Systematic Review and Meta-Analysis of Clinical Outcome After Implantable Cardioverter-Defibrillator Therapy in Patients With Chagas Heart Disease

Fabio Mahamed Rassi, MD,[a,b] Lucas Minohara, MD,[b] Anis Rassi, Jr, MD, PhD,[a] Luis Claudio Lemos Correia, MD, PhD,[c] José Antonio Marin-Neto, MD, PhD,[d] Anis Rassi, MD,[a] Antonio da Silva Menezes, Jr, MD, PhD[b]

ABSTRACT

OBJECTIVES The goal of this analysis was to pool data from published studies on outcomes after implantable cardioverter-defibrillator (ICD) therapy in patients with Chagas heart disease (CHD).

BACKGROUND CHD is characterized by a high burden of ventricular arrhythmias and an increased risk of sudden cardiac death. The indications for ICD are not well established.

METHODS An extensive literature search without language restrictions was performed to identify all studies on ICD therapy in patients with CHD. A random effects model was used to calculate percentages and 95% confidence intervals (CIs).

RESULTS Of 397 articles screened, 13 studies (all observational) were included. There were 1,041 patients (mean age at implantation 57 ± 11 years; 64% men), most of whom (92%) received an ICD for secondary prevention. Antiarrhythmic medication consisted of amiodarone (79%) and beta-blockers (44%). Overall, the annual all-cause mortality rate was 9.0% (95% CI: 6.9 to 11.7) in 2.8 ± 1.9 years of follow-up, and the annual sudden cardiac death rate was 2.0% (95% CI: 1.3 to 3.3) in 2.6 ± 1.9 years. In addition, 24.8% (95% CI: 15.7 to 37.0) of patients received 1 or more appropriate interventions (shocks or antitachycardia pacing), 4.7% (95% CI: 3.2 to 6.9) received inappropriate shocks, and 9.1% (95% CI: 5.5 to 14.7) had electric storms annually.

CONCLUSIONS In patients with an ICD, annual all-cause mortality rate was 9%. Appropriate ICD interventions and electric storms were frequent, occurring at a rate of 25% and 9% per year, respectively. Inappropriate ICD shocks were not infrequent (5% per year). The benefits and risks of ICD therapy in patients with CHD should be carefully weighed until data from better studies become available. Treatment with Benznidazole during the Chronic Phase of Experimental Chagas' Disease Decreases Cardiac Alterations

Simone Garcia,[1,2] Carolina O. Ramos,[1] Juliana F. V. Senra,[1] Fabio Vilas-Boas,[3] Maurício M. Rodrigues,[4] Antonio C. Campos-de-Carvalho,[2] Ricardo Ribeiro-dos-Santos,[1] and Milena B. P. Soares[1]*

Centro de Pesquisas Gonçalo Moniz, Fundação Oswaldo Cruz,[1] and Hospital Santa Izabel,[3] Salvador, Bahia, Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro,

These results demonstrate that treatment with benznidazole in the chronic phase of infection prevents the development of severe chronic cardiomyopathy, despite the lack of complete parasite eradication. In addition, our data highlight the role of parasite persistence in the development of chronic Chagas' disease and reinforce the importance of T. cruzi elimination …

Pacientes tratados com benznidazol tivereram um risco significantemente menor de eventos clínicos (71% menor (84 a 45% menor).
Até 18% de descontinuações do tratamento por efeitos colaterais.

Received 17 June 2009; returned 25 July 2009; revised 8 September 2009; accepted 10 September 2009

Results: **We identified 696 studies, from which we chose 9: 3 clinical trials and 6 observational studies. Compared with placebo or no treatment, benznidazole increases 18-fold the probability of a response to therapy [global odds ratio (OR), 18.8; 95% confidence interval (CI), 5.2–68.3]. This effect was mainly observed in clinical trials (OR, 70.8; 95% CI, 16.4–314), whereas in observational studies it was much less marked (OR, 7.8; 95% CI, 2.1–28.9), and even less so when only observational studies in adults were considered (OR, 6.3; 95% CI, 1.6–24.7). Patients treated with benznidazole had a significantly lower risk of clinical events (OR, 0.29; 95% CI, 0.16–0.53). Up to 18% of patients discontinued treatment due to toxicity (cutaneous reactions followed by gastrointestinal disturbances); this was less common in children than in adults.**

