

# Standard Test Method for Measurement of Fracture Toughness<sup>1</sup>

This standard is issued under the fixed designation E1820; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon ( $\epsilon$ ) indicates an editorial change since the last revision or reapproval.

## 1. Scope

1.1 This test method covers procedures and guidelines for the determination of fracture toughness of metallic materials using the following parameters:  $K$ ,  $J$ , and CTOD ( $\delta$ ). Toughness can be measured in the  $R$ -curve format or as a point value. The fracture toughness determined in accordance with this test method is for the opening mode (Mode I) of loading.

1.2 The recommended specimens are single-edge bend, [SE(B)], compact, [C(T)], and disk-shaped compact, [DC(T)]. All specimens contain notches that are sharpened with fatigue cracks.

1.2.1 Specimen dimensional (size) requirements vary according to the fracture toughness analysis applied. The guidelines are established through consideration of material toughness, material flow strength, and the individual qualification requirements of the toughness value per values sought.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—Other standard methods for the determination of fracture toughness using the parameters  $K$ ,  $J$ , and CTOD are contained in Test Methods E399, E1290, and E1921. This test method was developed to provide a common method for determining all applicable toughness parameters from a single test.

## 3. Terminology

3.1 Terminology E1823 is applicable to this test method. Only items that are exclusive to Test Method E1820, or that have specific discussion items associated, are listed in this section.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *compliance* [ $LF^{-1}$ ],  $n$ —the ratio of displacement increment to force increment.

3.2.2 *crack displacement* [ $L$ ],  $n$ —the separation vector between two points (on the surfaces of a deformed crack) that were coincident on the surfaces of an ideal crack in the undeformed condition.

3.2.2.1 *Discussion*—In this practice, displacement,  $v$ , is the total displacement measured by clip gages or other devices spanning the crack faces.

3.2.3 *crack extension*,  $\Delta a$  [ $L$ ],  $n$ —an increase in crack size.

3.2.4 *crack-extension force*,  $G$  [ $FL^{-1}$  or  $FLL^{-2}$ ],  $n$ —the elastic energy per unit of new separation area that is made available at the front of an ideal crack in an elastic solid during a virtual increment of forward crack extension.

3.2.5 crack size,  $a$  [L],  $n$ —a lineal measure of a principal planar dimension of a crack. This measure is commonly used in the calculation of quantities descriptive of the stress and displacement fields, and is often also termed crack length or depth.

3.2.5.1 Discussion—In practice, the value of  $a$  is obtained from procedures for measurement of physical crack size,  $a_p$ , original crack size,  $a_o$ , and effective crack size,  $a_e$ , as appropriate to the situation being considered.

3.2.6 crack-tip opening displacement (CTOD),  $\delta$  [L],  $n$ —the crack displacement resulting from the total deformation (elastic plus plastic) at variously defined locations near the original crack tip.

3.2.6.1 Discussion—In this test method, CTOD is the displacement of the crack surfaces normal to the original (unloaded) crack plane at the tip of the fatigue precrack,  $a_o$ . In this test method, CTOD is calculated at the original crack size,  $a_o$ , from measurements made from the force versus displacement record.

3.2.6.2 Discussion—In CTOD testing,  $\delta_{Ic}$  [L] is a value of CTOD near the onset of slow stable crack extension, here defined as occurring at  $\Delta a_p = 0.2$  mm (0.008 in.) +  $0.7\delta_{Ic}$ .

3.2.6.3 Discussion—In CTOD testing,  $\delta_c$  [L] is the value of CTOD at the onset of unstable crack extension (see 3.2.39) or pop-in (see 3.2.25) when  $\Delta a_p < 0.2$  mm (0.008 in.) +  $0.7\delta_c$ .  $\delta_c$  corresponds to the force  $P_c$  and clip-gage displacement  $v_c$  (see Fig. 1). It may be size-dependent and a function of test specimen geometry.

3.2.6.4 Discussion—In CTOD testing,  $\delta_u$  [L] is the value of CTOD at the onset of unstable crack extension (see 3.2.39) or pop-in (see 3.2.25) when the event is preceded by  $\Delta a_p > 0.2$  mm (0.008 in.) +  $0.7\delta_u$ . The  $\delta_u$  corresponds to the force  $P_u$  and the clip gage displacement  $v_u$  (see Fig. 1). It may be size-dependent and a function of test specimen geometry. It can be useful to define limits on ductile fracture behavior.

3.2.6.5 Discussion—In CTOD testing,  $\delta_c^*$  [L] characterizes the CTOD fracture toughness of materials at fracture instability

prior to the onset of significant stable tearing crack extension. The value of  $\delta_c^*$  determined by this test method represents a measure of fracture toughness at instability without significant stable crack extension that is independent of in-plane dimensions. However, there may be a dependence of toughness on thickness (length of crack front).

3.2.7 dial energy,  $KV$  [FL]—absorbed energy as indicated by the impact machine encoder or dial indicator, as applicable.

3.2.8 dynamic stress intensity factor,  $K_{Jd}$ —The dynamic equivalent of the stress intensity factor  $K_J$ , calculated from  $J$  using the equation specified in this test method.

3.2.9 dynamic ultimate tensile strength,  $\sigma_{TSd}$  [FL<sup>-2</sup>]—dynamic equivalent of the ultimate tensile strength, measured at the equivalent strain rate of the fracture toughness test.

3.2.10 dynamic yield strength,  $\sigma_{Ysd}$  [FL<sup>-2</sup>]—dynamic equivalent of the yield strength, measured at the equivalent strain rate of the fracture toughness test.

3.2.11 effective thickness,  $B_e$  [L],  $n$ —for side-grooved specimens  $B_e = B - (B - B_N)^2/B$ . This is used for the elastic unloading compliance measurement of crack size.

3.2.12 effective yield strength,  $\sigma_Y$  [FL<sup>-2</sup>],  $n$ —an assumed value of uniaxial yield strength that represents the influence of plastic yielding upon fracture test parameters.

3.2.12.1 Discussion—It is calculated as the average of the 0.2 % offset yield strength  $\sigma_{YS}$ , and the ultimate tensile strength,  $\sigma_{TS}$  as follows:

$$\sigma_Y = \frac{\sigma_{YS} + \sigma_{TS}}{2} \quad (1)$$

3.2.12.2 Discussion—In estimating  $\sigma_Y$ , influences of testing conditions, such as loading rate and temperature, should be considered.

3.2.12.3 Discussion—The dynamic effective yield strength,  $\sigma_{Yd}$ , is the dynamic equivalent of the effective yield strength, and is calculated as the average of the dynamic yield strength and dynamic ultimate tensile strength.

NOTE 1—Construction lines drawn parallel to the elastic loading slope to give  $v_p$ , the plastic component of total displacement,  $v_g$ .

NOTE 2—In curves b and d, the behavior after pop-in is a function of machine/specimen compliance, instrument response, etc.

FIG. 1 Types of Force versus Clip Gage Displacement Records

3.2.13 *general yield force*,  $P_{gy} [F]$ —in an instrumented impact test, applied force corresponding to general yielding of the specimen ligament. It corresponds to  $F_{gy}$ , as used in Test Method E2298.

3.2.14 *J-integral*,  $J [FL^{-1}]$ ,  $n$ —a mathematical expression, a line or surface integral that encloses the crack front from one crack surface to the other, used to characterize the local stress-strain field around the crack front.

3.2.14.1 *Discussion*—The  $J$ -integral expression for a two-dimensional crack, in the  $x$ - $z$  plane with the crack front parallel to the  $z$ -axis, is the line integral as follows:

$$J = \int_{\Gamma} \left( W dy - \bar{T} \cdot \frac{\partial \bar{u}}{\partial x} ds \right) \quad (2)$$

where:

$W$	= loading work per unit volume or, for elastic bodies, strain energy density,
$\Gamma$	= path of the integral, that encloses (that is, contains) the crack tip,
$ds$	= increment of the contour path,
$\bar{T}$	= outward traction vector on $ds$ ,
$\bar{u}$	= displacement vector at $ds$ ,
$x, y, z$	= rectangular coordinates, and
$\bar{T} \cdot \frac{\partial \bar{u}}{\partial x} ds$	= rate of work input from the stress field into the area enclosed by $\Gamma$ .

3.2.14.2 *Discussion*—The value of  $J$  obtained from this equation is taken to be path-independent in test specimens commonly used, but in service components (and perhaps in test specimens) caution is needed to adequately consider loading interior to  $\Gamma$  such as from rapid motion of the crack or the service component, and from residual or thermal stress.

3.2.14.3 *Discussion*—In elastic (linear or nonlinear) solids, the  $J$ -integral equals the crack-extension force,  $G$ . (See *crack extension force*.)

3.2.14.4 *Discussion*—In elastic (linear and nonlinear) solids for which the mathematical expression is path independent, the  $J$ -integral is equal to the value obtained from two identical bodies with infinitesimally differing crack areas each subject to stress. The parameter  $J$  is the difference in work per unit difference in crack area at a fixed value of displacement or, where appropriate, at a fixed value of force (1)<sup>3</sup>.

3.2.14.5 *Discussion*—The dynamic equivalent of  $J_c$  is  $J_{cd,X}$ , with  $X$  = order of magnitude of  $J$ -integral rate.

3.2.15  $J_c [FL^{-1}]$ —The property  $J_c$  determined by this test method characterizes the fracture toughness of materials at fracture instability prior to the onset of significant stable tearing crack extension. The value of  $J_c$  determined by this test method represents a measure of fracture toughness at instability without significant stable crack extension that is independent of in-plane dimensions; however, there may be a dependence of toughness on thickness (length of crack front).

3.2.16  $J_u [FL^{-1}]$ —The quantity  $J_u$  determined by this test method measures fracture instability after the onset of significant stable tearing crack extension. It may be size-dependent and a function of test specimen geometry. It can be useful to define limits on ductile fracture behavior.

3.2.16.1 *Discussion*—The dynamic equivalent of  $J_u$  is  $J_{ud,X}$ , with  $X$  = order of magnitude of  $J$ -integral rate.

3.2.17 *J-integral rate*,  $\dot{J} [FL^{-1}T^{-1}]$ —derivative of  $J$  with respect to time.

3.2.18 *machine capacity*,  $MC [FL]$ —maximum available energy of the impact testing machine.

3.2.19 *maximum force*,  $P_{max} [F]$ —in an instrumented impact test, maximum value of applied force. It corresponds to  $F_m$ , as used in Test Method E2298.

3.2.20 *net thickness*,  $B_N [L]$ ,  $n$ —distance between the roots of the side grooves in side-grooved specimens.

3.2.21 *original crack size*,  $a_o [L]$ ,  $n$ —the physical crack size at the start of testing.

3.2.21.1 *Discussion*—In this test method,  $a_{oq}$  is used to denote original crack size estimated from compliance.

3.2.22 *original remaining ligament*,  $b_o [L]$ ,  $n$ —distance from the original crack front to the back edge of the specimen, that is ( $b_o = W - a_o$ ).

3.2.23 *physical crack size*,  $a_p [L]$ ,  $n$ —the distance from a reference plane to the observed crack front. This distance may represent an average of several measurements along the crack front. The reference plane depends on the specimen form, and it is normally taken to be either the boundary, or a plane containing either the load-line or the centerline of a specimen or plate. The reference plane is defined prior to specimen deformation.

3.2.24 *plane-strain fracture toughness*,  $K_{Ic} [FL^{-3/2}]$ ,  $J_{Ic} [FL^{-1}]$ ,  $K_{JIc} [FL^{-3/2}]$ ,  $n$ —the crack-extension resistance under conditions of crack-tip plane-strain.

3.2.24.1 *Discussion*—For example, in Mode I for slow rates of loading and negligible plastic-zone adjustment, plane-strain fracture toughness is the value of the stress-intensity factor designated  $K_{Ic}$  as measured using the operational procedure (and satisfying all of the qualification requirements) specified in this test method, which provides for the measurement of crack-extension resistance at the start of crack extension and provides operational definitions of crack-tip sharpness, start of crack extension, and crack-tip plane-strain.

3.2.24.2 *Discussion*—For example, in Mode I for slow rates of loading and substantial plastic deformation, plane-strain fracture toughness is the value of the  $J$ -integral designated  $J_{Ic} [FL^{-1}]$  as measured using the operational procedure (and satisfying all of the qualification requirements) specified in this test method, that provides for the measurement of crack-extension resistance near the onset of stable crack extension.

3.2.24.3 *Discussion*—For example, in Mode I for slow rates of loading, plane-strain fracture toughness is the value of the stress intensity designated  $K_{JIc}$  calculated from  $J_{Ic}$  using the equation (and satisfying all of the qualification requirements) specified in this test method, that provides for the measurement of crack-extension resistance near the onset of stable crack extension under dominant elastic conditions (2).

3.2.24.4 *Discussion*—The dynamic equivalent of  $J_{Ic}$  is  $J_{Icd,X}$ , with  $X$  = order of magnitude of  $J$ -integral rate.

3.2.25 *pop-in*,  $n$ —a discontinuity in the force versus clip gage displacement record. The record of a pop-in shows a sudden increase in displacement and, generally a decrease in

<sup>3</sup> The boldface numbers in parentheses refer to the list of references at the end of this standard.

force. Subsequently, the displacement and force increase to above their respective values at pop-in.

3.2.26 *R-curve or J-R curve, n*—a plot of crack extension resistance as a function of stable crack extension,  $\Delta a_p$  or  $\Delta a_e$ .

3.2.26.1 *Discussion*—In this test method, the *J-R* curve is a plot of the far-field *J*-integral versus the physical crack extension,  $\Delta a_p$ . It is recognized that the far-field value of *J* may not represent the stress-strain field local to a growing crack.

3.2.27 *remaining ligament, b [L], n*—distance from the physical crack front to the back edge of the specimen, that is ( $b = W - a_p$ ).

3.2.28 *specimen center of pin hole distance, H\* [L], n*—the distance between the center of the pin holes on a pin-loaded specimen.

3.2.29 *specimen gage length, d [L], n*—the distance between the points of displacement measure (for example, clip gage, gage length).

3.2.30 *specimen span, S [L], n*—the distance between specimen supports.

3.2.31 *specimen thickness, B [L], n*—the side-to-side dimension of the specimen being tested.

3.2.32 *specimen width, W [L], n*—a physical dimension on a test specimen measured from a reference position such as the front edge in a bend specimen or the load-line in the compact specimen to the back edge of the specimen.

3.2.33 *stable crack extension [L], n*—a displacement-controlled crack extension beyond the stretch-zone width (see 3.2.37). The extension stops when the applied displacement is held constant.

3.2.34 *strain rate,  $\dot{\epsilon}$* —derivative of strain  $\epsilon$  with respect to time.

3.2.35 *stress-intensity factor, K, K<sub>1</sub>, K<sub>2</sub>, K<sub>3</sub>, K<sub>I</sub>, K<sub>II</sub>, K<sub>III</sub> [FL<sup>-3/2</sup>], n*—the magnitude of the ideal-crack-tip stress field (stress-field singularity) for a particular mode in a homogeneous, linear-elastic body.

3.2.35.1 *Discussion*—Values of *K* for the Modes 1, 2, and 3 are given by the following equations:

$$K_1 = \lim_{r \rightarrow 0} [\sigma_{yy} (2\pi r)^{1/2}] \quad (3)$$

$$K_2 = \lim_{r \rightarrow 0} [\tau_{xy} (2\pi r)^{1/2}] \quad (4)$$

$$K_3 = \lim_{r \rightarrow 0} [\tau_{yz} (2\pi r)^{1/2}] \quad (5)$$

where  $r$  = distance directly forward from the crack tip to a location where the significant stress is calculated.

3.2.35.2 *Discussion*—In this test method, Mode 1 or Mode II is assumed. See Terminology E1823 for definition of mode.

3.2.36 *stress-intensity factor rate,  $\dot{K}$  [FL<sup>-3/2</sup>T<sup>-1</sup>]*—derivative of *K* with respect to time.

3.2.37 *stretch-zone width, SZW [L], n*—the length of crack extension that occurs during crack-tip blunting, for example, prior to the onset of unstable brittle crack extension, pop-in, or slow stable crack extension. The SZW is in the same plane as the original (unloaded) fatigue precrack and refers to an extension beyond the original crack size.

3.2.38 *time to fracture, t<sub>f</sub> [T]*—time corresponding to specimen fracture.

3.2.39 *unstable crack extension [L], n*—an abrupt crack extension that occurs with or without prior stable crack

extension in a standard test specimen under crosshead or clip gage displacement control.

3.3 *Symbols:*

$t_i$  [T]—time corresponding to the onset of crack propagation.

$v_0$  [LT<sup>-1</sup>]*—*in an instrumented impact test, striker velocity at impact.

$W_m$  [FL]*—*in an instrumented impact test, absorbed energy at maximum force.

$W_t$  [FL]*—*in an instrumented impact test, total absorbed energy calculated from the complete force/displacement test record.

$W_0$  [FL]*—*in an instrumented impact test, available impact energy.

## 4. Summary of Test Method

4.1 The objective of this test method is to load a fatigue precracked test specimen to induce either or both of the following responses (1) unstable crack extension, including significant pop-in, referred to as “fracture instability” in this test method; (2) stable crack extension, referred to as “stable tearing” in this test method. Fracture instability results in a single point-value of fracture toughness determined at the point of instability. Stable tearing results in a continuous fracture toughness versus crack-extension relationship (*R*-curve) from which significant point-values may be determined. Stable tearing interrupted by fracture instability results in an *R*-curve up to the point of instability.

4.2 This test method requires continuous measurement of force versus load-line displacement or crack mouth opening displacement, or both. If any stable tearing response occurs, then an *R*-curve is developed and the amount of slow-stable crack extension shall be measured.

4.3 Two alternative procedures for measuring crack extension are presented, the basic procedure and the resistance curve procedure. The basic procedure involves physical marking of the crack advance and multiple specimens used to develop a plot from which a single point initiation toughness value can be evaluated. The resistance curve procedure is an elastic-compliance method where multiple points are determined from a single specimen. In the latter case, high precision of signal resolution is required. These data can also be used to develop an *R*-curve. Other procedures for measuring crack extension are allowed.

4.4 The commonality of instrumentation and recommended testing procedure contained herein permits the application of data to more than one method of evaluating fracture toughness. Annex A4-Annex A11 define the various data treatment options that are available, and these should be reviewed to optimize data transferability.

4.5 Data that are generated following the procedures and guidelines contained in this test method are labeled qualified data. Data that meet the size criteria in Annex A4-Annex A11 are insensitive to in-plane dimensions.

4.6 Supplementary information about the background of this test method and rationale for many of the technical requirements of this test method are contained in (3). The

formulas presented in this test method are applicable over the range of crack size and specimen sizes within the scope of this test method.

**5. Significance and Use**

5.1 Assuming the presence of a preexisting, sharp, fatigue crack, the material fracture toughness values identified by this test method characterize its resistance to: (1) fracture of a stationary crack, (2) fracture after some stable tearing, (3) stable tearing onset, and (4) sustained stable tearing. This test method is particularly useful when the material response cannot be anticipated before the test. Application of procedures in Test Method E1921 is recommended for testing ferritic steels that undergo cleavage fracture in the ductile-to-brittle transition.

5.1.1 These fracture toughness values may serve as a basis for material comparison, selection, and quality assurance. Fracture toughness can be used to rank materials within a similar yield strength range.

5.1.2 These fracture toughness values may serve as a basis for structural flaw tolerance assessment. Awareness of differences that may exist between laboratory test and field conditions is required to make proper flaw tolerance assessment.

5.2 The following cautionary statements are based on some observations.

5.2.1 Particular care must be exercised in applying to structural flaw tolerance assessment the fracture toughness value associated with fracture after some stable tearing has occurred. This response is characteristic of ferritic steel in the transition regime. This response is especially sensitive to material inhomogeneity and to constraint variations that may be induced by planar geometry, thickness differences, mode of loading, and structural details.

5.2.2 The *J-R* curve from bend-type specimens recommended by this test method (SE(B), C(T), and DC(T)) has been observed to be conservative with respect to results from tensile loading configurations.

5.2.3 The values of  $\delta_c$ ,  $\delta_u$ ,  $J_c$ , and  $J_u$  may be affected by specimen dimensions.

**6. Apparatus**

6.1 Apparatus is required for measurement of applied force, load-line displacement, and crack-mouth opening displacement. Force versus load-line displacement and force versus crack-mouth opening displacement may be recorded digitally for processing by computer or autographically with an *x-y* plotter. Test fixtures for each specimen type are described in the applicable Annex.

**6.2 Displacement Gages:**

6.2.1 Displacement measurements are needed for the following purposes: to evaluate  $P_Q$  in the  $K_{Ic}$  evaluation,  $J$  from the area under the force versus load-line displacement record, CTOD from the force versus crack-mouth opening displacement record and, for the elastic compliance method, to infer crack extension,  $\Delta a_p$ , from elastic compliance calculations.

6.2.2 The recommended displacement gage has a working range of not more than twice the displacement expected during the test. When the expected displacement is less than 3.75 mm (0.15 in.), the gage recommended in Fig. 2 may be used. When a greater working range is needed, an enlarged gage such as the one shown in Fig. 3 is recommended. Accuracy shall be within  $\pm 1\%$  of the full working range. In calibration, the maximum deviation of the individual data points from a fit (linear or curve) to the data shall be less than  $\pm 0.2\%$  of the working range of the gage when using the elastic compliance method and  $\pm 1\%$  otherwise. Knife edges are required for seating the

**FIG. 2 Double-Cantilever Clip-In Displacement Gage Mounted by Means of Integral Knife Edges**

RAZOR BLADE

NOTE 1—All dimensions are in millimeters.  
**FIG. 3 Clip Gage Design for 8.0 mm (0.3 in.) and More Working Range**

gage. Parallel alignment of the knife edges shall be maintained to within 1°. Direct methods for measuring load-line displacement are described in Refs (3-6).

6.2.2.1 *Gage Attachment Methods*—The specimen shall be provided with a pair of accurately machined knife edges that support the gage arms and serve as the displacement reference points. These knife edges can be machined integral with the specimen or they may be attached separately. Experience has shown that razor blades serve as effective attachable knife edges. The knife edges shall be positively attached to the specimen to prevent shifting of the knife edges during the test method. Experience has shown that machine screws or spot welds are satisfactory attachment methods.

6.2.3 For the elastic compliance method, the recommended signal resolution for displacement should be at least 1 part in 32 000 of the transducer signal range, and signal stability should be ±4 parts in 32 000 of the transducer signal range measured over a 10-min period. Signal noise should be less than ±2 parts in 32 000 of the transducer signal range.

6.2.4 Gages other than those recommended in 6.2.2 are permissible if the required accuracy and precision can be met or exceeded.

6.3 *Force Transducers:*

6.3.1 Testing is performed in a testing machine conforming to the requirements of Practices E4. Applied force may be

measured by any force transducer capable of being recorded continuously. Accuracy of force measurements shall be within ±1 % of the working range. In calibration, the maximum deviation of individual data points from a fit to the data shall be less than ±0.2 % of the calibrated range of the transducer when using elastic compliance, and ±1 % otherwise.

6.3.2 For the elastic compliance method, the signal resolution on force should be at least 1 part in 4000 of the transducer signal range and signal stability should be ±4 parts in 4000 of the transducer signal range measured over a 10-min period. Recommended maximum signal noise should be less than ±2 parts in 4000 of the transducer signal range.

6.4 *System Verification*—It is recommended that the performance of the force and displacement measuring systems be verified before beginning a series of continuous tests. Calibration accuracy of displacement transducers shall be verified with due consideration for the temperature and environment of the test. Force calibrations shall be conducted periodically and documented in accordance with the latest revision of Practices E4.

6.5 *Fixtures:*

6.5.1 *Bend-Test Fixture*—The general principles of the bend-test fixture are illustrated in Fig. 4. This fixture is designed to minimize frictional effects by allowing the support rollers to rotate and move apart slightly as the specimen is loaded, thus permitting rolling contact. Thus, the support rollers are allowed limited motion along plane surfaces parallel to the notched side of the specimen, but are initially positively positioned against stops that set the span length and are held in place by low-tension springs (such as rubber bands). Fixtures and rolls shall be made of high hardness (greater than 40 HRC) steels.

6.5.2 *Tension Testing Clevis:*

6.5.2.1 A loading clevis suitable for testing compact specimens is shown in Fig. 5. Both ends of the specimen are held in such a clevis and loaded through pins, in order to allow rotation of the specimen during testing. In order to provide rolling contact between the loading pins and the clevis holes, these holes are provided with small flats on the loading surfaces. Other clevis designs may be used if it can be demonstrated that

ROLLER PIN DETAIL  
**FIG. 4 Bend Test Fixture Design**

A - SURFACES MUST BE FLAT, IN-LINE AND PERPENDICULAR, AS APPLICABLE, TO WITHIN 0.002 in. T.I.R. (0.05 mm)

NOTE 1—Corners may be removed as necessary to accommodate the clip gage.

FIG. 5 Tension Testing Clevis Design

they will accomplish the same result as the design shown. Clevises and pins should be fabricated from steels of sufficient strength (greater than 40 HRC) to elastically resist indentation of the clevises or pins.

6.5.2.2 The critical tolerances and suggested proportions of the clevis and pins are given in Fig. 5. These proportions are based on specimens having  $W/B = 2$  for  $B > 12.7$  mm (0.5 in.) and  $W/B = 4$  for  $B \leq 12.7$  mm. If a 1930-MPa (280 000-psi) yield strength maraging steel is used for the clevis and pins, adequate strength will be obtained. If lower-strength grip material is used, or if substantially larger specimens are required at a given  $\sigma_{YS}/E$  ratio, then heavier grips will be required. As indicated in Fig. 5 the clevis corners may be cut off sufficiently to accommodate seating of the clip gage in specimens less than 9.5 mm (0.375 in.) thick.

6.5.2.3 Careful attention should be given to achieving good alignment through careful machining of all auxiliary gripping fixtures.

## 7. Specimen Size, Configuration, and Preparation

7.1 Specimen Configurations—The configurations of the standard specimens are shown in Annex A1-Annex A3.

7.2 Crack Plane Orientation—The crack plane orientation shall be considered in preparing the test specimen. This is discussed in Terminology E1823.

