# **pandas: powerful Python data analysis toolkit**

*Release 0.24.1*

**Wes McKinney & PyData Development Team**

**Feb 03, 2019**

## CONTENTS

**Date:** Feb 03, 2019 **Version:** 0.24.1

**Download documentation:** [PDF Version](#) | [Zipped HTML](#)

**Useful links:** [Binary Installers](#) | [Source Repository](#) | [Issues & Ideas](#) | [Q&A Support](#) | [Mailing List](#)

*pandas* is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the [Python](#) programming language.

See the *Package overview* for more detail about what's in the library.

## WHATS NEW IN 0.24.1 (FEBRUARY 3, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See *Plan for dropping Python 2.7* for more.

These are the changes in pandas 0.24.1. See *Release Notes* for a full changelog including other versions of pandas. See *What's New in 0.24.0 (January 25, 2019)* for the 0.24.0 changelog.

### 1.1 API Changes

#### 1.1.1 Changing the `sort` parameter for `Index` set operations

The default `sort` value for `Index.union()` has changed from `True` to `None` (GH24959). The default *behavior*, however, remains the same: the result is sorted, unless

1. `self` and `other` are identical
2. `self` or `other` is empty
3. `self` or `other` contain values that can not be compared (a `RuntimeWarning` is raised).

This change will allow `sort=True` to mean “always sort” in a future release.

The same change applies to `Index.difference()` and `Index.symmetric_difference()`, which would not sort the result when the values could not be compared.

The `sort` option for `Index.intersection()` has changed in three ways.

1. The default has changed from `True` to `False`, to restore the pandas 0.23.4 and earlier behavior of not sorting by default.
2. The behavior of `sort=True` can now be obtained with `sort=None`. This will sort the result only if the values in `self` and `other` are not identical.
3. The value `sort=True` is no longer allowed. A future version of pandas will properly support `sort=True` meaning “always sort”.

### 1.2 Fixed Regressions

- Fixed regression in `DataFrame.to_dict()` with `records` orient raising an `AttributeError` when the `DataFrame` contained more than 255 columns, or wrongly converting column names that were not valid python identifiers (GH24939, GH24940).

- Fixed regression in `read_sql()` when passing certain queries with MySQL/pymysql (GH24988).
- Fixed regression in `Index.intersection` incorrectly sorting the values by default (GH24959).
- Fixed regression in `merge()` when merging an empty `DataFrame` with multiple timezone-aware columns on one of the timezone-aware columns (GH25014).
- Fixed regression in `Series.rename_axis()` and `DataFrame.rename_axis()` where passing `None` failed to remove the axis name (GH25034)
- Fixed regression in `to_timedelta()` with `box=False` incorrectly returning a `datetime64` object instead of a `timedelta64` object (GH24961)
- Fixed regression where custom hashable types could not be used as column keys in `DataFrame.set_index()` (GH24969)

## 1.3 Bug Fixes

### Reshaping

- Bug in `DataFrame.groupby()` with `Groupby` when there is a time change (DST) and grouping frequency is `'1d'` (GH24972)

### Visualization

- Fixed the warning for implicitly registered matplotlib converters not showing. See *Restore Matplotlib datetime Converter Registration* for more (GH24963).

### Other

- Fixed `AttributeError` when printing a `DataFrame`'s HTML repr after accessing the IPython config object (GH25036)

## 1.4 Contributors

A total of 4 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Joris Van den Bossche
- MeeseeksMachine +
- Roman Yurchak
- Tom Augspurger

## INSTALLATION

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

### 2.1 Plan for dropping Python 2.7

The Python core team plans to stop supporting Python 2.7 on January 1st, 2020. In line with [NumPy's plans](#), all pandas releases through December 31, 2018 will support Python 2.

The 0.24.x feature release will be the last release to support Python 2. The released package will continue to be available on PyPI and through conda.

Starting **January 1, 2019**, all new feature releases (> 0.24) will be Python 3 only.

If there are people interested in continued support for Python 2.7 past December 31, 2018 (either backporting bug fixes or funding) please reach out to the maintainers on the issue tracker.

For more information, see the [Python 3 statement](#) and the [Porting to Python 3 guide](#).

### 2.2 Python version support

Officially Python 2.7, 3.5, 3.6, and 3.7.

### 2.3 Installing pandas

#### 2.3.1 Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution [can be found here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

### 2.3.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer [can be found here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```

### 2.3.3 Installing from PyPI

pandas can be installed via pip from PyPI.

```
pip install pandas
```

### 2.3.4 Installing with ActivePython

Installation instructions for ActivePython can be found [here](#). Versions 2.7 and 3.5 include pandas.

### 2.3.5 Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	<a href="#">official Debian repository</a>	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	<a href="#">NeuroDebian</a>	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	<a href="#">official Ubuntu repository</a>	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	<a href="#">OpenSuse Repository</a>	<code>zypper in python3-pandas</code>
Fedora	stable	<a href="#">official Fedora repository</a>	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	<a href="#">EPEL repository</a>	<code>yum install python3-pandas</code>

**However**, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the pip or conda methods described above.

### 2.3.6 Installing from source

See the *contributing guide* for complete instructions on building from the git source tree. Further, see *creating a development environment* if you wish to create a pandas development environment.

## 2.4 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest >= 3.6` and `Hypothesis >= 3.58`, then run:

```
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-
↳packages\pandas
===== test session starts =====
```

(continues on next page)

(continued from previous page)

```
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

.....S.....
.....S.....
.....

===== 12130 passed, 12 skipped in 368.339 seconds =====
```

## 2.5 Dependencies

- `setuptools`: 24.2.0 or higher
- `NumPy`: 1.12.0 or higher
- `python-dateutil`: 2.5.0 or higher
- `pytz`

### 2.5.1 Recommended Dependencies

- `numexpr`: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.6.1 or higher.
- `bottleneck`: for accelerating certain types of nan evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.0 or higher.

---

**Note:** You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

---

### 2.5.2 Optional Dependencies

- `Cython`: Only necessary to build development version. Version 0.28.2 or higher.
- `SciPy`: miscellaneous statistical functions, Version 0.18.1 or higher
- `xarray`: pandas like handling for > 2 dims, needed for converting Panels to xarray objects. Version 0.7.0 or higher is recommended.
- `PyTables`: necessary for HDF5-based storage, Version 3.4.2 or higher
- `pyarrow` (>= 0.9.0): necessary for feather-based storage.
- `Apache Parquet`, either `pyarrow` (>= 0.7.0) or `fastparquet` (>= 0.2.1) for parquet-based storage. The `snappy` and `brotli` are available for compression support.
- `SQLAlchemy`: for SQL database support. Version 0.8.1 or higher recommended. Besides `SQLAlchemy`, you also need a database specific driver. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#). Some common drivers are:
  - `psycopg2`: for PostgreSQL
  - `pymysql`: for MySQL.

- `SQLite`: for SQLite, this is included in Python’s standard library by default.
- `matplotlib`: for plotting, Version 2.0.0 or higher.
- For Excel I/O:
  - `xlrd/xlwt`: Excel reading (`xlrd`), version 1.0.0 or higher required, and writing (`xlwt`)
  - `openpyxl`: `openpyxl` version 2.4.0 for writing `.xlsx` files (`xlrd`  $\geq$  0.9.0)
  - `XlsxWriter`: Alternative Excel writer
- `Jinja2`: Template engine for conditional HTML formatting.
- `s3fs`: necessary for Amazon S3 access (`s3fs`  $\geq$  0.0.7).
- `blosc`: for msgpack compression using `blosc`
- `gcsfs`: necessary for Google Cloud Storage access (`gcsfs`  $\geq$  0.1.0).
- One of `qtpy` (requires `PyQt` or `PySide`), `PyQt5`, `PyQt4`, `pygtk`, `xsel`, or `xclip`: necessary to use `read_clipboard()`. Most package managers on Linux distributions will have `xclip` and/or `xsel` immediately available for installation.
- `pandas-gbq`: for Google BigQuery I/O. (`pandas-gbq`  $\geq$  0.8.0)
- `Backports.lzma`: Only for Python 2, for writing to and/or reading from an xz compressed DataFrame in CSV; Python 3 support is built into the standard library.
- One of the following combinations of libraries is needed to use the top-level `read_html()` function:  
Changed in version 0.23.0.

---

**Note:** If using `BeautifulSoup4` a minimum version of 4.2.1 is required

---

- `BeautifulSoup4` and `html5lib` (Any recent version of `html5lib` is okay.)
- `BeautifulSoup4` and `lxml`
- `BeautifulSoup4` and `html5lib` and `lxml`
- Only `lxml`, although see *HTML Table Parsing* for reasons as to why you should probably **not** take this approach.

**Warning:**

- if you install `BeautifulSoup4` you must install either `lxml` or `html5lib` or both. `read_html()` will **not** work with *only* `BeautifulSoup4` installed.
- You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

---

**Note:**

- if you’re on a system with `apt-get` you can do

```
sudo apt-get build-dep python-lxml
```

to get the necessary dependencies for installation of `lxml`. This will prevent further headaches down the line.

---

---

**Note:** Without the optional dependencies, many useful features will not work. Hence, it is highly recommended that you install these. A packaged distribution like [Anaconda](#), [ActivePython](#) (version 2.7 or 3.5), or [Enthought Canopy](#) may be worth considering.

---

## GETTING STARTED

### 3.1 Package overview

**pandas** is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis / manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, *Series* (1-dimensional) and *DataFrame* (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, *DataFrame* provides everything that R’s *data.frame* provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from DataFrame and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let *Series*, *DataFrame*, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based **slicing, fancy indexing, and subsetting** of large data sets
- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets
- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**

- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
- pandas is a dependency of [statsmodels](#), making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

### 3.1.1 Data Structures

Dimensions	Name	Description
1	Series	1D labeled homogeneously-typed array
2	DataFrame	General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column

#### Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
    series = df[col]
    # do something with series
```

### 3.1.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

### 3.1.3 Getting Support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

### 3.1.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to [all of our contributors](#).

If you're interested in contributing, please visit the [contributing guide](#).

pandas is a [NumFOCUS](#) sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to [donate](#) to the project.

### 3.1.5 Project Governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

### 3.1.6 Development Team

The list of the Core Team members and more detailed information can be found on the [people's page](#) of the governance repo.

### 3.1.7 Institutional Partners

The information about current institutional partners can be found on [pandas website page](#).

### 3.1.8 License

```
BSD 3-Clause License

OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE
OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
```

{{ header }}

## 3.2 10 Minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

### 3.2.1 Object Creation

See the *Data Structure Intro section*.

Creating a `Series` by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
In [4]: s
Out[4]:
0    1.0
1    3.0
2    5.0
3    NaN
4    6.0
5    8.0
dtype: float64
```

Creating a `DataFrame` by passing a NumPy array, with a datetime index and labeled columns:

```
In [5]: dates = pd.date_range('20130101', periods=6)
In [6]: dates
Out[6]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
```

(continues on next page)

(continued from previous page)

```
dtype='datetime64[ns]', freq='D')
In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list('ABCD'))
In [8]: df
Out [8]:
```

	A	B	C	D
2013-01-01	-1.357418	-0.142843	-0.744858	1.962986
2013-01-02	-1.349466	0.358791	-0.668969	-0.586338
2013-01-03	-0.588651	-0.837786	-1.244573	0.042724
2013-01-04	1.076448	0.275756	0.178572	-0.669920
2013-01-05	-0.876710	-0.830077	-1.053295	-0.977186
2013-01-06	0.940624	-0.657478	-0.658436	0.077478

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```
In [9]: df2 = pd.DataFrame({'A': 1.,
...:                       'B': pd.Timestamp('20130102'),
...:                       'C': pd.Series(1, index=list(range(4)), dtype='float32'),
...:                       'D': np.array([3] * 4, dtype='int32'),
...:                       'E': pd.Categorical(["test", "train", "test", "train"]),
...:                       'F': 'foo'})
In [10]: df2
Out [10]:
```

	A	B	C	D	E	F
0	1.0	2013-01-02	1.0	3	test	foo
1	1.0	2013-01-02	1.0	3	train	foo
2	1.0	2013-01-02	1.0	3	test	foo
3	1.0	2013-01-02	1.0	3	train	foo

The columns of the resulting DataFrame have different *dtypes*.

```
In [11]: df2.dtypes
Out [11]:
```

A	float64
B	datetime64[ns]
C	float32
D	int32
E	category
F	object
dtype:	object

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [12]: df2.<TAB> # noqa: E225, E999
df2.A          df2.bool
df2.abs        df2.boxplot
df2.add        df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.clip_lower
df2.align      df2.clip_upper
df2.all        df2.columns
df2.any        df2.combine
```

(continues on next page)

(continued from previous page)

```
df2.append          df2.combine_first
df2.apply           df2.compound
df2.applymap        df2.consolidate
df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

### 3.2.2 Viewing Data

See the *Basics section*.

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out [13]:
           A           B           C           D
2013-01-01 -1.357418 -0.142843 -0.744858  1.962986
2013-01-02 -1.349466  0.358791 -0.668969 -0.586338
2013-01-03 -0.588651 -0.837786 -1.244573  0.042724
2013-01-04  1.076448  0.275756  0.178572 -0.669920
2013-01-05 -0.876710 -0.830077 -1.053295 -0.977186

In [14]: df.tail(3)
↪
           A           B           C           D
2013-01-04  1.076448  0.275756  0.178572 -0.669920
2013-01-05 -0.876710 -0.830077 -1.053295 -0.977186
2013-01-06  0.940624 -0.657478 -0.658436  0.077478
```

Display the index, columns:

```
In [15]: df.index
Out [15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [16]: df.columns
↪ Index(['A', 'B', 'C', 'D'], dtype='object')
```

DataFrame.to\_numpy() gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column.** When you call DataFrame.to\_numpy(), pandas will find the NumPy dtype that can hold all of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.

For df, our DataFrame of all floating-point values, DataFrame.to\_numpy() is fast and doesn't require copying data.

```
In [17]: df.to_numpy()
Out [17]:
```

(continues on next page)

(continued from previous page)

```
array([[ -1.35741793,  -0.14284332,  -0.74485798,   1.96298552],
       [ -1.3494656 ,   0.35879089,  -0.66896897,  -0.58633758],
       [ -0.58865118,  -0.83778629,  -1.24457304,   0.04272407],
       [  1.07644808,   0.2757562 ,   0.17857179,  -0.66992021],
       [ -0.8767104 ,  -0.83007713,  -1.05329532,  -0.97718584],
       [  0.94062388,  -0.65747798,  -0.65843634,   0.07747846]])
```

For `df2`, the DataFrame with multiple dtypes, `DataFrame.to_numpy()` is relatively expensive.

```
In [18]: df2.to_numpy()
Out [18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']], dtype=object)
```

**Note:** `DataFrame.to_numpy()` does *not* include the index or column labels in the output.

`describe()` shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out [19]:
```

	A	B	C	D
count	6.000000	6.000000	6.000000	6.000000
mean	-0.359196	-0.305606	-0.698593	-0.025043
std	1.099832	0.545527	0.489481	1.058759
min	-1.357418	-0.837786	-1.244573	-0.977186
25%	-1.231277	-0.786927	-0.976186	-0.649025
50%	-0.732681	-0.400161	-0.706913	-0.271807
75%	0.558305	0.171106	-0.661069	0.068790
max	1.076448	0.358791	0.178572	1.962986

Transposing your data:

```
In [20]: df.T
Out [20]:
```

	2013-01-01	2013-01-02	2013-01-03	2013-01-04	2013-01-05	2013-01-06
A	-1.357418	-1.349466	-0.588651	1.076448	-0.876710	0.940624
B	-0.142843	0.358791	-0.837786	0.275756	-0.830077	-0.657478
C	-0.744858	-0.668969	-1.244573	0.178572	-1.053295	-0.658436
D	1.962986	-0.586338	0.042724	-0.669920	-0.977186	0.077478

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out [21]:
```

	D	C	B	A
2013-01-01	1.962986	-0.744858	-0.142843	-1.357418
2013-01-02	-0.586338	-0.668969	0.358791	-1.349466
2013-01-03	0.042724	-1.244573	-0.837786	-0.588651
2013-01-04	-0.669920	0.178572	0.275756	1.076448
2013-01-05	-0.977186	-1.053295	-0.830077	-0.876710
2013-01-06	0.077478	-0.658436	-0.657478	0.940624

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out [22]:
```

	A	B	C	D
2013-01-03	-0.588651	-0.837786	-1.244573	0.042724
2013-01-05	-0.876710	-0.830077	-1.053295	-0.977186
2013-01-06	0.940624	-0.657478	-0.658436	0.077478
2013-01-01	-1.357418	-0.142843	-0.744858	1.962986
2013-01-04	1.076448	0.275756	0.178572	-0.669920
2013-01-02	-1.349466	0.358791	-0.668969	-0.586338

### 3.2.3 Selection

---

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

---

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

#### Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df['A']
Out [23]:
```

2013-01-01	-1.357418
2013-01-02	-1.349466
2013-01-03	-0.588651
2013-01-04	1.076448
2013-01-05	-0.876710
2013-01-06	0.940624

Freq: D, Name: A, dtype: float64

Selecting via `[]`, which slices the rows.

```
In [24]: df[0:3]
Out [24]:
```

	A	B	C	D
2013-01-01	-1.357418	-0.142843	-0.744858	1.962986
2013-01-02	-1.349466	0.358791	-0.668969	-0.586338
2013-01-03	-0.588651	-0.837786	-1.244573	0.042724

```
In [25]: df['20130102': '20130104']
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
```

	A	B	C	D
2013-01-02	-1.349466	0.358791	-0.668969	-0.586338
2013-01-03	-0.588651	-0.837786	-1.244573	0.042724
2013-01-04	1.076448	0.275756	0.178572	-0.669920

#### Selection by Label

See more in *Selection by Label*.

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out [26]:
A    -1.357418
B    -0.142843
C    -0.744858
D     1.962986
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:, ['A', 'B']]
Out [27]:
           A         B
2013-01-01 -1.357418 -0.142843
2013-01-02 -1.349466  0.358791
2013-01-03 -0.588651 -0.837786
2013-01-04  1.076448  0.275756
2013-01-05 -0.876710 -0.830077
2013-01-06  0.940624 -0.657478
```

Showing label slicing, both endpoints are *included*:

```
In [28]: df.loc['20130102':'20130104', ['A', 'B']]
Out [28]:
           A         B
2013-01-02 -1.349466  0.358791
2013-01-03 -0.588651 -0.837786
2013-01-04  1.076448  0.275756
```

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out [29]:
A    -1.349466
B     0.358791
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out [30]: -1.3574179252656504
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out [31]: -1.3574179252656504
```

## Selection by Position

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out [32]:
A    1.076448
B     0.275756
C     0.178572
D    -0.669920
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out [33]:
```

	A	B
2013-01-04	1.076448	0.275756
2013-01-05	-0.876710	-0.830077

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out [34]:
```

	A	C
2013-01-02	-1.349466	-0.668969
2013-01-03	-0.588651	-1.244573
2013-01-05	-0.876710	-1.053295

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out [35]:
```

	A	B	C	D
2013-01-02	-1.349466	0.358791	-0.668969	-0.586338
2013-01-03	-0.588651	-0.837786	-1.244573	0.042724

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out [36]:
```

	B	C
2013-01-01	-0.142843	-0.744858
2013-01-02	0.358791	-0.668969
2013-01-03	-0.837786	-1.244573
2013-01-04	0.275756	0.178572
2013-01-05	-0.830077	-1.053295
2013-01-06	-0.657478	-0.658436

For getting a value explicitly:

```
In [37]: df.iloc[1, 1]
Out [37]: 0.35879089022289157
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1, 1]
Out [38]: 0.35879089022289157
```

### Boolean Indexing

Using a single column's values to select data.

```
In [39]: df[df.A > 0]
Out [39]:
           A         B         C         D
2013-01-04  1.076448  0.275756  0.178572 -0.669920
2013-01-06  0.940624 -0.657478 -0.658436  0.077478
```

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out [40]:
           A         B         C         D
2013-01-01      NaN      NaN      NaN  1.962986
2013-01-02      NaN  0.358791      NaN      NaN
2013-01-03      NaN      NaN      NaN  0.042724
2013-01-04  1.076448  0.275756  0.178572      NaN
2013-01-05      NaN      NaN      NaN      NaN
2013-01-06  0.940624      NaN      NaN  0.077478
```

Using the isin() method for filtering:

```
In [41]: df2 = df.copy()
In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']
In [43]: df2
Out [43]:
           A         B         C         D         E
2013-01-01 -1.357418 -0.142843 -0.744858  1.962986    one
2013-01-02 -1.349466  0.358791 -0.668969 -0.586338    one
2013-01-03 -0.588651 -0.837786 -1.244573  0.042724    two
2013-01-04  1.076448  0.275756  0.178572 -0.669920   three
2013-01-05 -0.876710 -0.830077 -1.053295 -0.977186   four
2013-01-06  0.940624 -0.657478 -0.658436  0.077478   three

In [44]: df2[df2['E'].isin(['two', 'four'])]
\-----
↪
           A         B         C         D         E
2013-01-03 -0.588651 -0.837786 -1.244573  0.042724    two
2013-01-05 -0.876710 -0.830077 -1.053295 -0.977186   four
```

### Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range('20130102',
↪ periods=6))
In [46]: s1
Out [46]:
2013-01-02    1
2013-01-03    2
```

(continues on next page)

(continued from previous page)

```
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64

In [47]: df['F'] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out [51]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	-0.744858	5	NaN
2013-01-02	-1.349466	0.358791	-0.668969	5	1.0
2013-01-03	-0.588651	-0.837786	-1.244573	5	2.0
2013-01-04	1.076448	0.275756	0.178572	5	3.0
2013-01-05	-0.876710	-0.830077	-1.053295	5	4.0
2013-01-06	0.940624	-0.657478	-0.658436	5	5.0

A where operation with setting.

```
In [52]: df2 = df.copy()
In [53]: df2[df2 > 0] = -df2
In [54]: df2
Out [54]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	-0.744858	-5	NaN
2013-01-02	-1.349466	-0.358791	-0.668969	-5	-1.0
2013-01-03	-0.588651	-0.837786	-1.244573	-5	-2.0
2013-01-04	-1.076448	-0.275756	-0.178572	-5	-3.0
2013-01-05	-0.876710	-0.830077	-1.053295	-5	-4.0
2013-01-06	-0.940624	-0.657478	-0.658436	-5	-5.0

### 3.2.4 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data section*.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])
```

```
In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1
```

```
In [57]: df1
```

```
Out [57]:
```

	A	B	C	D	F	E
2013-01-01	0.000000	0.000000	-0.744858	5	NaN	1.0
2013-01-02	-1.349466	0.358791	-0.668969	5	1.0	1.0
2013-01-03	-0.588651	-0.837786	-1.244573	5	2.0	NaN
2013-01-04	1.076448	0.275756	0.178572	5	3.0	NaN

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
```

```
Out [58]:
```

	A	B	C	D	F	E
2013-01-02	-1.349466	0.358791	-0.668969	5	1.0	1.0

Filling missing data.

```
In [59]: df1.fillna(value=5)
```

```
Out [59]:
```

	A	B	C	D	F	E
2013-01-01	0.000000	0.000000	-0.744858	5	5.0	1.0
2013-01-02	-1.349466	0.358791	-0.668969	5	1.0	1.0
2013-01-03	-0.588651	-0.837786	-1.244573	5	2.0	5.0
2013-01-04	1.076448	0.275756	0.178572	5	3.0	5.0

To get the boolean mask where values are nan.

```
In [60]: pd.isna(df1)
```

```
Out [60]:
```

	A	B	C	D	F	E
2013-01-01	False	False	False	False	True	False
2013-01-02	False	False	False	False	False	False
2013-01-03	False	False	False	False	False	True
2013-01-04	False	False	False	False	False	True

## 3.2.5 Operations

See the *Basic section on Binary Ops*.

### Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
```

```
Out [61]:
```

A	-0.132959
B	-0.281799
C	-0.698593
D	5.000000

(continues on next page)

(continued from previous page)

```
F      3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out [62]:
2013-01-01    1.063786
2013-01-02    0.868071
2013-01-03    0.865798
2013-01-04    1.906155
2013-01-05    1.247983
2013-01-06    1.924942
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)

In [64]: s
Out [64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03    1.0
2013-01-04    3.0
2013-01-05    5.0
2013-01-06    NaN
Freq: D, dtype: float64

In [65]: df.sub(s, axis='index')
//////////////////////////////////////////////////////////////////////////////////////////////////////
↪
      A         B         C    D    F
2013-01-01    NaN     NaN     NaN  NaN  NaN
2013-01-02    NaN     NaN     NaN  NaN  NaN
2013-01-03 -1.588651 -1.837786 -2.244573  4.0  1.0
2013-01-04 -1.923552 -2.724244 -2.821428  2.0  0.0
2013-01-05 -5.876710 -5.830077 -6.053295  0.0 -1.0
2013-01-06     NaN     NaN     NaN  NaN  NaN
```

### Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
Out [66]:
      A         B         C    D    F
2013-01-01  0.000000  0.000000 -0.744858  5  NaN
2013-01-02 -1.349466  0.358791 -1.413827  10  1.0
2013-01-03 -1.938117 -0.478995 -2.658400  15  3.0
2013-01-04 -0.861669 -0.203239 -2.479828  20  6.0
2013-01-05 -1.738379 -1.033316 -3.533124  25  10.0
2013-01-06 -0.797755 -1.690794 -4.191560  30  15.0
```

(continues on next page)

(continued from previous page)

```
In [67]: df.apply(lambda x: x.max() - x.min())
////////////////////////////////////////////////////////////////////////////////////////////////
→
A      2.425914
B      1.196577
C      1.423145
D      0.000000
F      4.000000
dtype: float64
```

## Histogramming

See more at *Histogramming and Discretization*.

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
```

```
In [69]: s
```

```
Out [69]:
0      0
1      4
2      6
3      5
4      5
5      2
6      2
7      0
8      4
9      2
dtype: int64
```

```
In [70]: s.value_counts()
```

```
////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
→
2      3
5      2
4      2
0      2
6      1
dtype: int64
Out [70]:
```

## String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses [regular expressions](#) by default (and in some cases always uses them). See more at *Vectorized String Methods*.

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [72]: s.str.lower()
```

```
Out [72]:
0      a
1      b
2      c
```

(continues on next page)

(continued from previous page)

```

3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object

```

## 3.2.6 Merge

### Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the *Merging section*.

Concatenating pandas objects together with `concat()`:

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [74]: df
```

```
Out [74]:
```

	0	1	2	3
0	1.231856	0.283952	0.118992	-0.724206
1	-1.653430	0.118499	1.300022	-1.526964
2	0.081166	0.233922	1.264717	0.935723
3	-0.689927	-0.517942	-0.277571	-1.175085
4	1.795727	-1.335807	-0.846357	0.062066
5	-0.408033	0.071026	0.528408	-0.646874
6	-1.151626	-0.323356	1.020479	-0.308118
7	-0.303478	-0.233435	2.130528	0.479592
8	0.061129	0.481290	0.259358	-0.979837
9	0.714785	0.176319	0.647529	1.651090

```
# break it into pieces
```

```
In [75]: pieces = [df[:3], df[3:7], df[7:]]
```

```
In [76]: pd.concat(pieces)
```

```
Out [76]:
```

	0	1	2	3
0	1.231856	0.283952	0.118992	-0.724206
1	-1.653430	0.118499	1.300022	-1.526964
2	0.081166	0.233922	1.264717	0.935723
3	-0.689927	-0.517942	-0.277571	-1.175085
4	1.795727	-1.335807	-0.846357	0.062066
5	-0.408033	0.071026	0.528408	-0.646874
6	-1.151626	-0.323356	1.020479	-0.308118
7	-0.303478	-0.233435	2.130528	0.479592
8	0.061129	0.481290	0.259358	-0.979837
9	0.714785	0.176319	0.647529	1.651090

### Join

SQL style merges. See the *Database style joining* section.

```
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})
In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})

In [79]: left
Out[79]:
   key  lval
0  foo     1
1  foo     2

In [80]: right
Out[80]:
   key  rval
0  foo     4
1  foo     5

In [81]: pd.merge(left, right, on='key')
Out[81]:
   key  lval  rval
0  foo     1     4
1  foo     1     5
2  foo     2     4
3  foo     2     5
```

Another example that can be given is:

```
In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})
In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})

In [84]: left
Out[84]:
   key  lval
0  foo     1
1  bar     2

In [85]: right
Out[85]:
   key  rval
0  foo     4
1  bar     5

In [86]: pd.merge(left, right, on='key')
Out[86]:
   key  lval  rval
0  foo     1     4
1  bar     2     5
```

## Append

Append rows to a dataframe. See the *Appending* section.

```
In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A', 'B', 'C', 'D'])
```

(continues on next page)

(continued from previous page)

```
In [88]: df
Out [88]:
```

	A	B	C	D
0	1.392422	0.748325	-0.436142	-1.278450
1	0.043423	-0.533787	-0.351340	0.716190
2	0.969599	-1.009690	-0.706241	1.735671
3	-0.602929	0.052976	0.317099	0.309610
4	-1.071123	-2.226177	-0.279247	-0.216166
5	0.386439	-0.072899	-0.985965	-0.626187
6	-0.008656	-0.771064	-0.377700	1.899199
7	-0.286120	-0.281921	-0.367725	-0.919801

```
In [89]: s = df.iloc[3]
```

```
In [90]: df.append(s, ignore_index=True)
```

```
Out [90]:
```

	A	B	C	D
0	1.392422	0.748325	-0.436142	-1.278450
1	0.043423	-0.533787	-0.351340	0.716190
2	0.969599	-1.009690	-0.706241	1.735671
3	-0.602929	0.052976	0.317099	0.309610
4	-1.071123	-2.226177	-0.279247	-0.216166
5	0.386439	-0.072899	-0.985965	-0.626187
6	-0.008656	-0.771064	-0.377700	1.899199
7	-0.286120	-0.281921	-0.367725	-0.919801
8	-0.602929	0.052976	0.317099	0.309610

### 3.2.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the *Grouping section*.

```
In [91]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
.....:                          'foo', 'bar', 'foo', 'foo'],
.....:                    'B': ['one', 'one', 'two', 'three',
.....:                          'two', 'two', 'one', 'three'],
.....:                    'C': np.random.randn(8),
.....:                    'D': np.random.randn(8)})
.....:
```

```
In [92]: df
```

```
Out [92]:
```

	A	B	C	D
0	foo	one	-1.304704	-0.260415
1	bar	one	-0.218177	1.004457
2	foo	two	-0.598015	-1.822984
3	bar	three	-0.342118	0.873662
4	foo	two	0.034035	1.571507
5	bar	two	-0.033906	-0.785660

(continues on next page)

(continued from previous page)

```
6 foo one -0.637461 0.191702
7 foo three 0.622365 0.771074
```

Grouping and then applying the `sum()` function to the resulting groups.

```
In [93]: df.groupby('A').sum()
Out [93]:
```

	C	D
A		
bar	-0.594201	1.092460
foo	-1.883780	0.450884

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```
In [94]: df.groupby(['A', 'B']).sum()
Out [94]:
```

		C	D
A	B		
bar	one	-0.218177	1.004457
	three	-0.342118	0.873662
	two	-0.033906	-0.785660
foo	one	-1.942164	-0.068713
	three	0.622365	0.771074
	two	-0.563980	-0.251477

## 3.2.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.

### Stack

```
In [95]: tuples = list(zip(*(['bar', 'bar', 'baz', 'baz',
.....:                        'foo', 'foo', 'qux', 'qux'],
.....:                        ['one', 'two', 'one', 'two',
.....:                        'one', 'two', 'one', 'two'])))
.....:

In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [98]: df2 = df[:4]

In [99]: df2
Out [99]:
```

		A	B
first	second		
bar	one	1.318905	0.645529
	two	-1.061967	-1.019842
baz	one	-0.428076	0.273714
	two	0.670740	0.674048

The `stack()` method “compresses” a level in the `DataFrame`’s columns.

```
In [100]: stacked = df2.stack()
```

```
In [101]: stacked
```

```
Out [101]:
```

```
first second
bar   one    A    1.318905
      one    B    0.645529
      two    A   -1.061967
      two    B   -1.019842
baz   one    A   -0.428076
      one    B    0.273714
      two    A    0.670740
      two    B    0.674048
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last level**:

```
In [102]: stacked.unstack()
```

```
Out [102]:
```

```
           A          B
first second
bar   one    1.318905  0.645529
      two   -1.061967 -1.019842
baz   one   -0.428076  0.273714
      two    0.670740  0.674048
```

```
In [103]: stacked.unstack(1)
```

```
////////////////////////////////////
↪
second      one      two
first
bar   A  1.318905 -1.061967
      B  0.645529 -1.019842
baz   A -0.428076  0.670740
      B  0.273714  0.674048
```

```
In [104]: stacked.unstack(0)
```

```
////////////////////////////////////
↪
first      bar      baz
second
one   A  1.318905 -0.428076
      B  0.645529  0.273714
two   A -1.061967  0.670740
      B -1.019842  0.674048
```

## Pivot Tables

See the section on *Pivot Tables*.

```
In [105]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3,
.....:                      'B': ['A', 'B', 'C'] * 4,
.....:                      'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
.....:                      'D': np.random.randn(12),
.....:                      'E': np.random.randn(12)})
```

(continues on next page)

(continued from previous page)

```

.....:
In [106]: df
Out [106]:
   A  B  C  D  E
0  one A  foo  1.286758 -0.434526
1  one B  foo  1.050525  0.587465
2  two C  foo -0.743868  2.197816
3  three A  bar  0.347013  0.353235
4  one B  bar  0.308812 -1.030456
5  one C  bar -0.345680 -0.319095
6  two A  foo -0.238305  0.718997
7  three B  foo -1.962755 -0.136761
8  one C  foo  1.446097  1.056697
9  one A  bar -0.293508 -0.566902
10 two B  bar  1.450870  0.272084
11 three C  bar  0.017218 -0.275535

```

We can produce pivot tables from this data very easily:

```

In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out [107]:
C          bar          foo
A  B
one  A -0.293508  1.286758
     B  0.308812  1.050525
     C -0.345680  1.446097
three A  0.347013         NaN
     B         NaN -1.962755
     C  0.017218         NaN
two  A         NaN -0.238305
     B  1.450870         NaN
     C         NaN -0.743868

```

### 3.2.9 Time Series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series section*.

```

In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [110]: ts.resample('5Min').sum()
Out [110]:
2012-01-01    24484
Freq: 5T, dtype: int64

```

Time zone representation:

```

In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)

```

(continues on next page)

(continued from previous page)

```
In [113]: ts
Out [113]:

```

(continues on next page)

```
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under Series .cat return a new Series by default).

```
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",
.....:                                                "good", "very good"])
.....:
```

```
In [132]: df["grade"]
```

```
Out [132]:
```

```
0    very good
1         good
2         good
3    very good
4    very good
5    very bad
```

```
Name: grade, dtype: category
```

```
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [133]: df.sort_values(by="grade")
```

```
Out [133]:
```

```
   id  raw_grade  grade
5   6         e  very bad
1   2         b    good
2   3         b    good
0   1         a  very good
3   4         a  very good
4   5         a  very good
```

Grouping by a categorical column also shows empty categories.

```
In [134]: df.groupby("grade").size()
```

```
Out [134]:
```

```
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64
```

### 3.2.11 Plotting

See the *Plotting* docs.

```
In [135]: ts = pd.Series(np.random.randn(1000),
.....:                  index=pd.date_range('1/1/2000', periods=1000))
.....:
```

```
In [136]: ts = ts.cumsum()
```

```
In [137]: ts.plot()
```

```
Out [137]: <matplotlib.axes._subplots.AxesSubplot at 0x7f9bd00be518>
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```
In [138]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
.....:                      columns=['A', 'B', 'C', 'D'])
.....:
```

```
In [139]: df = df.cumsum()
```

```
In [140]: plt.figure()
```

```
Out[140]: <Figure size 640x480 with 0 Axes>
```

```
In [141]: df.plot()
```

```
\\Out[141]: <matplotlib.axes._subplots.
↪AxesSubplot at 0x7f9bd00be358>
```

```
In [142]: plt.legend(loc='best')
```

```
\\
↪<matplotlib.legend.Legend at 0x7f9bcf984198>
```

### 3.2.12 Getting Data In/Out

#### CSV

*Writing to a csv file.*

```
In [143]: df.to_csv('foo.csv')
```

*Reading from a csv file.*

```
In [144]: pd.read_csv('foo.csv')
```

Out [144]:

### 3.2.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```

>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().

```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.

### 3.3 Essential Basic Functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. Here's how to create some of the objects used in the examples from the previous section:

```
In [1]: index = pd.date_range('1/1/2000', periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
...:                       columns=['A', 'B', 'C'])
...:
...:

In [4]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
...:                 major_axis=pd.date_range('1/1/2000', periods=5),
...:                 minor_axis=['A', 'B', 'C', 'D'])
...:
...:
```

#### 3.3.1 Head and Tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [5]: long_series = pd.Series(np.random.randn(1000))

In [6]: long_series.head()
Out [6]:
0    -2.211372
1     0.974466
2    -2.006747
3    -0.410001
4    -0.078638
dtype: float64

In [7]: long_series.tail(3)
Out [7]:
997    -0.196166
998     0.380733
999    -0.275874
dtype: float64
```

#### 3.3.2 Attributes and Underlying Data

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray
- **Axis labels**
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*
  - **Panel**: *items*, *major\_axis*, and *minor\_axis*

useful representations:

1. An object-dtype `numpy.ndarray` with *Timestamp* objects, each with the correct `tz`
2. A `datetime64[ns]` -dtype `numpy.ndarray`, where the values have been converted to UTC and the time-zone discarded

Timezones may be preserved with `dtype=object`

```
In [15]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
In [16]: ser.to_numpy(dtype=object)
Out [16]:
array([[Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
        Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')], dtype=object)
```

Or thrown away with `dtype='datetime64[ns]'`

```
In [17]: ser.to_numpy(dtype="datetime64[ns]")
Out [17]: array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
               dtype='datetime64[ns]')
```

Getting the “raw data” inside a *DataFrame* is possibly a bit more complex. When your *DataFrame* only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```
In [18]: df.to_numpy()
Out [18]:
array([[ -0.1732,  0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949],
       [ 1.0718,  0.7216, -0.7068],
       [-1.0396,  0.2719, -0.425 ],
       [ 0.567 ,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784],
       [ 0.525 ,  0.4047,  0.577 ],
       [-1.715 , -1.0393, -0.3706]])
```

If a *DataFrame* or *Panel* contains homogeneously-typed data, the `ndarray` can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the *DataFrame*’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

---

**Note:** When working with heterogeneous data, the dtype of the resulting `ndarray` will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

---

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a *Series* or *DataFrame*. You’ll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your *Series* contains an *extension type*, it’s unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an *ExtensionArray*, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.
2. When your *DataFrame* contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the *DataFrame*.

### 3.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row `DataFrames`):

Operation	0.11.0 (ms)	Prior Version (ms)	Ratio to Prior
<code>df1 &gt; df2</code>	13.32	125.35	0.1063
<code>df1 * df2</code>	21.71	36.63	0.5928
<code>df1 + df2</code>	22.04	36.50	0.6039

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

### 3.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. `DataFrame`) and lower-dimensional (e.g. `Series`) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

#### Matching / broadcasting behavior

`DataFrame` has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, `Series` input is of primary interest. Using these functions, you can use to either match on the *index* or *columns* via the **axis** keyword:

```
In [19]: df = pd.DataFrame({
.....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
.....:     'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
.....:     'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])
.....: })

In [20]: df
Out[20]:
```

	one	two	three
a	1.400810	-1.643041	NaN
b	-0.356470	1.045911	0.395023
c	0.797268	0.924515	-0.007090
d	NaN	1.553693	-1.670830

(continues on next page)

(continued from previous page)

```
In [21]: row = df.iloc[1]
```

```
In [22]: column = df['two']
```

```
In [23]: df.sub(row, axis='columns')
```

```
Out [23]:
```

```
      one      two      three
a  1.757280 -2.688953      NaN
b  0.000000  0.000000  0.000000
c  1.153738 -0.121396 -0.402113
d         NaN  0.507782 -2.065853
```

```
In [24]: df.sub(row, axis=1)
```

```

////////////////////////////////////
↪
      one      two      three
a  1.757280 -2.688953      NaN
b  0.000000  0.000000  0.000000
c  1.153738 -0.121396 -0.402113
d         NaN  0.507782 -2.065853
```

```
In [25]: df.sub(column, axis='index')
```

```

////////////////////////////////////
↪
      one  two      three
a  3.043851  0.0      NaN
b -1.402381  0.0 -0.650888
c -0.127247  0.0 -0.931605
d         NaN  0.0 -3.224524
```

```
In [26]: df.sub(column, axis=0)
```

```

////////////////////////////////////
↪
      one  two      three
a  3.043851  0.0      NaN
b -1.402381  0.0 -0.650888
c -0.127247  0.0 -0.931605
d         NaN  0.0 -3.224524
```

Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```
In [27]: dfmi = df.copy()
```

```
In [28]: dfmi.index = pd.MultiIndex.from_tuples([(1, 'a'), (1, 'b'),
.....:                                     (1, 'c'), (2, 'a')],
.....:                                     names=['first', 'second'])
.....:
```

```
In [29]: dfmi.sub(column, axis=0, level='second')
```

```
Out [29]:
```

```

      one      two      three
first second
1      a      3.043851  0.000000      NaN
      b     -1.402381  0.000000 -0.650888
      c     -0.127247  0.000000 -0.931605
2      a         NaN  3.196734 -0.027789
```

With Panel, describing the matching behavior is a bit more difficult, so the arithmetic methods instead (and perhaps confusingly?) give you the option to specify the *broadcast axis*. For example, suppose we wished to demean the data over a particular axis. This can be accomplished by taking the mean over an axis and broadcasting over the same axis:

```
In [30]: major_mean = wp.mean(axis='major')

In [31]: major_mean
Out [31]:
      Item1      Item2
A -0.378069  0.675929
B -0.241429 -0.018080
C -0.597702  0.129006
D  0.204005  0.245570

In [32]: wp.sub(major_mean, axis='major')
////////////////////////////////////
↪
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

And similarly for axis="items" and axis="minor".

---

**Note:** I could be convinced to make the **axis** argument in the DataFrame methods match the broadcasting behavior of Panel. Though it would require a transition period so users can change their code...

---

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```
In [33]: s = pd.Series(np.arange(10))

In [34]: s
Out [34]:
0    0
1    1
2    2
3    3
4    4
5    5
6    6
7    7
8    8
9    9
dtype: int64

In [35]: div, rem = divmod(s, 3)

In [36]: div
Out [36]:
0    0
1    0
2    0
3    1
4    1
```

(continues on next page)

(continued from previous page)

```

5    1
6    2
7    2
8    2
9    3
dtype: int64

In [37]: rem
\\Out [37]:
↪
0    0
1    1
2    2
3    0
4    1
5    2
6    0
7    1
8    2
9    0
dtype: int64

In [38]: idx = pd.Index(np.arange(10))

In [39]: idx
Out [39]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [40]: div, rem = divmod(idx, 3)

In [41]: div
Out [41]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [42]: rem
\\Out [42]:
↪Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')
```

We can also do elementwise `divmod()`:

```

In [43]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

In [44]: div
Out [44]:
0    0
1    0
2    0
3    1
4    1
5    1
6    1
7    1
8    1
9    1
dtype: int64

In [45]: rem
\\Out [45]:
↪
```

(continues on next page)

(continued from previous page)

```

0    0
1    1
2    2
3    0
4    0
5    1
6    1
7    2
8    2
9    3
dtype: int64

```

### Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill\_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```
In [46]: df
```

```
Out [46]:
```

```

      one      two      three
a  1.400810 -1.643041      NaN
b -0.356470  1.045911  0.395023
c  0.797268  0.924515 -0.007090
d      NaN  1.553693 -1.670830

```

```
In [47]: df2
```

```

=====
↪
      one      two      three
a  1.400810 -1.643041  1.000000
b -0.356470  1.045911  0.395023
c  0.797268  0.924515 -0.007090
d      NaN  1.553693 -1.670830

```

```
In [48]: df + df2
```

```

=====
↪
      one      two      three
a  2.801620 -3.286083      NaN
b -0.712940  2.091822  0.790046
c  1.594536  1.849030 -0.014180
d      NaN  3.107386 -3.341661

```

```
In [49]: df.add(df2, fill_value=0)
```

```

=====
↪
      one      two      three
a  2.801620 -3.286083  1.000000
b -0.712940  2.091822  0.790046
c  1.594536  1.849030 -0.014180
d      NaN  3.107386 -3.341661

```

## Flexible Comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```
In [50]: df.gt(df2)
Out [50]:
```

	one	two	three
a	False	False	False
b	False	False	False
c	False	False	False
d	False	False	False

```
In [51]: df2.ne(df)
\-----\Out [51]:
```

	one	two	three
a	False	False	True
b	False	False	False
c	False	False	False
d	True	False	False

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on *Boolean indexing*.

## Boolean Reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [52]: (df > 0).all()
Out [52]:
```

one	False
two	False
three	False

dtype: bool

```
In [53]: (df > 0).any()
\-----\Out [53]:
```

one	True
two	True
three	True

dtype: bool

You can reduce to a final boolean value.

```
In [54]: (df > 0).any().any()
Out [54]: True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [55]: df.empty
Out [55]: False

In [56]: pd.DataFrame(columns=list('ABC')).empty
\-----\Out [56]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [57]: pd.Series([True]).bool()
Out[57]: True

In [58]: pd.Series([False]).bool()
\\Out[58]: False

In [59]: pd.DataFrame([[True]]).bool()
\\Out[59]: True

In [60]: pd.DataFrame([[False]]).bool()
\\Out[60]: False
```

**Warning:** You might be tempted to do the following:

```
>>> if df:
...     pass
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.
→all().
```

See *gotchas* for a more detailed discussion.

### Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [61]: df + df == df * 2
Out[61]:
   one  two  three
a  True  True  False
b  True  True  True
c  True  True  True
d  False True  True

In [62]: (df + df == df * 2).all()
\\
→
one      False
two       True
three    False
dtype: bool
```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [63]: np.nan == np.nan
Out[63]: False
```

So, NDFrames (such as Series, DataFrames, and Panels) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [64]: (df + df).equals(df * 2)
Out[64]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [65]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
In [66]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [67]: df1.equals(df2)
Out[67]: False

In [68]: df1.equals(df2.sort_index())
Out[68]: True
```

### Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [69]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[69]:
0     True
1     False
2     False
dtype: bool

In [70]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[70]: array([ True, False,  False], dtype=bool)
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [71]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[71]:
0     True
1     True
2     False
dtype: bool

In [72]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[72]:
0     True
1     True
2     False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a `ValueError`:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [73]: np.array([1, 2, 3]) == np.array([2])
Out [73]: array([False,  True,  False], dtype=bool)
```

or it can return False if broadcasting can not be done:

```
In [74]: np.array([1, 2, 3]) == np.array([1, 2])
Out [74]: False
```

### Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [75]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
.....:                      'B': [np.nan, 2., 3., np.nan, 6.]})
.....:

In [76]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
.....:                      'B': [np.nan, np.nan, 3., 4., 6., 8.]})
.....:

In [77]: df1
Out [77]:
   A    B
0  1.0 NaN
1  NaN  2.0
2  3.0  3.0
3  5.0 NaN
4  NaN  6.0

In [78]: df2
Out [78]:
   A    B
0  5.0 NaN
1  2.0 NaN
2  4.0  3.0
3  NaN  4.0
4  3.0  6.0
5  7.0  8.0

In [79]: df1.combine_first(df2)
Out [79]:
   A    B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
```

(continues on next page)

(continued from previous page)

```
In [83]: df.mean(1)
////////////////////////////////////
↪
a    -0.121116
b     0.361488
c     0.571564
d    -0.058569
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (`True` by default):

```
In [84]: df.sum(0, skipna=False)
```

```
Out [84]:
```

```
one           NaN
two          1.881078
three         NaN
dtype: float64
```

```
In [85]: df.sum(axis=1, skipna=True)
```

```
////////////////////////////////////\\Out [85]:
```

```
↪
a    -0.242232
b     1.084464
c     1.714693
d    -0.117137
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```
In [86]: ts_stand = (df - df.mean()) / df.std()
```

```
In [87]: ts_stand.std()
```

```
Out [87]:
```

```
one          1.0
two          1.0
three        1.0
dtype: float64
```

```
In [88]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
```

```
In [89]: xs_stand.std(1)
```

```
Out [89]:
```

```
a          1.0
b          1.0
c          1.0
d          1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see *this note*.

```
In [90]: df.cumsum()
```

```
Out [90]:
```

```
one    two    three
```

(continues on next page)

(continued from previous page)

a	1.400810	-1.643041	NaN
b	1.044340	-0.597130	0.395023
c	1.841608	0.327385	0.387933
d	NaN	1.881078	-1.282898

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a *hierarchical index*.