Rationale and design of a randomized placebo-controlled trial assessing the effects of etiologic treatment in Chagas' cardiomyopathy: The BENznidazole Evaluation For Interrupting Trypanosomiasis (BENEFIT)

Jose Antonio Marin-Neto, MD,[a] Anis Rassi, Jr, MD,[b] Carlos A. Morillo, MD,[c] Alvaro Avezum, MD,[d] Stuart J. Connolly, MD,[c] Sergio Sosa-Estani, MD,[e] Fernando Rosas, MD,[f] and Salim Yusuf, MD[c] on behalf of BENEFIT Investigators *Sao Paulo and Goiania, Brazil; Hamilton, Ontario, Canada; Buenos Aires, Argentina; Bogota, Colombia*

2855 Pts followed for at least 3 years (mean = 6 years) – End of Study : 2015

Background Benznidazole is effective for treating acute and chronic (recently acquired) *Trypanosoma cruzi* infection (Chagas' disease). Recent data indicate that parasite persistence plays a pivotal role in the pathogenesis of chronic Chagas' cardiomyopathy. However, the efficacy of trypanocidal therapy in preventing clinical complications in patients with preexisting cardiac disease is unknown.

Study Design BENEFIT is a multicenter, randomized, double-blind, placebo-controlled clinical trial of 3,000 patients with Chagas' cardiomyopathy in Latin America. Patients are randomized to receive benznidazole (5 mg/kg per day) or matched placebo, for 60 days. The primary outcome is the composite of death; resuscitated cardiac arrest; sustained ventricular tachycardia; insertion of pacemaker or cardiac defibrillator; cardiac transplantation; and development of new heart failure, stroke, or systemic or pulmonary thromboembolic events. The average follow-up time will be 5 years, and the trial has a 90% power to detect a 25% relative risk reduction. The BENEFIT program also comprises a substudy evaluating the effects of benznidazole on parasite clearance and an echo substudy exploring the impact of etiologic treatment on left ventricular function. Recruitment started in November 2004, and >1,000 patients have been enrolled in 35 centers from Argentina, Brazil, and Colombia to date.

Conclusion This is the largest trial yet conducted in Chagas' disease. BENEFIT will clarify the role of trypanocidal therapy in preventing cardiac disease progression and death. (Am Heart J 2008;156:37-43.)