7.3 Alternative Specimens—In certain cases, it may be desirable to use specimens having  $W/B$  ratios other than two. Suggested alternative proportions for the single-edge bend specimen are  $1 \leq W/B \leq 4$  and for the compact (and disk-shaped compact) specimen are  $2 \leq W/B \leq 4$ . However, any thickness can be used as long as the qualification requirements are met.

7.4 Specimen Precracking—All specimens shall be precracked in fatigue. Experience has shown that it is impractical to obtain a reproducibly sharp, narrow machined notch that will simulate a natural crack well enough to provide a satisfactory fracture toughness test result. The most effective artifice for this purpose is a narrow notch from which extends a comparatively short fatigue crack, called the precrack. (A fatigue precrack is produced by cyclically loading the notched specimen for a number of cycles usually between about  $10^4$  and  $10^6$  depending on specimen size, notch preparation, and stress intensity level.) The dimensions of the notch and the precrack, and the sharpness of the precrack shall meet certain

conditions that can be readily met with most engineering materials since the fatigue cracking process can be closely controlled when careful attention is given to the known contributory factors. However, there are some materials that are too brittle to be fatigue-cracked since they fracture as soon as the fatigue crack initiates; these are outside the scope of the present test method.

**7.4.1 Fatigue Crack Starter Notch**—Three forms of fatigue crack starter notches are shown in Fig. 6. To facilitate fatigue cracking at low stress intensity factor levels, the root radius for a straight-through slot terminating in a V-notch should be 0.08 mm (0.003 in.) or less. If a chevron notch is used, the root radius may be 0.25 mm (0.010 in.) or less. In the case of a slot tipped with a hole it will be necessary to provide a sharp stress raiser at the end of the hole.

**7.4.2 Fatigue Crack Size**—The crack size (total average length of the crack starter configuration plus the fatigue crack) shall be between 0.45 and 0.70 *W* for *J* and  $\delta$  determination, but is restricted to the range from 0.45 to 0.55 for *K<sub>Ic</sub>* determination.

**7.4.3 Equipment**—The equipment for fatigue cracking should be such that the stress distribution is uniform through the specimen thickness; otherwise the crack will not grow uniformly. The stress distribution should also be symmetrical about the plane of the prospective crack; otherwise the crack may deviate from that plane and the test result can be significantly affected. The *K* calibration for the specimen, if it is different from the one given in this test method, shall be known with an uncertainty of less than 5%. Fixtures used for precracking should be machined with the same tolerances as those used for testing.

**7.4.4 Fatigue Loading Requirements**—Allowable fatigue force values are limited to keep the maximum stress intensity applied during precracking, *K<sub>MAX</sub>*, well below the material fracture toughness measured during the subsequent test. The fatigue precracking shall be conducted with the specimen fully heat-treated to the condition in which it is to be tested. No intermediate treatments between precracking and testing are

allowed. The combination of starter notch and fatigue precrack shall conform to the requirements shown in Fig. 7. There are several ways of promoting early crack initiation: (1) by providing a very sharp notch tip, (2) by using a chevron notch (Fig. 6), (3) by statically preloading the specimen in such a way that the notch tip is compressed in a direction normal to the intended crack plane (to a force not to exceed *P<sub>m</sub>* as defined in Annex A1-Annex A3), and (4) by using a negative fatigue force ratio; for a given maximum fatigue force, the more negative the force ratio, the earlier crack initiation is likely to occur. The peak compressive force shall not exceed *P<sub>m</sub>* as defined in Annex A1-Annex A3.

**7.4.5 Fatigue Precracking Procedure**—Fatigue precracking can be conducted under either force control or displacement control. If the force cycle is maintained constant, the maximum *K* and the *K* range will increase with crack size; if the displacement cycle is maintained constant, the reverse will happen. The initial value of the maximum fatigue force should be less than *P<sub>m</sub>*. The specimen shall be accurately located in the loading fixture. Fatigue cycling is then begun, usually with a sinusoidal waveform and near to the highest practical frequency. There is no known marked frequency effect on fatigue precrack formation up to at least 100 Hz in the absence of adverse environments. The specimen should be carefully monitored until crack initiation is observed on one side. If crack initiation is not observed on the other side before appreciable growth is observed on the first, then fatigue cycling should be stopped to try to determine the cause and find a remedy for the unsymmetrical behavior. Sometimes, simply turning the specimen around in relation to the fixture will solve the problem.

**7.4.5.1** The length of the fatigue precrack extension from the machined notch shall not be less than 0.05*B*, and not less than 1.3 mm (0.05 in.) for the wide notch, see Fig. 7, nor less than 0.025*B* or less than 0.6 mm (0.024 in.) for the narrow notch. Precracking shall be accomplished in at least two steps. For the first step the maximum stress intensity factor applied to the specimen shall be limited by:

$$K_{MAX} = \left( \frac{\sigma_{YS}^f}{\sigma_{YS}^T} \right) (0.063 \sigma_{YS}^f \text{ MPa} \sqrt{\text{m}}) \tag{6}$$

or

$$K_{MAX} = \left( \frac{\sigma_{YS}^f}{\sigma_{YS}^T} \right) (0.4 \sigma_{YS}^f \text{ ksi} \sqrt{\text{in.}})$$

where:  
 $\sigma_{YS}^f$  and  $\sigma_{YS}^T$  = the material yield stresses at the fatigue precrack and test temperatures respectively.

**7.4.5.2** It is generally most effective to use  $R = P_{MIN}/P_{MAX} = 0.1$ . The accuracy of the maximum force values shall be known within  $\pm 5\%$ . Precracking should be conducted at as low as a *K<sub>MAX</sub>* as practical. For some aluminum alloys and high strength steels the above *K<sub>MAX</sub>* relationship can give very high precracking forces. This is especially true if precracking and testing are conducted at the same temperature. It is suggested that the user start with approximately 0.7 *K<sub>MAX</sub>* given by the above relationship, and if the precrack does not

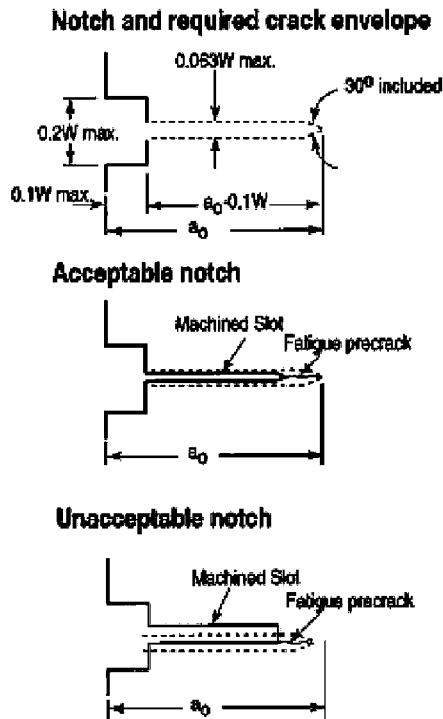

FIG. 6 Fatigue Crack Starter Notch Configurations

**Notch and precrack configurations**

	Wide Notch	Narrow Notch
maximum notch height	0.063W	0.01W
maximum notch angle	60°	as machined
minimum precrack length	0.05B	0.025B

NOTE 1—The crack-starter notch shall be centered between the top and bottom specimen edges within 0.005 W.

FIG. 7 Envelope of Fatigue Crack and Crack Starter Notches

grow after 10<sup>5</sup> cycles the loading can be incrementally increased until the crack begins to extend. For the second precracking step, which shall include at least the final 50 % of the fatigue precrack or 1.3 mm (0.05 in.) for the wide notch or 0.6 mm (0.024 in.) for the narrow notch, whichever is less, the maximum stress intensity factor that may be applied to the specimen shall be given by:

$$K_{MAX} = 0.6 \frac{\sigma_{YS}^f}{\sigma_{YS}} K_F \quad (7)$$

where:

$K_F = K_Q, K_{JQ}, K_{JQC}$  or  $K_{JQu}$  depending on the result of the test, and  $K_F$  is calculated from the corresponding  $J_F$  using the relationship that:

$$K_F = \sqrt{\frac{EJ_F}{(1 - \nu^2)}} \quad (8)$$

7.4.5.3 To transition between steps, intermediate levels of force shedding can be used if desired.

7.5 Side Grooves—Side grooves are highly recommended when the compliance method of crack size prediction is used. The specimen may also need side grooves to ensure a straight crack front as specified in Annex A4-Annex A11. The total thickness reduction shall not exceed 0.25B. A total reduction of 0.20B has been found to work well for many materials. Any included angle of side groove less than 90° is allowed. Root radius shall be 0.5 ± 0.2 mm (0.02 ± 0.01 in.). In order to produce nearly straight fatigue precrack fronts, the precracking should be performed prior to the side-grooving operation.  $B_N$  is the minimum thickness measured at the roots of the side

grooves. The root of the side groove should be located along the specimen centerline.

**8. Procedure**

8.1 Objective and Overview:

8.1.1 The overall objective of the test method is to develop a force-displacement record that can be used to evaluate  $K$ ,  $J$ , or CTOD. Two procedures can be used: (1) a basic procedure directed toward evaluation of a single  $K$ ,  $J$ , or CTOD value without the use of crack extension measurement equipment, or (2) a procedure directed toward evaluation of a complete fracture toughness resistance curve using crack extension measurement equipment. This also includes the evaluation of single-point toughness values.

8.1.2 The basic procedure utilizes a force versus displacement plot and is directed toward obtaining a single fracture toughness value such as  $K_{Ic}$ ,  $J_c$ , or  $\delta_c$ . Optical crack measurements are utilized to obtain both the initial and final physical crack sizes in this procedure. Multiple specimens can be used to evaluate  $J$  at the initiation of ductile cracking,  $J_{Ic}$  or  $\delta_{Ic}$ .

8.1.3 The resistance curve procedure utilizes an elastic unloading procedure or equivalent procedure to obtain a  $J$ - or CTOD-based resistance curve from a single specimen. Crack size is measured from compliance in this procedure and verified by post-test optical crack size measurements. An alternative procedure using the normalization method is presented in Annex A15: Normalization Data Reduction Technique.

8.1.4 Three or more determinations of the fracture toughness parameter are suggested to ascertain the effects of material

and test system variability. If fracture occurs by cleavage of ferritic steel, the testing and analysis procedures of Test Method [E1921](#) are recommended.

### 8.2 System and Specimen Preparation:

8.2.1 *Specimen Measurement*—Measure the dimensions,  $B_N$ ,  $B$ ,  $W$ ,  $H^*$ , and  $d$  to the nearest 0.050 mm (0.002 in.) or 0.5 %, whichever is larger.

#### 8.2.2 Specimen Temperature:

8.2.2.1 The temperature of the specimen shall be stable and uniform during the test. Hold the specimen at test temperature  $\pm 3$  °C for  $\frac{1}{2}$  h/25 mm of specimen thickness.

8.2.2.2 Measure the temperature of the specimen during the test to an accuracy of  $\pm 3$  °C, where the temperature is measured on the specimen surface within  $W/4$  from the crack tip. (See Test Methods [E21](#) for suggestions on temperature measurement.)

8.2.2.3 For the duration of the test, the difference between the indicated temperature and the nominal test temperature shall not exceed  $\pm 3$  °C.

8.2.2.4 The term “indicated temperature” means the temperature that is indicated by the temperature measuring device using good-quality pyrometric practice.

NOTE 2—It is recognized that specimen temperature may vary more than the indicated temperature. The permissible indicated temperature variations in [8.2.2.3](#) are not to be construed as minimizing the importance of good pyrometric practice and precise temperature control. All laboratories should keep both indicated and specimen temperature variations as small as practicable. It is well recognized, in view of the dependency of fracture toughness of materials on temperature, that close temperature control is necessary. The limits prescribed represent ranges that are common practice.

### 8.3 Alignment:

8.3.1 *Bend Testing*—Set up the bend test fixture so that the line of action of the applied force passes midway between the support roll centers within  $\pm 1$  % of the distance between the centers. Measure the span to within  $\pm 0.5$  % of the nominal length. Locate the specimen so that the crack tip is midway between the rolls to within 1 % of the span and square to roll axes within  $\pm 2^\circ$ .

8.3.1.1 When the load-line displacement is referenced from the loading jig, there is potential for introduction of error from two sources. They are the elastic compression of the fixture as the force increases and indentation of the specimen at the loading points. Direct methods for load-line displacement measurement are described in Refs [\(4-7\)](#). If a remote transducer is used for load-line displacement measurement, take care to exclude the elastic displacement of the load-train measurement and brinelling displacements at the load points [\(8\)](#).

8.3.2 *Compact Testing*—Loading pin friction and eccentricity of loading can lead to errors in fracture toughness determination. The centerline of the upper and lower loading rods should be coincident within 0.25 mm (0.01 in.). Center the specimen with respect to the clevis opening within 0.76 mm (0.03 in.). Seat the displacement gage in the knife edges firmly by wiggling the gage lightly.

8.4 *Basic Procedure*—Load all specimens under displacement gage or machine crosshead or actuator displacement control. If a loading rate that exceeds that specified here is

desired, please refer to [Annex A14](#): Special Requirements for Rapid-Load J-Integral Fracture Toughness Testing.

8.4.1 The basic procedure involves loading a specimen to a selected displacement level and determining the amount of crack extension that occurred during loading.

8.4.2 Load specimens at a constant rate such that the time taken to reach the force  $P_m$ , as defined in [Annex A1-Annex A3](#), lies between 0.3 to 3 min.

8.4.3 If the test ends by fracture instability, measure the initial crack size and any ductile crack extension by the procedure in [9](#). Ductile crack extension may be difficult to distinguish but should be defined on one side by the fatigue precrack and on the other by the brittle region. Proceed to [9](#) to evaluate fracture toughness in terms of  $K$ ,  $J$ , or CTOD.

8.4.4 If stable tearing occurs, test additional specimens to evaluate an initiation value of the toughness. Use the procedure in [8.5](#) to evaluate the amount of stable tearing that has occurred and thus determine the displacement levels needed in the additional tests. Five or more points favorably positioned are required to generate an R curve for evaluating an initiation point. See [Annex A9](#) and [Annex A11](#) to see how points shall be positioned for evaluating an initiation toughness value.

### 8.5 Optical Crack Size Measurement:

8.5.1 After unloading the specimen, mark the crack according to one of the following methods. For steels and titanium alloys, heat tinting at about 300 °C (570 °F) for 30 min works well. For other materials, fatigue cycling can be used. The use of liquid penetrants is not recommended. For both recommended methods, the beginning of stable crack extension is marked by the end of the flat fatigue precracked area. The end of crack extension is marked by the end of heat tint or the beginning of the second flat fatigue area.

8.5.2 Break the specimen to expose the crack, with care taken to minimize additional deformation. Cooling ferritic steel specimens to ensure brittle behavior may be helpful. Cooling nonferritic materials may help to minimize deformation during final fracture.

8.5.3 Along the front of the fatigue crack and the front of the marked region of stable crack extension, measure the size of the original crack and the final physical crack size at nine equally spaced points centered about the specimen centerline and extending to  $0.005 W$  from the root of the side groove or surface of plane-sided specimens. Calculate the original crack size,  $a_o$ , and the final physical crack size,  $a_p$ , as follows: average the two near-surface measurements, combine the result with the remaining seven crack size measurements and determine the average. Calculate the physical crack extension,  $\Delta a_p = a_p - a_o$ . The measuring instrument shall have an accuracy of 0.025 mm (0.001 in.).

8.5.4 None of the nine measurements of original crack size and final physical crack size may differ by more than  $0.05B$  from the average physical crack size defined in [8.5.3](#).

### 8.6 Resistance Curve Procedure:

8.6.1 The resistance curve procedure involves using an elastic compliance technique or other technique to obtain the  $J$  or CTOD resistance curve from a single specimen test. The elastic compliance technique is described here, while the normalization technique is described in [Annex A15](#).

8.6.2 Load the specimens under displacement gage or machine crosshead or actuator displacement control. Load the specimens at a rate such that the time taken to reach the force  $P_m$ , as defined in [Annex A1-Annex A3](#), lies between 0.3 and 3.0 min. The time to perform an unload/reload sequence should be as needed to accurately estimate crack size, but not more than 10 min. If a higher loading rate is desired, please refer to [Annex A14](#): Special Requirements for Rapid-Load J-Integral Fracture Toughness Testing.

8.6.3 Take each specimen individually through the following steps:

8.6.3.1 Measure compliance to estimate the original crack size,  $a_o$ , using unloading/reloading sequences in a force range from 0.5 to 1.0 times the maximum precracking force. Estimate a provisional initial crack size,  $a_{oq}$ , from at least three unloading/reloading sequences. No individual value shall differ from the mean by more than  $\pm 0.002 W$ .

8.6.3.2 Proceed with the test using unload/reload sequences that produce crack extension measurements at intervals prescribed by the applicable data analysis section of [Annex A8](#) or [Annex A10](#). Note that at least eight data points are required before specimen achieves maximum force. If fracture instability is an expected response, then it may be helpful to load the specimen monotonically over the range  $P_m < P < P_Q$ . (See [Annex A5](#) for a definition of  $P_Q$ ). If crack size values change negatively by more than  $0.005 a_o$  (backup), stop the test and check the alignment of the loading train. Crack size values determined at forces lower than the maximum precracking force should be ignored.

8.6.3.3 For many materials, load relaxation may occur prior to conducting compliance measurements, causing a time-dependent nonlinearity in the unloading slope. One method that may be used to remedy this effect is to hold the specimen for a period of time until the force becomes stable at a constant displacement prior to initiating the unloading.

8.6.3.4 The maximum recommended range of unload/reload for crack extension measurement should not exceed either 50 % of  $P_m$ , as defined in [Annex A1-Annex A3](#), or 50 % of the current force, whichever is smaller.

8.6.3.5 After completing the final unloading cycle, return the force to zero without additional crosshead displacement beyond the then current maximum displacement.

8.6.3.6 After unloading the specimen, use the procedure in [8.5](#) to optically measure the crack sizes.

### 8.7 Alternative Methods:

8.7.1 Alternative methods of measuring crack extension, such as the electric potential drop method, are allowed. Methods shall meet the qualification criteria given in [9.1.5.2](#). If an alternative method is used to obtain  $J_{Ic}$ , at least one additional, confirmatory specimen shall be tested at the same test rate and under the same test conditions. From the alternative method the load-line displacement corresponding to a ductile crack extension of 0.5 mm shall be estimated. The additional specimen shall then be loaded to this load-line displacement level, marked, broken open and the ductile crack growth measured. The measured crack extension shall be  $0.5 \pm 0.25$  mm in order for these results, and hence the  $J_{Ic}$  value, to be qualified according to this method.

8.7.2 If displacement measurements are made in a plane other than that containing the load-line, the ability to infer load-line displacement shall be demonstrated using the test material under similar test temperatures and conditions. Inferred load-line displacement values shall be accurate to within  $\pm 1$  %.

## 9. Analysis of Results

9.1 *Qualification of Data*—The data shall meet the following requirements to be qualified according to this test method. If the data do not pass these requirements, no fracture toughness measures can be determined in accordance with this test method.

NOTE 3—This section contains the requirements for qualification that are common for all tests. Additional qualification requirements are given with each type of test in the Annexes as well as requirements for determining whether the fracture toughness parameter developed is insensitive to in-plane dimensions.

9.1.1 All requirements on the test equipment in [Section 6](#) shall be met.

9.1.2 All requirements on machining tolerance and precracking in [Section 7](#) shall be met.

9.1.3 All requirements on fixture alignment, test rate, and temperature stability and accuracy in [Section 8](#) shall be met.

9.1.4 The following crack size requirements shall be met in all tests.

9.1.4.1 *Original Crack Size*—None of the nine physical measurements of initial crack size defined in [8.5.3](#) shall differ by more than  $0.05B$  from the average  $a_o$ .

9.1.4.2 *Final Crack Size*—None of the nine physical measurements of final physical crack size,  $a_p$ , defined in [8.5.3](#) shall differ by more than  $0.05B$  from the average  $a_p$ . In subsequent tests, the side-groove configuration may be modified within the requirements of [7.5](#) to facilitate meeting this requirement.

9.1.5 The following crack size requirements shall be met in the tests using the resistance curve procedure of [8.6](#).

9.1.5.1 *Crack Extension*—None of the nine physical measurements of crack extension shall be less than 50 % of the average crack extension.

9.1.5.2 *Crack Extension Prediction*—The crack extension,  $\Delta a_{predicted}$ , predicted from elastic compliance (or other method), at the last unloading shall be compared with the measured physical crack extension,  $\Delta a_p$ . The difference between these shall not exceed  $0.15 \Delta a_p$  for crack extensions less than  $0.2 b_o$ , and the difference shall not exceed  $0.03 b_o$  thereafter.

9.2 *Fracture Instability*—When the test terminates with fracture instability, evaluate whether the fracture occurred before stable tearing or after stable tearing. The beginning of stable tearing is defined in [A6.3](#) and [A7.3](#). For fracture instability occurring before stable tearing proceed to [Annex A5](#), [Annex A6](#), and [Annex A7](#) to evaluate the toughness values in terms of  $K$ ,  $J$ , or CTOD. For fracture instability occurring after stable tearing, proceed to [Annex A5](#), [Annex A6](#), and [Annex A7](#) to evaluate toughness values and then go to [9.3](#) to evaluate stable tearing.

### 9.3 Stable Tearing:

9.3.1 *Basic Procedure*—When the basic procedure is used, only an initiation toughness can be evaluated. Proceed to [Annex A9](#) and [Annex A11](#) to evaluate initiation toughness values.

9.3.2 *Resistance Curve Procedure*—When the resistance curve procedure is used, refer to [Annex A8](#) and [Annex A10](#) to develop the *R*-curves. Proceed to [Annex A9](#) and [Annex A11](#) to develop initiation values of toughness.

## 10. Report

10.1 Recommended tables for reporting results are given in [Fig. 8](#) and [Fig. 9](#).

10.2 Report the following information for each fracture toughness determination:

10.2.1 Type of test specimen and orientation of test specimen according to Terminology [E1823](#) identification codes,

10.2.2 Material designation (ASTM, AISI, SAE, and so forth), material product form (plate, forging, casting, and so forth), and material yield and tensile strength (at test temperature),

10.2.3 Specimen dimensions ([8.2.1](#)), thickness *B* and *B<sub>N</sub>*, and width *W*,

10.2.4 Test temperature ([8.2.2](#)), loading rate ([8.4.2](#) and [8.6.2](#)), and type of loading control,

10.2.5 Fatigue precracking conditions ([7.4](#)), *K<sub>max</sub>*,  $\Delta K$  range, and fatigue precrack size (average),

10.2.6 Load-displacement record and associated calculations (Section [9](#)),

10.2.7 If the loading rate is other than quasi-static, report the applied *dK/dt*,

10.2.8 Original measured crack size, *a<sub>o</sub>* ([8.5](#)), original predicted crack size, *a<sub>oq</sub>*, final measured crack size, *a<sub>p</sub>*, final predicted crack extension,  $\Delta a_{predicted}$ , physical crack extension during test,  $\Delta a_p$ , crack front appearance—straightness and planarity, and fracture appearance,

10.2.9 Qualification of fracture toughness measurement ([Annex A4-Annex A7](#) and [Annex A8-Annex A11](#)), based on size requirements, and based on crack extension, and

10.2.10 Qualified values of fracture toughness, including *R*-curve values.

## 11. Precision and Bias

11.1 *Bias*—There is no accepted “standard” value for any of the fracture toughness criteria employed in this test method. In the absence of such a true value no meaningful statement can be made concerning bias of data.

11.2 *Precision*—The precision of any of the various fracture toughness determinations cited in this test method is a function of the precision and bias of the various measurements of linear dimensions of the specimen and testing fixtures, the precision of the displacement measurement, the bias of the force measurement as well as the bias of the recording devices used to produce the force-displacement record, and the precision of the constructions made on this record. It is not possible to make meaningful statements concerning precision and bias for all these measurements. However, it is possible to derive useful information concerning the precision of fracture toughness measurements in a global sense from interlaboratory test programs. Most of the measures of fracture toughness that can

**ANNEXES**

**(Mandatory Information)**

**A1. SPECIAL REQUIREMENTS FOR TESTING SINGLE EDGE BEND SPECIMENS**

NOTE A1.1—Annex A1-Annex A3 cover specimen information.

**A1.1 Specimen**

A1.1.1 The standard bend specimen is a single edge-notched and fatigue-cracked beam loaded in three-point bending with a support span,  $S$ , equal to four times the width,  $W$ . The general proportions of the specimen configuration are shown in Fig. A1.1.

A1.1.2 Alternative specimens may have  $1 \leq W/B \leq 4$ . These specimens shall also have a nominal support span equal to  $4W$ .

**A1.2 Apparatus**

A1.2.1 For generally applicable specifications concerning the bend-test fixture and displacement gage see 6.5.1 and 6.2.

A1.3 *Specimen Preparation:*

NOTE 1—The two side planes and the two edge planes shall be parallel and perpendicular as applicable to within 0.5°.  
NOTE 2—The machined notch shall be perpendicular to specimen length and thickness to within ±2°.

FIG. A1.1 Recommended Single Edge Bend [SE(B)] Specimen

A1.3.1 For generally applicable specifications concerning specimen configuration and preparation see Section 7.

A1.3.2 All specimens shall be precracked in three-point bending fatigue based upon the force  $P_m$ , as follows:

$$P_m = \frac{0.5Bb_o^2\sigma_Y}{S} \quad (A1.1)$$

See 7.4.5 for fatigue precracking requirements.