Function	Description
<code>count</code>	Number of non-NA observations
<code>sum</code>	Sum of values
<code>mean</code>	Mean of values
<code>mad</code>	Mean absolute deviation
<code>median</code>	Arithmetic median of values
<code>min</code>	Minimum
<code>max</code>	Maximum
<code>mode</code>	Mode
<code>abs</code>	Absolute Value
<code>prod</code>	Product of values
<code>std</code>	Bessel-corrected sample standard deviation
<code>var</code>	Unbiased variance
<code>sem</code>	Standard error of the mean
<code>skew</code>	Sample skewness (3rd moment)
<code>kurt</code>	Sample kurtosis (4th moment)
<code>quantile</code>	Sample quantile (value at %)
<code>cumsum</code>	Cumulative sum
<code>cumprod</code>	Cumulative product
<code>cummax</code>	Cumulative maximum
<code>cummin</code>	Cumulative minimum

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [91]: np.mean(df['one'])
Out[91]: 0.6138692844180106

In [92]: np.mean(df['one'].to_numpy())
Out[92]: nan
```

`Series.unique()` will return the number of unique non-NA values in a Series:

```
In [93]: series = pd.Series(np.random.randn(500))

In [94]: series[20:500] = np.nan

In [95]: series[10:20] = 5

In [96]: series.unique()
Out[96]: 11
```

## Summarizing data: describe

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [97]: series = pd.Series(np.random.randn(1000))

In [98]: series[::2] = np.nan

In [99]: series.describe()
Out [99]:
count      500.000000
mean       -0.020695
std         1.011840
min        -2.683763
25%        -0.709297
50%        -0.070211
75%         0.712856
max         3.160915
dtype: float64

In [100]: frame = pd.DataFrame(np.random.randn(1000, 5),
.....:                          columns=['a', 'b', 'c', 'd', 'e'])
.....:

In [101]: frame.iloc[::2] = np.nan

In [102]: frame.describe()
Out [102]:
```

	a	b	c	d	e
count	500.000000	500.000000	500.000000	500.000000	500.000000
mean	0.026515	0.022952	-0.047307	-0.052551	0.011210
std	1.016752	0.980046	1.020837	1.008271	1.006726
min	-3.000951	-2.637901	-3.303099	-3.159200	-3.188821
25%	-0.647623	-0.593587	-0.709906	-0.691338	-0.689176
50%	0.047578	-0.026675	-0.029655	-0.032769	-0.015775
75%	0.723946	0.771931	0.603753	0.667044	0.652221
max	2.740139	2.752332	3.004229	2.728702	3.240991

You can select specific percentiles to include in the output:

```
In [103]: series.describe(percentiles=[.05, .25, .75, .95])
Out [103]:
count      500.000000
mean       -0.020695
std         1.011840
min        -2.683763
5%         -1.641337
25%        -0.709297
50%        -0.070211
75%         0.712856
95%         1.699176
max         3.160915
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```
In [104]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])
In [105]: s.describe()
Out [105]:
count      9
unique     4
top        a
freq       5
dtype: object
```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```
In [106]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})
In [107]: frame.describe()
Out [107]:
           b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```
In [108]: frame.describe(include=['object'])
Out [108]:
           a
count      4
unique     2
top        Yes
freq       2

In [109]: frame.describe(include=['number'])
Out [109]:
           b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000

In [110]: frame.describe(include='all')
Out [110]:
↪
           a           b
count      4  4.000000
unique     2         NaN
top        Yes        NaN
```

(continues on next page)

(continued from previous page)

```

freq      2      NaN
mean     NaN  1.500000
std      NaN  1.290994
min      NaN  0.000000
25%     NaN  0.750000
50%     NaN  1.500000
75%     NaN  2.250000
max      NaN  3.000000

```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

## Index of Min/Max Values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [111]: s1 = pd.Series(np.random.randn(5))
```

```
In [112]: s1
```

```
Out [112]:
0    -0.068822
1    -1.129788
2    -0.269798
3    -0.375580
4     0.513381
dtype: float64
```

```
In [113]: s1.idxmin(), s1.idxmax()
```

```

//////////////////////////////////////Out [113]:
→ (1, 4)

```

```
In [114]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])
```

```
In [115]: df1
```

```
Out [115]:
      A         B         C
0  0.333329 -0.910090 -1.321220
1  2.111424  1.701169  0.858336
2 -0.608055 -2.082155 -0.069618
3  1.412817 -0.562658  0.770042
4  0.373294 -0.965381 -1.607840
```

```
In [116]: df1.idxmin(axis=0)
```

```

//////////////////////////////////////Out [116]:
→
A      2
B      2
C      4
dtype: int64

```

```
In [117]: df1.idxmax(axis=1)
```

```

//////////////////////////////////////Out [117]:
→
0      A
1      A

```

(continues on next page)

(continued from previous page)

```
2    C
3    A
4    A
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [118]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))

In [119]: df3
Out[119]:
      A
e  2.0
d  1.0
c  1.0
b  3.0
a  NaN

In [120]: df3['A'].idxmin()
Out[120]: 'd'
```

**Note:** `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

### Value counts (histogramming) / Mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```
In [121]: data = np.random.randint(0, 7, size=50)

In [122]: data
Out[122]:
array([6, 4, 1, 3, 4, 4, 4, 6, 5, 2, 6, 1, 0, 4, 3, 2, 5, 3, 4, 0, 5, 3, 0,
       1, 5, 0, 1, 5, 3, 4, 1, 2, 3, 2, 4, 6, 1, 4, 3, 5, 2, 1, 2, 4, 1, 6,
       3, 6, 3, 3])

In [123]: s = pd.Series(data)

In [124]: s.value_counts()
Out[124]:
4     10
3     10
1      8
6      6
5      6
2      6
0      4
dtype: int64

In [125]: pd.value_counts(data)
Out[125]:
```

(continues on next page)

(continued from previous page)

```

4    10
3    10
1     8
6     6
5     6
2     6
0     4
dtype: int64

```

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

```

In [126]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [127]: s5.mode()
Out [127]:
0    3
1    7
dtype: int64

In [128]: df5 = pd.DataFrame({"A": np.random.randint(0, 7, size=50),
.....:                       "B": np.random.randint(-10, 15, size=50)})
.....:

In [129]: df5.mode()
Out [129]:
   A  B
0  0 -9

```

## Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```

In [130]: arr = np.random.randn(20)

In [131]: factor = pd.cut(arr, 4)

In [132]: factor
Out [132]:
[(1.27, 2.31], (0.231, 1.27], (-0.809, 0.231], (-1.853, -0.809], (1.27, 2.31], ..., ]
↪ (0.231, 1.27], (-0.809, 0.231], (-1.853, -0.809], (1.27, 2.31], (0.231, 1.27]]
Length: 20
Categories (4, interval[float64]): [(-1.853, -0.809] < (-0.809, 0.231] < (0.231, 1.
↪ 27] < (1.27, 2.31]]

In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [134]: factor
Out [134]:
[(1, 5], (0, 1], (-1, 0], (-5, -1], (1, 5], ..., (1, 5], (-1, 0], (-5, -1], (1, 5], ]
↪ (0, 1]]
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5]]

```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```
# f, g, and h are functions taking and returning ``DataFrames``  
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```
>>> (df.pipe(h)  
...   .pipe(g, arg1=1)  
...   .pipe(f, arg2=2, arg3=3))
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (callable, data\_keyword). `pipe` will route the `DataFrame` to the argument specified in the tuple.

For example, we can fit a regression using `statsmodels`. Their API expects a formula first and a `DataFrame` as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, 'data') to `pipe`:

```
In [142]: import statsmodels.formula.api as sm  
  
In [143]: bb = pd.read_csv('data/baseball.csv', index_col='id')  
  
In [144]: (bb.query('h > 0')  
.....:   .assign(ln_h=lambda df: np.log(df.h))  
.....:   .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')  
.....:   .fit()  
.....:   .summary()  
.....: )  
.....:  
Out [144]:  
<class 'statsmodels.iolib.summary.Summary'>  
"""

"""

```

The pipe method is inspired by unix pipes and more recently `dplyr` and `magrittr`, which have introduced the popular (`%>%`) (read pipe) operator for R. The implementation of `pipe` here is quite clean and feels right at home in python. We encourage you to view the source code of `pipe()`.

### Row or Column-wise Function Application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```

In [145]: df.apply(np.mean)
Out [145]:
one      0.613869
two      0.470270
three    -0.427633
dtype: float64

In [146]: df.apply(np.mean, axis=1)
Out [146]:
a      -0.121116
b       0.361488
c       0.571564
d      -0.058569
dtype: float64

In [147]: df.apply(lambda x: x.max() - x.min())
Out [147]:
one      1.757280
two      3.196734
three    2.065853
dtype: float64

In [148]: df.apply(np.cumsum)
Out [148]:
      one      two      three
a  1.400810 -1.643041      NaN
b  1.044340 -0.597130  0.395023
c  1.841608  0.327385  0.387933
d         NaN  1.881078 -1.282898

In [149]: df.apply(np.exp)
Out [149]:
      one      two      three
a  4.058485  0.193391      NaN

```

(continues on next page)

(continued from previous page)

```
b  0.700143  2.845991  1.484418
c  2.219469  2.520646  0.992935
d           NaN  4.728902  0.188091
```

The `apply()` method will also dispatch on a string method name.

```
In [150]: df.apply('mean')
Out [150]:
one      0.613869
two      0.470270
three   -0.427633
dtype: float64

In [151]: df.apply('mean', axis=1)
Out [151]:
a    -0.121116
b     0.361488
c     0.571564
d    -0.058569
dtype: float64
```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-like return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [152]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
.....:                       index=pd.date_range('1/1/2000', periods=1000))
.....:

In [153]: tsdf.apply(lambda x: x.idxmax())
Out [153]:
A    2000-06-10
B    2001-07-04
C    2002-08-09
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass `Series` methods to carry out some `Series` operation on each column or row:

```
In [154]: tsdf
```

```
Out [154]:
```

```

      A      B      C
2000-01-01 -0.652077 -0.239118  0.841272
2000-01-02  0.130224  0.347505 -0.385666
2000-01-03 -1.700237 -0.925899  0.199564
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08  0.339319 -0.978307  0.689492
2000-01-09  0.601495 -0.630417 -1.040079
2000-01-10  1.511723 -0.427952 -0.400154
```

```
In [155]: tsdf.apply(pd.Series.interpolate)
```

```

////////////////////////////////////
↪
      A      B      C
2000-01-01 -0.652077 -0.239118  0.841272
2000-01-02  0.130224  0.347505 -0.385666
2000-01-03 -1.700237 -0.925899  0.199564
2000-01-04 -1.292326 -0.936380  0.297550
2000-01-05 -0.884415 -0.946862  0.395535
2000-01-06 -0.476503 -0.957344  0.493521
2000-01-07 -0.068592 -0.967825  0.591507
2000-01-08  0.339319 -0.978307  0.689492
2000-01-09  0.601495 -0.630417 -1.040079
2000-01-10  1.511723 -0.427952 -0.400154
```

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a `Series` before applying the function. When set to `True`, the passed function will instead receive an `ndarray` object, which has positive performance implications if you do not need the indexing functionality.

## Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see *groupby API*, the *window functions API*, and the *resample API*. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [156]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [157]: tsdf.iloc[3:7] = np.nan
```

```
In [158]: tsdf
```

```
Out [158]:
```

```

      A      B      C
2000-01-01  0.396575 -0.364907  0.051290
2000-01-02 -0.310517 -0.369093 -0.353151
2000-01-03 -0.522441  1.659115 -0.272364
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
```

(continues on next page)

(continued from previous page)

```
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08 -0.057890  1.148901  0.011528
2000-01-09 -0.155578  0.742150  0.107324
2000-01-10  0.531797  0.080254  0.833297
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [159]: tsdf.agg(np.sum)
Out [159]:
A    -0.118055
B     2.896420
C     0.377923
dtype: float64

In [160]: tsdf.agg('sum')
Out [160]:
A    -0.118055
B     2.896420
C     0.377923
dtype: float64

# these are equivalent to a ``.sum()`` because we are aggregating
# on a single function
In [161]: tsdf.sum()
Out [161]:
A    -0.118055
B     2.896420
C     0.377923
dtype: float64
```

Single aggregations on a Series this will return a scalar value:

```
In [162]: tsdf.A.agg('sum')
Out [162]: -0.11805495013260869
```

### Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

```
In [163]: tsdf.agg(['sum'])
Out [163]:
      A      B      C
sum -0.118055  2.89642  0.377923
```

Multiple functions yield multiple rows:

```
In [164]: tsdf.agg(['sum', 'mean'])
Out [164]:
      A      B      C
sum -0.118055  2.896420  0.377923
mean -0.019676  0.482737  0.062987
```

On a Series, multiple functions return a Series, indexed by the function names:

```
In [165]: tsdf.A.agg(['sum', 'mean'])
Out[165]:
sum      -0.118055
mean     -0.019676
Name: A, dtype: float64
```

Passing a lambda function will yield a <lambda> named row:

```
In [166]: tsdf.A.agg(['sum', lambda x: x.mean()])
Out[166]:
sum      -0.118055
<lambda> -0.019676
Name: A, dtype: float64
```

Passing a named function will yield that name for the row:

```
In [167]: def mymean(x):
.....:     return x.mean()
.....:

In [168]: tsdf.A.agg(['sum', mymean])
Out[168]:
sum      -0.118055
mymean   -0.019676
Name: A, dtype: float64
```

## Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```
In [169]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[169]:
A      -0.019676
B       2.896420
dtype: float64
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

```
In [170]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[170]:
      A      B
mean -0.019676  NaN
min  -0.522441  NaN
sum      NaN  2.89642
```

## Mixed Dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `groupby` `.agg` works.

```
In [171]: mdf = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [1., 2., 3.],
.....:                      'C': ['foo', 'bar', 'baz'],
.....:                      'D': pd.date_range('20130101', periods=3)})
.....:
```

```
In [172]: mdf.dtypes
```

```
Out [172]:
A          int64
B          float64
C          object
D    datetime64[ns]
dtype: object
```

```
In [173]: mdf.agg(['min', 'sum'])
```

```
Out [173]:
   A    B    C    D
min 1  1.0  bar 2013-01-01
sum 6  6.0 foobarbaz      NaT
```

## Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in `describe` function.

```
In [174]: from functools import partial
```

```
In [175]: q_25 = partial(pd.Series.quantile, q=0.25)
```

```
In [176]: q_25.__name__ = '25%'
```

```
In [177]: q_75 = partial(pd.Series.quantile, q=0.75)
```

```
In [178]: q_75.__name__ = '75%'
```

```
In [179]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
```

```
Out [179]:
   count      A      B      C
mean -0.019676  0.482737  0.062987

max    0.531797  1.659115  0.833297
```

## Transform API

New in version 0.20.0.

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```
In [180]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [181]: tsdf.iloc[3:7] = np.nan
```

```
In [182]: tsdf
```

```
Out [182]:
```

	A	B	C
2000-01-01	-1.219234	-1.652700	-0.698277
2000-01-02	1.858653	-0.738520	0.630364
2000-01-03	-0.112596	1.525897	1.364225
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	-0.527790	-1.715506	0.387274
2000-01-09	-0.569341	0.569386	0.134136
2000-01-10	-0.413993	-0.862280	0.662690

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [183]: tsdf.transform(np.abs)
```

```
Out [183]:
```

2000-01-01	1.219234	1.652700	0.698277

(continues on next page)

(continued from previous page)

2000-01-02	1.858653	0.738520	0.630364
2000-01-03	0.112596	1.525897	1.364225
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	0.527790	1.715506	0.387274
2000-01-09	0.569341	0.569386	0.134136
2000-01-10	0.413993	0.862280	0.662690

Here `transform()` received a single function; this is equivalent to a `ufunc` application.

```
In [186]: np.abs(tsd)
Out [186]:
```

	A	B	C
2000-01-01	1.219234	1.652700	0.698277
2000-01-02	1.858653	0.738520	0.630364
2000-01-03	0.112596	1.525897	1.364225
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	0.527790	1.715506	0.387274
2000-01-09	0.569341	0.569386	0.134136
2000-01-10	0.413993	0.862280	0.662690

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.

```
In [187]: tsdf.A.transform(np.abs)
Out [187]:
```

2000-01-01	1.219234
2000-01-02	1.858653
2000-01-03	0.112596
2000-01-04	NaN
2000-01-05	NaN
2000-01-06	NaN
2000-01-07	NaN
2000-01-08	0.527790
2000-01-09	0.569341
2000-01-10	0.413993

Freq: D, Name: A, dtype: float64

### Transform with multiple functions

Passing multiple functions will yield a column `MultiIndexed DataFrame`. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```
In [188]: tsdf.transform([np.abs, lambda x: x + 1])
Out [188]:
```

	A		B		C	
	absolute	<lambda>	absolute	<lambda>	absolute	<lambda>
2000-01-01	1.219234	-0.219234	1.652700	-0.652700	0.698277	0.301723
2000-01-02	1.858653	2.858653	0.738520	0.261480	0.630364	1.630364
2000-01-03	0.112596	0.887404	1.525897	2.525897	1.364225	2.364225
2000-01-04	NaN	NaN	NaN	NaN	NaN	NaN

(continues on next page)

(continued from previous page)

2000-01-05	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-08	0.527790	0.472210	1.715506	-0.715506	0.387274	1.387274
2000-01-09	0.569341	0.430659	0.569386	1.569386	0.134136	1.134136
2000-01-10	0.413993	0.586007	0.862280	0.137720	0.662690	1.662690

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```
In [189]: tsdf.A.transform([np.abs, lambda x: x + 1])
```

```
Out [189]:
```

	absolute	<lambda>
2000-01-01	1.219234	-0.219234
2000-01-02	1.858653	2.858653
2000-01-03	0.112596	0.887404
2000-01-04	NaN	NaN
2000-01-05	NaN	NaN
2000-01-06	NaN	NaN
2000-01-07	NaN	NaN
2000-01-08	0.527790	0.472210
2000-01-09	0.569341	0.430659
2000-01-10	0.413993	0.586007

### Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```
In [190]: tsdf.transform({'A': np.abs, 'B': lambda x: x + 1})
```

```
Out [190]:
```

	A	B
2000-01-01	1.219234	-0.652700
2000-01-02	1.858653	0.261480
2000-01-03	0.112596	2.525897
2000-01-04	NaN	NaN
2000-01-05	NaN	NaN
2000-01-06	NaN	NaN
2000-01-07	NaN	NaN
2000-01-08	0.527790	-0.715506
2000-01-09	0.569341	1.569386
2000-01-10	0.413993	0.137720

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [191]: tsdf.transform({'A': np.abs, 'B': [lambda x: x + 1, 'sqrt']})
```

```
Out [191]:
```

	A	B	
	absolute	<lambda>	sqrt
2000-01-01	1.219234	-0.652700	NaN
2000-01-02	1.858653	0.261480	NaN
2000-01-03	0.112596	2.525897	1.235272
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN

(continues on next page)

(continued from previous page)

```
2000-01-08  0.527790 -0.715506      NaN
2000-01-09  0.569341  1.569386  0.754577
2000-01-10  0.413993  0.137720      NaN
```

### Applying Elementwise Functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [192]: df4
Out[192]:
      one      two      three
a  1.400810 -1.643041      NaN
b -0.356470  1.045911  0.395023
c  0.797268  0.924515 -0.007090
d           NaN  1.553693 -1.670830

In [193]: def f(x):
.....:     return len(str(x))
.....:

In [194]: df4['one'].map(f)
Out[194]:
a      18
b      19
c      18
d       3
Name: one, dtype: int64

In [195]: df4.applymap(f)
Out[195]:
      one  two  three
a     18   19     3
b     19   18    19
c     18   18    21
d      3   18    19
```

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```
In [196]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
.....:                  index=['a', 'b', 'c', 'd', 'e'])
.....:

In [197]: t = pd.Series({'six': 6., 'seven': 7.})

In [198]: s
Out[198]:
a      six
b     seven
c      six
d     seven
e      six
dtype: object
```

(continues on next page)

(continued from previous page)

```

In [199]: s.map(t)
Out [199]:
↪
a      6.0
b      7.0
c      6.0
d      7.0
e      6.0
dtype: float64

```

### 3.3.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, **fill** data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```

In [200]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [201]: s
Out [201]:
a      -0.368437
b      -0.036473
c       0.774830
d      -0.310545
e       0.709717
dtype: float64

In [202]: s.reindex(['e', 'b', 'f', 'd'])
Out [202]:
↪
e       0.709717
b      -0.036473
f           NaN
d      -0.310545
dtype: float64

```

Here, the `f` label was not contained in the Series and hence appears as `NaN` in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```

In [203]: df
Out [203]:
      one      two      three
a  1.400810 -1.643041      NaN
b -0.356470  1.045911  0.395023
c  0.797268  0.924515 -0.007090
d         NaN  1.553693 -1.670830

```

(continues on next page)

(continued from previous page)

```
In [204]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
////////////////////////////////////
↪
      three      two      one
c -0.007090  0.924515  0.797268
f          NaN          NaN          NaN
b  0.395023  1.045911 -0.356470
```

You may also use `reindex` with an `axis` keyword:

```
In [205]: df.reindex(['c', 'f', 'b'], axis='index')
Out [205]:
      one      two      three
c  0.797268  0.924515 -0.007090
f          NaN          NaN          NaN
b -0.356470  1.045911  0.395023
```

Note that the Index objects containing the actual axis labels can be **shared** between objects. So if we have a Series and a DataFrame, the following can be done:

```
In [206]: rs = s.reindex(df.index)

In [207]: rs
Out [207]:
a   -0.368437
b   -0.036473
c    0.774830
d   -0.310545
dtype: float64

In [208]: rs.index is df.index
////////////////////////////////////Out [208]: ↪
↪True
```

This means that the reindexed Series’s index is the same Python object as the DataFrame’s index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single labels argument and the axis it applies to.

```
In [209]: df.reindex(['c', 'f', 'b'], axis='index')
Out [209]:
      one      two      three
c  0.797268  0.924515 -0.007090
f          NaN          NaN          NaN
b -0.356470  1.045911  0.395023

In [210]: df.reindex(['three', 'two', 'one'], axis='columns')
////////////////////////////////////
↪
      three      two      one
a          NaN -1.643041  1.400810
b  0.395023  1.045911 -0.356470
c -0.007090  0.924515  0.797268
d -1.670830  1.553693          NaN
```

**See also:**

*MultiIndex / Advanced Indexing* is an even more concise way of doing reindexing.

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

**Reindexing to align with another object**

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [211]: df2
Out[211]:
```

	one	two
a	1.400810	-1.643041
b	-0.356470	1.045911
c	0.797268	0.924515

```
In [212]: df3
```

```

////////////////////////////////////
↪

```

	one	two
a	0.786941	-1.752170
b	-0.970339	0.936783
c	0.183399	0.815387

```
In [213]: df.reindex_like(df2)
////////////////////////////////////
↪

```

	one	two
a	1.400810	-1.643041
b	-0.356470	1.045911
c	0.797268	0.924515

**Aligning objects with each other with `align`**

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```
In [214]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

(continues on next page)

(continued from previous page)

```
In [215]: s1 = s[:4]
```

```
In [216]: s2 = s[1:]
```

```
In [217]: s1.align(s2)
```

```
Out [217]:
```

```
(a  -0.610263
 b  -0.170883
 c   0.367255
 d   0.273860
 e         NaN
 dtype: float64, a         NaN
 b  -0.170883
 c   0.367255
 d   0.273860
 e   0.314782
 dtype: float64)
```

```
In [218]: s1.align(s2, join='inner')
```

```
////////////////////////////////////
↪
(b  -0.170883
 c   0.367255
 d   0.273860
 dtype: float64, b  -0.170883
 c   0.367255
 d   0.273860
 dtype: float64)
```

```
In [219]: s1.align(s2, join='left')
```

```
////////////////////////////////////
↪
(a  -0.610263
 b  -0.170883
 c   0.367255
 d   0.273860
 dtype: float64, a         NaN
 b  -0.170883
 c   0.367255
 d   0.273860
 dtype: float64)
```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [220]: df.align(df2, join='inner')
```

```
Out [220]:
```

```
(      one      two
a  1.400810 -1.643041
b -0.356470  1.045911
c  0.797268  0.924515,      one      two
a  1.400810 -1.643041
b -0.356470  1.045911
c  0.797268  0.924515)
```

You can also pass an `axis` option to only align on the specified axis:

```
In [221]: df.align(df2, join='inner', axis=0)
Out [221]:
(
   one      two      three
a  1.400810 -1.643041      NaN
b -0.356470  1.045911  0.395023
c  0.797268  0.924515 -0.007090,      one      two
a  1.400810 -1.643041
b -0.356470  1.045911
c  0.797268  0.924515)
```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame's index or columns using the `axis` argument:

```
In [222]: df.align(df2.iloc[0], axis=1)
Out [222]:
(
   one      three      two
a  1.400810      NaN -1.643041
b -0.356470  0.395023  1.045911
c  0.797268 -0.007090  0.924515
d      NaN -1.670830  1.553693, one      1.400810
three      NaN
two      -1.643041
Name: a, dtype: float64)
```

### Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward
nearest	Fill from the nearest index value

We illustrate these fill methods on a simple Series:

```
In [223]: rng = pd.date_range('1/3/2000', periods=8)
In [224]: ts = pd.Series(np.random.randn(8), index=rng)
In [225]: ts2 = ts[[0, 3, 6]]

In [226]: ts
Out [226]:
2000-01-03    -0.082578
2000-01-04     0.768554
2000-01-05     0.398842
2000-01-06    -0.357956
2000-01-07     0.156403
2000-01-08    -1.347564
2000-01-09     0.253506
2000-01-10     1.228964
Freq: D, dtype: float64

In [227]: ts2
```

(continues on next page)

(continued from previous page)

```
Freq: D, dtype: float64
```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using *fillna* (except for `method='nearest'`) or *interpolate*:

```
In [232]: ts2.reindex(ts.index).fillna(method='ffill')
```

```
Out [232]:
```

```
2000-01-03    -0.082578
2000-01-04    -0.082578
2000-01-05    -0.082578
2000-01-06    -0.357956
2000-01-07    -0.357956
2000-01-08    -0.357956
2000-01-09     0.253506
2000-01-10     0.253506
Freq: D, dtype: float64
```

*reindex()* will raise a `ValueError` if the index is not monotonically increasing or decreasing. *fillna()* and *interpolate()* will not perform any checks on the order of the index.

### Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [233]: ts2.reindex(ts.index, method='ffill', limit=1)
```

```
Out [233]:
```

```
2000-01-03    -0.082578
2000-01-04    -0.082578
2000-01-05         NaN
2000-01-06    -0.357956
2000-01-07    -0.357956
2000-01-08         NaN
2000-01-09     0.253506
2000-01-10     0.253506
Freq: D, dtype: float64
```

In contrast, `tolerance` specifies the maximum distance between the index and indexer values:

```
In [234]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
```

```
Out [234]:
```

```
2000-01-03    -0.082578
2000-01-04    -0.082578
2000-01-05         NaN
2000-01-06    -0.357956
2000-01-07    -0.357956
2000-01-08         NaN
2000-01-09     0.253506
2000-01-10     0.253506
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

(continued from previous page)

```
E    0.314782
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [241]: df.rename(columns={'one': 'foo', 'two': 'bar'},
.....:                index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
.....:
Out [241]:
```

	foo	bar	three
apple	1.400810	-1.643041	NaN
banana	-0.356470	1.045911	0.395023
c	0.797268	0.924515	-0.007090
durian	NaN	1.553693	-1.670830

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [242]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out [242]:
```

	foo	bar	three
a	1.400810	-1.643041	NaN
b	-0.356470	1.045911	0.395023
c	0.797268	0.924515	-0.007090
d	NaN	1.553693	-1.670830

```
In [243]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
////////////////////////////////////
↪
```

	one	two	three
apple	1.400810	-1.643041	NaN
banana	-0.356470	1.045911	0.395023
c	0.797268	0.924515	-0.007090
durian	NaN	1.553693	-1.670830

The `rename()` method also provides an inplace named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

New in version 0.18.0.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```
In [244]: s.rename("scalar-name")
Out [244]:
```

a	-0.610263
b	-0.170883
c	0.367255
d	0.273860
e	0.314782

```
Name: scalar-name, dtype: float64
```

New in version 0.24.0.

The methods `rename_axis()` and `rename_index()` allow specific names of a *MultiIndex* to be changed (as opposed to the labels).

```
In [245]: df = pd.DataFrame({'x': [1, 2, 3, 4, 5, 6],
.....:                    'y': [10, 20, 30, 40, 50, 60]},
.....:                    index=pd.MultiIndex.from_product(['a', 'b', 'c'], [1, 2]),
.....:                    names=['let', 'num'])

In [246]: df
Out[246]:
```

	let	num	x	y
a	1	1	10	1
	2	2	20	2
b	1	3	30	3
	2	4	40	4
c	1	5	50	5
	2	6	60	6

```
In [247]: df.rename_axis(index={'let': 'abc'})
Out[247]:
```

	abc	num	x	y
a	1	1	10	1
	2	2	20	2
b	1	3	30	3
	2	4	40	4
c	1	5	50	5
	2	6	60	6

```
In [248]: df.rename_axis(index=str.upper)
Out[248]:
```

	LET	NUM	x	y
a	1	1	10	1
	2	2	20	2
b	1	3	30	3
	2	4	40	4
c	1	5	50	5
	2	6	60	6

### 3.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. Other data structures, like DataFrame and Panel, follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series:** values
- **DataFrame:** column labels
- **Panel:** item labels

Thus, for example, iterating over a DataFrame gives you the column names:

```
In [249]: df = pd.DataFrame({'col1': np.random.randn(3),
.....:                      'col2': np.random.randn(3)}, index=['a', 'b', 'c'])
.....:

In [250]: for col in df:
.....:     print(col)
.....:
col1
col2
```

Pandas objects also have the dict-like `iteritems()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on *function application*.
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the *enhancing performance* section for some examples of this approach.

**Warning:** You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [251]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [252]: for index, row in df.iterrows():
.....:     row['a'] = 10
.....:

In [253]: df
Out[253]:
   a  b
0  1  a
1  2  b
2  3  c
```

## iteritems

Consistent with the dict-like interface, `iteritems()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs
- **Panel:** (item, DataFrame) pairs

For example:

```
In [254]: for item, frame in wp.iteritems():
.....:     print(item)
.....:     print(frame)
.....:
```

Item1

	A	B	C	D
2000-01-01	-1.157892	-1.344312	0.844885	1.075770
2000-01-02	-0.109050	1.643563	-1.469388	0.357021
2000-01-03	-0.674600	-1.776904	-0.968914	-1.294524
2000-01-04	0.413738	0.276662	-0.472035	-0.013960
2000-01-05	-0.362543	-0.006154	-0.923061	0.895717

Item2

	A	B	C	D
2000-01-01	0.805244	-1.206412	2.565646	1.431256
2000-01-02	1.340309	-1.170299	-0.226169	0.410835
2000-01-03	0.813850	0.132003	-0.827317	-0.076467
2000-01-04	-1.187678	1.130127	-1.436737	-1.413681
2000-01-05	1.607920	1.024180	0.569605	0.875906

## iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [255]: for row_index, row in df.iterrows():
.....:     print(row_index, row, sep='\n')
.....:
```

0  
a 1  
b a  
Name: 0, dtype: object

1  
a 2  
b b  
Name: 1, dtype: object

2  
a 3  
b c  
Name: 2, dtype: object

**Note:** Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [256]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [257]: df_orig.dtypes
Out[257]:
int          int64
```

(continues on next page)

(continued from previous page)

```
float    float64
dtype: object

In [258]: row = next(df_orig.iterrows())[1]

In [259]: row
Out[259]:
int      1.0
float    1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a `Series`, are now upcasted to floats, also the original integer value in column `x`:

```
In [260]: row['int'].dtype
Out[260]: dtype('float64')

In [261]: df_orig['int'].dtype
Out[261]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns `namedtuples` of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the `DataFrame` would be:

```
In [262]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})

In [263]: print(df2)
   x  y
0  1  4
1  2  5
2  3  6

In [264]: print(df2.T)
      0  1  2
x  1  2  3
y  4  5  6

In [265]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [266]: print(df2_t)
   0  1  2
x  1  2  3
y  4  5  6
```

## itertuples

The `itertuples()` method will return an iterator yielding a `namedtuple` for each row in the `DataFrame`. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [267]: for row in df.itertuples():
.....:     print(row)
.....:
```

(continues on next page)

```
In [273]: s[s.dt.day == 2]
Out [273]:
1    2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produces tz aware transformations:

```
In [274]: stz = s.dt.tz_localize('US/Eastern')
```

```
In [275]: stz
Out [275]:
0    2013-01-01 09:10:12-05:00
1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

```
In [276]: stz.dt.tz
\\
\\
\\
↪ <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>
```

You can also chain these types of operations:

```
In [277]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out [277]:
0    2013-01-01 04:10:12-05:00
1    2013-01-02 04:10:12-05:00
2    2013-01-03 04:10:12-05:00
3    2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
In [278]: s = pd.Series(pd.date_range('20130101', periods=4))

In [279]: s
Out [279]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]
```

```
In [280]: s.dt.strftime('%Y/%m/%d')
\\
\\
\\
↪
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object
```

```
# PeriodIndex
In [281]: s = pd.Series(pd.period_range('20130101', periods=4))
```

(continues on next page)

(continued from previous page)

```

In [282]: s
Out[282]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: period[D]

In [283]: s.dt.strftime('%Y/%m/%d')
Out[283]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object

```

The `.dt` accessor works for period and timedelta dtypes.

```

# period
In [284]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [285]: s
Out[285]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: period[D]

In [286]: s.dt.year
Out[286]:

In [292]: s.dt.components
```

```

////////////////////////////////////
↪
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     1     0         0         5             0             0             0
1     1     0         0         6             0             0             0
2     1     0         0         7             0             0             0
3     1     0         0         8             0             0             0
```

---

**Note:** `Series.dt` will raise a `TypeError` if you access with a non-datetime-like values.

---

### 3.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [293]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog',
↪                    'cat'])
```

```
In [294]: s.str.lower()
```

```
Out [294]:
0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses [regular expressions](#) by default (and in some cases always uses them).

Please see *Vectorized String Methods* for a complete description.

### 3.3.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

#### By Index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [295]: df = pd.DataFrame({
.....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
.....:     'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
.....:     'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])})
.....:

In [296]: unsorted_df = df.reindex(index=['a', 'd', 'c', 'b'],
.....:                               columns=['three', 'two', 'one'])
.....:

In [297]: unsorted_df
Out[297]:
      three    two    one
a      NaN -0.867293  0.050162
d  1.215473 -0.051744    NaN
c -0.421091 -0.712097  0.953102
b  1.205223  0.632624 -1.534113

# DataFrame
In [298]: unsorted_df.sort_index()
\//////////////////////////////////////////////////////////////////////////////////////
↩
      three    two    one
a      NaN -0.867293  0.050162
b  1.205223  0.632624 -1.534113
c -0.421091 -0.712097  0.953102
d  1.215473 -0.051744    NaN

In [299]: unsorted_df.sort_index(ascending=False)
\//////////////////////////////////////////////////////////////////////////////////////
↩
      three    two    one
d  1.215473 -0.051744    NaN
c -0.421091 -0.712097  0.953102
b  1.205223  0.632624 -1.534113
a      NaN -0.867293  0.050162

In [300]: unsorted_df.sort_index(axis=1)
\//////////////////////////////////////////////////////////////////////////////////////
↩
      one    three    two
```

(continues on next page)

(continued from previous page)

```

a  0.050162      NaN -0.867293
d      NaN  1.215473 -0.051744
c  0.953102 -0.421091 -0.712097
b -1.534113  1.205223  0.632624

# Series
In [301]: unsorted_df['three'].sort_index()
/////////////////////////////////////////////////
↪
a      NaN
b  1.205223
c -0.421091
d  1.215473
Name: three, dtype: float64

```

### By Values

The `Series.sort_values()` method is used to sort a `Series` by its values. The `DataFrame.sort_values()` method is used to sort a `DataFrame` by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```

In [302]: df1 = pd.DataFrame({'one': [2, 1, 1, 1],
.....:                       'two': [1, 3, 2, 4],
.....:                       'three': [5, 4, 3, 2]})

In [303]: df1.sort_values(by='two')
Out [303]:
   one  two  three
0     2    1     5
2     1    2     3
1     1    3     4
3     1    4     2

```

The `by` parameter can take a list of column names, e.g.:

```

In [304]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
Out [304]:
   one  two  three
2     1    2     3
1     1    3     4
3     1    4     2
0     2    1     5

```

These methods have special treatment of NA values via the `na_position` argument:

```

In [305]: s[2] = np.nan

In [306]: s.sort_values()
Out [306]:
0     A
3  Aaba
1     B
4  Baca
6  CABA

```

(continues on next page)

(continued from previous page)

```

8    cat
7    dog
2    NaN
5    NaN
dtype: object

```

```
In [307]: s.sort_values(na_position='first')
```

```

////////////////////////////////////
↪
2    NaN
5    NaN
0    A
3    Aaba
1    B
4    Baca
6    CABA
8    cat
7    dog
dtype: object

```

## By Indexes and Values

New in version 0.23.0.

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```

# Build MultiIndex
In [308]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....:                                   ('b', 2), ('b', 1), ('b', 1)])
.....:

In [309]: idx.names = ['first', 'second']

# Build DataFrame
In [310]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....:                             index=idx)
.....:

In [311]: df_multi
Out [311]:

```

	first	second	A
a	1	2	6
	2	2	5
	2	1	4
b	2	2	3
	1	2	2
	1	1	1

Sort by 'second' (index) and 'A' (column)

```
In [312]: df_multi.sort_values(by=['second', 'A'])
```

```
Out [312]:
      A
      1
```

(continues on next page)

(continued from previous page)

first	second	
b	1	1
	1	2
a	1	6
b	2	3
a	2	4
	2	5

**Note:** If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [313]: ser = pd.Series([1, 2, 3])

In [314]: ser.searchsorted([0, 3])
Out[314]: array([0, 2])

In [315]: ser.searchsorted([0, 4])
Out[315]: array([0, 3])

In [316]: ser.searchsorted([1, 3], side='right')
Out[316]: array([1, 3])

In [317]: ser.searchsorted([1, 3], side='left')
Out[317]:
array([0, 2])

In [318]: ser = pd.Series([3, 1, 2])

In [319]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[319]: array([0, 2])
```

### smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest  $n$  values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [320]: s = pd.Series(np.random.permutation(10))

In [321]: s
Out[321]:
0    5
1    3
2    2
3    0
4    7
5    6
6    9
7    1
```

(continues on next page)

(continued from previous page)

```

8      4
9      8
dtype: int64

In [322]: s.sort_values()
\\Out [322]:
↪
3      0
7      1
2      2
1      3
8      4
0      5
5      6
4      7
9      8
6      9
dtype: int64

In [323]: s.nsmallest(3)
\\Out [323]:
↪
3      0
7      1
2      2
dtype: int64

In [324]: s.nlargest(3)
\\Out [324]:
↪
6      9
9      8
4      7
dtype: int64

```

DataFrame also has the `nlargest` and `nsmallest` methods.

```

In [325]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
.....:                      'b': list('abdceff'),
.....:                      'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})
.....:

In [326]: df.nlargest(3, 'a')
Out [326]:
   a  b  c
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN

In [327]: df.nlargest(5, ['a', 'c'])
\\Out [327]:
   a  b  c
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN
2   1 d  4.0
6  -1 f  4.0

```

(continues on next page)

(continued from previous page)

```
In [328]: df.nsmallest(3, 'a')
```

```

////////////////////////////////////
↪
   a  b   c
0 -2  a  1.0
1 -1  b  2.0
6 -1  f  4.0

```

```
In [329]: df.nsmallest(5, ['a', 'c'])
```

```

////////////////////////////////////
↪
   a  b   c
0 -2  a  1.0
1 -1  b  2.0
6 -1  f  4.0
2  1  d  4.0
4  8  e  NaN

```

### Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to `by`.

```
In [330]: df1.columns = pd.MultiIndex.from_tuples([('a', 'one'),
.....:                                          ('a', 'two'),
.....:                                          ('b', 'three')])
.....:
```

```
In [331]: df1.sort_values(by=('a', 'two'))
```

```
Out [331]:
```

```

   a      b
  one two three
0  2  1     5
2  1  2     3
1  1  3     4
3  1  4     2

```

### 3.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

### 3.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64 [ns]` and `datetime64 [ns]` (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries *extend* NumPy's type system in a few places. This section describes the extensions pandas has made internally. See *Extension Types* for how to write your own extension that works with pandas. See *Extension Data Types* for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. See the respective documentation sections for more on each type.

Kind of Data	Data Type	Scalar	Array	Documentation
tz-aware date-time	<code>DatetimeTZDtype</code>	<code>Timestamp</code>	<code>arrays.</code> <code>DatetimeArray</code>	<i>Time Zone Handling</i>
Categorical	<code>CategoricalDtype</code>	(none)	<code>Categorical</code>	<i>Categorical Data</i>
period (time spans)	<code>PeriodDtype</code>	<code>Period</code>	<code>arrays.</code> <code>PeriodArray</code>	<i>Time Span Representation</i>
sparse	<code>SparseDtype</code>	(none)	<code>arrays.</code> <code>SparseArray</code>	<i>Sparse data structures</i>
intervals	<code>IntervalDtype</code>	<code>Interval</code>	<code>arrays.</code> <code>IntervalArray</code>	<i>IntervalIndex</i>
nullable integer	<code>Int64Dtype, ...</code>	(none)	<code>arrays.</code> <code>IntegerArray</code>	<i>Nullable Integer Data Type</i>

Pandas uses the `object` dtype for storing strings.

Finally, arbitrary objects may be stored using the `object` dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See *object conversion*).

A convenient `dtypes` attribute for DataFrame returns a Series with the data type of each column.

```
In [332]: dft = pd.DataFrame({'A': np.random.rand(3),
.....:                       'B': 1,
.....:                       'C': 'foo',
.....:                       'D': pd.Timestamp('20010102'),
.....:                       'E': pd.Series([1.0] * 3).astype('float32'),
.....:                       'F': False,
.....:                       'G': pd.Series([1] * 3, dtype='int8')})

In [333]: dft
Out[333]:
   A      B    C      D      E      F      G
0  0.278831  1  foo  2001-01-02  1.0  False  1
1  0.242124  1  foo  2001-01-02  1.0  False  1
2  0.078031  1  foo  2001-01-02  1.0  False  1

In [334]: dft.dtypes
A      float64
B      int64
C      object
D      datetime64[ns]
E      float32
```

(continues on next page)

(continued from previous page)

```
F          bool
G          int8
dtype: object
```

On a Series object, use the `dtype` attribute.

```
In [335]: dft['A'].dtype
Out [335]: dtype('float64')
```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

```
# these ints are coerced to floats
In [336]: pd.Series([1, 2, 3, 4, 5, 6.])
Out [336]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an ``object`` dtype
In [337]: pd.Series([1, 2, 3, 6., 'foo'])
Out [337]:
0    1
1    2
2    3
3    6
4    foo
dtype: object
```

The number of columns of each type in a DataFrame can be found by calling `get_dtype_counts()`.

```
In [338]: dft.get_dtype_counts()
Out [338]:
float64      1
float32      1
int64        1
int8         1
datetime64[ns] 1
bool         1
object       1
dtype: int64
```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [339]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
In [340]: df1
Out [340]:
A
```

(continues on next page)

(continued from previous page)

```
In [347]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
\\Out [347]:
a      int64
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [348]: frame = pd.DataFrame(np.array([1, 2]))
```

## upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```
In [349]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

```
In [350]: df3
```

```
Out [350]:
```

	A	B	C
0	-1.510602	-1.143729	1.0
1	-0.024511	2.787500	0.0
2	-0.088385	-0.708143	254.0
3	1.158101	-1.512388	0.0
4	-0.867039	-0.243145	1.0
5	-2.852354	-0.650992	0.0
6	2.524329	2.090108	0.0
7	-1.895793	0.433098	0.0

```
In [351]: df3.dtypes
```

```
\\Out [351]:
↔
A      float32
B      float64
C      float64
dtype: object
```

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous typed NumPy array. This can force some *upcasting*.

```
In [352]: df3.to_numpy().dtype
```

```
Out [352]: dtype('float64')
```

## astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the `astype` operation is invalid.

Upcasting is always according to the **numpy** rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [353]: df3
Out [353]:
```

	A	B	C
0	-1.510602	-1.143729	1.0
1	-0.024511	2.787500	0.0
2	-0.088385	-0.708143	254.0
3	1.158101	-1.512388	0.0
4	-0.867039	-0.243145	1.0
5	-2.852354	-0.650992	0.0
6	2.524329	2.090108	0.0
7	-1.895793	0.433098	0.0

```
In [354]: df3.dtypes
```

```

\-----\
↪
A      float32
B      float64
C      float64
dtype: object

```

```
# conversion of dtypes
```

```
In [355]: df3.astype('float32').dtypes
```

```

\-----\
↪
A      float32
B      float32
C      float32
dtype: object

```

Convert a subset of columns to a specified type using `astype()`.

```
In [356]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [357]: dft[['a', 'b']] = dft[['a', 'b']].astype(np.uint8)
```

```
In [358]: dft
```

```
Out [358]:
```

	a	b	c
0	1	4	7
1	2	5	8
2	3	6	9

```
In [359]: dft.dtypes
```

```

\-----\Out [359]:
a      uint8
b      uint8
c      int64
dtype: object

```

New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```
In [360]: dft1 = pd.DataFrame({'a': [1, 0, 1], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [361]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})
```

```
In [362]: dft1
```

(continues on next page)

(continued from previous page)

```

Out [362]:
   a  b  c
0  True  4  7.0
1  False 5  8.0
2  True  6  9.0

In [363]: dft1.dtypes
\Out [363]:
↪
a      bool
b      int64
c      float64
dtype: object

```

**Note:** When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs.

`loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```

In [364]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [365]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
Out [365]:
a      uint8
b      uint8
dtype: object

In [366]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)

In [367]: dft.dtypes
Out [367]:
a      int64
b      int64
c      int64
dtype: object

```

### object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```

In [368]: import datetime

In [369]: df = pd.DataFrame([[1, 2],
.....:                      ['a', 'b'],
.....:                      [datetime.datetime(2016, 3, 2),
.....:                      datetime.datetime(2016, 3, 2)]]

In [370]: df = df.T

In [371]: df

```

(continues on next page)

(continued from previous page)

```
Out [371]:
   0  1          2
0  1  a  2016-03-02 00:00:00
1  2  b  2016-03-02 00:00:00
```

```
In [372]: df.dtypes
```

```
////////////////////////////////////
↪
0    object
1    object
2    object
dtype: object
```

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```
In [373]: df.infer_objects().dtypes
```

```
Out [373]:
0          int64
1          object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```
In [374]: m = ['1.1', 2, 3]
```

```
In [375]: pd.to_numeric(m)
```

```
Out [375]: array([ 1.1,  2. ,  3. ])
```

- `to_datetime()` (conversion to datetime objects)

```
In [376]: import datetime
```

```
In [377]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]
```

```
In [378]: pd.to_datetime(m)
```

```
Out [378]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]',
↪ freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```
In [379]: m = ['5us', pd.Timedelta('1day')]
```

```
In [380]: pd.to_timedelta(m)
```

```
Out [380]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype=
↪ 'timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```

In [381]: import datetime

In [382]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [383]: pd.to_datetime(m, errors='coerce')
Out[383]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [384]: m = ['apple', 2, 3]

In [385]: pd.to_numeric(m, errors='coerce')
Out[385]: array([ nan,   2.,   3.])

In [386]: m = ['apple', pd.Timedelta('1day')]

In [387]: pd.to_timedelta(m, errors='coerce')
Out[387]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)

```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```

In [388]: import datetime

In [389]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [390]: pd.to_datetime(m, errors='ignore')
Out[390]: Index(['apple', '2016-03-02 00:00:00'], dtype='object')

In [391]: m = ['apple', 2, 3]

In [392]: pd.to_numeric(m, errors='ignore')
Out[392]: array(['apple', 2, 3], dtype=object)

In [393]: m = ['apple', pd.Timedelta('1day')]

In [394]: pd.to_timedelta(m, errors='ignore')
Out[394]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)

```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```

In [395]: m = ['1', 2, 3]

In [396]: pd.to_numeric(m, downcast='integer') # smallest signed int dtype
Out[396]: array([1, 2, 3], dtype=int8)

In [397]: pd.to_numeric(m, downcast='signed') # same as 'integer'
Out[397]: array([1, 2, 3], dtype=int8)

In [398]: pd.to_numeric(m, downcast='unsigned') # smallest unsigned int dtype
Out[398]: array([1, 2, 3], dtype=uint8)

In [399]: pd.to_numeric(m, downcast='float') # smallest float dtype
Out[399]: array([ 1.,  2.,  3.], dtype=float32)

```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column

efficiently:

```
In [400]: import datetime

In [401]: df = pd.DataFrame([
.....:     ['2016-07-09', datetime.datetime(2016, 3, 2)] * 2, dtype='O')
.....:

In [402]: df
Out[402]:
           0           1
0  2016-07-09  2016-03-02 00:00:00
1  2016-07-09  2016-03-02 00:00:00

In [403]: df.apply(pd.to_datetime)
////////////////////////////////////Out[403]:
↔
           0           1
0  2016-07-09  2016-03-02
1  2016-07-09  2016-03-02

In [404]: df = pd.DataFrame([['1.1', 2, 3]] * 2, dtype='O')

In [405]: df
Out[405]:
           0  1  2
0  1.1  2  3
1  1.1  2  3

In [406]: df.apply(pd.to_numeric)
////////////////////////////////////Out[406]:
           0  1  2
0  1.1  2  3
1  1.1  2  3

In [407]: df = pd.DataFrame(['5us', pd.Timedelta('1day')] * 2, dtype='O')

In [408]: df
Out[408]:
           0           1
0  5us  1 days 00:00:00
1  5us  1 days 00:00:00

In [409]: df.apply(pd.to_timedelta)
////////////////////////////////////Out[409]:
↔
           0           1
0  00:00:00.000005  1 days
1  00:00:00.000005  1 days
```

### gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also *Support for integer NA*.

```
In [410]: dfi = df3.astype('int32')
```

```
In [411]: dfi['E'] = 1
```

```
In [412]: dfi
```

```
Out [412]:
```

	A	B	C	E
0	-1	-1	1	1
1	0	2	0	1
2	0	0	254	1
3	1	-1	0	1
4	0	0	1	1
5	-2	0	0	1
6	2	2	0	1
7	-1	0	0	1

```
In [413]: dfi.dtypes
```

```

////////////////////////////////////
↪
A      int32
B      int32
C      int32
E      int64
dtype: object
```

```
In [414]: casted = dfi[dfi > 0]
```

```
In [415]: casted
```

```
Out [415]:
```

	A	B	C	E
0	NaN	NaN	1.0	1
1	NaN	2.0	NaN	1
2	NaN	NaN	254.0	1
3	1.0	NaN	NaN	1
4	NaN	NaN	1.0	1
5	NaN	NaN	NaN	1
6	2.0	2.0	NaN	1
7	NaN	NaN	NaN	1

```
In [416]: casted.dtypes
```

```

////////////////////////////////////
↪
A      float64
B      float64
C      float64
E      int64
dtype: object
```

While float dtypes are unchanged.

```
In [417]: dfa = df3.copy()
```

```
In [418]: dfa['A'] = dfa['A'].astype('float32')
```

```
In [419]: dfa.dtypes
```

```
Out [419]:
```

	A
	float32

(continues on next page)

(continued from previous page)

```
B    float64
C    float64
dtype: object
```

```
In [420]: casted = dfa[df2 > 0]
```

```
In [421]: casted
```

```
Out [421]:
```

	A	B	C
0	-1.510602	NaN	1.0
1	-0.024511	2.787500	NaN
2	-0.088385	NaN	254.0
3	NaN	NaN	NaN
4	NaN	NaN	1.0
5	NaN	NaN	NaN
6	2.524329	2.090108	NaN
7	NaN	0.433098	NaN

```
In [422]: casted.dtypes
```

```

////////////////////////////////////
↪
A    float32
B    float64
C    float64
dtype: object
```

### 3.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let's create a `DataFrame` with a slew of different dtypes:

```
In [423]: df = pd.DataFrame({'string': list('abc'),
.....:                      'int64': list(range(1, 4)),
.....:                      'uint64': np.arange(3, 6).astype('u1'),
.....:                      'float64': np.arange(4.0, 7.0),
.....:                      'bool1': [True, False, True],
.....:                      'bool2': [False, True, False],
.....:                      'dates': pd.date_range('now', periods=3),
.....:                      'category': pd.Series(list("ABC")).astype('category')})

In [424]: df['tdeltas'] = df.dates.diff()

In [425]: df['uint64'] = np.arange(3, 6).astype('u8')

In [426]: df['other_dates'] = pd.date_range('20130101', periods=3)

In [427]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [428]: df
Out [428]:
```

	string	int64	uint8	float64	bool1	...	category	tdeltas	uint64	other_dates	tz_aware_dates
0	a	1	3	4.0	True	...	A	NaT	3	2013-01-01	2013-01-01 00:00:00-05:00

(continues on next page)

(continued from previous page)

```

1      b      2      4      5.0  False  ...      B  1 days      4  2013-01-02  2013-
↳01-02 00:00:00-05:00
2      c      3      5      6.0   True   ...      C  1 days      5  2013-01-03  2013-
↳01-03 00:00:00-05:00

[3 rows x 12 columns]

```

And the dtypes:

```

In [429]: df.dtypes
Out [429]:
string                object
int64                 int64
uint8                 uint8
float64               float64
bool1                 bool
bool2                 bool
dates                 datetime64[ns]
category              category
tdeltas               timedelta64[ns]
uint64                uint64
other_dates           datetime64[ns]
tz_aware_dates        datetime64[ns, US/Eastern]
dtype: object

```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (`include`) and/or “give the columns *without* these dtypes” (`exclude`).

For example, to select `bool` columns:

```

In [430]: df.select_dtypes(include=[bool])
Out [430]:
   bool1  bool2
0   True  False
1  False   True
2   True  False

```

You can also pass the name of a dtype in the [NumPy dtype hierarchy](#):

```

In [431]: df.select_dtypes(include=['bool'])
Out [431]:
   bool1  bool2
0   True  False
1  False   True
2   True  False

```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```

In [432]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out [432]:
   int64  float64  bool1  bool2  tdeltas
0      1      4.0   True  False     NaT
1      2      5.0  False   True  1 days
2      3      6.0   True  False  1 days

```

To select string columns you must use the `object` dtype:

```
In [433]: df.select_dtypes(include=['object'])
Out [433]:
  string
0      a
1      b
2      c
```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [434]: def subdtypes(dtype):
.....:     subs = dtype.__subclasses__()
.....:     if not subs:
.....:         return dtype
.....:     return [dtype, [subdtypes(dt) for dt in subs]]
.....:
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [435]: subdtypes(np.generic)
Out [435]:
[numpy.generic,
 [ [numpy.number,
   [ [numpy.integer,
     [ [numpy.signedinteger,
       [numpy.int8,
        numpy.int16,
        numpy.int32,
        numpy.int64,
        numpy.int64,
        numpy.timedelta64]],
       [numpy.unsignedinteger,
        [numpy.uint8,
         numpy.uint16,
         numpy.uint32,
         numpy.uint64,
         numpy.uint64]]]],
     [numpy.inexact,
      [ [numpy.floating,
        [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
        [numpy.complexfloating,
         [numpy.complex64, numpy.complex128, numpy.complex256]]]]]],
 [numpy.flexible,
  [ [numpy.character, [numpy.bytes_, numpy.str_]],
    [numpy.void, [numpy.record]]]],
 numpy.bool_,
 numpy.datetime64,
 numpy.object_]]
```

---

**Note:** Pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

---

## 3.4 Intro to Data Structures

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 3.4.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, *data* can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what **data** is:

#### From ndarray

If *data* is an ndarray, **index** must be the same length as **data**. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [4]: s
```

```
Out [4]:
a    0.469112
b   -0.282863
c   -1.509059
d   -1.135632
e    1.212112
dtype: float64
```

```
In [5]: s.index
```

```
Out [5]:
Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```
In [6]: pd.Series(np.random.randn(5))
```

```
Out [6]:
0   -0.173215
```

(continues on next page)

(continued from previous page)

```
1    0.119209
2   -1.044236
3   -0.861849
4   -2.104569
dtype: float64
```

---

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

---

### From dict

Series can be instantiated from dicts:

```
In [7]: d = {'b': 1, 'a': 0, 'c': 2}

In [8]: pd.Series(d)
Out [8]:
b    1
a    0
c    2
dtype: int64
```

---

**Note:** When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict's insertion order, if you're using Python version  $\geq 3.6$  and Pandas version  $\geq 0.23$ .

