BTE, Hanover, MD.)

FCEs can be (1) all inclusive when looking at case closure or settlement; (2) job specific when making a match between a person's abilities and the job description, such as "cashier at XYZ store" or a broader occupational title such as "cashier"; or (3) injury specific, such as an upper extremity evaluation after bilateral carpal tunnel release. Joe, the 26-year-old man with T11 paraplegia, could benefit from a job-specific FCE to determine whether he can meet the physical demands of the alternative job as a laundry attendant.

A well-designed FCE is comprehensive, standardized, practical, objective, reliable, and valid.[45,50,86]

A comprehensive FCE will include all of the physical demands of work as defined by the *Dictionary of Occupational Titles* (DOT), published by the U.S. Department of Labor and last revised in 1991 (Box 14.1).[97] The main focus of Joe's FCE will be on the physical demands of work that he can still reasonably do from the wheelchair, such as lifting, carrying, pushing, pulling, balancing, reaching, handling, fingering, feeling, talking, hearing, and seeing.

It is also important for the individual being tested to understand the correlation between the test items and the functions of the job. The application of meaningful activity can improve individuals' cooperation during testing and encourage maximum effort. For example, an individual who performs secretarial duties may have difficulty understanding the need to test her ability to climb ladders if she does not actually perform this function during the course of her job.[1,75]

An FCE needs to be practical in terms of length of testing, cost, space, and report generation.[50,75]

Standardization in FCEs means having a procedure manual, task definitions and instructions, a scoring methodology, and equipment requirements and set-up.[50,52,76] This type of structure helps ensure that individuals are being assessed in a fair and consistent manner, and it demonstrates the effort to minimize observer bias. Verbal instructions are critical in establishing rapport between the evaluator and the individual being tested. During the initial interview, the tone is set for the course of the evaluation, and the individual's trust in the evaluator is implicit in maximizing cooperation and effort during the evaluation.[50] Objectivity is not limited to weights, distances, heights, or some other numerical quantity; subjective measures can be made objective with operational definitions. Objectivity during the course of an FCE does not exclude clinical judgment and decision making, but it does require the measure to be as free as possible of examiner bias.[86] This includes physical performance, in addition to client cooperation during testing. Objectivity is accomplished through standardization of the testing protocol and a structured scoring methodology.

The most important aspects of an FCE are reliability and validity of the testing protocol. Two types of reliability are deemed important in an FCE: interrater and test-retest reliability.[52] Interrater reliability in an FCE means consistency; if two therapists administer the same test to the same client, will they get the same results?[45] King and Barrett state that “test-retest reliability or intra-rater reliability refers to the stability of a score derived from one administration of an FCE to another when administered by the same rater.”[45] Being able to establish reliability is the first step in determining the validity or accuracy of the results.[86] If there is not agreement between evaluators, it is difficult to determine whose results are correct.[45] Once reliability has been proved, validity can be assessed. The term *validity* is used in many ways, often with significance placed on issues surrounding sincerity of effort. In scientific terms validity means accuracy; in other words, does the FCE provide results that truly describe how the client can perform at work?[50,86]

There are several types of validity, with content, criterion (both concurrent and predictive), and construct validity having the most impact on the results of an FCE.[45,50] Content validity is the easiest to establish in an FCE because this measure refers to whether the evaluation tests the physical demands of work, as defined by a panel of experts, by job analysis, or by a recognized document, such as the DOT.[50,52,75,97]

Criterion validity refers to whether conclusions can be drawn from the measures taken, and in an FCE this refers to whether a person can actually perform at the level demonstrated during testing.[45,50,52] Criterion validity is often determined by comparing the methodology in question with a gold standard—another instrument that has been proved to be reliable and valid.[45,50,52] This is difficult to do in an FCE because there are a limited number of available assessments with proven reliability and validity to compare against and because other methods, such as comparing the person's tested ability with the actual work level, can be seriously flawed.[50,52,56] Criterion validity includes concurrent and predictive validity.

Concurrent validity refers to the ability of a test to measure existing abilities, and in an FCE this would be demonstrated by the test's ability to determine which clients can perform at a given level and which clients cannot perform at a given level.[45,50,52]

Predictive validity is indicated by the test's capacity to predict future ability and has great value in an FCE by determining who can safely return to work and remain without injury.[45,50,59] The first FCE to be studied for validity and published in peer-reviewed literature was developed by the occupational therapist Susan Smith and has served as an important contribution to the knowledge base.[92] Without reliability and validity, a referral source cannot know whether the results of the evaluation would vary if the individual were tested by another therapist or whether the results are accurate.[45,50,52]

Vocational Evaluations

Work evaluations, or **vocational evaluations**, are "a comprehensive process that systematically uses work, real or simulated, as the focal point for vocational assessment and exploration to assist individuals in their vocational development."[25] According to CARF, the following factors are addressed in the traditional vocational evaluation model: physical and psychomotor capacities; intellectual capacities; emotional stability; interests, attitudes, and knowledge of occupational information; aptitudes and achievements (vocational and educational); work skills and work tolerances; work habits; work-related capabilities; and job-seeking skills.[35] These assessments can last from 3 to 10 consecutive days, depending on the goals of the assessment. Vocational evaluators generally conduct these types of assessments in private vocational agencies; however, some occupational therapists also have been involved in conducting these evaluations in public and private medical or nonmedical settings. Vocational rehabilitation, worker's compensation, and long-term disability carriers pay for these services, but most medical plans do not.

Standardized work samples, such as the Valpar Component Work Sample System or the Jewish Employment Vocational Services, are used to assess specific skills in the areas of data or other job-related topics (Fig. 14.3). Dexterity tests, such as the Bennett Hand Tool (Fig. 14.4), Crawford Small Parts, and Purdue Pegboard, are used to evaluate motor skills.[35] When no standardized work samples are available to assess the specific skills needed for a particular occupation, specially designed situational assessments are also used to create real-life work situations that are related to actual work tasks that would be conducted on particular jobs. For example, a person who is interested in working as a floral arranger could have her motor skills evaluated to see whether she has the coordination, energy, and strength and effort to grip and manipulate tools to cut the stems of flowers and plants and arrange them in floral containers. Individuals can also be evaluated in real worksites and perform actual job tasks that one would perform on the job.

Ethical Considerations

The tasks need to take clients' safety into account and not jeopardize their health or put them at risk for injury by allowing them to perform in an unsafe manner or push beyond their maximum level of performance.[50]

FIG 14.3 **A,** Valpar 9 Total Body Range of Motion work sample, which is used to evaluate functional abilities such as standing, bending, crouching, reaching, and gross manipulation and handling. **B,** The Valpar 10 Tri-Level Measurement is used to evaluate a person's ability to follow a multistep sequence to inspect metal parts with various jigs and tools.

FIG 14.4 The Bennett Hand Tool is a dexterity test to assess a person's ability to use hand tools.

There are generally two different types of vocational evaluation: a general vocational evaluation and a specific vocational evaluation. A **general vocational evaluation** is a comprehensive assessment to evaluate a person's potential to do any type of work. For an individual who has never worked, does not have a job to return to, or cannot return to the previous job because of a disability, this type of evaluation is beneficial in determining one's aptitudes, abilities, and interests to explore all reasonable options for work. For example, Henry, the roofer who experienced a traumatic brain injury from a fall while working, could benefit most from a general vocational evaluation to explore other options for employment. A general vocational evaluation could help identify other vocational interests and abilities by exploring a person's cognitive and motor skills and physical and mental tolerances that could be applied to a different occupation. A **specific vocational evaluation** assesses a person's readiness to return to a particular occupation. For a person who has suffered a stroke and wants to return to work as a general office clerk, a specifically tailored vocational evaluation to assess the person's ability to return to this particular type of work can be done. Clerical work samples and specially designed situational assessments that gauge the person's ability to multitask, pay attention to detail, file, answer a telephone, and take messages can be incorporated as an integral component of the vocational evaluation.

Job Demands Analysis

Assessing the physical demands of a job by JDA is often beneficial in the rehabilitation process inasmuch as recommendations for initiation or return to work require objective information about both the client's abilities and the job itself. A well-written job description that includes the essential tasks of the job, physical requirements, cognitive aptitudes, educational requirements, equipment operated, and environmental exposure assists in selecting suitable candidates for employment, setting compensation packages, and making appropriate return-to-work decisions after an injury.[8]

A JDA does not need to be confused with ergonomic evaluations or identification and abatement of hazards. A **job demands analysis** seeks to define the actual demands of the job, whereas ergonomic evaluations and hazard assessment focus more on work practice and risk for injury secondary to postural or manual material-handling extremes or excesses.[7] Certainly these areas can overlap, but it is important to be clear about the differences and the reasons behind the request for information and to use suitable methods for each.[7]

Approaches to a JDA include questionnaires, interviews, observations, and formal measurement.[7] It is common to interview incumbents or supervisors about the job requirements.[75] Such an informal approach often leads to narrative descriptions with little functional information and questionable accuracy of demand estimates.[36,62,75] As with other types of assessment, it is important to have an objective process for analyzing the demands of the job. In the context of attempting to make return-to-work decisions based on matching the results of an FCE with the job description, many FCEs include a JDA component.[50] However, these are often subjective interviews with the client and can lack accuracy regarding the physical demands.

The occupational therapist who was working with Joe contacted the employer and conducted a JDA to obtain a complete picture of the job demands and requirements of the laundry attendant position. The occupational therapist spoke to the supervisor and to other employees while they were performing the actual job at the worksite. Being able to actually observe the job being done in the real work environment allowed the occupational therapist to gather the information needed to adequately assess Joe's ability to carry out the essential functions of this job.

A standardized classification system is crucial to ensure consistency in terminology and among professionals. The DOT defines occupations in the United States, in addition to the physical demands of work (Tables 14.1 to 14.3).[97] It provides definitions of the overall level of work, strength demands, and frequency of the physical demands.[97,98] Many countries around the world use the DOT as their primary reference for generic occupational descriptions.

TABLE 14.1

Definitions for Overall Level of Work

Level of Work	Definition
Sedentary	Exerting up to 10 lb of force occasionally or a negligible amount of force frequently to lift, carry, push, pull, or otherwise move objects, including the human body. Sedentary work involves sitting most of the time but may involve walking or standing for brief periods. Jobs are sedentary if walking and standing are required only occasionally but all other sedentary criteria are met.
Light	Exerting up to 20 lb of force occasionally, up to 10 lb of force frequently, or a negligible amount of force constantly to move objects. Physical demand requirements are in excess of those for sedentary work. Even though the weight lifted may be only a negligible amount, a job should be rated light work (1) when it requires a significant degree of walking or standing, (2) when it requires sitting most of the time but entails pushing or pulling arm or leg controls, or (3) when the job requires working at a production rate pace entailing constant pushing or pulling of material even though the weight of the material is negligible. *Note:* The constant stress and strain of maintaining a production rate pace, especially in an industrial setting, can be and is physically demanding on a worker even though the amount of force exerted is negligible.
Medium	Exerting 20-50 lb of force occasionally, 10-25 lb of force frequently, or greater than negligible and up to 10 lb of force constantly to move objects. Physical demand requirements are in excess of those for light work.
Heavy	Exerting 50-100 lb of force occasionally, 25-50 lb of force frequently, or 10-20 lb of force constantly to move objects. Physical demand requirements are in excess of those for medium work.
Very heavy	Exerting force in excess of 100 lb of force occasionally, in excess of 50 lb of force frequently, or in excess of 20 lb of force constantly to move objects. Physical demand requirements are in excess of those for heavy work.

Data compiled from the US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles*, vols I and II, ed 4, Washington, DC, 1991, US Government Printing Office; and the US Department of Labor, Employment and Training Administration: *The revised handbook for analyzing jobs*, Indianapolis, IN, 1991, JIST Works.

TABLE 14.2

Definitions of Physical Demand Frequencies

Physical Demand Frequency	Definition
Never	Activity or condition does not exist
Occasionally	Up to $\frac{1}{3}$ of the day
Frequently	

	$\frac{1}{3}$ to $\frac{2}{3}$ of the day
Constantly	$\frac{2}{3}$ to full day

Data compiled from the US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles,* vols I and II, ed 4, Washington, DC, 1991, US Government Printing Office; and US Department of Labor, Employment and Training Administration: *The revised handbook for analyzing jobs,* Indianapolis, IN, 1991, JIST Works.

TABLE 14.3

Strength Demands of Work: Frequency of Force Exertion or Weight Carried

Strength Rating	Occasional (Up to $\frac{1}{3}$ of the Day)	Frequent ($\frac{1}{3}$ to $\frac{2}{3}$ of the Day)	Constant (Over $\frac{2}{3}$ of the Day)
Sedentary	10 lb	Negligible	Negligible
Light	20 lb	10 lb	Negligible
Medium	20-50 lb	10-25 lb	10 lb
Heavy	50-100 lb	25-50 lb	10-20 lb
Very heavy	Over 100 lb	50-100 lb	20-50 lb

Data from the US Department of Labor, Employment and Training Administration: *Revised dictionary of occupational titles,* vols I and II, ed 4, Washington, DC, 1991, US Government Printing Office.

The DOT was last revised in 1991. In the early 1990s the U.S. government made the decision not to revise the DOT again; instead, it created a new format for classifying occupations.[26] The intent was to create a more generic classification system, or framework, for defining work. The American Institutes of Research (AIR) was awarded a contract for this purpose by the Utah Department of Employment Security, acting on behalf of the U.S. Department of Labor. AIR developed O*NET, an online, searchable database for information about occupations. Although the format includes an enormous amount of data, its definitions can make it difficult for rehabilitation professionals to use in a qualitative fashion.[74] O*NET is not intended to take the place of the DOT, but rather to provide a more structured approach for "career exploration."[74] It is recommended that both the DOT and O*NET be consulted when obtaining occupational information.[26]

In terms of recent legislation that has had an impact on employment law, both the ADA and the Equal Employment Opportunities Commission (EEOC) have defined **essential tasks** as being the reason that a job exists.[6,7] The ADA further defines essential tasks as those that are highly specialized (i.e., the reason the incumbent was hired to perform the job), and for which a limited number of people are available at the job site to perform the tasks.[6] During the course of a JDA, it is important to distinguish between tasks that are essential and those that are not. This can be challenging because it is a nontraditional way for both the employee and the employer to look at the job. It is important that both hiring and return-to-work decisions be based on job descriptions that define the essential tasks to be congruent with both the ADA and EEOC language.

OT Practice Notes

In preparation for an observational JDA, an interview can be conducted on the telephone to glean initial information about the job to allow adequate research on the job title and equipment. Advance preparation also aids in selecting the personal protective equipment that needs to be worn while performing the analysis.

Jobs are composed of the tasks that are performed, the physical demands that make up the tasks, and the frequency with which the physical demands are performed, including weights handled, forces exerted, and distances both ambulated and reached.[7] The frequency of each physical demand must be weighted appropriately for the given duration of each task because there is often a significant difference in the amount of time spent on each task during the workday. For example, the job of "loader" in ABC warehouse is composed of two tasks: (1) loading crates with boxes and (2) wrapping the crate with packing tape when loaded. The loader completes 48 cycles of loading and taping in an 8-hour shift, with loading the crate taking approximately 80% of the work shift. The boxes weigh 10 pounds (lb) each. To correctly assess the overall level of work, the amount of weight lifted must be determined, in addition to the frequency of the manual materials handling.

Task 1 is composed of the physical demands of lifting, carrying, stooping, walking, reaching, handling, and standing. Task 2 is composed of walking, reaching, handling, fingering, and standing. To correctly sum the amount of the physical demands for the job of loader, one must determine how much time is spent on each physical demand within each task and then account for the proportion of the time that the task is performed during the workday. This type of assessment can be performed manually or through the use of various software protocols available in the marketplace.