#### A1.4 Calculation

A1.4.1 Calculation of  $K$ —For the bend specimen at a force  $P_{(i)}$ , calculate  $K$  as follows:

$$K_{(i)} = \left[ \frac{P_i S}{(BB_N)^{1/2} W^{3/2}} \right] f(a_i/W) \quad (A1.2)$$

where:

$$f\left(\frac{a_i}{W}\right) = \quad (A1.3)$$

$$3\left(\frac{a_i}{W}\right)^{1/2} \left[ \frac{1.99 - \left(\frac{a_i}{W}\right) \left(1 - \frac{a_i}{W}\right) \left(2.15 - 3.93\left(\frac{a_i}{W}\right) + 2.7\left(\frac{a_i}{W}\right)^2\right)}{2\left(1 + 2\frac{a_i}{W}\right) \left(1 - \frac{a_i}{W}\right)^{3/2}} \right]$$

A1.4.2 Calculation of  $J$ :

For the single edge bend specimen, calculate  $J$  as follows:

$$J = J_{el} + J_{pl} \quad (A1.4)$$

where:

$J_{el}$  = elastic component of  $J$ , and

$J_{pl}$  = plastic component of  $J$ .

A1.4.2.1  $J$  Calculations for the Basic Test Method—At a point corresponding to  $v$  and  $P$  on the specimen force versus displacement record, calculate the  $J$  integral as follows:

$$J = \frac{K^2 (1 - v^2)}{E} + J_{pl} \quad (A1.5)$$

where  $K$  is from A1.4.1 with  $a = a_o$ , and

$$J_{pl} = \frac{\eta_{pl} A_{pl}}{B_N b_o} \quad (A1.6)$$

where:

$A_{pl}$  = area under force versus displacement record as shown in Fig. A1.2,

$\eta_{pl} = 1.9$  if the load-line displacement is used for  $A_{pl}$ ,  
 $= 3.667 - 2.199(a_o/W) + 0.437(a_o/W)^2$  if the crack mouth opening displacement record is used for  $A_{pl}$ ,

$B_N$  = net specimen thickness ( $B_N = B$  if no side grooves are present), and

$b_o = W - a_o$ .

All basic test method  $J$  integral values shall be corrected for crack growth using the procedure of Annex A16.

A1.4.2.2  $J$  Calculations for the Resistance Curve Test Method—At a point corresponding to  $a_{(i)}$ ,  $v_{(i)}$ , and  $P_{(i)}$  on the specimen force versus displacement record, calculate the  $J$  integral as follows:

$$J_{(i)} = \frac{(K_{(i)})^2 (1 - v^2)}{E} + J_{pl(i)} \quad (A1.7)$$

where  $K_{(i)}$  is from A1.4.1, and

$$J_{pl(i)} = \left[ J_{pl(i-1)} + \left( \frac{\eta_{pl(i-1)}}{b_{(i-1)}} \right) \left( \frac{A_{pl(i)} - A_{pl(i-1)}}{B_N} \right) \right] \times \left[ 1 - \gamma_{pl(i-1)} \left( \frac{a_{(i)} - a_{(i-1)}}{b_{(i-1)}} \right) \right] \quad (A1.8)$$

where:

$\eta_{pl(i-1)} = 1.9$ , and

$\gamma_{pl(i-1)} = 0.9$

if the load-line displacement is used to measure  $A_{pl}$  and,

$$\eta_{pl} = 3.667 - 2.199\left(\frac{a_{(i-1)}}{W}\right) + 0.437\left(\frac{a_{(i-1)}}{W}\right)^2$$

and

$$\gamma_{pl} = 0.131 + 2.131\left(\frac{a_{(i-1)}}{W}\right) - 1.465\left(\frac{a_{(i-1)}}{W}\right)^2$$

if the crack mouth opening displacement is used to measure  $A_{pl}$ .

In Eq A1.8, the quantity  $A_{pl(i)} - A_{pl(i-1)}$  is the increment of plastic area under the chosen force versus plastic displacement record between lines of constant plastic displacement at points  $i-1$  and  $i$  shown in Fig. A1.3. The quantity  $J_{pl(i)}$  represents the total crack growth corrected plastic  $J$  at point  $i$  and is obtained in two steps by first incrementing the existing  $J_{pl(i-1)}$  and then by modifying the total accumulated result to account for the crack growth increment. Accurate evaluation of  $J_{pl(i)}$  from the Eq A1.8 relationship requires small and uniform crack growth increments consistent with the suggested elastic compliance spacing of Annex A8 and Annex A10. The quantity  $A_{pl(i)}$  can be calculated from the following equation:

$$A_{pl(i)} = A_{pl(i-1)} + [P_{(i)} + P_{(i-1)}] [v_{pl(i)} - v_{pl(i-1)}] / 2 \quad (A1.9)$$

FIG. A1.2 Definition of Area for *J* Calculation Using the Basic Method

FIG. A1.3 Definition of Plastic Area for Resistance Curve *J* Calculation

where:

- v<sub>pl(i)</sub> = plastic part of the load-line or crack mouth opening displacement = v<sub>(i)</sub> - (P<sub>(i)</sub> C<sub>(i)</sub>), and
- C<sub>(i)</sub> = experimental compliance, (Δv/ΔP)<sub>(i)</sub>, corresponding to the current crack size, a<sub>i</sub>.

For test methods that do not evaluate an experimental load-line elastic compliance, the load-line compliance C<sub>(i)</sub> can be determined from the following equation:

$$C_{(i)} = \frac{1}{EB_e} \left( \frac{S}{W - a_i} \right)^2 \times \quad (A1.10)$$

$$\left[ 1.193 - 1.98\left(\frac{a_i}{W}\right) + 4.478\left(\frac{a_i}{W}\right)^2 - 4.443\left(\frac{a_i}{W}\right)^3 + 1.739\left(\frac{a_i}{W}\right)^4 \right]$$

where:

$$B_e = B - (B - B_N)^2/B$$

while for the crack mouth opening displacement case:

$$C_{(i)} = \frac{6S}{EWB_e} \left(\frac{a_i}{W}\right) \times \quad (\text{A1.11})$$

$$\left[ 0.76 - 2.28\left(\frac{a_i}{W}\right) + 3.87\left(\frac{a_i}{W}\right)^2 - 2.04\left(\frac{a_i}{W}\right)^3 + \frac{0.66}{(1-a_i/W)^2} \right]$$

where:

$$B_e = B - (B - B_N)^2/B$$

The compliance estimated using Eq A1.10 or Eq A1.11 should be verified by calibrating against the initial experimental force versus load-line displacement data to assure the integrity of the load-line displacement measurement system.

**A1.4.3 Calculation of Crack Size**—For a resistance curve test method using an elastic compliance technique on single edge bend specimens with crack mouth opening displacements measured at the notched edge, the crack size is given as follows:

$$\frac{a_i}{W} = [0.999748 - 3.9504u + 2.9821u^2 - 3.21408u^3 + 51.51564u^4 - 113.031u^5] \quad (\text{A1.12})$$

where:

$$u = \frac{1}{\left[ \frac{B_e W E C_i}{S/4} \right]^{1/2} + 1} \quad (\text{A1.13})$$

$$\begin{aligned} C_i &= (\Delta v_m / \Delta P) \text{ on an unloading/reloading sequence,} \\ v_m &= \text{crack mouth opening displacement at notched edge,} \\ B_e &= B - (B - B_N)^2/B. \end{aligned}$$

NOTE A1.2—Crack size on a single edge bend specimen is normally determined from crack mouth opening compliance. It can be determined from load-line compliance if the correct calibration is available.

A1.4.4 Other compliance equations are acceptable if the resulting accuracy is equal to or greater than those described and the accuracy has been verified experimentally.

**A1.4.5 Calculation of CTOD:**

**A1.4.5.1 Calculation of CTOD for the Basic Test Method**—

For the basic test method, calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta = \frac{J}{m\sigma_Y} \quad (\text{A1.14})$$

where: J is defined in A1.4.2.1 with  $a = a_o$ , the original crack size, and then crack growth corrected using Annex A16 and:

$$m = A_0 - A_1 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right) + A_2 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^2 - A_3 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^3 \quad (\text{A1.15})$$

with :

$$A_0 = 3.18 - 0.22 * (a_o/W),$$

$$A_1 = 4.32 - 2.23 * (a_o/W),$$

$$A_2 = 4.44 - 2.29 * (a_o/W), \text{ and}$$

$$A_3 = 2.05 - 1.06 * (a_o/W).$$

Calculation of  $\delta$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

**A1.4.5.2 Calculations of CTOD for the Resistance Curve Test Method**—For the resistance curve test method, calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta_i = \frac{J_i}{m_i\sigma_Y} \quad (\text{A1.16})$$

where  $J_i$  is defined in A1.4.2.2 with  $a = a_i$ , the current crack size and:

$$m = A_0 - A_1 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right) + A_2 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^2 - A_3 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^3 \quad (\text{A1.17})$$

with :

$$A_0 = 3.18 - 0.22 * (a_i/W),$$

$$A_1 = 4.32 - 2.23 * (a_i/W),$$

$$A_2 = 4.44 - 2.29 * (a_i/W), \text{ and}$$

$$A_3 = 2.05 - 1.06 * (a_i/W).$$

Calculation of  $\delta_i$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

## A2. SPECIAL REQUIREMENTS FOR TESTING COMPACT SPECIMENS

### A2.1 Specimen

A2.1.1 The standard compact specimen,  $C(T)$ , is a single edge-notched and fatigue cracked plate loaded in tension. Two specimen geometries which have been used successfully for  $J$  testing are shown in Fig. A2.1.

A2.1.2 The compact specimen in Fig. A2.2 has generally been used only for  $K_{Ic}$  testing; it has no provision for load-line displacement measurement. Do not use this specimen for ductile fracture toughness measurement. Use it only when  $K_{Ic}$  behavior is expected.

A2.1.3 Alternative specimens may have  $2 \leq W/B \leq 4$  but with no change in other proportions.

### A2.2 Apparatus

A2.2.1 For generally applicable specifications concerning the loading clevis and displacement gage, see 6.5.2 and 6.2.

### A2.3 Specimen Preparation

A2.3.1 For generally applicable specifications concerning specimen size and preparation, see Section 7.

A2.3.2 All specimens shall be precracked in fatigue at a force value based upon the force  $P_m$  as follows:

$$P_m = \frac{0.4Bb_o^2\sigma_Y}{2W + a_o} \quad (\text{A2.1})$$

See Section 7 for fatigue precracking requirements.

### A2.4 Calculation

A2.4.1 **Calculation of  $K$** —For the compact specimen at a force  $P_{(i)}$ , calculate  $K$  as follows:

$$K_{(i)} = \frac{P_{(i)}}{(BB_N W)^{1/2}} f\left(\frac{a_i}{W}\right) \quad (\text{A2.2})$$

with:

COMPACT TEST SPECIMEN FOR PIN OF 0.24W (+0.000W/-0.005W) DIAMETER

COMPACT TEST SPECIMEN FOR PIN OF 0.1875W(+0.000W/-0.001W)DIAMETER

FIG. A2.1 Two Compact Specimen Designs That Have Been Used Successfully for Fracture Toughness Testing

$$f\left(\frac{a_i}{W}\right) = \quad (A2.3)$$

A2.4.2 Calculation of  $J$ —For the compact specimen calculate  $J$  as follows:

$$\frac{\left\{ \left( 2 + \frac{a_i}{W} \right) \left[ 0.886 + 4.64 \left( \frac{a_i}{W} \right) - 13.32 \left( \frac{a_i}{W} \right)^2 + 14.72 \left( \frac{a_i}{W} \right)^3 - 5.6 \left( \frac{a_i}{W} \right)^4 \right] \right\}}{\left( 1 - \frac{a_i}{W} \right)^{3/2}} \quad J = J_{el} + J_{pl} \quad (A2.4)$$

NOTE 1—A surfaces shall be perpendicular and parallel as applicable to within 0.002 W TIR.

NOTE 2—The intersection of the crack starter notch tips with the two specimen surfaces shall be equally distant from the top and bottom edges of the specimen within 0.005 W.

NOTE 3—Integral or attachable knife edges for clip gage attachment to the crack mouth may be used.

NOTE 4—For starter-notch and fatigue-crack configuration see Fig. 7.

FIG. A2.2 Compact Specimen for  $K_{Ic}$  Testing

where:

$J_{el}$  = elastic component of  $J$ , and

$J_{pl}$  = plastic component of  $J$ .

A2.4.2.1  $J$  Calculations for the Basic Test Method—For the compact specimen at a point corresponding to  $v$ ,  $P$  on the specimen force versus load-line displacement record, calculate as follows:

$$J = \frac{K^2(1 - \nu^2)}{E} + J_{pl} \quad (A2.5)$$

where:

$K$  is from A2.4.1 with  $a = a_o$ , and

$$J_{pl} = \frac{\eta_{pl} A_{pl}}{B_N b_o} \quad (A2.6)$$

where:

$A_{pl}$  = area shown in Fig. A1.2,

$B_N$  = net specimen thickness ( $B_N = B$  if no side grooves are present),

$b_o$  = uncracked ligament, ( $W - a_o$ ), and

$\eta_{pl} = 2 + 0.522b/W$ .

All basic test method  $J$  integral values shall be corrected for crack growth using the procedure of Annex A16.

A2.4.2.2  $J$  Calculation for the Resistance Curve Test Method—For the  $C(T)$  specimen at a point corresponding  $a_{(i)}$ ,  $v_{(i)}$ , and  $P_{(i)}$  on the specimen force versus load-line displacement record calculate as follows:

$$J_{(i)} = \frac{(K_{(i)})^2 (1 - \nu^2)}{E} + J_{pl(i)} \quad (A2.7)$$

where  $K_{(i)}$  is from A2.4.1, and:

$$J_{pl(i)} = \left[ J_{pl(i-1)} + \left( \frac{\eta_{pl(i-1)}}{b_{(i-1)}} \right) \frac{A_{pl(i)} - A_{pl(i-1)}}{B_N} \right] \left[ 1 - \gamma_{(i-1)} \left( \frac{a_{(i)} - a_{(i-1)}}{b_{(i-1)}} \right) \right] \quad (A2.8)$$

where:

$\eta_{pl(i-1)} = 2.0 + 0.522 b_{(i-1)}/W$ , and

$\gamma_{(i-1)} = 1.0 + 0.76 b_{(i-1)}/W$ .

In Eq A2.8, the quantity  $A_{pl(i)} - A_{pl(i-1)}$  is the increment of plastic area under the force versus plastic load-line displacement record between lines of constant displacement at points  $i-1$  and  $i$  shown in Fig. A1.3. The quantity  $J_{pl(i)}$  represents the total crack growth corrected plastic  $J$  at point  $i$  and is obtained in two steps by first incrementing the existing  $J_{pl(i-1)}$  and then by modifying the total accumulated result to account for the crack growth increment. Accurate evaluation of  $J_{pl(i)}$  from the above relationship requires small and uniform crack growth increments consistent with the suggested elastic compliance spacing of Annex A8 and Annex A10. The quantity  $A_{pl(i)}$  can be calculated from the following equation:

$$A_{pl(i)} = A_{pl(i-1)} + \frac{[P_{(i)} + P_{(i-1)}] [v_{pl(i)} - v_{pl(i-1)}]}{2} \quad (A2.9)$$

where:

- $v_{pl(i)}$  = plastic part of the load-line displacement,  $v_i - P_{(i)} C_{LL(i)}$ , and
- $C_{LL(i)}$  = experimental compliance,  $(\Delta v/\Delta P)_i$ , corresponding to the current crack size,  $a_i$ .

For test methods that do not evaluate an experimental elastic compliance,  $C_{LL(i)}$  can be determined from the following equation:

$$C_{LL(i)} = \frac{1}{EB_e} \left( \frac{W + a_i}{W - a_i} \right)^2 \left[ 2.1630 + 12.219 \left( \frac{a_i}{W} \right) - 20.065 \left( \frac{a_i}{W} \right)^2 - 0.9925 \left( \frac{a_i}{W} \right)^3 + 20.609 \left( \frac{a_i}{W} \right)^4 - 9.9314 \left( \frac{a_i}{W} \right)^5 \right] \quad (A2.10)$$

where:

$$B_e = B - \frac{(B - B_N)^2}{B} \quad (A2.11)$$

The load-line compliance estimated using Eq A2.10 should be verified by calibrating against the initial experimental compliance to assure the integrity of the load-line displacement measurement system.

In an elastic compliance test, the rotation corrected compliance,  $C_c(i)$ , described in A2.4.4 shall be used instead of  $C_{LL(i)}$  in Eq A2.10.

A2.4.3 Calculation of Crack Size—For a single specimen test method using an elastic compliance technique on the compact specimen with crack opening displacements measured on the load-line, the crack size is given as follows:

$$a_i/W = 1.000196 - 4.06319u + 11.242u^2 - 106.043u^3 + 464.335u^4 - 650.677u^5 \quad (A2.12)$$

where:

$$u = \frac{1}{[B_e EC_{c(i)}]^{1/2} + 1} \quad (A2.13)$$

$C_{c(i)}$  = specimen load-line crack opening elastic compliance  $(\Delta v/\Delta P)$  on an unloading/reloading sequence corrected for rotation (see A2.4.4),

$B_e = B - (B - B_N)^2/B$ .

A2.4.4 To account for crack opening displacement in  $C(T)$  specimens, the crack size estimation shall be corrected for rotation. Compliance is corrected as follows:

$$C_{c(i)} = \frac{C_i}{\left( \frac{H^*}{R} \sin \theta_i - \cos \theta_i \right) \left( \frac{D}{R} \sin \theta_i - \cos \theta_i \right)} \quad (A2.14)$$

where (Fig. A2.3):

- $C_i$  = measured specimen elastic compliance (at the load-line),
- $H^*$  = initial half-span of the load points (center of the pin holes),
- $R$  = radius of rotation of the crack centerline,  $(W + a)/2$ , where  $a$  is the updated crack size,
- $D$  = one half of the initial distance between the displacement measurement points,
- $\theta$  = angle of rotation of a rigid body element about the unbroken midsection line, or

$$\theta = \sin^{-1} \left[ \frac{\left( \frac{d_m}{2} + D \right)}{(D^2 + R^2)^{1/2}} \right] - \tan^{-1} \left( \frac{D}{R} \right), \text{ and} \quad (A2.15)$$

$d_m$  = total measured load-line displacement.

A2.4.5 Other compliance equations are acceptable if the resulting accuracy is equal to or greater than those described and the accuracy has been verified experimentally.

A2.4.6 Calculation of CTOD:

A2.4.6.1 Calculation of CTOD for the Basic Test Method—

For the basic test method, calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta = \frac{J}{m\sigma_y} \quad (A2.16)$$

where  $J$  is defined in A2.4.2.1 with  $a = a_o$ , the original crack size, and then crack growth corrected using Annex A16 and:

$$m = A_0 - A_1 * \left( \frac{\sigma_{YS}}{\sigma_{TS}} \right) + A_2 * \left( \frac{\sigma_{YS}}{\sigma_{TS}} \right)^2 - A_3 * \left( \frac{\sigma_{YS}}{\sigma_{TS}} \right)^3 \quad (A2.17)$$

FIG. A2.3 Elastic Compliance Correction for Specimen Rotation

with:  $A_0=3.62$ ,  $A_1=4.21$ ,  $A_2=4.33$ , and  $A_3=2.00$ . Calculation of  $\delta$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

**A2.4.6.2 Calculation of CTOD for the Resistance Curve Test Method**—For the resistance curve test method, calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta_i = \frac{J_i}{m\sigma_Y} \quad (A2.18)$$

where  $J$  is defined in **A2.4.2.2** with  $a = a_i$ , the current crack size, and,

$$m = A_0 - A_1 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right) + A_2 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^2 - A_3 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^3 \quad (A2.19)$$

with:  $A_0=3.62$ ,  $A_1=4.21$ ,  $A_2=4.33$ , and  $A_3=2.00$ . Calculation of  $\delta_i$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

### A3. SPECIAL REQUIREMENTS FOR TESTING DISK-SHAPED COMPACT SPECIMENS

#### A3.1 Specimen

**A3.1.1** The standard disk-shaped compact specimen, DC(T), is a single edge-notched and fatigue cracked plate loaded in tension. The specimen geometry which has been used successfully is shown in **Fig. A3.1**.

**A3.1.2** Alternative specimens may have  $2 \leq W/B \leq 4$  but with no change in other proportions.

#### A3.2 Apparatus

**A3.2.1** For generally applicable specifications concerning the loading clevis and displacement gage see **6.5.2** and **6.2**.

#### A3.3 Specimen Preparation

**A3.3.1** For generally applicable specifications concerning specimen size and preparation, see **Section 7**.

**A3.3.2** All specimens shall be precracked in fatigue at a force value based upon the force  $P_m$  as follows:

$$P_m = \frac{0.4Bb_o^2\sigma_Y}{2W + a_o} \quad (A3.1)$$

See **section 7.4** for precracking requirements.

#### A3.4 Procedure

**A3.4.1 Measurement**—The analysis assumes the specimen was machined from a circular blank, and, therefore, measurements of circularity as well as width,  $W$ ; crack size,  $a$ ; and thicknesses,  $B$  and  $B_N$ , shall be made. Measure the dimensions  $B_N$  and  $B$  to the nearest 0.05 mm (0.002 in.) or 0.5 %, whichever is larger.

**A3.4.1.1** The specimen blank shall be checked for circularity before specimen machining. Measure the diameter at eight equally spaced points around the circumference of the specimen blank. One of these measurements shall lie in the intended notch plane. Average these readings to obtain the diameter,  $D$ . If any measurement differs from the average diameter,  $D$ , by more than 5 %, machine the blank to the required circularity. Otherwise,  $D = 1.35 W$ .

**A3.4.1.2** Measure the width,  $W$ , and the crack size,  $a$ , from the plane of the centerline of the loading holes (the notched

**NOTE 1**—All surfaces shall be perpendicular and parallel as applicable within 0.002  $W$  TIR.

**NOTE 2**—The intersection of the crack starter notch tips on each surface of the specimen shall be equally distant within 0.005 $W$  from the centerline of the loading holes.

**NOTE 3**—Integral or attached knife edges for clip gage attachment to the crack mouth may be used.

**NOTE 4**—For starter-notch and fatigue-crack configuration see **Fig. 7**.

**NOTE 5**—Required circularity measurements shall be made at eight equally spaced points around the circumference. One of these points shall be the notch plane. Average the readings to obtain the radius. All values shall be within 5 % of the average.

**FIG. A3.1 Disk-Shaped Compact Specimen, DC(T), Standard Proportions and Dimensions**

edge is a convenient reference line but the distance from the centerline of the holes to the notched edge must be subtracted to determine  $W$  and  $a$ ). Measure the width,  $W$ , to the nearest 0.05 mm (0.002 in.) or 0.5 %, whichever is larger.

### A3.5 Calculation

**A3.5.1 Calculation of  $K$** —For the DC(T) specimen at a force  $P_{(i)}$ , calculate  $K$  as follows:

$$K_{(i)} = \frac{P_{(i)}}{(BB_N W)^{1/2}} f(a_i/W) \quad (\text{A3.2})$$

where:

$$f\left(\frac{a_i}{W}\right) = \quad (\text{A3.3})$$

$$\left\{ \left( 2 + \frac{a_i}{W} \right) \left[ 0.76 + 4.8 \left( \frac{a_i}{W} \right) - 11.58 \left( \frac{a_i}{W} \right)^2 + 11.43 \left( \frac{a_i}{W} \right)^3 - 4.08 \left( \frac{a_i}{W} \right)^4 \right] \right\} \\ \left( 1 - \frac{a_i}{W} \right)^{3/2}$$

**A3.5.2 Calculation of  $J$** —For the DC(T) specimen, calculate  $J$  as follows:

$$J = J_{el} + J_{pl} \quad (\text{A3.4})$$

where:

$J_{el}$  = elastic component of  $J$ , and

$J_{pl}$  = plastic component of  $J$ .

**A3.5.2.1  $J$  Calculation for the Basic Test Method**—For the DC(T) specimen at a point corresponding to  $v_{(i)}$ ,  $P_{(i)}$  on the specimen force versus load-line displacement record, calculate as follows:

$$J = \frac{K^2(1 - v^2)}{E} + J_{pl} \quad (\text{A3.5})$$

where  $K$  is from A3.5.1 with  $a = a_o$ , and

$$J_{pl} = \frac{\eta_{pl} A_{pl}}{B_N b_o} \quad (\text{A3.6})$$

where:

$A_{pl}$  = area shown in Fig. A1.2,

$B_N$  = net specimen thickness ( $B_N = B$  if no side grooves are present),

$b_o$  = uncracked ligament,  $(W - a_o)$ , and

$\eta_{pl} = 2 + 0.522b_o/W$ .

All basic test method  $J$  integral values shall be corrected for crack growth using the procedure of Annex A16.

**A3.5.2.2  $J$  Calculation for the Resistance Curve Test Method**—For the DC(T) specimen at a point corresponding to  $a_i$ ,  $v_i$ , and  $P_i$  on the specimen force versus load-line displacement record, calculate as follows:

$$J_{(i)} = \frac{(K_{(i)})^2 (1 - v^2)}{E} + J_{pl(i)} \quad (\text{A3.7})$$

where  $K_{(i)}$  is from A3.5.1 and:

$$J_{pl(i)} = \quad (\text{A3.8})$$

$$\left[ J_{pl(i-1)} + \left( \frac{\eta_{(i-1)}}{b_{(i-1)}} \right) \frac{A_{pl(i)} - A_{pl(i-1)}}{B_N} \right] \left[ 1 - \gamma_{(i-1)} \frac{a_{(i)} - a_{(i-1)}}{b_{(i-1)}} \right]$$

where:

$\eta_{(i-1)} = 2.0 + 0.522 b_{(i-1)}/W$ , and

$\gamma_{(i-1)} = 1.0 + 0.76 b_{(i-1)}/W$ .

In the preceding equation, the quantity  $A_{pl(i)} - A_{pl(i-1)}$  is the increment of plastic area under the force versus load-line displacement record between lines of constant displacement at points  $i-1$  and  $i$  shown in Fig. A1.3. The quantity  $J_{pl(i)}$  represents the total crack growth corrected plastic  $J$  at point  $i$  and is obtained in two steps by first incrementing the existing  $J_{pl(i-1)}$  and then by modifying the total accumulated result to account for the crack growth increment. Accurate evaluation of  $J_{pl(i)}$  from the preceding relationship requires small and uniform crack growth increments consistent with the suggested elastic compliance spacing of Annex A8 and Annex A10. The quantity  $A_{pl(i)}$  can be calculated from the following equation:

$$A_{pl(i)} = A_{pl(i-1)} + \frac{[P_{(i)} + P_{(i-1)}] [v_{pl(i)} - v_{pl(i-1)}]}{2} \quad (\text{A3.9})$$

where:

$v_{pl(i)}$  = plastic part of the load-line displacement,

$v_i - P_{(i)} C_{LL(i)}$ , and

$C_{LL(i)}$  = experimental compliance,  $(\Delta v/\Delta P)_i$ , corresponding to the current crack size,  $a_i$ .