If you're using Python  $< 3.6$  or Pandas  $< 0.23$ , and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

---

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a': 0., 'b': 1., 'c': 2.}

In [10]: pd.Series(d)
Out [10]:
a    0.0
b    1.0
c    2.0
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out [11]:
b    1.0
c    2.0
d    NaN
a    0.0
dtype: float64
```

---

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

---

### From scalar value

If `data` is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
a    5.0
b    5.0
c    5.0
d    5.0
e    5.0
dtype: float64
```

### Series is ndarray-like

`Series` acts very similarly to a `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.46911229990718628
```

```
In [14]: s[:3]
Out[14]:
a    0.469112
b   -0.282863
c   -1.509059
dtype: float64
```

```
In [15]: s[s > s.median()]
Out[15]:
a    0.469112
e    1.212112
dtype: float64
```

```
In [16]: s[[4, 3, 1]]
Out[16]:
e    1.212112
d   -1.135632
b   -0.282863
dtype: float64
```

```
In [17]: np.exp(s)
Out[17]:
a    1.598575
b    0.753623
c    0.221118
d    0.321219
e    3.360575
dtype: float64
```

**Note:** We will address array-based indexing like `s[[4, 3, 1]]` in *section*.

Like a NumPy array, a pandas `Series` has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy's type system in a few places, in which case the dtype would be a *ExtensionDtype*. Some examples within pandas are *Categorical Data* and *Nullable Integer Data Type*. See *dtypes* for more.

If you need the actual array backing a Series, use *Series.array*.

```
In [19]: s.array
Out[19]:
<PandasArray>
[ 0.46911229990718628, -0.28286334432866328,  -1.5090585031735124,
 -1.1356323710171934,   1.2121120250208506]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable *automatic alignment*, for example).

*Series.array* will always be an *ExtensionArray*. Briefly, an *ExtensionArray* is a thin wrapper around one or more *concrete* arrays like a `numpy.ndarray`. Pandas knows how to take an *ExtensionArray* and store it in a Series or a column of a DataFrame. See *dtypes* for more.

While Series is ndarray-like, if you need an *actual* ndarray, then use *Series.to\_numpy()*.

```
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])
```

Even if the Series is backed by a *ExtensionArray*, *Series.to\_numpy()* will return a NumPy ndarray.

## Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```
In [21]: s['a']
Out[21]: 0.46911229990718628
```

```
In [22]: s['e'] = 12.
```

```
In [23]: s
Out[23]:
a      0.469112
b     -0.282863
c     -1.509059
d     -1.135632
e      12.000000
dtype: float64
```

```
In [24]: 'e' in s
```

```
True
```

```
In [25]: 'f' in s
```

```
False
```

If a label is not contained, an exception is raised:

```
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [26]: s.get('f')
In [27]: s.get('f', np.nan)
Out[27]: nan
```

See also the *section on attribute access*.

## Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
Out[28]:
a      0.938225
b     -0.565727
c     -3.018117
d     -2.271265
e     24.000000
dtype: float64
```

```
In [29]: s * 2
↪
a      0.938225
b     -0.565727
c     -3.018117
d     -2.271265
e     24.000000
dtype: float64
```

```
In [30]: np.exp(s)
↪
a      1.598575
b      0.753623
c      0.221118
d      0.321219
e    162754.791419
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
Out[31]:
a      NaN
b     -0.565727
c     -3.018117
d     -2.271265
```

(continues on next page)

(continued from previous page)

```
e      NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the **dropna** function.

### Name attribute

Series can also have a name attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name='something')

In [33]: s
Out [33]:
0    -0.494929
1     1.071804
2     0.721555
3    -0.706771
4    -1.039575
Name: something, dtype: float64

In [34]: s.name
\\repeated characters\\
→ 'something'
```

The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

New in version 0.18.0.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [35]: s2 = s.rename("different")

In [36]: s2.name
Out [36]: 'different'
```

Note that `s` and `s2` refer to different objects.

### 3.4.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and `columns` is not specified, the `DataFrame` columns will be ordered by the dict's insertion order, if you are using Python version `>= 3.6` and Pandas `>= 0.23`.

If you are using Python `< 3.6` or Pandas `< 0.23`, and `columns` is not specified, the `DataFrame` columns will be the lexically ordered list of dict keys.

### From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
.....:      'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
.....:

In [38]: df = pd.DataFrame(d)

In [39]: df
Out[39]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0

In [40]: pd.DataFrame(d, index=['d', 'b', 'a'])
Out[40]:
   one  two
d  NaN  4.0
b  2.0  2.0
a  1.0  1.0

In [41]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
Out[41]:
   two three
d  4.0  NaN
b  2.0  NaN
a  1.0  NaN
```

The row and column labels can be accessed respectively by accessing the **index** and **columns** attributes:

**Note:** When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [42]: df.index
Out [42]: Index(['a', 'b', 'c', 'd'], dtype='object')

In [43]: df.columns
Out [43]: Index(['one', 'two'], dtype='object')
```

### From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be range (n), where n is the array length.

```
In [44]: d = {'one': [1., 2., 3., 4.],
.....:      'two': [4., 3., 2., 1.]}
.....:

In [45]: pd.DataFrame(d)
Out [45]:
   one  two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0

In [46]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
Out [46]:
   one  two
a  1.0  4.0
b  2.0  3.0
c  3.0  2.0
d  4.0  1.0
```

### From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2, ), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])

In [48]: data[:] = [(1, 2., 'Hello'), (2, 3., "World")]

In [49]: pd.DataFrame(data)
Out [49]:
   A    B    C
0  1  2.0 b'Hello'
1  2  3.0 b'World'

In [50]: pd.DataFrame(data, index=['first', 'second'])
Out [50]:
   A    B    C
first  1  2.0 b'Hello'
```

(continues on next page)

(continued from previous page)

```
second 2 3.0 b'World'
```

```
In [51]: pd.DataFrame(data, columns=['C', 'A', 'B'])
```

```

////////////////////////////////////
↪
      C  A   B
0  b'Hello'  1  2.0
1  b'World'  2  3.0

```

**Note:** DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

### From a list of dicts

```
In [52]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]
```

```
In [53]: pd.DataFrame(data2)
```

```
Out [53]:
   a  b   c
0  1  2  NaN
1  5 10 20.0
```

```
In [54]: pd.DataFrame(data2, index=['first', 'second'])
```

```

////////////////////////////////////Out [54]:
      a  b   c
first  1  2  NaN
second 5 10 20.0

```

```
In [55]: pd.DataFrame(data2, columns=['a', 'b'])
```

```

////////////////////////////////////
↪
   a  b
0  1  2
1  5 10

```

### From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame({'(a', 'b)': {'(A', 'B)': 1, '(A', 'C)': 2},
.....:                  ('a', 'a)': {'(A', 'C)': 3, '(A', 'B)': 4},
.....:                  ('a', 'c)': {'(A', 'B)': 5, '(A', 'C)': 6},
.....:                  ('b', 'a)': {'(A', 'C)': 7, '(A', 'B)': 8},
.....:                  ('b', 'b)': {'(A', 'D)': 9, '(A', 'B)': 10}})
```

```
Out [56]:
```

```

      a      b
      b  a  c  a  b
A B  1.0  4.0  5.0  8.0  10.0
C   2.0  3.0  6.0  7.0  NaN
D   NaN  NaN  NaN  NaN  9.0

```

## From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

## Missing Data

Much more will be said on this topic in the *Missing data* section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

## Alternate Constructors

### DataFrame.from\_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the `orient` parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [57]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out [57]:
   A  B
0  1  4
1  2  5
2  3  6
```

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [58]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
.....:                             orient='index', columns=['one', 'two', 'three'])
.....:
Out [58]:
   one  two  three
A     1    2     3
B     4    5     6
```

### DataFrame.from\_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [59]: data
Out [59]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [60]: pd.DataFrame.from_records(data, index='C')
↪
   A  B
C
b'Hello'  1  2.0
b'World'  2  3.0
```

## Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [61]: df['one']
Out[61]:
a    1.0
b    2.0
c    3.0
d    NaN
Name: one, dtype: float64

In [62]: df['three'] = df['one'] * df['two']

In [63]: df['flag'] = df['one'] > 2

In [64]: df
Out[64]:
   one  two  three  flag
a  1.0  1.0    1.0  False
b  2.0  2.0    4.0  False
c  3.0  3.0    9.0   True
d  NaN  4.0    NaN  False
```

Columns can be deleted or popped like with a dict:

```
In [65]: del df['two']

In [66]: three = df.pop('three')

In [67]: df
Out[67]:
   one  flag
a  1.0  False
b  2.0  False
c  3.0   True
d  NaN  False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [68]: df['foo'] = 'bar'

In [69]: df
Out[69]:
   one  flag  foo
a  1.0  False  bar
b  2.0  False  bar
c  3.0   True  bar
d  NaN  False  bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [70]: df['one_trunc'] = df['one'][:2]

In [71]: df
Out[71]:
```

(continues on next page)

(continued from previous page)

```

    one  flag  foo  one_trunc
a  1.0  False  bar         1.0
b  2.0  False  bar         2.0
c  3.0   True  bar         NaN
d  NaN  False  bar         NaN

```

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```

In [72]: df.insert(1, 'bar', df['one'])

In [73]: df
Out [73]:
    one  bar  flag  foo  one_trunc
a  1.0  1.0  False  bar         1.0
b  2.0  2.0  False  bar         2.0
c  3.0  3.0   True  bar         NaN
d  NaN  NaN  False  bar         NaN

```

### Assigning New Columns in Method Chains

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```

In [74]: iris = pd.read_csv('data/iris.data')

In [75]: iris.head()
Out [75]:
   SepalLength  SepalWidth  PetalLength  PetalWidth      Name
0           5.1           3.5           1.4           0.2  Iris-setosa
1           4.9           3.0           1.4           0.2  Iris-setosa
2           4.7           3.2           1.3           0.2  Iris-setosa
3           4.6           3.1           1.5           0.2  Iris-setosa
4           5.0           3.6           1.4           0.2  Iris-setosa

In [76]: (iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength'])
.....:              .head())
.....:
↪
   SepalLength  SepalWidth  PetalLength  PetalWidth      Name  sepal_ratio
0           5.1           3.5           1.4           0.2  Iris-setosa    0.686275
1           4.9           3.0           1.4           0.2  Iris-setosa    0.612245
2           4.7           3.2           1.3           0.2  Iris-setosa    0.680851
3           4.6           3.1           1.5           0.2  Iris-setosa    0.673913
4           5.0           3.6           1.4           0.2  Iris-setosa    0.720000

```

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the `DataFrame` being assigned to.

```

In [77]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth'] / x['SepalLength'])).
↪head()
Out [77]:

```

(continues on next page)

(continued from previous page)

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

`assign` **always** returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don't have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```
In [78]: (iris.query('SepalLength > 5')
.....:         .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
.....:                 PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
.....:         .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
.....:
Out [78]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a2be9c128>
```

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or `NumPy` array), or a function of one argument to be called on the `DataFrame`. A *copy* of the original `DataFrame` is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [79]: dfa = pd.DataFrame({"A": [1, 2, 3],
.....:                      "B": [4, 5, 6]})
.....:

In [80]: dfa.assign(C=lambda x: x['A'] + x['B'],
.....:              D=lambda x: x['A'] + x['C'])
.....:

Out[80]:
   A  B  C  D
0  1  4  5  6
1  2  5  7  9
2  3  6  9 12
```

In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`.

To write code compatible with all versions of Python, split the assignment in two.

```
In [81]: dependent = pd.DataFrame({"A": [1, 1, 1]})

In [82]: (dependent.assign(A=lambda x: x['A'] + 1)
.....:         .assign(B=lambda x: x['A'] + 2))
.....:

Out[82]:
   A  B
0  2  4
1  2  4
2  2  4
```

**Warning:** Dependent assignment may subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish write code that supports versions of python before and after 3.6, you'll need to take care when passing `assign` expressions that

- Updating an existing column
- Referring to the newly updated column in the same `assign`

For example, we'll update column "A" and then refer to it when creating "B".

```
>>> dependent = pd.DataFrame({"A": [1, 1, 1]})
>>> dependent.assign(A=lambda x: x["A"] + 1, B=lambda x: x["A"] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the "old" value of A, `[1, 1, 1]`. The output is then

```
   A  B
0  2  3
1  2  3
2  2  3
```

For Python 3.6 and later, the expression creating A refers to the “new” value of A, [2, 2, 2], which results in

```

A B
0 2 4
1 2 4
2 2 4

```

## Indexing / Selection

The basics of indexing are as follows:

Operation	Syntax	Result
Select column	<code>df[col]</code>	Series
Select row by label	<code>df.loc[label]</code>	Series
Select row by integer location	<code>df.iloc[loc]</code>	Series
Slice rows	<code>df[5:10]</code>	DataFrame
Select rows by boolean vector	<code>df[bool_vec]</code>	DataFrame

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```

In [83]: df.loc['b']
Out [83]:
one            2
bar            2
flag          False
foo           bar
one_trunc      2
Name: b, dtype: object

```

```

In [84]: df.iloc[2]
//////////
↪
one            3
bar            3
flag           True
foo           bar
one_trunc     NaN
Name: c, dtype: object

```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the *section on indexing*. We will address the fundamentals of reindexing / conforming to new sets of labels in the *section on reindexing*.

## Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on **both the columns and the index (row labels)**. Again, the resulting object will have the union of the column and row labels.

```

In [85]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [86]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [87]: df + df2

```

(continues on next page)

2000-01-07 22.579530  3.521204  0.829033
2000-01-08  4.577374  9.233151  0.466834
```

Boolean operators work as well:

```
In [97]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [0, 1, 1]}, dtype=bool)
```

```
In [98]: df2 = pd.DataFrame({'a': [0, 1, 1], 'b': [1, 1, 0]}, dtype=bool)
```

```
In [99]: df1 & df2
```

```
Out [99]:
```

```

   a      b
0  False False
1  False  True
2   True False
```

```
In [100]: df1 | df2
```

```

////////////////////////////////////Out [100]:
   a      b
0  True  True
1  True  True
2  True  True
```

```
In [101]: df1 ^ df2
```

```

////////////////////////////////////
↪
   a      b
0  True  True
1  True False
2 False  True
```

```
In [102]: -df1
```

```

////////////////////////////////////
↪
   a      b
0 False  True
1  True False
2 False False
```

## Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an ndarray:

```
# only show the first 5 rows
In [103]: df[:5].T
Out [103]:
2000-01-01  2000-01-02  2000-01-03  2000-01-04  2000-01-05
A   -1.226825   -0.727707    0.695775   -1.110336   -0.732339
B    0.769804   -0.121306    0.341734   -0.619976    0.687738
C   -1.281247   -0.097883    0.959726    0.149748    0.176444
```

### DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on DataFrame, assuming the data within are numeric:

```
In [104]: np.exp(df)
Out [104]:
                A          B          C
2000-01-01  0.293222  2.159342  0.277691
2000-01-02  0.483015  0.885763  0.906755
2000-01-03  2.005262  1.407386  2.610980
2000-01-04  0.329448  0.537957  1.161542
2000-01-05  0.480783  1.989212  1.192968
2000-01-06  1.496770  0.856457  1.352053
2000-01-07  0.113057  0.254145  0.385117
2000-01-08  4.317584  0.174966  0.437538
```

```
In [105]: np.asarray(df)
////////////////////////////////////
↪
array([[ -1.2268,  0.7698, -1.2812],
       [ -0.7277, -0.1213, -0.0979],
       [ 0.6958,  0.3417,  0.9597],
       [ -1.1103, -0.62   ,  0.1497],
       [ -0.7323,  0.6877,  0.1764],
       [ 0.4033, -0.155  ,  0.3016],
       [ -2.1799, -1.3698, -0.9542],
       [ 1.4627, -1.7432, -0.8266]])
```

The dot method on DataFrame implements matrix multiplication:

```
In [106]: df.T.dot(df)
Out [106]:
                A          B          C
A  11.341858 -0.059772  3.007998
B  -0.059772  6.520556  2.083308
C   3.007998  2.083308  4.310549
```

Similarly, the dot method on Series implements dot product:

```
In [107]: s1 = pd.Series(np.arange(5, 10))
In [108]: s1.dot(s1)
Out [108]: 255
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics are quite different in places from a matrix.

```
In [112]: print(baseball.iloc[-20:, :12].to_string())
```

	id	player	year	stint	team	lg	g	ab	r	h	X2b	X3b

99	89534	alomasa02	2007	1	NYN	NL	8	22	1	3	1	0

Wide DataFrames will be printed across multiple rows by default:

```
In [113]: pd.DataFrame(np.random.randn(3, 12))
```

```
Out [113]:
```

	0	1	2	3	4	...	7	8	9
↪	10	11							
0	-0.345352	1.314232	0.690579	0.995761	2.396780	...	-0.317441	-1.236269	0.
↪	896171	-0.487602	-0.082240						
1	-2.182937	0.380396	0.084844	0.432390	1.519970	...	0.274230	0.132885	-0.
↪	023688	2.410179	1.450520						
2	0.206053	-0.251905	-2.213588	1.063327	1.266143	...	0.408204	-1.048089	-0.
↪	025747	-0.988387	0.094055						

[3 rows x 12 columns]

You can change how much to print on a single row by setting the `display.width` option:

```
In [114]: pd.set_option('display.width', 40) # default is 80
```

```
In [115]: pd.DataFrame(np.random.randn(3, 12))
```

```
Out [115]:
```

	0	1	2	3	4	...	7	8	9
↪	10	11							
0	1.262731	1.289997	0.082423	-0.055758	0.536580	...	-0.034571	-2.484478	-0.
↪	281461	0.030711	0.109121						
1	1.126203	-0.977349	1.474071	-0.064034	-1.282782	...	0.441153	2.353925	0.
↪	583787	0.221471	-0.744471						
2	0.758527	1.729689	-0.964980	-0.845696	-1.340896	...	1.682706	-1.717693	0.
↪	888782	0.228440	0.901805						

[3 rows x 12 columns]

You can adjust the max width of the individual columns by setting `display.max_colwidth`

### 3.4.3 Panel

**Warning:** In 0.20.0, `Panel` is deprecated and will be removed in a future version. See the section *Deprecate Panel*.

Panel is a somewhat less-used, but still important container for 3-dimensional data. The term [panel data](#) is derived from econometrics and is partially responsible for the name pandas: pan(el)-da(ta)-s. The names for the 3 axes are intended to give some semantic meaning to describing operations involving panel data and, in particular, econometric analysis of panel data. However, for the strict purposes of slicing and dicing a collection of `DataFrame` objects, you may find the axis names slightly arbitrary:

- **items:** axis 0, each item corresponds to a `DataFrame` contained inside
- **major\_axis:** axis 1, it is the **index** (rows) of each of the `DataFrames`
- **minor\_axis:** axis 2, it is the **columns** of each of the `DataFrames`

Construction of Panels works about like you would expect:

#### From 3D ndarray with optional axis labels

```
In [124]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
.....:                 major_axis=pd.date_range('1/1/2000', periods=5),
.....:                 minor_axis=['A', 'B', 'C', 'D'])
.....:
```

```
In [125]: wp
```

```
Out [125]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

#### From dict of `DataFrame` objects

```
In [126]: data = {'Item1': pd.DataFrame(np.random.randn(4, 3)),
.....:            'Item2': pd.DataFrame(np.random.randn(4, 2))}
.....:
```

```
In [127]: pd.Panel(data)
```

```
Out [127]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 3
Minor_axis axis: 0 to 2
```

Note that the values in the dict need only be **convertible to `DataFrame`**. Thus, they can be any of the other valid inputs to `DataFrame` as per above.

One helpful factory method is `Panel.from_dict`, which takes a dictionary of `DataFrames` as above, and the following named parameters:

Parameter	Default	Description
intersect	False	drops elements whose indices do not align
orient	items	use minor to use DataFrames' columns as panel items

For example, compare to the construction above:

```
In [128]: pd.Panel.from_dict(data, orient='minor')
Out [128]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: 0 to 2
Major_axis axis: 0 to 3
Minor_axis axis: Item1 to Item2
```

Orient is especially useful for mixed-type DataFrames. If you pass a dict of DataFrame objects with mixed-type columns, all of the data will get upcasted to dtype=object unless you pass orient='minor':

```
In [129]: df = pd.DataFrame({'a': ['foo', 'bar', 'baz'],
.....:                      'b': np.random.randn(3)})
.....:

In [130]: df
Out [130]:
   a      b
0  foo -0.308853
1  bar -0.681087
2  baz  0.377953

In [131]: data = {'item1': df, 'item2': df}

In [132]: panel = pd.Panel.from_dict(data, orient='minor')

In [133]: panel['a']
Out [133]:
   item1 item2
0  foo   foo
1  bar   bar
2  baz   baz

In [134]: panel['b']
Out [134]:
   item1 item2
0 -0.308853 -0.308853
1 -0.681087 -0.681087
2  0.377953  0.377953

In [135]: panel['b'].dtypes
Out [135]:
item1    float64
item2    float64
dtype: object
```

**Note:** Panel, being less commonly used than Series and DataFrame, has been slightly neglected feature-wise. A number of methods and options available in DataFrame are not available in Panel.

## From DataFrame using `to_panel` method

`to_panel` converts a DataFrame with a two-level index to a Panel.

```
In [136]: midx = pd.MultiIndex(levels=[['one', 'two'], ['x', 'y']],
.....:                        codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
.....:

In [137]: df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [5, 6, 7, 8]}, index=midx)

In [138]: df.to_panel()
Out[138]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: A to B
Major_axis axis: one to two
Minor_axis axis: x to y
```

## Item selection / addition / deletion

Similar to DataFrame functioning as a dict of Series, Panel is like a dict of DataFrames:

```
In [139]: wp['Item1']
Out[139]:
           A           B           C           D
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02 -0.014805 -0.284319  0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921  1.613616
2000-01-04  0.464000  0.227371 -0.496922  0.306389
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838

In [140]: wp['Item3'] = wp['Item1'] / wp['Item2']
```

The API for insertion and deletion is the same as for DataFrame. And as with DataFrame, if the item is a valid Python identifier, you can access it as an attribute and tab-complete it in IPython.

## Transposing

A Panel can be rearranged using its `transpose` method (which does not make a copy by default unless the data are heterogeneous):

```
In [141]: wp.transpose(2, 0, 1)
Out[141]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 5 (minor_axis)
Items axis: A to D
Major_axis axis: Item1 to Item3
Minor_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
```

## Indexing / Selection

Operation	Syntax	Result
Select item	<code>wp[item]</code>	DataFrame
Get slice at major_axis label	<code>wp.major_xs(val)</code>	DataFrame
Get slice at minor_axis label	<code>wp.minor_xs(val)</code>	DataFrame

For example, using the earlier example data, we could do:

```
In [142]: wp['Item1']
Out [142]:
           A         B         C         D
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02 -0.014805 -0.284319  0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921  1.613616
2000-01-04  0.464000  0.227371 -0.496922  0.306389
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838

In [143]: wp.major_xs(wp.major_axis[2])
////////////////////////////////////
↪
           Item1      Item2      Item3
A -1.137707   0.800193 -1.421791
B -0.891060   0.782098 -1.139320
C -0.693921  -1.069094  0.649074
D  1.613616  -1.099248 -1.467927

In [144]: wp.minor_axis
////////////////////////////////////
↪ Index(['A', 'B', 'C', 'D'], dtype='object')

In [145]: wp.minor_xs('C')
////////////////////////////////////
↪
           Item1      Item2      Item3
2000-01-01  0.473424 -0.902937 -0.524316
2000-01-02  0.650776 -1.144073 -0.568824
2000-01-03 -0.693921 -1.069094  0.649074
2000-01-04 -0.496922  0.661084 -0.751678
2000-01-05 -1.561819 -1.056652  1.478083
```

## Squeezing

Another way to change the dimensionality of an object is to squeeze a 1-len object, similar to `wp['Item1']`.

```
In [146]: wp.reindex(items=['Item1']).squeeze()
Out [146]:
           A         B         C         D
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02 -0.014805 -0.284319  0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921  1.613616
2000-01-04  0.464000  0.227371 -0.496922  0.306389
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838

In [147]: wp.reindex(items=['Item1'], minor=['B']).squeeze()
```

(continues on next page)

In addition, the `xarray` package was built from the ground up, specifically in order to support the multi-dimensional analysis that is one of Panel's main use cases. [Here is a link to the xarray panel-transition documentation.](#)

```
In [150]: import pandas.util.testing as tm

In [151]: p = tm.makePanel()

In [152]: p
Out[152]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 30 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-02-11 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame.

```
In [153]: p.to_frame()
Out[153]:
```

		ItemA	ItemB	ItemC
major	minor			
2000-01-03	A	-0.390201	-1.624062	-0.605044

```

You can see the full-documentation for the [xarray package](#).

## 3.5 Comparison with other tools

### 3.5.1 Comparison with R / R libraries

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the [R language](#) and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility:** what can/cannot be done with each tool
- **Performance:** how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use:** Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see [External Compatibility](#) for an example.

#### Quick Reference

We'll start off with a quick reference guide pairing some common R operations using [dplyr](#) with pandas equivalents.

#### Querying, Filtering, Sampling

R	pandas
<code>dim(df)</code>	<code>df.shape</code>
<code>head(df)</code>	<code>df.head()</code>
<code>slice(df, 1:10)</code>	<code>df.iloc[:9]</code>
<code>filter(df, col1 == 1, col2 == 1)</code>	<code>df.query('col1 == 1 &amp; col2 == 1')</code>
<code>df[df\$col1 == 1 &amp; df\$col2 == 1,]</code>	<code>df[(df.col1 == 1) &amp; (df.col2 == 1)]</code>
<code>select(df, col1, col2)</code>	<code>df[['col1', 'col2']]</code>
<code>select(df, col1:col3)</code>	<code>df.loc[:, 'col1':'col3']</code>
<code>select(df, -(col1:col3))</code>	<code>df.drop(cols_to_drop, axis=1)</code> but see <sup>1</sup>
<code>distinct(select(df, col1))</code>	<code>df[['col1']].drop_duplicates()</code>
<code>distinct(select(df, col1, col2))</code>	<code>df[['col1', 'col2']].drop_duplicates()</code>
<code>sample_n(df, 10)</code>	<code>df.sample(n=10)</code>
<code>sample_frac(df, 0.01)</code>	<code>df.sample(frac=0.01)</code>

#### Sorting

R	pandas
<code>arrange(df, col1, col2)</code>	<code>df.sort_values(['col1', 'col2'])</code>
<code>arrange(df, desc(col1))</code>	<code>df.sort_values('col1', ascending=False)</code>

<sup>1</sup> R's shorthand for a subrange of columns (`select(df, col1:col3)`) can be approached cleanly in pandas, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.

## Transforming

R	pandas
<code>select(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})['col_one']</code>
<code>rename(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})</code>
<code>mutate(df, c=a-b)</code>	<code>df.assign(c=df.a-df.b)</code>

## Grouping and Summarizing

R	pandas
<code>summary(df)</code>	<code>df.describe()</code>
<code>gdf &lt;- group_by(df, col1)</code>	<code>gdf = df.groupby('col1')</code>
<code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code>	<code>df.groupby('col1').agg({'col1': 'mean'})</code>
<code>summarise(gdf, total=sum(col1))</code>	<code>df.groupby('col1').sum()</code>

## Base R

### Slicing with R's c

R makes it easy to access `data.frame` columns by name

```
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))
```

```
In [2]: df[['a', 'c']]
```

```
Out [2]:
```

```
      a         c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892
```

```
In [3]: df.loc[:, ['a', 'c']]
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
      a      c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892

```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```

In [4]: named = list('abcdefg')

In [5]: n = 30

In [6]: columns = named + np.arange(len(named), n).tolist()

In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)

In [8]: df.iloc[:, np.r_[:10, 24:30]]
Out [8]:

```

## aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups by `by1` and `by2`:

```

df <- data.frame(
  v1 = c(1, 3, 5, 7, 8, 3, 5, NA, 4, 5, 7, 9),
  v2 = c(11, 33, 55, 77, 88, 33, 55, NA, 44, 55, 77, 99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)

```

The `groupby()` method is similar to base R aggregate function.

```

In [9]: df = pd.DataFrame(
...:     {'v1': [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
...:      'v2': [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
...:      'by1': ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
...:      'by2': ["wet", "dry", 99, 95, np.nan, "damp", 95, 99, "red", 99, np.nan,
...:              np.nan]})
...:

In [10]: g = df.groupby(['by1', 'by2'])

In [11]: g[['v1', 'v2']].mean()
Out[11]:

```

		v1	v2
by1	by2		
1	95	5.0	55.0
	99	5.0	55.0
2	95	7.0	77.0
	99	NaN	NaN
big	damp	3.0	33.0
blue	dry	3.0	33.0
red	red	4.0	44.0
	wet	1.0	11.0

For more details and examples see *the groupby documentation*.

## match / %in%

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```

s <- 0:4
s %in% c(2, 4)

```

The `isin()` method is similar to R `%in%` operator:

```
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)
In [13]: s.isin([2, 4])
Out[13]:
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```
s <- 0:4
match(s, c(2,4))
```

For more details and examples see *the reshaping documentation*.

### tapply

`tapply` is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a `data.frame` called `baseball`, and retrieving information based on the array `team`:

```
baseball <-
  data.frame(team = gl(5, 5,
    labels = paste("Team", LETTERS[1:5])),
    player = sample(letters, 25),
    batting.average = runif(25, .200, .400))

tapply(baseball$batting.average, baseball$team,
  max)
```

In pandas we may use `pivot_table()` method to handle this:

```
In [14]: import random
In [15]: import string

In [16]: baseball = pd.DataFrame(
  ....:     {'team': ["team %d" % (x + 1) for x in range(5)] * 5,
  ....:      'player': random.sample(list(string.ascii_lowercase), 25),
  ....:      'batting avg': np.random.uniform(.200, .400, 25)})
  ....:

In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
Out[17]:
team      team 1    team 2    team 3    team 4    team 5
batting avg 0.352134 0.295327 0.397191 0.394457 0.396194
```

For more details and examples see *the reshaping documentation*.

### subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column's values are less than another column's values:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,] # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
```

```
In [19]: df.query('a <= b')
```

```
Out [19]:
```

```
      a      b
1  0.174950  0.552887
2 -0.023167  0.148084
3 -0.495291 -0.300218
4 -0.860736  0.197378
5 -1.134146  1.720780

8  0.238636  0.946550
```

For more details and examples see *the query documentation*.

### with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

(continued from previous page)

```

z = runif(120, 1.7, 20.7),
month = rep(c(5,6,7,8),30),
week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))

```

In pandas the equivalent expression, using the `groupby()` method, would be:

```

In [25]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 120),
.....:                    'y': np.random.uniform(7., 334., 120),
.....:                    'z': np.random.uniform(1.7, 20.7, 120),
.....:                    'month': [5, 6, 7, 8] * 30,
.....:                    'week': np.random.randint(1, 4, 120)})
.....:

In [26]: grouped = df.groupby(['month', 'week'])

In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:

```

month	week	mean	std
5	1	63.653367	40.601965
	2	78.126605	53.342400
	3	92.091886	57.630110
6	1	81.747070	54.339218
	2	70.971205	54.687287
	3	100.968344	54.010081
7	1	61.576332	38.844274
	2	61.733510	48.209013
	3	71.688795	37.595638
8	1	62.741922	34.618153
	2	91.774627	49.790202
	3	73.936856	60.773900

For more details and examples see *the groupby documentation*.

## reshape / reshape2

### melt.array

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```

a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))

```

In Python, since `a` is a list, you can simply use list comprehension.

```

In [28]: a = np.array(list(range(1, 24)) + [np.NaN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
   0  1  2  3

```

(continues on next page)

(continued from previous page)

```
0  0  0  0  1.0
1  0  0  1  2.0
2  0  0  2  3.0
3  0  0  3  4.0
4  0  1  0  5.0
5  0  1  1  6.0
6  0  1  2  7.0
.. .. .. .. ...
17 1  1  1 18.0
18 1  1  2 19.0
19 1  1  3 20.0
20 1  2  0 21.0
21 1  2  1 22.0
22 1  2  2 23.0
23 1  2  3  NaN

[24 rows x 4 columns]
```

### melt.list

An expression using a list called `a` in R where you want to melt it into a data.frame:

```
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NaN]))

In [31]: pd.DataFrame(a)
Out[31]:
   0  1
0  0  1.0
1  1  2.0
2  2  3.0
3  3  4.0
4  4  NaN
```

For more details and examples see *the Into to Data Structures documentation*.

### melt.data.frame

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```
cheese <- data.frame(
  first = c('John', 'Mary'),
  last  = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```
In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....:                        'last': ['Doe', 'Bo'],
.....:                        'height': [5.5, 6.0],
.....:                        'weight': [130, 150]})
.....:
```

```
In [33]: pd.melt(cheese, id_vars=['first', 'last'])
```

```
Out [33]:
```

```
  first last variable  value
0  John  Doe   height    5.5
1  Mary  Bo   height    6.0
2  John  Doe  weight   130.0
3  Mary  Bo  weight   150.0
```

```
In [34]: cheese.set_index(['first', 'last']).stack() # alternative way
```

```

////////////////////////////////////
↪
first  last
John   Doe   height    5.5
              weight   130.0
Mary   Bo    height    6.0
              weight   150.0
dtype: float64
```

For more details and examples see *the reshaping documentation*.

## cast

In R `acast` is an expression using a data.frame called `df` in R to cast into a higher dimensional array:

```
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
  week = rep(c(1,2), 6)
)

mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python the best way is to make use of `pivot_table()`:

```
In [35]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 12),
.....:                    'y': np.random.uniform(7., 334., 12),
.....:                    'z': np.random.uniform(1.7, 20.7, 12),
.....:                    'month': [5, 6, 7] * 4,
.....:                    'week': [1, 2] * 6})
.....:
```

```
In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])
```

```
In [37]: pd.pivot_table(mdf, values='value', index=['variable', 'week'],
.....:                  columns=['month'], aggfunc=np.mean)
.....:
```

```
Out [37]:
```

(continues on next page)

(continued from previous page)

month		5	6	7
variable	week			
x	1	93.888747	98.762034	55.219673
	2	94.391427	38.112932	83.942781
y	1	94.306912	279.454811	227.840449
	2	87.392662	193.028166	173.899260
z	1	11.016009	10.079307	16.170549
	2	8.476111	17.638509	19.003494

Similarly for `dcast` which uses a `data.frame` called `df` in R to aggregate information based on `Animal` and `FeedType`:

```
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
            'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```
In [38]: df = pd.DataFrame({
.....:     'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
.....:                'Animal2', 'Animal3'],
.....:     'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
.....:     'Amount': [10, 7, 4, 2, 5, 6, 2],
.....: })
.....:

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType',
.....:                    aggfunc='sum')
.....:

Out [39]:
FeedType    A    B
Animal
Animal1   10.0  5.0
Animal2    2.0 13.0
Animal3    6.0 NaN
```

The second approach is to use the `groupby()` method:

```
In [40]: df.groupby(['Animal', 'FeedType'])['Amount'].sum()
Out [40]:
Animal  FeedType
Animal1  A          10
         B           5
Animal2  A           2
         B          13
Animal3  A           6
Name: Amount, dtype: int64
```

For more details and examples see *the reshaping documentation* or *the groupby documentation*.

(continued from previous page)

```
In [4]: tips = pd.read_csv(url)

In [5]: tips.head()
Out[5]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

## SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a \* to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
Out[6]:
```

	total_bill	tip	smoker	time
0	16.99	1.01	No	Dinner
1	10.34	1.66	No	Dinner
2	21.01	3.50	No	Dinner
3	23.68	3.31	No	Dinner
4	24.59	3.61	No	Dinner

Calling the DataFrame without the list of column names would display all columns (akin to SQL's \*).

## WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner'
LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using [boolean indexing](#).

```
In [7]: tips[tips['time'] == 'Dinner'].head(5)
Out[7]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [8]: is_dinner = tips['time'] == 'Dinner'

In [9]: is_dinner.value_counts()
Out[9]:
True      176
False      68
Name: time, dtype: int64

In [10]: tips[is_dinner].head(5)
Out[10]:
   total_bill  tip  sex smoker  day  time  size
0     16.99  1.01 Female    No  Sun  Dinner    2
1     10.34  1.66   Male    No  Sun  Dinner    3
2     21.01  3.50   Male    No  Sun  Dinner    3
3     23.68  3.31   Male    No  Sun  Dinner    2
4     24.59  3.61 Female    No  Sun  Dinner    4
```

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

```
-- tips of more than $5.00 at Dinner meals
SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

```
# tips of more than $5.00 at Dinner meals
In [11]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]
Out[11]:
   total_bill  tip  sex smoker  day  time  size
23     39.42  7.58   Male    No  Sat  Dinner    4
44     30.40  5.60   Male    No  Sun  Dinner    4
47     32.40  6.00   Male    No  Sun  Dinner    4
52     34.81  5.20 Female    No  Sun  Dinner    4
59     48.27  6.73   Male    No  Sat  Dinner    4
116    29.93  5.07   Male    No  Sun  Dinner    4
155    29.85  5.14 Female    No  Sun  Dinner    5
170    50.81 10.00   Male   Yes  Sat  Dinner    3
172     7.25  5.15   Male   Yes  Sun  Dinner    2
181    23.33  5.65   Male   Yes  Sun  Dinner    2
183    23.17  6.50   Male   Yes  Sun  Dinner    4
211    25.89  5.16   Male   Yes  Sat  Dinner    4
212    48.33  9.00   Male    No  Sat  Dinner    4
214    28.17  6.50 Female   Yes  Sat  Dinner    3
239    29.03  5.92   Male    No  Sat  Dinner    3
```

```
-- tips by parties of at least 5 diners OR bill total was more than $45
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```
# tips by parties of at least 5 diners OR bill total was more than $45
In [12]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
Out[12]:
   total_bill  tip  sex smoker  day  time  size
59     48.27  6.73   Male    No  Sat  Dinner    4
125    29.80  4.20 Female    No  Thur  Lunch    6
141    34.30  6.70   Male    No  Thur  Lunch    6
```

(continues on next page)

(continued from previous page)

142	41.19	5.00	Male	No	Thur	Lunch	5
143	27.05	5.00	Female	No	Thur	Lunch	6
155	29.85	5.14	Female	No	Sun	Dinner	5
156	48.17	5.00	Male	No	Sun	Dinner	6
170	50.81	10.00	Male	Yes	Sat	Dinner	3
182	45.35	3.50	Male	Yes	Sun	Dinner	3
185	20.69	5.00	Male	No	Sun	Dinner	5
187	30.46	2.00	Male	Yes	Sun	Dinner	5
212	48.33	9.00	Male	No	Sat	Dinner	4
216	28.15	3.00	Male	Yes	Sat	Dinner	5

NULL checking is done using the `notna()` and `isna()` methods.

```
In [13]: frame = pd.DataFrame({'col1': ['A', 'B', np.NaN, 'C', 'D'],
.....:                        'col2': ['F', np.NaN, 'G', 'H', 'I']})
.....:
```

```
In [14]: frame
```

```
Out [14]:
   col1 col2
0     A     F
1     B  NaN
2  NaN     G
3     C     H
4     D     I
```

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```
In [15]: frame[frame['col2'].isna()]
```

```
Out [15]:
   col1 col2
1     B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```
In [16]: frame[frame['col1'].notna()]
```

```
Out [16]:
   col1 col2
0     A     F
1     B  NaN
3     C     H
4     D     I
```

## GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female      87
Male       157
*/
```

The pandas equivalent would be:

```
In [17]: tips.groupby('sex').size()
Out[17]:
sex
Female      87
Male       157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of not null records within each.

```
In [18]: tips.groupby('sex').count()
Out[18]:
```

sex	total_bill	tip	smoker	day	time	size
Female	87	87	87	87	87	87
Male	157	157	157	157	157	157

Alternatively, we could have applied the `count()` method to an individual column:

```
In [19]: tips.groupby('sex')['total_bill'].count()
Out[19]:
sex
Female      87
Male       157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri  2.734737  19
Sat  2.993103  87
Sun  3.255132  76
Thur 2.771452  62
*/
```

```
In [20]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
```

```
Out [20]:
```

	tip	day
day		
Fri	2.734737	19
Sat	2.993103	87
Sun	3.255132	76
Thur	2.771452	62

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
```

```
FROM tips
```

```
GROUP BY smoker, day;
```

```
/*
```

```
smoker day
No    Fri      4  2.812500
      Sat     45  3.102889
      Sun     57  3.167895
      Thur    45  2.673778
Yes   Fri     15  2.714000
      Sat     42  2.875476
      Sun     19  3.516842
      Thur    17  3.030000
```

```
*/
```

```
In [21]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
```

```
Out [21]:
```

		tip	
smoker	day	size	mean
No	Fri	4.0	2.812500
	Sat	45.0	3.102889
	Sun	57.0	3.167895
	Thur	45.0	2.673778
Yes	Fri	15.0	2.714000
	Sat	42.0	2.875476
	Sun	19.0	3.516842
	Thur	17.0	3.030000

## JOIN

JOINS can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```
In [22]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                       'value': np.random.randn(4)})
.....:
```

```
In [23]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                       'value': np.random.randn(4)})
.....:
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINS.

## INNER JOIN

```
SELECT *
FROM df1
INNER JOIN df2
  ON df1.key = df2.key;
```

```
# merge performs an INNER JOIN by default
```

```
In [24]: pd.merge(df1, df2, on='key')
```

```
Out [24]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209

`merge()` also offers parameters for cases when you'd like to join one DataFrame's column with another DataFrame's index.

```
In [25]: indexed_df2 = df2.set_index('key')
```

```
In [26]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)
```

```
Out [26]:
```

	key	value_x	value_y
1	B	-0.282863	1.212112
3	D	-1.135632	-0.173215
3	D	-1.135632	0.119209

## LEFT OUTER JOIN

```
-- show all records from df1
```

```
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from df1
```

```
In [27]: pd.merge(df1, df2, on='key', how='left')
```

```
Out [27]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209

## RIGHT JOIN

```
-- show all records from df2
```

```
SELECT *
```

(continues on next page)

(continued from previous page)

```

FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;

```

```

# show all records from df2
In [28]: pd.merge(df1, df2, on='key', how='right')
Out [28]:
   key  value_x  value_y
0    B -0.282863  1.212112
1    D -1.135632 -0.173215
2    D -1.135632  0.119209
3    E          NaN -1.044236

```

## FULL JOIN

pandas also allows for FULL JOINS, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINS are not supported in all RDBMS (MySQL).

```

-- show all records from both tables
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;

```

```

# show all records from both frames
In [29]: pd.merge(df1, df2, on='key', how='outer')
Out [29]:
   key  value_x  value_y
0    A  0.469112        NaN
1    B -0.282863  1.212112
2    C -1.509059        NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E          NaN -1.044236

```

## UNION

UNION ALL can be performed using `concat()`.

```

In [30]: df1 = pd.DataFrame({'city': ['Chicago', 'San Francisco', 'New York City'],
.....:                      'rank': range(1, 4)})
.....:
In [31]: df2 = pd.DataFrame({'city': ['Chicago', 'Boston', 'Los Angeles'],
.....:                      'rank': [1, 4, 5]})
.....:

```

```

SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;

```

(continues on next page)

(continued from previous page)

```
/*
    city  rank
    Chicago  1
San Francisco  2
New York City  3
    Chicago  1
    Boston  4
    Los Angeles  5
*/
```

```
In [32]: pd.concat([df1, df2])
```

```
Out [32]:
```

```
   city  rank
0  Chicago  1
1 San Francisco  2
2 New York City  3
0  Chicago  1
1  Boston  4
2  Los Angeles  5
```

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
    city  rank
    Chicago  1
San Francisco  2
New York City  3
    Boston  4
    Los Angeles  5
*/
```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```
In [33]: pd.concat([df1, df2]).drop_duplicates()
```

```
Out [33]:
```

```
   city  rank
0  Chicago  1
1 San Francisco  2
2 New York City  3
1  Boston  4
2  Los Angeles  5
```

## Pandas equivalents for some SQL analytic and aggregate functions

### Top N rows with offset

```
-- MySQL
SELECT * FROM tips
```

(continues on next page)

(continued from previous page)

```
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

```
In [34]: tips.nlargest(10 + 5, columns='tip').tail(10)
```

```
Out [34]:
```

	total_bill	tip	sex	smoker	day	time	size
183	23.17	6.50	Male	Yes	Sun	Dinner	4
214	28.17	6.50	Female	Yes	Sat	Dinner	3
47	32.40	6.00	Male	No	Sun	Dinner	4
239	29.03	5.92	Male	No	Sat	Dinner	3
88	24.71	5.85	Male	No	Thur	Lunch	2
181	23.33	5.65	Male	Yes	Sun	Dinner	2
44	30.40	5.60	Male	No	Sun	Dinner	4
52	34.81	5.20	Female	No	Sun	Dinner	4
85	34.83	5.17	Female	No	Thur	Lunch	4
211	25.89	5.16	Male	Yes	Sat	Dinner	4

## Top N rows per group

```
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (
  SELECT
    t.*,
    ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
  FROM tips t
)
WHERE rn < 3
ORDER BY day, rn;
```

```
In [35]: (tips.assign(rn=tips.sort_values(['total_bill'], ascending=False)
.....:                .groupby(['day'])
.....:                .cumcount() + 1)
.....:         .query('rn < 3')
.....:         .sort_values(['day', 'rn']))
.....:
```

```
Out [35]:
```

	total_bill	tip	sex	smoker	day	time	size	rn
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1
212	48.33	9.00	Male	No	Sat	Dinner	4	2
156	48.17	5.00	Male	No	Sun	Dinner	6	1
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1
142	41.19	5.00	Male	No	Thur	Lunch	5	2

the same using `rank(method='first')` function

```
In [36]: (tips.assign(rnk=tips.groupby(['day'])['total_bill']
.....:                .rank(method='first', ascending=False))
.....:         .query('rnk < 3')
.....:         .sort_values(['day', 'rnk']))
.....:
```

```
Out [36]:
```

(continues on next page)

(continued from previous page)

	total_bill	tip	sex	smoker	day	time	size	rnk
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1.0
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2.0
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1.0
212	48.33	9.00	Male	No	Sat	Dinner	4	2.0
156	48.17	5.00	Male	No	Sun	Dinner	6	1.0
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2.0
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1.0
142	41.19	5.00	Male	No	Thur	Lunch	5	2.0

```
-- Oracle's RANK() analytic function
SELECT * FROM (
  SELECT
    t.*,
    RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
  FROM tips t
  WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;
```

Let's find tips with (rank < 3) per gender group for (tips < 2). Notice that when using rank(method='min') function `rnk_min` remains the same for the same `tip` (as Oracle's RANK() function)

```
In [37]: (tips[tips['tip'] < 2]
....:      .assign(rnk_min=tips.groupby(['sex'])['tip']
....:              .rank(method='min'))
....:      .query('rnk_min < 3')
....:      .sort_values(['sex', 'rnk_min']))
....:
Out [37]:
   total_bill  tip  sex  smoker  day  time  size  rnk_min
67         3.07  1.00 Female    Yes  Sat  Dinner     1     1.0
92         5.75  1.00 Female    Yes  Fri  Dinner     2     1.0
111        7.25  1.00 Female     No  Sat  Dinner     1     1.0
236        12.60  1.00 Male     Yes  Sat  Dinner     2     1.0
237        32.83  1.17 Male     Yes  Sat  Dinner     2     2.0
```

## UPDATE

```
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [38]: tips.loc[tips['tip'] < 2, 'tip'] *= 2
```

## DELETE

```
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain, instead of deleting them

```
In [39]: tips = tips.loc[tips['tip'] <= 9]
```

### 3.5.3 Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

**Note:** Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. [Jupyter notebook](#) or terminal) - the equivalent in SAS would be:

```
proc print data=df(obs=5);  
run;
```

---

## Data Structures

### General Terminology Translation

pandas	SAS
<code>DataFrame</code>	data set
column	variable
row	observation
groupby	BY-group
NaN	.

### `DataFrame` / `Series`

A `DataFrame` in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS's `DATA` step, can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. SAS doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column in the `DATA` step.

### Index

Every `DataFrame` and `Series` has an `Index` - which are labels on the *rows* of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be

accessed during the DATA step (`_N_`).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the *indexing documentation* for much more on how to use an `Index` effectively.

## Data Input / Output

### Constructing a DataFrame from Values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```
data df;
  input x y;
  datalines;
  1 2
  3 4
  5 6
  ;
run;
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

### Reading External Data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (`csv`) will be used in many of the following examples.

SAS provides `PROC IMPORT` to read `csv` data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev/'
...:         'pandas/master/pandas/tests/data/tips.csv')
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
```

(continues on next page)

(continued from previous page)

```
Out [7]:
   total_bill  tip    sex smoker  day    time  size
0     16.99   1.01  Female     No  Sun  Dinner    2
1     10.34   1.66   Male     No  Sun  Dinner    3
2     21.01   3.50   Male     No  Sun  Dinner    3
3     23.68   3.31   Male     No  Sun  Dinner    2
4     24.59   3.61  Female     No  Sun  Dinner    4
```

Like PROC IMPORT, read\_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a pd.read\_\* function. See the *IO documentation* for more details.

## Exporting Data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of read\_csv is to\_csv(), and other data formats follow a similar api.

```
tips.to_csv('tips2.csv')
```

## Data Operations

### Operations on Columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2.0
In [10]: tips.head()
Out[10]:
   total_bill  tip    sex smoker  day    time  size  new_bill
0     14.99   1.01  Female     No  Sun  Dinner    2     7.495
```

(continues on next page)

(continued from previous page)

1	8.34	1.66	Male	No	Sun	Dinner	3	4.170
2	19.01	3.50	Male	No	Sun	Dinner	3	9.505
3	21.68	3.31	Male	No	Sun	Dinner	2	10.840
4	22.59	3.61	Female	No	Sun	Dinner	4	11.295

## Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*

```
In [11]: tips[tips['total_bill'] > 10].head()
Out[11]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4

## If/Then Logic

In SAS, `if/then` logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;

  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```
In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
In [13]: tips.head()
Out[13]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low

(continues on next page)

(continued from previous page)

2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high

## Date Functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmdyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the *timeseries documentation* for more details.

```
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')
In [15]: tips['date2'] = pd.Timestamp('2015-02-15')
In [16]: tips['date1_year'] = tips['date1'].dt.year
In [17]: tips['date2_month'] = tips['date2'].dt.month
In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
In [19]: tips['months_between'] = (
.....:     tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
.....:
In [20]: tips[['date1', 'date2', 'date1_year', 'date2_month',
.....:         'date1_next', 'months_between']].head()
.....:
Out[20]:
   date1      date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
1 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
2 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
3 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
4 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
```

## Selection of Columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```

data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;

```

The same operations are expressed in pandas below.

```

# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
   sex  total_bill  tip
0  Female      14.99  1.01
1   Male       8.34  1.66
2   Male      19.01  3.50
3   Male      21.68  3.31
4  Female      22.59  3.61

# drop
In [22]: tips.drop('sex', axis=1).head()
Out[22]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01     No  Sun  Dinner    2
1       8.34  1.66     No  Sun  Dinner    3
2      19.01  3.50     No  Sun  Dinner    3
3      21.68  3.31     No  Sun  Dinner    2
4      22.59  3.61     No  Sun  Dinner    4

# rename
In [23]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[23]:
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
1       8.34  1.66   Male     No  Sun  Dinner    3
2      19.01  3.50   Male     No  Sun  Dinner    3
3      21.68  3.31   Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4

```

## Sorting by Values

Sorting in SAS is accomplished via PROC SORT

```

proc sort data=tips;
  by sex total_bill;
run;

```

pandas objects have a `sort_values()` method, which takes a list of columns to sort by.