Safety: Adverse Events Leading to Drug Interruption

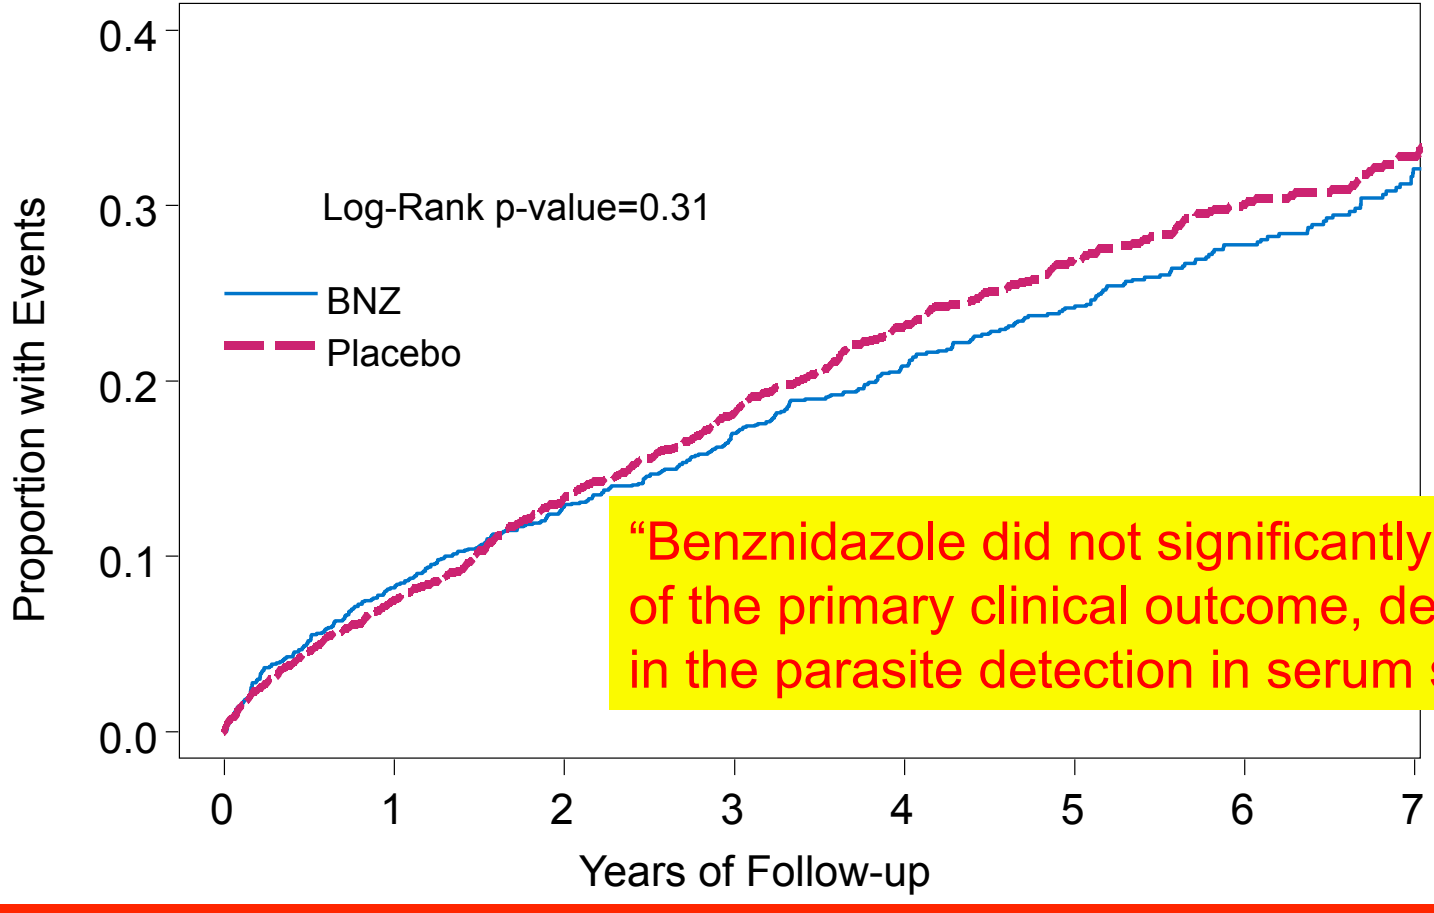
BENEFIT

Primary Outcome

Morillo C, Marin-Neto JA et al
N Engl J Med 2015



"Benznidazole did not significantly reduce the rate of the primary clinical outcome, despite reductions in the parasite detection in serum samples".

"Our findings do not challenge current guidelines that recommend trypanocidal therapy in the early stages of chronic Chagas' infection… and should not detract from the pursuit of goals for exploring more effective or earlier treatments with new drugs or combinations".

The BENEFIT trial

Conclusion:

Trypanocidal therapy with benznidazole in patients with established Chagas' cardiomyopathy significantly reduced serum parasite detection but did not significantly reduce cardiac clinical deterioration through 5 years of follow-up.

Clear the parasite but do not change disease evolution?!?

ORIGINAL ARTICLE

Randomized Trial of Benznidazole for Chronic Chagas' Cardiomyopathy

C.A. Morillo, J.A. Marin-Neto, A. Avezum, S. Sosa-Estani, A. Rassi, Jr., F. Rosas, E. Villena, R. Quiroz, R. Bonilla, C. Britto, F. Guhl, E. Velazquez, L. Bonilla, B. Meeks, P. Rao-Melacini, J. Pogue, A. Mattos, J. Lazdins, A. Rassi, S.J. Connolly, and S. Yusuf, for the BENEFIT Investigators*

ABSTRACT

BACKGROUND

The role of trypanocidal therapy in patients with established Chagas' cardiomyopathy is unproven.

METHODS

We conducted a prospective, multicenter, randomized study involving 2854 patients with Chagas' cardiomyopathy who received benznidazole or placebo for up to 80 days and were followed for a mean of 5.4 years. The primary outcome in the time-to-event analysis was the first event of any of the components of the composite outcome of death, resuscitated cardiac arrest, sustained ventricular tachycardia, insertion of a pacemaker or implantable cardioverter–defibrillator, cardiac transplantation, new heart failure, stroke, or other thromboembolic event.