For test methods that do not evaluate an experimental elastic compliance,  $C_{LL(i)}$  can be determined from the following equation:

$$C_{LL(i)} = \frac{1}{EB_e} \left( \frac{1 + \frac{a_{(i)}}{W}}{\frac{a_{(i)}}{W}} \right)^2 \times \quad (\text{A3.10})$$

$$\left[ 2.0462 + 9.6496 \left( \frac{a_{(i)}}{W} \right) - 13.7346 \left( \frac{a_{(i)}}{W} \right)^2 + 6.1748 \left( \frac{a_{(i)}}{W} \right)^3 \right]$$

where:

$B_e = B - (B - B_N)^2/B$ .

The compliance estimated using Eq A3.10 should be verified by calibrating against the initial experimental compliance to assure the integrity of the load-line displacement measurement system.

In an elastic compliance test, the rotation corrected compliance,  $C_c(i)$ , described in A3.5.4 shall be used instead of  $C_{LL(i)}$  given above.

**A3.5.3 Calculation of Crack Size**—For a single-specimen test method using an elastic compliance technique on DC(T) specimens with crack opening displacements measured at the load-line, the crack size is given as follows:

$$\frac{a_{(i)}}{W} = 0.998193 - 3.88087u + 0.187106u^2 + 20.3714u^3 \\ - 45.2125u^4 + 44.5270u^5 \quad (\text{A3.11})$$

where:

$$u = \frac{1}{[(B_e EC_c(i))^{1/2} + 1]} \quad (\text{A3.12})$$

where:

$C_c(i)$  = specimen crack opening compliance  $(\Delta v/\Delta P)$  on an unloading/reloading sequence, corrected for rotation (see A3.5.4),

$B_e = B - (B - B_N)^2/B$ .

**A3.5.4** To account for crack opening displacement in DC(T) specimens, the crack size estimation shall be corrected for rotation. Compliance shall be corrected as follows:

$$C_{c(i)} = \frac{C_i}{\left(\frac{H^*}{R} \sin\theta_i - \cos\theta_i\right)\left(\frac{D}{R} \sin\theta_i - \cos\theta_i\right)} \quad (\text{A3.13})$$

where (Fig. A2.3):

- $C_i$  = measured specimen elastic compliance (at the load-line),
- $H^*$  = initial half-span of the load points (center of the pin holes),
- $R$  = radius of rotation of the crack centerline,  $(W + a)/2$ , where  $a$  is the updated crack size,
- $D$  = one half of the initial distance between the displacement measurement points,
- $\theta$  = angle of rotation of a rigid body element about the unbroken midsection line, or

$$\theta = \sin^{-1} \left[ \frac{\left(\frac{d_m}{2} + D\right)}{(D^2 + R^2)^{1/2}} \right] - \tan^{-1} \left( \frac{D}{R} \right), \text{ and} \quad (\text{A3.14})$$

$d_m$  = total measured load-line displacement.

A3.5.5 Other compliance equations are acceptable if the resulting accuracy is equal to or greater than those described and the accuracy has been verified experimentally.

#### A3.5.6 Calculation of CTOD:

##### A3.5.6.1 Calculation of CTOD for the Basic Test Method—

For the basic test method calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta = \frac{J}{m\sigma_Y} \quad (\text{A3.15})$$

where  $J$  is defined in A3.5.2.1 with  $a = a_0$ , the original crack size and then crack growth corrected using Annex A16 and:

$$m = A_0 - A_1 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right) + A_2 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^2 - A_3 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^3 \quad (\text{A3.16})$$

with:  $A_0=3.62$ ,  $A_1=4.21$ ,  $A_2=4.33$ , and  $A_3=2.00$ . Calculation of  $\delta$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

A3.5.6.2 Calculation of CTOD for the Resistance Curve Test Method—For the resistance curve test method, calculations of CTOD for any point on the force-displacement curve are made from the following expression:

$$\delta = \frac{J_i}{m\sigma_Y} \quad (\text{A3.17})$$

where  $J$  is defined in A3.5.2.2 with  $a = a_i$ , the current crack size and,

$$m = A_0 - A_1 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right) + A_2 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^2 - A_3 * \left(\frac{\sigma_{YS}}{\sigma_{TS}}\right)^3 \quad (\text{A3.18})$$

with:  $A_0=3.62$ ,  $A_1=4.21$ ,  $A_2=4.33$ , and  $A_3=2.00$ . Calculation of  $\delta$  requires  $\sigma_{YS}/\sigma_{TS} \geq 0.5$ .

## A4. METHODS FOR EVALUATING INSTABILITY AND POP-IN

A4.1 Assessment of Force/Clip Gage Displacement Records—The applied force-displacement record obtained from a fracture test on a notched specimen will usually be one of the four types shown in Fig. A4.1.

A4.1.1 In the case of a smooth continuous record in which the applied force rises with increasing displacement up to the onset of unstable brittle crack extension or pop-in, and where no significant slow stable crack growth has occurred (see 3.2 and Fig. A4.1a and Fig. A4.1b), the critical CTOD,  $\delta_c$ , shall be determined from the force and plastic component of clip gage displacement,  $v_p$ , corresponding to the points  $P_c$  and  $v_c$ . If failure occurs close to the linear range, apply the procedure of Annex A5 to test whether a valid  $K_{Ic}$  measurement can be made.

A4.1.2 In the event that significant slow stable crack extension precedes either unstable brittle crack extension or pop-in, or a maximum force plateau occurs, the force-displacement curves will be of the types shown in Fig. A4.1c, Fig. A4.1d, respectively. These figures illustrate the values of  $P$  and  $v$  to be used in the calculation of  $\delta_u$ .

A4.1.3 If the pop-in is attributed to an arrested unstable brittle crack extension in the plane of the fatigue precrack, the result must be considered as a characteristic of the material tested.

NOTE A4.1—Splits and delaminations can result in pop-ins with no arrested brittle crack extension in the plane of the fatigue precrack.

For this test method, pop-in crack extension in the plane of the fatigue precrack can be assessed by a specific change in compliance. The following procedure may be used to assess the significance of small pop-ins (see Fig. A4.1b and Fig. A4.1d). Referring to Fig. A4.1 and Fig. A4.2, measure the values of  $P_c$  and  $v_c$  or  $P_u$  and  $v_u$  from the test record at points corresponding to: (a) the earliest significant pop-in fracture, that is, for which  $F > 0.05$  and (b) fracture, when pop-ins prior to fracture may be ignored, that is, for which  $F < 0.05$  as follows:

$$F = 1 - \frac{v_1}{P_1} \cdot \left(\frac{P_n - y_n}{v_n + x_n}\right) \quad (\text{A4.1})$$

where:

$F$  = factor representing the accumulated increase in compliance and crack size due to all stable crack extensions, or pop-ins, or both, prior to and including the  $n$ th pop-in, and

$n$  = sequential number (see Fig. A4.2) of the last of the particular series of pop-ins being assessed.

NOTE A4.2—When only one pop-in occurs,  $n = 1$ . When multiple pop-ins occur it may be necessary to make successive assessments of  $F$  with  $n = 1, 2, 3$ , or more.

$v_1$  = elastic displacement at pop-in No. 1 (see Fig. A4.2),

$P_n$  = force at the  $n$ th pop-in, and  
 $v_n$  = elastic displacement at the  $n$ th pop-in.

NOTE A4.3— $v_n$  may be determined graphically or analytically (see Fig. A4.2).

$y_n$  = force drop at the  $n$ th pop-in, and  
 $x_n$  = displacement increase at the  $n$ th pop-in

NOTE A4.4—Although an individual pop-in may be ignored on the basis of these criteria, this does not necessarily mean that the lower bound of fracture toughness has been measured. For instance, in an inhomogeneous material such as a weld, a small pop-in may be recorded because of

fortuitous positioning of the fatigue precrack tip. Thus, a slightly different fatigue precrack position may give a larger pop-in, which could not be ignored. In such circumstances the specimens should be sectioned after testing, and examined metallographically to ensure that the crack tips have sampled the weld or base metal region of interest (26).

A4.1.4 The initial compliance  $C_1$  shall be determined by constructing the tangent OA to the initial portion of the force-clip gage displacement curve as shown in Fig. A4.3. The initial compliance  $C_1$  is the inverse of the slope of the tangent line OA:

$$C_1 = \frac{\Delta v_g}{\Delta P} \quad (A4.2)$$

NOTE 1—Construction lines drawn parallel to the elastic loading slope to give  $v_p$ , the plastic component of total displacement,  $v_g$ .  
 NOTE 2—In curves b and d, the behavior after pop-in is a function of machine/specimen compliance, instrument response, etc.

FIG. A4.1 Types of Force versus Clip Gage Displacement Records

NOTE 1— $C_1$  is the initial compliance.  
 NOTE 2—The pop-ins have been exaggerated for clarity.

FIG. A4.2 Significance of Pop-In

FIG. A4.3 Determination of Initial Compliance

A5. METHOD FOR  $K_{Ic}$  DETERMINATION

A5.1 This annex describes the methods and calculations required to determine the linear elastic, plane-strain fracture toughness,  $K_{Ic}$ , and the associated requirements for qualifying the data according to this test method. Data meeting all of the qualification requirements of 9.1 and those of this annex result in a size-insensitive  $K_{Ic}$  value.

A5.2 Test Record—Conduct the test following the procedure in Section 8, recording a force versus crack mouth opening displacement as shown in Fig. A5.1. Digital data is

recommended.

A5.3 Calculation of Results—In order to determine  $K_{Ic}$  in accordance with this test method, it is necessary first to calculate a conditional result,  $K_Q$ , which involves a construction on the test record, and then to determine whether this result is consistent with size and yield strength requirements. The procedure is as follows:

A5.3.1 Construct a secant line as shown on Fig. A5.1 with a slope  $(P/v)_5 = 0.95(P/v)_o$  where  $(P/v)_o$  is the slope of the

FIG. A5.1 Principal Types of Force-Displacement Records

tangent  $OA$  to the initial portion of the data record. This slope can be obtained using digital data or fit to an autographic record as desired.

NOTE A5.1—Slight nonlinearity often occurs at the very beginning of a record and should be ignored. However, it is important to establish the initial slope of the record with high precision and therefore it is advisable to minimize this nonlinearity by a preliminary loading and unloading with the maximum force not producing a stress intensity level exceeding that used in the final stage of fatigue cracking.

The force  $P_Q$  is then defined as follows: if the force at every point on the record that precedes  $P_5$  is lower than  $P_5$ , then  $P_5$  is  $P_Q$  (Fig. A5.1, Type I); if, however, there is a maximum force preceding  $P_5$  that exceeds it, then this maximum force is  $P_Q$  (Fig. A5.1, Types II and III).

NOTE A5.2—For the Annex A1-Annex A3 specimens over the range  $0.45 \leq a/W \leq 0.55$ , the 95 % offset criterion corresponds to an increase in elastic compliance equivalent to that caused by a crack extension of approximately 2 % of the original remaining ligament,  $b_o$  or the original crack size,  $a_o$ .

A5.3.2 Calculate  $K_Q$  using the appropriate expression from A12.1.1 with  $P = P_Q$ .

#### A5.4 Qualification of $K_Q$ as $K_{Ic}$ :

A5.4.1 For  $K_Q$  to be qualified as a  $K_{Ic}$  value according to this method, it must meet the qualification requirements of 9.1 and the following requirements:

A5.4.2 Calculate the ratio  $P_{max}/P_Q$ , where  $P_{max}$  is the maximum force the specimen was able to sustain (see Fig. A5.1). The ratio  $P_{max}/P_Q$  must be  $\leq 1.10$  in order for  $K_Q$  to be equal to  $K_{Ic}$ . The use of side grooved specimens is recommended to keep  $P_{max}/P_Q \leq 1.10$ .

A5.4.3 Calculate  $2.5(K_Q/\sigma_{YS})^2$  where  $\sigma_{YS}$  is the 0.2 % offset yield strength in tension (see Test Methods E8/E8M). This quantity must be less than the length of the initial uncracked ligament,  $b_o$ , in order for  $K_Q$  to be equal to  $K_{Ic}$ . Otherwise, the test is not a qualified  $K_{Ic}$  test according to this standard.

A5.4.4 If the test result fails to meet the qualification requirements in 9.1 or in A5.4, or both, it will be necessary to use a larger specimen to determine  $K_{Ic}$ . The dimensions of the larger specimen can be estimated on the basis of  $K_Q$  but generally will be at least 1.5 times those of the specimen that

failed to yield a  $K_{Ic}$  value qualified according to this method. A test result that fails to meet the qualification requirements in A5.4 generally corresponds to a specimen size that is too small for the 95 % secant method to correspond to the point on the force versus crack opening displacement record adequately close to the onset of crack extension. In this instance a fracture toughness measurement cannot be based on force and crack size measurements alone. The unqualified  $K_{Ic}$  test specimen record can be evaluated by the methods of Annex A4-Annex A7 and Annex A8-Annex A11 to determine whether other measures of fracture toughness can be developed from this test. The normalization method of Annex A15 might also be useful to obtain other fracture toughness measures from this test.

A5.5 Significance of  $K_{Ic}$ —The property  $K_{Ic}$  determined by this test method characterizes the resistance of a material to fracture in a neutral environment in the presence of a sharp crack under severe tensile constraint, such that the state of stress near the crack front approaches plane-strain, and the crack-tip plastic region is small compared to both the crack size and thickness.

A5.5.1 Variation in the value of  $K_{Ic}$  can be expected within the allowable range of specimen proportions,  $a/W$  and  $W/B$ .  $K_{Ic}$  may also be expected to rise with increasing ligament size. Notwithstanding these variations, however,  $K_{Ic}$  is believed to represent a lower limiting value of fracture toughness (for 2 % apparent crack extension) in the environment and at the speed and temperature of the test.

A5.5.2 Lower values of  $K_{Ic}$  can be obtained for materials that fail by cleavage fracture; for example, ferritic steels in the ductile-to-brittle transition region or below, where the crack front length affects the measurement in a stochastic manner independent of crack front constraint. The present test method does not apply to such materials and the user is referred to Test Method E1921 and (25) for applicable guidance. Likewise,  $K_{Ic}$ , as a measure of fracture toughness does not apply to high toughness or high tearing resistance materials whose failure is accompanied by appreciable amounts of plasticity. Procedures for characterizing the fracture toughness of elastic-plastic materials are given in Annex A6-Annex A11.

## A6. FRACTURE INSTABILITY TOUGHNESS DETERMINATION USING $J$

A6.1 This annex describes the method for characterizing fracture toughness values based on  $J$ ,  $J_c$ , or  $J_u$ , for a fracture instability and the associated requirements for qualifying the data according to this test method. Data meeting all of the qualification requirements of 9.1 and those of this annex result in qualified values of  $J_c$  or  $J_u$ . Data meeting the size requirement result in a value of  $J_c$  that is insensitive to the in-plane dimensions of the specimen.

A6.2 Fracture Instability Before Stable Tearing—When fracture occurs before stable tearing, a single-point toughness value may be obtained labeled  $J_c$ .

A6.2.1  $J$  is calculated at the final point of instability, using the  $J$  formulas for the basic method including the crack growth correction in Annex A16. This point is labeled  $J_{Qc}$ , a provisional  $J_c$  value.

A6.2.2 Qualification of  $J_{Qc}$  as  $J_c$ — $J_{Qc} = J_c$ , a measure of fracture toughness at instability without significant stable crack extension that is independent of in-plane dimensions, provided the following two conditions are both met: (1)  $B$ ,  $b_o \geq 100 J_Q/\sigma_Y$ , and (2) crack extension  $\Delta a_p < 0.2 \text{ mm} + J_Q/2\sigma_Y$ . Note that even if these conditions are met,  $J_c$  may be dependent on thickness (length of crack front).

**A6.3 Fracture Instability After Stable Tearing**—When fracture occurs after stable tearing crack extension  $\Delta a_p > 0.2$  mm (0.008 in.) +  $J_{Qc}/2\sigma_y$ , a single-point fracture toughness value may be obtained, labeled  $J_{Qu}$ . In addition, part of an *R*-curve may be developed or the final point may be used in the evaluation of an initiation toughness value  $J_{Ic}$  (these are described in [Annex A8-Annex A11](#)).

**A6.3.1** *J* is calculated at the final point where instability occurs using the *J* formulas for the basic method including the crack growth correction of [Annex A16](#). This point is a  $J_u$  value.

**A6.3.2 Qualification of  $J_{Qu}$  as  $J_u$** — $J_{Qu} = J_u$  if crack extension  $\Delta a_p \geq 0.2$  mm (0.008 in.) +  $J_{Qc}/2\sigma_y$ .

**A6.4 Significance of  $J_c$  and  $J_u$** —Values of  $J_{Qc}$  that meet the size criteria are labeled  $J_c$  and are considered to be insensitive to the in-plane dimensions of the specimen. For ferritic steel specimens that have failed unstably by cleavage in the ductile to brittle transition, the analysis procedure of Test Method [E1921](#) is recommended. Values of  $J_{Qc}$  that do not meet validity remain  $J_{Qc}$  and may be size-dependent.  $J_u$  is not considered to be a size-insensitive property and therefore is not subject to a size criterion. It is a characteristic of the material and specimen geometry and size. It signifies that at the test temperature the material is not completely ductile and can sustain only limited *R*-curve behavior.

## 7. FRACTURE INSTABILITY TOUGHNESS DETERMINATION USING CTOD ( $\delta$ )

**A7.1** This annex describes the method for characterizing fracture toughness values based on  $\delta$ ,  $\delta_c$ , or  $\delta_u$  for a fracture instability and the associated requirements for qualifying the data according to this test method. Data meeting all of the qualification requirements of [9.1](#) and those in this annex result in qualified values of  $\delta_c$  or  $\delta_u$ . Data meeting the size requirement result in a value of  $\delta_c^*$  that is insensitive to in-plane dimensions of the specimen.

**A7.2 Fracture Instability Before Stable Tearing**—When fracture occurs before stable tearing, a single-point toughness value may be obtained labeled  $\delta_c$ , the force  $P_c$  and the clip gage displacement  $v_c$ , for  $\delta_c$  are indicated in [Fig. 1](#).

**A7.2.1**  $\delta$  is calculated at the final point, instability, using the  $\delta$  formulas from [Annex A1-Annex A3](#). This point is labeled  $\delta_{Qc}$ , a provisional  $\delta_c$  value.

**A7.2.2 Qualification of  $\delta_{Qc} = \delta_c^*$** , a fracture toughness value that is insensitive to the in-plane dimensions of the specimen, if the following two conditions are met: (1)  $B$ ,  $b_o \geq 300 \delta_{Qc}$ , and (2) crack extension  $\Delta a_p < 0.2$  mm (0.008 in.) +  $\delta_{Qc}/1.4$ . Data that fail to meet the size criterion based on  $B$  or  $b_o$ , but still meet the restriction on crack extension, are labeled  $\delta_c$ .

**A7.3 Fracture Instability After Stable Tearing**—When fracture occurs after stable tearing, crack extension  $\Delta a_p \geq 0.2$  mm (0.008 in.) +  $\delta_{Qc}/1.4$ , a single-point fracture toughness value may be obtained, labeled  $\delta_u$ . In addition, part of an *R*-curve may be developed or the final point may be used in the evaluation of an initiation toughness value (these are described in [Annex A8-Annex A11](#)).

**A7.3.1**  $\delta$  is calculated at the final point where instability occurs, using the  $\delta$  formulas for the basic method. This point is labeled  $\delta_{Qu}$ , a provisional  $\delta_u$  value.

**A7.3.2 Qualification of  $\delta_{Qu}$  as  $\delta_u$** — $\delta_{Qu} = \delta_u$ , if crack extension,  $\Delta a_p > 0.2$  mm (0.008 in.) +  $\delta_{Qu}/1.4$ .

**A7.3.3 Significance of  $\delta_c$  and  $\delta_u$** —Values of  $\delta_{Qc}$  that meet the qualification requirements are labeled  $\delta_c^*$  and are considered to be insensitive to the in-plane dimensions of the specimen. Values of  $\delta_{Qc}$  that do not meet the size requirement are labeled  $\delta_c$  and may be size-dependent.  $\delta_u$  is not considered to be a size-insensitive property and, therefore, is not subject to a size criterion. It is a characteristic of the material and specimen geometry and size. It signifies that at the test temperature the material is not completely ductile and can sustain only limited *R*-curve behavior.

## 8. J-R CURVE DETERMINATION

NOTE A8.1—[Annex A8-Annex A11](#) cover methods for evaluating toughness for stable tearing.

**A8.1** This method describes a single-specimen technique for determining the *J*-*R* curve of metallic materials. The *J*-*R* curve consists of a plot of *J* versus crack extension in the region of *J* controlled growth. The *J*-*R* curve is qualified provided that the criteria of [9.1](#) and [A8.3](#) are satisfied.

### A8.2 *J* Calculation:

**A8.2.1** *J* can be calculated at any point on the force versus load-line displacement record using the equations suggested in the calculation section of [Annex A1-Annex A3](#) for the different specimen geometries.

**A8.2.2** If the basic method is used, *J* values must be crack growth corrected using the procedure of [Annex A16](#). In this case, crack size values are obtained from direct optical measurements from the specimen fracture surfaces using the procedure of [8.5](#).

**A8.2.3** If a resistance curve method is used, the values of crack size are calculated using the compliance equations described in [Annex A1-Annex A3](#) (or an alternative method for measuring crack size). The rotation correction shall be applied to account for geometry changes due to deformation for the compact, C(T), and disk-shaped compact, DC(T), specimens.

**A8.2.4** If an elastic compliance method is used, the unload/reload sequences should be spaced with the displacement interval not to exceed  $0.01b_o$ , the average being about  $0.005b_o$ .

The use of larger increments between unloadings will lead to less accurate *J-R* curves although the result will be conservative. If an initiation value of toughness is being evaluated, more unload/reload sequences may be necessary in the early region of the *J-R* curve.

A8.3 Measurement Capacity of Specimen:

A8.3.1 The maximum *J*-integral capacity for a specimen is given by the smaller of the following:

$$J_{max} = b_o \sigma_Y / 10, \text{ or}$$

$$J_{max} = B \sigma_Y / 10.$$

A8.3.2 The maximum crack extension capacity for a specimen is given by the following:

$$\Delta a_{max} = 0.25 b_o$$

A8.4 Constructing the *J-R* Curve:

A8.4.1 The *J*-integral values and the corresponding crack extension values must be plotted as shown in Fig. A8.1. If an elastic compliance method is used, shift the *J-R* curve according to the procedure described in A9.3. The *J-R* curve is defined as the data in a region bounded by the coordinate axes and the  $J_{max}$  and  $\Delta a_{max}$  limits given in A8.3.1 and A8.3.2.

FIG. A8.1 Typical *J-R* Curve

A9.  $J_{Ic}$  and  $K_{J_{Ic}}$  EVALUATION

A9.1 Significance—The property  $J_{Ic}$  determined by this method characterizes the toughness of a material near the onset of crack extension from a preexisting fatigue crack. The  $J_{Ic}$  value marks the beginning stage of material crack growth resistance development, the full extent of which is covered in Annex A8.  $J_{Ic}$  is qualified provided that the criteria of 9.1 and A9.7 and A9.8 are satisfied.

A9.2 *J* Calculation—Calculations of the *J* integral are

made using the equations in Annex A1-Annex A3.

A9.3 Corrections and Adjustments to Data:

A9.3.1 If the basic method is used, calculate crack growth corrected *J* values using the procedure of Annex A16.

A9.3.2 If an elastic compliance method is used, a correction is applied to the estimated  $\Delta a_i$  data values to obtain an improved  $a_{oq}$ . This correction is intended to obtain the best value of  $a_{oq}$ , based on the initial set of crack size estimates,  $a_i$ ,

data. For data generated using the basic procedure of 8.4, no adjustments to the crack size and crack extension data are necessary. To evaluate  $J_{Ic}$  using data from the basic procedure, proceed to A9.6.

A9.3.3 Adjustment of  $a_{oq}$ —The value of  $J_Q$  is very dependent on the  $a_{oq}$  used to calculate the  $\Delta a_i$  quantities. The value obtained for  $a_{oq}$  in 8.6.3.1 might not be the correct value and the following adjustment procedure is required.

A9.3.3.1 Identify all  $J_i$  and  $a_i$  pairs that were determined before the specimen reached the maximum force for the test. Use this data set of points to calculate a revised  $a_{oq}$  from the following equation:

$$a = a_{oq} + \frac{J}{2\sigma_Y} + BJ^2 + CJ^3 \quad (A9.1)$$

The coefficients of this equation shall be found using a least squares fit procedure, see Appendix X1.

A9.3.3.2 If the number of points used in A9.3.3.1 to determine  $a_{oq}$  is less than 8 or of these 8 there are less than 3 between  $0.4 J_Q$  and  $J_Q$  or the correlation coefficient of this fit is less than 0.96, the data set is not adequate to evaluate any toughness measures in accordance with this test method.

A9.4 If the optically measured crack size,  $a_o$ , differs from  $a_{oq}$  by more than the larger of  $0.01W$  or  $0.5\text{mm}$ , the data set is not adequate according to this test method.

A9.5 Evaluate the final  $J_i$  values using the adjusted  $a_{oq}$  of A9.3.3 and the equations of the applicable Annex A1, Annex A2, or Annex A3.