```
In [24]: tips = tips.sort_values(['sex', 'total_bill'])

In [25]: tips.head()
Out [25]:
```

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2

## String Processing

### Length

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```
data _null_;
set tips;
put (LENGTHN(time));
put (LENGTHC(time));
run;
```

Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [26]: tips['time'].str.len().head()
Out [26]:
```

67	6
92	6
111	6
145	5
135	5

Name: time, dtype: int64

```
In [27]: tips['time'].str.rstrip().str.len().head()
Out [27]:
```

67	6
92	6
111	6
145	5
135	5

Name: time, dtype: int64

### Find

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
data _null_;
set tips;
put (FINDW(sex, 'ale'));
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

## Substring

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```
data _null_;
set tips;
put (substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [29]: tips['sex'].str[0:1].head()
Out[29]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

## Scan

The SAS `SCAN` function returns the `n`th word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]
In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]
In [33]: firstlast
Out[33]:
```

	String	First_Name	Last_Name
0	John Smith	John	John
1	Jane Cook	Jane	Jane

### Uppcase, Lowcase, and Propcase

The SAS `UPCASE` `LOWCASE` and `PROPCASE` functions change the case of the argument.

```
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [35]: firstlast['string_up'] = firstlast['String'].str.upper()
In [36]: firstlast['string_low'] = firstlast['String'].str.lower()
In [37]: firstlast['string_prop'] = firstlast['String'].str.title()
In [38]: firstlast
Out[38]:
```

	String	string_up	string_low	string_prop
0	John Smith	JOHN SMITH	john smith	John Smith
1	Jane Cook	JANE COOK	jane cook	Jane Cook

### Merging

The following tables will be used in the merge examples

```
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                      'value': np.random.randn(4)})
.....:
```

(continues on next page)

(continued from previous page)

```

In [40]: df1
Out[40]:
   key  value
0    A  0.469112
1    B -0.282863
2    C -1.509059
3    D -1.135632

In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                       'value': np.random.randn(4)})
.....:

In [42]: df2
Out[42]:
   key  value
0    B  1.212112
1    D -0.173215
2    D  0.119209
3    E -1.044236

```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```

proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);

  if a and b then output inner_join;
  if a then output left_join;
  if b then output right_join;
  if a or b then output outer_join;
run;

```

pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```

In [43]: inner_join = df1.merge(df2, on='key', how='inner')

In [44]: inner_join
Out[44]:
   key  value_x  value_y
0    B -0.282863  1.212112
1    D -1.135632 -0.173215
2    D -1.135632  0.119209

In [45]: left_join = df1.merge(df2, on='key', how='left')

In [46]: left_join
Out[46]:

```

(continues on next page)

(continued from previous page)

```

key  value_x  value_y
0    A  0.469112      NaN
1    B -0.282863  1.212112
2    C -1.509059      NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209

```

```
In [47]: right_join = df1.merge(df2, on=['key'], how='right')
```

```
In [48]: right_join
```

```
Out[48]:
```

```

key  value_x  value_y
0    B -0.282863  1.212112
1    D -1.135632 -0.173215
2    D -1.135632  0.119209
3    E          NaN -1.044236

```

```
In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [50]: outer_join
```

```
Out[50]:
```

```

key  value_x  value_y
0    A  0.469112      NaN
1    B -0.282863  1.212112
2    C -1.509059      NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E          NaN -1.044236

```

## Missing Data

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [51]: outer_join
```

```
Out[51]:
```

```

key  value_x  value_y
0    A  0.469112      NaN
1    B -0.282863  1.212112
2    C -1.509059      NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E          NaN -1.044236

```

```
In [52]: outer_join['value_x'] + outer_join['value_y']
```

```

////////////////////////////////////
↪
0          NaN
1    0.929249
2          NaN
3   -1.308847
4   -1.016424
5          NaN
dtype: float64

```

(continues on next page)

(continued from previous page)

```
In [53]: outer_join['value_x'].sum()
//////////
↪ -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

Which doesn't work in pandas. Instead, the `pd.isna` or `pd.notna` functions should be used for comparisons.

```
In [54]: outer_join[pd.isna(outer_join['value_x'])]
Out [54]:
   key  value_x  value_y
5    E         NaN -1.044236

In [55]: outer_join[pd.notna(outer_join['value_x'])]
//////////Out [55]:
   key  value_x  value_y
0    A  0.469112         NaN
1    B -0.282863  1.212112
2    C -1.509059         NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
```

pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the *missing data documentation* for more.

```
In [56]: outer_join.dropna()
Out [56]:
   key  value_x  value_y
1    B -0.282863  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209

In [57]: outer_join.fillna(method='ffill')
//////////
↪
   key  value_x  value_y
0    A  0.469112         NaN
1    B -0.282863  1.212112
2    C -1.509059  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E -1.135632 -1.044236
```

(continues on next page)

*(continued from previous page)*

```
In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
//////////////////////////////////////////////////
↪
0     0.469112
1    -0.282863
2    -1.509059
3    -1.135632
4    -1.135632
5    -0.718815
Name: value_x, dtype: float64
```

## GroupBy

### Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```
proc summary data=tips nway;
  class sex smoker;
  var total_bill tip;
  output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the *groupby documentation* for more details and examples.

```
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()
```

```
In [60]: tips_summed.head()
```

```
Out[60]:
```

sex	smoker	total_bill	tip
Female	No	869.68	149.77
	Yes	527.27	96.74
Male	No	1725.75	302.00
	Yes	1217.07	183.07

### Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```
proc summary data=tips missing nway;
  class smoker;
  var total_bill;
  output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;
```

*(continues on next page)*

(continued from previous page)

```

data tips;
  merge tips(in=a) smoker_means(in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;

```

pandas groupby provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```

In [61]: gb = tips.groupby('smoker')['total_bill']

In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [63]: tips.head()
Out[63]:
   total_bill  tip  sex smoker  day  time  size  adj_total_bill
67         1.07  1.00  Female   Yes  Sat  Dinner    1        -17.686344
92         3.75  1.00  Female   Yes  Fri  Dinner    2        -15.006344
111        5.25  1.00  Female   No   Sat  Dinner    1        -11.938278
145        6.35  1.50  Female   No   Thur  Lunch    2        -10.838278
135        6.51  1.25  Female   No   Thur  Lunch    2        -10.678278

```

## By Group Processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```

proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;

```

In pandas this would be written as:

```

In [64]: tips.groupby(['sex', 'smoker']).first()
Out[64]:
   sex  smoker  total_bill  tip  day  time  size  adj_total_bill
Female No         5.25  1.00  Sat  Dinner    1        -11.938278
       Yes         1.07  1.00  Sat  Dinner    1        -17.686344
Male   No         5.51  2.00  Thur  Lunch    2        -11.678278
       Yes         5.25  5.15  Sun  Dinner    2        -13.506344

```

## Other Considerations

## Disk vs Memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine's memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the `dask.dataframe` library (currently in development) which provides a subset of pandas functionality for an on-disk `DataFrame`

## Data Interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```
libname xportout xport 'transport-file.xpt';
data xportout.tips;
    set tips(rename=(total_bill=tbill));
    * xport variable names limited to 6 characters;
run;
```

```
df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```
df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows

In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

## 3.5.4 Comparison with Stata

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

---

**Note:** Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. [Jupyter notebook](#) or

terminal) – the equivalent in Stata would be:

```
list in 1/5
```

## Data Structures

### General Terminology Translation

pandas	Stata
DataFrame	data set
column	variable
row	observation
groupby	by sort
NaN	.

### DataFrame / Series

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. Stata doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column of a data set in Stata.

### Index

Every `DataFrame` and `Series` has an `Index` – labels on the *rows* of the data. Stata does not have an exactly analogous concept. In Stata, a data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed with `_n`.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the *indexing documentation* for much more on how to use an `Index` effectively.

## Data Input / Output

### Constructing a DataFrame from Values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out [4]:
   x  y
0  1  2
1  3  4
2  5  6
```

### Reading External Data

Like Stata, pandas provides utilities for reading in data from many formats. The `tips` data set, found within the pandas tests (`csv`) will be used in many of the following examples.

Stata provides `import delimited` to read `csv` data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev'
...:         '/pandas/master/pandas/tests/data/tips.csv')
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
Out [7]:
   total_bill  tip  sex smoker  day  time  size
0     16.99   1.01 Female    No  Sun  Dinner    2
1     10.34   1.66  Male    No  Sun  Dinner    3
2     21.01   3.50  Male    No  Sun  Dinner    3
3     23.68   3.31  Male    No  Sun  Dinner    2
4     24.59   3.61 Female    No  Sun  Dinner    4
```

Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata('data.dta')
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the *IO documentation* for more details.

## Exporting Data

The inverse of `import delimited` in Stata is `export delimited`

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata('tips2.dta')
```

## Data Operations

### Operations on Columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides similar vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2
In [10]: tips.head()
Out[10]:
   total_bill  tip  sex smoker  day  time  size  new_bill
0     14.99   1.01 Female    No  Sun  Dinner    2     7.495
1      8.34   1.66   Male    No  Sun  Dinner    3     4.170
2     19.01   3.50   Male    No  Sun  Dinner    3     9.505
3     21.68   3.31   Male    No  Sun  Dinner    2    10.840
4     22.59   3.61 Female    No  Sun  Dinner    4    11.295

In [11]: tips = tips.drop('new_bill', axis=1)
```

## Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

`DataFrames` can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4

## If/Then Logic

In Stata, an `if` clause can also be used to create new columns.

```
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```
In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')

In [14]: tips.head()
Out[14]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high

## Date Functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")

generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the *timeseries documentation* for more details.

```
In [15]: tips['date1'] = pd.Timestamp('2013-01-15')

In [16]: tips['date2'] = pd.Timestamp('2015-02-15')
```

(continues on next page)

(continued from previous page)

```

In [17]: tips['date1_year'] = tips['date1'].dt.year

In [18]: tips['date2_month'] = tips['date2'].dt.month

In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()

In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M')
.....:                               - tips['date1'].dt.to_period('M'))
.....:

In [21]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next',
.....:           'months_between']].head()
.....:
Out [21]:
   date1      date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15        2013          2 2013-02-01 <25 * MonthEnds>
1 2013-01-15 2015-02-15        2013          2 2013-02-01 <25 * MonthEnds>
2 2013-01-15 2015-02-15        2013          2 2013-02-01 <25 * MonthEnds>
3 2013-01-15 2015-02-15        2013          2 2013-02-01 <25 * MonthEnds>
4 2013-01-15 2015-02-15        2013          2 2013-02-01 <25 * MonthEnds>

```

### Selection of Columns

Stata provides keywords to select, drop, and rename columns.

```

keep sex total_bill tip

drop sex

rename total_bill total_bill_2

```

The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

```

# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out [22]:
   sex  total_bill  tip
0  Female     14.99  1.01
1   Male      8.34  1.66
2   Male     19.01  3.50
3   Male     21.68  3.31
4  Female     22.59  3.61

# drop
In [23]: tips.drop('sex', axis=1).head()
\////////////////////////////////////////////////////////////////////////////////////
↳
   total_bill  tip smoker  day  time  size
0     14.99   1.01    No  Sun  Dinner    2
1      8.34   1.66    No  Sun  Dinner    3
2     19.01   3.50    No  Sun  Dinner    3
3     21.68   3.31    No  Sun  Dinner    2
4     22.59   3.61    No  Sun  Dinner    4

```

(continues on next page)

(continued from previous page)

```
In [28]: tips['time'].str.rstrip().str.len().head()
Out[28]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64
```

### Finding Position of Substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
generate str_position = strpos(sex, "ale")
```

Python determines the position of a character in a string with the `find()` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

### Extracting Substring by Position

Stata extracts a substring from a string based on its position with the `substr()` function.

```
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [30]: tips['sex'].str[0:1].head()
Out[30]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

## Extracting nth Word

The Stata `word()` function returns the `nth` word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [31]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [32]: firstlast['First_Name'] = firstlast['string'].str.split(" ", expand=True)[0]
In [33]: firstlast['Last_Name'] = firstlast['string'].str.rsplit(" ", expand=True)[0]
In [34]: firstlast
Out[34]:
      string First_Name Last_Name
0  John Smith      John      John
1   Jane Cook      Jane      Jane
```

## Changing Case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [35]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [36]: firstlast['upper'] = firstlast['string'].str.upper()
In [37]: firstlast['lower'] = firstlast['string'].str.lower()
In [38]: firstlast['title'] = firstlast['string'].str.title()
```

(continues on next page)

(continued from previous page)

```
In [39]: firstlast
Out [39]:
```

	string	upper	lower	title
0	John Smith	JOHN SMITH	john smith	John Smith
1	Jane Cook	JANE COOK	jane cook	Jane Cook

## Merging

The following tables will be used in the merge examples

```
In [40]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                      'value': np.random.randn(4)})
.....:

In [41]: df1
Out [41]:
```

	key	value
0	A	0.469112
1	B	-0.282863
2	C	-1.509059
3	D	-1.135632

```
In [42]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                      'value': np.random.randn(4)})
.....:

In [43]: df2
Out [43]:
```

	key	value
0	B	1.212112
1	D	-0.173215
2	D	0.119209
3	E	-1.044236

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both `DataFrames` already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

```
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
```

(continues on next page)

(continued from previous page)

```

A
B
C
D
end
generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta

```

pandas DataFrames have a `DataFrame.merge()` method, which provides similar functionality. Note that different join types are accomplished via the `how` keyword.

```

In [44]: inner_join = df1.merge(df2, on=['key'], how='inner')

In [45]: inner_join
Out[45]:
   key  value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209

In [46]: left_join = df1.merge(df2, on=['key'], how='left')

In [47]: left_join
Out[47]:
   key  value_x  value_y
0   A  0.469112      NaN
1   B -0.282863  1.212112
2   C -1.509059      NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209

In [48]: right_join = df1.merge(df2, on=['key'], how='right')

In [49]: right_join
Out[49]:
   key  value_x  value_y
0   B -0.282863  1.212112

```

(continues on next page)

(continued from previous page)

```

1  D -1.135632 -0.173215
2  D -1.135632  0.119209
3  E           NaN -1.044236

```

```
In [50]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [51]: outer_join
```

```
Out [51]:
```

```

    key  value_x  value_y
0  A  0.469112     NaN
1  B -0.282863  1.212112
2  C -1.509059     NaN
3  D -1.135632 -0.173215
4  D -1.135632  0.119209
5  E           NaN -1.044236

```

### Missing Data

Like Stata, pandas has a representation for missing data – the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [52]: outer_join
```

```
Out [52]:
```

```

    key  value_x  value_y
0  A  0.469112     NaN
1  B -0.282863  1.212112
2  C -1.509059     NaN
3  D -1.135632 -0.173215
4  D -1.135632  0.119209
5  E           NaN -1.044236

```

```
In [53]: outer_join['value_x'] + outer_join['value_y']
```

```

\//////////////////////////////////////////////////////////////////////////////////
↪
0         NaN
1    0.929249
2         NaN
3   -1.308847
4   -1.016424
5         NaN
dtype: float64

```

```
In [54]: outer_join['value_x'].sum()
```

```

\//////////////////////////////////////////////////////////////////////////////////
↪-3.5940742896293765

```

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```

* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .

```

This doesn't work in pandas. Instead, the `pd.isna()` or `pd.notna()` functions should be used for comparisons.

```
In [55]: outer_join[pd.isna(outer_join['value_x'])]
Out [55]:
   key  value_x  value_y
5    E         NaN -1.044236

In [56]: outer_join[pd.notna(outer_join['value_x'])]
Out [56]:
   key  value_x  value_y
0    A  0.469112         NaN
1    B -0.282863  1.212112
2    C -1.509059         NaN
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
```

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the *missing data documentation* for more.

```
# Drop rows with any missing value
In [57]: outer_join.dropna()
Out [57]:
   key  value_x  value_y
1    B -0.282863  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209

# Fill forwards
In [58]: outer_join.fillna(method='ffill')
Out [58]:
   key  value_x  value_y
0    A  0.469112         NaN
1    B -0.282863  1.212112
2    C -1.509059  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E -1.135632 -1.044236

# Impute missing values with the mean
In [59]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
Out [59]:
0    0.469112
1   -0.282863
2   -1.509059
3   -1.135632
4   -1.135632
5   -0.718815
Name: value_x, dtype: float64
```

## GroupBy

### Aggregation

Stata’s collapse can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the *groupby documentation* for more details and examples.

```
In [60]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()
```

```
In [61]: tips_summed.head()
```

```
Out [61]:
```

		total_bill	tip
sex	smoker		
Female	No	869.68	149.77
	Yes	527.27	96.74
Male	No	1725.75	302.00
	Yes	1217.07	183.07

## Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort` with `egen()`. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas `groupby` provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']
```

```
In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')
```

```
In [64]: tips.head()
```

```
Out [64]:
```

	total_bill	tip	sex	smoker	day	time	size	adj_total_bill
67	1.07	1.00	Female	Yes	Sat	Dinner	1	-17.686344
92	3.75	1.00	Female	Yes	Fri	Dinner	2	-15.006344
111	5.25	1.00	Female	No	Sat	Dinner	1	-11.938278
145	6.35	1.50	Female	No	Thur	Lunch	2	-10.838278
135	6.51	1.25	Female	No	Thur	Lunch	2	-10.678278

## By Group Processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex', 'smoker']).first()
```

```
Out [65]:
```

		total_bill	tip	day	time	size	adj_total_bill
sex	smoker						

(continues on next page)

(continued from previous page)

Female	No	5.25	1.00	Sat	Dinner	1	-11.938278
	Yes	1.07	1.00	Sat	Dinner	1	-17.686344
Male	No	5.51	2.00	Thur	Lunch	2	-11.678278
	Yes	5.25	5.15	Sun	Dinner	2	-13.506344

## Other Considerations

### Disk vs Memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine's memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk `DataFrame`.

## 3.6 Tutorials

This is a guide to many pandas tutorials, geared mainly for new users.

### 3.6.1 Internal Guides

pandas' own *10 Minutes to pandas*.

More complex recipes are in the *Cookbook*.

A handy pandas [cheat sheet](#).

### 3.6.2 Community Guides

#### pandas Cookbook by Julia Evans

The goal of this 2015 cookbook (by [Julia Evans](#)) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the [pandas-cookbook GitHub repository](#).

#### Learn Pandas by Hernan Rojas

A set of lesson for new pandas users: <https://bitbucket.org/hrojas/learn-pandas>

#### Practical data analysis with Python

This [guide](#) is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as [munging data](#), [aggregating data](#), [visualizing data](#) and [time series](#).

#### Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

## USER GUIDE

The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min.

Further information on any specific method can be obtained in the *API Reference*.

### 4.1 IO Tools (Text, CSV, HDF5, ...)

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available readers and writers.

Format Type	Data Description	Reader	Writer
text	CSV	<code>read_csv</code>	<code>to_csv</code>
text	JSON	<code>read_json</code>	<code>to_json</code>
text	HTML	<code>read_html</code>	<code>to_html</code>
text	Local clipboard	<code>read_clipboard</code>	<code>to_clipboard</code>
binary	MS Excel	<code>read_excel</code>	<code>to_excel</code>
binary	HDF5 Format	<code>read_hdf</code>	<code>to_hdf</code>
binary	Feather Format	<code>read_feather</code>	<code>to_feather</code>
binary	Parquet Format	<code>read_parquet</code>	<code>to_parquet</code>
binary	Msgpack	<code>read_msgpack</code>	<code>to_msgpack</code>
binary	Stata	<code>read_stata</code>	<code>to_stata</code>
binary	SAS	<code>read_sas</code>	
binary	Python Pickle Format	<code>read_pickle</code>	<code>to_pickle</code>
SQL	SQL	<code>read_sql</code>	<code>to_sql</code>
SQL	Google Big Query	<code>read_gbq</code>	<code>to_gbq</code>

Here is an informal performance comparison for some of these IO methods.

---

**Note:** For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

---

### 4.1.1 CSV & Text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the *cookbook* for some advanced strategies.

#### Parsing options

`read_csv()` accepts the following common arguments:

##### Basic

**filepath\_or\_buffer** [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including `http`, `ftp`, and `S3` locations), or any object with a `read()` method (such as an open file or `StringIO`).

**sep** [str, defaults to `,` for `read_csv()`, `\t` for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `\s+` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\\r\\t'`.

**delimiter** [str, default `None`] Alternative argument name for `sep`.

**delim\_whitespace** [boolean, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\t'`) will be used as the delimiter. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

##### Column and Index Locations and Names

**header** [int or list of ints, default `'infer'`] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a `MultiIndex` on the columns e.g. `[0, 1, 3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int or sequence or `False`, default `None`] Column to use as the row labels of the `DataFrame`. If a sequence is given, a `MultiIndex` is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to *not* use the first column as the index (row names).

**usecols** [list-like or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from `data` with element order preserved use `pd.read_csv(data, usecols=['foo',`

'bar']))[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read\_csv(data, usecols=['foo', 'bar']))[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```
In [1]: from pandas.compat import StringIO, BytesIO

In [2]: data = ('col1,col2,col3\n'
...:          'a,b,1\n'
...:          'a,b,2\n'
...:          'c,d,3')
...:

In [3]: pd.read_csv(StringIO(data))
Out[3]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3

In [4]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3
Out[4]:
   col1 col3
0     a    1
1     a    2
2     c    3
```

Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, default None] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

**mangle\_dupe\_cols** [boolean, default True] Duplicate columns will be specified as 'X', 'X.1'...'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

### General Parsing Configuration

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype.

New in version 0.20.0: support for the Python parser.

**engine** [{'c', 'python'}] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, default None] Values to consider as True.

**false\_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.

**skiprows** [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [5]: data = ('col1,col2,col3\n'
...:          'a,b,1\n'
...:          'a,b,2\n'
...:          'c,d,3')
...:

In [6]: pd.read_csv(StringIO(data))
Out [6]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3

In [7]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out [7]:
   col1 col2 col3
0     a    b    2
```

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

**nrows** [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

**low\_memory** [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

**memory\_map** [boolean, default False] If a filepath is provided for filepath\_or\_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

### NA and Missing Data Handling

**na\_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See *na values const* below for a list of the values interpreted as NaN by default.

**keep\_default\_na** [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is True, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is True, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as False, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [boolean, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter*=False can improve the performance of reading a large file.

**verbose** [boolean, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [boolean, default `True`] If `True`, skip over blank lines rather than interpreting as `NaN` values.

## Datetime Handling

**parse\_dates** [boolean or list of ints or names or list of lists or dict, default `False`.]

- If `True` -> try parsing the index.
- If `[1, 2, 3]` -> try parsing columns 1, 2, 3 each as a separate date column.
- If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- If `{'foo': [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'. A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [boolean, default `False`] If `True` and `parse_dates` is enabled for a column, attempt to infer the datetime format to speed up the processing.

**keep\_date\_col** [boolean, default `False`] If `True` and `parse_dates` specifies combining multiple columns then keep the original columns.

**date\_parser** [function, default `None`] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [boolean, default `False`] DD/MM format dates, international and European format.

## Iteration

**iterator** [boolean, default `False`] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, default `None`] Return `TextFileReader` object for iteration. See *iterating and chunking* below.

## Quoting, Compression, and File Format

**compression** [`{'infer', 'gzip', 'bz2', 'zip', 'xz', None}`, default `'infer'`] For on-the-fly decompression of on-disk data. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if `filepath_or_buffer` is a string ending in `'.gz'`, `'.bz2'`, `'.zip'`, or `'.xz'`, respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to `None` for no decompression.

New in version 0.18.1: support for 'zip' and 'xz' compression.

Changed in version 0.24.0: 'infer' option added and set to default.

**thousands** [str, default `None`] Thousands separator.

**decimal** [str, default `'.'`] Character to recognize as decimal point. E.g. use `','` for European data.

**float\_precision** [string, default `None`] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

**lineterminator** [str (length 1), default `None`] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote** [boolean, default True] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements **inside** a field as a single `quotechar` element.

**escapechar** [str (length 1), default None] One-character string used to escape delimiter when quoting is `QUOTE_NONE`.

**comment** [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing `'#empty\na,b,c\n1,2,3'` with `header=0` will result in `'a,b,c'` being treated as the header.

**encoding** [str, default None] Encoding to use for UTF when reading/writing (e.g. `'utf-8'`). [List of Python standard encodings](#).

**dialect** [str or `csv.Dialect` instance, default None] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

**tupleize\_cols** [boolean, default False]

Deprecated since version 0.21.0.

This argument will be removed and will always convert to `MultiIndex`

Leave a list of tuples on columns as is (default is to convert to a `MultiIndex` on the columns).

## Error Handling

**error\_bad\_lines** [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will be dropped from the `DataFrame` that is returned. See *bad lines* below.

**warn\_bad\_lines** [boolean, default True] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

## Specifying column data types

You can indicate the data type for the whole `DataFrame` or individual columns:

```
In [8]: data = ('a,b,c,d\n'
...:          '1,2,3,4\n'
...:          '5,6,7,8\n'
...:          '9,10,11')
...:
```

```
In [9]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11
```

```
In [10]: df = pd.read_csv(StringIO(data), dtype=object)
```

(continues on next page)

(continued from previous page)

```

In [11]: df
Out[11]:
   a  b  c  d
0  1  2  3  4
1  5  6  7  8
2  9 10 11 NaN

In [12]: df['a'][0]
Out[12]:
1

In [13]: df = pd.read_csv(StringIO(data),
.....:                    dtype={'b': object, 'c': np.float64, 'd': 'Int64'})
.....:

In [14]: df.dtypes
Out[14]:
a      int64
b      object
c      float64
d      Int64
dtype: object

```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you're unfamiliar with these concepts, you can see [here](#) to learn more about dtypes, and [here](#) to learn more about object conversion in pandas.

For instance, you can use the `converters` argument of `read_csv()`:

```

In [15]: data = ("col_1\n"
.....:           "1\n"
.....:           "2\n"
.....:           "'A'\n"
.....:           "4.22")
.....:

In [16]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [17]: df
Out[17]:
   col_1
0      1
1      2
2      'A'
3  4.22

In [18]: df['col_1'].apply(type).value_counts()
Out[18]:
<class 'str'>    4
Name: col_1, dtype: int64

```

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

```

In [19]: df2 = pd.read_csv(StringIO(data))

In [20]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')

```

(continues on next page)

(continued from previous page)

```

In [21]: df2
Out[21]:
   col_1
0    1.00
1    2.00
2     NaN
3    4.22

In [22]: df2['col_1'].apply(type).value_counts()
Out[22]:
<class 'float'>    4
Name: col_1, dtype: int64

```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

New in version 0.20.0: support for the Python parser.

The `dtype` option is supported by the 'python' engine.

**Note:** In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```

In [23]: col_1 = list(range(500000)) + ['a', 'b'] + list(range(500000))

In [24]: df = pd.DataFrame({'col_1': col_1})

In [25]: df.to_csv('foo.csv')

In [26]: mixed_df = pd.read_csv('foo.csv')

In [27]: mixed_df['col_1'].apply(type).value_counts()
Out[27]:
<class 'int'>    737858
<class 'str'>   262144
Name: col_1, dtype: int64

In [28]: mixed_df['col_1'].dtype
Out[28]:
dtype('O')

```

will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of `object`, which is used for columns with mixed dtypes.

## Specifying Categorical dtype

New in version 0.19.0.

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```
In [29]: data = ('col1,col2,col3\n'
.....:          'a,b,1\n'
.....:          'a,b,2\n'
.....:          'c,d,3')
.....:

In [30]: pd.read_csv(StringIO(data))
Out [30]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3

In [31]: pd.read_csv(StringIO(data)).dtypes
Out [31]:
col1    object
col2    object
col3    int64
dtype: object

In [32]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out [32]:
col1    category
col2    category
col3    category
dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification:

```
In [33]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out [33]:
col1    category
col2    object
col3    int64
dtype: object
```

New in version 0.21.0.

Specifying `dtype='category'` will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a CategoricalDtype ahead of time, and pass that for that column's dtype.

```
In [34]: from pandas.api.types import CategoricalDtype

In [35]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)

In [36]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out [36]:
col1    category
col2    object
col3    int64
dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as

missing values.

```
In [37]: dtype = CategoricalDtype(['a', 'b', 'd']) # No 'c'

In [38]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out [38]:
0      a
1      a
2     NaN
Name: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of `Categorical.set_categories()`.

---

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [39]: df = pd.read_csv(StringIO(data), dtype='category')

In [40]: df.dtypes
Out [40]:
col1    category
col2    category
col3    category
dtype: object

In [41]: df['col3']
Out [41]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [42]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [43]: df['col3']
Out [43]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
```

---

## Naming and Using Columns

### Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

(continued from previous page)

```
1 4 5 6
2 7 8 9
```

---

**Note:** Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

---

## Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [52]: data = ('a,b,a\n'
.....:          '0,1,2\n'
.....:          '3,4,5')
.....:

In [53]: pd.read_csv(StringIO(data))
Out[53]:
   a  b  a.1
0  0  1    2
1  3  4    5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns 'X', ..., 'X' to become 'X', 'X.1', ..., 'X.N'. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  2  1  2
1  5  4  5
```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

## Filtering columns (`usecols`)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

New in version 0.20.0: support for callable `usecols` arguments

```
In [54]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'
```

(continues on next page)

(continued from previous page)

```

In [55]: pd.read_csv(StringIO(data))
Out[55]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz

In [56]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[56]:
   b  d
0  2  foo
1  5  bar
2  8  baz

In [57]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
Out[57]:
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz

In [58]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
Out[58]:
   a  c
0  1  3
1  4  6
2  7  9

```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```

In [59]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[59]:
   b  d
0  2  foo
1  5  bar
2  8  baz

```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

## Comments and Empty Lines

### Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```

In [60]: data = ('\n'
.....:           'a,b,c\n'
.....:           '\n'
.....:           '# commented line\n'
.....:           '1,2,3\n'
.....:           '\n'
.....:           '4,5,6')

```

(continues on next page)

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:

```
In [69]: data = ('# empty\n'
.....:          '# second empty line\n'
.....:          '# third emptyline\n'
.....:          'X,Y,Z\n'
.....:          '1,2,3\n'
.....:          'A,B,C\n'
.....:          '1,2.,4.\n'
.....:          '5.,NaN,10.0\n')
.....:

In [70]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.
5.,NaN,10.0

In [71]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
Out[71]:
↪
   A    B    C
0  1.0  2.0  4.0
1  5.0  NaN 10.0
```

## Comments

Sometimes comments or meta data may be included in a file:

```
In [72]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```
In [73]: df = pd.read_csv('tmp.csv')

In [74]: df
Out[74]:
   ID    level          category
0  Patient1  123000  x # really unpleasant
1  Patient2   23000  y # wouldn't take his medicine
2  Patient3 1234018  z # awesome
```

We can suppress the comments using the `comment` keyword:

```
In [75]: df = pd.read_csv('tmp.csv', comment='#')
```

```
In [76]: df
```

```
Out [76]:
```

```
      ID  level category
0  Patient1  123000      x
1  Patient2   23000      y
2  Patient3 1234018      z
```

## Dealing with Unicode Data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```
In [77]: data = (b'word,length\n'
.....:          b'Tr\xc3\xa4umen,7\n'
.....:          b'Gr\xc3\xbc\xc3\xfe,5')
.....:
```

```
In [78]: data = data.decode('utf8').encode('latin-1')
```

```
In [79]: df = pd.read_csv(BytesIO(data), encoding='latin-1')
```

```
In [80]: df
```

```
Out [80]:
```

```
      word  length
0  Tr\u00e4umen      7
1   Gr\u00fc\u00dfe      5
```

```
In [81]: df['word'][1]
```

```
Out [81]: 'Gr\u00fc\u00dfe'
```

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. [Full list of Python standard encodings](#).

## Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame's row names:

```
In [82]: data = ('a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
.....:
```

```
In [83]: pd.read_csv(StringIO(data))
```

```
Out [83]:
```

```
      a  b  c
4  apple bat  5.7
8  orange cow 10.0
```

```
In [84]: data = ('index,a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////Out [93]:
      b   c
4  bat NaN
8  cow NaN

```

## Date Handling

### Specifying Date Columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into datetime objects.

The simplest case is to just pass in `parse_dates=True`:

```

# Use a column as an index, and parse it as dates.
In [94]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)

In [95]: df
Out [95]:
           A  B  C
date
2009-01-01  a  1  2
2009-01-02  b  3  4
2009-01-03  c  4  5

# These are Python datetime objects
In [96]: df.index
////////////////////////////////////
↳ DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]',
↳ name='date', freq=None)

```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```

In [97]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [98]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])

In [99]: df
Out [99]:
           1_2           1_3    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD -0.59

```

(continues on next page)

(continued from previous page)

```

3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```

In [100]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
.....:                  keep_date_col=True)
.....:

In [101]: df
Out[101]:

```

	1_2	1_3	0	1	2	3	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	19990127	19:00:00	18:56:00	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	19990127	20:00:00	19:56:00	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	19990127	21:00:00	20:56:00	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	19990127	21:00:00	21:18:00	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	19990127	22:00:00	21:56:00	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	19990127	23:00:00	22:56:00	-0.59

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```

In [102]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [104]: df
Out[104]:

```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```

In [105]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                  index_col=0) # index is the nominal column
.....:

In [107]: df
Out[107]:

```

	nominal	actual	0	4
1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81	

(continues on next page)

(continued from previous page)

```
1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

**Note:** If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** `read_csv` has a `fast_path` for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

**Note:** When passing a dict as the `parse_dates` argument, the order of the columns prepended is not guaranteed, because `dict` objects do not impose an ordering on their keys. On Python 2.7+ you may use `collections.OrderedDict` instead of a regular `dict` if this matters to you. Because of this, when using a dict for ‘`parse_dates`’ in conjunction with the `index_col` argument, it’s best to specify `index_col` as a column label rather than as an index on the resulting frame.

## Date Parsing Functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```
In [108]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                   date_parser=pd.io.date_converters.parse_date_time)
.....:

In [109]: df
Out[109]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

### Parsing a CSV with mixed Timezones

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```
In [110]: content = """\
.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [111]: df = pd.read_csv(StringIO(content), parse_dates=['a'])

In [112]: df['a']
Out[112]:
0    2000-01-01 00:00:00+05:00
1    2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```
In [113]: df = pd.read_csv(StringIO(content), parse_dates=['a'],
.....:                      date_parser=lambda col: pd.to_datetime(col, utc=True))
.....:

In [114]: df['a']
Out[114]:
0    1999-12-31 19:00:00+00:00
1    1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

### Inferring Datetime Format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

(continued from previous page)

```
Patient2|23,000|y
Patient3|1,234,018|z
```

```
In [130]: df = pd.read_csv('tmp.csv', sep='|', thousands=',')
```

```
In [131]: df
```

```
Out [131]:
```

	ID	level	category
0	Patient1	123000	x
1	Patient2	23000	y
2	Patient3	1234018	z

```
In [132]: df.level.dtype
```

```
dtype('int64')
```

## NA Values

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', '#N/A', 'N/A', 'n/a', 'NA', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```
pd.read_csv('path_to_file.csv', na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=[""])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv('path_to_file.csv', na_values=["Nope"])
```

The default values, in addition to the string "Nope" are recognized as NaN.

## Infinity

`inf` like values will be parsed as `np.inf` (positive infinity), and `-inf` as `-np.inf` (negative infinity). These will ignore the case of the value, meaning `Inf`, will also be parsed as `np.inf`.

## Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a `Series`:

```
In [133]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [134]: output = pd.read_csv('tmp.csv', squeeze=True)

In [135]: output
Out[135]:
Patient1      123000
Patient2       23000
Patient3     1234018
Name: level, dtype: int64

In [136]: type(output)
\\////////////////////////////////////Out
↪pandas.core.series.Series
```

## Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

```
In [137]: data = ('a,b,c\n'
.....:             '1,Yes,2\n'
.....:             '3,No,4')
.....:

In [138]: print(data)
a,b,c
1,Yes,2
3,No,4

In [139]: pd.read_csv(StringIO(data))
\\////////////////////////////////////Out[139]:
   a  b  c
0  1  Yes  2
1  3  No  4

In [140]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
\\////////////////////////////////////Out[140]:
   a  b  c
0  1  True  2
1  3  False  4
```

## Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```

In [141]: data = ('a,b,c\n'
.....:          '1,2,3\n'
.....:          '4,5,6,7\n'
.....:          '8,9,10')
.....:

In [142]: pd.read_csv(StringIO(data))

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader.read()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._read_low_memory()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._read_rows()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._tokenize_rows()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.raise_parser_error()

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4

```

You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4

Out [29]:
   a  b  c
0  1  2  3
1  8  9 10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])

Out [30]:
   a  b  c
0  1  2  3
1  4  5  6
2  8  9 10
```

## Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [143]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [144]: import csv

In [145]: dia = csv.excel()

In [146]: dia.quoting = csv.QUOTE_NONE

In [147]: pd.read_csv(StringIO(data), dialect=dia)
Out [147]:
   label1 label2 label3
index1   "a      c      e
index2    b      d      f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [148]: data = 'a,b,c~1,2,3~4,5,6'

In [149]: pd.read_csv(StringIO(data), lineterminator='~')
Out [149]:
   a  b  c
```

(continues on next page)

```
In [156]: print(open('bar.csv').read())
id8141    360.242940    149.910199    11950.7
id1594    444.953632    166.985655    11788.4
id1849    364.136849    183.628767    11806.2
id1230    413.836124    184.375703    11916.8
id1948    502.953953    173.237159    12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [157]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [158]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)

In [159]: df
Out[159]:
```

	1	2	3
0			
id8141	360.242940	149.910199	11950.7
id1594	444.953632	166.985655	11788.4
id1849	364.136849	183.628767	11806.2
id1230	413.836124	184.375703	11916.8
id1948	502.953953	173.237159	12468.3

Note how the parser automatically picks column names X.<column number> when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```
# Widths are a list of integers
In [160]: widths = [6, 14, 13, 10]

In [161]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [162]: df
Out[162]:
```

	0	1	2	3
0	id8141	360.242940	149.910199	11950.7
1	id1594	444.953632	166.985655	11788.4
2	id1849	364.136849	183.628767	11806.2
3	id1230	413.836124	184.375703	11916.8
4	id1948	502.953953	173.237159	12468.3

The parser will take care of extra white spaces around the columns so it's ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file's `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [163]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [164]: df
Out[164]:
```

	1	2	3
0			
id8141	360.242940	149.910199	11950.7
id1594	444.953632	166.985655	11788.4

(continues on next page)

(continued from previous page)

```
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3
```

New in version 0.20.0.

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [165]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[165]:
1    float64
2    float64
3    float64
dtype: object

In [166]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[166]:
0    object
1    float64
2    object
3    float64
dtype: object
```

## Indexes

### Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [167]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the `DataFrame`:

```
In [168]: pd.read_csv('foo.csv')
Out[168]:
      A  B  C
20090101  a  1  2
20090102  b  3  4
20090103  c  4  5
```

Note that the dates weren't automatically parsed. In that case you would need to do as before:

```
In [169]: df = pd.read_csv('foo.csv', parse_dates=True)

In [170]: df.index
Out[170]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype=
  ↳ 'datetime64[ns]', freq=None)
```

## Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [171]: print(open('data/minindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:

```
In [172]: df = pd.read_csv("data/minindex_ex.csv", index_col=[0, 1])
```

```
In [173]: df
```

```
Out[173]:
```

year	indiv	zit	xit
1977	A	1.20	0.60
	B	1.50	0.50
	C	1.70	0.80
1978	A	0.20	0.06
	B	0.70	0.20
	C	0.80	0.30
	D	0.90	0.50
	E	1.40	0.90
1979	C	0.20	0.15
	D	0.14	0.05
	E	0.50	0.15
	F	1.20	0.50
	G	3.40	1.90
	H	5.40	2.70
	I	6.40	1.20

```
In [174]: df.loc[1978]
```

```

////////////////////////////////////
↪
      zit  xit
indiv
A      0.2  0.06
B      0.7  0.20
C      0.8  0.30
D      0.9  0.50
E      1.4  0.90
```

## Reading columns with a MultiIndex

By specifying list of row locations for the header argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```
In [175]: from pandas.util.testing import makeCustomDataframe as mkdf
```

```
In [176]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
```

```
In [177]: df.to_csv('mi.csv')
```

```
In [178]: print(open('mi.csv').read())
```

```
C0,,C_10_g0,C_10_g1,C_10_g2
C1,,C_11_g0,C_11_g1,C_11_g2
C2,,C_12_g0,C_12_g1,C_12_g2
C3,,C_13_g0,C_13_g1,C_13_g2
R0,R1,,,
R_10_g0,R_11_g0,R0C0,R0C1,R0C2
R_10_g1,R_11_g1,R1C0,R1C1,R1C2
R_10_g2,R_11_g2,R2C0,R2C1,R2C2
R_10_g3,R_11_g3,R3C0,R3C1,R3C2
R_10_g4,R_11_g4,R4C0,R4C1,R4C2
```

```
In [179]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])
```

```
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
C0             C_10_g0 C_10_g1 C_10_g2
C1             C_11_g0 C_11_g1 C_11_g2
C2             C_12_g0 C_12_g1 C_12_g2
C3             C_13_g0 C_13_g1 C_13_g2
R0             R1
R_10_g0 R_11_g0   R0C0   R0C1   R0C2
R_10_g1 R_11_g1   R1C0   R1C1   R1C2
R_10_g2 R_11_g2   R2C0   R2C1   R2C2
R_10_g3 R_11_g3   R3C0   R3C1   R3C2
R_10_g4 R_11_g4   R4C0   R4C1   R4C2
```

read\_csv is also able to interpret a more common format of multi-columns indices.

```
In [180]: print(open('mi2.csv').read())
```

```
,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12
```

```
In [181]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)
```

```
\\////////////////////////////////////////////////////////////////\\\Out [181]:
      a      b      c
q  r  s  t  u  v
one 1  2  3  4  5  6
two 7  8  9 10 11 12
```

Note: If an index\_col is not specified (e.g. you don't have an index, or wrote it with df.to\_csv(..., index=False), then any names on the columns index will be *lost*.

## Automatically “sniffing” the delimiter

`read_csv` is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the `csv` module. For this, you have to specify `sep=None`.

```
In [182]: print(open('tmp2.csv').read())
:0:1:2:3
0:0.4691122999071863:-0.2828633443286633:-1.5090585031735124:-1.1356323710171934

## Reading multiple files to create a single DataFrame

It’s best to use `concat()` to combine multiple files. See the *cookbook* for an example.

## Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [184]: print(open('tmp.csv').read())
|0|1|2|3
0|0.4691122999071863|-0.2828633443286633|-1.5090585031735124|-1.1356323710171934
1|1.2121120250208506|-0.17321464905330858|0.11920871129693428|-1.0442359662799567
2|-0.8618489633477999|-2.1045692188948086|-0.4949292740687813|1.071803807037338
3|0.7215551622443669|-0.7067711336300845|-1.0395749851146963|0.27185988554282986
4|-0.42497232978883753|0.567020349793672|0.27623201927771873|-1.0874006912859915
5|-0.6736897080883706|0.1136484096888855|-1.4784265524372235|0.5249876671147047

8|1.0757697837155533|-0.10904997528022223|1.6435630703622064|-1.4693879595399115
9|0.35702056413309086|-0.6746001037299882|-1.776903716971867|-0.9689138124473498
```

(continues on next page)

## Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

## Reading remote files

You can pass in a URL to a CSV file:

```
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                sep='\t')
```

S3 URLs are handled as well but require installing the [S3Fs](#) library:

```
df = pd.read_csv('s3://pandas-test/tips.csv')
```

If your S3 bucket requires credentials you will need to set them as environment variables or in the `~/.aws/credentials` config file, refer to the [S3Fs documentation on credentials](#).

## Writing out Data

### Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a `StringIO`
- `sep`: Field delimiter for the output file (default “,”)
- `na_rep`: A string representation of a missing value (default “”)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default `None`)
- `header`: Whether to write out the column names (default `True`)
- `index`: whether to write row (index) names (default `True`)
- `index_label`: Column label(s) for index column(s) if desired. If `None` (default), and `header` and `index` are `True`, then the index names are used. (A sequence should be given if the `DataFrame` uses `MultiIndex`).
- `mode`: Python write mode, default ‘w’
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default ‘\n’)

- `quoting`: Set quoting rules as in `csv` module (default `csv.QUOTE_MINIMAL`). Note that if you have set a `float_format` then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- `quotechar`: Character used to quote fields (default `"`)
- `doublequote`: Control quoting of `quotechar` in fields (default `True`)
- `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default `None`)
- `chunksize`: Number of rows to write at a time
- `tupleize_cols`: If `False` (default), write as a list of tuples, otherwise write in an expanded line format suitable for `read_csv`
- `date_format`: Format string for datetime objects

### Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default `None`, for example a `StringIO` object
- `columns` default `None`, which columns to write
- `col_space` default `None`, minimum width of each column.
- `na_rep` default `NaN`, representation of NA value
- `formatters` default `None`, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default `None`, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`.
- `sparsify` default `True`, set to `False` for a `DataFrame` with a hierarchical index to print every `MultiIndex` key at each row.
- `index_names` default `True`, will print the names of the indices
- `index` default `True`, will print the index (ie, row labels)
- `header` default `True`, will print the column labels
- `justify` default `left`, will print column headers left- or right-justified

The `Series` object also has a `to_string` method, but with only the `buf`, `na_rep`, `float_format` arguments. There is also a `length` argument which, if set to `True`, will additionally output the length of the `Series`.

## 4.1.2 JSON

Read and write JSON format files and strings.

### Writing JSON

A `Series` or `DataFrame` can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf`: the pathname or buffer to write the output This can be `None` in which case a JSON string is returned

- `orient` :

**Series:**

- default is `index`
- allowed values are `{split, records, index}`

**DataFrame:**

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<code>split</code>	dict like <code>{index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</code>
<code>records</code>	list like <code>[{column -&gt; value}, ... , {column -&gt; value}]</code>
<code>index</code>	dict like <code>{index -&gt; {column -&gt; value}}</code>
<code>columns</code>	dict like <code>{column -&gt; {index -&gt; value}}</code>
<code>values</code>	just the values array

- `date_format` : string, type of date conversion, 'epoch' for timestamp, 'iso' for ISO8601.
- `double_precision` : The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii` : force encoded string to be ASCII, default True.
- `date_unit` : The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us' or 'ns' for seconds, milliseconds, microseconds and nanoseconds respectively. Default 'ms'.
- `default_handler` : The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines` : If `records` orient, then will write each record per line as json.

Note NaN's, NaT's and None will be converted to null and datetime objects will be converted based on the `date_format` and `date_unit` parameters.

```
In [192]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [193]: json = dfj.to_json()
In [194]: json
Out[194]: '{"A":{"0":-1.2945235903,"1":0.2766617129,"2":-0.0139597524,"3":-0.
↪0061535699,"4":0.8957173022},"B":{"0":0.4137381054,"1":-0.472034511,"2":-0.
↪3625429925,"3":-0.923060654,"4":0.8052440254}}'
```

## Orient Options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [195]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
.....:                          columns=list('ABC'), index=list('xyz'))
.....:
In [196]: dfjo
Out[196]:
```

(continues on next page)

(continued from previous page)

```

    A  B  C
x  1  4  7
y  2  5  8
z  3  6  9

In [197]: sjo = pd.Series(dict(x=15, y=16, z=17), name='D')

In [198]: sjo
Out [198]:
x      15
y      16
z      17
Name: D, dtype: int64

```

**Column oriented** (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

```

In [199]: dfjo.to_json(orient="columns")
Out [199]: '{"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'

# Not available for Series

```

**Index oriented** (the default for Series) similar to column oriented but the index labels are now primary:

```

In [200]: dfjo.to_json(orient="index")
Out [200]: '{"x":{"A":1,"B":4,"C":7},"y":{"A":2,"B":5,"C":8},"z":{"A":3,"B":6,"C":9}}'

In [201]: sjo.to_json(orient="index")
Out [201]:
\\Out [201]:
↪ '{"x":15,"y":16,"z":17}'

```

**Record oriented** serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

```

In [202]: dfjo.to_json(orient="records")
Out [202]: '[{"A":1,"B":4,"C":7}, {"A":2,"B":5,"C":8}, {"A":3,"B":6,"C":9}]'

In [203]: sjo.to_json(orient="records")
Out [203]:
\\Out [203]:
↪ '[15,16,17]'

```

**Value oriented** is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

```

In [204]: dfjo.to_json(orient="values")
Out [204]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series

```

**Split oriented** serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

```

In [205]: dfjo.to_json(orient="split")
Out [205]: '{"columns":["A","B","C"],"index":["x","y","z"],"data":[[1,4,7],[2,5,8],[3,6,9]]}'

```

(continues on next page)

(continued from previous page)

```
In [206]: sjo.to_json(orient="split")
Out [206]: '["name": "D", "index": ["x", "y", "z"], "data": [15, 16, 17]]'
```

**Table oriented** serializes to the JSON **Table Schema**, allowing for the preservation of metadata including but not limited to dtypes and index names.

**Note:** Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the *split* option as it uses ordered containers.

## Date Handling

Writing in ISO date format:

```
In [207]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [208]: dfd['date'] = pd.Timestamp('20130101')
In [209]: dfd = dfd.sort_index(1, ascending=False)
In [210]: json = dfd.to_json(date_format='iso')
In [211]: json
Out [211]: '{"date":{"0":"2013-01-01T00:00:00.000Z", "1":"2013-01-01T00:00:00.000Z", "2":
↳ "2013-01-01T00:00:00.000Z", "3":"2013-01-01T00:00:00.000Z", "4":"2013-01-01T00:00:00.
↳ 000Z"}, "B":{"0":2.5656459463, "1":1.3403088498, "2":-0.2261692849, "3":0.8138502857, "4
↳ :-0.8273169356}, "A":{"0":-1.2064117817, "1":1.4312559863, "2":-1.1702987971, "3":0.
↳ 4108345112, "4":0.1320031703}}'
```

Writing in ISO date format, with microseconds:

```
In [212]: json = dfd.to_json(date_format='iso', date_unit='us')
In [213]: json
Out [213]: '{"date":{"0":"2013-01-01T00:00:00.000000Z", "1":"2013-01-01T00:00:00.000000Z
↳ ", "2":"2013-01-01T00:00:00.000000Z", "3":"2013-01-01T00:00:00.000000Z", "4":"2013-01-
↳ 01T00:00:00.000000Z"}, "B":{"0":2.5656459463, "1":1.3403088498, "2":-0.2261692849, "3
↳ :0.8138502857, "4":-0.8273169356}, "A":{"0":-1.2064117817, "1":1.4312559863, "2":-1.
↳ 1702987971, "3":0.4108345112, "4":0.1320031703}}'
```

Epoch timestamps, in seconds:

```
In [214]: json = dfd.to_json(date_format='epoch', date_unit='s')
In [215]: json
Out [215]: '{"date":{"0":1356998400, "1":1356998400, "2":1356998400, "3":1356998400, "4
↳ :1356998400}, "B":{"0":2.5656459463, "1":1.3403088498, "2":-0.2261692849, "3":0.
↳ 8138502857, "4":-0.8273169356}, "A":{"0":-1.2064117817, "1":1.4312559863, "2":-1.
↳ 1702987971, "3":0.4108345112, "4":0.1320031703}}'
```

Writing to a file, with a date index and a date column:

```

In [216]: dfj2 = dfj.copy()

In [217]: dfj2['date'] = pd.Timestamp('20130101')

In [218]: dfj2['ints'] = list(range(5))

In [219]: dfj2['bools'] = True

In [220]: dfj2.index = pd.date_range('20130101', periods=5)

In [221]: dfj2.to_json('test.json')

In [222]: with open('test.json') as fh:
.....:     print(fh.read())
.....:
{"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,"1357171200000":-0.
↪0139597524,"1357257600000":-0.0061535699,"1357344000000":0.8957173022},"B":{"
↪"1356998400000":0.4137381054,"1357084800000":-0.472034511,"1357171200000":-0.
↪3625429925,"1357257600000":-0.923060654,"1357344000000":0.8052440254},"date":{"
↪"1356998400000":1356998400000,"1357084800000":1356998400000,"1357171200000
↪":1356998400000,"1357257600000":1356998400000,"1357344000000":1356998400000},"ints":
↪{"1356998400000":0,"1357084800000":1,"1357171200000":2,"1357257600000":3,
↪"1357344000000":4},"bools":{"1356998400000":true,"1357084800000":true,"1357171200000
↪":true,"1357257600000":true,"1357344000000":true}}

```

## Fallback Behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. `np.complex`) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a `toDict` method and call it. A `toDict` method should return a `dict` which will then be JSON serialized.
  - invoke the `default_handler` if one was provided.
  - convert the object to a `dict` by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:

```

>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json() # raises
RuntimeError: Unhandled numpy dtype 15

```

can be dealt with by specifying a simple `default_handler`:

```

In [223]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out [223]: '{"0":{"0":"(1+0j)", "1":"(2+0j)", "2":"(1+2j)"}}'

```

## Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a `DataFrame` if `typ` is not supplied or is `None`. To explicitly force `Series` parsing, pass `typ=series`

- `filepath_or_buffer` : a **VALID** JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file `://localhost/path/to/table.json`
- `typ` : type of object to recover (series or frame), default 'frame'
- `orient` :

**Series :**

- default is `index`
- allowed values are `{split, records, index}`

**DataFrame**

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<code>split</code>	dict like <code>{index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</code>
<code>records</code>	list like <code>[{column -&gt; value}, ... , {column -&gt; value}]</code>
<code>index</code>	dict like <code>{index -&gt; {column -&gt; value}}</code>
<code>columns</code>	dict like <code>{column -&gt; {index -&gt; value}}</code>
<code>values</code>	just the values array
<code>table</code>	adhering to the JSON <a href="#">Table Schema</a>

- `dtype` : if `True`, infer dtypes, if a dict of column to dtype, then use those, if `False`, then don't infer dtypes at all, default is `True`, apply only to the data.
- `convert_axes` : boolean, try to convert the axes to the proper dtypes, default is `True`
- `convert_dates` : a list of columns to parse for dates; If `True`, then try to parse date-like columns, default is `True`.
- `keep_default_dates` : boolean, default `True`. If parsing dates, then parse the default date-like columns.
- `numpy` : direct decoding to NumPy arrays. default is `False`; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering **MUST** be the same for each term if `numpy=True`.
- `precise_float` : boolean, default `False`. Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (`False`) is to use fast but less precise builtin functionality.
- `date_unit` : string, the timestamp unit to detect if converting dates. Default `None`. By default the timestamp precision will be detected, if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines` : reads file as one json object per line.
- `encoding` : The encoding to use to decode py3 bytes.
- `chunksize` : when used in combination with `lines=True`, return a `JsonReader` which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see *Orient Options* for an overview.

## Data Conversion

The default of `convert_axes=True`, `dtype=True`, and `convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. '1', '2') in an axes.

---

**Note:** Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear 'date-like'. The exact threshold depends on the `date_unit` specified. 'date-like' means that the column label meets one of the following criteria:

- it ends with '\_at'
- it ends with '\_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

---

**Warning:** When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of 1.
- `bool` columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [224]: pd.read_json(json)
```

```
Out [224]:
```

	date	B	A
0	2013-01-01	2.565646	-1.206412
1	2013-01-01	1.340309	1.431256
2	2013-01-01	-0.226169	-1.170299
3	2013-01-01	0.813850	0.410835
4	2013-01-01	-0.827317	0.132003

Reading from a file:

```
In [225]: pd.read_json('test.json')
```

```
Out [225]:
```

	A	B	date	ints	bools
2013-01-01	-1.294524	0.413738	2013-01-01	0	True
2013-01-02	0.276662	-0.472035	2013-01-01	1	True
2013-01-03	-0.013960	-0.362543	2013-01-01	2	True
2013-01-04	-0.006154	-0.923061	2013-01-01	3	True
2013-01-05	0.895717	0.805244	2013-01-01	4	True

Don't convert any data (but still convert axes and dates):

```
In [244]: randfloats = np.random.uniform(-100, 1000, 10000)
```

```
In [245]: randfloats.shape = (1000, 10)
```

```
In [246]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))
```

```
In [247]: jsonfloats = dffloats.to_json()
```

```
In [248]: %timeit pd.read_json(jsonfloats)
11.8 ms +- 612 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [249]: %timeit pd.read_json(jsonfloats, numpy=True)
8.59 ms +- 192 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [250]: jsonfloats = dffloats.head(100).to_json()
```

```
In [251]: %timeit pd.read_json(jsonfloats)
7.78 ms +- 155 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [252]: %timeit pd.read_json(jsonfloats, numpy=True)
6.88 ms +- 164 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Warning:** Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

## Normalization

pandas provides a utility function to take a dict or list of dicts and *normalize* this semi-structured data into a flat table.