Whatever methods are selected, clinicians should strive to provide an accurate picture of the job and its requirements, with an emphasis on functional demands, for easier application in the rehabilitation continuum.

Ethical Considerations

Whatever methods are selected, clinicians should strive to provide an accurate picture of the job and its requirements, with an emphasis on functional demands, for easier application in the rehabilitation continuum.

Work Hardening/Work Conditioning

The idea of using work for rehabilitation is at the very core of occupational therapy. In the 1970s the idea of occupational rehabilitation developed from the necessity of improving strategies to control work-related injuries.[19,44,51,73] Work hardening was first illustrated conceptually by Leonard Matheson, a psychologist at Rancho Los Amigos, who worked very closely with Linda Dempster, an occupational therapist, in developing his material.[44,51,73] The goal was then and remains rehabilitation of injured workers, maximization of their function, and returning them to work as quickly and safely as possible. The delivery system for this type of rehabilitation has evolved over time from a lengthy, hospital-based program, to structured interdisciplinary programs in outpatient settings, to the more progressive partnership between outpatient intervention and transitional work, in addition to rehabilitation occurring at the workplace in company-sponsored clinics. In the 1980s CARF developed guidelines for work-hardening programs and offered certification for a fee through adherence to their guidelines and periodic surveys.[19,44,51,73] In 1991 a committee of the American Physical Therapy Association (APTA) developed another set of principles for clinics that wanted to follow recognized standards but did not desire to undertake the CARF accreditation process.[19,44,51]

Work hardening refers to formal, multidisciplinary programs for rehabilitating an injured worker.[19,44,51,73] The disciplines represented on the team can often include occupational and physical therapists and assistants, psychologists, vocational evaluators and counselors, licensed professional counselors, addiction counselors, exercise physiologists, and dieticians.[19,44,51] The programs typically range from 4 to 8 weeks and consist of an entry and exit evaluation (usually an FCE or a derivative thereof), a job site evaluation, graded activity, both work simulation and strength and cardiovascular conditioning, education, and individualized goal setting and program modification, with the goal of return to work at either full or modified duty.[19,44,51] Actual equipment from the job is preferred during the work simulation to maximize cooperation of the worker and more closely replicate the actual demands of the job.[44] **Work conditioning** is more often defined as physical conditioning alone, which covers strength, aerobic fitness, flexibility, coordination, and endurance and generally involves a single discipline.[19,42,44] Job simulation may also occur during work conditioning. Both approaches involve evaluation of the worker to establish a baseline from which to plan treatment and measure progress.

Motivational issues are a constant concern and are often thought to be at the forefront of unsuccessful return to work.[91] Maladaptive behavior regarding return to work can develop in an injured worker as a result of depression, financial issues, family pressures, and feelings of being manipulated by the “system.”[91] This can lead to employer mistrust, interest in litigation, and a need to exaggerate symptoms. Fraud on the part of the injured worker is also an issue.[91] Employer indifference is a concern and can have a remarkable impact on a worker's attitude toward returning to the job.[91] Surveys of attitudes among employers have indicated that activity on the part of the employer can affect costs; as many as 90% of respondents indicated that how well the employee perceived that he or she was treated at the time of the injury was associated with decreased costs as a result of the injury.[91]

OT Practice Notes

It is essential for the therapist to recommend that the employer be involved with the employee after the injury; the employer should be encouraged to investigate injury claims that are worthy of investigation, to call to inquire about how the employee is feeling, and to consider modified duty and transitional work options to promote a successful return to work.

Think about Lorna, the upholsterer who is experiencing hand problems, and the difficulties that she is experiencing at work. An occupational therapist could evaluate her symptoms and her job description and make suggestions to the employer about modifying her job demands so that she can continue to work during treatment. This demonstrates to Lorna that her well-being matters and can help her have a positive outcome with treatment.

Ensuring a positive outcome for the injured worker requires early intervention and a customized plan of treatment to address the various areas affected by the injury, including both physical and psychosocial.[91] Incorporation of a multidisciplinary team allows the patient to have the benefit of many areas of expertise working toward his or her common good. Intervening and initiating the rehabilitation program as soon as possible after the injury dramatically increase the chance for successful return to work. Based on a study of 5620 worker's compensation beneficiaries, there was a 47% return-to-work rate in workers referred to rehabilitation within the first 3 months after injury, with a cost savings of 71%. When referred during months 4 through 6, the rates dropped to 33% for return to work and 61% for cost savings. For those referred beyond 12 months after injury, only 18% returned to work and cost savings dropped to 51%.[91]

Transitional work and modified duty programs involve a combination or a progression of acute rehabilitation and return to work at a level consistent with the individual's current ability, with the goal of returning to work at full duty or maximizing the individual's work capacity. An example of transitional duty would have a worker performing work-conditioning activities under supervision in an outpatient clinic from 8 to 10 a.m., going to the worksite and performing the less physically demanding portions of his job from 11 a.m. to 1 p.m., breaking for lunch, and then returning to the “lighter” duties of the job for the duration of the shift. More regular duty activities are added under supervision as the worker's skill and strength improve, with eventual return to full duty. This type of structure provides a much better environment for the worker to be involved in the work culture and allows coworkers and supervisors to participate in job modification and overall recovery of the injured worker.[91] Modified duty follows a similar path but typically does not include the clinical portion of the day. There are challenges to return to work at less than full duty, however; some employers do not want workers to return to the site unless they are at “100%.” It is imperative to demonstrate the benefit to the company and the employee, both economically and psychologically, of early transitional return to the long-term success of returning the employee to the workforce.

Industrial rehabilitation programs will continue to evolve as the tides of economy, industry needs, and legislation change. Occupational therapists play a key role in directing the changes that lie ahead.

Worksite Evaluations

Worksite evaluations are on-the-job assessments to determine whether an individual can return to work after the onset of a disability or whether a person can benefit from reasonable accommodations to maintain employment.[41,95] For example, a man who worked at a manufacturing company as a machine operator has a stroke, and the employer is willing to take him back as long as he can meet the physical and cognitive demands of the job. An occupational therapist can go to the worksite to evaluate the person's ability to safely and adequately operate the machinery and carry out the essential functions of the job. Consider another example. A person who previously worked as an office clerk without any difficulty is now experiencing extreme fatigue, pain, and muscle weakness with repetitive tasks as a result of post-polio syndrome. This person could benefit from a worksite evaluation to identify reasonable accommodations to allow her to continue working at this job while minimizing her symptoms. Several factors are assessed at the worksite with the worker present: the essential functions of the job, the functional assets and limitations of the worker, and the physical environment of the workplace.[55]

A worksite evaluation is usually conducted after a job analysis has been done. Larger companies may already have information on job analyses done on specific jobs. If a job analysis has not been done, the occupational therapist can conduct a job analysis if the employer is willing, or a job description could be obtained from the employer before going out to the worksite. If there is no written job description, a phone call to the supervisor/manager of the worker should be made to obtain verbal information regarding the essential functions of the job and the physical and cognitive requirements for the job. After this information has been obtained, the occupational therapist schedules a time with the employer and the worker to meet at the worksite. This is exactly what happened with Joe as he prepared to switch from the job of janitor to laundry attendant at the hotel and spa. After the occupational therapist conducted the job analysis, Joe met with both the occupational therapist and the employer at the worksite for the worksite evaluation.

When the occupational therapist meets the employer and worker at the worksite, the occupational therapist assesses the work, the worker, and the workplace.[47] The evaluation begins with an analysis of the essential functions that may require accommodation.[95] The occupational therapist should have an idea of what these functions are, based on the information obtained, before going to the worksite. The desired outcome of the work tasks should be emphasized, not just the process of performing the essential function.[95] The occupational therapist should find out certain details, such as how the outcome will be affected if a particular task is done incorrectly, in a different sequence, or omitted; whether there are quotas, standards, or time constraints that must be met[79]; and whether the frequency with which a task is done will affect the outcome.

Activity analysis is a useful tool for evaluating a person at the worksite.[11] It can be used to address all areas, including motor, sensory, cognitive, perceptual, emotional and behavioral, cultural, and social. When assessing a person's ability to carry out the essential functions of the job, the occupational therapist has expertise in breaking down the tasks and determining the parts of the task with which the worker is having difficulty or may have difficulty over the course of a workday. The occupational therapist can suggest accommodations to allow the worker to carry out the essential functions of the job.

The final step in the worksite evaluation is to assess the work environment. The environment outside the immediate work area should be evaluated (parking if driving or access to public transportation; access into the building, break room, and restroom), as well as the workstation itself. All work areas that the worker may use need to be investigated to identify obstacles and solutions to increase accessibility. The location and placement of machines, supplies, and equipment that the worker needs to access should be assessed, as well as other environmental factors such as lighting, temperature, and noise level.

Taking photographs or video recordings at the worksite can be very useful; however, permission must be obtained from both the employer and the worker to do so. The occupational therapist should also bring a tape measure to measure the height of work surfaces, width of doorways, and other factors, depending on the person's needs. Drawing a layout of the work area to scale on graph paper is also very helpful, especially when the worker is in a wheelchair. Critical measurements can be recorded on the diagram.

The outcome of the worksite evaluation is to determine whether the person can safely and adequately carry out the essential functions of the job with or without any reasonable accommodations. Ergonomic principles (addressed in the following section) should be considered and applied when recommending reasonable accommodations. The process of identifying reasonable accommodations requires cooperation between the person with the disability, the employer, and the occupational therapist.[79] Each person has valuable insights and information to contribute to the process of identifying the best accommodations. The Job Accommodation Network (JAN) is a service provided by the Office of Disability Employment Policy (ODEP), an agency of the U.S. Department of Labor, and is the best resource for assisting employers and disabled workers in making reasonable accommodations (http://askjan.org).[87] JAN's website points out that most job accommodations are not usually expensive. According to JAN, more than half of all accommodations cost nothing. JAN offers one-on-one guidance on workplace accommodations, the ADA, and self-employment options for people with disabilities. JAN consultants can be contacted both over the phone and online. JAN's toll-free number is (800) 526-7324.

The occupational therapist analyzes the need for modification of the equipment that the worker is using or modification of the workplace to help the person perform with greater efficiency, effectiveness, and safety.[5]

After the worksite evaluation has been completed, a report is prepared and sent to the qualified employee, the referring party, and the employer. The problem areas that relate to the essential job functions should be listed clearly, in addition to the accommodations necessary to solve them. If training is necessary to use a recommended accommodation, sources for the training should be identified. If commercially available equipment is recommended, exact model numbers, local sources, and approximate expenses should be provided.[95] If custom equipment needs to be fabricated, sources, cost estimates, and the amount of time required to fabricate the equipment also should be included. The report should summarize the findings of the evaluation and the accommodations that were recommended.

After Joe's worksite evaluation, it was determined that he could safely and dependably carry out the essential functions of the job from his wheelchair. Just one accommodation was recommended and implemented. Because it gets very hot in the laundry room and Joe is sensitive to the heat, the employer agreed to purchase additional fans to ventilate the room better, and to allow the door to the laundry room to be propped open. The employer agreed to schedule Joe's shift in the evening or early morning, when it was cooler, so that he would not have to work in the heat of the day.

The occupational therapy practitioner thus evaluates the worker, the work, the workplace, and the relationship among them. Therapeutic intervention is used when deficits in performance are found. The occupational therapist can modify the way that the worker performs the work or modify the work environment to allow the worker to perform optimally.

Ergonomics

All aspects of the domain of occupational therapy must be in harmony for people to fully engage in the occupation of work. The activity demands of the job and the context in which the job is performed must fit with the employee's abilities and physical/psychosocial makeup. Any mismatch between the activity demands of the job and context, individual client factors, and performance patterns will interfere with successful execution of the appropriate performance skills required to do the job.

Occupational therapists use the science of ergonomics to assist clients in fully engaging in the occupation of work. **Ergonomics** addresses human performance and well-being in relation to one's job, equipment, tools, and environment. The goal of ergonomics is to improve the health, safety, and efficiency of both the worker and the workplace.[67] The term *ergonomics* is derived from the Greek words *ergos*, meaning "work," and *nomos*, meaning "laws"—hence, the laws of work.[20] The Polish educator and scientist Wojciech Jastrzebowski (1799–1882) introduced the term ergonomics in the literature about 150 years ago.[19] However, the concept of ergonomics—that there is some connection between physical well-being and the type of work performed—is as old as humanity: "From the very first tool of the Stone Age, humans have tried to find better ways of working, taking advantage of human talents and making up for human shortcomings."[56]

The idea behind ergonomics is that every worker brings his or her own unique set of performance skills, performance patterns, and client factors to the workplace. Many times work settings and work processes are designed to satisfy space and budget limitations and the demands of productivity and aesthetics. When these designs fail to take into account the people who will be using the work setting and process, injury and inefficiency can result. Finding a way to match individual employees' strengths and limitations with the context and activity demands of a job can improve both worker safety and workplace productivity.

The principles of ergonomics help address a variety of work-related issues. Common issues include workplace and work process design, work-related stress, the disabled and aging workforces, tool and equipment design, architectural design, and accessibility. Ergonomic intervention can be applied proactively, preventing problems before they occur, or reactively, adjusting the worker-job-context "fit" when problems do occur. Many occupational therapists use ergonomic principles as part of their comprehensive rehabilitation or wellness and prevention client-centered programs. A few occupational therapists specialize in ergonomics and become professional ergonomists.

With regard to ergonomic services, the occupational therapist's client base may include the individual worker, workers in the context of employee groups, and/or the employer itself. The environment for an occupational therapist providing ergonomic services is generally at the client's place of work. These occupational therapists must become skilled in navigating what can be an unfamiliar business world with its unique lingo, social norms, and traditions. However, an occupational therapist providing ergonomic services shares a similar focus with occupational therapists in all areas of practice—that is, a focus on marketing and sale of the product (in ergonomics, wellness), cost-effectiveness, definable outcomes, and client satisfaction.

Occupational therapists are not the only professionals suited to specialize in the field of ergonomics. Ergonomics professionals come from a variety of backgrounds. It is not unusual to see ergonomists who have been academically trained in industrial hygiene, engineering, safety, business administration, human resources, medicine, physical/occupational rehabilitation, psychology, architecture, epidemiology, or computer science.[18] For the occupational therapist, the road to becoming a professional ergonomist can take many paths. Box 14.2 outlines a variety of methods for acquiring advanced knowledge and certification in the field of ergonomics.

Box 14.2

Education and Training Opportunities in Ergonomics

Education and training beyond occupational therapy entry-level practice are necessary for achieving advanced competence in ergonomics.

• University-sponsored graduate certificate programs in ergonomics are available through Texas

Women's University, Cleveland State University, University of Central Florida, and University of Massachusetts. These graduate-level courses typically require four to five courses for a total of 12 to 16 credit hours.

- Continuing education providers offer several-day courses that, on completion, allow the occupational therapist eligibility for certifications, such as the Ergonomics Evaluation Specialist available through Roy Matheson and Associates, Inc. (http://www.roymatheson.com), and the Certified Ergonomics Assessment Specialist available through the Back School of Atlanta (http://www.backschoolofatlanta.com).

- The Oxford Research Institute (http://www.oxfordresearch.org) offers the following advanced-level certifications: Certified Industrial Ergonomist, Certified Associate Ergonomist, and Certified Human Factors Engineering Professional.

- The Board of Certification in Professional Ergonomics (BCPE) (http://www.bcpe.org) offers the highest level of certification in the field of ergonomics—the Certified Professional Ergonomist. Other advanced-level certifications available through the BCPE include Associate Ergonomics Professional, Certified Ergonomics Associate, Certified Human Factors Professional, and Associate Human Factors Professional.