RESULTS

The primary outcome occurred in 394 patients (27.5%) in the benznidazole group and in 414 (29.1%) in the placebo group (hazard ratio, 0.93; 95% confidence interval [CI], 0.81 to 1.07; P=0.31). At baseline, a polymerase-chain-reaction (PCR) assay was performed on blood samples obtained from 1896 patients; 60.5% had positive results for *Trypanosoma cruzi* on PCR. The rates of conversion to negative PCR results (PCR conversion) were 66.2% in the benznidazole group and 33.5% in the placebo group at the end of treatment, 55.4% and 35.3%, respectively, at 2 years, and 46.7% and 33.1%, respectively, at 5 years or more (P<0.001 for all comparisons). The effect of treatment on PCR conversion varied according to geographic region: in Brazil, the odds ratio for PCR conversion was 3.03 (95% CI, 2.12 to 4.34) at 2 years and 1.87 (95% CI, 1.33 to 2.63) at 5 or more years; in Colombia and El Salvador, the odds ratio was 1.33 (95% CI, 0.90 to 1.98) at 2 years and (95%

*composite of death, resuscitated CA, SVT, insertion of a pacemaker or ICD, cardiac transplantation, new HF, stroke, or other thromboembolic event.

On the basis of the BENEFIT results, we suggest trypanocidal therapy to treat Brazilian patients with chronic CD, even if there is established cardiomyopathy of mild-to-moderate severity, but not in those with more advanced stages of CCC

(iii) Once promising drug candidates have been identified, they should be checked for broad activity against two or three representatives of each DTU (secondary screens). Priority should be given to DTUs that are more often associated with human infection (TcI_{DOM}, TcII, TcV and TcVI), preferably with dissimilar characteristics regarding geographical origin, replication rates, as this parameter may impact the response to some classes of drugs, and level of susceptibility to BZ or NF. This last item is particularly relevant when any drug candidates are analogues of BZ and/or NF. An extensive list of strains reports susceptibility and natural resistance to the two drugs (Filardi & Brener 1987). There is a large panel of clones representing the different DTUs, from which