```
In [253]: from pandas.io.json import json_normalize
```

```
In [254]: data = [{'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},
.....:             {'name': {'given': 'Mose', 'family': 'Regner'}},
.....:             {'id': 2, 'name': 'Faye Raker'}]
.....:
```

```
In [255]: json_normalize(data)
```

```
Out[255]:
```

	id	name	name.family	name.first	name.given	name.last
0	1.0	NaN	NaN	Coleen	NaN	Volk
1	NaN	NaN	Regner	NaN	Mose	NaN
2	2.0	Faye Raker	NaN	NaN	NaN	NaN

```
In [256]: data = [{'state': 'Florida',
.....:             'shortname': 'FL',
.....:             'info': {'governor': 'Rick Scott'},
.....:             'counties': [{'name': 'Dade', 'population': 12345},
.....:                           {'name': 'Broward', 'population': 40000},
.....:                           {'name': 'Palm Beach', 'population': 60000}]},
.....: {'state': 'Ohio',
.....:     'shortname': 'OH',
.....:     'info': {'governor': 'John Kasich'},
.....:     'counties': [{'name': 'Summit', 'population': 1234},
.....:                   {'name': 'Cuyahoga', 'population': 1337}]}]

In [257]: json_normalize(data, 'counties', ['state', 'shortname', ['info', 'governor
↪']])
Out [257]:
```

	name	population	state	shortname	info.governor
0	Dade	12345	Florida	FL	Rick Scott
1	Broward	40000	Florida	FL	Rick Scott
2	Palm Beach	60000	Florida	FL	Rick Scott
3	Summit	1234	Ohio	OH	John Kasich
4	Cuyahoga	1337	Ohio	OH	John Kasich

### Line delimited json

New in version 0.19.0.

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```
In [258]: jsonl = '''
.....:     {"a": 1, "b": 2}
.....:     {"a": 3, "b": 4}
.....: '''
.....:

In [259]: df = pd.read_json(jsonl, lines=True)

In [260]: df
Out [260]:
```

	a	b
0	1	2
1	3	4

```
In [261]: df.to_json(orient='records', lines=True)
Out [261]: '{"a":1,"b":2}\n{"a":3,"b":4}'

# reader is an iterator that returns `chunksize` lines each iteration
In [262]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [263]: reader
Out [263]: <pandas.io.json.json.JsonReader at 0x7f7a09505898>
```

(continues on next page)

Pandas type	Table Schema type
int64	integer
float64	number
bool	boolean
datetime64[ns]	datetime
timedelta64[ns]	duration
categorical	any
object	str

A few notes on the generated table schema:

- The schema object contains a `pandas_version` field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.
- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

```
In [268]: from pandas.io.json import build_table_schema

In [269]: s = pd.Series(pd.date_range('2016', periods=4))

In [270]: build_table_schema(s)
Out[270]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. 'US/Central').

```
In [271]: s_tz = pd.Series(pd.date_range('2016', periods=12,
.....:                                     tz='US/Central'))
.....:

In [272]: build_table_schema(s_tz)
Out[272]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field `freq` with the period's frequency, e.g. 'A-DEC'.

```
In [273]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
.....:                                               periods=4))
.....:

In [274]: build_table_schema(s_per)
Out[274]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
             {'name': 'values', 'type': 'integer'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Categoricals use the `any` type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

```
In [275]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [276]: build_table_schema(s_cat)
Out[276]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values',
             'type': 'any',
             'constraints': {'enum': ['a', 'b']},
             'ordered': False}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- A `primaryKey` field, containing an array of labels, is included *if the index is unique*:

```
In [277]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [278]: build_table_schema(s_dupe)
Out[278]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
 'pandas_version': '0.20.0'}
```

- The `primaryKey` behavior is the same with `MultiIndexes`, but in this case the `primaryKey` is an array:

```
In [279]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
.....:                                                             (0, 1)]))
.....:

In [280]: build_table_schema(s_multi)
Out[280]:
{'fields': [{'name': 'level_0', 'type': 'string'},
            {'name': 'level_1', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
 'primaryKey': FrozenList(['level_0', 'level_1']),
 'pandas_version': '0.20.0'}
```

- The default naming roughly follows these rules:
  - For series, the object `.name` is used. If that's none, then the name is `values`
  - For DataFrames, the stringified version of the column name is used
  - For Index (not `MultiIndex`), `index.name` is used, with a fallback to `index` if that is `None`.
  - For `MultiIndex`, `mi.names` is used. If any level has no name, then `level_<i>` is used.

New in version 0.23.0.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [281]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
.....:                      'bar': ['a', 'b', 'c', 'd'],
.....:                      'baz': pd.date_range('2018-01-01', freq='d',
↳ periods=4),
.....:                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])
.....:                      }, index=pd.Index(range(4), name='idx'))
```

(continues on next page)

(continued from previous page)

```

.....:

In [282]: df
Out[282]:
   foo bar      baz qux
idx
0     1  a 2018-01-01  a
1     2  b 2018-01-02  b
2     3  c 2018-01-03  c
3     4  d 2018-01-04  c

```

```

In [283]: df.dtypes
////////////////////////////////////
↪
foo          int64
bar          object
baz    datetime64[ns]
qux          category
dtype: object

```

```
In [284]: df.to_json('test.json', orient='table')
```

```
In [285]: new_df = pd.read_json('test.json', orient='table')
```

```

In [286]: new_df
Out[286]:
   foo bar      baz qux
idx
0     1  a 2018-01-01  a
1     2  b 2018-01-02  b
2     3  c 2018-01-03  c
3     4  d 2018-01-04  c

```

```

In [287]: new_df.dtypes
////////////////////////////////////
↪
foo          int64
bar          object
baz    datetime64[ns]
qux          category
dtype: object

```

Please note that the literal string ‘index’ as the name of an *Index* is not round-trippable, nor are any names beginning with ‘level\_’ within a *MultiIndex*. These are used by default in *DataFrame.to\_json()* to indicate missing values and the subsequent read cannot distinguish the intent.

```

In [288]: df.index.name = 'index'

In [289]: df.to_json('test.json', orient='table')

In [290]: new_df = pd.read_json('test.json', orient='table')

In [291]: print(new_df.index.name)
None

```

### 4.1.3 HTML

#### Reading HTML Content

**Warning:** We **highly encourage** you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let's look at a few examples.

**Note:** `read_html` returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [292]: url = 'https://www.fdic.gov/bank/individual/failed/banklist.html'

In [293]: dfs = pd.read_html(url)

In [294]: dfs
Out[294]:
```

	Bank Name	...	Updated Date
0	Washington Federal Bank for Savings	...	February 21, 2018
1	The Farmers and Merchants State Bank of Argonia	...	February 21, 2018
2	Fayette County Bank	...	January 29, 2019
3	Guaranty Bank, (d/b/a BestBank in Georgia & Mi...	...	March 22, 2018
4	First NBC Bank	...	January 29, 2019
5	Proficio Bank	...	January 29, 2019
6	Seaway Bank and Trust Company	...	January 29, 2019
..	...	...	...
548	Hamilton Bank, NA En Espanol	...	September 21, 2015
549	Sinclair National Bank	...	October 6, 2017
550	Superior Bank, FSB	...	August 19, 2014
551	Malta National Bank	...	November 18, 2002
552	First Alliance Bank & Trust Co.	...	February 18, 2003
553	National State Bank of Metropolis	...	March 17, 2005
554	Bank of Honolulu	...	March 17, 2005

```
[555 rows x 7 columns]]
```

**Note:** The data from the above URL changes every Monday so the resulting data above and the data below may be slightly different.

Read in the content of the file from the above URL and pass it to `read_html` as a string:

```
In [295]: with open(file_path, 'r') as f:
.....:     dfs = pd.read_html(f.read())
.....:

In [296]: dfs
Out[296]:
```

	Bank Name	City	...	Closing Date
↔	Updated Date			(continues on next page)

(continued from previous page)

0	Banks of Wisconsin d/b/a Bank of Kenosha	Kenosha	...	May 31, 2013	↵
↵	May 31, 2013

↵	March 17, 2005				
[505 rows x 7 columns]					

You can even pass in an instance of StringIO if you so desire:

```
In [297]: with open(file_path, 'r') as f:
.....:     sio = StringIO(f.read())
.....:

In [298]: dfs = pd.read_html(sio)

In [299]: dfs
Out[299]:
[
      Updated Date      Bank Name      City  ...      Closing Date  ↵
0  Banks of Wisconsin d/b/a Bank of Kenosha      Kenosha  ...      May 31, 2013  ↵
↵  May 31, 2013
1          Central Arizona Bank      Scottsdale  ...      May 14, 2013  ↵
↵  May 20, 2013
2          Sunrise Bank      Valdosta  ...      May 10, 2013  ↵
↵  May 21, 2013
3  Pisgah Community Bank      Asheville  ...      May 10, 2013  ↵
↵  May 14, 2013
4  Douglas County Bank      Douglasville  ...      April 26, 2013  ↵
↵  May 16, 2013
5          Parkway Bank      Lenoir  ...      April 26, 2013  ↵
↵  May 17, 2013
```

(continues on next page)

(continued from previous page)

[505 rows x 7 columns]					

**Note:** The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn't run, please do not hesitate to report it over on [pandas GitHub issues page](#).

Read a URL and match a table that contains specific text:

```
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a `MultiIndex` is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (`xrange` (Python 2 only) works as well):

```
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```
dfs1 = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})
print(np.array_equal(dfs1[0], dfs2[0])) # Should be True
```

Specify values that should be converted to NaN:

```
dfs = pd.read_html(url, na_values=['No Acquirer'])
```

New in version 0.19.

Specify whether to keep the default set of NaN values:

```
dfs = pd.read_html(url, keep_default_na=False)
```

New in version 0.19.

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```
url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0,
                  converters={'MNC': str})
```

New in version 0.19.

Use some combination of the above:

```
dfs = pd.read_html(url, match='Metcalfe Bank', index_col=0)
```

Read in pandas `to_html` output (with some loss of floating point precision):

```
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format='{0:.40g}'.format)
dfin = pd.read_html(s, index_col=0)
```

The `lxml` backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor=['lxml'])
```

Or you could pass `flavor='lxml'` without a list:

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor='lxml')
```

However, if you have `bs4` and `html5lib` installed and pass `None` or `['lxml', 'bs4']` then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return*.

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor=['lxml', 'bs4'])
```

## Writing to HTML files

`DataFrame` objects have an instance method `to_html` which renders the contents of the `DataFrame` as an HTML table. The function arguments are as in the method `to_string` described above.

---

**Note:** Not all of the possible options for `DataFrame.to_html` are shown here for brevity's sake. See `to_html()` for the full set of options.

---

```
In [300]: df = pd.DataFrame(np.random.randn(2, 2))

In [301]: df
Out[301]:
     0         1
0 -0.184744  0.496971
1 -0.856240  1.857977

In [302]: print(df.to_html()) # raw html
////////////////////////////////////<table_
↪border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-0.184744</td>
      <td>0.496971</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.856240</td>
      <td>1.857977</td>
    </tr>
  </tbody>
</table>
```

HTML:

The columns argument will limit the columns shown:

```
In [303]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-0.184744</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.856240</td>
    </tr>
  </tbody>
</table>
```

HTML:

float\_format takes a Python callable to control the precision of floating point values:

```
In [304]: print(df.to_html(float_format='{0:.10f}'.format))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-0.1847438576</td>
      <td>0.4969711327</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.8562396763</td>
      <td>1.8579766508</td>
    </tr>
  </tbody>
</table>
```

**HTML:**

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [305]: print(df.to_html(bold_rows=False))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>0</td>
      <td>-0.184744</td>
      <td>0.496971</td>
    </tr>
    <tr>
      <td>1</td>
      <td>-0.856240</td>
      <td>1.857977</td>
    </tr>
  </tbody>
</table>
```

The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are *appended* to the existing 'dataframe' class.

```
In [306]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class
↵']))
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
  <thead>
    <tr style="text-align: right;">
```

(continues on next page)

(continued from previous page)

```

        <th></th>
        <th>0</th>
        <th>1</th>
    </tr>
</thead>
<tbody>
    <tr>
        <th>0</th>
        <td>-0.184744</td>
        <td>0.496971</td>
    </tr>
    <tr>
        <th>1</th>
        <td>-0.856240</td>
        <td>1.857977</td>
    </tr>
</tbody>
</table>

```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

New in version 0.24.

```

In [307]: url_df = pd.DataFrame({
.....:     'name': ['Python', 'Pandas'],
.....:     'url': ['https://www.python.org/', 'http://pandas.pydata.org']})
.....:

In [308]: print(url_df.to_html(render_links=True))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>name</th>
      <th>url</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>Python</td>
      <td><a href="https://www.python.org/" target="_blank">https://www.python.org/</
↪a></td>
    </tr>
    <tr>
      <th>1</th>
      <td>Pandas</td>
      <td><a href="http://pandas.pydata.org" target="_blank">http://pandas.pydata.org
↪</a></td>
    </tr>
  </tbody>
</table>

```

HTML:

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`

```
In [309]: df = pd.DataFrame({'a': list('&<'), 'b': np.random.randn(3)})
```

Escaped:

```
In [310]: print(df.to_html())
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>a</th>
      <th>b</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>&amp;</td>
      <td>-0.474063</td>
    </tr>
    <tr>
      <th>1</th>
      <td>&lt;</td>
      <td>-0.230305</td>
    </tr>
    <tr>
      <th>2</th>
      <td>&gt;></td>
      <td>-0.400654</td>
    </tr>
  </tbody>
</table>
```

Not escaped:

```
In [311]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>a</th>
      <th>b</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>&</td>
      <td>-0.474063</td>
    </tr>
    <tr>
      <th>1</th>
      <td><<</td>
      <td>-0.230305</td>
    </tr>
    <tr>
      <th>2</th>
      <td>>>>/td>
```

(continues on next page)

(continued from previous page)

```

    <td>-0.400654</td>
  </tr>
</tbody>
</table>

```

---

**Note:** Some browsers may not show a difference in the rendering of the previous two HTML tables.

---

## HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

### Issues with `lxml`

- Benefits
  - `lxml` is very fast.
  - `lxml` requires Cython to install correctly.
- Drawbacks
  - `lxml` does *not* make any guarantees about the results of its parse *unless* it is given **strictly valid markup**.
  - In light of the above, we have chosen to allow you, the user, to use the `lxml` backend, but **this backend will use `html5lib` if `lxml` fails to parse**
  - It is therefore *highly recommended* that you install both `BeautifulSoup4` and `html5lib`, so that you will still get a valid result (provided everything else is valid) even if `lxml` fails.

### Issues with `BeautifulSoup4` using `lxml` as a backend

- The above issues hold here as well since `BeautifulSoup4` is essentially just a wrapper around a parser backend.

### Issues with `BeautifulSoup4` using `html5lib` as a backend

- Benefits
  - `html5lib` is far more lenient than `lxml` and consequently deals with *real-life markup* in a much saner way rather than just, e.g., dropping an element without notifying you.
  - `html5lib` *generates valid HTML5 markup from invalid markup automatically*. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - `html5lib` is pure Python and requires no additional build steps beyond its own installation.
- Drawbacks
  - The biggest drawback to using `html5lib` is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

## 4.1.4 Excel files

The `read_excel()` method can read Excel 2003 (`.xls`) and Excel 2007+ (`.xlsx`) files using the `xlrd` Python module. The `to_excel()` instance method is used for saving a `DataFrame` to Excel. Generally the semantics are similar to working with `csv` data. See the *cookbook* for some advanced strategies.

### Reading Excel Files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', sheet_name='Sheet1')
```

### ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The `ExcelFile` class can also be used as a context manager.

```
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=None,
                                  na_values=['NA'])

# equivalent using the read_excel function
data = pd.read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'],
                    index_col=None, na_values=['NA'])
```

## Specifying Sheets

---

**Note:** The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

---

**Note:** An `ExcelFile`'s attribute `sheet_names` provides access to a list of sheets.

---

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

Using the sheet index:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])
```

Using all default values:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls')
```

Using `None` to get all sheets:

```
# Returns a dictionary of DataFrames
pd.read_excel('path_to_file.xls', sheet_name=None)
```

Using a list to get multiple sheets:

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

## Reading a MultiIndex

`read_excel` can read a `MultiIndex` index, by passing a list of columns to `index_col` and a `MultiIndex` column by passing a list of rows to `header`. If either the `index` or `columns` have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a `MultiIndex` index without names:

```
In [312]: df = pd.DataFrame({'a': [1, 2, 3, 4], 'b': [5, 6, 7, 8]},
.....:                      index=pd.MultiIndex.from_product(['a', 'b'], ['c', 'd
↪']))
.....:

In [313]: df.to_excel('path_to_file.xlsx')

In [314]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [315]: df
Out [315]:
      a  b
a c  1  5
  d  2  6
b c  3  7
  d  4  8
```

If the index has level names, they will be parsed as well, using the same parameters.

```
In [316]: df.index = df.index.set_names(['lvl1', 'lvl2'])

In [317]: df.to_excel('path_to_file.xlsx')

In [318]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [319]: df
Out [319]:
      a  b
lvl1 lvl2
a     c   1  5
     d   2  6
b     c   3  7
     d   4  8
```

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

```
In [320]: df.columns = pd.MultiIndex.from_product(['a'], ['b', 'd']),
.....:                      names=['c1', 'c2'])
.....:

In [321]: df.to_excel('path_to_file.xlsx')

In [322]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])

In [323]: df
Out [323]:
c1      a
c2      b  d
lvl1 lvl2
a     c   1  5
     d   2  6
b     c   3  7
     d   4  8
```

## Parsing Specific Columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Deprecated since version 0.24.0.

Passing in an integer for `usecols` has been deprecated. Please pass in a list of ints from 0 to `usecols` inclusive instead.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

You can also specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols='A,C:E')
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

New in version 0.24.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=['foo', 'bar'])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

New in version 0.24.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=lambda x: x.isalpha())
```

## Parsing Dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel('path_to_file.xls', 'Sheet1', parse_dates=['date_strings'])
```

## Cell Converters

It is possible to transform the contents of Excel cells via the `converters` option. For instance, to convert a column to boolean:

```
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```
def cfun(x):
    return int(x) if x else -1

pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

### dtype Specifications

New in version 0.20.

As an alternative to converters, the type for an entire column can be specified using the *dtype* keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type `str` or `object`.

```
pd.read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

### Writing Excel Files

#### Writing Excel Files to Disk

To write a `DataFrame` object to a sheet of an Excel file, you can use the `to_excel` instance method. The arguments are largely the same as `to_csv` described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the `DataFrame` should be written. For example:

```
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a `.xls` extension will be written using `xlwt` and those with a `.xlsx` extension will be written using `xlsxwriter` (if available) or `openpyxl`.

The `DataFrame` will be written in a way that tries to mimic the REPL output. The `index_label` will be placed in the second row instead of the first. You can place it in the first row by setting the `merge_cells` option in `to_excel()` to `False`:

```
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate `DataFrames` to separate sheets in a single Excel file, one can pass an `ExcelWriter`.

```
with pd.ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```

---

**Note:** Wringing a little more performance out of `read_excel` Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn't lose information (`1.0 --> 1`). You can pass `convert_float=False` to disable this behavior, which may give a slight performance improvement.

---

## Writing Excel Files to Memory

Pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

## Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the `XlsxWriter` for `.xlsx`, `openpyxl` for `.xlsm`, and `xlwt` for `.xls` files. If you have multiple engines installed, you can set the default engine through *setting the config options* `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on `openpyxl` for `.xlsx` files if `Xlsxwriter` is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt

```
# By setting the 'engine' in the DataFrame and Panel 'to_excel()' methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
```

(continues on next page)

(continued from previous page)

```
from pandas import options # noqa: E402
options.io.excel.xlsx.writer = 'xlsxwriter'

df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

## Style and Formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame's `to_excel` method.

- `float_format` : Format string for floating point numbers (default `None`).
- `freeze_panes` : A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default `None`).

### 4.1.5 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a DataFrame by calling:

```
clipdf = pd.read_clipboard()
```

```
In [324]: clipdf
Out [324]:
   A  B  C
x  1  4  p
y  2  5  q
z  3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```
In [325]: df = pd.DataFrame(np.random.randn(5, 3))

In [326]: df
Out [326]:
   0         1         2
0 -0.288267 -0.084905  0.004772
1  1.382989  0.343635 -1.253994
2 -0.124925  0.212244  0.496654
3  0.525417  1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129

In [327]: df.to_clipboard()
```

(continues on next page)

(continued from previous page)

```

-----
PyperclipException                                          Traceback (most recent call last)

    137
    138          if PY2:

PyperclipException:
Pyperclip could not find a copy/paste mechanism for your system.
For more information, please visit https://pyperclip.readthedocs.org

```

We can see that we got the same content back, which we had earlier written to the clipboard.

**Note:** You may need to install xclip or xsel (with gtk, PyQt5, PyQt4 or qtpy) on Linux to use these methods.

---

## 4.1.6 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```
In [329]: df
Out [329]:
```

	0	1	2
0	-0.288267	-0.084905	0.004772
1	1.382989	0.343635	-1.253994
2	-0.124925	0.212244	0.496654
3	0.525417	1.238640	-1.210543
4	-1.175743	-0.172372	-0.734129

```
In [330]: df.to_pickle('foo.pkl')
```

The `read_pickle` function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [331]: pd.read_pickle('foo.pkl')
Out [331]:
```

	0	1	2
0	-0.288267	-0.084905	0.004772
1	1.382989	0.343635	-1.253994
2	-0.124925	0.212244	0.496654
3	0.525417	1.238640	-1.210543
4	-1.175743	-0.172372	-0.734129

**Warning:** Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html>

**Warning:** Several internal refactoring have been done while still preserving compatibility with pickles created with older versions of pandas. However, for such cases, pickled `DataFrames`, `Series` etc, must be read with `pd.read_pickle`, rather than `pickle.load`.

See [here](#) and [here](#) for some examples of compatibility-breaking changes. See [this question](#) for a detailed explanation.

## Compressed pickle files

New in version 0.20.0.

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in `'.gz'`, `'.bz2'`, `'.zip'`, or `'.xz'`, respectively.

```
In [332]: df = pd.DataFrame({
.....:     'A': np.random.randn(1000),
.....:     'B': 'foo',
.....:     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:
```

```
In [333]: df
```

```
Out [333]:
```

	A	B	C
0	0.478412	foo	2013-01-01 00:00:00
1	-0.783748	foo	2013-01-01 00:00:01
2	1.403558	foo	2013-01-01 00:00:02
3	-0.539282	foo	2013-01-01 00:00:03
4	-1.651012	foo	2013-01-01 00:00:04
5	0.692072	foo	2013-01-01 00:00:05
6	1.022171	foo	2013-01-01 00:00:06
..	...	...	...
993	-1.613932	foo	2013-01-01 00:16:33
994	1.088104	foo	2013-01-01 00:16:34
995	-0.632963	foo	2013-01-01 00:16:35
996	-0.585314	foo	2013-01-01 00:16:36
997	-0.275038	foo	2013-01-01 00:16:37
998	-0.937512	foo	2013-01-01 00:16:38
999	0.632369	foo	2013-01-01 00:16:39

```
[1000 rows x 3 columns]
```

Using an explicit compression type:

```
In [334]: df.to_pickle("data.pkl.compress", compression="gzip")
```

```
In [335]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
```

```
In [336]: rt
```

```
Out [336]:
```

	A	B	C
0	0.478412	foo	2013-01-01 00:00:00
1	-0.783748	foo	2013-01-01 00:00:01
2	1.403558	foo	2013-01-01 00:00:02
3	-0.539282	foo	2013-01-01 00:00:03
4	-1.651012	foo	2013-01-01 00:00:04
5	0.692072	foo	2013-01-01 00:00:05
6	1.022171	foo	2013-01-01 00:00:06
..	...	...	...
993	-1.613932	foo	2013-01-01 00:16:33

### 4.1.7 msgpack

pandas supports the msgpack format for object serialization. This is a lightweight portable binary format, similar to binary JSON, that is highly space efficient, and provides good performance both on the writing (serialization), and reading (deserialization).

**Warning:** This is a very new feature of pandas. We intend to provide certain optimizations in the io of the msgpack data. Since this is marked as an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```

In [346]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
In [347]: df.to_msgpack('foo.msg')
In [348]: pd.read_msgpack('foo.msg')
Out[348]:
   A      B
0  0.170801  0.895366
1  0.838238  0.052592
2  0.664140  0.289750
3  0.449593  0.872087
4  0.983618  0.744359
In [349]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))

```

You can pass a list of objects and you will receive them back on deserialization.

```

In [350]: pd.to_msgpack('foo.msg', df, 'foo', np.array([1, 2, 3]), s)
In [351]: pd.read_msgpack('foo.msg')
Out[351]:
[
   A      B
0  0.170801  0.895366
1  0.838238  0.052592
2  0.664140  0.289750

```

(continues on next page)

(continued from previous page)

```

3  0.449593  0.872087
4  0.983618  0.744359, 'foo', array([1, 2, 3]), 2013-01-01    0.548134
2013-01-02    0.503447
2013-01-03    0.348438
2013-01-04    0.707267
2013-01-05    0.261656
Freq: D, dtype: float64]

```

You can pass `iterator=True` to iterate over the unpacked results:

```

In [352]: for o in pd.read_msgpack('foo.msg', iterator=True):
.....:     print(o)
.....:
           A           B
0  0.170801  0.895366
1  0.838238  0.052592
2  0.664140  0.289750
3  0.449593  0.872087
4  0.983618  0.744359
foo
[1 2 3]
2013-01-01    0.548134
2013-01-02    0.503447
2013-01-03    0.348438
2013-01-04    0.707267
2013-01-05    0.261656
Freq: D, dtype: float64

```

You can pass `append=True` to the writer to append to an existing pack:

```

In [353]: df.to_msgpack('foo.msg', append=True)

In [354]: pd.read_msgpack('foo.msg')
Out[354]:
[
  0  0.170801  0.895366
  1  0.838238  0.052592
  2  0.664140  0.289750
  3  0.449593  0.872087
  4  0.983618  0.744359, 'foo', array([1, 2, 3]), 2013-01-01    0.548134
2013-01-02    0.503447
2013-01-03    0.348438
2013-01-04    0.707267
2013-01-05    0.261656
Freq: D, dtype: float64,           A           B
0  0.170801  0.895366
1  0.838238  0.052592
2  0.664140  0.289750
3  0.449593  0.872087
4  0.983618  0.744359]

```

Unlike other io methods, `to_msgpack` is available on both a per-object basis, `df.to_msgpack()` and using the top-level `pd.to_msgpack(...)` where you can pack arbitrary collections of Python lists, dicts, scalars, while intermixing pandas objects.

```

In [355]: pd.to_msgpack('foo2.msg', {'dict': [{'df': df}, {'string': 'foo'}],

```

(continues on next page)

(continued from previous page)

```

.....:                                     {'scalar': 1.}, {'s': s}}})
.....:
In [356]: pd.read_msgpack('foo2.msg')
Out [356]:
{'dict': ({'df':
  0  0.170801  0.895366
  1  0.838238  0.052592
  2  0.664140  0.289750
  3  0.449593  0.872087
  4  0.983618  0.744359},
{'string': 'foo'},
{'scalar': 1.0},
{'s': 2013-01-01    0.548134
 2013-01-02    0.503447
 2013-01-03    0.348438
 2013-01-04    0.707267
 2013-01-05    0.261656
Freq: D, dtype: float64})}

```

## Read/Write API

Msgpacks can also be read from and written to strings.

```

In [357]: df.to_msgpack()
Out [357]: b'\x84\xa3typ\xadbloc_
→manager\xa5klass\xa9DataFrame\xa4axes\x92\x86\xa3typ\xa5index\xa5klass\xa5Index\xa4name\xc0\xa5dtype
→index\xa5klass\xaaRangeIndex\xa4name\xc0\xa5start\x00\xa4stop\x05\xa4step\x01\xa6blocks\x91\x86\xa
→<\xfd\xd2f\xcf\xdc\xc5?0\x15\xebN\xd9\xd2\xea?, \x9c\x16A\xa2@\xe5?\xd8/\xdd\xfd
→"\xc6\xdc?\x11\x1e\x97\x1b\xcdy\xef?&\x1e<\xee\xd6\xa6\xec?p\xd3;\xb2N\xed\xaa?
→h\xcb\xb1\xbdB\x8b\xd2?\xaf4\x01r"\xe8\xeb?)G6\xd9\xc9\xd1\xe7?
→\xa5shape\x92\x02\x05\xa5dtype\xa7float64\xa5klass\xaaFloatBlock\xa8compress\xc0'

```

Furthermore you can concatenate the strings to produce a list of the original objects.

```

In [358]: pd.read_msgpack(df.to_msgpack() + s.to_msgpack())
Out [358]:
[
  0  0.170801  0.895366
  1  0.838238  0.052592
  2  0.664140  0.289750
  3  0.449593  0.872087
  4  0.983618  0.744359, 2013-01-01    0.548134
 2013-01-02    0.503447
 2013-01-03    0.348438
 2013-01-04    0.707267
 2013-01-05    0.261656
Freq: D, dtype: float64]

```

## 4.1.8 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent [PyTables](#) library. See the *cookbook* for some advanced strategies

(continued from previous page)

```
# dotted (attribute) access provides get as well
```

```
In [371]: store.df
```

```

////////////////////////////////////
↪
           A          B          C
2000-01-01  0.954551  0.859671 -1.170458
2000-01-02 -1.211386 -0.852728 -0.450781
2000-01-03  1.064650  1.014927 -0.810399
2000-01-04  0.254343 -0.875526 -0.980856
2000-01-05 -0.906920  0.988185 -1.596540
2000-01-06  0.205007 -0.772889 -0.043509
2000-01-07  0.768606  0.298656 -1.294022
2000-01-08 -0.618845  1.122438 -0.914616

```

Deletion of the object specified by the key:

```
# store.remove('wp') is an equivalent method
```

```
In [372]: del store['wp']
```

```
In [373]: store
```

```
Out[373]:
```

```
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Closing a Store and using a context manager:

```
In [374]: store.close()
```

```
In [375]: store
```

```
Out[375]:
```

```
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

```
In [376]: store.is_open
```

```
Out[376]: False
```

```
# Working with, and automatically closing the store using a context manager
```

```
In [377]: with pd.HDFStore('store.h5') as store:
```

```
.....:     store.keys()
```

```
.....:
```

## Read/Write API

HDFStore supports a top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```
In [378]: df_tl = pd.DataFrame({'A': list(range(5)), 'B': list(range(5))})
```

```
In [379]: df_tl.to_hdf('store_tl.h5', 'table', append=True)
```

```
In [380]: pd.read_hdf('store_tl.h5', 'table', where=['index>2'])
```

```
Out[380]:
```

```

  A  B
3  3  3
4  4  4

```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```
In [381]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
.....:                                'col2': [1, np.nan, np.nan]})
.....:

In [382]: df_with_missing
Out[382]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

In [383]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                           format='table', mode='w')
.....:

In [384]: pd.read_hdf('file.h5', 'df_with_missing')
Out[384]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

In [385]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                           format='table', mode='w', dropna=True)
.....:

In [386]: pd.read_hdf('file.h5', 'df_with_missing')
Out[386]:
   col1  col2
0    0.0    1.0
2    2.0    NaN
```

This is also true for the major axis of a Panel:

```
In [387]: matrix = [[np.nan, np.nan, np.nan], [1, np.nan, np.nan]],
.....:               [[np.nan, np.nan, np.nan], [np.nan, 5, 6]],
.....:               [[np.nan, np.nan, np.nan], [np.nan, 3, np.nan]]
.....:

In [388]: panel_with_major_axis_all_missing = pd.Panel(matrix,
.....:                                                  items=['Item1', 'Item2', 'Item3
↵'],
.....:                                                  major_axis=[1, 2],
.....:                                                  minor_axis=['A', 'B', 'C'])
.....:

In [389]: panel_with_major_axis_all_missing
Out[389]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 2 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item3
Major_axis axis: 1 to 2
Minor_axis axis: A to C

In [390]: panel_with_major_axis_all_missing.to_hdf('file.h5', 'panel',
.....:                                             dropna=True,
```

(continues on next page)

(continued from previous page)

```

.....:                                     format='table',
.....:                                     mode='w')
.....:

In [391]: reloaded = pd.read_hdf('file.h5', 'panel')

In [392]: reloaded
Out [392]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 1 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item3
Major_axis axis: 2 to 2
Minor_axis axis: A to C

```

## Fixed Format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the `fixed` format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they **queryable**; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The `fixed` format stores offer very fast writing and slightly faster reading than `table` stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

**Warning:** A `fixed` format will raise a `TypeError` if you try to retrieve using a `where`:

```

>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf('test_fixed.h5', 'df')
>>> pd.read_hdf('test_fixed.h5', 'df', where='index>5')
TypeError: cannot pass a where specification when reading a fixed format.
        this store must be selected in its entirety

```

## Table Format

`HDFStore` supports another PyTables format on disk, the `table` format. Conceptually a table is shaped very much like a `DataFrame`, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to append or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format', 'table')` to enable `put`/`append`/`to_hdf` to by default store in the table format.

```

In [393]: store = pd.HDFStore('store.h5')

In [394]: df1 = df[0:4]

In [395]: df2 = df[4:]

# append data (creates a table automatically)
In [396]: store.append('df', df1)

In [397]: store.append('df', df2)

In [398]: store
Out [398]:

```

(continues on next page)

(continued from previous page)

```

<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
In [399]: store.select('df')
\\Out [399]:
          A         B         C
2000-01-01  0.954551  0.859671 -1.170458
2000-01-02 -1.211386 -0.852728 -0.450781
2000-01-03  1.064650  1.014927 -0.810399
2000-01-04  0.254343 -0.875526 -0.980856
2000-01-05 -0.906920  0.988185 -1.596540
2000-01-06  0.205007 -0.772889 -0.043509
2000-01-07  0.768606  0.298656 -1.294022
2000-01-08 -0.618845  1.122438 -0.914616

# the type of stored data
In [400]: store.root.df._v_attrs.pandas_type
\\Out [400]:
↪ 'frame_table'

```

**Note:** You can also create a table by passing `format='table'` or `format='t'` to a put operation.

## Hierarchical Keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading `/` and are **always** absolute (e.g. `'foo'` refers to `'/foo'`). Removal operations can remove everything in the sub-store and **below**, so be *careful*.

```

In [401]: store.put('foo/bar/bah', df)

In [402]: store.append('food/orange', df)

In [403]: store.append('food/apple', df)

In [404]: store
Out [404]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [405]: store.keys()
\\Out [405]: ['/df',
↪ '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [406]: store.remove('food')

In [407]: store
Out [407]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

New in version 0.24.0.

```
In [408]: for (path, subgroups, subkeys) in store.walk():
.....:     for subgroup in subgroups:
.....:         print('GROUP: {}'.format(path, subgroup))
.....:     for subkey in subkeys:
.....:         key = '/'.join([path, subkey])
.....:         print('KEY: {}'.format(key))
.....:         print(store.get(key))
.....:
```

```
GROUP: /foo
```

```
KEY: /df
```

2000-01-08	-0.618845	1.122438	-0.914616

**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```
In [8]: store.foo.bar.bah
```

```
AttributeError: 'HDFStore' object has no attribute 'foo'
```

```
# you can directly access the actual PyTables node but using the root node
```

```
In [9]: store.root.foo.bar.bah
```

```
Out [9]:
```

```
/foo/bar/bah (Group) ''
```

```
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
  ↪ 'axis1' (Array)]
```

Instead, use explicit string based keys:

```
In [409]: store['foo/bar/bah']
```

```
Out [409]:
```

## Storing Types

### Storing Mixed Types in a Table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={'values': size}` as a parameter to `append` will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to `append` will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [410]: df_mixed = pd.DataFrame({'A': np.random.randn(8),
.....:                          'B': np.random.randn(8),
.....:                          'C': np.array(np.random.randn(8), dtype='float32'),
.....:                          'string': 'string',
.....:                          'int': 1,
.....:                          'bool': True,
.....:                          'datetime64': pd.Timestamp('20010102')},
.....:                          index=list(range(8)))
```

```
In [411]: df_mixed.loc[df_mixed.index[3:5],
.....:                 ['A', 'B', 'string', 'datetime64']] = np.nan
.....:
```

```
In [412]: store.append('df_mixed', df_mixed, min_itemsize={'values': 50})
```

```
In [413]: df_mixed1 = store.select('df_mixed')
```

```
In [414]: df_mixed1
```

```
Out[414]:
```

## Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```
In [417]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
.....:                                ['one', 'two', 'three']],
.....:                           codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
.....:                                [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
.....:                           names=['foo', 'bar'])
.....:

In [418]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
.....:                           columns=['A', 'B', 'C'])
.....:

In [419]: df_mi
Out[419]:
```

	A	B	C
foo bar

   two  1.096917  0.516017 -0.501550

```

## Querying

### Querying a Table

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of a `DataFrames`.
- `major_axis`, `minor_axis`, and `items` are supported indexers of the `Panel`.
- if `data_columns` are specified, these can be used as additional indexers.

Valid comparison operators are:

`=`, `==`, `!=`, `>`, `>=`, `<`, `<=`

Valid boolean expressions are combined with:

- `|` : or
- `&` : and
- `( and )` : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

---

### Note:

- `=` will be automatically expanded to the comparison operator `==`
  - `~` is the not operator, but can only be used in very limited circumstances
  - If a list/tuple of expressions is passed they will be combined via `&`
- 

The following are valid expressions:

- `'index >= date'`
- `"columns = ['A', 'D']"`
- `"columns in ['A', 'D']"`
- `'columns = A'`
- `'columns == A'`
- `"~(columns = ['A', 'B'])"`
- `'index > df.index[3] & string = "bar"'`
- `'(index > df.index[3] & index <= df.index[6]) | string = "bar"'`
- `"ts >= Timestamp('2012-02-01')"`
- `"major_axis>=20130101"`

The indexers are on the left-hand side of the sub-expression:

```
columns,major_axis,ts
```

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. `"bar"`
- date-like, e.g. `20130101`, or `"20130101"`
- lists, e.g. `['A', 'B']`
- variables that are defined in the local names space, e.g. `date`

**Note:** Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will **not** work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the string variable.

If you *must* interpolate, use the `'%r'` format specifier

```
store.select('df', 'index == %r' % string)
```

which will quote string.

Here are some examples:

```
In [423]: dfq = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'),
.....:                       index=pd.date_range('20130101', periods=10))
.....:
In [424]: store.append('dfq', dfq, format='table', data_columns=True)
```

(continued from previous page)

```
2000-01-08 -0.618845  1.122438
```

start and stop parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

```
# this is effectively what the storage of a Panel looks like
```

```
In [431]: wp.to_frame()
```

```
Out [431]:
```

```
          Item1  Item2
major  minor
2000-01-01 A   -0.340872  0.758552
         B   -0.303900  0.384775
         C   -0.871948 -1.133177
         D    0.151508 -1.002973
2000-01-02 A    0.587939 -1.644393
         B    0.043096 -0.311536
         C    0.362451 -0.615506
...
2000-01-04 B    0.479460  0.542245
         C   -0.630652 -0.384429
         D   -0.182400  0.170697
2000-01-05 A   -0.789979 -0.200289
         B   -0.282700  1.220322
         C   -0.813404 -1.001273
         D    1.252998  0.162172
```

```
[20 rows x 2 columns]
```

```
# limiting the search
```

```
In [432]: store.select('wp', "major_axis>20000102 & minor_axis=['A', 'B']",
.....:                  start=0, stop=10)
.....:
```

```
////////////////////////////////////
```

```
↪
```

```
<class 'pandas.core.panel.Panel'>
```

```
Dimensions: 2 (items) x 1 (major_axis) x 2 (minor_axis)
```

```
Items axis: Item1 to Item2
```

```
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-03 00:00:00
```

```
Minor_axis axis: A to B
```

**Note:** select will raise a ValueError if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is **not** a data\_column.

select will raise a SyntaxError if the query expression is not valid.

## Using timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: <float><unit>, where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here's an example:

```
In [433]: from datetime import timedelta
```

(continues on next page)

(continued from previous page)

```
In [434]: dftd = pd.DataFrame({'A': pd.Timestamp('20130101'),
.....:                       'B': [pd.Timestamp('20130101') + timedelta(days=i,
.....:                                                                    seconds=10)
.....:                               for i in range(10)]})
.....:
```

```
In [435]: dftd['C'] = dftd['A'] - dftd['B']
```

```
In [436]: dftd
Out[436]:
```

	A	B	C
0	2013-01-01 2013-01-01 00:00:10	-1 days +23:59:50	
1	2013-01-01 2013-01-02 00:00:10	-2 days +23:59:50

```
In [437]: store.append('dftd', dftd, data_columns=True)
```

```
In [438]: store.select('dftd', "C<-3.5D")
Out[438]:
```

	A	B	C
4	2013-01-01 2013-01-05 00:00:10	-5 days +23:59:50	
5	2013-01-01 2013-01-06 00:00:10	-6 days +23:59:50	
6	2013-01-01 2013-01-07 00:00:10	-7 days +23:59:50	
7	2013-01-01 2013-01-08 00:00:10	-8 days +23:59:50	
8	2013-01-01 2013-01-09 00:00:10	-9 days +23:59:50	
9	2013-01-01 2013-01-10 00:00:10	-10 days +23:59:50	

## Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and append/put operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a select with the indexed dimension as the where.

**Note:** Indexes are automatically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```
# we have automatically already created an index (in the first section)
In [439]: i = store.root.df.table.cols.index.index

In [440]: i.optlevel, i.kind
Out[440]: (6, 'medium')

# change an index by passing new parameters
In [441]: store.create_table_index('df', optlevel=9, kind='full')

In [442]: i = store.root.df.table.cols.index.index
```

(continues on next page)

(continued from previous page)

```
In [443]: i.optlevel, i.kind
Out [443]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```
In [444]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [445]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [446]: st = pd.HDFStore('appends.h5', mode='w')
In [447]: st.append('df', df_1, data_columns=['B'], index=False)
In [448]: st.append('df', df_2, data_columns=['B'], index=False)
In [449]: st.get_storer('df').table
Out [449]:
/df/table (Table(20,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
  "B": Float64Col(shape=(), dflt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)
```

Then create the index when finished appending.

```
In [450]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [451]: st.get_storer('df').table
Out [451]:
/df/table (Table(20,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
  "B": Float64Col(shape=(), dflt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)
autoindex := True
colindexes := {
  "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [452]: st.close()
```

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

## Query via Data Columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the *indexable* columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

(continued from previous page)

```

/df_dc/table (Table(8,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
  "B": Float64Col(shape=(), dflt=0.0, pos=2),
  "C": Float64Col(shape=(), dflt=0.0, pos=3),
  "string": StringCol(itemsize=3, shape=(), dflt=b'', pos=4),
  "string2": StringCol(itemsize=4, shape=(), dflt=b'', pos=5)}
byteorder := 'little'
chunkshape := (1680,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}

```

There is some performance degradation by making lots of columns into *data columns*, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

## Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to select and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```

In [465]: for df in store.select('df', chunksize=3):
.....:     print(df)
.....:
           A          B          C
2000-01-01  0.954551  0.859671 -1.170458
2000-01-02 -1.211386 -0.852728 -0.450781
2000-01-03  1.064650  1.014927 -0.810399
           A          B          C
2000-01-04  0.254343 -0.875526 -0.980856
2000-01-05 -0.906920  0.988185 -1.596540
2000-01-06  0.205007 -0.772889 -0.043509
           A          B          C
2000-01-07  0.768606  0.298656 -1.294022
2000-01-08 -0.618845  1.122438 -0.914616

```

**Note:** You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```

for df in pd.read_hdf('store.h5', 'df', chunksize=3):
    print(df)

```

Note, that the `chunksize` keyword applies to the **source** rows. So if you are doing a query, then the `chunksize` will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```
In [466]: dfreq = pd.DataFrame({'number': np.arange(1, 11)})
In [467]: dfreq
Out [467]:
   number
0        1
1        2
2        3
3        4
4        5
5        6
6        7
7        8
8        9
9       10

In [468]: store.append('dfreq', dfreq, data_columns=['number'])

In [469]: def chunks(l, n):
.....:     return [l[i:i + n] for i in range(0, len(l), n)]
.....:

In [470]: evens = [2, 4, 6, 8, 10]

In [471]: coordinates = store.select_as_coordinates('dfreq', 'number=evens')

In [472]: for c in chunks(coordinates, 2):
.....:     print(store.select('dfreq', where=c))
.....:
   number
1        2
3        4
   number
5        6
7        8
   number
9       10
```

## Advanced Queries

### Select a Single Column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```
In [473]: store.select_column('df_dc', 'index')
Out [473]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
5    2000-01-06
6    2000-01-07
```

(continues on next page)

(continued from previous page)

[268 rows x 2 columns]

## Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```
In [480]: df_mask = pd.DataFrame(np.random.randn(1000, 2),
.....:                          index=pd.date_range('20000101', periods=1000))
.....:

In [481]: store.append('df_mask', df_mask)

In [482]: c = store.select_column('df_mask', 'index')

In [483]: where = c[pd.DatetimeIndex(c).month == 5].index

In [484]: store.select('df_mask', where=where)
Out[484]:
```

	0	1
2000-05-01	0.498698	-0.643722
2000-05-02	-0.028228	0.070209
2000-05-03	-0.791176	0.393495
2000-05-04	2.410230	-0.368339

2002-05-31	-1.565489	0.005781

```
[93 rows x 2 columns]
```

## Storer Object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```
In [485]: store.get_storer('df_dc').nrows
Out[485]: 8
```

## Multiple Table Queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and

**Warning:** Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To *repack and clean* the file, use *ptrepack*.

## Notes & Caveats

### Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

**`complevel` specifies if and how hard data is to be compressed.** `complevel=0` and `complevel=None` disables compression and  $0 < \text{complevel} < 10$  enables compression.

**`complib` specifies which compression library to use. If nothing is specified the default library `zlib` is used.** A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:

- `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
- `lzo`: Fast compression and decompression.
- `bzip2`: Good compression rates.
- `blosc`: Fast compression and decompression.

New in version 0.20.2: Support for alternative `blosc` compressors:

- `blosc:blosclz` This is the default compressor for `blosc`
- `blosc:lz4`: A compact, very popular and fast compressor.
- `blosc:lz4hc`: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- `blosc:snappy`: A popular compressor used in many places.
- `blosc:zlib`: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- `blosc:zstd`: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

**Note:** If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```
store_compressed = pd.HDFStore('store_compressed.h5', complevel=9,
                               complib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```
store.append('df', df, complib='zlib', complevel=5)
```

## ptrepack

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

## Caveats

**Warning:** HDFStore is **not-threadsafe for writing**. The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsyntax=True)` to do this for you.
- Once a table is created its items (Panel) / columns (DataFrame) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** PyTables will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

## DataTypes

HDFStore will map an object dtype to the PyTables underlying dtype. This means the following types are known to work:

Type	Represents missing values
floating: float64, float32, float16	np.nan
integer: int64, int32, int8, uint64, uint32, uint8	
boolean	
datetime64[ns]	NaT
timedelta64[ns]	NaT
categorical: see the section below	
object: strings	np.nan

unicode columns are not supported, and **WILL FAIL**.

## Categorical Data

You can write data that contains `category` dtypes to a `HDFStore`. Queries work the same as if it was an object array. However, the `category` typed data is stored in a more efficient manner.