A9.6 Calculation of an Interim  $J_Q$ :

A9.6.1 Basic Procedure—For each specimen, calculate  $\Delta a$  as follows:

$$\Delta a = a_p - a_o \quad (A9.2)$$

Resistance Curve Procedure—For each  $a_i$  value, calculate a corresponding  $\Delta a_i$  as follows:

$$\Delta a_i = a_i - a_{oq} \quad (A9.3)$$

Plot  $J$  versus  $\Delta a$  as shown in Fig. A9.1. Determine a construction line in accordance with the following equation:

$$J = 2\sigma_Y \Delta a \quad (A9.4)$$

A9.6.2 Plot the construction line, then draw an exclusion line parallel to the construction line intersecting the abscissa at  $0.15\text{ mm}$  ( $0.006\text{ in.}$ ). Draw a second exclusion line parallel to the construction line intersecting the abscissa at  $1.5\text{ mm}$  ( $0.06\text{ in.}$ ). Plot all  $J - \Delta a$  data points that fall inside the area enclosed by these two parallel lines and capped by  $J_{\text{limit}} = b_o \sigma_Y / 7.5$ .

A9.6.3 Plot a line parallel to the construction and exclusion lines at an offset value of  $0.2\text{ mm}$  ( $0.008\text{ in.}$ ).

A9.6.4 At least one  $J - \Delta a$  point shall lie between the  $0.15\text{-mm}$  ( $0.006\text{-in.}$ ) exclusion line and a parallel line with an offset of  $0.5\text{ mm}$  ( $0.02\text{ in.}$ ) from the construction line as shown in Fig. A9.2. At least one  $J - \Delta a$  point shall lie between this  $0.5\text{-mm}$  offset line and the  $1.5\text{-mm}$  ( $0.06\text{-in.}$ ) exclusion line. Acceptable data are shown in Fig. A9.2. The other  $J - \Delta a$  pairs can be anywhere inside the exclusion zone.

A9.6.5 Using the method of least squares, determine a linear regression line of the following form:

$$\ln J = \ln C_1 + C_2 \ln \left( \frac{\Delta a}{k} \right) \quad (A9.5)$$

FIG. A9.1 Definition of Construction Lines for Data Qualification

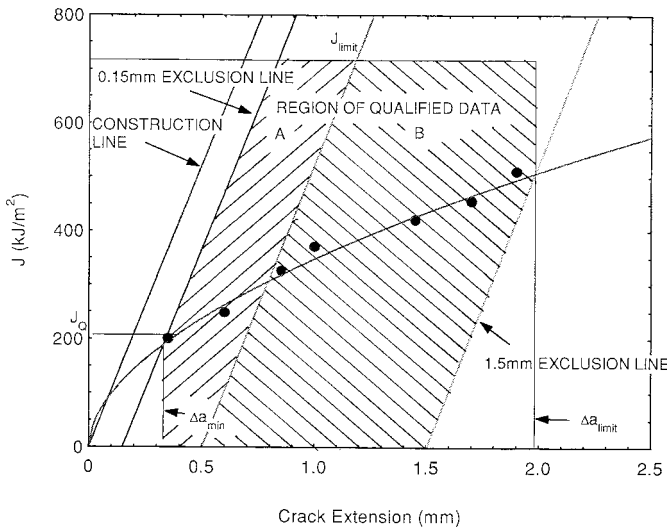

FIG. A9.2 Definition of Regions for Data Qualification

where  $k = 1.0 \text{ mm}$  or  $0.0394 \text{ in.}$  Use only the data which conform to the requirements stated in the previous sections. Draw the regression line as illustrated in Fig. A9.1.

A9.6.6 The intersection of the regression line of A9.6.5 with the 0.2-mm offset line defines  $J_Q$  and  $\Delta a_Q$ . To determine this intersection the following procedure is recommended.

A9.6.6.1 As a starting point estimate an interim  $J_{Q(i)} = J_{Q(i)}$  value from the data plot of Fig. A9.1.

A9.6.6.2 Evaluate  $\Delta a_{(i)}$  from the following:

$$\Delta a_{(i)} = \frac{J_{Q(i)}}{2\sigma_Y} + 0.2 \text{ mm (0.008 in.)} \quad (\text{A9.6})$$

A9.6.6.3 Evaluate an interim  $J_{Q(i+1)}$  from the following power law relationship:

$$J_{Q(i+1)} = C_1 \left( \frac{\Delta a_{(i)}}{k} \right)^{C_2} \quad (\text{A9.7})$$

where  $k = 1.0 \text{ mm}$  or  $0.0394 \text{ in.}$

A9.6.6.4 Increment  $i$  and return to A9.6.6.2 and A9.6.6.3 to get  $\Delta a_{(i)}$  and interim  $J_{Q(i+1)}$  until the interim  $J_Q$  values converge to within  $\pm 2 \%$ .

A9.6.6.5 Project the intercepts of the power law curve with the 0.15-mm (0.006-in.) and the 1.5-mm (0.06-in.) exclusion lines vertically down to the abscissa. This indicates  $\Delta a_{min}$  and  $\Delta a_{limit}$ , respectively. Eliminate all data points that do not fall between  $\Delta a_{min}$  and  $\Delta a_{limit}$  as shown in Fig. A9.1. Also eliminate all data points which lie above the limiting  $J$  capacity where  $J_{limit} = b_o \sigma_Y / 7.5$ . The region of qualified data is shown in Fig. A9.2.

A9.6.6.6 At least five data points must remain between  $\Delta a_{min}$ ,  $\Delta a_{limit}$ , and  $J_{limit}$ . Data point spacing must meet the requirements of A9.6.4. If these data points are different from those used in A9.6.6 to evaluate  $J_Q$ , obtain a new value of  $J_Q$  based only on qualified data.

A9.7 Qualification of Data—The data shall satisfy the requirements of 9.1 and all of the following requirements to be qualified according to this test method. If the data do not pass these requirements no fracture toughness values can be determined according to this test method.

A9.7.1 The power coefficient  $C_2$  of A9.6.5 shall be less than 1.0.

A9.7.2 For the Resistance Curve Procedure the following additional requirements must be satisfied:

A9.7.2.1 If an elastic compliance method is used,  $a_{oq}$  shall not differ from  $a_o$  by more than the larger of  $0.01W$  or  $0.5 \text{ mm}$ .

A9.7.2.2 The number of data available to calculate  $a_{oq}$  shall be  $\geq 8$ ; the number of data between  $0.4J_Q$  and  $J_Q$  shall be  $\geq 3$ ; and the correlation coefficient of the least squares fit of A9.3.3.1 shall be greater than 0.96.

A9.8 Qualification of  $J_Q$  as  $J_{Ic} - J_Q = J_{Ic}$ , a size-independent value of fracture toughness, if:

A9.8.1 Thickness,  $B > 10 J_Q / \sigma_Y$ ,

A9.8.2 Initial ligament,  $b_o > 10 J_Q / \sigma_Y$ ,

A9.9 Evaluation of  $K_{Jic}$ —Calculate  $K_{Jic} = \sqrt{(E' J_{Ic})}$  using  $E' = E/(1-\nu^2)$  and the qualified  $J_{Ic}$  of A9.8.

### A10. METHOD FOR $\delta$ -R CURVE DETERMINATION

A10.1 This annex describes a single-specimen technique for determining the  $\delta$ -R curve of metallic materials. The  $\delta$ -R curve consists of a plot of  $\delta$  versus crack extension. To measure the  $\delta$ -R curve the resistance curve procedure of 8.6 must be used. The  $\delta$ -R curve is qualified provided that the criteria of 9.1 and A10.3 are satisfied.

#### A10.2 $\delta$ Calculation:

A10.2.1  $\delta$  can be evaluated at any point along the force versus load-line displacement record using the equations suggested in the calculation section of Annex A1-Annex A3 for the different specimen geometries.

A10.2.2 The values of crack size are calculated using the compliance equations described in Annex A1-Annex A3. The

rotation correction shall be applied to account for geometry changes due to deformation for the compact, C(T), and disk-shaped compact, DC(T), specimens.

A10.2.3 The unload/reload sequences should be spaced with the displacement interval less than  $0.01 W$ , the average being about  $0.005 W$ . If an initiation value of toughness is being evaluated, more unload/reload sequences may be necessary in the early region of the  $\delta$ -R Curve.

#### A10.3 Measurement Capacity of a Specimen:

A10.3.1 The maximum  $\delta$  capacity for a specimen is given as follows:

$$\delta_{max} = b_o / 10m$$

where  $m$  is defined in Annex A1 through Annex A3 for the different specimen geometries.

A10.3.2 The maximum crack extension capacity for a specimen is given as follows:

$$\Delta a_{\max} = 0.25 b_o.$$

A10.4 Constructing the  $\delta$ - $R$  Curve:

A10.4.1 The  $\delta$  values and the corresponding crack extension values must be plotted as shown in Fig. A10.1. A  $\delta$ - $R$  curve is established by smoothly fitting the data points in the region bounded by the coordinate axes and the  $\delta_{\max}$  and  $\Delta a_{\max}$  limits.

FIG. A10.1 Typical  $\delta$ - $R$  Curve

A11. METHOD FOR  $\delta_{Ic}$  DETERMINATION

A11.1 Significance—The value of CTOD,  $\delta_{Ic}$ , determined by this method characterizes the fracture toughness of materials near the onset of stable crack extension from a preexisting fatigue crack.  $\delta_{Ic}$  is qualified provided that the criteria of 9.1 and A11.7 and A11.8 are satisfied.

A11.2  $\delta$  Calculation—Calculations of  $\delta$  are made using the equations in Annex A1-Annex A3.

A11.3 Corrections and Adjustments to Data:

A11.3.1 A correction is applied to the estimated  $a_i$  data values to obtain an improved  $a_{oq}$ . This correction is intended to obtain the best value of  $a_{oq}$ , based on the initial set of crack size estimates,  $a_i$ , data. For data generated using the basic procedure of 8.4, no adjustments to the data are necessary. To evaluate  $\delta_{Ic}$  using data from the basic procedure, proceed to A11.6.

A11.3.2 Adjustment of  $a_{oq}$ —The value of  $\delta_Q$  is very dependent on the  $a_{oq}$  used to calculate the  $\Delta a_i$  quantities. The value obtained for  $a_{oq}$  in 8.6.3.1 might not be the correct value, and the following adjustment procedure is required.

A11.3.2.1 Identify all  $\delta_i$  and  $a_i$  pairs that were determined before the specimen reached the maximum force for the test. Use this data set of points to calculate a revised  $a_{oq}$  from the following equation:

$$a = a_{oq} + \frac{\delta}{1.4} + B\delta^2 + C\delta^3 \tag{A11.1}$$

The coefficients of this equation shall be found using a least squares fit procedure, see Appendix X1.

A11.3.2.2 If the number of points used in A11.3.2.1 to calculate  $a_{oq}$  is less than 8, or of these 8 there are less than 3 between  $0.4\delta_Q$  and  $\delta_Q$ , or the correlation coefficient of this fit is  $< 0.96$ , the data set is not adequate to evaluate any toughness measures in accordance with this method.

A11.4 If the optically measured crack size,  $a_o$ , differs from  $a_{oq}$  by more than the larger of 0.01 W or 0.5 mm, the data set is not adequate in accordance with this method.

A11.5 Evaluate the final  $\delta_i$  values using the adjusted  $a_{oq}$  of A11.3.2.1 and the equations of the applicable Annex A1, Annex A2, or Annex A3.

A11.6 Calculation of an Interim  $\delta_Q$ :

A11.6.1 Basic Procedure—for each specimen, calculate  $\Delta a$  as follows:

$$\Delta a = a_p - a_o \tag{A11.2}$$

Resistance Curve Procedure—for each  $a_i$  value, calculate a corresponding  $\Delta a_i$  as follows:

$$\Delta a_i = a_i - a_{oq} \tag{A11.3}$$

Plot  $\delta$  versus  $\Delta a$  as shown in Fig. A11.1. Draw a construction line in accordance with the following equation:

$$\delta = 1.4 \Delta a \tag{A11.4}$$

FIG. A11.1 Definition of Construction Lines for Data Qualification

A11.6.2 Plot the construction line. Draw an exclusion line parallel to the construction line intersecting the abscissa at 0.15 mm (0.006 in.) as shown in Fig. A11.1. Draw a second exclusion line intersecting the abscissa at 1.5 mm (0.06 in.). Plot all  $\delta-\Delta a_p$  data points that fall inside the area enclosed by these two parallel lines and capped by  $\delta_{limit} = b_o / 7.5m$ , where  $m$  is defined in Annex A1 through Annex A3 for the different specimen geometries.

A11.6.3 One  $\delta-\Delta a_p$  point must lie between the 0.15-mm (0.006-in.) exclusion line and a parallel line with an offset of 0.5 mm (0.02 in.) from the construction line. One  $\delta-\Delta a_p$  point must lie between a line parallel to the construction line at an offset of 0.5 mm (0.020 in.) and the 1.5-mm exclusion line. Acceptable data is shown in Fig. A11.2 with one point in Zone A and one point in Zone B. The other  $\delta-\Delta a_p$  pairs can be placed anywhere inside the exclusion zone.

A11.6.4 Plot a line parallel to the construction line and exclusion lines at an offset value of 0.2 mm (0.008 in.).

A11.6.5 To establish a crack initiation measurement point under dominant slow-stable crack growth, a power law curve fitting procedure shall be used. This has the following form:

$$\delta_Q = C_1 \left( \frac{\Delta a}{k} \right)^{C_2} \quad (A11.5)$$

where  $k = 1$  mm (or 0.0394 in.) depending upon units used. This power law can be determined by using a method of least squares to determine a linear regression line of the following form:

$$\ln \delta = \ln C_1 + C_2 \ln \left( \frac{\Delta a}{k} \right) \quad (A11.6)$$

Use only the data that conform to the criteria stated in the previous sections. Plot the regression line as illustrated in Fig. A11.1.

FIG. A11.2 Definition of Regions for Data Qualification

A11.6.6 The intersection of the regression line of A11.6.4 with the offset line of A11.6.5 defines  $\delta_Q$  and  $\Delta a_Q$ . To determine this intersection the following procedure is recommended:

A11.6.6.1 Estimate a  $\delta_{Q(1)}$  value from the data plot of Fig. A11.1.

A11.6.6.2 Evaluate  $\Delta a_{p(1)}$  from the following:

$$\Delta a_{p(1)} = \frac{\delta_{Q(1)}}{1.4} + 0.2 \text{ mm (0.008 in.)} \quad (A11.7)$$

A11.6.6.3 Evaluate

$$\delta_{Q(1)} = C_1 \left( \frac{\Delta a_{p(1)}}{k} \right)^{C_2} \quad (A11.8)$$

A11.6.6.4 Return to A11.6.6.2 and A11.6.6.3 to get  $\Delta a_{(i)}$  and  $\delta_{Q(i+1)}$  until the  $\delta_Q$  values converge to within 2 %.

A11.6.6.5 Project the intercepts of the power law curve with the 0.15-mm (0.006-in.) and the 1.5-mm (0.06-in.) exclusion lines vertically down to the abscissa. This indicates  $\Delta a_{min}$  and  $\Delta a_{limit}$ , respectively. Eliminate all data points that do not fall between  $\Delta a_{min}$  and  $\Delta a_{limit}$  as shown in Fig. A11.1. Also eliminate all data points which lie above the limiting  $\delta$  capacity where  $\delta_{limit} = b_o/7.5m$ , where  $m$  is defined in Annex A1 through Annex A3 for the different specimen geometries.

A11.6.6.6 At least five data points must remain between  $\Delta a_{min}$ ,  $\Delta a_{limit}$ , and  $\delta_{limit}$ . Data point spacing must meet the requirements of A11.6.3. If these data points are different from those used in A11.6.6 to evaluate  $\delta_Q$ , obtain a new value of  $\delta_Q$  based only on qualified data.

A11.7 *Qualification of Data*—The data shall satisfy the requirements of 9.1 and all of the following requirements to be qualified according to this method. If the data do not pass these

requirements, no fracture toughness values can be determined according to this method.

A11.7.1 The power coefficient  $C_2$  of A11.6.5 shall be less than 1.0.

A11.7.2 For the *Resistance Curve Procedure* the following additional requirements must be satisfied:

A11.7.2.1  $a_{oq}$  shall not differ from  $a_o$  by more than the greater of 0.01W or 0.5 mm.

A11.7.2.2 The number of data available to calculate  $a_{oq}$  shall be  $\geq 8$ ; the number of data between  $0.4\delta_Q$  and  $\delta_Q$  shall be  $\geq 3$ ; and the correlation coefficient of the least squares fit of A11.6.5 shall be greater than 0.96.

A11.8 *Qualification of  $\delta_Q$  as  $\delta_{Ic}$* :

$\delta_Q = \delta_{Ic}$ , a size-independent value of fracture toughness, if:

A11.8.1 The initial ligament,  $b_o \geq 10m\delta_Q$ ,

where  $m$  is defined in Annex A1 through Annex A3 for the different specimen geometries.

## A12. COMMON EXPRESSIONS

NOTE A12.1—Annex A12 and Annex A13 cover miscellaneous information.

A12.1 *Stress-Intensity Factor*:

A12.1.1 The elastic stress intensity factor for a specimen is expressed as follows:

$$K = \frac{Pf(a/W)}{(BB_N W)^{1/2}} \quad (\text{A12.1})$$

where:

$$f\left(\frac{a}{W}\right) = \left(\frac{\xi}{\zeta}\right) \left[ C_0 + C_1\left(\frac{a}{W}\right) + C_2\left(\frac{a}{W}\right)^2 + C_3\left(\frac{a}{W}\right)^3 + C_4\left(\frac{a}{W}\right)^4 \right]$$

A12.1.2 The parameters for  $f(a/W)$  are listed in Table A12.1.

A12.2 *Compliance from Crack Size*:

A12.2.1 Compliance,  $C$ , of a specimen is expressed as a function of crack size as follows:

$$C = \frac{v}{P} = \quad (\text{A12.2})$$

$$\frac{Y^2}{B_e E'} [A_0 + A_1(a/W) + A_2(a/W)^2 + A_3(a/W)^3 + A_4(a/W)^4 + A_5(a/W)^5]$$

A12.2.2  $B_e = B - (B - B_N)^2/B$  and  $E' = E/(1 - \nu^2)$  for all cases and the other parameters for compliance are listed in Table A12.2.

**TABLE A12.1 Parameters for Stress-Intensity Factors**

### A13. METHOD FOR RAPID LOADING $K_{Ic}$ DETERMINATION

A13.1 This annex describes the determination of plane-strain fracture toughness ( $K_{Ic}$ ) properties of metallic materials under conditions where the loading rates exceed those for conventional (static) testing [2.75 MPa·m<sup>1/2</sup>/s (2.5 ksi·in.<sup>1/2</sup>/s)].

A13.2 *Summary of Requirements*—Special requirements are necessary for plane-strain fracture toughness testing at loading rates exceeding those of conventional (static) plane-strain fracture toughness testing. This description of these requirements does not include impact or quasi-impact testing (free-falling or swinging masses). Conventional fracture toughness test specimens are prepared as described in this method, tested under rapid-load conditions, and a fracture toughness value is calculated. Force-deflection, force-time, and deflection-time curves are recorded for each test. The force-deflection curves resulting from these tests are analyzed to ensure that the initial linear portion of the force-displacement record is sufficiently well-defined that  $P_Q$  can be determined unambiguously. In addition, a test time ( $t$ ), restricted to not less than one millisecond, is determined. This test time and an optionally calculated average stress intensity factor rate,  $dK/dt$ , characterize the rapid load test. The yield strength of the material must be determined or estimated for the loading time of the fracture test and is used in the analysis of the fracture test data. All of the criteria for static  $K_{Ic}$  determination apply to the rapid-load plane-strain fracture toughness test. The toughness property is denoted by  $K_{Ic}(\ )$  where the time to reach the force corresponding to  $K_Q$  in milliseconds is indicated in the parentheses ( ).

A13.3 *Significance and Use*—The significance of the conventional (static)  $K_{Ic}$  properties applies also to the case of rapid loading. The plane-strain fracture toughness of certain materials is sensitive to the loading rate and substantial decreases in toughness may be noted as the loading rate increases. Generally, such materials also show a pronounced dependence of  $K_{Ic}$  on test temperature. For example, the loading rate sensitivity of structural grade steels has required the development of a lower bound  $K_{IR}$  curve, given in Appendix G of Division III of the ASME Boiler and Pressure

Vessel Code,<sup>5</sup> for the fracture-safe design of heavy-wall nuclear pressure vessels. Additionally,  $K_{Ic}$  values for steels tested at various temperatures and loading rates are required for correlation with small-scale production control tests (such as the Charpy V-notch test) for setting material specifications and fracture-safe design procedures.

#### A13.4 Apparatus:

A13.4.1 *Loading*—Generally, hydraulic machines with rapid-acting servo controlled valves are used. Depending on the compliance of the loading system and the pump capacity, an accumulator may be required.

A13.4.2 *Fixtures*—The fixtures used for static plane-strain fracture toughness tests are generally suitable for rapid-load tests. However, consideration should be given to the possibility that the toughness of the fixture material may be reduced by rapid loading.

A13.4.3 *Force and Displacement Transducers*—The transducers used for static plane-strain fracture toughness tests are generally suitable for rapid-load tests. However, these transducers must have response characteristics that will ensure that inertial effects will not influence the force and displacement signals.

NOTE A13.1—While not required, the resonant frequencies of these transducers may be determined by suitably exciting them and observing the wave characteristic on an oscilloscope. If ringing (high-frequency oscillation) is observed within the time period required to reach the  $P_Q$  force, the stiffness of the transducers should be increased or their mass reduced. Force cells are quite stiff and should provide no problem at the minimum loading time of 1 ms. The displacement transducer might be cause for concern depending on its design. The cantilever beam displacement gage described in Section 6 has been used successfully at loading times slightly lower than 1 ms. The resonant frequency of this gage when mounted in a specimen in a conventional manner and excited by tapping is about 3300 Hz. The free-arm resonant frequency is about 750 Hz. Other gages of the same type but having different dimensions should operate satisfactorily if their free-arm resonance is at least 750 Hz. The following

<sup>5</sup> Available from American Society of Mechanical Engineers (ASME), ASME International Headquarters, Three Park Ave., New York, NY 10016-5990, <http://www.asme.org>.

equation may be used to estimate the free-arm resonant frequency of such a gage:

$$f = RC \left[ \frac{B^2 E g}{\rho l^4} \right] \quad (A13.1)$$

where:

$RC = 51.7$ ,

$f =$  resonant frequency, Hz,

$B =$  arm thickness, m,

$E =$  elastic modulus of the arms, MPa,

$g =$  gravitational acceleration, 9.804 m/s<sup>2</sup>,

$\rho =$  density of the arm material, kg/m<sup>3</sup>, and

$l =$  length of the uniform thickness section of the arms, m.

The coefficient  $RC$  becomes 0.162 if inch-pound units are used where  $B$  is in inches,  $E$  is in pound-force per square inch,  $g$  is 386 in./s<sup>2</sup>,  $\rho$  is pounds per cubic inch, and  $l$  is in inches.

**A13.4.4 Signal Conditioners**—Amplification or filtering of the transducer signals may be necessary. Such signal conditioning units should have a frequency response from dc to at least  $20/t$  (kilohertz) where  $t$  is the test time in milliseconds as defined in **A13.6.3**. As described in **A13.4.3**, conventional mechanical recording devices may not have sufficient frequency response to permit direct plotting of the force versus time and the displacement versus time signals.

**A13.5 Procedure:**

**A13.5.1 Loading Rate**—The rate of loading is optional with the investigator, but the time to reach the force corresponding to  $K_Q$  shall not be less than 1 ms. Use a preload to eliminate ringing in the force or displacement transducers associated with clearances in the load train being suddenly taken up by the start of rapid loading.

**A13.5.2** For each test conducted, a force versus time, a displacement versus time, and a force versus displacement record shall be obtained. The time scale of these records shall be accurately determined since the time is used to characterize the test. Examine the time-dependent records for the presence of ringing before reaching the  $P_Q$  force. Such ringing can result from inertial effects as described in **Note A13.2**. The special record analysis procedure described in **A13.6** may be helpful in assessing the magnitude of such effects.

**NOTE A13.2**—It should be recognized that some materials may exhibit a burst of crack extension at forces less than  $P_Q$  that is sufficiently abrupt to produce ringing in the displacement transducer signal. Such an abrupt advance of the crack may be associated with material inhomogeneities local to the fatigue crack tip. If the ringing is severe it may not be possible to unambiguously determine a value for  $P_Q$ . The presence of such bursts of crack extension should be recorded for those tests having analyzable force versus displacement records.

**NOTE A13.3**—The test data may be directly recorded if the recording devices have sufficient frequency response. Generally, it is advantageous to use a storage device that will capture the data and permit playing it out at a sufficiently slow speed that a pen recorder can be used in producing the required records. Such storage devices are commonly available in the form of digital storage oscilloscopes having pen recorder outputs. Separate storage instruments are also available. In general these digital storage devices have performance characteristics that are more than adequate to capture, store, and replay the transducer signals from a 1-ms test. For example, calculations show that for a typical fracture test, the crack-mouth displacement resolution would be about 0.76 mm/sample (0.030 mil/sample) and the force resolution would be about 712 N/sample (160 lbf/sample). It should be possible to obtain at least 1000 simultaneous

samples of force and displacement during such a test. A digital storage scope capable of at least this performance would have the following characteristics: maximum digitizing rate of 1 MHz, maximum sensitivity of  $\pm 100$  mV, resolution of 0.025 %, and memory of 4096 words by 12 bits. It may be necessary to amplify the output of the clip gage moderately and possibly that of the force cell depending on its capacity in terms of the range required. These values of resolution are based on a total noise figure of about 50 mV.

**A13.6 Calculation and Interpretation of Results:**

**A13.6.1** Special requirements are placed on the analysis of the force versus displacement record. These take into account the fact that experience **(18)** has shown force versus displacement records from rapid-load fracture toughness tests are not always as smooth in the linear range as those obtained from static tests. The special requirements of this annex are designed to ensure that an unambiguous value of  $P_Q$  can be determined. The test time must be determined from the force versus time record.