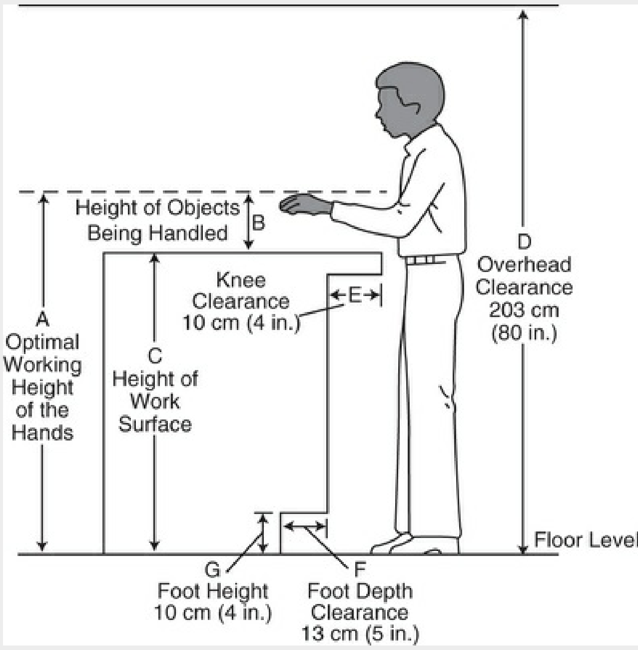
Data from Snodgrass J: Getting comfortable: developing a clinical specialty in ergonomics has its own challenges and rewards, *Rehab Manag* July:24, 2004.

For occupational therapists interested in the field of ergonomics, the holistic nature of occupational therapy training is an asset. The occupational therapist immediately understands that the goal of ergonomic intervention, or achieving a perfect fit between an individual worker and his or her job and context, is never simplistic. In the domain of occupational therapy, the worker component is composed of performance skills, performance patterns, and client factors (Box 14.3). The job component is composed of activity demands, both of the job tasks and of tools/equipment. Engaging in the occupation of work occurs in a variety of contexts, including the environment and organization, as well as the worker's personal, cultural, social, and spiritual contexts.

Box 14.3

Anthropometry

Anthropometry is the study of people in terms of their physical dimensions. It includes the measurement of human body characteristics such as size, breadth, girth, and distance between anatomical points. It also includes segment masses, centers of gravity of body segments, and ranges of motion, which are used for biomechanical analysis of work and postures. Standard anthropometric tables are available to assist designers of work areas, work surfaces, chairs, and equipment. The tables outline the average dimensions of adult men and women in the 5th, 50th, and 95th percentiles of the population. Ideally, designs should “fit” a wide range of persons between the 5th percentile (smallest people) and the 95th percentile (largest people). Retail merchandise labeled “ergonomic” is based on these anthropometric dimensions. In practice, however, few designs meet the needs of such a wide range of people, which explains why expensive equipment labeled “ergonomic” does not always produce the desired results. Professional ergonomic intervention seeks to create a better “fit” for the individual user.



An example of ergonomic chair design based on anthropometric data is presented in Fig. 14.7A.

(Reproduced with permission from Eastman Kodak Company [Adapted from Nachemson, 1975]).

Observing independent aspects of the domain offers the observer limited insight. Rather, it is the interactions between the various aspects of the domain that reveal the whole picture. This way of looking at worker performance via the interactions of all aspects of the domain of occupational therapy is known as **system theory**. Rannell Dahl, MS, OTR, explains that the "components of work systems are workers, job tasks, tools and equipment, work environments, and organizational structure, and the interactions among these components."[18] Dahl offers an excellent schematic of this concept of the ergonomics work system (Fig. 14.5).

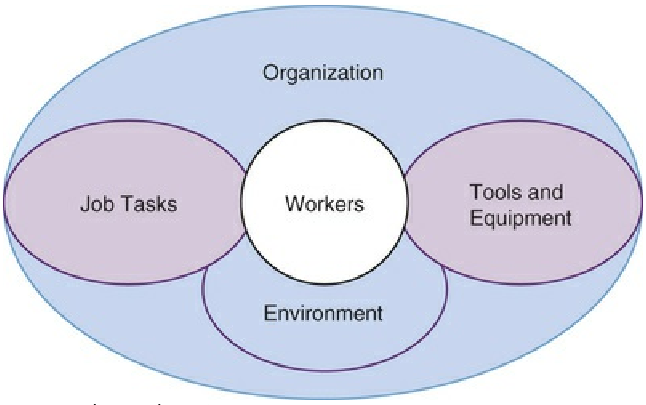


FIG 14.5 Dahl's ergonomics work system. (From Dahl R: Ergonomics. In Kornblau B, Jacobs K, editors: *Work: principles and practice*, Bethesda, MD, 2000, American Occupational Therapy Association.)

In his groundbreaking text *Conceptual Aspects of Human Factors*, David Meister explained that in human factors (ergonomics), the system concept is the belief that human performance in work can be meaningfully conceptualized only in terms of organized wholes. He emphasized the fundamental Gestalt ideas that "the whole is more than the sum of its parts, that the parts cannot be understood if isolated from the whole, and that the parts are dynamically interrelated or interdependent."[59] Occupational therapists understand that one can conceive of worker performance only in terms of the interaction between performance skills, performance patterns, context, activity demands, and client factors. The OTPF-3 supports this concept: "Engagement in occupation as the focus of occupational therapy intervention involves addressing both subjective (emotional and psychological) and objective (physically observable) aspects of performance. Occupational therapy practitioners understand engagement from this dual and holistic perspective and address all aspects of performance when providing interventions" (OTPF-3, p. 628).[1]

Occupational therapist Jeffrey Crabtree adds that it is "the subjective meaning of the interactions in the human-work-machine-environment model [that] is central to occupational therapy and ergonomics."[16]

The system theory does not discount the importance of the adequacy of independent aspects of the domain of occupational therapy. The quality of the work system can suffer if there are deficiencies or deviations in performance skills, performance patterns, context, activity demands, or individual client factors. Dahl explains that each component of the ergonomics work system (see Fig. 14.5) "has its own set of characteristics that affect the performance of the work system"[18] as a whole. It is here that ergonomic assessment and intervention seek to make a difference in the quality of our clients' engagement in the occupation of work. The ergonomic practitioner modifies and strengthens certain aspects of the system with the goal of enhancing the overall quality of the work system interactions (i.e., improving the fit between the worker and his or her job).

Although it is beyond the scope of this chapter to comprehensively review the complete array of ergonomic design considerations, the following is a discussion of selected ergonomic design principles. There are, however, a multitude of resources for occupational therapists interested in learning more about the science of ergonomics. The authors of this chapter direct you to the references listed at the end of the chapter. Additionally, readers may be interested in the ergonomics information available through OSHA (http://www.osha.gov) and NIOSH (http://www.cdc.gov/niosh/).

When discussing ergonomic design, it is important to understand that it is the relationship between the worker and work equipment, tools, or processes that is the problem, not any particular characteristic on either side. This can be confusing to an employer who orders expensive ergonomic tools and equipment for his or her workers and is disappointed when the workers continue to suffer work-related injuries and illnesses. The specialists in ergonomics must explain to their clients that a tool or piece of equipment is never in itself ergonomic; rather, it is the fit between a particular piece of equipment, tool, or process and the intended user of that equipment, tool, or process that creates a proper ergonomic situation.

Workstations

There are three major types of workstations: seated, standing, and combination sit/stand. The type of task being performed dictates the best choice. Seated workstations are best for fine assembly and writing tasks and when all required task items can be supplied and handled within comfortable arm's reach in the seated work space. Items handled in a seated workstation should not require hands to work more than 6 inches (15 cm) above the work space, and the items handled should not weigh more than 10 lb (4.5 kg). For this reason, the height of the work surface should be above elbow height for precision work. Standing workstations are appropriate for all kinds of work tasks but are preferred when downward force must be exerted (i.e., packaging and wrapping tasks) and when frequent movement or multilevel reaching is required around the work area. Items weighing more than 10 lb (4.5 kg) should be handled in a standing workstation. Work surface heights for heavy work should be 4 to 6 inches (10 to 15 cm) below elbow height for heavy work. The combination sit/stand workstation is best for jobs consisting of multiple tasks, some best done sitting and some best done standing.[22] Fig. 14.6 shows the recommended dimensions for both a seated workstation and a standing workstation.

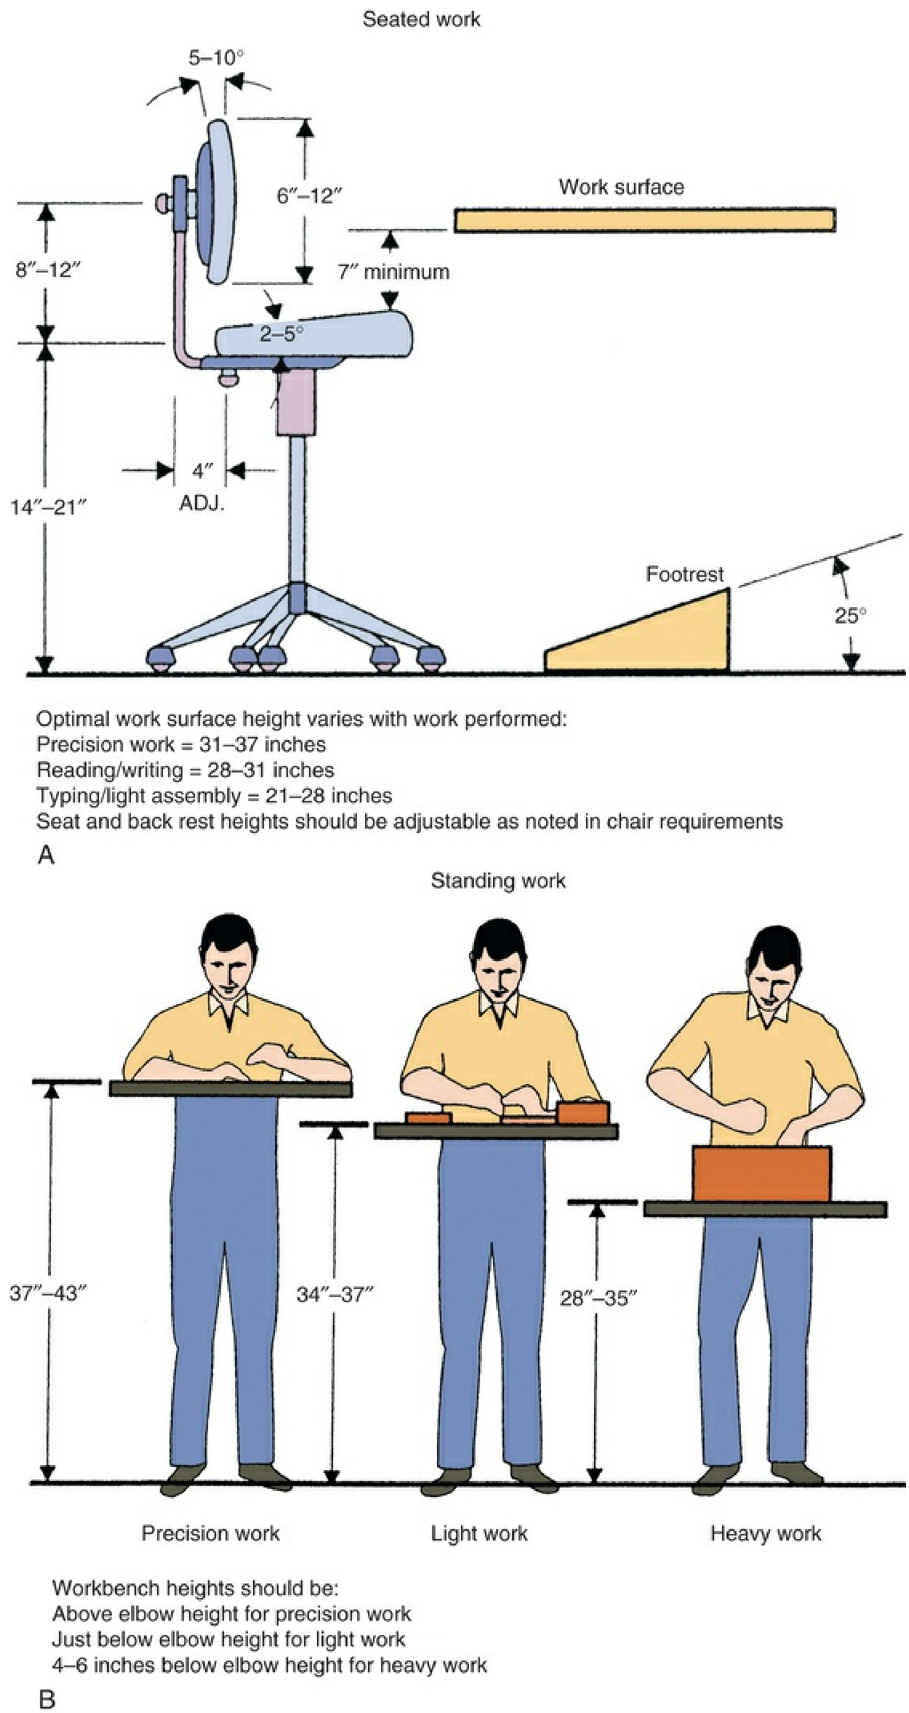

FIG 14.6 Recommended dimensions of workstations. **A,** Seated work. **B,** Standing work. (From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.)

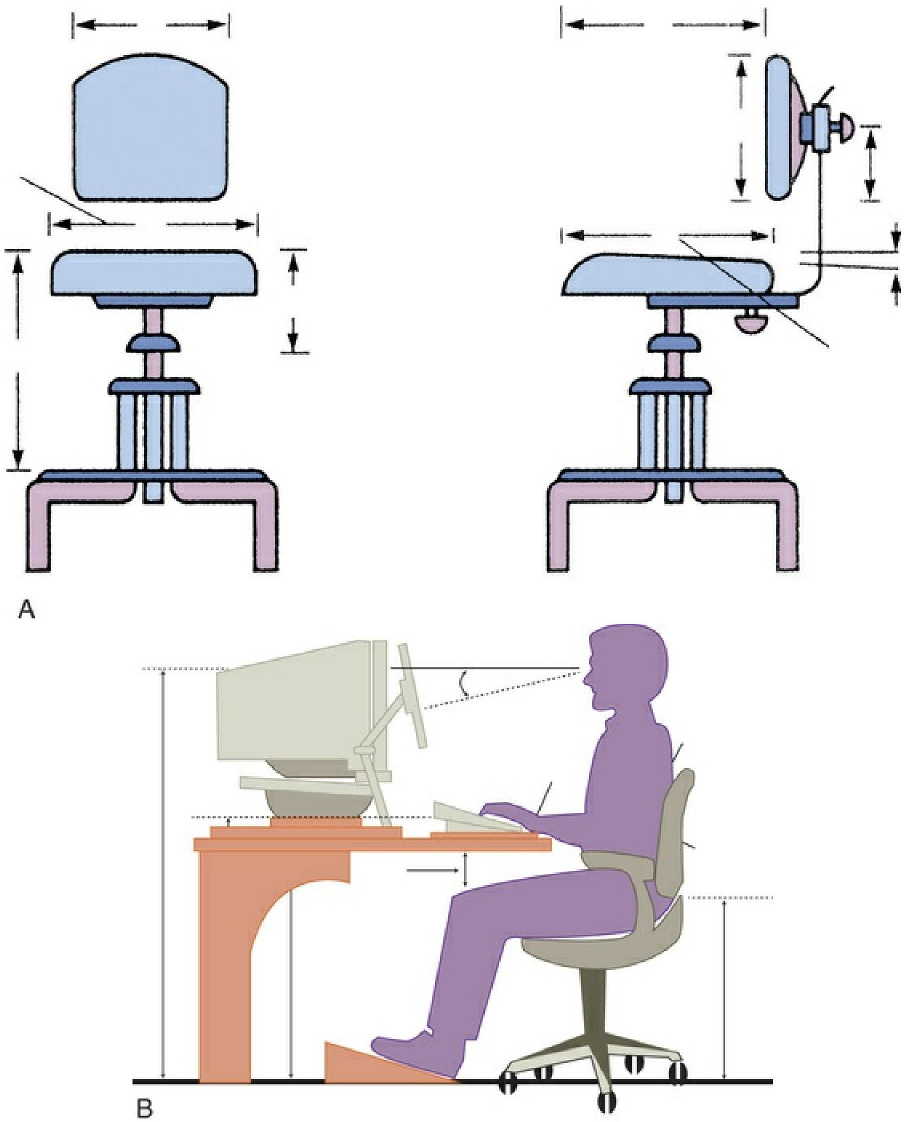
Seating

If seating is required, the design of the chair is of paramount importance for worker comfort and support. Poor seating leads to poor working posture. The result can be fatigue, musculoskeletal injury, and/or poor work performance. Although chair preference is highly variable among the population, there are some basic characteristics to consider. Chairs should be easily adjustable for height, backrest position, and seat pan tilt. Appropriate lumbar support is important. Seats upholstered in woven fabric are cooler and more comfortable in warmer work environments.[22] Chair casters should match the flooring (i.e., hard floor versus carpet casters). A seat pan that is too deep will cut into the back of the leg and compromise lower extremity circulation. Sitting in a chair without the feet supported will also cause pressure on the back of the legs. When the worker is seated at the workstation and performing a task, both feet should be supported on the floor or a footrest. Choosing a seat pan with a front-edge "waterfall" design will also decrease pressure on the back of the legs. Armrests are an area of controversy but should generally be provided when the work task requires the arms to be held away from the body.[37] Fig. 14.7A illustrates the recommended chair characteristics for generalized seated workstations. Fig. 14.7B illustrates a seated position for computer users.