```
In [496]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdba')).astype('category'),
.....:                        'B': np.random.randn(8)})
.....:
```

```
In [497]: dfcat
```

```
Out [497]:
   A      B
0  a -2.367211
1  a -0.058314
2  b -0.432893
3  b -0.056124
4  c  1.692911
5  d  0.771411
6  b -0.132217
7  a  1.575762
```

```
In [498]: dfcat.dtypes
```

```

\-----/
↪
A      category
B      float64
dtype: object
```

```
In [499]: cstore = pd.HDFStore('cats.h5', mode='w')
```

```
In [500]: cstore.append('dfcat', dfcat, format='table', data_columns=['A'])
```

```
In [501]: result = cstore.select('dfcat', where="A in ['b', 'c']")
```

```
In [502]: result
```

```
Out [502]:
   A      B
2  b -0.432893
3  b -0.056124
4  c  1.692911
6  b -0.132217
```

```
In [503]: result.dtypes
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////Out [503]:
↪
A    category
B    float64
dtype: object

```

## String Columns

### min\_itemsize

The underlying implementation of `HDFStore` uses a fixed column width (`itemsize`) for string columns. A string column `itemsize` is calculated as the maximum of the length of data (for that column) that is passed to the `HDFStore`, **in the first append**. Subsequent appends, may introduce a string for a column **larger** than the column can hold, an `Exception` will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all *indexables* or *data\_columns* to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as *data\_columns* automatically.

---

**Note:** If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed

---

```
In [504]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))
```

```
In [505]: dfs
```

```
Out [505]:
   A  B
0  foo bar
1  foo bar
2  foo bar
3  foo bar
4  foo bar
```

```
# A and B have a size of 30
```

```
In [506]: store.append('dfs', dfs, min_itemsize=30)
```

```
In [507]: store.get_storer('dfs').table
```

```
Out [507]:
/dfs/table (Table(5,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
byteorder := 'little'
chunkshape := (963,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

```
# A is created as a data_column with a size of 30
```

```
# B is size is calculated
```

(continues on next page)

(continued from previous page)

```
In [508]: store.append('dfs2', dfs, min_itemsize={'A': 30})

In [509]: store.get_storer('dfs2').table
Out [509]:
/dfs2/table (Table(5,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
    "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
  byteorder := 'little'
  chunkshape := (1598,)
  autoindex := True
  colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "A": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

### nan\_rep

String columns will serialize a `np.nan` (a missing value) with the `nan_rep` string representation. This defaults to the string value `nan`. You could inadvertently turn an actual `nan` value into a missing value.

```
In [510]: dfss = pd.DataFrame({'A': ['foo', 'bar', 'nan']})

In [511]: dfss
Out [511]:
   A
0  foo
1  bar
2  nan

In [512]: store.append('dfss', dfss)

In [513]: store.select('dfss')
Out [513]:
   A
0  foo
1  bar
2  NaN

# here you need to specify a different nan rep
In [514]: store.append('dfss2', dfss, nan_rep='_nan_')

In [515]: store.select('dfss2')
Out [515]:
   A
0  foo
1  bar
2  nan
```

## External Compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the `rhd5` library ([Package website](#)). Create a table format store like this:

```
In [516]: df_for_r = pd.DataFrame({"first": np.random.rand(100),
.....:                          "second": np.random.rand(100),
.....:                          "class": np.random.randint(0, 2, (100, ))},
.....:                          index=range(100))
.....:

In [517]: df_for_r.head()
Out[517]:
   first    second  class
0  0.365127  0.012583     0
1  0.004826  0.607160     1
2  0.373122  0.092975     1
3  0.207335  0.828299     0
4  0.515948  0.832586     1

In [518]: store_export = pd.HDFStore('export.h5')

In [519]: store_export.append('df_for_r', df_for_r, data_columns=df_dc.columns)

In [520]: store_export
Out[520]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
```

In R this file can be read into a `data.frame` object using the `rhdf5` library. The following example function reads the corresponding column names and data values from the values and assembles them into a `data.frame`:

```
# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

  listing <- h5ls(h5File)
  # Find all data nodes, values are stored in *_values and corresponding column
  # titles in *_items
  data_nodes <- grep("_values", listing$name)
  name_nodes <- grep("_items", listing$name)
  data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
  name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
  columns = list()
  for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain
    # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
  }

  data <- data.frame(columns)

  return(data)
}
```

Now you can import the `DataFrame` into R:

```

> data = loadhdf5data("transfer.hdf5")
> head(data)
   first    second class
1 0.4170220047 0.3266449    0
2 0.7203244934 0.5270581    0
3 0.0001143748 0.8859421    1
4 0.3023325726 0.3572698    1
5 0.1467558908 0.9085352    1
6 0.0923385948 0.6233601    1

```

**Note:** The R function lists the entire HDF5 file's contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

## Performance

- `tables` format come with a writing performance penalty as compared to `fixed` stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of expected rows that `PyTables` will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by `PyTables` (rather than stored as endemic types). See [Here](#) for more information and some solutions.

### 4.1.9 Feather

New in version 0.20.0.

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize `DataFrames`, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats.

- This is a newer library, and the format, though stable, is not guaranteed to be backward compatible to the earlier versions.
- The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

See the [Full Documentation](#).

(continued from previous page)

```
In [527]: result.dtypes
```

```

////////////////////////////////////
↪
a                object

c                uint8
d                float64
e                bool
f                category
g                datetime64[ns]
h  datetime64[ns, US/Eastern]
i                datetime64[ns]
dtype: object

```

### 4.1.10 Parquet

New in version 0.21.0.

[Apache Parquet](#) provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string column names are not supported.
- The `pyarrow` engine always writes the index to the output, but `fastparquet` only writes non-default indexes. This extra column can cause problems for non-Pandas consumers that are not expecting it. You can force including or omitting indexes with the `index` argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- Categorical dtypes can be serialized to parquet, but will de-serialize as `object` dtype.
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

You can specify an engine to direct the serialization. This can be one of `pyarrow`, or `fastparquet`, or `auto`. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also `auto`, then `pyarrow` is tried, and falling back to `fastparquet`.

See the documentation for [pyarrow](#) and [fastparquet](#).

---

**Note:** These engines are very similar and should read/write nearly identical parquet format files. Currently `pyarrow` does not support `timedelta` data, `fastparquet`  $\geq 0.1.4$  supports timezone aware datetimes. These libraries differ by having different underlying dependencies (`fastparquet` by using `numba`, while `pyarrow` uses a c-library).

---

```

In [528]: df = pd.DataFrame({'a': list('abc'),
.....:                      'b': list(range(1, 4)),
.....:                      'c': np.arange(3, 6).astype('u1'),
.....:                      'd': np.arange(4.0, 7.0, dtype='float64'),
.....:                      'e': [True, False, True],
.....:                      'f': pd.date_range('20130101', periods=3),

```

(continues on next page)

## Handling Indexes

Serializing a `DataFrame` to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [538]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
In [539]: df.to_parquet('test.parquet', engine='pyarrow')
```

creates a parquet file with *three* columns if you use `pyarrow` for serialization: `a`, `b`, and `__index_level_0__`. If you're using `fastparquet`, the index may or may not be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn't exist in the target table.

If you want to omit a dataframe's indexes when writing, pass `index=False` to `to_parquet()`:

```
In [540]: df.to_parquet('test.parquet', index=False)
```

This creates a parquet file with just the two expected columns, `a` and `b`. If your `DataFrame` has a custom index, you won't get it back when you load this file into a `DataFrame`.

Passing `index=True` will *always* write the index, even if that's not the underlying engine's default behavior.

## Partitioning Parquet files

New in version 0.24.0.

Parquet supports partitioning of data based on the values of one or more columns.

```
In [541]: df = pd.DataFrame({'a': [0, 0, 1, 1], 'b': [0, 1, 0, 1]})
In [542]: df.to_parquet(fname='test', engine='pyarrow',
.....:                  partition_cols=['a'], compression=None)
.....:
```

The `fname` specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
├── a=0
│   ├── 0bac803e32dc42ae83fddfd029cbdebc.parquet
│   └── ...
└── a=1
    ├── e6ab24a4f45147b49b54a662f0c412a3.parquet
    └── ...
```

### 4.1.11 SQL Queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by `SQLAlchemy` if installed. In addition you will need a driver library for your database. Examples of such drivers are `psycopg2` for PostgreSQL or `pymysql` for MySQL. For `SQLite` this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#).

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the [Python DB-API](#).

See also some *cookbook examples* for some advanced strategies.

The key functions are:

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.
<code>DataFrame.to_sql(name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.

## **pandas.read\_sql\_table**

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`  
Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

### **Parameters**

**table\_name** [string] Name of SQL table in database.

**con** [SQLAlchemy connectable (or database string URI)] SQLite DBAPI connection mode not supported.

**schema** [string, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table

**chunksize** [int, default None] If specified, returns an iterator where *chunksize* is the number of rows to include in each chunk.

### **Returns**

**DataFrame**

See also:

`read_sql_query` Read SQL query into a DataFrame.

`read_sql`

## Notes

Any datetime values with time zone information will be converted to UTC.

## pandas.read\_sql\_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

### Parameters

- sql** [string SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.
- con** [SQLAlchemy connectable(engine/connection), database string URI,] or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
- index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).
- coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.
- params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}
- parse\_dates** [list or dict, default: None]
  - List of column names to parse as dates.
  - Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- chunksize** [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

### Returns

**DataFrame**

See also:

**`read_sql_table`** Read SQL database table into a DataFrame.

`read_sql`

## Notes

Any datetime values with time zone information parsed via the `parse_dates` parameter will be converted to UTC.

## pandas.read\_sql

`pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)`

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

### Parameters

- sql** [string or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.
- con** [SQLAlchemy connectable (engine/connection) or database string URI] or DBAPI2 connection (fallback mode)
- Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
- index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).
- coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}
- parse\_dates** [list or dict, default: None]
- List of column names to parse as dates.
  - Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- columns** [list, default: None] List of column names to select from SQL table (only used when reading a table).
- chunksize** [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

### Returns

**DataFrame**

See also:

**`read_sql_table`** Read SQL database table into a DataFrame.

**`read_sql_query`** Read SQL query into a DataFrame.

## **pandas.DataFrame.to\_sql**

`DataFrame.to_sql` (*name*, *con*, *schema=None*, *if\_exists='fail'*, *index=True*, *index\_label=None*, *chunksize=None*, *dtype=None*, *method=None*)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

### **Parameters**

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### **Raises**

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

**See also:**

**`read_sql`** Read a DataFrame from a table.

## Notes

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

## References

[?], [?]

## Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**Note:** The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the `SQLite` SQL database engine. You can use a temporary `SQLite` database where data are stored in “memory”.

To connect with `SQLAlchemy` you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the `SQLAlchemy` [documentation](#)

```
In [543]: from sqlalchemy import create_engine

# Create your engine.
In [544]: engine = create_engine('sqlite:///memory:')
```

If you want to manage your own connections you can pass one of those instead:

```
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

## Writing DataFrames

Assuming the following data is in a `DataFrame` `data`, we can insert it into the database using `to_sql()`.

id	Date	Col_1	Col_2	Col_3
26	2012-10-18	X	25.7	True
42	2012-10-19	Y	-12.4	False
63	2012-10-20	Z	5.73	True

```
In [545]: data
Out[545]:
   id  Date      Col_1  Col_2  Col_3
0  26  2010-10-18     X   27.50   True
1  42  2010-10-19     Y  -12.50  False
2  63  2010-10-20     Z    5.73   True

In [546]: data.to_sql('data', engine)
```

With some databases, writing large `DataFrames` can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

```
In [547]: data.to_sql('data_chunked', engine, chunksize=1000)
```

## SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
In [548]: from sqlalchemy.types import String
In [549]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

---

**Note:** Due to the limited support for `timedelta`'s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

---

---

**Note:** Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

---

## Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

Database	SQL Datetime Types	Timezone Support
SQLite	TEXT	No
MySQL	TIMESTAMP or DATETIME	No
PostgreSQL	TIMESTAMP or TIMESTAMP WITH TIME ZONE	Yes

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

## Insertion Method

New in version 0.24.0.

The parameter `method` controls the SQL insertion clause used. Possible values are:

- None: Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause. It uses a *special* SQL syntax not supported by all backends. This usually provides better performance for analytic databases like *Presto* and *Redshift*, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy [documentation](#).
- callable with signature (pd\_table, conn, keys, data\_iter): This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL COPY clause:

```
# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)

        columns = ', '.join("{}{}".format(k) for k in keys)
        if table.schema:
            table_name = '{}.{}'.format(table.schema, table.name)
        else:
            table_name = table.name

        sql = 'COPY {} ({} FROM STDIN WITH CSV'.format(
            table_name, columns)
        cur.copy_expert(sql=sql, file=s_buf)
```

## Reading Tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you **must** have the SQLAlchemy optional dependency installed.

```
In [550]: pd.read_sql_table('data', engine)
Out[550]:
   index  id  Date Col_1  Col_2  Col_3
0      0  26 2010-10-18    X  27.50   True
1      1  42 2010-10-19    Y -12.50  False
2      2  63 2010-10-20    Z   5.73   True
```

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [551]: pd.read_sql_table('data', engine, index_col='id')
Out[551]:
   index  Date Col_1  Col_2  Col_3
id
26      0 2010-10-18    X  27.50   True
```

(continues on next page)

(continued from previous page)

```
42      1 2010-10-19      Y -12.50  False
63      2 2010-10-20      Z   5.73   True
```

```
In [552]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
```

```

////////////////////////////////////
↪
  Col_1  Col_2
0      X  27.50
1      Y -12.50
2      Z   5.73

```

And you can explicitly force columns to be parsed as dates:

```
In [553]: pd.read_sql_table('data', engine, parse_dates=['Date'])
```

```
Out [553]:
```

```

  index  id      Date  Col_1  Col_2  Col_3
0      0  26 2010-10-18      X  27.50   True
1      1  42 2010-10-19      Y -12.50  False
2      2  63 2010-10-20      Z   5.73   True

```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```

pd.read_sql_table('data', engine, parse_dates={'Date': '%Y-%m-%d'})
pd.read_sql_table('data', engine,
                  parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})

```

You can check if a table exists using `has_table()`

## Schema support

Reading from and writing to different schema's is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema's). For example:

```

df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')

```

## Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```
In [554]: pd.read_sql_query('SELECT * FROM data', engine)
```

```
Out [554]:
```

```

  index  id      Date  Col_1  Col_2  Col_3
0      0  26 2010-10-18 00:00:00.000000      X  27.50      1
1      1  42 2010-10-19 00:00:00.000000      Y -12.50      0
2      2  63 2010-10-20 00:00:00.000000      Z   5.73      1

```

Of course, you can specify a more “complex” query.

```
In [555]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;",
↳engine)
Out[555]:
   id Col_1 Col_2
0  42     Y -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```
In [556]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
In [557]: df.to_sql('data_chunks', engine, index=False)
```

```
In [558]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks",
.....:                                 engine, chunksize=5):
.....:     print(chunk)
.....:
      a      b      c
0  1.892774 -0.253477  0.714395
1  0.664179  0.897140  0.455791

```

You can also run a plain query without creating a `DataFrame` with `execute()`. This is useful for queries that don't return values, such as `INSERT`. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine,
           params=[('id', 1, 12.2, True)])
```

## Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```
from sqlalchemy import create_engine

engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')

engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')

engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')

engine = create_engine('mssql+pyodbc://mydsn')

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine('sqlite:///foo.db')

# or absolute, starting with a slash:
engine = create_engine('sqlite:///absolute/path/to/foo.db')
```

For more information see the examples the SQLAlchemy documentation

### Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [559]: import sqlalchemy as sa

In [560]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:coll1'),
.....:                engine, params={'coll1': 'X'})
.....:
Out[560]:
   index  id  Date Col_1  Col_2  Col_3
0      0  26 2010-10-18 00:00:00.000000  X   27.5      1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [561]: metadata = sa.MetaData()

In [562]: data_table = sa.Table('data', metadata,
.....:                          sa.Column('index', sa.Integer),
.....:                          sa.Column('Date', sa.DateTime),
.....:                          sa.Column('Col_1', sa.String),
.....:                          sa.Column('Col_2', sa.Float),
.....:                          sa.Column('Col_3', sa.Boolean),
.....:                          )

In [563]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True),
→engine)
Out[563]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [564]: import datetime as dt

In [565]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date
↪'))

In [566]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})
Out[566]:
   index  Date Col_1  Col_2  Col_3
0      1 2010-10-19     Y -12.50  False
1      2 2010-10-20     Z   5.73   True
```

## Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the [Python DB-API](#).

You can create connections like so:

```
import sqlite3
con = sqlite3.connect(':memory:')
```

And then issue the following queries:

```
data.to_sql('data', con)
pd.read_sql_query("SELECT * FROM data", con)
```

## 4.1.12 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can `pip install pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

`pandas` integrates with this external package. If `pandas-gbq` is installed, you can use the `pandas` methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

## 4.1.13 Stata Format

### Writing to Stata format

The method `to_stata()` will write a `DataFrame` into a `.dta` file. The format version of this file is always 115 (Stata 12).

```
In [567]: df = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [568]: df.to_stata('stata.dta')
```

*Stata* data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in `.dta` files. Additionally, *Stata* reserves certain values to represent missing

data. Exporting a non-missing value that is outside of the permitted range in Stata for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in Stata, and so variables with values above 100 will trigger a conversion to `int16`. `nan` values in floating points data types are stored as the basic missing data type (`.` in Stata).

---

**Note:** It is not possible to export missing data values for integer data types.

---

The Stata writer gracefully handles other data types including `int64`, `bool`, `uint8`, `uint16`, `uint32` by casting to the smallest supported type that can represent the data. For example, data with a type of `uint8` will be cast to `int8` if all values are less than 100 (the upper bound for non-missing `int8` data in Stata), or, if values are outside of this range, the variable is cast to `int16`.

**Warning:** Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than `2**53`.

**Warning:** `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`.

## Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```
In [569]: pd.read_stata('stata.dta')
```

```
Out [569]:
```

```
   index      A      B
0      0  1.789587 -1.454551
1      1  0.420343 -1.046421
2      2  0.104704 -1.113877
3      3 -0.837801 -0.257054
4      4 -2.735632  0.702059
5      5 -0.015027  0.123337
6      6 -0.163379 -0.702725
7      7  1.885344  1.187743
8      8 -0.061320 -0.413435
9      9  0.037276  0.006548
```

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```
In [570]: reader = pd.read_stata('stata.dta', chunksize=3)
```

```
In [571]: for df in reader:
.....:     print(df.shape)
.....:
```

```
(3, 3)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```
In [572]: reader = pd.read_stata('stata.dta', iterator=True)
```

```
In [573]: chunk1 = reader.read(5)
```

```
In [574]: chunk2 = reader.read(5)
```

Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have object data type.

---

**Note:** `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

---

---

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

---

## Categorical Data

Categorical data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about *whether* the variable is ordered is lost when exporting.

**Warning:** *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as `Categorical` variables using the keyword argument `convert_categoricals` (`True` by default). The keyword argument `order_categoricals` (`True` by default) determines whether imported `Categorical` variables are ordered.

---

**Note:** When importing categorical data, the values of the variables in the *Stata* data file are not preserved since `Categorical` variables always use integer data types between `-1` and `n-1` where `n` is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported `Categorical` variables: missing values are assigned code `-1`, and the smallest original value is assigned `0`, the second smallest is assigned `1` and so on until the largest original value is assigned the code `n-1`.

---

---

**Note:** *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and

numeric categories for values with no label.

---

#### 4.1.14 SAS Formats

The top-level function `read_sas()` can read (but not write) SAS *xport* (.XPT) and (since *v0.18.0*) *SAS7BDAT* (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For *xport* files, there is no automatic type conversion to integers, dates, or categoricals. For *SAS7BDAT* files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a `DataFrame`.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (`XportReader` or `SAS7BDATReader`) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a *SAS7BDAT* file:

```
df = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an *XPORT* file 100,000 lines at a time:

```
def do_something(chunk):
    pass

rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The [specification](#) for the *xport* file format is available from the SAS web site.

No official documentation is available for the *SAS7BDAT* format.

#### 4.1.15 Other file formats

`pandas` itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from `pandas`, we recommend these packages from the broader community.

##### netCDF

`xarray` provides data structures inspired by the `pandas DataFrame` for working with multi-dimensional datasets, with a focus on the `netCDF` file format and easy conversion to and from `pandas`.

#### 4.1.16 Performance Considerations

This is an informal comparison of various IO methods, using `pandas 0.20.3`. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [2]: df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

In [3]: df.info()
```

(continues on next page)

(continued from previous page)

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A      1000000 non-null float64
B      1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

Given the next test set:

```
from numpy.random import randn

sz = 1000000
df = pd.DataFrame({'A': randn(sz), 'B': [1] * sz})

def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
    df.to_sql(name='test_table', con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
    pd.read_sql_query("select * from test_table", sql_db)
    sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')

def test_hdf_fixed_read():
    pd.read_hdf('test_fixed.hdf', 'test')

def test_hdf_fixed_write_compress(df):
    df.to_hdf('test_fixed_compress.hdf', 'test', mode='w', complib='blosc')

def test_hdf_fixed_read_compress():
    pd.read_hdf('test_fixed_compress.hdf', 'test')

def test_hdf_table_write(df):
    df.to_hdf('test_table.hdf', 'test', mode='w', format='table')

def test_hdf_table_read():
    pd.read_hdf('test_table.hdf', 'test')

def test_hdf_table_write_compress(df):
    df.to_hdf('test_table_compress.hdf', 'test', mode='w',
              complib='blosc', format='table')
```

(continues on next page)

(continued from previous page)

```
def test_hdf_table_read_compress():
    pd.read_hdf('test_table_compress.hdf', 'test')

def test_csv_write(df):
    df.to_csv('test.csv', mode='w')

def test_csv_read():
    pd.read_csv('test.csv', index_col=0)

def test_feather_write(df):
    df.to_feather('test.feather')

def test_feather_read():
    pd.read_feather('test.feather')

def test_pickle_write(df):
    df.to_pickle('test.pkl')

def test_pickle_read():
    pd.read_pickle('test.pkl')

def test_pickle_write_compress(df):
    df.to_pickle('test.pkl.compress', compression='xz')

def test_pickle_read_compress():
    pd.read_pickle('test.pkl.compress', compression='xz')
```

When writing, the top-three functions in terms of speed are `test_pickle_write`, `test_feather_write` and `test_hdf_fixed_write_compress`.

```
In [14]: %timeit test_sql_write(df)
2.37 s ± 36.6 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_write(df)
194 ms ± 65.9 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [26]: %timeit test_hdf_fixed_write_compress(df)
119 ms ± 2.15 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_table_write(df)
623 ms ± 125 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [27]: %timeit test_hdf_table_write_compress(df)
563 ms ± 23.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [17]: %timeit test_csv_write(df)
```

(continues on next page)

(continued from previous page)

```

3.13 s ± 49.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [30]: %timeit test_feather_write(df)
103 ms ± 5.88 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [31]: %timeit test_pickle_write(df)
109 ms ± 3.72 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [32]: %timeit test_pickle_write_compress(df)
3.33 s ± 55.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

```

When reading, the top three are `test_feather_read`, `test_pickle_read` and `test_hdf_fixed_read`.

```

In [18]: %timeit test_sql_read()
1.35 s ± 14.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [19]: %timeit test_hdf_fixed_read()
14.3 ms ± 438 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [28]: %timeit test_hdf_fixed_read_compress()
23.5 ms ± 672 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [20]: %timeit test_hdf_table_read()
35.4 ms ± 314 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [29]: %timeit test_hdf_table_read_compress()
42.6 ms ± 2.1 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [22]: %timeit test_csv_read()
516 ms ± 27.1 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [33]: %timeit test_feather_read()
4.06 ms ± 115 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [34]: %timeit test_pickle_read()
6.5 ms ± 172 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [35]: %timeit test_pickle_read_compress()
588 ms ± 3.57 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

```

## 4.2 Indexing and Selecting Data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

---

**Note:** The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

---

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see *here*.

See the *MultiIndex / Advanced Indexing* for `MultiIndex` and more advanced indexing documentation.

See the *cookbook* for some advanced strategies.

### 4.2.1 Different Choices for Indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
  - A single label, e.g. `5` or `'a'` (Note that `5` is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
  - A list or array of labels `['a', 'b', 'c']`.
  - A slice object with labels `'a': 'f'` (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.).
  - A boolean array
  - A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Label*.

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Position*, *Advanced Indexing* and *Advanced Hierarchical*.

- `.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. See more at *Selection By Callable*.

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:`, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

Object Type	Indexers
Series	<code>s.loc[indexer]</code>
DataFrame	<code>df.loc[row_indexer, column_indexer]</code>
Panel	<code>p.loc[item_indexer, major_indexer, minor_indexer]</code>

## 4.2.2 Basics

As mentioned when introducing the data structures in the *last section*, the primary function of indexing with `[]` (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with `[]`:

Object Type	Selection	Return Value Type
Series	<code>series[label]</code>	scalar value
DataFrame	<code>frame[colname]</code>	Series corresponding to colname
Panel	<code>panel[itemname]</code>	DataFrame corresponding to the itemname

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)

In [2]: df = pd.DataFrame(np.random.randn(8, 4),
...:                      index=dates, columns=['A', 'B', 'C', 'D'])
...:

In [3]: df
Out[3]:
```

	A	B	C	D
2000-01-01	0.469112	-0.282863	-1.509059	-1.135632
2000-01-02	1.212112	-0.173215	0.119209	-1.044236
2000-01-03	-0.861849	-2.104569	-0.494929	1.071804
2000-01-04	0.721555	-0.706771	-1.039575	0.271860
2000-01-05	-0.424972	0.567020	0.276232	-1.087401
2000-01-06	-0.673690	0.113648	-1.478427	0.524988
2000-01-07	0.404705	0.577046	-1.715002	-1.039268
2000-01-08	-0.370647	-1.157892	-1.344312	0.844885

(continues on next page)

(continued from previous page)

```
In [4]: panel = pd.Panel({'one': df, 'two': df - df.mean()})
In [5]: panel
Out[5]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 8 (major_axis) x 4 (minor_axis)
Items axis: one to two
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-08 00:00:00
Minor_axis axis: A to D
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [6]: s = df['A']
In [7]: s[dates[5]]
Out[7]: -0.67368970808837059
In [8]: panel['two']
Out[8]:
A          B          C          D
2000-01-01  0.409571  0.113086 -0.610826 -0.936507
2000-01-02  1.152571  0.222735  1.017442 -0.845111
2000-01-03 -0.921390 -1.708620  0.403304  1.270929
2000-01-04  0.662014 -0.310822 -0.141342  0.470985
2000-01-05 -0.484513  0.962970  1.174465 -0.888276
2000-01-06 -0.733231  0.509598 -0.580194  0.724113
2000-01-07  0.345164  0.972995 -0.816769 -0.840143
2000-01-08 -0.430188 -0.761943 -0.446079  1.044010
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [9]: df
Out[9]:
A          B          C          D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
In [10]: df[['B', 'A']] = df[['A', 'B']]
In [11]: df
Out[11]:
A          B          C          D
2000-01-01 -0.282863  0.469112 -1.509059 -1.135632
2000-01-02 -0.173215  1.212112  0.119209 -1.044236
2000-01-03 -2.104569 -0.861849 -0.494929  1.071804
```

(continues on next page)

(continued from previous page)

```

2000-01-04 -0.706771  0.721555 -1.039575  0.271860
2000-01-05  0.567020 -0.424972  0.276232 -1.087401
2000-01-06  0.113648 -0.673690 -1.478427  0.524988
2000-01-07  0.577046  0.404705 -1.715002 -1.039268
2000-01-08 -1.157892 -0.370647 -1.344312  0.844885

```

You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting Series and DataFrame from `.loc`, and `.iloc`.

This will **not** modify `df` because the column alignment is before value assignment.

```
In [12]: df[['A', 'B']]
```

```
Out [12]:
```

	A	B
2000-01-01	-0.282863	0.469112
2000-01-02	-0.173215	1.212112
2000-01-03	-2.104569	-0.861849
2000-01-04	-0.706771	0.721555
2000-01-05	0.567020	-0.424972
2000-01-06	0.113648	-0.673690
2000-01-07	0.577046	0.404705
2000-01-08	-1.157892	-0.370647

```
In [13]: df.loc[:, ['B', 'A']] = df[['A', 'B']]
```

```
In [14]: df[['A', 'B']]
```

```
Out [14]:
```

	A	B
2000-01-01	-0.282863	0.469112
2000-01-02	-0.173215	1.212112
2000-01-03	-2.104569	-0.861849
2000-01-04	-0.706771	0.721555
2000-01-05	0.567020	-0.424972
2000-01-06	0.113648	-0.673690
2000-01-07	0.577046	0.404705
2000-01-08	-1.157892	-0.370647

The correct way to swap column values is by using raw values:

```
In [15]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()
```

```
In [16]: df[['A', 'B']]
```

```
Out [16]:
```

	A	B
2000-01-01	0.469112	-0.282863
2000-01-02	1.212112	-0.173215
2000-01-03	-0.861849	-2.104569
2000-01-04	0.721555	-0.706771
2000-01-05	-0.424972	0.567020
2000-01-06	-0.673690	0.113648
2000-01-07	0.404705	0.577046
2000-01-08	-0.370647	-1.157892

### 4.2.3 Attribute Access

You may access an index on a Series, column on a DataFrame, and an item on a Panel directly as an attribute:

```
In [17]: sa = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [18]: dfa = df.copy()
```

```
In [19]: sa.b
```

```
Out[19]: 2
```

```
In [20]: dfa.A
```

```
Out[20]:
```

```
2000-01-01    0.469112
2000-01-02    1.212112
2000-01-03   -0.861849
2000-01-04    0.721555
2000-01-05   -0.424972
2000-01-06   -0.673690
2000-01-07    0.404705
2000-01-08   -0.370647
```

```
Freq: D, Name: A, dtype: float64
```

```
In [21]: panel.one
```

```
Out[21]:
```

	A	B	C	D
2000-01-01	0.469112	-0.282863	-1.509059	-1.135632
2000-01-02	1.212112	-0.173215	0.119209	-1.044236
2000-01-03	-0.861849	-2.104569	-0.494929	1.071804
2000-01-04	0.721555	-0.706771	-1.039575	0.271860
2000-01-05	-0.424972	0.567020	0.276232	-1.087401
2000-01-06	-0.673690	0.113648	-1.478427	0.524988
2000-01-07	0.404705	0.577046	-1.715002	-1.039268
2000-01-08	-0.370647	-1.157892	-1.344312	0.844885

```
In [22]: sa.a = 5
```

```
In [23]: sa
```

```
Out[23]:
```

```
a    5

2000-01-04	3	-0.706771	-1.039575	0.271860
2000-01-05	4	0.567020	0.276232	-1.087401
2000-01-06	5	0.113648	-1.478427	0.524988
2000-01-07	6	0.577046	-1.715002	-1.039268

(continues on next page)

(continued from previous page)

```

2000-01-08  7 -1.157892 -1.344312  0.844885

In [26]: dfa['A'] = list(range(len(dfa.index))) # use this form to create a new_
↳column

In [27]: dfa
Out [27]:
      A          B          C          D
2000-01-01  0 -0.282863 -1.509059 -1.135632
2000-01-02  1 -0.173215  0.119209 -1.044236
2000-01-03  2 -2.104569 -0.494929  1.071804
2000-01-04  3 -0.706771 -1.039575  0.271860
2000-01-05  4  0.567020  0.276232 -1.087401
2000-01-06  5  0.113648 -1.478427  0.524988
2000-01-07  6  0.577046 -1.715002 -1.039268
2000-01-08  7 -1.157892 -1.344312  0.844885

```

**Warning:**

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here](#) for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

```

In [28]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [29]: x.iloc[1] = {'x': 9, 'y': 99}

In [30]: x
Out [30]:
   x  y
0  1  3
1  9 99
2  3  5

```

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```

In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns -
↳see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out [3]:
   one

```

(continues on next page)

```
In [4]: df1.loc[2:3]
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
↳with these indexers [2] of <type 'int'>
```

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```
In [41]: df1.loc['20130102':'20130104']
Out [41]:
```

	A	B	C	D
2013-01-02	0.357021	-0.674600	-1.776904	-0.968914
2013-01-03	-1.294524	0.413738	0.276662	-0.472035
2013-01-04	-0.013960	-0.362543	-0.006154	-0.923061

**Warning:** Starting in 0.21.0, pandas will show a FutureWarning if indexing with a list with missing labels. In the future this will raise a KeyError. See *list-like Using loc with missing keys in a list is Deprecated*.

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.).
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [42]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [43]: s1
```

```
Out [43]:
```

a	1.431256
b	1.340309
c	-1.170299
d	-0.226169
e	0.410835
f	0.813850

dtype: float64

```
In [44]: s1.loc['c:']
```

```

////////////////////////////////////
↳
c    -1.170299
d    -0.226169
e     0.410835
f     0.813850
dtype: float64
```

(continues on next page)

(continued from previous page)

```
A    0.132003
B   -0.827317
C   -0.076467
D   -1.187678
Name: a, dtype: float64
```

For getting values with a boolean array:

```
In [53]: df1.loc['a'] > 0
Out [53]:
A     True
B    False
C    False
D    False
Name: a, dtype: bool

In [54]: df1.loc[:, df1.loc['a'] > 0]
Out [54]:
\Out [54]:
      A
a  0.132003
b  1.130127
c  1.024180
d  0.974466
e  0.545952
f -1.281247
```

For getting a value explicitly (equivalent to deprecated `df.get_value('a', 'A')`):

```
# this is also equivalent to ``df1.at['a','A']``
In [55]: df1.loc['a', 'A']
Out [55]: 0.13200317033032932
```

## Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [56]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
In [57]: s.loc[3:5]
Out [57]:
3    b
2    c
5    d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [58]: s.sort_index()
Out [58]:
0    a
2    c
3    b
4    e
```

(continues on next page)

(continued from previous page)

```

5      d
dtype: object

In [59]: s.sort_index().loc[1:6]
\\Out [59]:
2      c
3      b
4      e
5      d
dtype: object

```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

## 4.2.6 Selection By Position

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bounds is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [60]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))
```

```
In [61]: s1
```

```
Out [61]:
0      0.695775
2      0.341734
4      0.959726
6     -1.110336
8     -0.619976
dtype: float64
```

```
In [62]: s1.iloc[:3]
```

```
\\Out [62]:

```

```

# this is also equivalent to ``df1.iat[1,1]``

```

```

In [73]: df1.iloc[1, 1]
Out [73]: -0.15495077442490321

```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```

In [74]: df1.iloc[1]
Out [74]:
0    0.403310
2   -0.154951
4    0.301624
6   -2.179861
Name: 2, dtype: float64

```

Out of range slice indexes are handled gracefully just as in Python/Numpy.

```

# these are allowed in python/numpy.

```

```

In [75]: x = list('abcdef')

```

```

In [76]: x

```

```

Out [76]: ['a', 'b', 'c', 'd', 'e', 'f']

```

```

In [77]: x[4:10]

```

```

\\Out [77]: ['e', 'f']

```

```

In [78]: x[8:10]

```

```

\\Out [78]: []

```

```

In [79]: s = pd.Series(x)

```

```

In [80]: s

```

```

Out [80]:

```

```

0    a
1    b

```

(continues on next page)

(continued from previous page)

```

2    c
3    d
4    e
5    f
dtype: object

```

```

In [81]: s.iloc[4:10]
Out[81]:
4    e
5    f
dtype: object

```

```

In [82]: s.iloc[8:10]
Out[82]:
↪Series([], dtype: object)

```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

```

In [83]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

```

```

In [84]: df1

```

```

Out[84]:
   A         B
0 -0.082240 -2.182937
1  0.380396  0.084844
2  0.432390  1.519970
3 -0.493662  0.600178
4  0.274230  0.132885

```

```

In [85]: df1.iloc[:, 2:3]

```

```

↪
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

```

```

In [86]: df1.iloc[:, 1:3]

```

```

```

```

In [87]: df1.iloc[4:6]

```

```

↪
   A         B
4  0.27423  0.132885

```

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```

>>> df1.iloc[[4, 5, 6]]

```

(continues on next page)

(continued from previous page)

```

IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds

```

## 4.2.7 Selection By Callable

New in version 0.18.1.

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing.

```

In [88]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                      index=list('abcdef'),
.....:                      columns=list('ABCD'))
.....:

```

```

In [89]: df1
Out[89]:

```

	A	B	C	D
a	-0.023688	2.410179	1.450520	0.206053
b	-0.251905	-2.213588	1.063327	1.266143
c	0.299368	-0.863838	0.408204	-1.048089
d	-0.025747	-0.988387	0.094055	1.262731
e	1.289997	0.082423	-0.055758	0.536580
f	-0.489682	0.369374	-0.034571	-2.484478

```

In [90]: df1.loc[lambda df: df.A > 0, :]

```

```

////////////////////////////////////
↪

```

c     0.299368
d    -0.025747
e     1.289997
f    -0.489682
Name: A, dtype: float64

```

You can use callable indexing in Series.

```
In [94]: df1.A.loc[lambda s: s > 0]
```

```
Out [94]:
```

```

c     0.299368
e     1.289997
Name: A, dtype: float64

```

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [95]: bb = pd.read_csv('data/baseball.csv', index_col='id')
```

```
In [96]: (bb.groupby(['year', 'team']).sum()
```

```
.....:     .loc[lambda df: df.r > 100])
```

```
.....:
Out [96]:
```

```

## 4.2.8 IX Indexer is Deprecated

**Warning:** Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [97]: dfd = pd.DataFrame({'A': [1, 2, 3],
.....:                    'B': [4, 5, 6]},
.....:                    index=list('abc'))
.....:

In [98]: dfd
Out [98]:
   A  B
a  1  4
b  2  5
c  3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: dfd.ix[[0, 2], 'A']
Out [3]:
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [99]: dfd.loc[dfd.index[[0, 2]], 'A']
Out [99]:
a    1
c    3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [100]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out [100]:
a    1
c    3
Name: A, dtype: int64
```

For getting *multiple* indexers, using `.get_indexer`:

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out [101]:
   A  B
a  1  4
c  3  6
```

## 4.2.9 Indexing with list with missing labels is Deprecated

**Warning:** Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```
In [102]: s = pd.Series([1, 2, 3])

In [103]: s
Out[103]:
0      1
1      2
2      3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [104]: s.loc[[1, 2]]
Out[104]:
1      2
2      3
dtype: int64
```

### Previous Behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

### Current Behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex->listlike

Out[4]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

## Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on *reindexing*.

```
In [105]: s.reindex([1, 2, 3])
Out [105]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [106]: labels = [1, 2, 3]
In [107]: s.loc[s.index.intersection(labels)]
Out [107]:
1      2
2      3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [108]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [109]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [110]: s.loc[s.index.intersection(labels)].reindex(labels)
Out [110]:
c      3.0
d      NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']
In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

### 4.2.10 Selecting Random Samples

A random selection of rows or columns from a Series, DataFrame, or Panel with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [111]: s = pd.Series([0, 1, 2, 3, 4, 5])
# When no arguments are passed, returns 1 row.
```

(continues on next page)

(continued from previous page)

```

    col1  col2
2      3     4
1      2     3

```

## 4.2.11 Setting With Enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the `Series` case this is effectively an appending operation.

```
In [130]: se = pd.Series([1, 2, 3])
```

```
In [131]: se
```

```
Out[131]:
```

```
0      1
1      2
2      3
dtype: int64
```

```
In [132]: se[5] = 5.
```

```
In [133]: se
```

```
Out[133]:
```

```
0      1.0
1      2.0
2      3.0
5      5.0
dtype: float64
```

A `DataFrame` can be enlarged on either axis via `.loc`.

```
In [134]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....:                       columns=['A', 'B'])
.....:
```

```
In [135]: dfi
```

```
Out[135]:
```

```
   A  B
0  0  1
1  2  3
2  4  5
```

```
In [136]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [137]: dfi
```

```
Out[137]:
```

```
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
```

This is like an append operation on the `DataFrame`.

```
In [138]: dfi.loc[3] = 5
```

(continues on next page)

(continued from previous page)

```
In [139]: dfi
Out[139]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

## 4.2.12 Fast scalar value getting and setting

Since indexing with `[]` must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

```
In [140]: s.iat[5]
Out[140]: 5

In [141]: df.at[dates[5], 'A']
Out[141]: -0.67368970808837059

In [142]: df.iat[3, 0]
Out[142]: 0.72155516224436689
```

You can also set using these same indexers.

```
In [143]: df.at[dates[5], 'E'] = 7
In [144]: df.iat[3, 0] = 7
```

`at` may enlarge the object in-place as above if the indexer is missing.

```
In [145]: df.at[dates[-1] + 1, 0] = 7

In [146]: df
Out[146]:
              A          B          C          D          E          0
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632      NaN      NaN
2000-01-02  1.212112 -0.173215  0.119209 -1.044236      NaN      NaN
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804      NaN      NaN
2000-01-04  7.000000 -0.706771 -1.039575  0.271860      NaN      NaN
2000-01-05 -0.424972  0.567020  0.276232 -1.087401      NaN      NaN
2000-01-06 -0.673690  0.113648 -1.478427  0.524988  7.0      NaN
2000-01-07  0.404705  0.577046 -1.715002 -1.039268      NaN      NaN
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885      NaN      NaN
2000-01-09         NaN         NaN         NaN         NaN      NaN  7.0
```

## 4.2.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: `|` for `or`, `&` for `and`, and `~` for `not`. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as

`df.A > 2 & df.B < 3` as `df.A > (2 & df.B) < 3`, while the desired evaluation order is `(df.A > 2) & (df.B < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [147]: s = pd.Series(range(-3, 4))

In [148]: s
Out[148]:
0    -3
1    -2
2    -1
3     0
4     1
5     2
6     3
dtype: int64

In [149]: s[s > 0]
Out[149]:
4     1
5     2
6     3
dtype: int64

In [150]: s[(s < -1) | (s > 0.5)]
Out[150]:
0    -3
1    -2
4     1
5     2
6     3
dtype: int64

In [151]: s[~(s < 0)]
Out[151]:
3     0
4     1
5     2
6     3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example, something derived from one of the columns of the DataFrame):

```
In [152]: df[df['A'] > 0]
Out[152]:
```

	A	B	C	D	E	0
2000-01-01	0.469112	-0.282863	-1.509059	-1.135632	NaN	NaN
2000-01-02	1.212112	-0.173215	0.119209	-1.044236	NaN	NaN
2000-01-04	7.000000	-0.706771	-1.039575	0.271860	NaN	NaN
2000-01-07	0.404705	0.577046	-1.715002	-1.039268	NaN	NaN

List comprehensions and map method of Series can also be used to produce more complex criteria:

```
In [153]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six']},
Out[153]:
```

(continues on next page)

(continued from previous page)

```

.....:          'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
.....:          'c': np.random.randn(7)}
.....:

# only want 'two' or 'three'
In [154]: criterion = df2['a'].map(lambda x: x.startswith('t'))

In [155]: df2[criterion]
Out[155]:
   a b      c
2  two y  0.041290
3  three x  0.361719
4  two y -0.238075

# equivalent but slower
In [156]: df2[[x.startswith('t') for x in df2['a']]]
\-----/
↪
   a b      c
2  two y  0.041290
3  three x  0.361719
4  two y -0.238075

# Multiple criteria
In [157]: df2[criterion & (df2['b'] == 'x')]
\-----/
↪
   a b      c
3  three x  0.361719

```

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.

```

In [158]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[158]:
   b      c
3  x  0.361719

```

#### 4.2.14 Indexing with `isin`

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```

In [159]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')

In [160]: s
Out[160]:
4    0
3    1
2    2
1    3
0    4
dtype: int64

In [161]: s.isin([2, 4, 6])

```

(continues on next page)

## 4.2.15 The where () Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```
In [177]: s[s > 0]
Out [177]:
3      1
2      2
1      3
0      4
dtype: int64
```

To return a Series of the same shape as the original:

```
In [178]: s.where(s > 0)
Out [178]:
4      NaN
3      1.0
2      2.0
1      3.0
0      4.0
dtype: float64
```

Selecting values from a `DataFrame` with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```
In [179]: df[df < 0]
Out [179]:
           A          B          C          D
2000-01-01 -2.104139 -1.309525      NaN      NaN
2000-01-02 -0.352480      NaN -1.192319      NaN
2000-01-03 -0.864883      NaN -0.227870      NaN
2000-01-04      NaN -1.222082      NaN -1.233203
2000-01-05      NaN -0.605656 -1.169184      NaN
2000-01-06      NaN -0.948458      NaN -0.684718
2000-01-07 -2.670153 -0.114722      NaN -0.048048
2000-01-08      NaN      NaN -0.048788 -0.808838
```

In addition, `where` takes an optional `other` argument for replacement of values where the condition is `False`, in the returned copy.

```
In [180]: df.where(df < 0, -df)
Out [180]:
           A          B          C          D
2000-01-01 -2.104139 -1.309525 -0.485855 -0.245166
2000-01-02 -0.352480 -0.390389 -1.192319 -1.655824
2000-01-03 -0.864883 -0.299674 -0.227870 -0.281059
2000-01-04 -0.846958 -1.222082 -0.600705 -1.233203
2000-01-05 -0.669692 -0.605656 -1.169184 -0.342416
2000-01-06 -0.868584 -0.948458 -2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 -0.168904 -0.048048
2000-01-08 -0.801196 -1.392071 -0.048788 -0.808838
```

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [181]: s2 = s.copy()

In [182]: s2[s2 < 0] = 0

In [183]: s2
Out[183]:
4    0
3    1
2    2
1    3
0    4
dtype: int64

In [184]: df2 = df.copy()

In [185]: df2[df2 < 0] = 0

In [186]: df2
Out[186]:
```

	A	B	C	D
2000-01-01	0.000000	0.000000	0.485855	0.245166
2000-01-02	0.000000	0.390389	0.000000	1.655824
2000-01-03	0.000000	0.299674	0.000000	0.281059
2000-01-04	0.846958	0.000000	0.600705	0.000000
2000-01-05	0.669692	0.000000	0.000000	0.342416
2000-01-06	0.868584	0.000000	2.297780	0.000000
2000-01-07	0.000000	0.000000	0.168904	0.000000
2000-01-08	0.801196	1.392071	0.000000	0.000000

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```
In [187]: df_orig = df.copy()

In [188]: df_orig.where(df > 0, -df, inplace=True)

In [189]: df_orig
Out[189]:
```

	A	B	C	D
2000-01-01	2.104139	1.309525	0.485855	0.245166
2000-01-02	0.352480	0.390389	1.192319	1.655824
2000-01-03	0.864883	0.299674	0.227870	0.281059
2000-01-04	0.846958	1.222082	0.600705	1.233203
2000-01-05	0.669692	0.605656	1.169184	0.342416
2000-01-06	0.868584	0.948458	2.297780	0.684718
2000-01-07	2.670153	0.114722	0.168904	0.048048
2000-01-08	0.801196	1.392071	0.048788	0.808838

**Note:** The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

```
In [190]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[190]:
```

	A	B	C	D
2000-01-01	True	True	True	True
2000-01-02	True	True	True	True

(continues on next page)

(continued from previous page)

```

2000-01-03  True  True  True  True
2000-01-04  True  True  True  True
2000-01-05  True  True  True  True
2000-01-06  True  True  True  True
2000-01-07  True  True  True  True
2000-01-08  True  True  True  True

```

## alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```

In [191]: df2 = df.copy()

In [192]: df2[df2[1:4] > 0] = 3

In [193]: df2
Out [193]:

```

	A	B	C	D
2000-01-01	-2.104139	-1.309525	0.485855	0.245166
2000-01-02	-0.352480	3.000000	-1.192319	3.000000
2000-01-03	-0.864883	3.000000	-0.227870	3.000000
2000-01-04	3.000000	-1.222082	3.000000	-1.233203
2000-01-05	0.669692	-0.605656	-1.169184	0.342416
2000-01-06	0.868584	-0.948458	2.297780	-0.684718
2000-01-07	-2.670153	-0.114722	0.168904	-0.048048
2000-01-08	0.801196	1.392071	-0.048788	-0.808838

`where` can also accept `axis` and `level` parameters to align the input when performing the `where`.

```

In [194]: df2 = df.copy()

In [195]: df2.where(df2 > 0, df2['A'], axis='index')
Out [195]:

```

	A	B	C	D
2000-01-01	-2.104139	-2.104139	0.485855	0.245166
2000-01-02	-0.352480	0.390389	-0.352480	1.655824
2000-01-03	-0.864883	0.299674	-0.864883	0.281059
2000-01-04	0.846958	0.846958	0.600705	0.846958
2000-01-05	0.669692	0.669692	0.669692	0.342416
2000-01-06	0.868584	0.868584	2.297780	0.868584
2000-01-07	-2.670153	-2.670153	0.168904	-2.670153
2000-01-08	0.801196	1.392071	0.801196	0.801196

This is equivalent to (but faster than) the following.

```

In [196]: df2 = df.copy()

In [197]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])
Out [197]:

```

	A	B	C	D
2000-01-01	-2.104139	-2.104139	0.485855	0.245166
2000-01-02	-0.352480	0.390389	-0.352480	1.655824
2000-01-03	-0.864883	0.299674	-0.864883	0.281059
2000-01-04	0.846958	0.846958	0.600705	0.846958
2000-01-05	0.669692	0.669692	0.669692	0.342416

(continues on next page)

(continued from previous page)

```

2000-01-06  0.868584  0.868584  2.297780  0.868584
2000-01-07 -2.670153 -2.670153  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196

```

New in version 0.18.1.

Where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

```

In [198]: df3 = pd.DataFrame({'A': [1, 2, 3],
.....:                       'B': [4, 5, 6],
.....:                       'C': [7, 8, 9]})
.....:

In [199]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[199]:
   A  B  C
0  11 14  7
1  12  5  8
2  13  6  9

```

## Mask

`mask()` is the inverse boolean operation of `where`.