**A13.6.2** The additional analysis of the force versus displacement record is illustrated in **Fig. A13.1**. The procedure is as follows: Construct the straight line  $OA$  best representing the initial portion of the test record that ideally should be linear but may not be smooth. Then construct the line  $OP_5$  as described in **Annex A5** and determine  $P_Q$ . Draw a vertical line at  $v_p$  passing through  $P_Q$  and define  $P_v$  at the point of intersection of this line with the line  $OA$ . Determine 5 % of  $P_v$  and construct two lines  $BC$  and  $DE$  parallel to  $OA$  with  $BC$  passing through  $P_v + 0.05 P_v$  and  $DE$  passing through  $P_Q$  ( $P_v - 0.05 P_v$ ). Draw a horizontal line at  $P = 0.5 P_Q$ . For the test to be valid that recorded force versus displacement curve up to  $P_Q$  must lie within the envelope described by these parallel lines for the portion of the record with  $P \leq 0.5 P_Q$ .

**A13.6.3** The test time  $t$  in milliseconds is determined from the record of force versus time as indicated in **Fig. A13.2**.

**FIG. A13.1 Special Requirements for Analysis of Force versus Displacement Records (5 % Secant Line Not Shown)**

FIG. A13.2 Determination of Test Time from Force versus Time Record

Construct the best straight line  $OA$  through the most linear portion of the record. The value  $t$  is then determined from the point of intersection of this line with the time axis to the time corresponding to  $P_Q$ . This time,  $t$  is shown in the parentheses ( ) following  $K_{Ic}$ . An average stress intensity rate,  $dK/dt$ , may be calculated by dividing  $K_Q$  or  $K_{Ic}$  by  $t$  with the result being expressed in  $\text{MPa}\cdot\text{m}^{1/2}/\text{s}$  or  $\text{ksi}\cdot\text{in.}^{1/2}/\text{s}$ . It should be recognized

that minor errors in determining the loading time are not significant because significant changes in the toughness require a change of several orders of magnitude in loading rate.

A13.6.4 The 0.2 % offset tensile yield strength  $\sigma_{YS}$  is used in determining the specimen size requirements for a valid test as described in Annex A5. If the rapid force value of  $K_Q$  is valid using a static yield strength value determined at a temperature at or above that of the rapid-load test, no further yield strength considerations are necessary.

A13.6.5 If the test is invalid using such a yield strength, a tension test should be conducted on the test material at the temperature and loading time of the rapid-load toughness test with the time to reach the yield load in the tension test approximately equal to the time  $t$  defined in A13.6.3.

A13.6.6 In the absence of  $\sigma_{YS}$  values as defined in A13.6.5, the dynamic yield strength  $\sigma_{YD}$  of certain steels may be estimated using the following equation:

$$\sigma_{YD} = \sigma_{YD} + \frac{A}{T_x \log_{10}(2 \times 10^7 t)} - B \quad (\text{A13.2})$$

where:

$\sigma_{YS}$  = 0.2 % offset room temperature static yield strength,

$t$  = loading time, ms, and

$T_x$  = temperature of the rapid-load toughness test.

Units:

If  $\sigma_{YS}$  is in megapascals, then  $A = 1\,198\,860$ ,  $B = 187.4$  MPa,

If  $\sigma_{YS}$  is in pound force per square inch, then

$A = 174\,000$ ,  $B = 27.2$  ksi,

If the test temperature  $T$  is measured in K, then  $T_x = 1.8 T$ , and

If the test temperature  $T$  is measured in °F, then  $T_x = (T + 460)$ .

NOTE A13.4—The equation in A13.6.6 has been found useful only in estimating the low-temperature dynamic yield strength of constructional steels having room temperature yield strengths below 480 MPa (70 ksi).

## A14. SPECIAL REQUIREMENTS FOR RAPID-LOAD $J$ -INTEGRAL FRACTURE TOUGHNESS TESTING<sup>6</sup>

### A14.1 Scope

A14.1.1 This annex covers the determination of the rate dependent  $J_{Ic}(t)$  and the  $J$ -integral versus crack growth resistance curve ( $J$ - $R(t)$  curve) for metallic materials under conditions where the loading rate exceeds that allowed for conventional (static) testing, see Section 8.4.2.

### A14.2 Summary of Requirements

A14.2.1 Special requirements are necessary for  $J$ -integral fracture toughness testing of metallic materials at loading rates exceeding those of conventional (static) testing. Standard fracture toughness test specimens are prepared as described in this method, tested under rapid-load or drop weight conditions, and a  $J$ - $R(t)$  curve is calculated. From this  $J$ - $R(t)$  curve a  $J_{Qc}(t)$  can be evaluated using Section 9 of this method. If unstable

fracture intervenes, a  $J_{Qc}(t)$  can be evaluated at the onset of unstable behavior as in the static case.

A14.2.1.1 Force, load-line displacement, and time are recorded for each test. The force versus displacement curve resulting from each test is analyzed to ensure that the initial portion of the curve is sufficiently well defined that an unambiguous curve can be determined from the  $J(t)$  versus crack size ( $a(t)$ ) data. In addition, a minimum test time is calculated from the specimen stiffness and effective mass that sets a maximum allowed test rate for the material and geometry being tested. At times less than the minimum test time a significant kinetic energy component is present in the specimen relative to the internal energy, and the static  $J$  integral equations presented in this method are not accurate. Evaluation of a  $J_Q(t)$  or  $J_{Qc}(t)$  at a time less than the minimum test time is not allowed by this method.

A14.2.1.2 Evaluation of the  $J$ - $R(t)$  curve requires estimation of crack extension as a function of load-line displacement or time using the normalization method of Annex A15. An elastic compliance method cannot be used. A multiple specimen

<sup>6</sup> This test method is an Annex to ASTM E1820. It is under the jurisdiction of ASTM Committee E08 on Fatigue and Fracture and is the direct responsibility of Subcommittee E08.08 on Elastic-Plastic and Fracture Mechanics Technology.

method can be used to evaluate  $J_Q(t)$  from a series of tests, which can be corrected using [Annex A16](#) and assembled into a  $J$ - $R(t)$  curve. The  $J$ - $R(t)$  curve is valid if it meets the requirements of this method.

A14.2.1.3 All of the criteria for the static  $J_{Ic}$ ,  $J_c$ , and  $J$ - $R$  curve evaluations apply to the rapid load  $J$  integral fracture toughness test. The rapid load  $J$  integral resistance curve is denoted  $J$ - $R(t)$ , the stable initiation property  $J_{Ic}(t)$ , and the unstable initiation property by  $J_c(t)$ , where the time to reach the instant corresponding to  $J_Q$  in milliseconds is indicated in the brackets.

### A14.3. Terminology

#### A14.3.1 Definitions:

A14.3.1.1 The definitions given in Terminology [E1823](#) are applicable to this annex.

A14.3.1.2 The definitions given in Section [3](#) of this method are applicable.

A14.3.1.3 *Rapid Load*—In  $J$  integral fracture testing, any loading rate such that the time taken to reach  $P_m$  (see [7.4.4](#)) is less than 0.1 minutes.

A14.3.1.4 *Minimum Test Time,  $t_w(t)$* —In  $J$  integral fracture testing, the minimum time to the rate dependent  $J_Q(t)$  or  $J_{Qc}(t)$  accepted by this method ([19](#)). Test times less than  $t_w$  will lead to inaccurate  $J$  integral results since large kinetic energy components will be present. In this method:

$$t_w = \frac{2\pi}{\sqrt{k_s M_{eff}}} \quad (\text{A14.1})$$

where:

$k_s$  = specimen load-line stiffness, (N/m),

$M_{eff}$  = effective mass of the specimen, taken here to be half of the specimen mass (kg).

A14.3.1.5 *Test Time,  $t_Q(t)/[T]$* —In  $J$  integral fracture testing, the observed time to the rate dependent  $J_Q(t)$ .

A14.3.1.6  $J_c(t)/[FL^{-1}]$ —In  $J$  integral fracture testing, the rate dependent  $J$  integral at the onset of fracture instability prior to the onset of significant stable tearing crack extension, see Section [3.2.15](#), as defined in this annex.

A14.3.1.7  $J_{Qc}(t)/[FL^{-1}]$ —In  $J$  integral fracture testing, the provisional rate dependent  $J$  integral at the onset of fracture instability prior to the onset of significant stable tearing crack extension, as defined in this annex.

A14.3.1.8  $J_u(t)/[FL^{-1}]$ —In  $J$  integral testing, the rate dependent  $J$  integral at the onset of fracture instability after significant stable tearing crack extension, see section [3.2.16](#), as defined in this annex.

A14.3.1.9  $J_{Ic}(t)/[FL^{-1}]$ —In  $J$  integral testing, the rate dependent  $J$  integral at the onset of stable crack extension as defined in this annex.

A14.3.1.10  $J_Q(t)/[FL^{-1}]$ —In  $J$  integral fracture toughness testing, the provisional, rate dependent,  $J$  integral at the onset of stable crack extension as defined in this annex.

A14.3.1.11  $dJ/dt [FL^{-1}T^{-1}]$ —In  $J$  integral fracture testing, the rate of change of the  $J$  integral per unit time. Two loading rate quantities are defined in this method,  $(dJ/dt)_I$  measured before  $J_Q(t)$ , and  $(dJ/dt)_T$  measured after  $J_Q(t)$ , as defined by this annex.

### A14.4 Significance and Use

A14.4.1 The significance of the static  $J$ - $R$  curve,  $J_{Ic}$ , and  $J_c$  properties applies also to the case of rapid loading. The  $J$  integral fracture toughness of certain metallic materials is sensitive to the loading rate and to the temperature of test. The  $J$ - $R(t)$  curve and  $J_{Ic}(t)$  properties are usually elevated by higher test rates while  $J_c(t)$  can be dramatically lowered by higher test rates.

### A14.5 Apparatus

A14.5.1 *Loading*—Two types of high rate loading systems are anticipated. Servohydraulic machines with high flow rate servovalves and high capacity accumulators, or alternatively, drop weight impact machines can be used. On-specimen force measurements are recommended for high rate tests. Remote force cells or other transducers can be used for high rate tests if the requirements of this annex are met. Strain gage bridges are recommended for on-specimen force measurement, as shown in [Fig. A14.1](#) and [Fig. A14.2](#). For each specimen type, four gages are connected to construct a four-arm bridge and calibrated statically before the rapid load test (see [A14.5.4](#)). Strain gages with grid patterns of approximately 0.25B are recommended. For SE(B) specimens, gages should be positioned on the specimen mid-plane at the specimen span quarterpoints. For C(T) specimens, the gages should be positioned on the specimen upper and lower surfaces near the specimen mid-plane with the gage edge at least 0.1W behind the initial crack,  $a_o$ .

A14.5.2 *Servohydraulic Testing Fixtures*—The fixtures used for static fracture toughness tests generally require some modification for rapid load tests. Slack grip fixtures are often necessary to reduce the applied force oscillation and to allow the actuator to accelerate before force is applied to the specimen. Soft metal absorbers are generally used in drop tower tests to reduce the inertial shock caused by the impact of the test machine striker on the specimen surface.

Both initial and final crack sizes are required by the normalization method of  $J$ - $R(t)$  curve development of [Annex A15](#). The high rate test must be stopped abruptly to obtain a limited specimen deformation and a crack extension increment satisfying the requirement of [A15.1.1](#). Rigid stop block fixtures can be used to obtain the abrupt stop. In some cases a ramp and hold or square wave command signal can be used to obtain limited specimen deformation for the specimen test.

A14.5.3 *Drop Tower Testing Fixtures*—Special fixtures are necessary for drop tower testing according to this standard. Recommended fixtures for SE(B) and C(T) specimens are shown in [Figs. A14.3](#) and [A14.4](#) respectively ([20](#)). Stop block fixtures are required to obtain a limited extent of stable crack growth for  $J$ - $R(t)$  curve development. Soft metal absorbers are recommended to reduce the initial shock resulting from the impact of the drop tower striker on the specimen surface. A high frequency load-line displacement transducer and signal conditioner is required for drop tower tests.

FIG. A14.1 Strain Gages Mounted on SE(B) Specimen for Measurement of Transmitted Force

FIG. A14.2 Strain Gages Mounted on C(T) Specimen for Measurement of Transmitted Force

FIG. A14.3 Test Fixture for Drop Tower SE(B) Specimens

FIG. A14.4 Test Fixtures for Drop Tower C(T) Specimens

A14.5.4 *Force Transducers*—If remote force transducers are used, they shall meet the requirements of Practice E4. Requirements on the measured initial specimen stiffness and on the force and displacement signal smoothness are presented in A14.7.4. Static calibration of the on-specimen strain gage bridge should be done over a force range from 20 to 100 % of the final precracking force. At least five force calibration values shall be used, spaced evenly over this interval, and at least two repeat data sets are required. The applied force shall exceed ¼ of the calibrated range of the reference force cell used. The on-specimen, transmitted force measuring system shall be accurate to within 2 % of the final precracking force over the calibration range.

A14.5.5 *Displacement Transducers*—The transducer shall have response characteristics that allow it to follow the motion of the specimen while not introducing excessive mechanical noise into the measured displacement.

A14.5.5.1 Cantilever beam displacement gages such as those used in static fracture toughness testing may be suitable

for rapid-load testing, see A13.4.3. The cantilever beam displacement gage described in Annex A1 of Test Method E399 has been used successfully at loading times ( $t_0$ ) slightly less than 1 ms.

A14.5.5.2 Gap measuring transducers that use either capacitance or optical means to measure displacement have also been used successfully in rapid-load testing (20). These transducers have the advantage that they can be rigidly attached to the specimen, and the vibration characteristics of the transducer generally do not affect the measured displacement. The disadvantages are that the output may be non-linear, and the signal conditioners used with these transducers are often the limiting component in frequency response of the displacement measurement system. Capacitive transducers have been designed to fit in the notch of the C(T) specimen as shown in Fig. A14.5. Fiber-optic transducers have been used to measure load-line displacement of SE(B) specimens. If the load-line displacement is measured relative to the test fixture, care must be taken to account for the effects of fixture compliance and brinnelling on the measured displacement, as discussed in 8.3.1.1.

FIG. A14.5 High Rate Capacitance COD Gage and C(T) Specimen with Attachment Holes

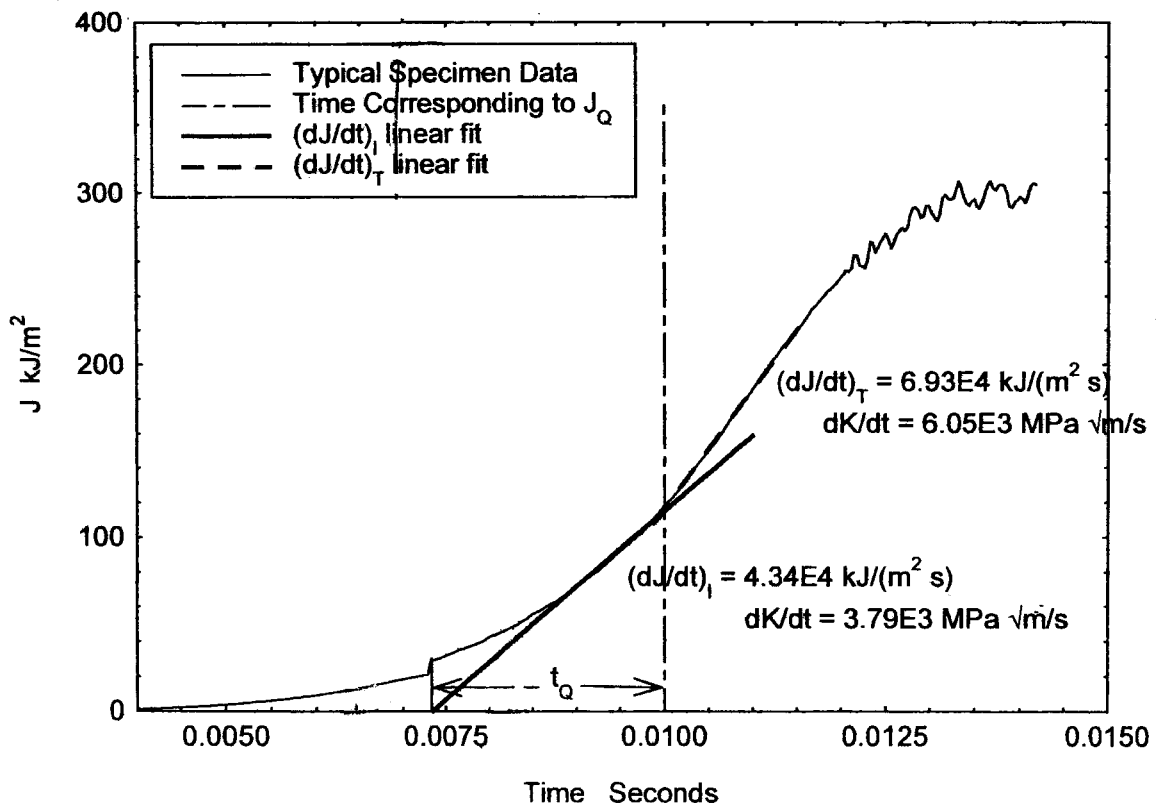

FIG. A14.6 Evaluation of  $t_Q$  and the Test Rates  $(dJ/dt)_I$  and  $(dJ/dt)_T$

A14.5.6 *Signal Conditioners*—The user is referred to Guide E1942 for a detailed discussion of requirements for data acquisitions systems. The signal conditioner must have sufficient bandwidth to capture the transducer signal without introducing distortion.

A14.5.6.1 Signal conditioners shall have a frequency bandwidth in excess of  $10/t_Q$  for the force signal and  $2/t_Q$  for the

displacement signal(s). The more stringent requirement on the force signal is necessary to obtain an accurate measurement of the elastic component of the  $J$  integral near crack initiation. No “phase shifting” of transducer signals is allowed by this method. The bandwidth required to accurately capture a signal of that frequency will depend on the type of low-pass filter in the signal conditioner, and the tolerable error. If a low-pass

filter is present in the measurement system it should not introduce more than 0.5 % measurement error, see Guide E1942.

A14.5.7 *Data Sampling*—The user is referred to Guide E1942 for a detailed discussion of requirements for data acquisitions systems. The rate at which an analog signal is sampled to create a digital signal shall be high enough to ensure that the peak value is accurately captured. The rate of data acquisition shall result in the time per data set being less than  $t_Q/50$ .

## A14.6 Procedure

A14.6.1 Follow the procedure of Sections 7 and 8 to prepare and test specimens. The following items are additional steps necessary for high rate testing.

A14.6.2 Calculate  $t_w$ , the minimum test time from Eq A14.1. The loading rate is optional but the time to reach  $J_Q(t)$  or  $J_{Qc}(t)$  shall not be less than  $t_w$ .

A14.6.3 For each test, force and load-line displacement are required as functions of time. Additional crack opening displacement data, electric potential data, or both, can be acquired as well if desired.

A14.6.4 Install and align the specimen in the test fixtures, establish the test temperature, conduct the test at the desired test rate, collect and store the data required. Remove the test specimen from the fixture and mark the extent of the ductile crack growth according to 8.5.3, break the specimen open according to 8.5.4 to expose the fracture surface, and measure the initial crack size  $a_o$ , and the final crack size  $a_f$  according to 8.5.4.

A14.6.5 If the specimen is characterized by ductile upper shelf behavior, the normalization method of Annex A15 can be used to develop the  $J$ - $R(t)$  curve for the test specimen. A multi-specimen method can also be used with  $J$  evaluated using the basic method relationships corrected for crack extension using Annex A16. Using Section 9, calculate  $J_Q$  (the tentative  $J_{Ic}$ ) and the corresponding force  $P_Q$  and time  $t_Q$ . If a ductile instability occurs so that the final stable crack size  $a_f$  cannot be determined, the normalization method cannot be used to develop the  $J$ - $R(t)$  curve or the corresponding  $J_Q$  for this test specimen.

A14.6.5.1 The dynamic yield strength and dynamic ultimate tensile strength at the relevant strain rate are required for the evaluation of  $J_Q$ . An approximate equivalent strain rate to be used for dynamic tensile testing shall be obtained from (31, 32)

$$\dot{\varepsilon} = \frac{2\sigma_{YS}}{t_Q E} \quad (\text{A14.2})$$

where  $\sigma_{YS}$  and  $E$  are values corresponding to quasistatic strain rates and evaluated at the temperature of the fracture toughness test and  $t_Q$  is the time to fracture from A14.6.

A14.6.5.2 If a pop-in is present, refer to Annex A4 to assess its significance. If the pop-in is significant,  $J_c(t)$  or  $J_u(t)$  values corresponding to the point of onset can be calculated using Annex A6. If fracture instability occurs without significant ductile crack extension,  $J_c(t)$  or  $J_u(t)$  values corresponding to the point of onset can be calculated as defined in Annex A6. If fracture instability follows significant ductile crack extension, the  $J$ - $R(t)$  and  $J_{Ic}(t)$  can be determined providing that  $a_f$  is

distinguishable. The validity of the  $J$ - $R(t)$  curve and  $J_{Ic}(t)$  are subject to the requirements of Annex A8, Annex A9, and Section 9.

## A14.7 Qualification of the Data

A14.7.1 Test equipment, specimen geometries, specimen fixture alignment, and measured data must meet all requirements of Sections 6, 7, 8, and 9, except as specifically replaced in A14.5. Additional requirements specified here are necessary for high rate testing.

A14.7.2 All of the test equipment requirements of A14.5 shall be met.

A14.7.3 Plot the  $J$  integral versus the time as shown in Fig. A14.6. If fracture instability occurs, calculate  $J$  based on  $a_o$  using the basic analysis procedure and plot the data up to and including  $J_{Qc}(t)$  or  $J_{Qu}(t)$ . Use a linear regression analysis to evaluate  $(dJ/dt)_I$  as shown in the example of Fig. A14.5 using the data from  $0.5J_Q(t)$  to  $J_Q(t)$ , from  $0.5J_{Qc}(t)$  to  $J_{Qc}(t)$ , or from  $0.5J_{Qu}(t)$  to  $J_{Qu}(t)$ , as the case may be. Extrapolate this line to the abscissa to evaluate the quantity  $t_Q$ , as shown in Fig. A14.6.

A14.7.3.1 A second loading rate,  $(dJ/dt)_T$ , is defined as the slope of the  $J$  versus time data beyond maximum force, as shown in Fig. A14.6, over the range from  $J_Q$  to  $J_Q + 0.5(J_{max} - J_Q)$  or the end of test, if fracture instability occurs.

A14.7.4 Plot force versus load-line displacement for the time interval  $0 \leq t \leq t_Q$ , as shown schematically in Fig. A14.7. Use a linear regression analysis to evaluate the initial specimen stiffness  $k_s$  using data over the range from 20 % to 50 % of the maximum force measured in the test. Plot this best fit line on the figure, and also plot two parallel lines of the same slope with the y-intercept offset by  $\pm 10$  % of  $P_{max}$  as shown in Fig. A14.7. Locate the final crossover  $\Delta_{LL}^F$ .

A14.7.4.1 For this data set to be qualified according to this method, the compliance,  $1/k_s$ , shall agree with the predictions of Eq A2.10 for the C(T) specimen and Eq A1.10 for the SE(B) specimen within  $\pm 10$  %. Additionally, the measured force displacement data in the region between  $0.3\Delta_{LL}^F$  and  $0.8\Delta_{LL}^F$  should remain within the bounds of the parallel lines constructed on Fig. A14.7. If these requirements are not met, slack grips or impact absorbers must be added or modified or the test rate reduced to obtain a smoother data set that can be qualified according to this method.

A14.7.5 If  $t_Q < t_w$ , the test data are not qualified according to this method. A slower loading rate must be used, or the specimen geometry changed to decrease  $t_w$  for the test to be qualified according to this method.

A14.7.6 If the normalization method of Annex A15 is used to obtain  $J_{Ic}$ , the  $J$  resistance curve, or both, at least one confirmatory specimen must be tested at the same test rate and under the same test conditions. From the normalization method the load-line displacement corresponding to a ductile crack extension of 0.5 mm shall be estimated. The additional specimen shall then be loaded to this load-line displacement level, marked, broken open and the ductile crack growth measured. The measured crack extension shall be  $0.5 \pm 0.25$  mm in order for these results to be qualified according to this method.

FIG. A14.7 Force Smoothness Verification Schematic

### A14.8 Qualifying the High Rate Results

A14.8.1 All qualification requirements of 9.1, Annex A6, Annex A8, Annex A9, and A14.7 must be met to qualify the  $J$ - $R(t)$  curve,  $J_Q(t)$  as  $J_{Ic}(t)$ , or  $J_{Qc}(t)$  as  $J_c(t)$  according to this method. If the normalization method of Annex A15 is used, the additional requirements of this annex shall also be met.

A14.8.2 The maximum crack extension capacity for a specimen to qualify the  $J$ - $R(t)$  curve is given by the following:

$$\Delta a_{max} = 0.15b_o \quad (A14.3)$$

### A14.9 Report

A14.9.1 The report shall include all the items of Section 10 as well as the following:

A14.9.1.1 The minimum test time,  $t_w$ , according to A14.6.2.

A14.9.1.2 The  $P_Q$  and  $t_Q$ , corresponding to the calculated  $J_Q(t)$  or  $J_{Qc}(t)$ .

A14.9.1.3 The  $(dJ/dt)_I$ ,  $(dJ/dt)_T$  values, or both.

A14.9.1.4 If  $J_{Ic}(t)$  is being reported, the final crack extension obtained on the confirmatory specimen of A14.7.6 shall be reported.

### A14.10 Precision and Bias

A14.10.1 Precision—The precision of  $J$  versus crack growth is a function of material variability, the precision of the

various measurements of linear dimensions of the specimen and testing fixtures, precision of the displacement measurement, precision of the force measurement, as well as the precision of the recording devices used to produce the force displacement record used to calculate  $J$  and crack size. For the test rates allowed by this annex, if the procedures outlined in this annex are followed, the force and load-line displacement can be measured with an precision comparable with that of the static loading as described in the main body. If the normalization function method of Annex A15 is used, the crack size and crack extension information must be inferred from initial and final crack size measurements. The requirement for the additional specimen to be tested near to the point of crack initiation has been added to validate the  $J_{Ic}(t)$  measurement. A round robin used to evaluate the overall test procedures of this method is reported in (21).

A14.10.2 Bias—There is no accepted “standard” value for measures of elastic-plastic fracture toughness of any material. In absence of such a true value, any statement concerning bias is not meaningful.