A

B

FIG 14.7 **A,** Recommended chair characteristics. Dimensions are given from both front and side views for width *(A)*, depth *(E)*, vertical adjustability *(D)*, and angle *(I)* and for backrest width *(C)*, height *(F)*, and vertical *(H)* and horizontal *(G)* adjustability relative to the chair seat. The angle of the backrest should be adjustable horizontally from 12 to 17 inches (30 to 43 cm) by either a slide adjust or a spring and vertically from 7 to 10 inches (18 to 25 cm). Adjustability is needed to provide back support during different types of seated work. The seat should be adjustable within at least a 6-inch (15-cm) range. The height of the chair seat above the floor with this adjustment range will be determined by the workplace, with or without a footrest. **B,** Proper seated position for a computer user. (**A** reproduced with permission from Eastman Kodak Company [Adapted from Nachemson, 1975]; **B** from the Occupational Safety and Health Administration: *Working safely with video display terminals,* Washington, DC, 1997, US Government Printing Office. http://www.osha.gov/publications/osha3092.pdf.)

Visualizing the Job Task

Visual factors to consider are the location of task items and lighting. Again, recommendations depend on the type of task being performed. The goal is clear, direct viewing without straining the eyes or neck. Tasks should be located as directly in front of the worker as possible. Tasks requiring close-range viewing should be positioned 6 to 10 inches (15 to 25 cm) above the work surface. Minimum and maximum viewing distances depend on the size of the object being viewed. Bifocal eyeglass wearers have difficulty observing any object closer than 7 inches (18 cm) in front of the body that is above eye level or near the floor. Additionally, bifocal wearers have difficulty focusing on signs or dials located 24 to 36 inches (61 to 91 cm) in front of them.[20]

Three basic lighting factors need to be considered for performance of work: quantity, contrast, and glare. Lighting should be adequate for the worker to perform the job task, but not so bright that it causes discomfort. General work environment illumination is typically provided by sunlight and light fixtures at 50 to 100 foot-candles (ft-c). Computer users may find that this amount of illumination washes out the display screen and causes eyestrain. The recommended illumination level for computer workstations is 28 to 50 ft-c. Too much contrast between the task items and the surrounding areas can also stress the eyes. Therefore, the illuminance between the task items, equipment, horizontal work surface, and surrounding areas should be minimized. Finally, the color and finish of the workstation walls and equipment, as well as the arrangement of the lighting sources, should all be designed to avoid reflective glare on the job task (Fig. 14.8).[72]

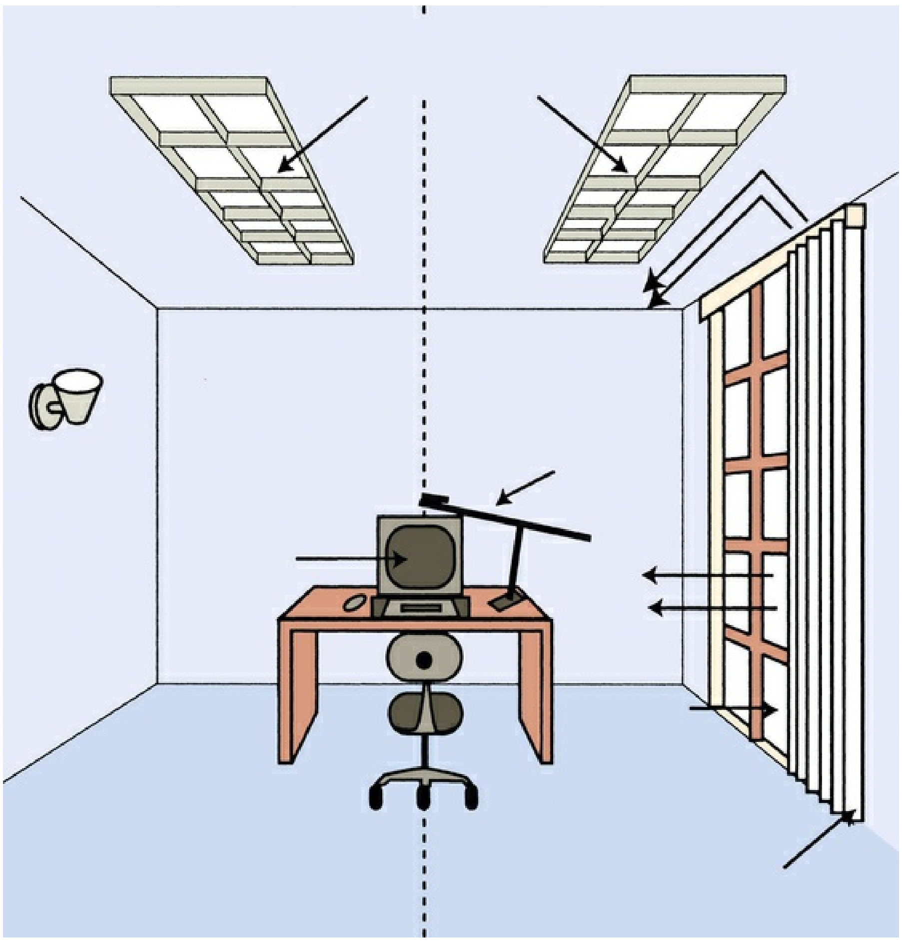


FIG 14.8 Lighting position considerations for computer workstations. Most of these lighting position principles can be applied to workstations in general. (From the Occupational Safety and Health Administration: *Working safely with video display terminals,* Washington, DC, 1997, US Government Printing Office. http://www.osha.gov/publications/osha3092.pdf.)

Tools

Tools should be designed to protect the worker from hand vibration, extreme temperatures, and soft tissue compression. Therefore, handles on tools are essential. "A properly designed tool handle should isolate the hand from contact with the tool surface, enhance tool control and stability, and serve to increase the mechanical advantage while reducing the amount of required exertion."[81] Because the average worker's hand is 4 inches (10 cm) across, the length of the tool handle must be at least 4 inches to avoid unnecessary pressure on the palm of the hand. Handles of scissors and pliers should be spring loaded to avoid trauma to the back and sides of the hands.[81]

Tool design should minimize muscular effort and awkward posturing of the upper extremity. Whenever possible, opt for power tools to minimize the human effort required. Choose tool shapes that allow the wrist to stay straight and the elbow to stay bent and close to the body during use. The shape of the tool will depend on the job task and work surface (Fig. 14.9). Tools that weigh between 10 and 15 lb (4 to 6.5 kg) cannot be held in a horizontal position more than a couple of minutes without the worker experiencing pain and fatigue. Suspension systems and counterweights should be designed for use with heavy hand tools.[81]

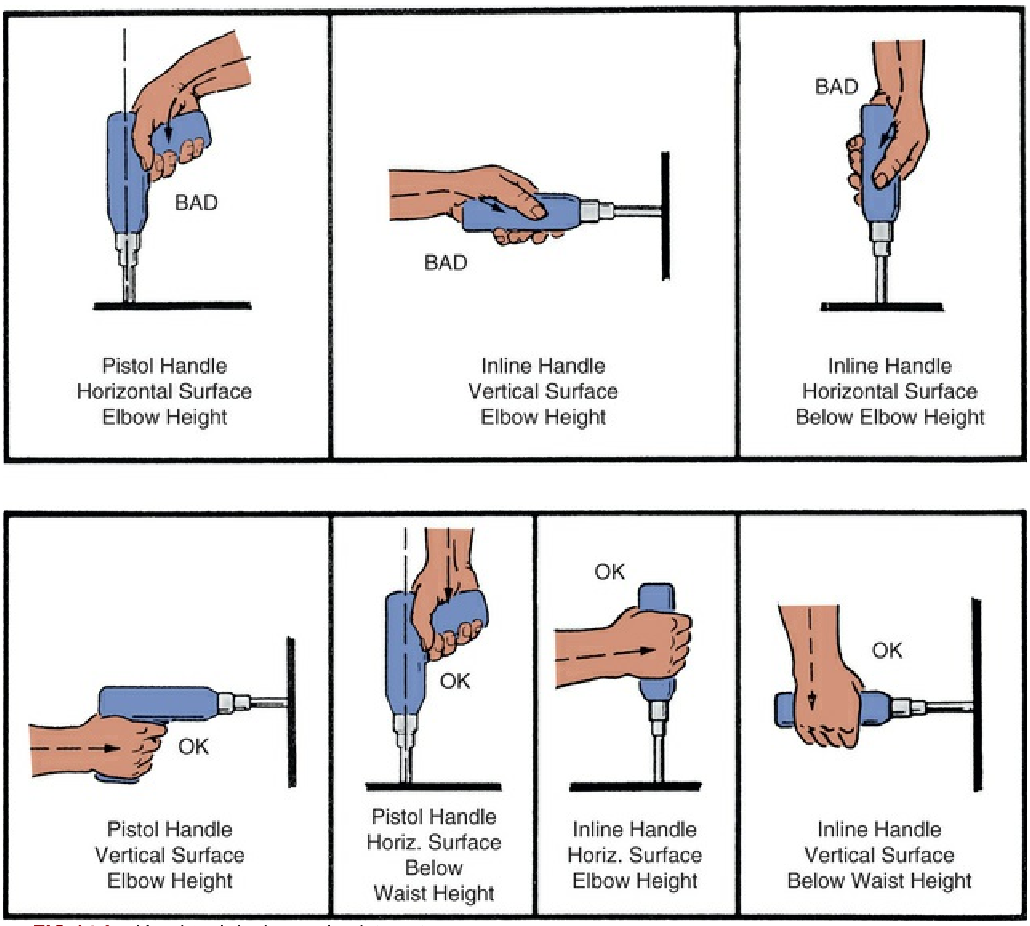

FIG 14.9 Hand tool design and wrist posture. (From Armstrong T: *An ergonomic guide to carpal tunnel syndrome,* Akron, OH, 1983, American Industrial Hygiene Association.)

Whole-body vibration can cause back pain and performance problems when the workstation vibrates, as in the case of long-distance truck drivers and in production industries using high-powered drills or saws in the work area.[14] Hand-arm vibration has been linked to vascular compromise, peripheral nerve damage, muscular fatigue, bone cysts, and central nervous system disturbances.[29] The effects of hand tool vibration should be minimized as much as possible. Use antivibration tools at low speeds when available. Ensure that tool handles and gloves fit the workers' hands. Train workers to grip tool handles as lightly as possible and allow the tool to do all the work instead of the worker adding force behind the tool. Encourage frequent rest breaks and educate workers that smoking increases the risk for vibration-related hand problems.[18,29]

Materials Handling

Concerns regarding handling materials center on back injury and include lifting, pushing, pulling, bending, and twisting. The heavier the material, the more risk for injury. Low back injuries are seldom the result of a single traumatic episode, but rather the result of repeated microtrauma that ultimately leads to injury.[33] Therefore workstation and work process design becomes integral for the safety of materials handling workers.

Design considerations for heavy lifting include the use of mechanical assist devices whenever feasible (e.g., use of a Hoyer lift for moving immobile patients in the hospital). When mechanical assist devices are not available, training in proper lifting technique and proper body mechanics is important to promote worker safety. Providing workers with back support is controversial, but many believe that the use of an elastic back support "has a preventative function, protecting the tissues … thus making injury less common."[46] Training workers and providing them with back support is only effective, however, when "supervisors and managers encourage the use of safe procedures and write policies that enforce them."[85]

The following suggestions are useful for addressing safe handling of materials. Design workstations to keep large items that require lifting off the floor. Provide platforms that will keep items at midthigh height to allow workers to stand nearly erect for lifting. Provide foot clearance so that workers can get as close to the item as possible when lifting and face the load head-on. Adjustable lift tables are excellent for this purpose. Objects should be against the torso during the lift to minimize force on the spine. Workers should never be forced to twist their torsos to lift an object. Use carts or conveyors to transport heavy materials instead of carrying them. Orient packages for easy pick-up and provide adequate handles or handhold cutouts on packages.[18]

As stated earlier, these ergonomic design principles can be applied proactively to work situations to prevent problems before they even occur. For many occupational therapists, however, introduction to ergonomic considerations comes secondarily as part of a comprehensive rehabilitation program for injured workers. After a work-related injury, ergonomic intervention is essential to the client's successful re-engagement in the occupation of work. Without the ergonomic intervention aspect, the rehabilitation process cannot be considered complete.

A significant amount of effort goes into the rehabilitation of an injured worker. Physical injuries require the attention of a medical doctor to prescribe rest, medications, and rehabilitative therapies. The occupational therapist will provide acute care of the injuries by fabricating splints, instructing workers in stretching and strengthening exercise, and using physical agent modalities such as heat and ice to calm the soft tissues in preparation for functional rehabilitative activities. Other aspects of the occupational therapy plan include educating the injured worker about the nature of the injury and training in general body mechanics and personal injury management strategies to help prevent recurrence of injury on return to work. In some cases, the injured worker will require specialized conditioning before return to work and will be referred to a work-hardening program.

When the client is ready to return to work, it is important to remember that an injured worker cannot be safely returned to the same job without ergonomic intervention.

It seems obvious that returning an injured worker to the same conditions that caused the injury will certainly result in reinjury; therefore, those conditions must be eliminated before the employee's return to work. However, ergonomic intervention is sometimes overlooked as an integral part of the rehabilitation program. The goal of ergonomic evaluation and intervention in an injured employee's work environment is to eliminate factors that contributed to the injury in the first place. If we do not eliminate the major cause of the original injury, it will not be long before the worker suffers a recurrence. If that happens, we have failed as occupational therapists to provide a successful rehabilitation process.