```

In [200]: s.mask(s >= 0)
Out[200]:
4  NaN
3  NaN
2  NaN
1  NaN
0  NaN
dtype: float64

In [201]: df.mask(df >= 0)
Out[201]:
   A         B         C         D
2000-01-01 -2.104139 -1.309525      NaN      NaN
2000-01-02 -0.352480      NaN -1.192319      NaN
2000-01-03 -0.864883      NaN -0.227870      NaN
2000-01-04      NaN -1.222082      NaN -1.233203
2000-01-05      NaN -0.605656 -1.169184      NaN
2000-01-06      NaN -0.948458      NaN -0.684718
2000-01-07 -2.670153 -0.114722      NaN -0.048048
2000-01-08      NaN      NaN -0.048788 -0.808838

```

## 4.2.16 The `query()` Method

`DataFrame` objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```
In [202]: n = 10
```

(continues on next page)

(continued from previous page)

```
In [203]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [204]: df
```

```
Out [204]:
```

	a	b	c
0	0.438921	0.118680	0.863670
1	0.138138	0.577363	0.686602
2	0.595307	0.564592	0.520630
3	0.913052	0.926075	0.616184
4	0.078718	0.854477	0.898725
5	0.076404	0.523211	0.591538
6	0.792342	0.216974	0.564056
7	0.397890	0.454131	0.915716
8	0.074315	0.437913	0.019794
9	0.559209	0.502065	0.026437

```
# pure python
```

```
In [205]: df[(df.a < df.b) & (df.b < df.c)]
```

```

////////////////////////////////////
↪

```

	a	b	c
1	0.138138	0.577363	0.686602
4	0.078718	0.854477	0.898725
5	0.076404	0.523211	0.591538
7	0.397890	0.454131	0.915716

```
# query
```

```
In [206]: df.query('(a < b) & (b < c)')
```

```

////////////////////////////////////
↪

```

	a	b	c
1	0.138138	0.577363	0.686602
4	0.078718	0.854477	0.898725
5	0.076404	0.523211	0.591538
7	0.397890	0.454131	0.915716

Do the same thing but fall back on a named index if there is no column with the name a.

```
In [207]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
```

```
In [208]: df.index.name = 'a'
```

```
In [209]: df
```

```
Out [209]:
```

a	b	c
0	0	4
1	0	1
2	3	4
3	4	3
4	1	4
5	0	3
6	0	1
7	3	4
8	2	3
9	1	1

(continues on next page)

(continued from previous page)

```
In [210]: df.query('a < b and b < c')
```

```

////////////////////////////////////
↪
   b  c
a
2  3  4

```

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

```
In [211]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
```

```
In [212]: df
```

```
Out [212]:
```

```

   b  c
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9

```

```
In [213]: df.query('index < b < c')
```

```

////////////////////////////////////
↪
   b  c
2  5  6

```

**Note:** If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [214]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
```

```
In [215]: df.index.name = 'a'
```

```
In [216]: df.query('a > 2') # uses the column 'a', not the index
```

```
Out [216]:
```

```

   a
a
1  3
3  3

```

You can still use the index in a query expression by using the special identifier `'index'`:

```
In [217]: df.query('index > 2')
```

```
Out [217]:
```

```

   a
a
3  3
4  2

```

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

### MultiIndex query () Syntax

You can also use the levels of a DataFrame with a *MultiIndex* as if they were columns in the frame:

```
In [218]: n = 10

In [219]: colors = np.random.choice(['red', 'green'], size=n)

In [220]: foods = np.random.choice(['eggs', 'ham'], size=n)

In [221]: colors
Out[221]:
array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green',
       'green', 'green'],
      dtype='<U5')

In [222]: foods
////////////////////////////////////
↪
array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs',
       'eggs'],
      dtype='<U4')

In [223]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])

In [224]: df = pd.DataFrame(np.random.randn(n, 2), index=index)

In [225]: df
Out[225]:
          0          1
color food
red  ham  0.194889 -0.381994
     ham  0.318587  2.089075
     eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
     eggs -2.029766  0.792652
     ham  0.461007 -0.542749
     ham -0.305384 -0.479195
     eggs  0.095031 -0.270099
     eggs -0.707140 -0.773882
     eggs  0.229453  0.304418

In [226]: df.query('color == "red"')
////////////////////////////////////
↪
          0          1
color food
red  ham  0.194889 -0.381994
     ham  0.318587  2.089075
     eggs -0.728293 -0.090255
```

If the levels of the *MultiIndex* are unnamed, you can refer to them using special names:

```
In [227]: df.index.names = [None, None]

In [228]: df
Out[228]:
          0          1
```

(continues on next page)

(continued from previous page)

```

red   ham    0.194889 -0.381994
      ham    0.318587  2.089075
      eggs  -0.728293 -0.090255
green eggs  -0.748199  1.318931
      eggs  -2.029766  0.792652
      ham    0.461007 -0.542749
      ham   -0.305384 -0.479195
      eggs   0.095031 -0.270099
      eggs  -0.707140 -0.773882
      eggs   0.229453  0.304418

```

```
In [229]: df.query('ilevel_0 == "red"')
```

```

////////////////////////////////////
↔
           0         1
red ham    0.194889 -0.381994
      ham    0.318587  2.089075
      eggs  -0.728293 -0.090255

```

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

### query () Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you’re interested in querying

```
In [230]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [231]: df
```

```
Out [231]:
           a         b         c
0  0.224283  0.736107  0.139168
1  0.302827  0.657803  0.713897
2  0.611185  0.136624  0.984960
3  0.195246  0.123436  0.627712
4  0.618673  0.371660  0.047902
5  0.480088  0.062993  0.185760
6  0.568018  0.483467  0.445289
7  0.309040  0.274580  0.587101
8  0.258993  0.477769  0.370255
9  0.550459  0.840870  0.304611

```

```
In [232]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
```

```
In [233]: df2
```

```
Out [233]:
           a         b         c
0  0.357579  0.229800  0.596001
1  0.309059  0.957923  0.965663
2  0.123102  0.336914  0.318616
3  0.526506  0.323321  0.860813
4  0.518736  0.486514  0.384724
5  0.190804  0.505723  0.614533
6  0.891939  0.623977  0.676639

```

(continues on next page)

(continued from previous page)

```
7    0.480559  0.378528  0.460858
8    0.420223  0.136404  0.141295
9    0.732206  0.419540  0.604675
10   0.604466  0.848974  0.896165
11   0.589168  0.920046  0.732716

In [234]: expr = '0.0 <= a <= c <= 0.5'

In [235]: map(lambda frame: frame.query(expr), [df, df2])
Out [235]: <map at 0x7f7a0e884dd8>
```

### query () Python versus pandas Syntax Comparison

Full numpy-like syntax:

```
In [236]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))

In [237]: df
Out [237]:
```

	a	b	c
0	7	8	9
1	1	0	7
2	2	7	2
3	6	2	2
4	2	6	3
5	3	8	2
6	1	7	2
7	5	1	5
8	9	8	0
9	1	5	0

```
In [238]: df.query('(a < b) & (b < c)')
\//////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↔
     a  b  c
0    7  8  9

In [239]: df[(df.a < df.b) & (df.b < df.c)]
\//////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↔
     a  b  c
0    7  8  9
```

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than & and |).

```
In [240]: df.query('a < b & b < c')
Out [240]:
```

	a	b	c
0	7	8	9

Use English instead of symbols:

```
In [241]: df.query('a < b and b < c')
Out [241]:
```

(continues on next page)

(continued from previous page)

```

2 b a 1 6
3 b a 2 1
4 c b 3 6
5 c b 0 2

```

```
In [247]: df.query('a not in b')
```

```

////////////////////////////////////
↪
   a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2

```

```
# pure Python
```

```
In [248]: df[~df.a.isin(df.b)]
```

```

////////////////////////////////////
↪
   a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2

```

You can combine this with other expressions for very succinct queries:

```
# rows where cols a and b have overlapping values
# and col c's values are less than col d's
```

```
In [249]: df.query('a in b and c < d')
```

```
Out [249]:
```

```

   a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
4 c b 3 6
5 c b 0 2

```

```
# pure Python
```

```
In [250]: df[df.b.isin(df.a) & (df.c < df.d)]
```

```

////////////////////////////////////
↪
   a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
4 c b 3 6
5 c b 0 2
10 f c 0 6
11 f c 1 2

```

Out [250]:

**Note:** Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

### Special use of the `==` operator with `list` objects

Comparing a `list` of values to a column using `==/!=` works similarly to `in/not in`.

```
In [251]: df.query('b == ["a", "b", "c"]')
```

```
Out[251]:
   a b c d
0  a a 2 6
1  a a 4 7
2  b a 1 6
3  b a 2 1
4  c b 3 6
5  c b 0 2
6  d b 3 3
7  d b 2 1
8  e c 4 3
9  e c 2 0
10 f c 0 6
11 f c 1 2
```

```
# pure Python
```

```
In [252]: df[df.b.isin(["a", "b", "c"])]
```

```

////////////////////////////////////
↪
   a b c d
0  a a 2 6
1  a a 4 7
2  b a 1 6
3  b a 2 1
4  c b 3 6
5  c b 0 2
6  d b 3 3
7  d b 2 1
8  e c 4 3
9  e c 2 0
10 f c 0 6
11 f c 1 2
```

```
In [253]: df.query('c == [1, 2]')
```

```

////////////////////////////////////
↪
   a b c d
0  a a 2 6
2  b a 1 6
3  b a 2 1
7  d b 2 1
9  e c 2 0
11 f c 1 2
```

```
In [254]: df.query('c != [1, 2]')
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# using in/not in
In [255]: df.query('[1, 2] in c')
////////////////////////////////////
↪
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [256]: df.query('[1, 2] not in c')
////////////////////////////////////
↪
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# pure Python
In [257]: df[df.c.isin([1, 2])]
////////////////////////////////////
↪
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

```

## Boolean Operators

You can negate boolean expressions with the word `not` or the `~` operator.

```
In [258]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [259]: df['bools'] = np.random.rand(len(df)) > 0.5
```

```
In [260]: df.query('~bools')
```

```
Out [260]:
```

(continues on next page)

(continued from previous page)

```

      a      b      c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

In [261]: df.query('not bools')
\////////////////////////////////////////////////////////////////////////////////\
↪
      a      b      c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

In [262]: df.query('not bools') == df[~df.bools]
\////////////////////////////////////////////////////////////////////////////////\
↪
      a      b      c  bools
2  True  True  True  True
7  True  True  True  True
8  True  True  True  True

```

Of course, expressions can be arbitrarily complex too:

```

# short query syntax
In [263]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [264]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]

In [265]: shorter
Out[265]:
      a      b      c  bools
7  0.275396  0.691034  0.826619  False

In [266]: longer
\////////////////////////////////////////////////////////////////////////////////\Out[266]:
↪
      a      b      c  bools
7  0.275396  0.691034  0.826619  False

In [267]: shorter == longer
\////////////////////////////////////////////////////////////////////////////////\
↪
      a      b      c  bools
7  True  True  True  True

```

### Performance of query ()

DataFrame.query() using numexpr is slightly faster than Python for large frames.

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

#### 4.2.17 Duplicate Data

If you want to identify and remove duplicate rows in a `DataFrame`, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.

- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [268]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four
↳'],
      .....:                  'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
      .....:                  'c': np.random.randn(7)})
      .....:
```

```
In [269]: df2
```

```
Out [269]:
```

	a	b	c
0	one	x	-1.067137
1	one	y	0.309500
2	two	x	-0.211056
3	two	y	-1.842023
4	two	x	-0.390820
5	three	x	-1.964475
6	four	x	1.298329

```
In [270]: df2.duplicated('a')
```

```

↳
0    False
1     True
2    False
3     True
4     True
5    False
6    False
dtype: bool
```

```
In [271]: df2.duplicated('a', keep='last')
```

```

↳
0     True
1    False
2     True
3     True
4    False
5    False
6    False
dtype: bool
```

```
In [272]: df2.duplicated('a', keep=False)
```

```

↳
0     True
1     True
2     True
3     True
```

(continues on next page)

(continued from previous page)

```

4     True
5     False
6     False
dtype: bool

```

```
In [273]: df2.drop_duplicates('a')
```

```

////////////////////////////////////
↪
      a  b      c
0  one  x -1.067137
2  two  x -0.211056
5 three  x -1.964475
6  four  x  1.298329

```

```
In [274]: df2.drop_duplicates('a', keep='last')
```

```

////////////////////////////////////
↪
      a  b      c
1  one  y  0.309500
4  two  x -0.390820
5 three  x -1.964475
6  four  x  1.298329

```

```
In [275]: df2.drop_duplicates('a', keep=False)
```

```

////////////////////////////////////
↪
      a  b      c
5 three  x -1.964475
6  four  x  1.298329

```

Also, you can pass a list of columns to identify duplications.

```
In [276]: df2.duplicated(['a', 'b'])
```

```

Out [276]:
0     False
1     False
2     False
3     False
4      True
5     False
6     False
dtype: bool

```

```
In [277]: df2.drop_duplicates(['a', 'b'])
```

```

////////////////////////////////////
↪
      a  b      c
0  one  x -1.067137
1  one  y  0.309500
2  two  x -0.211056
3  two  y -1.842023
5 three  x -1.964475
6  four  x  1.298329

```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

## Set operations on Index objects

The two main operations are union (`|`) and intersection (`&`). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```
In [309]: a = pd.Index(['c', 'b', 'a'])
In [310]: b = pd.Index(['c', 'e', 'd'])
In [311]: a | b
Out[311]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
In [312]: a & b
Out[312]: Index(['c'], dtype='object')
In [313]: a.difference(b)
Out[313]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference (^)` operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [314]: idx1 = pd.Index([1, 2, 3, 4])
In [315]: idx2 = pd.Index([2, 3, 4, 5])
In [316]: idx1.symmetric_difference(idx2)
Out[316]: Int64Index([1, 5], dtype='int64')
In [317]: idx1 ^ idx2
Out[317]: Int64Index([1, 5], dtype='int64')
```

---

**Note:** The resulting index from a set operation will be sorted in ascending order.

---

## Missing values

**Important:** Even though Index can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

---

`Index.fillna` fills missing values with specified scalar value.

```
In [318]: idx1 = pd.Index([1, np.nan, 3, 4])
In [319]: idx1
Out[319]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')
In [320]: idx1.fillna(2)
Out[320]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')
```

(continues on next page)

The append keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```
In [329]: frame = data.set_index('c', drop=False)
In [330]: frame = frame.set_index(['a', 'b'], append=True)
In [331]: frame
Out [331]:
```

	c	d
c a b		
z bar one z	1.0	
y bar two y	2.0	
x foo one x	3.0	
w foo two w	4.0	

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [332]: data.set_index('c', drop=False)
Out [332]:
```

	a	b	c	d
c				
z bar one z			1.0	
y bar two y			2.0	
x foo one x			3.0	
w foo two w			4.0	

```
In [333]: data.set_index(['a', 'b'], inplace=True)
In [334]: data
Out [334]:
```

	c	d
a b		
bar one z	1.0	
two y	2.0	
foo one x	3.0	
two w	4.0	

### Reset the index

As a convenience, there is a new function on `DataFrame` called `reset_index()` which transfers the index values into the `DataFrame`'s columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```
In [335]: data
Out [335]:
```

	c	d
a b		
bar one z	1.0	
two y	2.0	
foo one x	3.0	
two w	4.0	

```
In [336]: data.reset_index()
///////////////////////////////////////////////////
↪
```

	a	b	c	d
bar one z			1.0	
two y			2.0	
foo one x			3.0	
two w			4.0	

(continues on next page)

(continued from previous page)

```

0 bar one z 1.0
1 bar two y 2.0
2 foo one x 3.0
3 foo two w 4.0

```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [337]: frame
```

```
Out [337]:
```

```

      c    d
c a  b
z bar one z 1.0
y bar two y 2.0
x foo one x 3.0
w foo two w 4.0

```

```
In [338]: frame.reset_index(level=1)
```

```

////////////////////////////////////
↪
      a    c    d
c b
z one bar z 1.0
y two bar y 2.0
x one foo x 3.0
w two foo w 4.0

```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

### Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

## 4.2.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```

In [339]: dfmi = pd.DataFrame([list('abcd'),
.....:                        list('efgh'),
.....:                        list('ijkl'),
.....:                        list('mnop')],
.....:                        columns=pd.MultiIndex.from_product([['one', 'two'],
.....:                                                              ['first', 'second
↪ ]]))
.....:

```

```
In [340]: dfmi
```

```
Out [340]:
```

(continues on next page)

(continued from previous page)

```

      one      two
first second first second
0      a      b      c      d
1      e      f      g      h
2      i      j      k      l
3      m      n      o      p

```

Compare these two access methods:

```
In [341]: dfmi['one']['second']
```

```
Out [341]:
```

```
0      b
1      f
2      j
3      n
Name: second, dtype: object
```

```
In [342]: dfmi.loc[:, ('one', 'second')]
```

```
Out [342]:
```

```
0      b
1      f
2      j
3      n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by 'second'. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:, ('one', 'second')]` which passes a nested tuple of `(slice(None), ('one', 'second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

### Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

**Note:** You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__` / `dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. **These** are the bugs that `SettingWithCopy` is designed to catch! Pandas is probably trying to warn you that you've done this:

```
def do_something(df):
    foo = df[['bar', 'baz']] # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

## Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option.mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.
- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- None will suppress the warnings entirely.

```
In [343]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
.....:                          'three', 'two', 'one', 'six'],
.....:                      'c': np.arange(7)})
.....:

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [344]: dfb['c'][dfb.a.str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment', 'warn')
>>> dfb[dfb.a.str.startswith('o')]['c'] = 42
Traceback (most recent call last)
...
SettingWithCopyWarning:
```

(continues on next page)

(continued from previous page)

A value is trying to be set on a copy of a slice from a DataFrame.  
Try using `.loc[row_index,col_indexer] = value` instead

A chained assignment can also crop up in setting in a mixed dtype frame.

---

**Note:** These setting rules apply to all of `.loc/.iloc`.

---

This is the correct access method:

```
In [345]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [346]: dfc.loc[0, 'A'] = 11
In [347]: dfc
Out[347]:
   A  B
0  11  1
1  bbb  2
2  ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [348]: dfc = dfc.copy()
In [349]: dfc['A'][0] = 111
In [350]: dfc
Out[350]:
   A  B
0  111  1
1  bbb  2
2  ccc  3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last)
...
SettingWithCopyException:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

## 4.3 MultiIndex / Advanced Indexing

This section covers *indexing with a MultiIndex* and *other advanced indexing features*.

See the *Indexing and Selecting Data* for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

See the *cookbook* for some advanced strategies.

### 4.3.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like `Series` (1d) and `DataFrame` (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing *group by* and *pivoting and reshaping data*, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the *cookbook* for some advanced strategies.

Changed in version 0.24.0: `MultiIndex.labels` has been renamed to `MultiIndex.codes` and `MultiIndex.set_labels` to `MultiIndex.set_codes`.

#### Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays()`), an array of tuples (using `MultiIndex.from_tuples()`), a crossed set of iterables (using `MultiIndex.from_product()`), or a `DataFrame` (using `MultiIndex.from_frame()`). The `Index` constructor will attempt to return a `MultiIndex` when it is passed a list of tuples. The following examples demonstrate different ways to initialize `MultiIndexes`.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out [3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out [5]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
            codes=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]])
```

(continues on next page)

(continued from previous page)

```

names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out [7]:
first second
bar    one    0.469112
      two   -0.282863
baz    one   -1.509059
      two   -1.135632
foo    one    1.212112
      two   -0.173215
qux    one    0.119209
      two   -1.044236
dtype: float64

```

When you want every pairing of the elements in two iterables, it can be easier to use the *MultiIndex.from\_product()* method:

```

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out [9]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
            codes=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
            names=['first', 'second'])

```

You can also construct a MultiIndex from a DataFrame directly, using the method *MultiIndex.from\_frame()*. This is a complementary method to *MultiIndex.to\_frame()*.

New in version 0.24.0.

```

In [10]: df = pd.DataFrame(['bar', 'one'], ['bar', 'two'],
.....:                    ['foo', 'one'], ['foo', 'two']],
.....:                    columns=['first', 'second'])
.....:

In [11]: pd.MultiIndex.from_frame(df)
Out [11]:
MultiIndex(levels=[['bar', 'foo'], ['one', 'two']],
            codes=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=['first', 'second'])

```

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```

In [12]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
.....:              np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
.....:

In [13]: s = pd.Series(np.random.randn(8), index=arrays)

In [14]: s
Out [14]:
bar one   -0.861849
     two  -2.104569

```

(continues on next page)

(continued from previous page)

```

baz one -0.494929
    two  1.071804
foo one  0.721555
    two -0.706771
qux one -1.039575
    two  0.271860
dtype: float64

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [16]: df
Out [16]:
           0          1          2          3
bar one -0.424972  0.567020  0.276232 -1.087401
    two -0.673690  0.113648 -1.478427  0.524988
baz one  0.404705  0.577046 -1.715002 -1.039268
    two -0.370647 -1.157892 -1.344312  0.844885
foo one  1.075770 -0.109050  1.643563 -1.469388
    two  0.357021 -0.674600 -1.776904 -0.968914
qux one -1.294524  0.413738  0.276662 -0.472035
    two -0.013960 -0.362543 -0.006154 -0.923061

```

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

```

In [17]: df.index.names
Out [17]: FrozenList([None, None])

```

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

```

In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
↳ columns=index)

In [19]: df
Out [19]:
first      bar          baz          foo          qux
second     one      two     one      two     one      two     one      two
A      0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299 -0.226169
B      0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C     -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747

In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
\
↳
first      bar          baz          foo
second     one      two     one      two     one      two
first second
bar one -0.410001 -0.078638  0.545952 -1.219217 -1.226825  0.769804
    two -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734
baz one  0.959726 -1.110336 -0.619976  0.149748 -0.732339  0.687738
    two  0.176444  0.403310 -0.154951  0.301624 -2.179861 -1.369849
foo one -0.954208  1.462696 -1.743161 -0.826591 -0.345352  1.314232
    two  0.690579  0.995761  2.396780  0.014871  3.357427 -0.317441

```

We've “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the multi\_sparse option in pandas.set\_options():

(continued from previous page)

```
MultiIndex(levels=[['foo', 'qux'], ['one', 'two']],
            codes=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=['first', 'second'])
```

### Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an `Index` of tuples:

```
In [34]: s + s[:-2]
```

```
Out [34]:
```

```
bar one    -1.723698
   two    -4.209138
baz one    -0.989859
   two     2.143608
foo one     1.443110
   two    -1.413542
qux one         NaN
   two         NaN
```

```
dtype: float64
```

```
In [35]: s + s[:, :2]
```

```
////////////////////////////////////
```

```
↪
bar one    -1.723698
   two         NaN
baz one    -0.989859
   two         NaN
foo one     1.443110
   two         NaN
qux one    -2.079150
   two         NaN
```

```
dtype: float64
```

The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```
In [36]: s.reindex(index[:3])
```

```
Out [36]:
```

```
first second
bar one    -0.861849
   two    -2.104569
baz one    -0.494929
```

```
dtype: float64
```

```
In [37]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
```

```
////////////////////////////////////
```

```
↪
foo two    -0.706771
bar one    -0.861849
qux one    -1.039575
baz one    -0.494929
```

```
dtype: float64
```

### 4.3.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we've made every effort to do so. In general, `MultiIndex` keys take the form of tuples. For example, the following works as you would expect:

```
In [38]: df = df.T
```

```
In [39]: df
```

```
Out [39]:
```

		A	B	C
first	second			
bar	one	0.895717	0.410835	-1.413681
	two	0.805244	0.813850	1.607920
baz	one	-1.206412	0.132003	1.024180
	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372
qux	one	-1.170299	1.130127	0.974466
	two	-0.226169	-1.436737	-2.006747

```
In [40]: df.loc[('bar', 'two')]
```

```

////////////////////////////////////
→
A    0.805244
B    0.813850
C    1.607920
Name: (bar, two), dtype: float64

```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [41]: df.loc[('bar', 'two'), 'A']
```

```
Out [41]: 0.80524402538637851
```

You don't have to specify all levels of the `MultiIndex` by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```
df.loc['bar']
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',), ]` (equivalent to `df.loc['bar', ]` in this example).

“Partial” slicing also works quite nicely.

```
In [42]: df.loc['baz':'foo']
```

```
Out [42]:
```

		A	B	C
first	second			
baz	one	-1.206412	0.132003	1.024180
	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [43]: df.loc[('baz', 'two'):(('qux', 'one'))]
```

```
Out [43]:
```

		A	B	C
first	second			
baz	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372
qux	one	-1.170299	1.130127	0.974466

```
In [44]: df.loc[('baz', 'two'):'foo']
```

```
Out [44]:
```

		A	B	C
first	second			
baz	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372

Passing a list of labels or tuples works similar to reindexing:

```
In [45]: df.loc[(['bar', 'two'], ('qux', 'one'))]
```

```
Out [45]:
```

		A	B	C
first	second			
bar	two	0.805244	0.813850	1.607920
qux	one	-1.170299	1.130127	0.974466

**Note:** It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

```
In [46]: s = pd.Series([1, 2, 3, 4, 5, 6],
.....:                  index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e
↳ "]]))
.....:
```

```
In [47]: s.loc[("A", "c"), ("B", "d")] # list of tuples
```

```
Out [47]:
```

A	c	1
B	d	5

dtype: int64

```
In [48]: s.loc([["A", "B"], ["c", "d"]]) # tuple of lists
```

```
Out [48]:
```

A	c	1
	d	2
B	c	4
	d	5

dtype: int64

## Using slicers

You can slice a `MultiIndex` by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the `MultiIndex` for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), ...), :] # noqa: E999
```

You should **not** do this:

```
df.loc[(slice('A1', 'A3'), ...)] # noqa: E999
```

```
In [49]: def mklbl(prefix, n):
.....:     return ["%s%s" % (prefix, i) for i in range(n)]
.....:

In [50]: miindex = pd.MultiIndex.from_product([mklbl('A', 4),
.....:                                         mklbl('B', 2),
.....:                                         mklbl('C', 4),
.....:                                         mklbl('D', 2)])
.....:

In [51]: micolumns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
.....:                                         ('b', 'foo'), ('b', 'bah')],
.....:                                         names=['lv10', 'lv11'])
.....:

In [52]: dfmi = pd.DataFrame(np.arange(len(miindex) * len(micolumns))
.....:                          .reshape((len(miindex), len(micolumns))),
.....:                          index=miindex,
.....:                          columns=micolumns).sort_index().sort_index(axis=1)
.....:

In [53]: dfmi
Out [53]:

      D1  252   254
```

[32 rows x 2 columns]

Using a boolean indexer you can provide selection related to the *values*.

```
In [59]: mask = dfmi[('a', 'foo')] > 200
```

```
In [60]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out [60]:
```

```
lvl0      a      b
lvl1      foo    foo
```

(continues on next page)

(continued from previous page)

```
A3 B0 C1 D1 204 206
      C3 D0 216 218
          D1 220 222
      B1 C1 D0 232 234
          D1 236 238
          C3 D0 248 250
          D1 252 254
```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```
In [61]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
```

```
Out [61]:
```

```
lvl0      a      b
lvl1      bar  foo  bah  foo
A0 B0 C1 D0    9    8   11   10
          D1   13   12   15   14
          C3 D0   25   24   27   26
          D1   29   28   31   30
      B1 C1 D0   41   40   43   42
          D1   45   44   47   46
          C3 D0   57   56   59   58
...
A3 B0 C1 D1  205  204  207  206
      C3 D0  217  216  219  218
          D1  221  220  223  222
      B1 C1 D0  233  232  235  234
          D1  237  236  239  238
          C3 D0  249  248  251  250
          D1  253  252  255  254
```

```
[32 rows x 4 columns]
```

Furthermore, you can *set* the values using the following methods.

```
In [62]: df2 = dfmi.copy()
```

```
In [63]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10
```

```
In [64]: df2
```

```
Out [64]:
```

```
lvl0      a      b
lvl1      bar  foo  bah  foo
A0 B0 C0 D0    1    0    3    2
          D1    5    4    7    6
      C1 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10
      C2 D0   17   16   19   18
          D1   21   20   23   22
          C3 D0  -10  -10  -10  -10
...
A3 B1 C0 D1  229  228  231  230
      C1 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10
      C2 D0  241  240  243  242
          D1  245  244  247  246
          C3 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10
```

(continues on next page)

(continued from previous page)

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```
In [65]: df2 = dfmi.copy()
In [66]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
In [67]: df2
Out [67]:
```

lvl0	a	b					
lvl1	bar	foo	bah	foo			
A0	B0	C0	D0	1	0	3	2
			D1	5	4	7	6
		C1	D0	9000	8000	11000	10000
			D1	13000	12000	15000	14000
		C2	D0	17	16	19	18
			D1	21	20	23	22
		C3	D0	25000	24000	27000	26000
...	...	...	...	...	...	...	...
A3	B1	C0	D1	229	228	231	230
		C1	D0	233000	232000	235000	234000
			D1	237000	236000	239000	238000
		C2	D0	241	240	243	242
			D1	245	244	247	246
		C3	D0	249000	248000	251000	250000
			D1	253000	252000	255000	254000

[64 rows x 4 columns]

## Cross-section

The `xs()` method of `DataFrame` additionally takes a level argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [68]: df
Out [68]:
```

		A	B	C
first	second			
bar	one	0.895717	0.410835	-1.413681
	two	0.805244	0.813850	1.607920
baz	one	-1.206412	0.132003	1.024180
	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372
qux	one	-1.170299	1.130127	0.974466
	two	-0.226169	-1.436737	-2.006747

```
In [69]: df.xs('one', level='second')
\\//////////////////////////////////////////////////
↪

```

	A	B	C
first			
bar	0.895717	0.410835	-1.413681

(continues on next page)

(continued from previous page)

```

baz    -1.206412    0.132003    1.024180
foo     1.431256   -0.076467    0.875906
qux    -1.170299    1.130127    0.974466

```

```

# using the slicers
In [70]: df.loc[(slice(None), 'one'), :]
Out [70]:
           A         B         C
first second
bar  one    0.895717  0.410835 -1.413681
baz  one   -1.206412  0.132003  1.024180
foo  one    1.431256 -0.076467  0.875906
qux  one   -1.170299  1.130127  0.974466

```

You can also select on the columns with `xs`, by providing the axis argument.

```

In [71]: df = df.T

In [72]: df.xs('one', level='second', axis=1)
Out [72]:
first      bar      baz      foo      qux
A      0.895717 -1.206412  1.431256 -1.170299
B      0.410835  0.132003 -0.076467  1.130127
C     -1.413681  1.024180  0.875906  0.974466

```

```

# using the slicers
In [73]: df.loc[:, (slice(None), 'one')]
Out [73]:
first      bar      baz      foo      qux
second  one      one      one      one
A      0.895717 -1.206412  1.431256 -1.170299
B      0.410835  0.132003 -0.076467  1.130127
C     -1.413681  1.024180  0.875906  0.974466

```

`xs` also allows selection with multiple keys.

```

In [74]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out [74]:
first      bar
second     one
A      0.895717
B      0.410835
C     -1.413681

```

```

# using the slicers
In [75]: df.loc[:, ('bar', 'one')]
Out [75]:
A      0.895717
B      0.410835
C     -1.413681
Name: (bar, one), dtype: float64

```

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [76]: df.xs('one', level='second', axis=1, drop_level=False)
```

```
Out [76]:
```

	bar	baz	foo	qux
second	one	one	one	one
A	0.895717	-1.206412	1.431256	-1.170299
B	0.410835	0.132003	-0.076467	1.130127
C	-1.413681	1.024180	0.875906	0.974466

Compare the above with the result using `drop_level=True` (the default value).

```
In [77]: df.xs('one', level='second', axis=1, drop_level=True)
```

```
Out [77]:
```

	bar	baz	foo	qux
A	0.895717	-1.206412	1.431256	-1.170299
B	0.410835	0.132003	-0.076467	1.130127
C	-1.413681	1.024180	0.875906	0.974466

### Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```
In [78]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x', 'y']],
.....:                          codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
.....:
```

```
In [79]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)
```

```
In [80]: df
```

```
Out [80]:
```

		0	1
one	y	1.519970	-0.493662
	x	0.600178	0.274230
zero	y	0.132885	-0.023688
	x	2.410179	1.450520

```
In [81]: df2 = df.mean(level=0)
```

```
In [82]: df2
```

```
Out [82]:
```

		0	1
one	1.060074	-0.109716	
zero	1.271532	0.713416	

```
In [83]: df2.reindex(df.index, level=0)
```

```
Out [83]:
```

		0	1
one	y	1.060074	-0.109716
	x	1.060074	-0.109716
zero	y	1.271532	0.713416
	x	1.271532	0.713416

```
# aligning
```

```
In [84]: df_aligned, df2_aligned = df.align(df2, level=0)
```

(continues on next page)

(continued from previous page)

```
In [85]: df_aligned
Out [85]:
```

		0	1
one	y	1.519970	-0.493662
	x	0.600178	0.274230
zero	y	0.132885	-0.023688
	x	2.410179	1.450520

```
In [86]: df2_aligned
////////////////////////////////////
```

		0	1
one	y	1.060074	-0.109716
	x	1.060074	-0.109716
zero	y	1.271532	0.713416
	x	1.271532	0.713416

### Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```
In [87]: df[:5]
Out [87]:
```

		0	1
one	y	1.519970	-0.493662
	x	0.600178	0.274230
zero	y	0.132885	-0.023688
	x	2.410179	1.450520

```
In [88]: df[:5].swaplevel(0, 1, axis=0)
////////////////////////////////////
```

		0	1
y one		1.519970	-0.493662
x one		0.600178	0.274230
y zero		0.132885	-0.023688
x zero		2.410179	1.450520

### Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```
In [89]: df[:5].reorder_levels([1, 0], axis=0)
Out [89]:
```

		0	1
y one		1.519970	-0.493662
x one		0.600178	0.274230
y zero		0.132885	-0.023688
x zero		2.410179	1.450520

## Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```
In [90]: df.rename(columns={0: "col0", 1: "col1"})
Out [90]:
```

		col0	col1
one	y	1.519970	-0.493662
	x	0.600178	0.274230
zero	y	0.132885	-0.023688
	x	2.410179	1.450520

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```
In [91]: df.rename(index={"one": "two", "y": "z"})
Out [91]:
```

		0	1
two	z	1.519970	-0.493662
	x	0.600178	0.274230
zero	z	0.132885	-0.023688
	x	2.410179	1.450520

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```
In [92]: df.rename_axis(index=['abc', 'def'])
Out [92]:
```

		0	1
abc	def		
one	y	1.519970	-0.493662
	x	0.600178	0.274230
zero	y	0.132885	-0.023688
	x	2.410179	1.450520

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [93]: df.rename_axis(columns="Cols").columns
Out [93]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

### 4.3.3 Sorting a MultiIndex

For `MultiIndex`-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [94]: import random

In [95]: random.shuffle(tuples)

In [96]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))
```

(continues on next page)

(continued from previous page)

```
In [97]: s
Out[97]:
baz one    0.206053
foo two   -0.251905
qux one   -2.213588
baz two    1.063327
bar one    1.266143
qux two    0.299368
bar two   -0.863838
foo one    0.408204
dtype: float64
```

```
In [98]: s.sort_index()
~~~~~
↪
bar one    1.266143
   two   -0.863838
baz one    0.206053
   two    1.063327
foo one    0.408204
   two   -0.251905
qux one   -2.213588
   two    0.299368
dtype: float64
```

```
In [99]: s.sort_index(level=0)
~~~~~
↪
bar one    1.266143
   two   -0.863838
baz one    0.206053
   two    1.063327
foo one    0.408204
   two   -0.251905
qux one   -2.213588
   two    0.299368
dtype: float64
```

```
In [100]: s.sort_index(level=1)
~~~~~
↪
bar one    1.266143
baz one    0.206053
foo one    0.408204
qux one   -2.213588
bar two   -0.863838
baz two    1.063327
foo two   -0.251905
qux two    0.299368
dtype: float64
```

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

```
In [101]: s.index.set_names(['L1', 'L2'], inplace=True)
```

```
In [102]: s.sort_index(level='L1')
```

(continues on next page)

(continued from previous page)

**Out [102]:**

```
L1  L2
bar one    1.266143
    two   -0.863838
baz one    0.206053
    two    1.063327
foo one    0.408204
    two   -0.251905
qux one   -2.213588
    two    0.299368
dtype: float64
```

**In [103]:** s.sort\_index(level='L2')

```
////////////////////////////////////
↪
L1  L2
bar one    1.266143
baz one    0.206053
foo one    0.408204
qux one   -2.213588
bar two   -0.863838
baz two    1.063327
foo two   -0.251905
qux two    0.299368
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

**In [104]:** df.T.sort\_index(level=1, axis=1)**Out [104]:**

```
      one      zero      one      zero
      x      x      y      y
0  0.600178  2.410179  1.519970  0.132885
1  0.274230  1.450520 -0.493662 -0.023688
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
In [105]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
.....:                       'joe': ['x', 'x', 'z', 'y'],
.....:                       'jolie': np.random.rand(4)})
.....:
```

**In [106]:** dfm = dfm.set\_index(['jim', 'joe'])**In [107]:** dfm**Out [107]:**

```
      jolie
jim joe
0  x  0.490671
   x  0.120248
1  z  0.537020
   y  0.110968
```

**In [4]:** dfm.loc[(1, 'z')]

```
PerformanceWarning: indexing past lexsort depth may impact performance.
```

(continues on next page)

(continued from previous page)

```
Out [4]:
           jolie
jim joe
1    z    0.64094
```

Furthermore, if you try to index something that is not fully lexicographically sorted, this can raise:

```
In [5]: dfm.loc[(0, 'y'):(1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexicographic depth (1)'
```

The `is_lexsorted()` method on a `MultiIndex` shows if the index is sorted, and the `lexsort_depth` property returns the sort depth:

```
In [108]: dfm.index.is_lexsorted()
Out [108]: False

In [109]: dfm.index.lexsort_depth
Out [109]: 1
```

```
In [110]: dfm = dfm.sort_index()
```

```
In [111]: dfm
```

```
Out [111]:
           jolie
jim joe
0    x    0.490671
   x    0.120248
1    y    0.110968
   z    0.537020
```

```
In [112]: dfm.index.is_lexsorted()
```

```
Out [112]: True
```

```
In [113]: dfm.index.lexsort_depth
```

```
Out [113]: 2
```

And now selection works as expected.

```
In [114]: dfm.loc[(0, 'y'):(1, 'z')]
```

```
Out [114]:
           jolie
1    y    0.110968
   z    0.537020
```

### 4.3.4 Take Methods

Similar to NumPy `ndarrays`, pandas `Index`, `Series`, and `DataFrame` also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an `ndarray` of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

(continued from previous page)

```

In [127]: arr.take([False, False, True, True])
Out[127]: array([-1.1935, -1.1935,  0.6775,  0.6775])

In [128]: arr[[0, 1]]
Out[128]: array([-1.1935,  0.6775])

In [129]: ser = pd.Series(np.random.randn(10))

In [130]: ser.take([False, False, True, True])
Out[130]:
0    0.233141
0    0.233141
1   -0.223540
1   -0.223540
dtype: float64

In [131]: ser.iloc[[0, 1]]
Out[131]:
0    0.233141
1   -0.223540
dtype: float64

```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```

In [132]: arr = np.random.randn(10000, 5)

In [133]: indexer = np.arange(10000)

In [134]: random.shuffle(indexer)

In [135]: %timeit arr[indexer]
.....: %timeit arr.take(indexer, axis=0)
.....:
170 us +- 5.62 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
48.4 us +- 945 ns per loop (mean +- std. dev. of 7 runs, 10000 loops each)

```

### 4.3.5 Index Types

We have discussed `MultiIndex` in the previous sections pretty extensively. Documentation about `DatetimeIndex` and `PeriodIndex` are shown *here*, and documentation about `TimedeltaIndex` is found *here*.

In the following sub-sections we will highlight some other index types.

#### CategoricalIndex

*CategoricalIndex* is a type of index that is useful for supporting indexing with duplicates. This is a container around a *Categorical* and allows efficient indexing and storage of an index with a large number of duplicated elements.

```

In [136]: from pandas.api.types import CategoricalDtype

In [137]: df = pd.DataFrame({'A': np.arange(6),
.....:                      'B': list('aabbca')})
.....:

In [138]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [139]: df
Out[139]:
   A B
0  0 a
1  1 a
2  2 b
3  3 b
4  4 c
5  5 a

In [140]: df.dtypes
Out[140]:
A      int64
B      category
dtype: object

In [141]: df.B.cat.categories
Out[141]:
↪ Index(['c', 'a', 'b'], dtype='object')

```

Setting the index will create a `CategoricalIndex`.

```

In [142]: df2 = df.set_index('B')

In [143]: df2.index
Out[143]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↪ ordered=False, name='B', dtype='category')

```

Indexing with `__getitem__`/`.iloc`/`.loc` works similarly to an `Index` with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```

In [144]: df2.loc['a']
Out[144]:
   A
B
a  0
a  1
a  5

```

The `CategoricalIndex` is **preserved** after indexing:

```

In [145]: df2.loc['a'].index
Out[145]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↪ name='B', dtype='category')

```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is `cab`).

```
In [146]: df2.sort_index()
Out[146]:
   A
B
c  4
a  0
a  1
a  5
b  2
b  3
```

Groupby operations on the index will preserve the index nature as well.

```
In [147]: df2.groupby(level=0).sum()
Out[147]:
   A
B
c  4
a  6
b  5

In [148]: df2.groupby(level=0).sum().index
Out[148]: CategoricalIndex(['c', 'a', 'b'],
categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the **passed** Categorical dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [149]: df2.reindex(['a', 'e'])
Out[149]:
   A
B
a  0.0
a  1.0
a  5.0
e  NaN

In [150]: df2.reindex(['a', 'e']).index
Out[150]: Index(['a', 'a', 'a', 'e'],
dtype='object', name='B')

In [151]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[151]:
   A
B
a  0.0
a  1.0
a  5.0
e  NaN

In [152]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[152]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'],
ordered=False, name='B', dtype='category')
```

**Warning:** Reshaping and Comparison operations on a `CategoricalIndex` must have the same categories or a `TypeError` will be raised.

```
In [9]: df3 = pd.DataFrame({'A': np.arange(6), 'B': pd.Series(list('aabbca')).
→astype('category')})

In [11]: df3 = df3.set_index('B')

In [11]: df3.index
Out[11]: CategoricalIndex([u'a', u'a', u'b', u'b', u'c', u'a'], categories=[u'a', u
→'b', u'c'], ordered=False, name=u'B', dtype='category')

In [12]: pd.concat([df2, df3])
TypeError: categories must match existing categories when appending
```

## Int64Index and RangeIndex

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see [here](#).

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the `Int64Index` would provide the default index for all `NDFrame` objects.

`RangeIndex` is a sub-class of `Int64Index` added in version 0.18.0, now providing the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python [range](#) types.

## Float64Index

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[], ix, loc` for scalar indexing and slicing work exactly the same.

```
In [153]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [154]: indexf
Out[154]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [155]: sf = pd.Series(range(5), index=indexf)

In [156]: sf
Out[156]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64
```

Scalar selection for `[], .loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [157]: sf[3]
Out[157]: 2

In [158]: sf[3.0]
\\Out[158]: 2

In [159]: sf.loc[3]
\\Out[159]: 2

In [160]: sf.loc[3.0]
\\Out[160]: 2
```

The only positional indexing is via `iloc`.

```
In [161]: sf.iloc[3]
Out[161]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [162]: sf[2:4]
Out[162]:
2.0    1
3.0    2
dtype: int64

In [163]: sf.loc[2:4]
\\Out[163]:
2.0    1
3.0    2
dtype: int64

In [164]: sf.iloc[2:4]
\\Out[164]:
→
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats is allowed.

```
In [165]: sf[2.1:4.6]
Out[165]:
3.0    2
4.5    3
dtype: int64

In [166]: sf.loc[2.1:4.6]
\\Out[166]:
3.0    2
4.5    3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

(continued from previous page)

```
In [175]: df
Out[175]:
      A
(0, 1] 1
(1, 2] 2
(2, 3] 3
(3, 4] 4
```

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [176]: df.loc[2]
Out[176]:
A      2
Name: (1, 2], dtype: int64

In [177]: df.loc[[2, 3]]
Out[177]:
      A
(1, 2] 2
(2, 3] 3
```

If you select a label *contained* within an interval, this will also select the interval.

```
In [178]: df.loc[2.5]
Out[178]:
A      3
Name: (2, 3], dtype: int64

In [179]: df.loc[[2.5, 3.5]]
Out[179]:
      A
(2, 3] 3
(3, 4] 4
```

Interval and IntervalIndex are used by `cut` and `qcut`:

```
In [180]: c = pd.cut(range(4), bins=2)

In [181]: c
Out[181]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [182]: c.categories
Out[182]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
              closed='right',
              dtype='interval[float64]')
```

Furthermore, `IntervalIndex` allows one to bin *other* data with these same bins, with `NaN` representing a missing value similar to other dtypes.

```
In [183]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[183]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

## Generating Ranges of Intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```
In [184]: pd.interval_range(start=0, end=5)
Out[184]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')

In [185]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-
→ 01-04], (2017-01-04, 2017-01-05]],
              closed='right',
              dtype='interval[datetime64[ns]]')

In [186]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
→ (2 days 00:00:00, 3 days 00:00:00]],
              closed='right',
              dtype='interval[timedelta64[ns]]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of *frequency aliases* with datetime-like intervals:

```
In [187]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[187]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]],
              closed='right',
              dtype='interval[float64]')

In [188]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-
→ 01-22], (2017-01-22, 2017-01-29]],
              closed='right',
              dtype='interval[datetime64[ns]]')

In [189]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00],
→ (0 days 18:00:00, 1 days 03:00:00]],
```

(continues on next page)

(continued from previous page)

```
closed='right',
dtype='interval[timedelta64[ns]]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```
In [190]: pd.interval_range(start=0, end=4, closed='both')
```

```
Out [190]:
```

```
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]],
              closed='both',
              dtype='interval[int64]')
```

```
In [191]: pd.interval_range(start=0, end=4, closed='neither')
```

```
↪
```

```
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)],
              closed='neither',
              dtype='interval[int64]')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```
In [192]: pd.interval_range(start=0, end=6, periods=4)
```

```
Out [192]:
```

```
IntervalIndex([(0.0, 1.5], [1.5, 3.0], [3.0, 4.5], [4.5, 6.0]],
              closed='right',
              dtype='interval[float64]')
```

```
In [193]: pd.interval_range(pd.Timestamp('2018-01-01'),
.....:                      pd.Timestamp('2018-02-28'), periods=3)
.....:
↪
```

```
IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], [2018-01-20 08:00:00, 2018-02-08_
↪16:00:00], [2018-02-08 16:00:00, 2018-02-28]],
              closed='right',
              dtype='interval[datetime64[ns]]')
```

## 4.3.6 Miscellaneous indexing FAQ

### Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```
In [194]: s = pd.Series(range(5))
```

```
In [195]: s[-1]
```

```
-----
KeyError
```

```
Traceback (most recent call last)
```

(continues on next page)

(continued from previous page)

```

In [196]: df = pd.DataFrame(np.random.randn(5, 4))

In [197]: df
Out[197]:
      0         1         2         3
0 -0.130121 -0.476046  0.759104  0.213379
1 -0.082641  0.448008  0.656420 -1.051443
2  0.594956 -0.151360 -0.069303  1.221431
3 -0.182832  0.791235  0.042745  2.069775
4  1.446552  0.019814 -1.389212 -0.702312

In [198]: df.loc[-2:]
↪
      0         1         2         3
0 -0.130121 -0.476046  0.759104  0.213379
1 -0.082641  0.448008  0.656420 -1.051443
2  0.594956 -0.151360 -0.069303  1.221431
3 -0.182832  0.791235  0.042745  2.069775
4  1.446552  0.019814 -1.389212 -0.702312

```

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

## Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [199]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'],
↳data=list(range(5)))

In [200]: df.index.is_monotonic_increasing
Out [200]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [201]: df.loc[0:4, :]
\\Out [201]:
  data
2    0
3    1
3    2
4    3

# slice is are outside the index, so empty DataFrame is returned
In [202]: df.loc[13:15, :]
\\Out [202]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```
In [203]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5],
.....:                      columns=['data'], data=list(range(6)))
.....:

In [204]: df.index.is_monotonic_increasing
Out [204]: False

# OK because 2 and 4 are in the index
In [205]: df.loc[2:4, :]
\\Out [205]:
  data
2    0
3    1
1    2
4    3
```

```
# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.

## Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [214]: series1 = pd.Series([1, 2, 3])
```

```
In [215]: series1.dtype
Out [215]: dtype('int64')
```

```
In [216]: res = series1.reindex([0, 4])
```

```
In [217]: res.dtype
Out [217]: dtype('float64')
```

```
In [218]: res
Out [218]:
0      1.0
4      NaN
dtype: float64
```

```
In [219]: series2 = pd.Series([True])
```

```
In [220]: series2.dtype
Out [220]: dtype('bool')
```

```
In [221]: res = series2.reindex_like(series1)
```

```
In [222]: res.dtype
Out [222]: dtype('O')
```

```
In [223]: res
Out [223]:
0      True
1      NaN
2      NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [this old issue](#) for a more detailed discussion.

## 4.4 Merge, join, and concatenate

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

### 4.4.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```

In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
...:                       'B': ['B0', 'B1', 'B2', 'B3'],
...:                       'C': ['C0', 'C1', 'C2', 'C3'],
...:                       'D': ['D0', 'D1', 'D2', 'D3']},
...:                       index=[0, 1, 2, 3])
...:

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
...:                       'B': ['B4', 'B5', 'B6', 'B7'],
...:                       'C': ['C4', 'C5', 'C6', 'C7'],
...:                       'D': ['D4', 'D5', 'D6', 'D7']},
...:                       index=[4, 5, 6, 7])
...:

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
...:                       'B': ['B8', 'B9', 'B10', 'B11'],
...:                       'C': ['C8', 'C9', 'C10', 'C11'],
...:                       'D': ['D8', 'D9', 'D10', 'D11']},
...:                       index=[8, 9, 10, 11])
...:

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)

```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3
df2					4	A4	B4	C4	D4
	A	B	C	D	5	A5	B5	C5	D5
4	A4	B4	C4	D4	6	A6	B6	C6	D6
5	A5	B5	C5	D5	7	A7	B7	C7	D7
6	A6	B6	C6	D6	8	A8	B8	C8	D8
7	A7	B7	C7	D7	9	A9	B9	C9	D9
df3					10	A10	B10	C10	D10
	A	B	C	D	11	A11	B11	C11	D11
8	A8	B8	C8	D8					
9	A9	B9	C9	D9					
10	A10	B10	C10	D10					
11	A11	B11	C11	D11					

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False,
          keys=None, levels=None, names=None, verify_integrity=False,
          copy=True)
```

- `objs`: a sequence or mapping of Series, DataFrame, or Panel objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.
- `axis`: {0, 1, ...}, default 0. The axis to concatenate along.
- `join`: {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index`: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `join_axes`: list of Index objects. Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic.
- `keys`: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels`: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names`: list, default None. Names for the levels in the resulting hierarchical index.
- `verify_integrity`: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
- `copy`: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
	A	B	C	D	y	5	A5	B5	C5	D5
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	df3					
7	A7	B7	C7	D7		A	B	C	D	
df3					z	8	A8	B8	C8	D8
	A	B	C	D	z	9	A9	B9	C9	D9
8	A8	B8	C8	D8	z	10	A10	B10	C10	D10
9	A9	B9	C9	D9	z	11	A11	B11	C11	D11
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

As you can see (if you've read the rest of the documentation), the resulting object's index has a *hierarchical index*. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
Out [7]:
   A  B  C  D
4  A4 B4 C4 D4
5  A5 B5 C5 D5
6  A6 B6 C6 D6
7  A7 B7 C7 D7
```

It's not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

### Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following three ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.
- Use a specific index, as passed to the `join_axes` argument.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
...:                      'D': ['D2', 'D3', 'D6', 'D7'],
...:                      'F': ['F2', 'F3', 'F6', 'F7']},
...:                      index=[2, 3, 6, 7])

In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3
									6	NaN	NaN	NaN	NaN	B6	D6	F6
									7	NaN	NaN	NaN	NaN	B7	D7	F7

**Warning:** Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2								
1	A1	B1	C1	D1	3	B3	D3	F3								
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1, join_axes=[df1.index])
```

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3

### Concatenating using `append`

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

```
In [12]: result = df1.append(df2)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3
df2					4	A4	B4	C4	D4
4	A4	B4	C4	D4	5	A5	B5	C5	D5
5	A5	B5	C5	D5	6	A6	B6	C6	D6
6	A6	B6	C6	D6	7	A7	B7	C7	D7
7	A7	B7	C7	D7					

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

```
In [13]: result = df1.append(df4, sort=False)
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df4			
	B	D	F
2	B2	D2	F2
3	B3	D3	F3
6	B6	D6	F6
7	B7	D7	F7

Result					
	A	B	C	D	F
0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	NaN
2	NaN	B2	NaN	D2	F2
3	NaN	B3	NaN	D3	F3
6	NaN	B6	NaN	D6	F6
7	NaN	B7	NaN	D7	F7

append may take multiple objects to concatenate:

```
In [14]: result = df1.append([df2, df3])
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

**Note:** Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here **does not** modify `df1` and returns its copy with `df2` appended.

### Ignoring indexes on the concatenation axis

For `DataFrame` objects which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```
In [15]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN
df4					4	NaN	B2	NaN	D2	F2
	B	D	F	5	NaN	B3	NaN	D3	F3	
2	B2	D2	F2	6	NaN	B6	NaN	D6	F6	
3	B3	D3	F3	7	NaN	B7	NaN	D7	F7	
6	B6	D6	F6							
7	B7	D7	F7							

This is also a valid argument to `DataFrame.append()`:

```
In [16]: result = df1.append(df4, ignore_index=True, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN
df4					4	NaN	B2	NaN	D2	F2
	B	D	F	5	NaN	B3	NaN	D3	F3	
2	B2	D2	F2	6	NaN	B6	NaN	D6	F6	
3	B3	D3	F3	7	NaN	B7	NaN	D7	F7	
6	B6	D6	F6							
7	B7	D7	F7							

### Concatenating with mixed ndims

You can concatenate a mix of `Series` and `DataFrame` objects. The `Series` will be transformed to `DataFrame` with the column name as the name of the `Series`.

```
In [17]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
```

```
In [18]: result = pd.concat([df1, s1], axis=1)
```

df1					s1		Result					
	A	B	C	D		X		A	B	C	D	X
0	A0	B0	C0	D0	0	X0	0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	1	X1	1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	2	X2	2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	3	X3	3	A3	B3	C3	D3	X3

**Note:** Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [19]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
```

```
In [20]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

df1					s2		Result								
	A	B	C	D				A	B	C	D	0	1	2	
0	A0	B0	C0	D0	0	_0	0	A0	B0	C0	D0	_0	_0	_0	
1	A1	B1	C1	D1	1	_1	1	A1	B1	C1	D1	_1	_1	_1	
2	A2	B2	C2	D2	2	_2	2	A2	B2	C2	D2	_2	_2	_2	
3	A3	B3	C3	D3	3	_3	3	A3	B3	C3	D3	_3	_3	_3	

Passing `ignore_index=True` will drop all name references.

```
In [21]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

df1					s1		Result					
	A	B	C	D		X		0	1	2	3	4
0	A0	B0	C0	D0	0	X0	0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	1	X1	1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	2	X2	2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	3	X3	3	A3	B3	C3	D3	X3

### More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new `DataFrame` based on existing `Series`. Notice how the default behaviour consists on letting the resulting `DataFrame` inherit the parent `Series`' name, when these existed.