## A15. NORMALIZATION DATA REDUCTION TECHNIQUE

### A15.1 Scope

A15.1.1 The normalization technique can be used in some cases to obtain a  $J$ - $R$  curve directly from a force displacement record taken together with initial and final crack size measurements taken from the specimen fracture surface. Additional restrictions are applied (see A15.3) which limit the applicabil-

ity of this method. The normalization technique is described more fully in Herrera and Landes (22) and Landes, et al. (23), Lee (24), and Joyce (21). The normalization technique is most valuable for cases where high loading rates are used, or where high temperatures or aggressive environments are being used. In these, and other situations, unloading compliance methods

are impractical. The normalization method can be used for statically loaded specimens if the requirements of this section are met. The normalization method is not applicable for low toughness materials tested in large specimen sizes where large amounts of crack extension can occur without measurable plastic force line displacement.

**A15.2 Analysis**

A15.2.1 The starting point for this analysis is a force versus load point displacement record like that shown in Fig. A15.1. Also required are initial and final physical crack sizes optically measured from the fracture surface. This procedure is applicable only to Test Method E1820 standard specimen geometries with  $0.45 \leq a_o/W \leq 0.70$  and cannot be used if the final physical crack extension exceeds the lesser of 4 mm or 15 % of the initial uncracked ligament.

A15.2.2 Each force value  $P_i$  up to, but not including the maximum force  $P_{max}$ , is normalized using:

$$P_{Ni} = \frac{P_i}{WB \left( \frac{W - a_{bi}}{W} \right)^{n_m}} \tag{A15.1}$$

where  $a_{bi}$  is the blunting corrected crack size at the  $i$ th data point given by:

$$a_{bi} = a_o + \frac{J_i}{2 \sigma_Y} \tag{A15.2}$$

with  $J_i$  calculated from:

$$J_i = \frac{K_i^2 (1 - \nu^2)}{E} + J_{pli} \tag{A15.3}$$

where  $K_i$  and  $J_{pli}$  are calculated as in Annex A1 and Annex A2 for each specimen type using the crack size  $a_o$ .

A15.2.3 Each corresponding load-line displacement is normalized to give a normalized plastic displacement:

$$v'_{pli} = \frac{v_{pli}}{W} = \frac{v_i - P_i C_i}{W} \tag{A15.4}$$

where  $C_i$  is the specimen elastic load-line compliance based on the crack size  $a_{bi}$ , which can be calculated for each specimen type using the equations of Annex A1 and Annex A2.

A15.2.4 The final measured crack size shall correspond to a crack extension of not more than 4 mm or 15 % of the initial uncracked ligament, whichever is less. If this crack extension is exceeded, this specimen cannot be analyzed according to this annex.

A15.2.5 The final force displacement pair shall be normalized using the same equations as above except that the final measured crack size,  $a_f$ , is used. Typical normalized data are shown in Fig. A15.2.

A15.2.6 A line should be drawn from the final force displacement pair tangent to the remaining data as shown in Fig. A15.2. Data to the right of this tangent point shall be excluded from the normalization function fit. Data with  $v_{pli}/W \leq 0.001$  shall also be excluded from the normalization function fit.

FIG. A15.1 Typical Force versus Displacement Curve

FIG. A15.2 Normalized Force versus Displacement Curve Showing Points up to Maximum Force and the Final Data Point

FIG. A15.3 The Normalization Function Shown Fitted to the Normalization Data

A15.2.7 If at least ten data pairs conform with A15.2.6, the data of Fig. A15.2 can be fit with the following required analytical normalization function:

$$P_N = \frac{a + b v'_{pl} + c v'_{pl}{}^2}{d + v'_{pl}} \quad (A15.5)$$

where  $a$ ,  $b$ ,  $c$ , and  $d$  are fitting coefficients. This function can be fitted to the data of Fig. A15.1 using standard curve fitting packages available as part of computer spreadsheet programs or separately. An example fit for the data of Fig. A15.2 is shown in Fig. A15.3. The normalization function shall fit all the data pairs described above (including the final pair) with a maximum deviation less than 1 % of the  $P_N$  at the final point. Data should be evenly spaced between  $v_{pl}/W = 0.001$  and the tangency point. If less than ten data pairs are available for this fit, including the final measured data pair, this method cannot be used.

A15.2.8 An iterative procedure is now used to force  $P_{Ni}$ ,  $v_{pli}/W$ ,  $a_i$  data to lie on Equation A15.5. This involves adjusting the crack size of each data set to get the normalized force and displacement pair defined in A15.2.2 and A15.2.3 to fall on the function defined in Equation A15.5. To do so, start at the first data point with  $v_{pl}/W \geq 0.002$ , normalize the force and displacement using the initial measured crack size  $a_o$ , and compare the normalized force with the result of the normalization function of A15.2.7. Adjust the crack size until the

measured  $P_{Ni}$  and the functional value of  $P_N$  are within  $\pm 0.1$  %. Each subsequent data set is treated similarly. If each step is started with the crack size resulting from the previous data set, only small, positive adjustments of crack size are necessary, and the process of obtaining the crack sizes corresponding to each data set is relatively rapid.

A15.2.8.1 The data of Fig. A15.1, normalized and adjusted to fit the normalization function of Fig. A15.3, is shown in Fig. A15.4.

A15.2.9 Since force, load-line displacement, and crack size estimates are now available at each data point, the standard equations of Annex A1 and Annex A2 are used to evaluate the  $J$  integral at each data point, resulting in a  $J$ - $R$  curve as shown in Fig. A15.5. A  $J_{Ic}$  value can now be evaluated from this  $J$ - $R$  curve using the method of Section Annex A9.

### A15.3 Additional Requirements

A15.3.1 Requirements presented in 9.1, Annex A8, and Annex A9 shall be met to qualify a  $J$ - $R$  curve or a  $J_{Ic}$  value obtained by the normalization method. Additional requirements specific to the use of the normalization method are presented below.

A15.3.2 If the normalization method is used to obtain  $J_{Ic}$ , at least one additional, confirmatory specimen shall be tested at the same test rate and under the same test conditions. From the

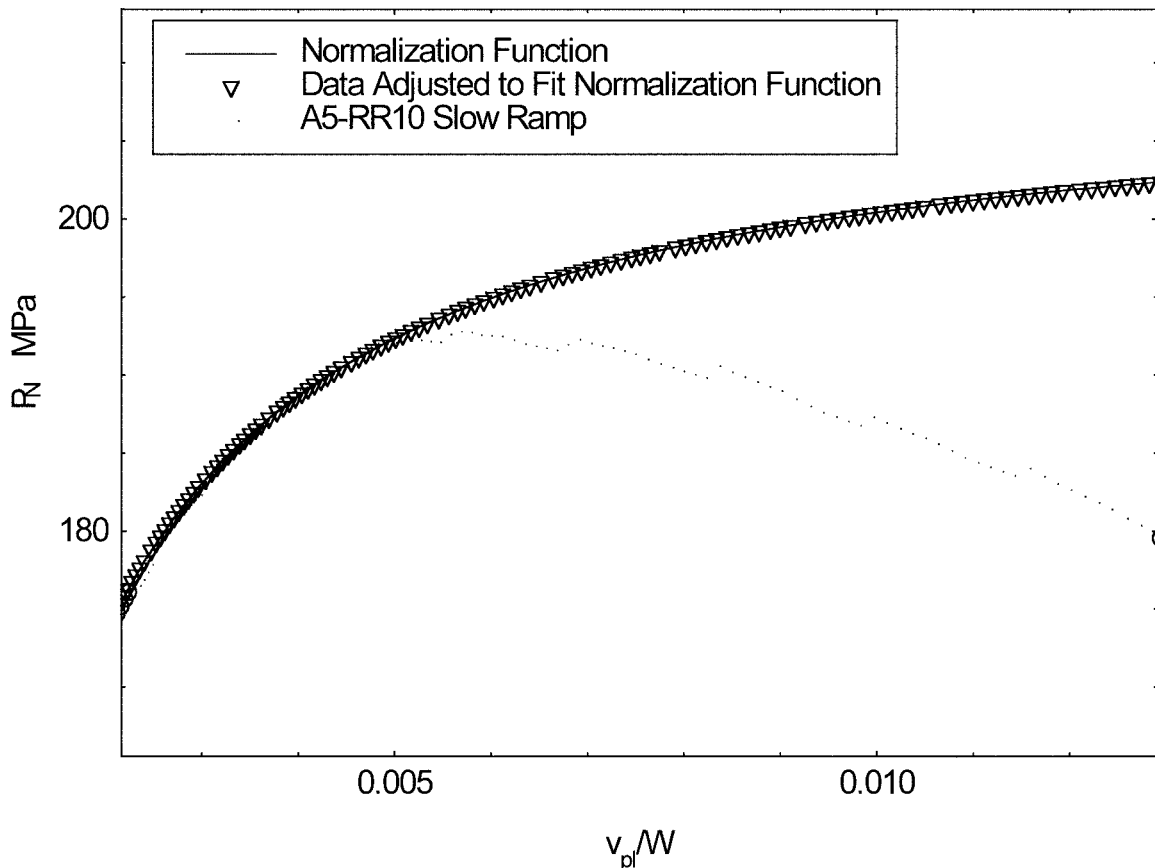

FIG. A15.4 Data is Adjusted, Defining the Crack Size Necessary to Place All Points on the Analytical Normalization Function (Only a portion of the data is shown for clarity)

FIG. A15.5 The Resulting  $J$ - $R$  Curve for this Specimen

normalization method the load-line displacement corresponding to a ductile crack extension of 0.5 mm shall be estimated. The additional specimen shall then be loaded to this load-line displacement level, marked, broken open and the ductile crack growth measured. The measured crack extension shall be  $0.5 \pm 0.25$  mm in order for these results, and hence the  $J_{Ic}$  value, to be qualified according to this method.

#### A15.4 Report

A15.4.1 Section 10 describes the reporting requirements for this method. If the normalization method is used, the following additional items shall be reported.

A15.4.2 If the normalization function is used the coefficients of the fit shall be reported as well as the maximum deviation of the fit and the number of data used.

A15.4.3 If  $J_{Ic}$  is reported, the accuracy of the confirmatory specimen of A15.3.2 shall be reported.

#### A15.5 Precision and Bias

A15.5.1 *Precision*—The precision of the  $J$  resistance curve is a function of material variability, the precision of the various measurements of linear dimensions of the specimen and testing fixtures, precision of the displacement measurement, precision of the force measurement, as well as the precision of the recording devices used to produce the force displacement record used to calculate  $J$  and crack size. For the test rates

allowed by this annex, if the procedures outlined in this annex are followed, the crack size throughout the fracture toughness test can be measured with a precision comparable with that of the unloading compliance procedure described in the main body. A round robin describing the use of the normalization procedure on rapidly loaded SE(B) and C(T) specimens is presented in (21). A requirement for the testing of a confirmatory specimen tested near the point of stable crack initiation is present to validate the  $J_{Ic}$  measurement.

A15.5.2 *Bias*—Crack sizes generally vary through the thickness of fracture toughness specimens. A nine point average procedure based on optical measurements obtained from the post-test fracture surface is generally used to give a reportable crack size. Different measurements would be obtained using more or less measurement points. Alternative crack sizes can be estimated using compliance methods, which obtain different average crack size estimates for irregular crack front shapes. Stringent crack front straightness requirements are present in this standard to minimize differences caused by these effects. The normalization method acts to interpolate between optically measured crack average lengths measured at the start and end of the stable resistance curve fracture toughness test. This method has been demonstrated in (21) to give results consistent with those obtained by unloading compliance procedures.

**A16. EVALUATION OF CRACK GROWTH CORRECTED J-INTEGRAL VALUES**

**A16.1 J Correction Procedure:**

A16.1.1 Evaluate  $J_{eI0}$  and  $J_{pI0}$  values for each specimen using the basic method equations of Annex A1-Annex A3 for the specimen type.

A16.1.2 Obtain initial crack growth corrected  $J$  values using the following relationship (27):

$$J = J_{eI0} + \frac{J_{pI0}}{1 + \left(\frac{\alpha - 0.5}{\alpha + 0.5}\right) \frac{\Delta a}{b_o}} \quad (A16.1)$$

with  $\alpha = 1$  for SE(B) specimens and  $\alpha = 0.9$  for C(T) and DC(T) specimens.

A16.1.3 Fit a power law expression  $J = J_{I_{mm}}\Delta a^m$  to the corrected  $J$  ( $\Delta a$ ) data for crack growths exceeding  $\Delta a/b_o \geq 0.05$ .

A16.1.4 Calculate the final crack growth corrected  $J$  ( $\Delta a$ ) data using:

$$J = J_{eI0} + \frac{J_{pI0}}{1 + \left(\frac{\alpha - m}{\alpha + m}\right) \frac{\Delta a}{b_o}} \quad (A16.2)$$

**A17. FRACTURE TOUGHNESS TESTS AT IMPACT LOADING RATES USING PRECRACKED CHARPY-TYPE SPECIMENS**

**A17.1 Scope**

A17.1.1 This Annex specifies requirements for performing and evaluating instrumented impact tests on precracked Charpy-type specimens using a fracture mechanics approach. Minimum requirements are given for measurement and recording equipment such that similar sensitivity and comparable measurements are achieved. Dynamic fracture mechanics properties determined are comparable to conventional large-scale fracture mechanics results when the validity criteria of Annex A8-Annex A11 and Annex A14 are met. However, because of the small absolute size of the Charpy specimen, this is often not the case. Nevertheless, the values obtained can be used in research and development of materials, in quality control and service evaluation and to establish the relative variation of properties with test temperature and loading rate measured on precracked Charpy-type specimens.

**A17.2 Principle**

A17.2.1 This Annex prescribes impact bend tests which are performed on fatigue precracked Charpy-type specimens to obtain dynamic fracture mechanics properties of materials. This Annex extends the procedure for V-notch impact bend tests in accordance with Test Methods E23, and may be used for evaluation of the Master Curve in accordance with Test Method E1921. Instrumented testing machines are required in order to utilize this Annex, together with ancillary instrumentation and recording equipment in accordance with Test Method E2298. The characteristic fracture toughness parameters depend on material response reflected in the force/time diagrams described in Table A17.1 and Fig. A17.1. Note that

only Type I diagrams can be linearly fit up to fracture.

NOTE A17.1—The symbol used in these Test Methods for force is  $P$ , while Test Method E2298 uses  $F$ . Therefore the parameters  $P_{max}$ ,  $P_{bf}$ ,  $P_{gy}$  used in the following sections correspond to the E2298 parameters  $F_m$ ,  $F_{bf}$ ,  $F_{gy}$ .

**A17.3 Specimen Size, Configuration, and Preparation**

A17.3.1 Specimens shall be prepared in accordance with the dimensions of the type A Charpy impact specimens of Test Methods E23, with or without the 2.0 mm V-notch, followed by fatigue precracking.

A17.3.2 Fatigue precracking shall be conducted in accordance with 7.4.

A17.3.3 Specimens are fatigue precracked to produce an initial crack size  $a_o$  in the range  $0.45 < a_o/W < 0.70$ .

A17.3.4 Side-grooving of the specimens in accordance with 7.5 is recommended.

**A17.4 Apparatus**

A17.4.1 The preferred testing apparatus is the instrumented Charpy pendulum impact testing machine according to Test Method E2298, modified to have a variable pendulum release position.

A17.4.2 Other pendulum machines may be used, with either fixed anvil/moving striker or fixed striker/moving anvil, and fixed or moving test specimen. The pendulum release position for such machines is normally variable, and the striker or anvils are normally instrumented to provide force/time or force/displacement records.

**TABLE A17.1 Fracture Toughness Properties to be Determined**

Material response/fracture behavior	Corresponding diagram type (See Fig. A17.1)	J-R curve	Characteristic Parameters
Linear-elastic	I	...	$J_{cd,x}$ , $K_{Jcd,x}$
Elastic-plastic, unstable fracture with $\Delta a < 0.2$ mm	II	...	$J_{cd,x}(B)$
Elastic-plastic, unstable fracture with $0.2$ mm $\leq \Delta a \leq 0.15$ ( $W-a_o$ )	II	...	$J_{ud,x}(B, \Delta a)$
Elastic-plastic, unstable fracture with $\Delta a \geq 0.15$ ( $W-a_o$ )	III	$J_d - \Delta a$	$J_{Qd,x}$ or $J_{Icd,x}$
Elastic plastic; no unstable fracture	IV	$J_d - \Delta a$	$J_{Qd,x}$ or $J_{Icd,x}$

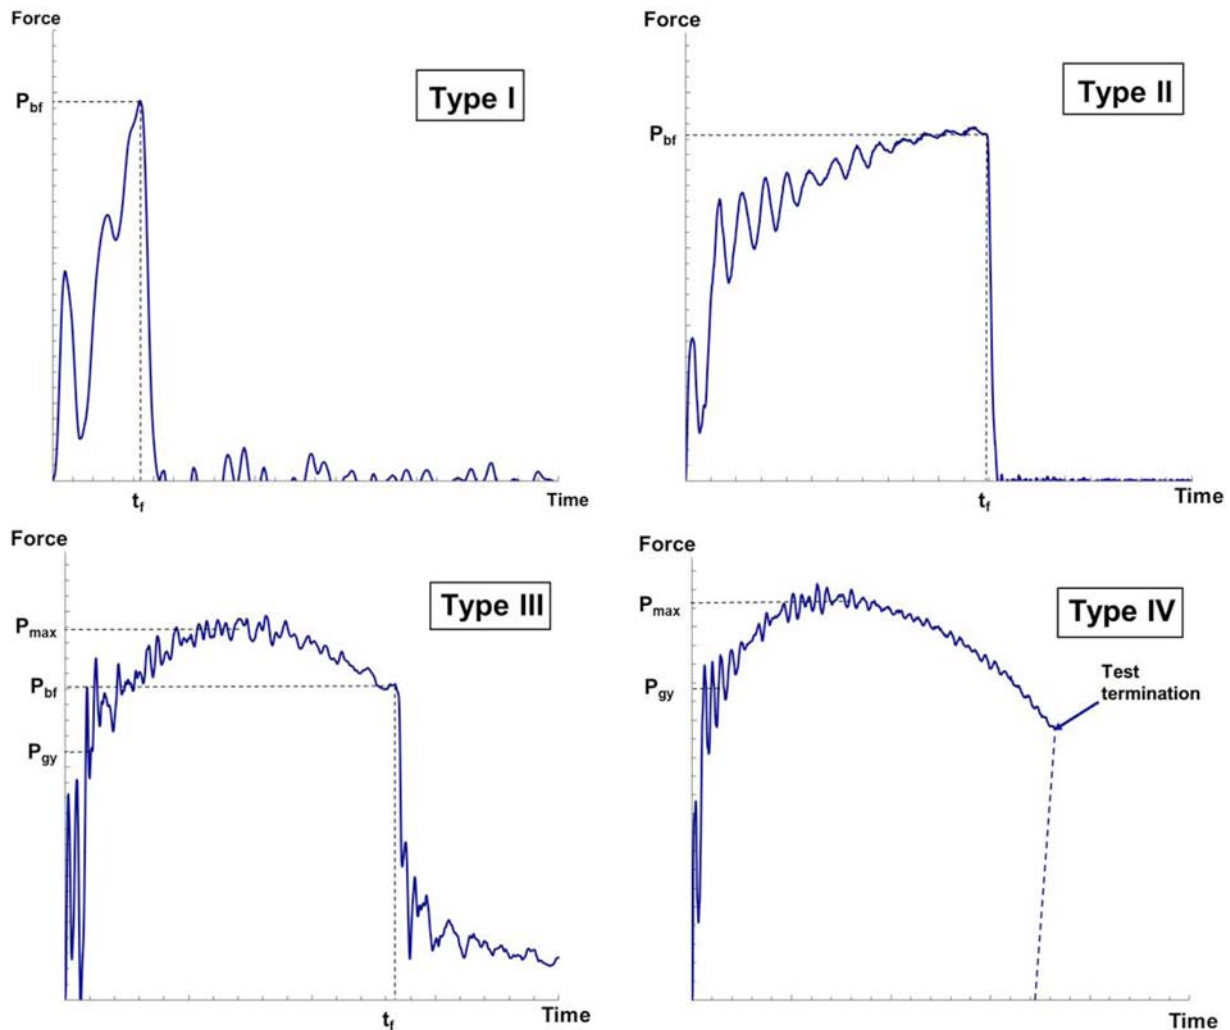

FIG. A17.1 Typical Force-time Diagrams (Schematic)

A17.4.3 Falling weight testing machines, which may be spring assisted, are allowed. The striker is normally instrumented to provide force/time or force/time and force/displacement records.

A17.4.4 Other testing machines which comply with the calibration and other requirements of Test Method E2298 are not excluded.

A17.4.5 *Requirements on Absorbed Energy*—The reliability of instrumented force values on which these tests are based depends on the quality of the acquisition system and the calibration of the instrumented striker. The calibration of the striker shall be performed in accordance with Test Method E2298. Additionally, for each test in which the entire force signal has been recorded (that is, until the force returns to the baseline), one of the following requirements shall be met:

(a) the difference between  $KV$  and  $W_t$  shall be within  $\pm 15\%$  of  $KV$  or  $\pm 1$  J, whichever is larger, or

(b) the difference between  $KV$  and  $W_t$  shall not exceed  $\pm 25\%$  or  $\pm 2$  J, whichever is larger.

For every test that fulfills requirement (b), but not (a), force values may be adjusted using an iterative procedure until the equivalence  $KV = W_t$  is achieved (28). If the difference between

$KV$  and  $W_t$  exceeds  $\pm 25\%$  of  $KV$  or  $\pm 2$  J, whichever is larger, the test shall be discarded and the user shall check and if necessary repeat the instrumented striker calibration. If recording of the entire force signal for an individual test is not achieved (for example due to the specimen being ejected from the machine without being fully broken), the user shall demonstrate conformance of the testing system using at least five specimens of the same test series, for which the entire force signal has been recorded, that fulfil one of the above requirements. Otherwise, conformance shall be demonstrated by testing at least five additional non-precracked or precracked Charpy specimens, and showing that in all cases the difference between  $KV$  and  $W_t$  is within  $\pm 15\%$  of  $KV$  or  $\pm 1$  J, whichever is larger. If this requirement is not met but the difference between  $KV$  and  $W_t$  does not exceed  $\pm 25\%$  of  $KV$  or  $\pm 2$  J, the force adjustment described above shall be applied.

NOTE A17.2—From a theoretical point of view,  $KV$  is expected to be slightly higher than  $W_t$ , the difference being due to vibrational energy losses and other smaller contributions such as secondary impacts between striker and specimen. For more insight on the difference between  $KV$  and  $W_t$ , see reference (29).

## A17.5 Test Procedures and Measurements

A17.5.1 Tests are performed in a manner similar to the standard Charpy impact test of Test Methods E23 and the instrumented impact test of Test Method E2298, especially with regard to the pendulum hammer and the handling of pre-cooled or pre-heated specimens.

A17.5.2 *Data recording*—The force/displacement diagram is recorded according to Test Method E2298, from which the key data values  $P_{max}$ ,  $P_{bf}$ ,  $W_m$ , and  $W_t$  are determined. In addition to the procedures of Test Method E2298, the following procedures are provided concerning impact velocity, available energy and time to fracture. These data form the basis for evaluation of toughness parameters according to A17.6-A17.9.

A17.5.2.1 *Impact velocity and available energy*—This standard applies to any impact velocity  $v_o$ , provided the time to fracture fulfills the requirements of A17.5.2.2. Impact velocities for pendulum or falling weight testing machines can be varied by adjusting the striker release height. The impact velocity  $v_o$  for a pendulum machine can be determined as follows: set the pointer to the end-of-scale position as in a conventional Charpy test per Test Methods E23, release the pendulum from the appropriately reduced height, with no specimen in place. Read the energy  $KV_o$  (in J) indicated by the pointer on the analogue scale. From this, the corresponding impact velocity is calculated as:

$$v_o = v_{os} \sqrt{\frac{MC - KV_o}{MC}} \quad (\text{A17.1})$$

where  $v_{os}$  is the maximum pendulum velocity corresponding to  $MC$ , the full pendulum capacity. A reduced velocity (1 to 2 m/s) can be advantageous, especially for brittle materials, since it reduces the effect of oscillations by lowering their relative amplitude and by increasing their number within the fracture time  $t_f$  (see A17.5.2.2).

A17.5.2.2 *Time to fracture*—When the time  $t_f$  to initiate unstable fracture is less than the minimum test time  $t_w$  of A14.3.1.4, the instant of crack initiation is not detectable in the force signal with adequate accuracy because of oscillations (see Fig. A17.1 - Type I), and fracture toughness cannot be evaluated using this test method.

A17.5.3 *Recording Apparatus*—Refer to Section 7 of Test Method E2298.

A17.5.4 *Execution of the Test*—Refer to Section 9 of Test Method E2298.

A17.5.5 *Evaluation of the Force-Displacement Curve*—Refer to Section 11 of Test Method E2298.

A17.5.6 *Calculation of fracture parameters*—The value of J-integral at unstable fracture,  $J_{cd}$  (force-time diagrams Type I and II in Fig. A17.1) or  $J_{ud}$  (force-time diagram of Type III in Fig. A17.1), or at test termination,  $J_d$  (force-time diagram of Type IV in Fig. A17.1) shall be calculated using the appropriate formulas Eq A1.4-A1.6 for the Basic Test Method. In particular, the specimen elastic compliance  $C_o$  is required to evaluate the plastic component of the area under the force-displacement curve (Fig. A1.2). This can be obtained using the following theoretical expression:

$$C_{o,th} = C_s + C_M \quad (\text{A17.2})$$

where  $C_s$  is the specimen compliance calculated using Eq A1.10 and  $C_M$  is the impact machine compliance. This latter can be measured with unnotched specimens using one of the methods described in (30). Alternatively, if  $C_M$  is not available,  $C_o$  can be estimated as the reciprocal of the initial elastic slope ( $C_{o,exp}$ ), by fitting force-displacement data between the second oscillation (that is, discarding the first inertia peak) and the onset of general yielding. If both  $C_{o,exp}$  and  $C_{o,th}$  are available,  $C_{o,th}$  shall be used and the difference between the two values shall be within  $\pm 15\%$ . Values of stress intensity factor shall be obtained from the corresponding J-integral values using:

$$K_{Jd} = \sqrt{\frac{EJ_d}{1-\nu^2}} \quad (\text{A17.3})$$

Calculated  $K_{Jd}$  values at the onset of cleavage fracture,  $K_{Jcd}$ , can be used to calculate the reference temperature,  $T_o$ , in accordance with Test Method E1921, provided all relevant requirements are met.