Ergonomic Evaluation

The **ergonomic evaluation** is an important assessment and intervention tool when used as part of a comprehensive rehabilitation or injury prevention program. This tool can be used along the entire continuum of prevention services. Ergonomic evaluation can be performed during workstation and work methods planning to assist in efforts to prevent worker injury. Ergonomic evaluation can also be performed for workers in whom symptoms of a **work-related musculoskeletal disorder** (WMSD) develop and for workers who come to therapy for rehabilitation and are ready to return to work, the goal being to prevent reinjury. Finally, ergonomic assessment can be useful in modifying a job in preparation for a disabled worker's return to work with the goal of preventing further injury related to the disability.

The ergonomic evaluation should begin with the occupational therapist scheduling a time to meet with both the worker (or workers) to be assessed and the direct supervisor of the work area. The evaluation should be scheduled during the normal work hours of the worker. The goal is to obtain the best understanding of what actually occurs during a typical work shift, so the conditions should be closely approximated. It is extremely important that the actual worker be present. The purpose of the evaluation is to look at the fit between the specific worker and the specific job methods, equipment, and setup. If any element is missing, the evaluation is of little or even no value.

Ideally the occupational therapist evaluator will arrive at the worksite and meet first with the direct supervisor of the work area to be evaluated. The supervisor will be asked to give an overview of the circumstances leading up to the request for ergonomic evaluation. The occupational therapist will want to know what kinds of injuries are occurring in the work area, when the problem started, and how many employees have been affected. The supervisor will be able to review how the organization has dealt with the problem to date. Frequently, the supervisor will also describe what sorts of psychosocial and environmental influences may be affecting the situation. Occasionally, an ergonomic assessment is requested before any problems occur at all. The supervisor may explain that the employer is just trying to be proactive. In either case, this brief encounter with the supervisor will give an observant occupational therapist evaluator a very good feel for the organization's management culture and organizational priorities.

After the supervisor interview, the occupational therapist evaluator will want to see the work area and meet the employees. The supervisor may give the evaluator a brief tour of the work area and describe the job tasks and methods that occur there. If the supervisor has identified any problem areas (areas that the supervisor thinks are contributing to injury), the supervisor should be encouraged to point these out. This part of the evaluation will give the evaluator an understanding of how management views the situation. Next, the evaluator will ask to meet with the workers.

Once alone with the workers, it is important to establish some level of trust. The evaluator will explain to the workers why the organization has asked for an ergonomic evaluation. It should be explained that the purpose of the evaluation is to make the job safer and more comfortable for the workers. The workers should be encouraged to give the evaluator a tour of the work area and to explain their job tasks. If there are any discrepancies between management's understanding of the job situation and the workers' understanding of the same, the evaluator must seek definitive clarification.

Finally, the workers should be asked to begin performing the job as normally as possible. The evaluator (to simplify the explanation, let's assume in this case that this is a woman) will explain that she will be watching and perhaps videotaping or taking notes. The evaluator should assure the workers that the information that is being recorded will be used to develop strategies to make the job tasks safer and more comfortable to perform. The evaluator must stress that she wants the workers to do the job just like any other day. The evaluator will not begin analysis of the work methods until at least 10 minutes has elapsed to allow the workers time to fall into a more normal work pattern.

The ergonomic workstation and work methods assessment should focus on identifying known risk factors for MSDs. It is often very useful to videotape the work area and work methods performed. Recording the workers performing their job tasks will allow the evaluator to return to her office and further analyze the data. If the evaluator plans to videotape any work areas or work methods, she should ask permission from the company before taping. It is becoming increasingly more difficult to gain permission for in-house videotaping because of confidentiality and trade secrets concerns. However, some companies are still willing to allow videotaping for the purpose of ergonomic evaluation. Always obtain prior written permission allowing you to videotape in-house. Box 14.4 suggests a protocol for videotaping jobs for the purpose of ergonomic evaluation.

Box 14.4

Protocol for Videotaping Jobs for Ergonomic Evaluation

The following is a guide for preparing a videotape and related task information to facilitate job analysis and assessment of risk factors for work-related musculoskeletal disorders.

Materials Needed

- Video camera and blank tapes
- Spare batteries (at least two) and battery charger
- Clipboard, pens, paper, blank checklists
- Stopwatch, strain gauge (optional) for weighing objects

Videotaping Procedures

1. To verify the accuracy of the video camera to record in real time, videotape a worker or job with a stopwatch running in the field of view for at least 1 minute. Playback of the tape should correspond to the elapsed time on the stopwatch.
2. Announce the name of the job on the voice channel of the video camera before taping any job. Restrict running time comments to the facts. Make no editorial comments.
3. Tape each job long enough to observe all aspects of the task. Tape 5 to 10 minutes for all jobs, including at least 10 complete cycles. Fewer cycles may be needed if all aspects of the job are recorded at least 3 to 4 times.
4. Hold the camera still with a tripod if available. Do not walk unless absolutely necessary.
5. Begin taping each task with a whole-body shot of the worker. Include the seat/chair and the surface that the worker is standing on. Hold this shot for 2 to 3 cycles and then zoom in on the hands/arms or other body parts that may be under stress because of the job task.
6. It is best to tape several workers to determine whether workers of varying body size adopt different postures or are affected in other ways. If possible, try to tape the best- and worst-case situations in terms of worker fit to the job. The following suspected upper body problems suggest focusing on the parts indicated:

- Wrist problems/complaints
- Hands/wrists/forearms
- Elbow problems/complaints
- Arms/elbows
- Shoulder problems/complaints
- Arms/shoulders

For back and lower limb problems, the focus would be on movements of the trunk of the body and the leg, knee, and foot areas under stress as a result of task loads or other requirements.

7. Tape from whatever angles are needed to capture the body part(s) under stress.

8. Briefly tape the jobs performed before and after the one under actual study to see how the targeted job fits into the total department process.

9. For each taped task, obtain the following information to the maximum extent possible:

- Whether the task is continuous or sporadic
- Whether the worker performs the work for the entire shift or whether there is rotation with other workers
- Measures of work surface heights and chair heights and whether adjustable
- Weight, size, and shape of handles and textures for tools in use; indications of vibration in power tool use
- Use of hand wear
- Weight of objects lifted, pushed, pulled, or carried
- Nature of the environment in which the work is performed (too cold or too hot?)

From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.

In light of these concerns, it may be helpful to develop an ergonomic checklist to assist in performing the on-site evaluation. The checklist should include the most common ergonomic risk factors and should be tailored to the specific needs and conditions of the workplace that the occupational therapist intends to evaluate. Fig. 14.10 is an example of a typical ergonomic risk factor identification checklist. Fig. 14.11 is an example of a checklist for computer workstation evaluation. Fig. 14.12 is a typical hand tool risk factor checklist.

General Ergonomic Risk Analysis Checklist

Check the box if your answer is "yes" to the question. A "yes" response indicates that an ergonomic risk factor that requires further analysis may be present.

Manual Material Handling

- ❑ Is there lifting of loads, tools, or parts?
- ❑ Is there lowering of loads, tools, or parts?
- ❑ Is there overhead reaching for loads, tools, or parts?
- ❑ Is there bending at the waist to handle loads, tools, or parts?
- ❑ Is there twisting at the waist to handle loads, tools, or parts?

Physical Energy Demands

- ❑ Do tools and parts weigh more than 10 lbs?
- ❑ Is reaching greater than 20 inches?
- ❑ Is bending, stooping, or squatting a primary task activity?
- ❑ Is lifting or lowering loads a primary task activity?
- ❑ Is walking or carrying loads a primary task activity?
- ❑ Is stair or ladder climbing with loads a primary task activity?
- ❑ Is pushing or pulling loads a primary task activity?
- ❑ Is reaching overhead a primary task activity?
- ❑ Do any of the above tasks require five or more complete work cycles to be done within a minute?
- ❑ Do workers complain that rest breaks and fatigue allowances are insufficient?

Other Musculoskeletal Demands

- ❑ Do manual jobs require frequent, repetitive motions?
- ❑ Do work postures require frequent bending of the neck, shoulder, elbow, wrist, or finger joints?
- ❑ For seated work, do reaches for tools and materials exceed 15 inches from the worker's position?
- ❑ Is the worker unable to change his or her position often?
- ❑ Does the work involve forceful, quick, or sudden motions?
- ❑ Does the work involve shock or rapid buildup of forces?
- ❑ Is finger-pinch gripping used?
- ❑ Do job postures involve sustained muscle contraction of any limb?

Computer Workstation

- ❑ Do operators use computer workstations for more than 4 hours a day?
- ❑ Are there complaints of discomfort from those working at these stations?
- ❑ Is the chair or desk nonadjustable?
- ❑ Is the display monitor, keyboard, or document holder nonadjustable?
- ❑ Does lighting cause glare or make the monitor screen hard to read?
- ❑ Is the room temperature too hot or too cold?
- ❑ Is there irritating vibration or noise?

Environment

- ❑ Is the temperature too hot or too cold?
- ❑ Are the worker's hands exposed to temperatures less than 70° F?
- ❑ Is the workplace poorly lit?
- ❑ Is there glare?
- ❑ Is there excessive noise that is annoying, distracting, or producing hearing loss?
- ❑ Is there upper extremity or whole body vibration?
- ❑ Is air circulation too high or too low?

General Workplace

- ❑ Are walkways uneven, slippery, or obstructed?
- ❑ Is housekeeping poor?
- ❑ Is there inadequate clearance or accessibility for performing tasks?
- ❑ Are stairs cluttered or lacking railings?
- ❑ Is proper footwear worn?

Tools

- ❑ Is the handle too small or too large?
- ❑ Does the handle shape cause the operator to bend the wrist in order to use the tool?
- ❑ Is the tool hard to access?
- ❑ Does the tool weigh more than 9 pounds?
- ❑ Does the tool vibrate excessively?
- ❑ Does the tool cause excessive kickback to the operator?
- ❑ Does the tool become too hot or too cold?

Gloves

- ❑ Do the gloves require the worker to use more force when performing job tasks?
- ❑ Do the gloves provide inadequate protection?
- ❑ Do the gloves present a hazard of catch points on the tool or in the workplace?

Administration

- ❑ Is there little worker control over the work process?
- ❑ Is the task highly repetitive and monotonous?
- ❑ Does the job involve critical tasks with high accountability and little or no tolerance for error?
- ❑ Are work hours and breaks poorly organized?

FIG 14.10 General ergonomic risk analysis checklist. (From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.)

Risk Analysis Checklist for Computer-User Workstations

"No" responses indicate potential problem areas which should receive further investigation.

1. Does the workstation ensure proper worker posture, such as		
• horizontal thighs?	☐ Yes	☐ No
• vertical lower legs?	☐ Yes	☐ No
• feet flat on floor or footrest?	☐ Yes	☐ No
• neutral wrists?	☐ Yes	☐ No
2. Does the chair		
• adjust easily?	☐ Yes	☐ No
• have a padded seat with a rounded front?	☐ Yes	☐ No
• have an adjustable backrest?	☐ Yes	☐ No
• provide lumbar support?	☐ Yes	☐ No
• have casters?	☐ Yes	☐ No
3. Are the height and tilt of the work surface on which the keyboard is located adjustable?	☐ Yes	☐ No
4. Is the keyboard detachable?	☐ Yes	☐ No
5. Do keying actions require minimal force?	☐ Yes	☐ No
6. Is there an adjustable document holder?	☐ Yes	☐ No
7. Are arm rests provided where needed?	☐ Yes	☐ No
8. Are glare and reflections avoided?	☐ Yes	☐ No
9. Does the monitor have brightness and contrast controls?	☐ Yes	☐ No
10. Do the operators judge the distance between eyes and work to be satisfactory for their viewing needs?	☐ Yes	☐ No
11. Is there sufficient space for knees and feet?	☐ Yes	☐ No
12. Can the workstation be used for either right- or left-handed activity?	☐ Yes	☐ No
13. Are adequate rest breaks provided for task demands?	☐ Yes	☐ No
14. Are high stroke rates avoided by		
• job rotation?	☐ Yes	☐ No
• self-pacing?	☐ Yes	☐ No
• adjusting the job to the skill of the worker?	☐ Yes	☐ No
15. Are employees trained in		
• proper postures?	☐ Yes	☐ No
• proper work methods?	☐ Yes	☐ No
• when and how to adjust their workstations?	☐ Yes	☐ No
• how to seek assistance for their concerns?	☐ Yes	☐ No

FIG 14.11 Risk analysis checklist for computer workstations. (From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.)

Handtool Risk Factor Checklist

"No" responses indicate potential problem areas which should receive further investigation.

1. Are tools selected to limit or minimize		
• exposure to excessive vibration?	☐ Yes	☐ No
• use of excessive force?	☐ Yes	☐ No
• bending or twisting the wrist?	☐ Yes	☐ No
• finger pinch grip?	☐ Yes	☐ No
• problems associated with trigger finger?	☐ Yes	☐ No
2. Are tools powered where necessary and feasible?	☐ Yes	☐ No
3. Are tools evenly balanced?	☐ Yes	☐ No
4. Are heavy tools suspended or counterbalanced in ways to facilitate use?	☐ Yes	☐ No
5. Does the tool allow adequate visibility of the work?	☐ Yes	☐ No
6. Does the tool grip/handle prevent slipping during use?	☐ Yes	☐ No
7. Are tools equipped with handles of textured, non-conductive material?	☐ Yes	☐ No
8. Are different handle sizes available to fit a wide range of hand sizes?	☐ Yes	☐ No
9. Is the tool handle designed not to dig in the palm of the hand?	☐ Yes	☐ No
10. Can the tool be used safely with gloves?	☐ Yes	☐ No
11. Can the tool be used by either hand?	☐ Yes	☐ No
12. Is there a preventive maintenance program to keep tools operating as designed?	☐ Yes	☐ No
13. Have employees been trained		
• in the proper use of tools?	☐ Yes	☐ No
• when and how to report problems with tools?	☐ Yes	☐ No
• in proper tool maintenance?	☐ Yes	☐ No

FIG 14.12 Hand tool risk factor checklist. (From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.)

Risk factors to look for include the following:

1. *Forceful exertions:* Heavy lifting, pushing, pulling, twisting, gripping, or pinching. Handling heavy tools, equipment, or products. Difficulty maintaining control of equipment or tools or lifting and moving an object of asymmetric size. Also using inappropriate or inadequate tools.

2. *Repetition:* Performing the same motion or series of motions continually or frequently for an extended period (Table 14.4).

TABLE 14.4

High-Risk Repetition Rates for the Upper Extremity

Body Part	Repetitions Per Minute
Shoulder	More than 2½
Upper part of arm/elbow	More than 10
Forearm/wrist	More than 10
Finger	More than 200

From Kilbom A: Repetitive work of the upper extremity. II. The scientific basis for the guide, *Int J Ind Erg* 14:59, 1994.

3. *Awkward or static posturing, either repetitively or for prolonged periods:* Assuming positions that place stress on the body, such as reaching above shoulder height, kneeling, squatting, leaning over a work surface, using a knife or keyboard with the wrists bent, twisting the torso while lifting, or looking at a computer monitor off to one side, which causes the neck to twist all day. Also, sitting all day at a desk with poor posture.

4. *Contact stress:* Pressing the body or part of the body (such as a hand or forearm) against hard or sharp surfaces and edges (e.g., using the hand as a hammer, resting the forearms on a sharp desk edge while typing, and using pliers with the handle pressing into the palm).

5. *Excessive vibration:* For example, from power tools or sitting in a truck cab all day while driving.

6. *Cold temperatures:* Either working in cold temperature or handling cold tools or products (e.g., construction workers outside during winter handling metal tools and equipment or meat packers or butchers handling frozen meat).