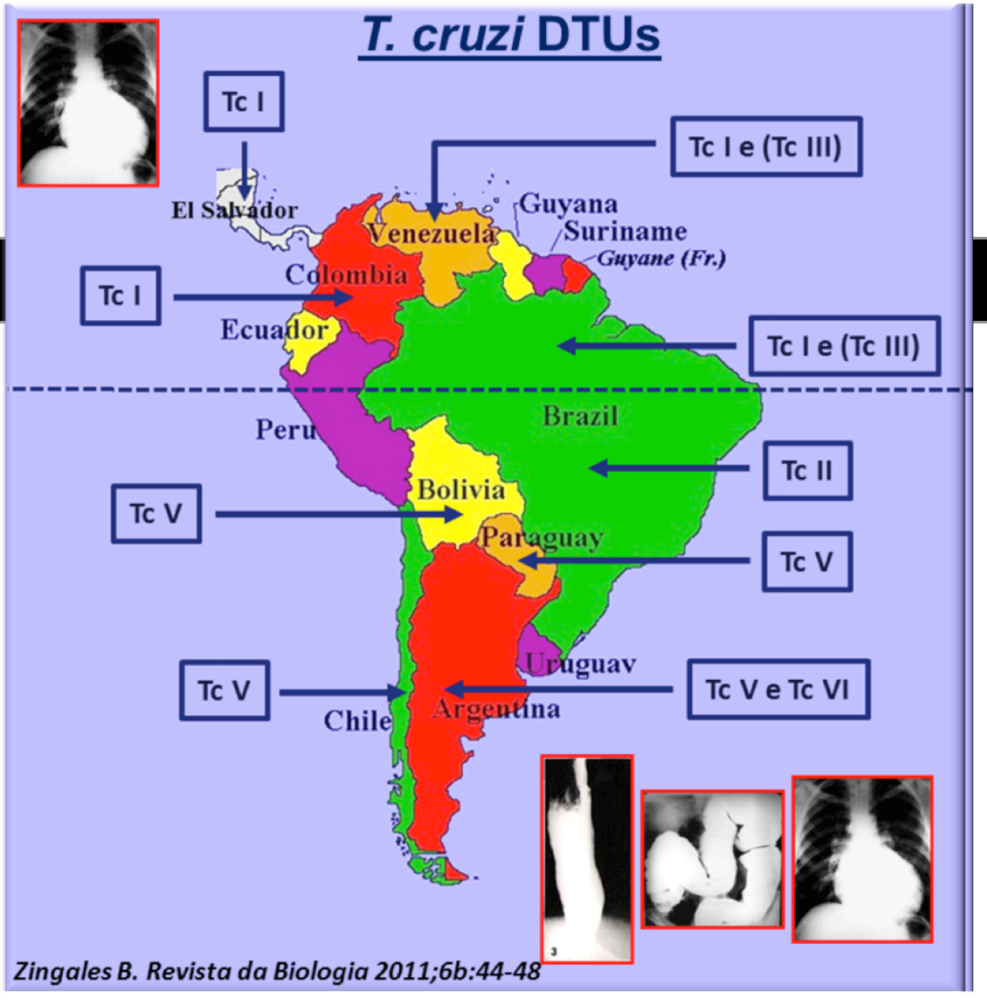

Table 1. Characteristics of the Patients at Baseline.*

Characteristic	Benznidazole (N=1431)	Placebo (N=1423)
Age — yr	55.4±10.7	55.2±11.2
Male sex — no. (%)	726 (50.7)	682 (47.9)
Any abnormal result on electrocardiography — no./total no. (%)	1335/1431 (93.3)	1348/1423 (94.7)
Right bundle-branch block or left anterior fascicular block		
Right bundle-branch block	691/1335 (51.8)	702/1348 (52.1)
Left anterior fascicular block	643/1335 (48.2)	618/1348 (45.8)
Both conditions	465/1335 (34.8)	442/1348 (32.8)
Sinus bradycardia <50 beats/min	159/1335 (11.9)	161/1348 (11.9)
Low-voltage QRS	178/1335 (13.3)	163/1348 (12.1)
ST–T wave changes	393/1335 (29.4)	405/1348 (30.0)
Q waves	45/1335 (3.4)	24/1348 (1.8)
Atrial fibrillation — no. (%)	107 (7.5)	90 (6.3)
Complex ventricular arrhythmia — no. (%)	221 (15.4)	189 (13.3)
Resuscitated cardiac arrest — no. (%)	19 (1.3)	16 (1.1)
Previous heart failure — no. (%)	142 (9.9)	128 (9.0)
New York Heart Association class — no./total no. (%)		
Patients with score	1431/1431 (100)	1421/1423 (99.9)
Class I	1065/1431 (74.4)	1045/1421 (73.5)
Class II	327/1431 (22.9)	343/1421 (24.1)
Class III	39/1431 (2.7)	33/1421 (2.3)
Pacemaker — no. (%)	205 (14.3)	198 (13.9)
Implantable cardioverter–defibrillator — no. (%)	39 (2.7)	31 (2.2)
Stroke or transient ischemic attack — no. (%)	61 (4.3)	62 (4.4)
Systemic or pulmonary embolism — no. (%)	7 (0.5)	11 (0.8)
Echocardiography performed <1 yr before randomization		
Patients with results — no. (%)	1126 (78.7)	1121 (78.8)
Left ventricular ejection fraction		
Mean — %	54.4±14.8	54.6±14.6
Value <40% — no./total no. (%)	200/1126 (17.8)	189/1121 (16.9)
Wall-motion abnormality — no./total no. (%)	431/1126 (38.3)	422/1121 (37.6)

BENEFIT trial

RESULTS: Baseline characteristics were well balanced between the two study groups (Table 1).

→ **Not entirely true**

Imbalance in prognostic factors

Characteristic (RASSI score)	BZN (N=1431)	PCB (N=1423)
Male sex	50.7%	47.9%
Low voltage QRS	13.3%	12.1%
Complex ventricular arrhythmias	15.4%	13.3%
Wall motion abnormalities	38.3%	37.6%
Cardiomegaly	?	?
NYHA class III	2.7%	2.3%

→ **All more frequent in the BZN group**

- Trial results may not be valid if it is not well balanced across prognostic factors.
- P value should be adjusted for imbalances in prognostic baseline characteristics.

Table 2. Primary Outcome and Its Components, Hospitalizations, and Deaths.