A17.5.7 *Crack Size Measurements*—Original crack size and final physical crack size shall be measured in accordance with 8.5.

A17.5.8 *Multiple Specimen Tests*—To determine dynamic J-R curves by multi-specimen techniques, the fracture process is interrupted over a range of stable crack extension values, that are combined to obtain a single J-R curve. This procedure is described in A17.7.

A17.5.9 *Single Specimen Tests*—It is also possible to estimate dynamic J-R curves from an individual specimen using the Normalization Data Reduction technique, as described in A17.8.

## A17.6 Analysis of Results

A17.6.1 *Fracture Behavior*—The adequacy of fracture toughness parameters depends on the fracture behavior of the test specimen as reflected in the force-displacement diagrams described in Table A17.1. Therefore the measured force displacement or force-time diagram shall be assigned to one of the diagram types shown in Fig. A17.1, using the indications provided in Table A17.1.

A17.6.2 *Unstable Fracture*—In the case of unstable fracture as in Fig. A17.1 - Types I or II, the applicable evaluation method depends on the oscillations superimposed on the force signal. If time to fracture is more than the minimum test time of A14.3.1.4, fracture toughness shall be evaluated according to the quasi-static approach of Annex A6 and Annex A7. Impact velocity may be reduced in order for the time to fracture to fulfil the requirements of A14.3.1.4 and A17.5.2.

A17.6.3 *Stable Crack Extension*—In the case of stable crack extension as in Fig. A17.1 - Types III or IV, either multi specimen or single-specimen techniques described in A17.7 and A17.8, respectively, are to be used to determine the J R curve. The determination of characteristic fracture toughness values from dynamic J-R curves is described in A17.9.

A17.6.4 *Loading Rate*—As indicated in Table A17.1, fracture toughness values shall be stated with the corresponding loading rate added in parentheses. The latter may be estimated as follows:

Type I:

$$\dot{K} = \frac{K_{Jcd}}{t_f} \quad (\text{A17.4})$$

Types I and II:

$$\dot{J} = \frac{J_{cd}}{t_f} \quad (\text{A17.5})$$

or

$$\dot{J} = \frac{J_{ud}}{t_f}$$

Types III and IV:

$$\dot{J} = \frac{P_{max} \cdot v_o}{B_N \cdot (W - a_o)} \cdot \eta_{pl} \left( \frac{a_o}{W} \right) \quad (\text{A17.6})$$

In alternative to Eq A17.6, the procedures given in A14.7.3 and A14.7.3.1 can also be used for calculating  $(dJ/dt)_I$  and  $(dJ/dt)_T$  respectively. For practical purposes, the loading rate shall be indicated using its order of magnitude (for example, the stress intensity factor corresponding to a loading rate of  $4 \times 10^5$  MPa $\sqrt{\text{m/s}}$  shall be indicated as  $K_{Jcd5}$ ).

**A17.6.5 Dynamic Tensile Properties**—The dynamic yield and ultimate tensile stresses at the relevant strain rate may be required for certain evaluation procedures and validity checks. An approximate equivalent strain rate for the fracture mechanics test, which can be used for dynamic tensile testing, may be calculated from (31, 32):

$$\dot{\epsilon} = 2 \frac{\sigma_{YS}}{\bar{t} \cdot E} \quad (\text{A17.7})$$

where:  $\sigma_{YS}$  and  $E$  are values corresponding to quasistatic strain rates (that is, conforming to the requirements of Test Methods E8/E8M) and evaluated at the temperature of the fracture mechanics test;  $\bar{t}$  is the time to fracture in the case of small scale yielding (type I in Fig. A17.1), or the time interval of the initial linear part of the force-time record in the case of distinct elastic-plastic material behavior (types II-IV in Fig. A17.1). Eq A17.7 provides a general estimate of strain rate values associated with fracture in the test specimen.

### A17.7 Determination of J-R curves at Impact Loading Rates by Multiple Specimen Methods

**A17.7.1** The following methods make it possible to determine fracture toughness parameters in those cases where stable crack extension occurs, Fig. A17.1 – Types III and IV. The multi-specimen procedure involves loading a series of nominally identical specimens to selected displacement levels, resulting in corresponding amounts of stable crack extension. Each specimen tested provides one point on the resistance curve. The requirements and procedures of Annex A8-Annex A11 concerning number and spacing of data points shall be fulfilled.

**A17.7.2 Low-blow Test**—This test procedure is intended to limit the impact energy  $W_o$  of the pendulum hammer or drop weight so that it is sufficient to produce a certain stable crack extension, but not sufficient to fully break the specimen. By selecting different energy levels in a series of tests on nominally identical specimens, a series of different crack extensions  $\Delta a_i$  are produced. From the corresponding  $J$ -values,  $J$ - $\Delta a$  curves are constructed.

NOTE A17.3—An alternative method is the Stop Block approach,

whereby the hammer swing is arrested by using stop blocks, thus avoiding complete fracture of the specimen.

**A17.7.2.1** The following procedure is recommended:

(1) Prepare 7 – 10 specimens to nominally the same initial crack length  $a_o$ .

(2) Perform a full blow instrumented impact bending test on one of the specimens. Evaluate the energy at maximum force and the total fracture energy,  $W_m$  and  $W_f$ , in accordance with Test Method E2298.

(3) Determine the energy spacing as  $\Delta W_o = 2W_m/N$ , where  $N$  is the number of available specimens.

(4) Perform an impact test by setting the release position of the pendulum hammer, or the height of the drop weight, such that  $W_o = 2W_m/N$ . Avoid a second impact between the striker and the test specimen.

(5) Repeat the test on the remaining specimens, increasing the impact energy  $W_o$  by the amount  $\Delta W_o = 2W_m/N$  at each test.

(6) In order to mark the crack extension, post-test fatigue cycling or heat tinting may be used.

(7) Break all specimens open after testing. Care is to be taken to minimize post-test specimen deformation. Cooling ferritic steels may help to ensure brittle behavior during specimen opening.

(8) Measure  $a_o$  and  $\Delta a_p = \Delta a_i$  (where “ $i$ ” is the test index, with  $1 \leq i \leq N-1$ ) in accordance with 8.5.

(9) Calculate  $J_i$  according to A1.4.2.1.

(10) Plot the resulting  $N-1$  pairs of values ( $J_i, \Delta a_i$ ) in a  $J$ - $\Delta a$  diagram and determine the  $J$ -R curve according to Annex A8 and  $J_{Qd,X}$  (a provisional value of  $J_{Icd,X}$ ) according to Annex A9.

**A17.7.2.2** The differences in impact velocity and loading rate between the various tests are small enough to have a negligible influence on the results and can be ignored, provided velocity and loading rate do not vary by more than a factor 3 between the minimum and maximum values.

**A17.7.3 Cleavage J-R curve Method**—This test method can only be used for steels that exhibit a brittle-ductile transition. The test temperature is varied within the ductile-to-brittle transition zone so that stable crack extensions of varying lengths  $\Delta a_p$  are obtained from tests terminated by cleavage fracture.  $J_{ud}$  values calculated according to A1.4.2 and the corresponding  $\Delta a_p$  represent points on the cleavage  $J$ - $\Delta a$  curve which can be analyzed in accordance with Annex A8 and Annex A9. Differences between the temperatures of the various resistance points can be neglected, provided they don’t exceed 50 °C. The requirements of Annex A8 and Annex A9 shall be satisfied in order to obtain a valid  $J$ -R curve. Details of this method are given in (33).

**A17.7.4** The user is warned that results obtained using the Low-blow or Stop Block methods, in which the loading rate is progressively reduced down to zero, may differ from results obtained using tests leading to specimen fracture, such as the Cleavage  $J$ -R curve method.

### A17.8 J-R Curve Determination by Single Specimen Methods

**A17.8.1** The Normalization Data Reduction (NDR) technique can be applied to a Low-blow test performed in accordance with A17.7.1, provided the measured crack extension does not exceed 15 % of the initial uncracked ligament.

The provisions of **Annex A15** apply, including the additional requirements of **A15.3**. A study published in **(34)** shows that for two steels and two test temperatures, NDR single-specimen results are in good agreement with multiple specimen data generated using the Low-blow technique.

### A17.9 Determination of Fracture Toughness Near the Onset of Stable Crack Extension

A17.9.1 From J-R curves determined according to **A17.7** or **A17.8**, fracture toughness values near the onset of stable crack extension can be determined in conformance to **Annex A9**. Specimen qualification as per **Annex A9** requirements will be difficult to achieve if the specimen undergoes significant plasticity during crack extension because of the relatively small size of the specimen. In this case, values of  $J_{Qd}$  cannot be regarded as material properties independent of specimen size and their use in safety assessments may result in non conservative results. Nevertheless, these values can be used for research and development of materials, in quality control and service evaluation and to establish the variation of properties with test temperature.

A17.9.2 The construction line for  $J_Q$  calculation shall have the following expression, see also Eq A9.4:

$$J = 2\sigma_{Fsd}\Delta a \quad (\text{A17.8})$$

where  $\sigma_{Fsd}$ , the dynamic flow strength, is the average of the dynamic yield strength and the dynamic ultimate tensile strength:

$$\sigma_{Fsd} = \frac{\sigma_{Ysd} + \sigma_{Tsd}}{2} \quad (\text{A17.9})$$

$\sigma_{Ysd}$  and  $\sigma_{Tsd}$  shall preferably be obtained from dynamic tensile tests, provided that it can be demonstrated that the corresponding strain rate is equivalent to that of the fracture toughness tests (see **A17.6.5**). Alternatively, estimated values can be obtained from the force/displacement test record of the impact test as **(35)**:

$$\sigma_{Ysd} = \frac{2.732P_{gy}W}{(W-a_0)^2B_N} \quad (\text{A17.10})$$

and

$$\sigma_{Tsd} = \frac{2.732P_{max}W}{(W-a_0)^2B_N} \quad (\text{A17.11})$$

NOTE A17.4—For plane-sided specimens,  $B_N = B$ .

### A17.10 Report

A17.10.1 In addition to the information listed in Section 10 of the main body, the test report shall include the following.

A17.10.2 Identification and type of testing apparatus.

A17.10.3 Striker impact velocity  $v_o$  (**A17.5.3**).

A17.10.4 Nominal energy of the striker at velocity  $v_o$ .

A17.10.5 Absorbed energy  $KV$  according to Test Method **E2298**.

A17.10.6 Calibration of the instrumented striker.

A17.10.7 Details of force adjustment in accordance with **A17.4.5**, if applicable.

A17.10.8 Specimen elastic compliance (theoretical or experimental, or both) and, if available, machine compliance.

A17.10.9 Time to fracture or time at test termination, as appropriate.

A17.10.10 Fracture parameters determined as:

(1) value of  $K_{Jcd}$  obtained, if applicable,

(2) value of  $\dot{K}$  obtained, if applicable (only order of magnitude),

(3) value of  $J$  obtained, if applicable,

(4) value of  $\dot{J}$  obtained, if applicable (only order of magnitude),

(5) type of force-time diagram, with reference to **Fig. A17.1**, Types I – IV,

(6) for diagrams of Types III or IV, final crack extension, and

(7) a copy of the test record.

A17.10.11 In case of J-R curve determination, values of  $J$  and  $\Delta a$  in tabular form and values of  $J_{Qd,X}$  or  $J_{Icd,X}$  obtained.

A17.10.12 Dynamic tensile properties used, if applicable.

## APPENDIXES

### (Nonmandatory Information)

#### X1. FITTING OF EQUATION A9.1

X1.1 To fit Eq A9.1 to the  $J_i$ ,  $a_i$  data using the method of least squares, the following equation must be set up and solved for  $a_{oq}$ ,  $B$ , and  $C$ :

$$\begin{Bmatrix} \sum a_i - \frac{\sum J_i}{2\sigma_Y} \\ \sum a_i J_i^2 - \frac{\sum J_i^3}{2\sigma_Y} \\ \sum a_i J_i^3 - \frac{\sum J_i^4}{2\sigma_Y} \end{Bmatrix} = \begin{bmatrix} n \sum J_i^2 & \sum J_i^3 \\ \sum J_i^2 & \sum J_i^4 & \sum J_i^5 \\ \sum J_i^3 & \sum J_i^5 & \sum J_i^6 \end{bmatrix} \begin{Bmatrix} a_{oq} \\ B \\ C \end{Bmatrix} \quad (\text{X1})$$

X1.2 This equation can be set up and solved using a standard spreadsheet or using a mathematical analysis program like MathCad, Maple, or Mathematica.

## X2. GUIDELINES FOR MEASURING THE FRACTURE TOUGHNESS OF MATERIALS WITH SHALLOW CRACKS

### X2.1 Significance and Use

X2.1.1 Fracture toughness measurements may be made using specimens with relatively shallow cracks,  $0.05 < a/W < 0.45$ , which are not permitted by the standard test method. The resulting measures of fracture toughness, designated  $J_{xSC0}$  and  $\delta_{xSC0}$ , will be dependent upon the size of the specimen and the crack length. The fracture toughness determined from specimens with shallow cracks is usually non-conservative when compared to the fracture toughness determined from standard, deep crack specimen geometries and may exhibit considerably more scatter, particularly in the ductile to brittle transition region for ferritic materials. The J resistance curves determined according to this appendix are not corrected for crack growth and will be non-conservative relative to crack growth corrected resistance curves.

X2.1.2 This appendix is provided to give recommended procedures for conducting fracture toughness tests of specimens containing shallow cracks. Special requirements for the instrumentation, specimen, testing procedure and data analysis are described.

X2.1.3 Particular care must be exercised when using these non-standard measures of fracture toughness for structural integrity assessments. The user is cautioned that differences may exist between laboratory test and field conditions and that the fracture toughness of a shallow crack specimen may be strongly influenced by the size of the crack and the specimen geometry.

### X2.2 Terminology

X2.2.1 All of the following parameters describe various measures of fracture toughness determined using specimens containing shallow cracks. These parameters are similar to the corresponding parameters for standard specimens except that they include the subscript  $SC(a_0/W)$  to indicate a shallow crack specimen. The number in the parentheses is the original crack size to specimen width ratio for the shallow crack specimen.

X2.2.1.1  $\delta_{icSC0}[L]$ — is a value of CTOD near the onset of slow stable crack extension in a specimen with a shallow crack, here defined as occurring at  $\Delta a_p = 0.2 \text{ mm (0.008 in.)} + 0.7\delta_{ic}$ .

X2.2.1.2  $\delta_{SC0}[L]$ —is the value of CTOD at the onset of unstable crack extension (see 3.2.39) or pop-in (see 3.2.25) in a specimen with a shallow crack when  $\Delta a_p < 0.2 \text{ mm (0.008 in.)} + 0.7\delta_{cSC0}$ .  $\delta_{cSC0}$  corresponds to the force  $P_c$  and clip-gage displacement  $v_c$  (see Fig. 1).

X2.2.1.3  $\delta_{uSC0}[L]$ —is the value of CTOD at the onset of unstable crack extension (see 3.2.39) or pop-in (see 3.2.25) in a specimen with a shallow crack when the event is preceded by  $\Delta a_p \geq 0.2 \text{ mm (0.008 in.)} + 0.7\delta_{uSC0}$ .  $\delta_{uSC0}$  corresponds to the force  $P_u$  and the clip gage displacement  $v_u$  (see Fig. 1). It may be size dependent and a function of test specimen geometry. It can be useful to define limits on ductile fracture behavior.

X2.2.1.4  $J_{icSC0}[FL^{-1}]$  - The property  $J_{ic}$  determined by this test method characterizes the fracture toughness of materials in a specimen with a shallow crack near the onset of stable tearing

crack extension here defined as occurring at  $\Delta a_p = 0.2 \text{ mm (0.008 in.)} + J_{icSC0}/2\sigma_Y$ .

X2.2.1.5  $J_{cSC0}[FL^{-1}]$ —The property  $J_c$  determined by this test method characterizes the fracture toughness of materials at fracture instability prior to the onset of significant stable tearing crack extension,  $\Delta a_p < 0.2 \text{ mm (0.008 in.)} + J_{cSC0}/2\sigma_Y$ , in a specimen with a shallow crack.

X2.2.1.6  $J_{uSC0}[FL^{-1}]$  The quantity  $J_u$  determined by this test method measures fracture instability after the onset of significant stable tearing crack extension,  $\Delta a_p \geq 0.2 \text{ mm (0.008 in.)} + J_{uSC0}/2\sigma_Y$ , in a specimen with a shallow crack.

### X2.3 Specimen Size and Configuration

X2.3.1 *Recommended Specimen*—The recommended specimen is a single-edge notch, bend specimen SE(B), similar to that shown in Fig. A1.1.

X2.3.1.1 The initial crack size to specimen width shall be  $0.05 \leq a/W \leq 0.45$  and the specimen width to thickness shall be in the range  $1 \leq W/B \leq 4$ .

X2.3.1.2 The narrow notch configuration of Fig. 6 is recommended; however, the notch opening at the front face of the specimen may need to be modified from the dimensions shown in Fig. 7, particularly for specimens with  $a/W < 0.2$ . The notch opening should be made as small as practical to minimize the influence of the machined notch on the elastic compliance of the specimen and the fracture response of the specimen. Notches produced using the wire electrical discharge machining process with a wire diameter less than 0.25 mm (0.010 in.) usually produce satisfactory results.

X2.3.1.3 An alternative method for producing a shallow crack specimen involves machining an SE(B) specimen with an over-sized W dimension. A fatigue crack is extended from the starter notch and then the specimen is remachined to remove the starter notch leaving a specimen with only a fatigue crack. Integral knife edges may subsequently be machined into the specimen.

X2.3.1.4 Integral knife edges or features for the seating of the crack mouth opening displacement gage may be particularly advantageous for specimens containing shallow cracks. Suggested configurations are shown in Fig. X2.1. The square notch configuration along with the ring-type crack mouth opening displacement gage of Fig. X2.2 is well-suited to small specimens and shallow cracks. The integral knife edges shown in Fig. X2.1 may not be suitable for very small cracks, a  $< 2 \text{ mm (0.079 in.)}$ .

### X2.4 Apparatus

X2.4.1 Apparatus is required for the measurement of the applied force and the crack mouth opening displacement. Standard force transducers as described in 6.3 are satisfactory. Load-line displacement measurements are not required for the shallow crack SE(B) specimens.

X2.4.1.1 *Crack Mouth Opening Displacement Gages*—The standard gage described in 6.2.2 may be suitable for measuring the CMOD on specimens which have a notch opening that is large enough to accommodate the arms of the gage. For small

Integral knife edges for standard CMOD gage

Square notch configuration for ring-type CMOD gage

FIG. X2.1 Recommended notch configurations with integral features for mounting crack mouth opening displacement gages. These notch configurations are only recommended for  $a \geq 2\text{mm}$  (0.079 in.)

**25mm Crack Mouth Opening Displacement Ring Gage**

Gage body machined from 7075-T6 Al

**Contact Detail**

Contacts machined from Titanium 6Al-4V

All dimensions are in mm.

FIG. X2.2 Alternative crack opening displacement gage suitable for use with very narrow Notches.

specimens and for specimens with very shallow cracks, an alternative gage design such as the ring gage in Fig. X2.2 is recommended. Alternative means for measuring CMOD may be required for specimens with very shallow cracks, a < 2 mm (0.079 in.).

X2.4.1.2 The bend-test fixture recommended in 6.5.1 is suitable for testing SE(B) specimens with shallow cracks.

## X2.5 Specimen Preparation

X2.5.1 The requirements of Section 7 are generally applicable with the following notable exceptions.

X2.5.1.1 *Crack Starter Notch Configuration*—Only the straight through notch configuration of Fig. 5 is recommended for the shallow crack SE(B) specimen.

X2.5.1.2 *Fatigue crack length*—The crack size, total length of the starter notch plus the fatigue crack, shall be between 0.05W and 0.45W.

X2.5.1.3 *Fatigue Loading Requirements*—In order to promote early fatigue crack initiation it is recommended that the specimen be statically preloaded in such a way that the notch tip is compressed in a direction normal to the intended crack plane (not to exceed a force equal in magnitude to  $2P_i$ ). The fatigue crack shall be grown a minimum of  $1.5\times$  the size of the plastic zone resulting from the compression preload,  $r_p$ , where:

$$r_p = \frac{1}{3\pi} \left( \frac{K}{\sigma_{ys}} \right)^2 \quad (X2.1)$$

with  $K$  evaluated using the expression in A1.4.1 and the maximum compressive force used to preload the notch.

## X2.6 Procedure

X2.6.1 The requirements of Section 8 for the SE(B) specimens are generally applicable for conducting the tests. The resistance curve procedure is recommended. It may be necessary to use unload/reload cycles near the maximum recommended range of either 50 % of  $P_i$  or 50 % of the current force, whichever is smaller, in order to get accurate estimates of the specimen compliance.

X2.6.2 The user is cautioned that specimens with shallow cracks can store greater amounts of elastic energy than the standard deeply cracked specimen. If the specimen fails in an unstable manner, the broken halves of the specimen may be forcefully ejected from the testing machine and suitable restraints should be fashioned.

## X2.7 Calculation

X2.7.1 *Calculation of  $K$* —The stress intensity factor,  $K$ , is calculated using the expression in A1.4.1.

X2.7.2 *Calculation of  $J$* :

X2.7.2.1  *$J$  Calculation for the Basic Method*— $J$  is calculated according to A1.4.2 except that the crack growth correction of Annex A16 shall not be employed because it is not applicable to shallow cracks.

X2.7.2.2  *$J$  Calculations for the Resistance Curve Method*—At a point corresponding to  $v_{(i)}$ ,  $P_{(i)}$  on the force versus crack-mouth opening displacement record, calculate  $J$  as follows:

$$J = \frac{K_{(i)}^2 (1-\nu^2)}{E} + J_{pl} \quad (X2.2)$$

where  $K_{(i)}$  is from A1.4.1 and

$$J_{pl(i)} = J_{pl(i-1)} + \frac{\eta_{CMODpl(i-1)} [A_{CMODpl(i)} - A_{CMODpl(i-1)}]}{B_N b_{(i-1)}} \quad (X2.3)$$

In Eq X2.3, the quantity  $A_{CMODpl(i)} - A_{CMODpl(i-1)}$  is the increment of area under the force versus plastic component of CMOD record between lines of constant displacement at  $i-1$  and  $i$  as shown in Fig. A1.3. The quantity  $A_{CMODpl(i)}$  can be evaluated from the following equation:

$$A_{CMODpl(i)} + A_{CMODpl(i-1)} + \frac{(P_i - P_{i-1})}{2} (v_{pl(i)} - v_{pl(i-1)}) \quad (X2.4)$$

where:

$v_{pl(i)}$  = plastic part of the CMOD =  $v_{(i)} - P_i C_i$  and  
 $C_i$  = slope  $(\Delta v_m / \Delta P)_i$  of the current unload/reload cycle.

In Eq X2.3,  $\eta_{CMOD}$  is a function of crack size and is given by the following expression:

$$\eta_{CMOD(i-1)} = 3.667 - 2.199 \left( \frac{a}{w} \right) + 0.437 \left( \frac{a}{w} \right)^2 \quad (X2.5)$$

X2.7.2.3 For a resistance curve test method using an elastic compliance technique with crack mouth opening displacement measured at the notched edge of a shallow crack specimen with  $0.05 \leq a/W \leq 0.45$ , the crack length is given as follows (36):

$$\frac{a}{W} = 1.01878 - 4.5367u + 9.0101u^2 - 27.333u^3 + 74.4u^4 - 71.489u^5 \quad (X2.6)$$

where:

$$u = \frac{1}{\left[ \frac{B_e W E C_i}{S/4} \right]^{1/2} + 1}$$

$C_i$  =  $(\Delta v_m / \Delta P)$  on an unloading/reloading sequence, and  
 $B_e$  =  $B - (B - B_N)^2 / B$

X2.7.3 *Calculation of CTOD*:

X2.7.3.1 For the shallow crack SE(B) specimen, calculations of CTOD for any point on the force-displacement record are made using A1.4.5 except that  $J$  values shall not be crack growth corrected when using equations Eq A1.14 or Eq A1.16.

## X2.8 Analysis of Results

X2.8.1 The data shall meet the following requirements to be qualified according to this method. If the data do not pass these requirements no fracture toughness measures can be determined according to this method.

X2.8.1.1 All requirements on the test equipment in 6 or as modified in X2.4 shall be met.

X2.8.1.2 All requirements on machining tolerance and pre-cracking in Section 7 or as modified in X2.5 shall be met.

X2.8.1.3 All requirements on fixture alignment, test rate, and temperature stability and accuracy in 8 shall be met.

X2.8.1.4 The crack size requirements in 9.1.4 and 9.1.5 shall be met for shallow crack fracture toughness tests.

X2.8.2 *Fracture Toughness Calculation*—The reported fracture toughness values for shallow crack specimens shall include the subscript SC( $a_0/W$ ) where  $a_0/W$  is replaced by the original crack size to specimen width ratio. When the test terminates with fracture instability, evaluate whether the fracture occurred before significant stable tearing or after significant stable tearing. The beginning of significant stable tearing

is defined in A6.3 and A7.3. For fracture instability, proceed to Annex A6 and Annex A7 to evaluate the toughness values in terms of J or CTOD. For fracture instability occurring after significant stable tearing, proceed to Annex A6 and Annex A7 to evaluate toughness values and then go to Annex A8 and

Annex A10 to develop R-curves. Proceed to Annex A9 and Annex A11 to develop initiation values of toughness.

X2.8.2.1 The maximum crack extension capacity for a specimen in A8.3.2 and A10.3.2 is limited to  $\Delta a_{\max} = 0.1b_0$  for a shallow crack specimen.