Once the workstation and work methods risk factors have been identified and the workers have had a chance to familiarize themselves with the occupational therapist, focus should turn to the psychosocial aspects of the job. Frequently these factors will surface during the evaluation process without any prompting whatsoever. Factors such as workload and productivity stressors, quality of the relationship between the workers and other coworkers and the supervisor, genuine job task enjoyment, and overall health and fitness cannot be overlooked. Work-related musculoskeletal injury is never the result of any one factor; rather, it is the accumulation of a variety of risk factors and situations that ultimately result in injury. Occupational therapists look at the entire occupational profile to determine what is occurring.

Finally, it is important to ask the workers for their perspective on problem areas or risk factors in their work area. If their perspective matches what has been identified in the ergonomic evaluation of the work area and work methods, the workers should be encouraged to share their ideas for correcting the problem. Although the occupational therapist is the expert in workstation and work methods analysis, the on-site workers know their job better than anyone. The workers have probably spent hours formulating and discussing how they would change things if ever given the chance. Ask them. Often, one will find a wealth of knowledge and many useful ideas for reducing or eliminating risk factors in the people who perform the job. It is important to exercise caution before using each suggestion. As the expert, it is the occupational therapist's responsibility to ensure that the changes implemented will serve to reduce and prevent injury. Sometimes, worker-driven suggestions inadvertently cause new problems if not assessed appropriately by the ergonomic consultant.

After the on-site evaluation, the occupational therapist returns to her office to analyze the data and prepare a report. The report will be shared with whomever requested the ergonomic evaluation. The report should contain an introduction explaining the background and purpose of the ergonomic evaluation, a description of the actual work area and work methods assessment, and finally the evaluator's findings and recommendations with clear and comprehensive information regarding how to implement the recommendations and resources for securing and purchasing any equipment or services. Job tasks found to contain several risk factors for the development of WSMD have the greatest risk for injury and should be addressed first by the company. Recommendations will focus on ways to eliminate or reduce risk factors (Table 14.5).

TABLE 14.5
Combating Ergonomic Risk Factors

Risk Factor	Suggestions for Improvement
Using Excessive Force	**Reduce Force Required to Perform Activity**
Occupational therapist lifts/transfers heavy clients several times daily	Use Hoyer lift or get help from coworker
Employee uses heavy drill in a manufacturing plant	Suspend tools from ceiling with tension wire

Chef has difficulty cutting chicken in restaurant kitchen	Provide equipment to sharpen knives after every shift
Repetition	**Reduce Prolonged Exposure to Repetitive Activity**
Multiple scans required to activate grocery scanner	Implement program for regular preventive maintenance on scanners
Executive secretary required to type 5 hours in an 8-hour workday	Alternate typing task every 30 minutes with other office tasks, such as making phone calls and filing
Awkward/Static Posturing	**Reduce or Eliminate Awkward/Static Posturing**
Medical transcriptionist types with her head turned to the right to see computer screen	Move computer monitor on desk so that it is directly in line with the computer keyboard and worker's face as she looks straight ahead
Same medical transcriptionist sits in same position all day to type	Require worker to stand and gently march in place for 60 seconds after every 30 minutes of typing; provide timer to remind worker
Grocery store checkout clerk bends at waist and grabs case of soda from bottom of cart with right hand several times daily	Teach body mechanics for proper lift technique and use of two-hand power grip
Contact Stress	**Reduce or Eliminate Contact Stress**
Typist rests her forearms on sharp desk edge to type	Provide soft wrist rest until budget allows purchase of new desk with rounded edges
Jewelry maker uses pliers with short handle to twist wires; end of handle rests in palm of hand	Provide pliers with longer handle that is gently curved to fit hand
Teacher uses side of fist to punch stapler several times daily	Provide electric stapler
Excessive Vibration	**Reduce Vibration**
Drill vibrates in hand of assembly line worker in manufacturing plant	Wrap handle of power tool in vibration-dampening tape and have the worker wear antivibration gloves that fit correctly (to avoid grasping tighter than necessary to handle tool)
Cold Temperature	**Reduce Exposure to Cold**
Construction workers outside in winter handle cold metal equipment and tools	Wrap tool and equipment handles with neoprene and provide workers with thermal gloves to wear; make sure that gloves fit the workers correctly to avoid grasping objects tighter than necessary
Meat and deli teams at grocery store handle frozen foods frequently	Provide well-fitting thermal gloves to wear when handling frozen items and provide grasping tool to use for handling smaller frozen packages

Lorna benefited from a worksite evaluation. The occupational therapist went to her worksite to observe her and the other workers perform some of the essential functions of the job in their actual work environment. Risk factors were identified, such as excessive force from pinching and pulling the fabric tightly over the padded wooden frame and from using the heavy staple gun. A significant amount of force is required to push the heavy furniture to the next workstation. Her work tasks are repetitive; for example, pulling the trigger of the staple gun and pushing and pulling the fabric and furniture all day long. Lorna and the other workers were observed to have awkward posturing with frequent bending, twisting, and squatting to move the bulky furniture around to staple the fabric down.

Lorna's employer was open to the suggestions that the occupational therapist made and was willing to make the appropriate accommodations. A special tool with a padded and curved handle to fit the shape of most hands was purchased to allow the workers to use a grasp-release motion to activate a material clamp rather than using the fingers so forcefully to pinch and pull the fabric. To lessen the amount of bending, twisting, and squatting required, it was recommended that the company purchase commercially available platforms on wheels to easily move the wooden furniture frames around. Additionally, the platforms contain a simple hydraulic lift that elevates the frame to whatever height is needed for easy stapling. The occupational therapist researched and located a resource for purchase of this helpful equipment, which facilitated the employer's timely implementation of the worksite recommendations. Worksite evaluations and ergonomic interventions can also be important aspects of a comprehensive injury prevention program, as discussed in the next section.

Injury Prevention Programs

For decades the majority of occupational therapy practice has been in the area of rehabilitation. Occupational therapists are unquestionably skilled in facilitating client independence during and/or after an injury, illness, or disease. Although it is not an entirely new concept, we are now recognizing occupational therapy's potential to facilitate and perpetuate independence before or even in avoidance of these events. As we move into the 21st century, increasing numbers of occupational therapists are broadening their practices to include wellness and prevention.

Support for this movement is ubiquitous. The 1994–1996 landmark University of Southern California Well Elderly Study supports occupational therapy's preventive intervention role in enhancing physical and mental health, occupational functioning, and life satisfaction.[40] The OTPF-3 provides further support and lists health promotion, performance maintenance, and disability prevention as occupational therapy intervention approaches that facilitate "participation in life through engagement in occupations" (OTPF-3, p. S2).[1] In 2004, AOTA President Carolyn Baum, PhD, OTR/L, FAOTA, identified several prevention-related businesses as "hot" occupational therapy emerging practice areas.[57]

With regard to occupational therapy and work, prevention can take on three forms: primary prevention, secondary prevention, and tertiary prevention. **Primary prevention** efforts help protect healthy workers against a targeted condition before the condition occurs. Interventions are directed to an entire workforce to prevent a specific work-related medical problem. **Secondary prevention** emphasizes early identification of and intervention for asymptomatic workers who have risk factors for the development of work-related medical problems, in addition to identification and treatment of workers with mild medical symptoms in the early reversible stages of injury. The goal is to identify risk factors so that they can be minimized or eliminated and to reverse any medical problems that might be developing. **Tertiary prevention** occurs after a worker suffers nonreversible injury, illness, or disease. Interventions include treatment of the medical problem, attempts to restore maximum function in the workplace, and prevention of injury, illness, or disease-related complications. The goal is to return the affected worker to gainful employment within the confines of the medical problem and to prevent further injury. Once a permanent work-related injury occurs, primary and secondary prevention measures have failed. However, early risk factor detection and intervention through secondary prevention may have minimized the severity of the permanent injury.[85,99]

Most occupational therapists are familiar with the process of tertiary prevention of work-related medical problems. Typically, the occupational therapist becomes involved after a worker suffers an injury, and it becomes the therapist's job to help the client regain maximum function in the workplace and prevent further injury. Occupational therapists are also commonly involved in secondary prevention efforts. Workers are referred with mild work-related medical conditions, and intervention is planned to reverse the symptoms. When these clients get ready to return to work, the occupational therapist may assist the client in identification and modification of risk factors to reduce the risk for reinjury. Worksite evaluation and ergonomic intervention are generally part of the process for successfully reengaging these workers.

Worksite evaluation and ergonomic intervention can also be part of a comprehensive primary prevention program designed to prevent work-related injury, illness, and disease.

Helping employers improve worker fitness, job comfort, and workplace safety reduces work-related medical problems. It can also lead to improved employee morale and increased productivity.[39] Occupational therapists, acting as consultants, can assist corporate clients in establishing injury prevention programs. This is one way that occupational therapists can incorporate the concepts of wellness and health promotion into their daily practices.

Occupational therapist Michael Melnick wrote that "the success or failure of a prevention program has less to do with specific activities implemented and more to do with the methods of implementation."[60] Melnick outlines the four characteristics that are common among successful injury prevention programs: ongoing management support, supervisor "buy in," employee participation, and ongoing support and reinforcement.[60] Melnick explains that successful prevention programs are grounded in the consultant's ability to instill in the corporate client a culture of safety and wellness. The focus should be on the process of implementing safety and wellness activities and not on the activities themselves.

One common reason that an occupational therapist might be asked to consult with an industrial client is to control the severity and incidence of WMSDs. WMSDs are a class of soft injuries affecting the muscles, tendons, and nerves. Other names for WMSDs are cumulative trauma disorders, overuse syndromes, and repetitive strain disorders. WMSDs come on slowly and develop over time. They are thought to be the result of repeated microtrauma to a body and occur when the body is denied the opportunity to adequately rest and repair itself. Common diagnoses within the class of WMSDs include carpal tunnel syndrome, de Quervain tendinitis, lateral epicondylitis, and some types of back injuries.[81]

According to the Bureau of Labor Statistics, WMSDs accounted for 29% of all workplace injuries requiring time away from work in 2007.[9a] Employers pay more than $45 billion annually in worker's compensation and other expenses associated with these disorders.[4] These statistics indicate that WMSDs are at a crisis level in the workplace. However, the financial losses to industry and the economy pale in comparison to the physical and emotional pain and suffering endured by today's injured workers.

Lorna and several of her coworkers were experiencing WMSDs. Their employer agreed to implement an in-house ergonomics program and injury prevention program at the recommendation of the occupational therapy consultant. An ergonomics team was developed that consisted of the company's chief financial officer, the stapling station supervisor, the employee health nurse, the safety manager, the occupational therapist consultant, and three employees who worked in the stapling station, including Lorna.

There are a multitude of resources available for prevention consultants interested in helping corporate clients develop effective programs for evaluating and addressing musculoskeletal concerns in the workplace. OSHA and NIOSH are excellent starting points. Box 14.5 offers information on these two government entities and provides a partial list of their ergonomic and injury prevention resource materials.

Box 14.5

OSHA and NIOSH

The Occupational Safety and Health Act of 1970 created both the National Institute for Occupational Safety and Health (NIOSH) and the Occupational Safety and Health Administration (OSHA). Although NIOSH and OSHA were created by the same act of Congress, they are two distinct agencies with separate responsibilities.

OSHA

OSHA is in the U.S. Department of Labor and, as a regulatory agency, is responsible for developing and enforcing workplace safety and health regulations. OSHA developed the following publication guidelines to assist industries in developing in-house ergonomic programs:

- Ergonomic Program Management Guidelines for Meatpacking Plants (1993) (OSHA Publication 3123)
- Guidelines for Nursing Homes: Ergonomics for the Prevention of Musculoskeletal Disorders (Revised 2009) (OSHA Publication 3182)
- Guidelines for Retail Grocery Stores: Ergonomics for the Prevention of Musculoskeletal Disorders (2004) (OSHA Publication 3192-05N)
- Guidelines for Poultry Processing: Ergonomics for the Prevention of Musculoskeletal Disorders (2004) (OSHA Publication 3213-09N)
- Guidelines for Shipyards: Ergonomics for the Prevention of Musculoskeletal Disorders (2008) (OSHA Publication 3341-03N)

These publications can be ordered at http://www.osha.gov or by calling 1-800-321-OSHA.

NIOSH

NIOSH is part of the Centers for Disease Control and Prevention (CDC) within the U.S.

Department of Health and Human Services. NIOSH is an agency established to conduct research and make recommendations for preventing work-related injury and illness. NIOSH and OSHA often work together toward the common goal of protecting worker safety and health. NIOSH currently offers several publications to assist in ergonomic intervention efforts. The following may be of interest to occupational therapy practitioners wanting to get involved in ergonomics:

- Elements of Ergonomic Programs: A Primer Based on Workplace Evaluations of Musculoskeletal Disorders (1997) (NIOSH Publication 97-117)
- Simple Solutions: Ergonomics for Construction Workers (2007) (NIOSH Publication 2007-122)
- Ergonomic Guidelines for Manual Material Handling (2007) (NIOSH Publication 2007-131)
- Safe Lifting and Movement of Nursing Home Residents (2006) (NIOSH Publication 2006-117)
- Conference Proceedings: Prevention of Musculoskeletal Disorders for Children and Adolescents Working in Agriculture (2004) (NIOSH Publication 2004-119)
- Easy Ergonomics: A Guide to Selecting Non-Powered Hand Tools (2004) (NIOSH Publication 2004-164)
- Simple Solutions: Ergonomics for Farm Workers (2001) (NIOSH Publication 2001-111)
- Ergonomic Interventions for the Soft Drink Beverage Delivery Industry (1996) (NIOSH Publication 96-109)

These publications (and others) can be ordered from the CDC-NIOSH website (http://www.cdc.gov/niosh) and also by telephone from NIOSH at 1-800-CDC-INFO (1-800-232-4636); outside the United States at 513-533-8328.

It is important to remember that every corporate client is unique and that the consultant's recommendations must work within the corporate culture, goals, and budget constraints. Melnick also reminds us that we must help our corporate clients recognize that “injury prevention consultants do not reduce injuries. This would occur only if the consultant stepped in and performed each worker's job. Rather, prevention consultants help companies reduce their losses by guiding them through various activities.”[60]

As a guiding framework, however, the injury prevention consultant will want to incorporate the following elements into the corporate plan:

- A process for the organization to initially identify the potential risk for musculoskeletal problems or other risk factors in the workplace
- A strategy for showcasing management's commitment to addressing problems and encouraging open worker involvement in problem-solving activities
- Skill training to ensure that management and workers can evaluate work areas and work methods for risk factors that could lead to musculoskeletal problems
- Protocols for gathering data to identify jobs or work conditions that are most problematic and at risk by using strategies such as ergonomic evaluation
- A strategy for developing effective controls for identified risk factors that, if left untouched, could lead to musculoskeletal injury
- Protocols for outcomes assessment to see whether the musculoskeletal injury risk factor controls have actually reduced or eliminated the problem
- A plan for establishing a healthcare management program that emphasizes the importance of early detection and treatment of MSDs because early identification and treatment of these disorders almost always reduce the severity of injury and disability and their associated costs
- A plan for minimizing future risk factors for musculoskeletal injury when new work processes and work areas are in development since it is less costly to build good design into the workplace than it is to redesign or retrofit later

These essential elements of musculoskeletal injury prevention programs are based on recommendations from both OSHA and NIOSH.[14,68-71] In the 1990s and early 2000s these two agencies developed guidelines and recommendations for public and private sector organizations seeking to establish in-house musculoskeletal injury prevention programs. These informational documents are available through OSHA and NIOSH and are an invaluable resource for occupational therapists wanting to offer prevention consulting services to address WMSDs.