Outcome	Benznidazole (N=1431)	Placebo (N=1423)	Hazard Ratio (95% CI)	P Value
	number (percent)			
Primary composite outcome	394 (27.5)	414 (29.1)	0.93 (0.81–1.07)	0.31
Death	246 (17.2)	257 (18.1)	0.95 (0.79–1.13)	—
Resuscitated cardiac arrest	10 (0.7)	17 (1.2)	0.58 (0.27–1.28)	—
Sustained ventricular tachycardia	33 (2.3)	41 (2.9)	0.80 (0.50–1.26)	—
New or worsening heart failure	109 (7.6)	122 (8.6)	0.88 (0.68–1.14)	—
Pacemaker or implantable cardioverter–defibrillator	109 (7.6)	125 (8.8)	0.86 (0.66–1.11)	—
Stroke or transient ischemic attack, systemic embolism, or pulmonary embolism	54 (3.8)	61 (4.3)	0.88 (0.61–1.26)	—
Cardiac transplantation	3 (0.2)	9 (0.6)	0.33 (0.09–1.22)	—
Hospitalization				
Any	358 (25.0)	397 (27.9)	0.89 (0.77–1.03)	0.11
For cardiovascular causes	242 (16.9)	286 (20.1)	0.83 (0.70–0.98)	0.03
Death from cardiovascular causes	194 (13.6)	203 (14.3)	0.94 (0.77–1.15)	0.55
Death from or hospitalization for cardiovascular causes	348 (24.3)	380 (26.7)	0.89 (0.77–1.03)	0.13

- **All components of the composite end-point were less frequent in the treated group, although without statistical significance in all but one of them. This was not highlighted in the NEJM discussion, but may bear clinical relevance.**
- **The rate of hospitalization for CV causes was significantly reduced with BZN (p=0.03)**
- **And if recurrent events were included in the analysis?**

Chronic Chagas cardiomyopathy: a review of the main pathogenic

MARIN-NETO, JA et alii "Doença de Chagas: Moléstia Negligenciada", in: *Tratado de Prevenção Cardiovascular. Um Desafio Global*. Andrade, JP; Arnett, DK Et alii (editores). Editora Atheneu, São Paulo, 1ª edição, 221 páginas, v. 1, 2014, pp. 111-27.

Anis Rassi Jr[1]/+, José Antonio Marin-Neto[2], Anis Rassi[1]

Dep

We strongly believe that the risk of incurring an alfa-error (not to apply a promising therapy with tolerable side-effects) is much less acceptable than incurring a beta-error (Marin-Neto et al 2015b). On the basis of current evidence, doctor's failure to even consider the possibility of aetiological treatment for their patients is questionable from an ethical standpoint − after all, absence of evidence is not evidence of absence (Altman & Bland 1995)

BENEFIT trial, benznidazole seems to have no benefit for arresting disease progression in patients with chronic Chagas cardiomyopathy. In this review, we give an update on the main pathogenic mechanisms of Chagas disease, and re-examine and discuss the results of the BENEFIT trial, together with its limitations and implications.

Key words: chronic Chagas cardiomyopathy - Chagas heart disease - pathogenesis - aetiological treatment - Benznidazole - BENEFIT trial

Event	Recommendation class	Level of evidence
Antiparasitic treatment in the acute phase of Chagas disease	I	B
Antiparasitic treatment in congenital Chagas disease	I	B
Antipar treat in the chronic phase of Chagas disease in children aged ≤12 years	I	A
Antipar treatment in the chronic phase of Chagas disease with recent infection	IIa	C
Antiparasitic treatment in the chronic phase of Chagas disease with late infection, wtih indeterminate form	IIa	B
Antiparasitic treatment in the chronic phase of Chagas disease with late infection and cardiomyopathy without advanced disease	IIb	C
Antiparasitic treatment in the chronic phase of Chagas disease with advanced cardiac form of the disease	III	C

JC Dias et al - 2 nd Brazilian Consensus on Chagas Disease, Rev Soc Bras Med Trop 2015.

For individuals with Chagas disease aged 19–50 years with no recent documented infection, antiparasitic treatment should be considered on an individual basis, whether in ICF(120) (252) (Class IIa, level of evidence B) or in the determined chronic form, without advanced cardiopathy(42) (120) (252) (295) (296) (297) (298) (Class IIb, level of evidence C).

Specifically, treatment of chronically infected women of childbearing age, when provided before pregnancy, can reduce congenital transmission(104) (109) .

2 nd Brazilian Consensus on Chagas Disease, 2015.