Empowering Corporate Clients: The Injury Prevention Team

Corporate clients initially realize they may have a problem with WMSDs in a variety of ways. Signs of potential problems include worker reports of frequent aches and pains via employee health visits or organized symptom surveys, injury and illness trends among workers performing the same job tasks, and identification of injury risk factors as a result of preventive ergonomic job analysis.[14] Fig. 14.13 presents an example of a typical symptom survey used by companies to screen for potential work-related musculoskeletal problems. Once an organization recognizes that it has a problem with WMSDs, it must develop a strategy to address the problem. At this point, corporate clients frequently seek an injury prevention consultant to "make the problem go away."

<u>Symptoms Survey: *Ergonomics Program*</u>

Date ______/______/______/

_______ Plant   _______ Dept #   Job Name ______________________________

_______ Shift   ______________________ Hours worked/week   ______ years ______ months Time on THIS Job

Other jobs you have done in the last year (for more than 2 weeks)

_______ Plant   _______ Dept #   ______________________ Job Name   ______ months ______ weeks Time on THIS Job

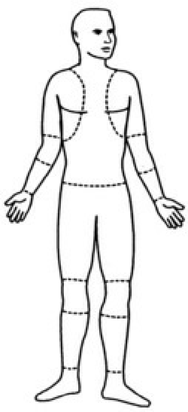
_______ Plant   _______ Dept #   ______________________ Job Name   ______ months ______ weeks Time on THIS Job

(If more than 2 jobs, include those you worked on the most)

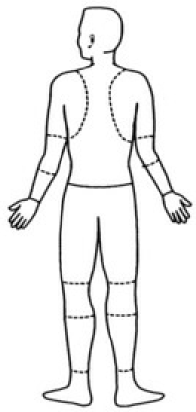
Have you had any pain or discomfort during the last year?

☐ Yes   ☐ No (If NO, stop here)

If YES, carefully shade in area of the drawing which bothers you the MOST.



Front



Back

(Continued)

(Complete a separate page for each area that bothers you)

Check Area: ☐ Neck ☐ Shoulder ☐ Elbow/Forearm ☐ Hand/Wrist ☐ Fingers
☐ Upper Back ☐ Low Back ☐ Thigh/Knee ☐ Low Leg ☐ Ankle/Foot

1. Please put a check by the words(s) that best describe your problem

☐ Aching	☐ Numbness (asleep)	☐ Tingling
☐ Burning	☐ Pain	☐ Weakness
☐ Cramping	☐ Swelling	☐ Other
☐ Loss of Color	☐ Stiffness	

2. When did you first notice the problem?__________ (month)________ (year)
3. How long does each episode last? (Mark an X along the line)

__________/__________/__________/__________/__________/
1 hour 1 day 1 week 1 month 6 months

4. How many separate episodes have you had in the last year?____________________
5. What do you think caused the problem?____________________

____

6. Have you had this problem in the last 7 days? ☐ Yes ☐ No
7. How would you rate this problem? (mark an X on the line)

NOW

____
None Unbearable

When it is the WORST

____
None Unbearable

8. Have you had medical treatment for this problem? ☐ Yes ☐ No

8a. If NO, why not?____________________

8b. If YES, where did you receive treatment?

☐ 1. Company Medical Times in past year ____________
☐ 2. Personal doctor Times in past year ____________
☐ 3. Other Times in past year ____________

Did treatment help? ☐ Yes ☐ No ____________

9. How much time have you lost in the last year because of this problem?_____days
10. How many days in the last year were you on restricted or light duty because of this problem?

_____ days

11. Please comment on what you think would improve your symptoms

FIG 14.13 Symptom surveys are sometimes used as screening tools in companies that suspect problems with work-related musculoskeletal disorders. Workers are asked to voluntarily fill out the survey. The surveys are analyzed for trends indicating similar musculoskeletal symptoms within certain work groups. If workers from a specific work group tend to have similar complaints, the job tasks and workstations should be analyzed further. (From Cohen AL, Gjessing CC, Fine LJ, et al: *Elements of ergonomics programs: a primer based on workplace evaluations of musculoskeletal disorders,* Washington, DC, 1997, US Government Printing Office.)

Corporate clients frequently seek injury prevention specialists in the hope of achieving a quick and definitive fix. However, controlling WMSDs needs to be an ongoing process of control and management. The injury prevention consultant must work toward empowering the corporate client to maintain a successful injury prevention program consistently over time. The consultant must ensure that the client company has the knowledge and skills to follow through with the program.

The role of the injury prevention consultant is to help the organization put together a team and a strategy for ongoing identification and control of risk factors for musculoskeletal injury.

In the same way that occupational therapists teach individuals to be self-sufficient in performing activities of daily living, they can also teach their corporate clients to be self-sufficient in controlling risk factors for musculoskeletal injury in the work environment. This client-centered approach has occupational therapy intervention focused on the corporate client's priority of controlling work-related injuries and their associated costs. The occupational therapy intervention plan is the development of a corporate in-house injury prevention team. Another name for this team is the ergonomics team.

Usually the injury prevention consultant will decide with corporate management who will be a part of the ergonomics team. Ideally the team will be composed of representatives from management; front-line supervisors; production workers; labor unions; employee health, safety and/or industrial hygiene; engineering; and the injury prevention/ergonomics consultant. The exact makeup of the team will vary, depending on the nature of the organization and corporate structure. The team meets and formulates a strategy for developing and implementing the injury prevention program.

Initial meetings will typically focus on the nature and scope of reported injuries and the effects that these injuries have had on production, worker's compensation and associated costs, employee retention, and employee morale. An analysis of existing medical, safety, and insurance records can be conducted for the purpose of identifying injuries associated with MSDs. Healthcare team members should be encouraged to present medical record and injury information in a way that protects the confidentiality of individual workers. The team can then determine incidence rates of MSDs and look at trends that indicate problem work areas or job tasks.

Once the scope of the problem has been analyzed, the team will decide on a plan of attack for prevention of injury. In general the magnitude and location of existing problems will suggest the magnitude and direction of the initial team efforts. The consultant will want to direct the corporate client to address the most grievous and resource-draining problems first. If, on analysis of the data, the problems seem widespread and involve a large percentage of the workforce, the plan of attack will probably be an aggressive company-wide program. On the other hand, if the problems seem to be isolated to just a few work areas or employees, the initial plan would probably be more focused and direct.[14]

Management Commitment

The industrial safety and health literature stresses that the support of management in injury prevention efforts is crucial for successful implementation and outcomes.[14] The consultant will want to ensure that management commitment to the process is genuine. If there is a lack of sincere, top-level support for the injury prevention program, a consultant would be wise to pass on his or her involvement. Consultants are judged on their record of success. Prevention efforts without management support are destined to fail.

A good injury prevention consultant knows that employees want to see evidence of management support for all new programs. One of several ways to assist corporate clients in demonstrating support to the workforce is to encourage management to issue policy statements that give injury prevention efforts equal priority with productivity standards and cost control. Management should also meet with employee or union representatives (who should ideally be part of the ergonomics team) to discuss new policy and injury prevention program plans and show evidence of committing resources to implement the injury prevention program. Goals should be set and timelines established for meeting these goals, with specific people assigned responsibility and held accountable for overseeing various aspects of the program. Finally, information about the program should be disseminated to the entire workforce, from planning, to implementation, to evaluation. Employees want and need to feel that they are a part of the organization's commitment to safety.[10,14]

Training in Risk Factor Identification/Ergonomic Evaluation and Problem Solving

Research has identified specific physical activity demands that place people at risk for the development of WMSDs: repetition, force, awkward or static posturing, prolonged direct pressure on soft tissue, vibration, exposure to cold, and inappropriate or inadequate hand tools.[14,68-71,81] Additionally, psychosocial stressors at work can contribute to the development of WMSDs.[14] Although this is an area in need of further study, these types of stressors can include excessive volume or productivity expectations, work that is "too difficult" or beyond the intellectual or emotional capacity of the employee, or a superior who does not express appreciation for a job well done. It is the combination of physical and psychosocial risk factors that the ergonomics team must address as part of an injury prevention program for WMSDs.

The ergonomics team will probably have the injury prevention consultant perform the first ergonomics evaluations at the workplace and present the first suggestions for improvement. However, key members of the injury prevention team should receive training in performing these evaluations themselves and training on how to formulate solutions. In this way the evaluation part of the process is not reliant on an outside source. The goal, eventually, is to have the injury prevention consultant step out of the picture and leave behind a self-sufficient team of in-house experts to implement an ongoing process of risk factor identification for control of MSDs.

Fig. 14.10 is an example of a general ergonomic injury risk analysis checklist. Members of the injury prevention team could be trained to use this tool to screen a variety of jobs for risk factors for musculoskeletal injury. Similarly, Fig. 14.11 is an example of a job-specific screening tool. This checklist helps evaluators identify risk factors for musculoskeletal injury in computer users. Fig. 14.12 is a hand tool analysis checklist. The injury prevention consultant or ergonomics team members could choose to modify any of these screening tools to match jobs specific to the organization.

The NIOSH publication "Elements for Ergonomics Programs 12," lists several objectives for team member training. A successfully trained team member will be able to do the following:

- Recognize risk factors for musculoskeletal injury and understand basic methods for their control
- Identify signs and symptoms of musculoskeletal injury in workers
- Understand the company's injury prevention program thoroughly and everyone's role and responsibility from top-level management to front-line worker
- Know the company's procedure for reporting identified risk factors and signs and symptoms of musculoskeletal injury
- Demonstrate the ability to perform a basic ergonomic evaluation for identifying risk factors for musculoskeletal injury
- Recommend ways to control injury risk factors based on collaboration with employees, management, and other members of the ergonomics team
- Select ways to implement and evaluate the control measures
- Demonstrate skill in team building, consensus development, and problem solving

Some companies will decide to extend training to other members of the workforce. General training can be provided to employees who may potentially be exposed to hazards for musculoskeletal injury. Training can include how to recognize and report early signs and symptoms of musculoskeletal injury, information on identifying risk factors for musculoskeletal injury both at work and outside work, and strategies for workers to protect themselves from the development of musculoskeletal injury. Supervisors should receive the same training as workers, in addition to training in techniques to reinforce proper body mechanics and other important aspects of the injury prevention program.[71]

Training the ergonomics team in skills required to sustain the injury prevention program is a substantial aspect of the consultant's role. The consultant selects or designs the training and training materials to be understandable to the layperson in accordance with the participants' educational levels and literacy ability. Consideration of language skills is also important, and attempts should be made to provide materials in the primary language of the employee.[14] Outside training courses are also valuable in bringing perspective to the organization's situation. Interaction with other companies' course attendees provides opportunities for company-to-company networking. Many resources exist for locating appropriate training courses, including NIOSH and OSHA.

Developing Risk Factor Controls

The ergonomics evaluations will identify known risk factors for the development of MSDs. Risk factors might include forceful exertions, awkward or static posturing, repetition, contact stressors, vibration, exposure to cold, and/or psychosocial stressors. These identified risk factors will be brought back to the ergonomics team for discussion. Once high-risk areas or tasks have been identified, the task of the team then becomes formulating ways to reduce or eliminate the risk factors for musculoskeletal injury.

At this point it is important to use as many front-line production workers in the problem-solving process as possible. Workers know their jobs better than anyone and may have already formulated some ideas about improving the work area or work methods. Promoting worker involvement at this point has several benefits: enhanced worker motivation and job satisfaction, added team problem-solving capabilities, greater acceptance of workplace change, and greater knowledge of the work and organization.[12,14,48,49,66]

When workers present ideas for risk factor modification, it is essential that the injury prevention consultant and the in-house ergonomics team ensure that these potential solutions are appropriate and do not carry with them any potential for creating new problems. Union representatives should ensure that the suggested solutions do not violate employee-management understandings and contracts. Engineering's role is to evaluate suggested solutions for practical and physical feasibility. Management's role is to provide input regarding the organizational and financial appropriateness of the suggested solutions.

There are a variety of ways to reduce or eliminate risk factors for musculoskeletal injury. The 1991 OSHA publication *Ergonomics Program Management Guidelines for Meatpacking Plants* outlines a variety of risk factor control strategies applicable to most any workplace situation. These strategies can be categorized as either engineering controls, work practice controls, administrative controls, or use of personal protective equipment.[71]

Engineering controls include strategies for designing or modifying the workstation, work methods, and/or tools. The goal is to eliminate or reduce excessive exertion, awkward postures, and repetition. Workstations should be designed or modified to accommodate the actual worker at that workstation. If more than one person uses a workstation, elements of the workstation should be adjustable to fit each worker and be comfortable for the workers to use. Work methods should be designed or modified to minimize static and awkward posturing, repetitive motions, and excessive force. Tools and handles should be designed for a specific job and minimize contact stress, vibration, and forceful motions/gripping by the worker's hands.[71]

Work practice controls include policies and procedures for safe and proper performance of tasks that are understood by all and enforced by supervisors. Workers should receive training in proper body mechanics, tool maintenance, and use of workstation adjustability features. New workers and those who have been away for a while should be allowed adequate break-in periods to condition and recondition their bodies for the physical demands of the job. Supervisors and management should constantly monitor the use and effectiveness of work practice controls and make adjustments in techniques, line speed, and staffing as needed to maintain a safe and healthy work environment.[71]

Selection and use of personal protective equipment should be in line with the overall injury prevention program. Equipment should be available in a variety of sizes to accommodate the size differences among workers. Proper fit is especially important for gloves because improperly fitting gloves can reduce blood flow and sensory feedback and lead to slippage and use of excessive grip and pinch force. Protection against extreme cold (below 40° F) is required to protect joints and soft tissues. Back braces and upper extremity splints should not be considered personal protective equipment. These devices are part of the medical management aspect of the program and should be used only with the advice and under the supervision of the healthcare team.[71]

Finally, administrative controls must be an option in situations in which musculoskeletal risk factors cannot be adequately reduced or eliminated via engineering controls, work practice controls, and the use of personal protective equipment. Administrative controls reduce the duration, frequency, and severity of exposure to risk factors. Methods include decreasing production rates, limiting overtime work, providing periodic rest breaks throughout the day, increasing staffing levels, and using job rotation/job enlargement to other jobs and tasks that involve the use of different muscle-tendon groups.[71]

When the team comes to a consensus on which methods to use to reduce or eliminate the risk factors for musculoskeletal injury, it is time to formulate a plan and implement the proposed solutions. However, before any changes are made, it is important to again solicit employee feedback regarding these plans, especially from employees who are not involved in the ergonomics team. Most people are resistant to change; it is human nature. Soliciting and sincerely listening to feedback improve employee buy-in for the proposed changes. Additionally, this feedback might identify implementation problems that the ergonomics team overlooked. Even the best idea for improving the comfort and safety of a job cannot be successfully implemented without employee support. Performing this step in the process is well worth the time and effort.

Medical Management Strategies

In addition to identifying risk factors for musculoskeletal injury and implementing plans to reduce or eliminate these risk factors, it is important for the ergonomics team to develop a medical management plan. Initiating early conservative medical treatment is key to minimizing serious disorder and dysfunction.[63] Workers should be trained to identify early symptoms of MSDs so that they can seek medical care. The employee health staff should formulate guidelines for the management of employees with early symptoms of MSDs. This plan might include oral antiinflammatories, splinting, rotation to light duty or time off work, and occupational therapy. The physician and/or employee health nurse will usually lead the effort in developing medical management guidelines for the organization.

As occupational therapists, it is important to understand the role and implications of upper extremity splinting of work-related injuries. The healthcare team should think about the possible ramifications of prescribing an upper extremity splint to a worker who plans to remain on the job. It is true that splinting helps rest the injured body part and that this can be helpful for recovery from a musculoskeletal injury. However, when a worker is restricted from moving (e.g., the wrist during work), the result is often that the elbow or shoulder will compensate by positioning itself awkwardly to get the task accomplished. Splinting during work may protect the wrist, but the result could be injury to the elbow, shoulder, neck, or back. Therefore splints should not be used at work unless the healthcare team understands the worker's job tasks and can ensure that using the splint will not place stress on other parts of the body.

Outcomes Assessment and Preventing Future Problems

Once the ergonomics team has implemented both efforts at controlling risk factors for musculoskeletal injury and the medical management process, the entire injury prevention program must be evaluated for effectiveness. Outcomes measures are useful in determining whether the program is working and to what extent. If the program does not seem to be working to any significant degree, the team will continue to modify its efforts until the incidence of WMSDs has declined to acceptable levels. The injury prevention program should be considered an ongoing process rather than a short-term solution to an identified incident or problem work area. Most ergonomics teams find that as soon as one problem work area is under control, another problem is identified that requires the focus of the team's efforts.

The occupational therapist is an invaluable resource for helping organizations develop in-house injury prevention programs to control risk factors related to the development of musculoskeletal injury. The occupational therapist's basic training in occupational performance analysis, problem identification, intervention planning and implementation, and outcomes assessment makes the fields of ergonomics and injury prevention ideally suited for practitioners of our profession. The NIOSH and OSHA are valuable resources for occupational therapists interested in working in ergonomics and injury prevention.

Fitness for Duty Testing

A frequent use of functional testing includes assessing a person's ability to meet certain physical requirements before being hired for a job; hence the term "fitness for duty."[78] Some preemployment testing may consist of isometric strength testing, ROM testing, or actual measurement of a person's ability to perform selected tasks from the job description. These types of testing may be known by a variety of names: Post Offer Employment Testing (POET), Post Offer Screening (POS), Pre Employment Testing (PET), Post Offer Physical (POP), Essential Function Testing (EFT) among others. This type of testing can be an integral part of a company's comprehensive injury prevention and management strategy.[78]

OT Practice Notes

Because of their task analysis training and holistic approach, occupational therapists are excellent candidates for assisting companies with expansion of plans to more effectively manage employee injuries.

When a company is looking at the overall impact of an employee injury on the bottom line, it goes much further than simply the cost associated with the injury itself. It extends beyond the medical costs to include the employee's compensation, benefit package payments, training of replacement personnel, replacement personnel wages, and overtime payment for existing personnel if they are needed for coverage. This does not include the indirect costs of diminished productivity during the period when coverage is being arranged. The total impact can be quite staggering. The cost of developing an employment screening process is significant; however, the cost savings to the company can be dramatic.[78]

The EEOC's *Uniform Guidelines on Employee Selection Procedures* sets forth guidelines for the structure and function of human resource departments within companies and businesses. The guidelines also address how an organization can select and manage employees and places strong emphasis on the necessity of policies and procedures being job related.[24,78] The EEOC also mandates that an employer's selection process not have an adverse impact on any group of people and must not discriminate on the basis of race, color, religion, gender, or national origin, as established by Title VII of the Civil Rights Act of 1964.[24,78] Meeting these criteria requires that the selection procedures demonstrate validation, be of business necessity, and be a bona fide occupational requirement.[24,78]

To be compliant with the ADA, preemployment screening must be based on an accurate job description, test only the essential functions (although not every function need be assessed), and have high face validity, often referred to as content validity (i.e., it tests what the examiner really wants to know), or closely mirror the aspects of the job for which the person is being tested.[6,78] Dynamic testing (actually replicating physical tasks from the job) is recommended; it can be conducted on-site at the company or off-site, and it needs to use equipment from the job as it is available.[78] It is vital that companies take the time to thoroughly develop their screening process to be able to defend why the screening was considered necessary, maintain awareness and vigilance in the development phase of good test design, and be prepared to explain and demonstrate the applicability of the screening to the job in question.[78]

Preemployment testing can also occur at several points in the hiring process; however, many healthcare providers and legal experts recommend conducting such testing after an offer of employment has been extended.[31,54] With postoffer screening (POS), the most advantageous progression is to interview the applicant and determine whether the person is an acceptable candidate for employment.[78] A conditional offer is extended to the applicant based on the applicant's ability to meet a variety of conditions, such as passing a drug screen, acceptable background check, and physical testing. A problem with preoffer testing is that Title 29 of the Code of Federal Regulations specifically states that medical examination is permissible "after making an offer of employment to a job applicant."[13] Monitoring blood pressure or the heart rate or inquiring about past medical history is considered to be part of a medical examination and is precluded in preoffer testing.[78]

Anything that a therapist does in the way of evaluating an applicant might be deemed medical simply because an occupational therapist is a medical professional. It is also important to look critically at any testing that is considered to be general strength testing because it has been found to be a poor predictor of potential for injury.[21,65,78] Normative databases also are of little use in making hiring decisions because, according to both the ADA and the EEOC, it does not matter whether the applicant falls into the 5th percentile or the 95th percentile; the only thing of importance is whether the applicant can perform the tasks of the job.[6,24]

If the applicant passes the screening, he or she is hired and begins working. If the applicant does not pass, the employer must assess whether the applicant has a disability as defined under the ADA (see Chapter 15).[6] If the applicant does, the employer must determine whether reasonable accommodation can be offered to the applicant so that the individual may be able to perform the job. Reasonable accommodation means providing accommodation in such a way that the employer is not placed under undue financial strain for the accommodation to be implemented. If the company can and does offer accommodation to the applicant, the hiring process is completed and the employment begins. If the company cannot offer reasonable accommodation or if the applicant does not have a disability yet fails the screening, the employer can choose to rescind the offer of employment, examine opportunities for alternative placement elsewhere in the company, or offer remediation of some type and allow the applicant to retest if certain criteria are met.[78] For example, if a nondisabled applicant does not pass the lifting portion of a POS and otherwise meets the employment criteria, the company might elect to allow the applicant 2 weeks to improve strength with the goal of returning for a retest screen in an attempt to pass the lifting portion.

Suppose Henry (the roofer in the case study) had difficulty balancing on one leg as a result of an early childhood accident but that this balance problem was not something that was readily apparent. If a POS had been conducted on Henry before he was hired at the roofing company, and balance was a component of testing for working as a roofer, his difficulty could have been detected and Henry could have been denied the job or offered alternative placement. Either way Henry would have been protected from a fall that would radically change his life.

A company does not have to test applicants for every job. Typically, it is suggested that a company survey all of its injuries and determine where the majority of injuries are occurring and if they are occurring within the first 6 months of hiring. If so, this company is a good candidate for implementing a physical screen as part of the hiring process. Once it has been determined which jobs are going to be selected for testing, the physical demands of the job must be evaluated. This can be done by survey, questionnaire, or observation (either direct or video).[7] The job description must include information that is functional in terms of physical demands, describe the essential tasks of the job, and be presented in such language that one can test for an individual's ability to perform them.[7] In the case of a company requesting that existing job descriptions be used for development of the screen, it is extremely important to document that the company provided the job descriptions and that the therapist does not assume any liability for errors in their accuracy.

Physical demand items can then be selected for testing during screening based on either the difficulty or the frequency of the item. It is not necessary to test all of the physical demands for each job. For instance, a job might include carrying 10 lb a distance of 10 feet twice a day and lifting 40 lb from pallet height to waist height 200 times per day. Testing the ability to lift 40 lb would be a better selection for testing because if the applicant is able to lift 40 lb from pallet height to waist height, it is likely that he or she will also be able to carry 10 lb a distance of 10 feet. It is important to select a method of testing the tasks that is reliable and valid and demonstrates job applicability, whether choosing from a standardized battery of physical demand tests or developing job-specific tasks to improve the applicant's understanding of the relevance of the task and defensibility of hiring decisions.[24,78]

After tasks have been selected, implementation can begin. It is suggested that a statistically significant sample of incumbents be tested to ensure that the correct demands have been selected and that the minimum requirements for each demand have been set appropriately. Once pilot testing has been completed, the screening can be administered consistently to all applicants for a given job. It is also recommended that the screening process be monitored to ensure that fair and nondiscriminatory selection of applicants is occurring and that modifications in the screening process can occur as needed.[78]

Ethical Considerations

It is imperative for the clinician to encourage companies to have written policies regarding the screening process, including how to handle screening failures.[78] It is also important to extricate the therapist from the hiring process in that all communications come from the employer, so the therapist is allowed to maintain objectivity and third-party distance from the course of action.[78] Continuing documentation and follow-up help establish a definitive paper trail demonstrating the business necessity for implementing a pre-employment screening process, the steps taken to select and analyze the job and tasks to be tested, the implementation phase, ongoing quality assurance to monitor any changes in the job and reflect subsequent changes in the screening and the actions taken to handle screening failures, reasonable accommodation, and avoidance of adverse impact.[78]

Transition Services From School to Work

Occupational therapy practitioners can make a valuable contribution to students with disabilities who are transitioning from school to the community. The 1997 amendments to the Individuals with Disabilities Education Act (IDEA) of 1990 specified that transition planning is to be part of the Individualized Education Program (IEP). Representatives from community agencies that provide postschool services, such as state-sponsored vocational rehabilitation, must join the education team. Related services, such as occupational therapy, are formal contributors to the transition planning for students who need these types of services.[94] Transition services are defined by the IDEA as "a coordinated set of activities for a student designed within an outcome-oriented process, which promotes movement from school to post-school activities, includes postsecondary education, vocational training, integrated employment (including supported employment), continuing and adult education, adult services, independent living, or community participation."[93] Occupational therapy's unique focus on occupational performance can be a strong asset to the transition team.

The three main roles that an occupational therapist will participate in are transition-related evaluation, service planning, and service implementation. The occupational therapist contributes vital information about students' performance abilities and needs in any of the transition domains: domestic, vocational, school, recreational, and community.

Transition-Related Evaluation

Effective transition-related evaluation primarily uses nonstandardized interviews, situational observation, and activity analysis approaches. These approaches are top-down, which means that they first consider what the student wants or needs to do and secondarily identify the occupational performance issues that are causing difficulties.[7] The transition team helps the student identify a positive, shared vision for the future. This can include living alone or with others in the community, attending postsecondary schools or training programs, working in a paid or volunteer job, using community services, and participating in activities of interest. The occupational therapist and other members of the team work together to identify the student's present interests and abilities within the context in which performance is expected or needed. The evaluation process also allows the team to identify areas in which the student is likely to need ongoing support and resources to achieve his or her vision and goals for the future.

Service Planning

In a collaborative transition team, the team members collectively share information and write down the student's goals.[94] The team members do not record discipline-specific goals that focus on remediating the student's underlying deficits. The occupational therapist, for example, does not need to write specific goals addressing cognitive, motor, or psychosocial skills. Instead, two or more group members work together to write the goals and work collaboratively with the student to accomplish the goals. A student with limited movement in her arms and hands may have the goal of being able to complete written assignments. The occupational therapist may take the lead in evaluating the effectiveness of using alternative writing methods such as assistive technology. Recommendations are made to the student and the team. If the team supports the recommendations, the team would assign responsibility for obtaining the equipment and also provide training to the student and other team members. Rainforth and York-Barr define collaboration as "an interactive process in which persons with varied life perspectives and experiences join together in a spirit of willingness to share resources, responsibility, and regards in creating inclusive and effective educational programs and environments for students with unique learning needs."[82]

Program Implementation

The occupational therapist provides services in collaboration with the student and his or her teachers, parents, employers, coworkers, and others as necessary to address the student's goals in the domestic, vocational, school, recreation, and community areas. Occupational therapy personnel (including the occupational therapist and the OTA) deliver transition services in the student's natural environments. Therefore occupational therapy may provide intervention in the student's school, workplace, home, or any other relevant setting in the community. Collaborative problem solving with others involved in the student's environment is essential to help the student use alternative methods to complete the necessary activities. For example, an occupational therapist may introduce and train the teacher in using assistive technology to help a student be able to access the computer at school to do written assignments. The occupational therapy practitioner may provide direct or consultative services to help minimize discrepancies in the student's abilities and the demands of any environment. Evaluating whether the student reaches his or her goals should be the outcome measure to evaluate the effectiveness of occupational therapy services.

Work Readiness Programs

Many times people who have survived a major accident or illness cannot return to their prior employment and need to explore other options for employment. For example, Henry can no longer meet the job demands of a roofer. Henry may really want to return to some type of meaningful work but needs guidance and direction to explore what his present abilities and work skills are so that he can set some realistic vocational goals.

A **work readiness program** is designed to help individuals who desire to work identify vocational options that match their interests, skills, and abilities. At Rancho Los Amigos National Rehabilitation Center in Downey, California, an occupational therapist developed and implemented an ongoing work readiness program as part of the Occupational Therapy Vocational Services. This is an 8-week program that meets two times a week for 2 hours. It consists of people with various diagnoses (e.g., stroke, traumatic brain injury, and spinal cord injury) who meet as a group. Topics addressed include work habits, goals, interests, work skills, vocational exploration, job hunting strategies, and community resources. Instruction, group discussion, and hands-on exploration of work skills via standardized work samples and situational assessments are used to help people explore their readiness to work and discover their potential for pursuing training for a different occupation. Field trips to a real business in the community are sometimes conducted to allow participants to practice actual work tasks in the community. For example, one field trip may be to a hardware store to practice dusting shelves, reorganizing and moving misplaced merchandise in the aisles and to practice visual scanning, dynamic standing balance, reaching, and bending.

Each person's program is individualized to address specific goals and interests. For example, Henry may be interested in working with a computer. He would be given the opportunity to do different work-related tasks using a computer so that he could see whether he has an aptitude for this type of work. If Henry was not familiar with the types of jobs that a person could do with a computer, he would learn how to do vocational research by using various reference books in the library or on the Internet.

A work readiness program can help people identify specific goals to pursue and develop a plan to help them work toward their goals. This program can help a person prepare for returning to work, but it does not provide a job for the participant. At the completion of the program, if a person demonstrates readiness to work, he or she can be referred to the state's Department of Rehabilitation for assistance in job training and job placement. After completing a work readiness program, the occupational therapist can provide valuable information on a person's skills, aptitudes, and interests to assist the rehabilitation counselor in developing a feasible plan for the worker. While Henry was attending the work readiness program, he identified the goal of becoming a computer support technician. Based on the vocational testing and research that he did during the program, this was determined to be a reasonable goal for him to pursue. He was referred to his state's Department of Rehabilitation for job training and job placement in his new career.

Work Activity Groups

Occupational therapists can develop and implement work-related activity groups for people with physical disabilities to build the strength and stamina, hand dexterity, standing balance and endurance to engage in productive activities. By engaging in various activities, such as woodworking, basic carpentry, ceramics, card making, sewing, and jewelry making, people can improve their physical and cognitive performance skills while producing tangible products. Participants can also learn adaptive strategies to use tools and complete tasks using one hand after a stroke, or can practice using the affected hand as an active assist to complete a bimanual task.

At Rancho Los Amigos National Rehabilitation Center, clients who have had a stroke, brain injury, spinal cord injury, or amputations due to diabetes, or who have other neurologic illnesses, manufacture handcrafted gift items which are sold in the hospital gift shop operated by volunteers who have completed the vocational program. Individuals gain confidence and self-esteem and develop new work skills and interests by participating in this program.

Community-Based Services

Historically, work-related programs took place within medical model clinics, such as rehabilitation programs or settings designed for work intervention, as opposed to the site where the worker actually performed his or her role.[90] Today work programs are increasingly being located in the community in which the participant resides or within the work setting itself.[90] This trend toward increased community practice is probably due to changes in the field of occupational therapy and external forces influencing the practice. Current thinking in occupational therapy recognizes that "occupational dysfunction is multidimensional, resulting from the interplay of biological, psychological, and ecological factors."[90] Decreasing reimbursement in medical model settings has resulted in occupational therapists exploring other options for reimbursement in the community.