```
In [22]: s3 = pd.Series([0, 1, 2, 3], name='foo')
```

```
In [23]: s4 = pd.Series([0, 1, 2, 3])
```

```
In [24]: s5 = pd.Series([0, 1, 4, 5])
```

```
In [25]: pd.concat([s3, s4, s5], axis=1)
```

```
Out[25]:
```

	foo	0	1
0	0	0	0
1	1	1	1
2	2	2	4
3	3	3	5

Through the `keys` argument we can override the existing column names.

```
In [26]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
```

```
Out[26]:
```

	red	blue	yellow
0	0	0	0
1	1	1	1
2	2	2	4
3	3	3	5

Let's consider a variation of the very first example presented:

```
In [27]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
	A	B	C	D	y	5	A5	B5	C5	D5
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	z	8	A8	B8	C8	D8
7	A7	B7	C7	D7	z	9	A9	B9	C9	D9
df3					z	10	A10	B10	C10	D10
	A	B	C	D	z	11	A11	B11	C11	D11
8	A8	B8	C8	D8						
9	A9	B9	C9	D9						
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [28]: pieces = {'x': df1, 'y': df2, 'z': df3}
```

```
In [29]: result = pd.concat(pieces)
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result					
		A	B	C	D
x	0	A0	B0	C0	D0
x	1	A1	B1	C1	D1
x	2	A2	B2	C2	D2
x	3	A3	B3	C3	D3
y	4	A4	B4	C4	D4
y	5	A5	B5	C5	D5
y	6	A6	B6	C6	D6
y	7	A7	B7	C7	D7
z	8	A8	B8	C8	D8
z	9	A9	B9	C9	D9
z	10	A10	B10	C10	D10
z	11	A11	B11	C11	D11

```
In [30]: result = pd.concat(pieces, keys=['z', 'y'])
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result					
		A	B	C	D
z	8	A8	B8	C8	D8
z	9	A9	B9	C9	D9
z	10	A10	B10	C10	D10
z	11	A11	B11	C11	D11
y	4	A4	B4	C4	D4
y	5	A5	B5	C5	D5
y	6	A6	B6	C6	D6
y	7	A7	B7	C7	D7

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```
In [31]: result.index.levels
Out [31]: FrozenList([[ 'z', 'y' ], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [32]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
.....:                      levels=[['z', 'y', 'x', 'w']],
.....:                      names=['group_key'])
.....:
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
	A	B	C	D	y	5	A5	B5	C5	D5
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	z	8	A8	B8	C8	D8
7	A7	B7	C7	D7	z	9	A9	B9	C9	D9
df3					z	10	A10	B10	C10	D10
	A	B	C	D	z	11	A11	B11	C11	D11
8	A8	B8	C8	D8						
9	A9	B9	C9	D9						
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

```
In [33]: result.index.levels
Out [33]: FrozenList([[ 'z', 'y', 'x', 'w' ], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like `GroupBy` where the order of a categorical variable is meaningful.

## Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or `dict` to `append`, which returns a new `DataFrame` as above.

```
In [34]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
```

```
In [35]: result = df1.append(s2, ignore_index=True)
```

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

	A	X
		X0
B		X1
C		X2
D		X3

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3
4	X0	X1	X2	X3

You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```
In [36]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
.....:             {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
.....:

In [37]: result = df1.append(dicts, ignore_index=True, sort=False)
```

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

	A	B	C	X	Y
0	1	2	3	4.0	NaN
1	5	6	7	NaN	8.0

	A	B	C	D	X	Y
0	A0	B0	C0	D0	NaN	NaN
1	A1	B1	C1	D1	NaN	NaN
2	A2	B2	C2	D2	NaN	NaN
3	A3	B3	C3	D3	NaN	NaN
4	1	2	3	NaN	4.0	NaN
5	5	6	7	NaN	NaN	8.0

### 4.4.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the *cookbook* for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a *comparison with SQL*.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:

```
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
         left_index=False, right_index=False, sort=True,
         suffixes=('_x', '_y'), copy=True, indicator=False,
         validate=None)
```

- `left`: A DataFrame or named Series object.
- `right`: Another DataFrame or named Series object.
- `on`: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- `left_on`: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- `right_on`: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- `left_index`: If `True`, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- `right_index`: Same usage as `left_index` for the right DataFrame or Series
- `how`: One of 'left', 'right', 'outer', 'inner'. Defaults to `inner`. See below for more detailed description of each method.
- `sort`: Sort the result DataFrame by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- `suffixes`: A tuple of string suffixes to apply to overlapping columns. Defaults to ('\_x', '\_y').
- `copy`: Always copy data (default `True`) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- `indicator`: Add a column to the output DataFrame called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in 'left' DataFrame or Series, `right_only` for observations whose merge key only appears in 'right' DataFrame or Series, and `both` if the observation's merge key is found in both.
- `validate`: string, default `None`. If specified, checks if merge is of specified type.
  - “one\_to\_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one\_to\_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many\_to\_one” or “m:1”: checks if merge keys are unique in right dataset.
  - “many\_to\_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

---

**Note:** Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

---

The return type will be the same as `left`. If `left` is a DataFrame or named Series and `right` is a subclass of DataFrame, the return type will still be DataFrame.

`merge` is a function in the pandas namespace, and it is also available as a DataFrame instance method `merge()`, with the calling DataFrame being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

### Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [38]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:

In [39]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                          'C': ['C0', 'C1', 'C2', 'C3'],
.....:                          'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [40]: result = pd.merge(left, right, on='key')
```

left				right				Result					
	key	A	B		key	C	D		key	A	B	C	D
0	K0	A0	B0	0	K0	C0	D0	0	K0	A0	B0	C0	D0
1	K1	A1	B1	1	K1	C1	D1	1	K1	A1	B1	C1	D1
2	K2	A2	B2	2	K2	C2	D2	2	K2	A2	B2	C2	D2
3	K3	A3	B3	3	K3	C3	D3	3	K3	A3	B3	C3	D3

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [41]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:
```

(continues on next page)

(continued from previous page)

```
In [42]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K0', 'K0', 'K0'],
.....:                       'C': ['C0', 'C1', 'C2', 'C3'],
.....:                       'D': ['D0', 'D1', 'D2', 'D3']})
.....:
```

```
In [43]: result = pd.merge(left, right, on=['key1', 'key2'])
```

left					right					Result						
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3							

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be NA. Here is a summary of the `how` options and their SQL equivalent names:

Merge method	SQL Join Name	Description
left	LEFT OUTER JOIN	Use keys from left frame only
right	RIGHT OUTER JOIN	Use keys from right frame only
outer	FULL OUTER JOIN	Use union of keys from both frames
inner	INNER JOIN	Use intersection of keys from both frames

```
In [44]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

left					right					Result						
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K0	K1	A1	B1	NaN	NaN
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C1	D1
3	K2	K1	A3	B3	3	K2	K0	C3	D3	3	K1	K0	A2	B2	C2	D2
										4	K2	K1	A3	B3	NaN	NaN

```
In [45]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
```

left					right				Result							
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3	3	K2	K0	NaN	NaN	C3	D3

```
In [46]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])
```

left					right				Result							
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K0	K1	A1	B1	NaN	NaN
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C1	D1
3	K2	K1	A3	B3	3	K1	K0	A2	B2	3	K1	K0	A2	B2	C2	D2
					4	K2	K1	A3	B3	4	K2	K1	A3	B3	NaN	NaN
					5	K2	K0	NaN	NaN	5	K2	K0	NaN	NaN	C3	D3

```
In [47]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])
```

left					right				Result							
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3							

Here is another example with duplicate join keys in DataFrames:

```
In [48]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
```

```
In [49]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
```

```
In [50]: result = pd.merge(left, right, on='B', how='outer')
```

left			right			Result			
	A	B		A	B	A_x	B	A_y	
0	1	2	0	4	2	0	1	2	4
1	2	2	1	5	2	1	1	2	5
			2	6	2	2	1	2	6
						3	2	2	4
						4	2	2	5
						5	2	2	6

**Warning:** Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

### Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [51]: left = pd.DataFrame({'A' : [1,2], 'B' : [1, 2]})
```

```
In [52]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [53]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
```

```
Out[53]:
   A_x  B  A_y
0     1  1  NaN
1     2  2  4.0
2     2  2  5.0
3     2  2  6.0
```

### The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

Observation Origin	_merge value
Merge key only in 'left' frame	left_only
Merge key only in 'right' frame	right_only
Merge key in both frames	both

```
In [54]: df1 = pd.DataFrame({'coll': [0, 1], 'col_left': ['a', 'b']})
In [55]: df2 = pd.DataFrame({'coll': [1, 2, 2], 'col_right': [2, 2, 2]})
In [56]: pd.merge(df1, df2, on='coll', how='outer', indicator=True)
Out [56]:
   coll col_left  col_right  _merge
0     0         a         NaN  left_only
1     1         b         2.0    both
2     2         NaN         2.0  right_only
3     2         NaN         2.0  right_only
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [57]: pd.merge(df1, df2, on='coll', how='outer', indicator='indicator_column')
Out [57]:
   coll col_left  col_right indicator_column
0     0         a         NaN         left_only
1     1         b         2.0            both
2     2         NaN         2.0         right_only
3     2         NaN         2.0         right_only
```

## Merge Dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

```
In [58]: left = pd.DataFrame({'key': [1], 'v1': [10]})
In [59]: left
Out [59]:
   key  v1
0    1  10
In [60]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
In [61]: right
Out [61]:
   key  v1
0    1  20
1    2  30
```

We are able to preserve the join keys:

```
In [62]: pd.merge(left, right, how='outer')
Out [62]:
   key  v1
0    1  10
```

(continues on next page)

(continued from previous page)

```

1    1    20
2    2    30

In [63]: pd.merge(left, right, how='outer').dtypes
\\Out [63]:
key      int64
v1       int64
dtype: object

```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```

In [64]: pd.merge(left, right, how='outer', on='key')
Out [64]:
   key  v1_x  v1_y
0    1  10.0    20
1    2   NaN    30

In [65]: pd.merge(left, right, how='outer', on='key').dtypes
\\Out [65]:
key      int64
v1_x     float64
v1_y     int64
dtype: object

```

New in version 0.20.0.

Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

```

In [66]: from pandas.api.types import CategoricalDtype

In [67]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [68]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [69]: left = pd.DataFrame({'X': X,
.....:                       'Y': np.random.choice(['one', 'two', 'three'],
.....:                                               size=(10,))})
.....:

In [70]: left
Out [70]:
   X      Y
0  bar  one
1  foo  one
2  foo three
3  bar three
4  foo  one
5  bar  one
6  bar three
7  bar three
8  bar three
9  foo three

In [71]: left.dtypes
\\

```

(continues on next page)

## Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```
In [78]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=['K0', 'K1', 'K2'])
.....:

In [79]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
.....:                         'D': ['D0', 'D2', 'D3']},
.....:                         index=['K0', 'K2', 'K3'])
.....:

In [80]: result = left.join(right)
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

```
In [81]: result = left.join(right, how='outer')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
			K3	NaN	NaN	K3	NaN	NaN	C3	D3

The same as above, but with `how='inner'`.

```
In [82]: result = left.join(right, how='inner')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2					
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [83]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer'
↳')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
						K3	NaN	NaN	C3	D3

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner'
↳');
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2					
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

### Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed `DataFrame` is to be aligned on that column in the `DataFrame`. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
        how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the `DataFrame`'s is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [85]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key': ['K0', 'K1', 'K0', 'K1']})
.....:
```

```
In [86]: right = pd.DataFrame({'C': ['C0', 'C1'],
.....:                        'D': ['D0', 'D1']},
.....:                        index=['K0', 'K1'])
.....:
```

```
In [87]: result = left.join(right, on='key')
```

left				right			Result					
	A	B	key		C	D		A	B	key	C	D
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

```
In [88]: result = pd.merge(left, right, left_on='key', right_index=True,
.....:                    how='left', sort=False);
.....:
```

left				right			Result					
	A	B	key		C	D		A	B	key	C	D
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

To join on multiple keys,

the passed DataFrame must have a MultiIndex:

```
In [89]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                      'B': ['B0', 'B1', 'B2', 'B3'],
.....:                      'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                      'key2': ['K0', 'K1', 'K0', 'K1']})
.....:

In [90]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
.....:                                     ('K2', 'K0'), ('K2', 'K1')])
.....:

In [91]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3']},
.....:                        index=index)
.....:
```

Now this can be joined by passing the two key column names:

```
In [92]: result = left.join(right, on=['key1', 'key2'])
```

left					right				Result					
	A	B	key1	key2		C	D		A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	K0	D0	0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	K0	D1	1	A1	B1	K0	K1	NaN	NaN
2	A2	B2	K1	K0	K2	K0	D2	2	A2	B2	K1	K0	C1	D1
3	A3	B3	K2	K1	K2	K1	D3	3	A3	B3	K2	K1	C3	D3

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily

performed:

```
In [93]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

left					right				Result						
	A	B	key1	key2			C	D		A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	K0	C0	D0	0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	K0	C1	D1	2	A2	B2	K1	K0	C1	D1
2	A2	B2	K1	K0	K2	K0	C2	D2	3	A3	B3	K2	K1	C3	D3
3	A3	B3	K2	K1	K2	K1	C3	D3							

As you can see, this drops any rows where there was no match.

### Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [94]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=pd.Index(['K0', 'K1', 'K2'], name='key'))
.....:
```

```
In [95]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                     ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                     names=['key', 'Y'])
.....:
```

```
In [96]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                         'D': ['D0', 'D1', 'D2', 'D3']},
.....:                         index=index)
.....:
```

```
In [97]: result = left.join(right, how='inner')
```

left			right				Result					
	A	B			C	D			A	B	C	D
K0	A0	B0	K0	Y0	C0	D0	K0	Y0	A0	B0	C0	D0
K1	A1	B1	K1	Y1	C1	D1	K1	Y1	A1	B1	C1	D1
K2	A2	B2	K2	Y2	C2	D2	K2	Y2	A2	B2	C2	D2
			K2	Y3	C3	D3	K2	Y3	A2	B2	C3	D3

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [98]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                      on=['key'], how='inner').set_index(['key', 'Y'])
.....:
```

left			right				Result					
	A	B			C	D			A	B	C	D
K0	A0	B0	K0	Y0	C0	D0	K0	Y0	A0	B0	C0	D0
K1	A1	B1	K1	Y1	C1	D1	K1	Y1	A1	B1	C1	D1
K2	A2	B2	K2	Y2	C2	D2	K2	Y2	A2	B2	C2	D2
			K2	Y3	C3	D3	K2	Y3	A2	B2	C3	D3

### Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [99]: leftindex = pd.MultiIndex.from_product([list('abc'), list('xy'), [1, 2]],
.....:                                         names=['abc', 'xy', 'num'])
.....:
```

```
In [100]: left = pd.DataFrame({'v1': range(12)}, index=leftindex)
```

```
In [101]: left
```

```
Out [101]:
          v1
abc xy num
a  x  1    0
   2    1
   y  1    2
   2    3
b  x  1    4
   2    5
   y  1    6
   2    7
c  x  1    8
   2    9
   y  1   10
   2   11
```

```
In [102]: rightindex = pd.MultiIndex.from_product([list('abc'), list('xy')],
.....:                                         names=['abc', 'xy'])
.....:
```

```
In [103]: right = pd.DataFrame({'v2': [100 * i for i in range(1, 7)]},
↳index=rightindex)
```

```
In [104]: right
```

```
Out [104]:
          v2
abc xy
a  x  100
   y  200
b  x  300
   y  400
c  x  500
   y  600
```

(continues on next page)

(continued from previous page)

```
In [105]: left.join(right, on=['abc', 'xy'], how='inner')
```

```

////////////////////////////////////
↪
      v1  v2
abc xy num
a  x  1    0  100
   2    1  100
   y  1    2  200
   2    3  200
b  x  1    4  300
   2    5  300
   y  1    6  400
   2    7  400
c  x  1    8  500
   2    9  500
   y  1   10  600
   2   11  600

```

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```

In [106]: leftindex = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                         ('K1', 'X2')],
.....:                                         names=['key', 'X'])
.....:

In [107]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                        'B': ['B0', 'B1', 'B2']},
.....:                        index=leftindex)
.....:

In [108]: rightindex = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                         ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                         names=['key', 'Y'])
.....:

In [109]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                          'D': ['D0', 'D1', 'D2', 'D3']},
.....:                          index=rightindex)
.....:

In [110]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                       on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:

```

left				right				Result						
		A	B			C	D				A	B	C	D
K0	X0	A0	B0	K0	Y0	C0	D0	K0	X0	Y0	A0	B0	C0	D0
K0	X1	A1	B1	K1	Y1	C1	D1	K0	X1	Y0	A1	B1	C0	D0
K1	X2	A2	B2	K2	Y2	C2	D2	K1	X2	Y1	A2	B2	C1	D1
				K2	Y3	C3	D3							

## Merging on a combination of columns and index levels

New in version 0.23.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```
In [111]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')
In [112]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                        'B': ['B0', 'B1', 'B2', 'B3'],
.....:                        'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                        index=left_index)
.....:
In [113]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')
In [114]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                          'D': ['D0', 'D1', 'D2', 'D3'],
.....:                          'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                          index=right_index)
.....:
In [115]: result = left.merge(right, on=['key1', 'key2'])
```

left				right			Result						
	A	B	key2		C	D	key2		A	B	key2	C	D
K0	A0	B0	K0	K0	C0	D0	K0	K0	A0	B0	K0	C0	D0
K0	A1	B1	K1	K1	C1	D1	K0	K1	A2	B2	K0	C1	D1
K1	A2	B2	K0	K2	C2	D2	K0	K2	A3	B3	K1	C3	D3
K2	A3	B3	K1	K2	C3	D3	K1						

**Note:** When `DataFrame`s are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting `DataFrame`.

**Note:** When `DataFrame`s are merged using only some of the levels of a `MultiIndex`, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use `reset_index` on those level names to move those levels to columns prior to doing the merge.

**Note:** If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

## Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input `DataFrame`s to disambiguate the result columns:

```
In [116]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})
```

```
In [117]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})
```

```
In [118]: result = pd.merge(left, right, on='k')
```

left			right			Result			
	k	v		k	v		k	v_x	v_y
0	K0	1	0	K0	4	0	K0	1	4
1	K1	2	1	K0	5	1	K0	1	5
2	K2	3	2	K3	6				

```
In [119]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])
```

left			right			Result			
	k	v		k	v		k	v_l	v_r
0	K0	1	0	K0	4	0	K0	1	4
1	K1	2	1	K0	5	1	K0	1	5
2	K2	3	2	K3	6				

`DataFrame.join()` has `lsuffix` and `rsuffix` arguments which behave similarly.

```
In [120]: left = left.set_index('k')
```

```
In [121]: right = right.set_index('k')
```

```
In [122]: result = left.join(right, lsuffix='_l', rsuffix='_r')
```

left		right		Result		
	v		v		v_l	v_r
K0	1	K0	4	K0	1	4.0
K1	2	K0	5	K0	1	5.0
K2	3	K3	6	K1	2	NaN
				K2	3	NaN

### Joining multiple DataFrame or Panel objects

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [123]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
```

```
In [124]: result = left.join([right, right2])
```

left		right		right2		Result			
	v		v		v	v_x	v_y	v	
K0	1	K0	4	K1	7	K0	1	4.0	NaN
K1	2	K0	5	K1	8	K0	1	5.0	NaN
K2	3	K3	6	K2	9	K1	2	NaN	7.0
						K1	2	NaN	8.0
						K2	3	NaN	9.0

### Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) `Series` or `DataFrame` objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [125]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
.....:                        [np.nan, 7., np.nan]])
.....:
.....:
In [126]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4]],
.....:                        index=[1, 2])
.....:
.....:
```

For this, use the `combine_first()` method:

```
In [127]: result = df1.combine_first(df2)
```

df1				df2				Result			
	0	1	2		0	1	2		0	1	2
0	NaN	3.0	5.0					0	NaN	3.0	5.0
1	-4.6	NaN	NaN	1	-42.6	NaN	-8.2	1	-4.6	NaN	-8.2
2	NaN	7.0	NaN	2	-5.0	1.6	4.0	2	-5.0	7.0	4.0

Note that this method only takes values from the right `DataFrame` if they are missing in the left `DataFrame`. A related method, `update()`, alters non-NA values in place:

```
In [128]: df1.update(df2)
```

df1				df2				Result			
	0	1	2		0	1	2		0	1	2
0	NaN	3.0	5.0					0	NaN	3.0	5.0
1	-4.6	NaN	NaN	1	-42.6	NaN	-8.2	1	-42.6	NaN	-8.2
2	NaN	7.0	NaN	2	-5.0	1.6	4.0	2	-5.0	1.6	4.0

### 4.4.3 Timeseries friendly merging

#### Merging Ordered Data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [129]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
.....:                        'lv': [1, 2, 3, 4],
.....:                        's': ['a', 'b', 'c', 'd']})
.....:

In [130]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
.....:                          'rv': [1, 2, 3]})
.....:

In [131]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[131]:
   k  lv  s  rv
0  K0  1.0 a  NaN
1  K1  1.0 a  1.0
2  K2  1.0 a  2.0
3  K4  1.0 a  3.0
4  K1  2.0 b  1.0
5  K2  2.0 b  2.0
6  K4  2.0 b  3.0
7  K1  3.0 c  1.0
8  K2  3.0 c  2.0
9  K4  3.0 c  3.0
10 K1  NaN d  1.0
11 K2  4.0 d  2.0
12 K4  4.0 d  3.0
```

#### Merging AsOf

New in version 0.19.0.

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the left DataFrame, we select the last row in the right DataFrame whose on key is less than the left's key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to `asof` merge them.

```
In [132]: trades = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                            '20160525 13:30:00.038',
.....:                            '20160525 13:30:00.048',
.....:                            '20160525 13:30:00.048',
.....:                            '20160525 13:30:00.048']),
.....:     'ticker': ['MSFT', 'MSFT',
.....:                'GOOG', 'GOOG', 'AAPL'],
.....:     'price': [51.95, 51.95,
.....:               720.77, 720.92, 98.00],
.....:     'quantity': [75, 155,
```

(continues on next page)

(continued from previous page)

```
.....:             100, 100, 100}},  
.....:         columns=['time', 'ticker', 'price', 'quantity'])  
.....:  
In [133]: quotes = pd.DataFrame(  
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',  
.....:                          '20160525 13:30:00.023',  
.....:                          '20160525 13:30:00.030',  
.....:                          '20160525 13:30:00.041',  
.....:                          '20160525 13:30:00.048',  
.....:                          '20160525 13:30:00.049',  
.....:                          '20160525 13:30:00.072',  
.....:                          '20160525 13:30:00.075'])),  
.....:     'ticker': ['GOOG', 'MSFT', 'MSFT',  
.....:              'MSFT', 'GOOG', 'AAPL', 'GOOG',  
.....:              'MSFT'],  
.....:     'bid': [720.50, 51.95, 51.97, 51.99,  
.....:            720.50, 97.99, 720.50, 52.01],  
.....:     'ask': [720.93, 51.96, 51.98, 52.00,  
.....:            720.93, 98.01, 720.88, 52.03]),  
.....:     columns=['time', 'ticker', 'bid', 'ask'])  
.....:
```

```
In [134]: trades  
Out [134]:  

|   | time                    | ticker | price  | quantity |
|---|-------------------------|--------|--------|----------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      |
| 3 | 2016-05-25 13:30:00.048 | GOOG   | 720.92 | 100      |
| 4 | 2016-05-25 13:30:00.048 | AAPL   | 98.00  | 100      |

  
In [135]: quotes  
////////////////////////////////////  
↪  

|   | time                    | ticker | bid    | ask    |
|---|-------------------------|--------|--------|--------|
| 0 | 2016-05-25 13:30:00.023 | GOOG   | 720.50 | 720.93 |
| 1 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 51.96  |
| 2 | 2016-05-25 13:30:00.030 | MSFT   | 51.97  | 51.98  |
| 3 | 2016-05-25 13:30:00.041 | MSFT   | 51.99  | 52.00  |
| 4 | 2016-05-25 13:30:00.048 | GOOG   | 720.50 | 720.93 |
| 5 | 2016-05-25 13:30:00.049 | AAPL   | 97.99  | 98.01  |
| 6 | 2016-05-25 13:30:00.072 | GOOG   | 720.50 | 720.88 |
| 7 | 2016-05-25 13:30:00.075 | MSFT   | 52.01  | 52.03  |

```

By default we are taking the asof of the quotes.

```
In [136]: pd.merge_asof(trades, quotes,  
.....:                   on='time',  
.....:                   by='ticker')  
.....:  
Out [136]:  

|   | time                    | ticker | price  | quantity | bid    | ask    |
|---|-------------------------|--------|--------|----------|--------|--------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       | 51.95  | 51.96  |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      | 51.97  | 51.98  |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      | 720.50 | 720.93 |

```

(continues on next page)

(continued from previous page)

3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

We only asof within 2ms between the quote time and the trade time.

```
In [137]: pd.merge_asof(trades, quotes,
.....:                 on='time',
.....:                 by='ticker',
.....:                 tolerance=pd.Timedelta('2ms'))
.....:
Out [137]:
```

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	51.95	51.96
1	2016-05-25 13:30:00.038	MSFT	51.95	155	NaN	NaN
2	2016-05-25 13:30:00.048	GOOG	720.77	100	720.50	720.93
3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes **do** propagate to that point in time.

```
In [138]: pd.merge_asof(trades, quotes,
.....:                 on='time',
.....:                 by='ticker',
.....:                 tolerance=pd.Timedelta('10ms'),
.....:                 allow_exact_matches=False)
.....:
Out [138]:
```

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	NaN	NaN
1	2016-05-25 13:30:00.038	MSFT	51.95	155	51.97	51.98
2	2016-05-25 13:30:00.048	GOOG	720.77	100	NaN	NaN
3	2016-05-25 13:30:00.048	GOOG	720.92	100	NaN	NaN
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

## 4.5 Reshaping and Pivot Tables

### 4.5.1 Reshaping by pivoting DataFrame objects

# Pivot

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
```

	date	variable	value
0	2000-01-03	A	0.469112
1	2000-01-04	A	-0.282863
2	2000-01-05	A	-1.509059
3	2000-01-03	B	-1.135632
4	2000-01-04	B	1.212112
5	2000-01-05	B	-0.173215
6	2000-01-03	C	0.119209
7	2000-01-04	C	-1.044236
8	2000-01-05	C	-0.861849
9	2000-01-03	D	-2.104569
10	2000-01-04	D	-0.494929
11	2000-01-05	D	1.071804

For the curious here is how the above DataFrame was created:

```
import pandas.util.testing as tm

tm.N = 3

def unpivot(frame):
    N, K = frame.shape
    data = {'value': frame.to_numpy().ravel('F'),
           'variable': np.asarray(frame.columns).repeat(N),
           'date': np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])

df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

```
In [2]: df[df['variable'] == 'A']
Out [2]:
```

	date	variable	value
0	2000-01-03	A	0.469112
1	2000-01-04	A	-0.282863
2	2000-01-05	A	-1.509059

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```
In [3]: df.pivot(index='date', columns='variable', values='value')
Out [3]:
```

variable	A	B	C	D
date				
2000-01-03	0.469112	-1.135632	0.119209	-2.104569
2000-01-04	-0.282863	1.212112	-1.044236	-0.494929
2000-01-05	-1.509059	-0.173215	-0.861849	1.071804

If the `values` argument is omitted, and the input `DataFrame` has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” `DataFrame` will have *hierarchical columns* whose topmost level indicates the respective value column:

```
In [4]: df['value2'] = df['value'] * 2
In [5]: pivoted = df.pivot(index='date', columns='variable')
In [6]: pivoted
Out [6]:
```

	value				value2			
↪ variable	A	B	C	D	A	B	C	↪
↪ D								
↪ date								
↪ 2000-01-03	0.469112	-1.135632	0.119209	-2.104569	0.938225	-2.271265	0.238417	-4.209138
↪ 2000-01-04	-0.282863	1.212112	-1.044236	-0.494929	-0.565727	2.424224	-2.088472	-0.989859
↪ 2000-01-05	-1.509059	-0.173215	-0.861849	1.071804	-3.018117	-0.346429	-1.723698	2.143608

(continues on next page)

(continued from previous page)

---

You can then select subsets from the pivoted DataFrame:

```
In [7]: pivoted['value2']
Out [7]:
```

variable	A	B	C	D
date				
2000-01-03	0.938225	-2.271265	0.238417	-4.209138
2000-01-04	-0.565727	2.424224	-2.088472	-0.989859
2000-01-05	-3.018117	-0.346429	-1.723698	2.143608

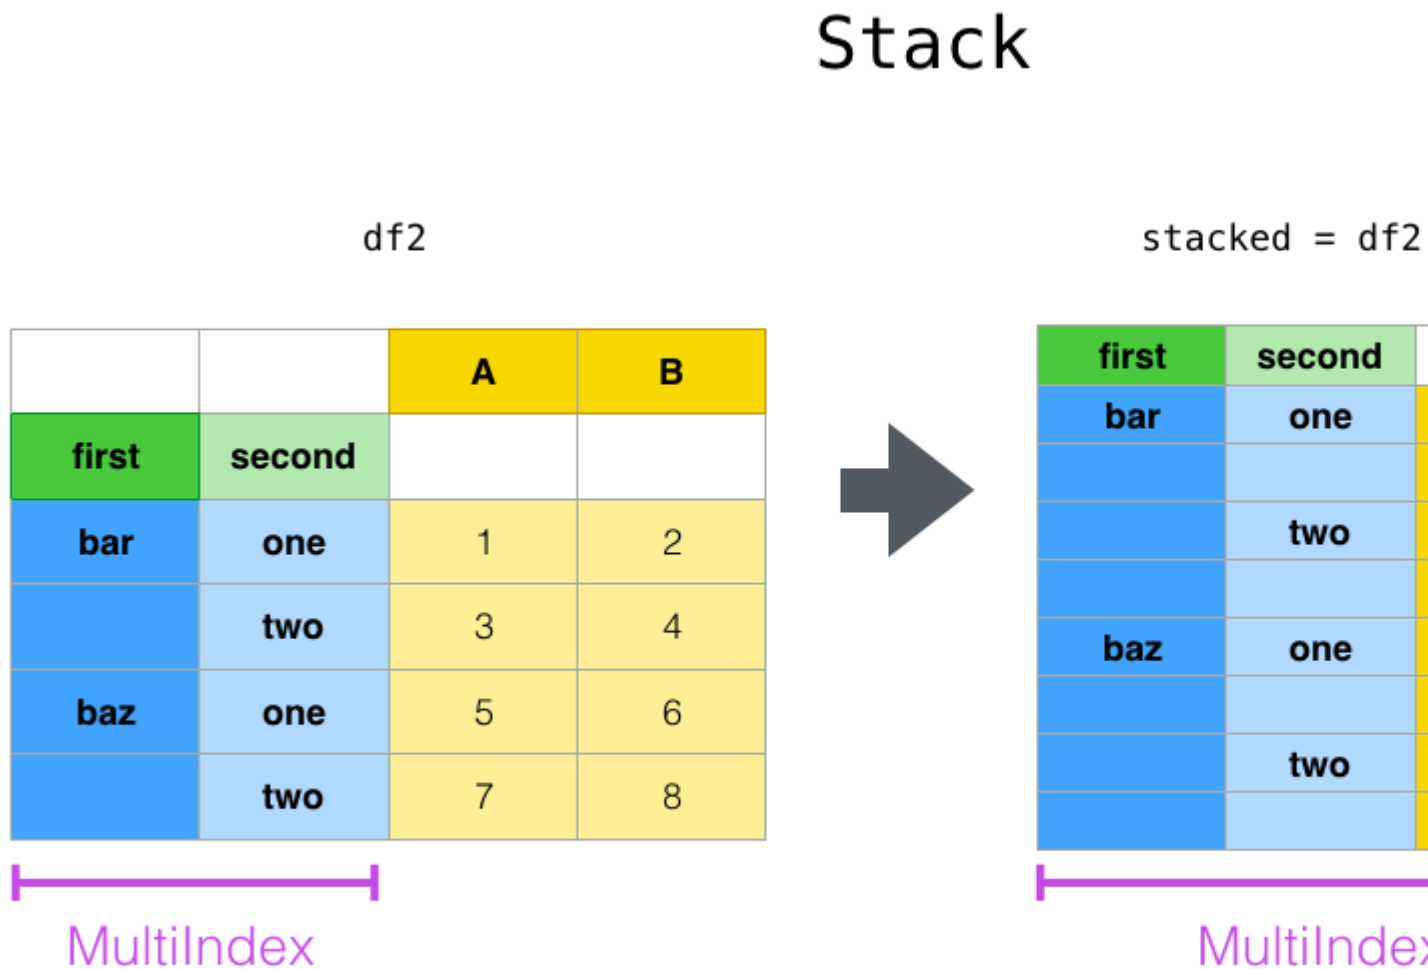

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

---

**Note:** `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape if the index/column pair is not unique.` In this case, consider using `pivot_table()` which is a generalization of `pivot` that can handle duplicate values for one index/column pair.

---

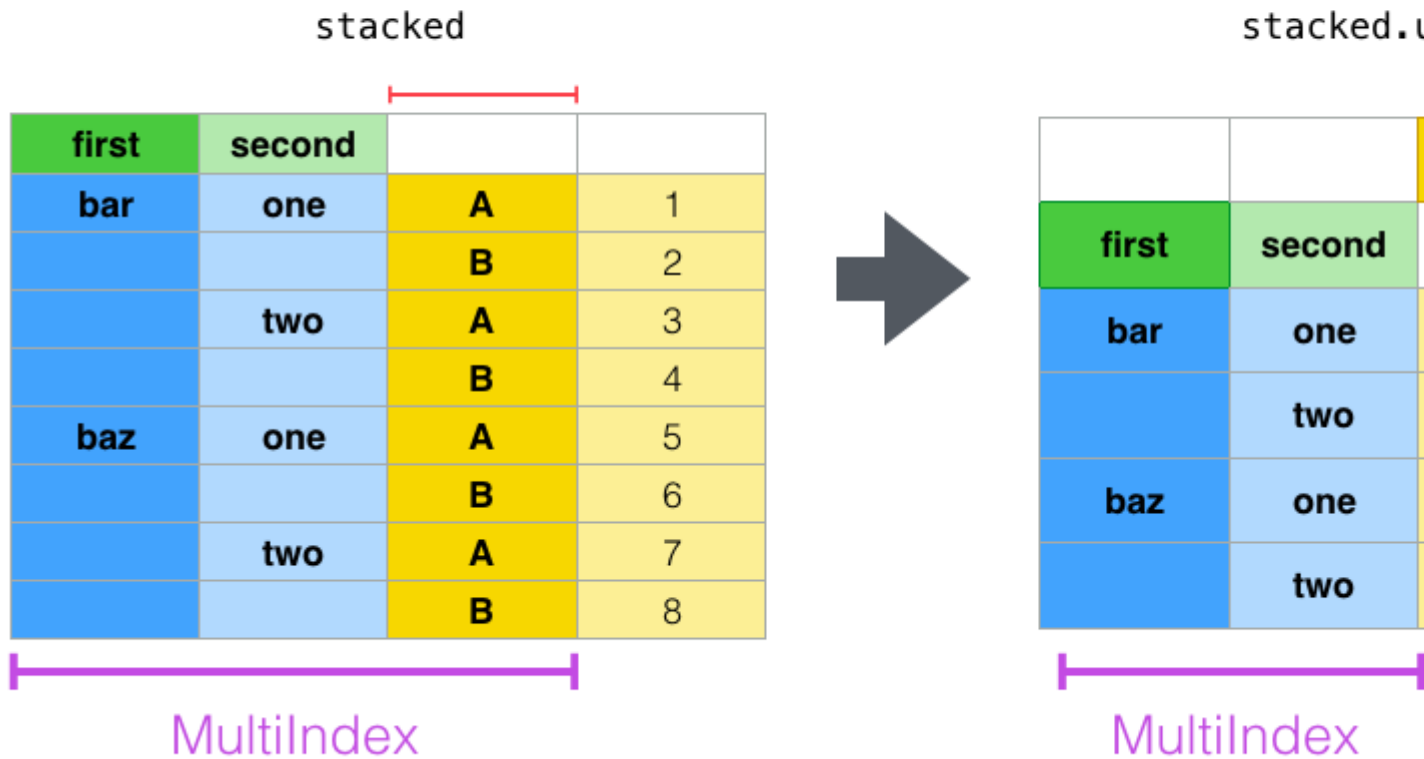

## 4.5.2 Reshaping by stacking and unstacking

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on *hierarchical indexing*). Here are essentially what these methods do:

- `stack`: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
- `unstack`: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.

# Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*(['bar', 'bar', 'baz', 'baz',
...:                        'foo', 'foo', 'qux', 'qux'],
...:                        ['one', 'two', 'one', 'two',
...:                        'one', 'two', 'one', 'two'])))
...:

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

In [12]: df2
Out[12]:
```

		A	B
first	second		
bar	one	0.721555	-0.706771
	two	-1.039575	0.271860

(continues on next page)

(continued from previous page)

```

baz    one    -0.424972  0.567020
      two     0.276232 -1.087401

```

The stack function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:

```

In [13]: stacked = df2.stack()

In [14]: stacked
Out [14]:
first second
bar    one    A    0.721555
          B   -0.706771
          two   A   -1.039575
          B    0.271860
baz    one    A   -0.424972
          B    0.567020
          two   A    0.276232
          B   -1.087401

dtype: float64

```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the last level:

```

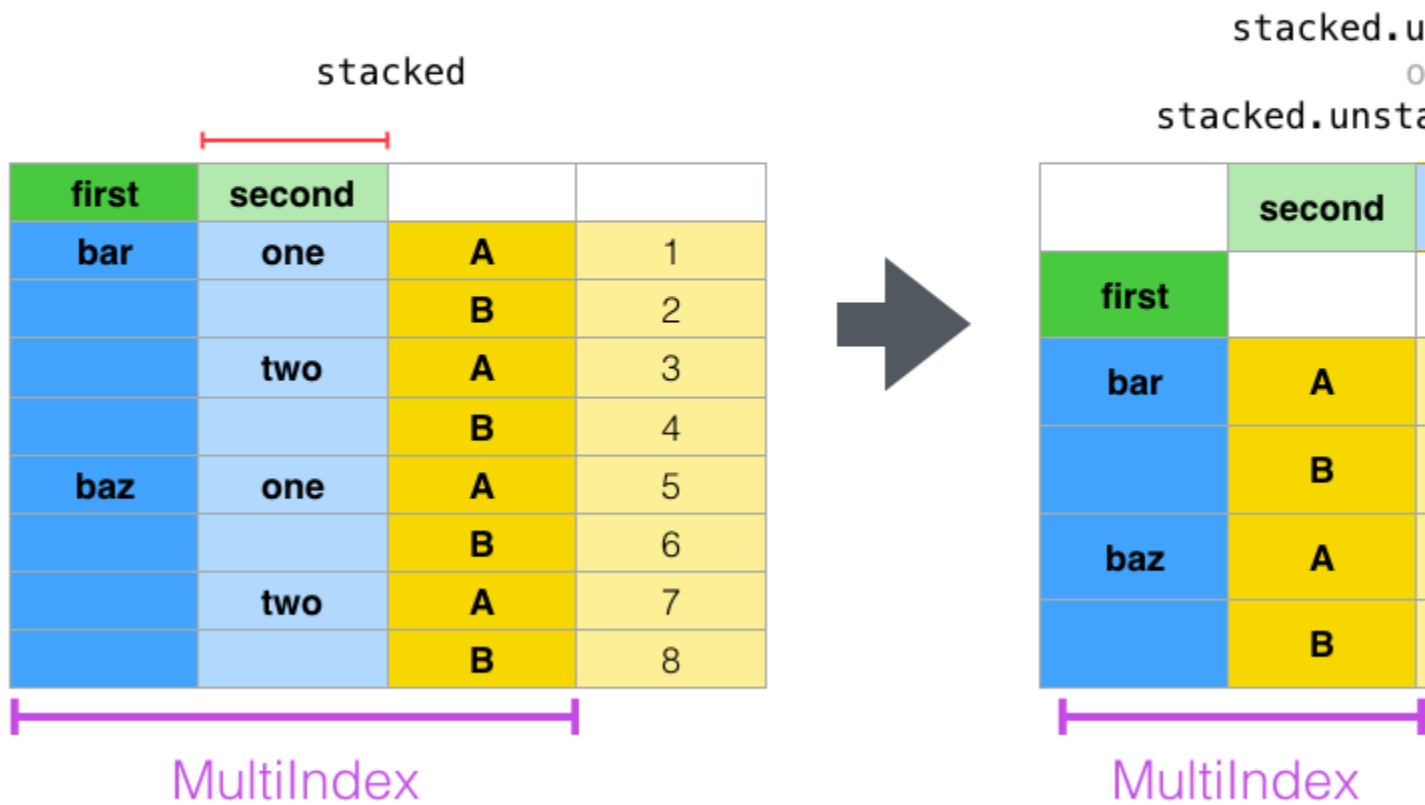

In [15]: stacked.unstack()
Out [15]:
          A    B
first second
bar    one    0.721555 -0.706771
          two  -1.039575  0.271860
baz    one   -0.424972  0.567020
          two   0.276232 -1.087401

In [16]: stacked.unstack(1)
Out [16]:
second      one      two
first
bar    A  0.721555 -1.039575
          B -0.706771  0.271860
baz    A -0.424972  0.276232
          B  0.567020 -1.087401

In [17]: stacked.unstack(0)
Out [17]:
first      bar      baz
second
one    A  0.721555 -0.424972
          B -0.706771  0.567020
two    A -1.039575  0.276232
          B  0.271860 -1.087401

```

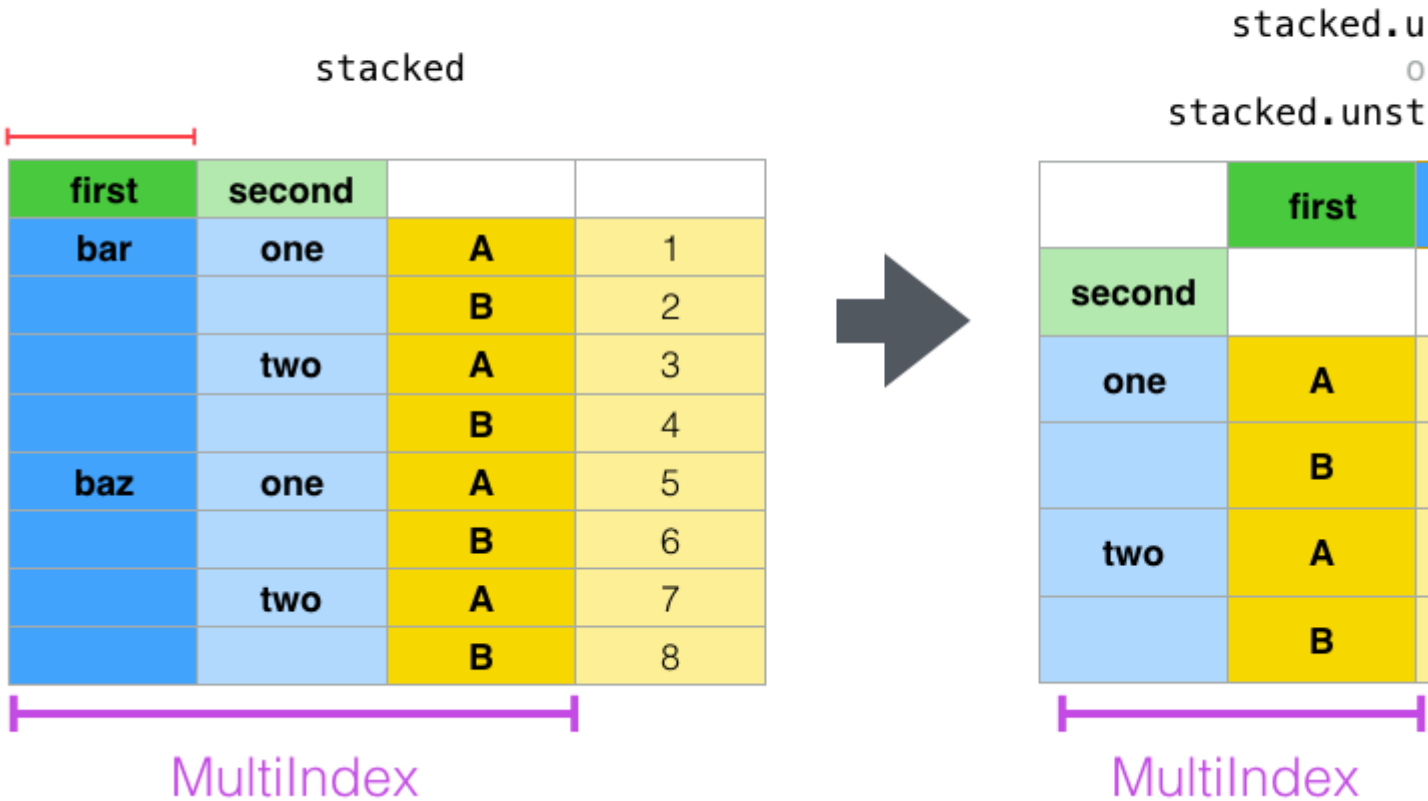

# Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
second      one      two
first
bar  A  0.721555 -1.039575
     B -0.706771  0.271860
baz  A -0.424972  0.276232
     B  0.567020 -1.087401
```

# Unstack(0)

Notice that the `stack` and `unstack` methods implicitly sort the index levels involved. Hence a call to `stack` and then `unstack`, or vice versa, will result in a **sorted** copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])

In [21]: df
Out[21]:
           A
2 a -0.370647
  b -1.157892
1 a -1.344312
  b  0.844885

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]:
↳ True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

Missing Data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```
In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
.....:                                   ('B', 'cat'), ('A', 'dog')],
.....:                                   names=['exp', 'animal'])

In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
.....:                                     ('one', 'two')],
.....:                                     names=['first', 'second'])

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out [32]:
exp          A          B            A
animal      cat      dog      cat      dog
first second
bar   one   0.895717  0.805244 -1.206412  2.565646
      two   1.431256  1.340309 -1.170299 -0.226169
baz   one   0.410835  0.813850  0.132003 -0.827317
foo   one  -1.413681  1.607920  1.024180  0.569605
      two   0.875906 -2.211372  0.974466 -2.006747
qux   two  -1.226825  0.769804 -1.281247 -0.727707
```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
Out [33]:
animal      cat      dog
first second exp
bar   one   A    0.895717  2.565646
      two   A    1.431256 -0.226169
      two   B   -1.170299  1.340309
baz   one   A    0.410835 -0.827317
      two   B    0.132003  0.813850
foo   one   A   -1.413681  0.569605
      two   A    0.875906 -2.006747
      two   B    0.974466 -2.211372
qux   two   A   -1.226825 -0.727707
      two   B   -1.281247  0.769804

In [34]: df2.stack('animal')
////////////////////////////////////////////////////////////////////////////////////
↪
exp          A          B
first second animal
bar   one   cat    0.895717 -1.206412
      two   dog    2.565646  0.805244
```

(continues on next page)

```
In [39]: df[:3].unstack(0)
Out [39]:
exp          A          B
animal      cat      dog
first      bar      baz      bar      baz      bar      baz      bar      baz
second
one      0.895717  0.410835  0.805244  0.81385 -1.206412  0.132003  2.565646 -0.827317
two      1.431256      NaN  1.340309      NaN -1.170299      NaN -0.226169      NaN

In [40]: df2.unstack(1)
////////////////////////////////////
↔
exp          A          B          A
animal      cat      dog      dog

qux          NaN -1.226825      NaN  0.769804      NaN -1.281247      NaN -0.727707
```

### 4.5.3 Reshaping by Melt

# Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....:                        'last': ['Doe', 'Bo'],
.....:                        'height': [5.5, 6.0],
.....:                        'weight': [130, 150]})
.....:

In [42]: cheese
Out[42]:
   first last  height  weight
0  John  Doe     5.5     130
1  Mary  Bo     6.0     150

In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
   first last variable  value
0  John  Doe   height     5.5
1  Mary  Bo   height     6.0
2  John  Doe   weight    130.0
3  Mary  Bo   weight    150.0

In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')
Out[44]:
   first last quantity  value
0  John  Doe   height     5.5
1  Mary  Bo   height     6.0
2  John  Doe   weight    130.0
3  Mary  Bo   weight    150.0
```

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [45]: dft = pd.DataFrame({"A1970": {0: "a", 1: "b", 2: "c"},
.....:                      "A1980": {0: "d", 1: "e", 2: "f"},
.....:                      "B1970": {0: 2.5, 1: 1.2, 2: .7},
.....:                      "B1980": {0: 3.2, 1: 1.3, 2: .1},
.....:                      "X": dict(zip(range(3), np.random.randn(3)))
.....:                      })

In [46]: dft["id"] = dft.index

In [47]: dft
Out[47]:
   A1970 A1980  B1970  B1980         X  id
0     a     d     2.5     3.2 -0.121306  0
1     b     e     1.2     1.3 -0.097883  1
2     c     f     0.7     0.1  0.695775  2

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
```

(continues on next page)

(continued from previous page)

```

\\\
↪
      X  A   B
id year
0  1970 -0.121306 a  2.5
1  1970 -0.097883 b  1.2
2  1970  0.695775 c  0.7
0  1980 -0.121306 d  3.2
1  1980 -0.097883 e  1.3
2  1980  0.695775 f  0.1
```

## 4.5.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
```

```
Out [49]:
```

```
exp          A          B
animal       cat          dog
first second
bar  one      0.895717  0.805244 -1.206412  2.565646
     two      1.431256  1.340309 -1.170299 -0.226169
baz  one      0.410835  0.813850  0.132003 -0.827317
     two     -0.076467 -1.187678  1.130127 -1.436737
foo  one     -1.413681  1.607920  1.024180  0.569605
     two      0.875906 -2.211372  0.974466 -2.006747
qux  one     -0.410001 -0.078638  0.545952 -1.219217
     two     -1.226825  0.769804 -1.281247 -0.727707
```

```
In [50]: df.stack().mean(1).unstack()
```

```

\\\
↪

```

## 4.5.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the *cookbook* for some advanced strategies.

It takes a number of arguments:

- `data`: a DataFrame object.
- `values`: a column or a list of columns to aggregate.
- `index`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc`: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```
In [54]: import datetime
```

```
In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
.....:                    'B': ['A', 'B', 'C'] * 8,
.....:                    'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
.....:                    'D': np.random.randn(24),
.....:                    'E': np.random.randn(24),
.....:                    'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)]
.....:                    + [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
.....:
```

```
In [56]: df
```

```
Out[56]:
```

(continues on next page)

(continued from previous page)

```

      A B   C      D      E      F
0   one A  foo  0.341734 -0.317441 2013-01-01
1   one B  foo  0.959726 -1.236269 2013-02-01
2   two C  foo -1.110336  0.896171 2013-03-01
3  three A  bar -0.619976 -0.487602 2013-04-01
4   one B  bar  0.149748 -0.082240 2013-05-01
5   one C  bar -0.732339 -2.182937 2013-06-01
6   two A  foo  0.687738  0.380396 2013-07-01
..   ... ..  ...      ...      ...      ...
17  one C  bar -0.345352  0.206053 2013-06-15
18  two A  foo  1.314232 -0.251905 2013-07-15
19  three B  foo  0.690579 -2.213588 2013-08-15
20  one C  foo  0.995761  1.063327 2013-09-15
21  one A  bar  2.396780  1.266143 2013-10-15
22  two B  bar  0.014871  0.299368 2013-11-15
23  three C  bar  3.357427 -0.863838 2013-12-15

[24 rows x 6 columns]

```

We can produce pivot tables from this data very easily:

```

In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out [57]:
C      bar      foo
A  B
one  A  1.120915 -0.514058
     B -0.338421  0.002759
     C -0.538846  0.699535
three A -1.181568      NaN
     B      NaN  0.433512
     C  0.588783      NaN
two   A      NaN  1.000985
     B  0.158248      NaN
     C      NaN  0.176180

In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.
↳sum)
↳
A      one      three      two
C      bar      foo      bar      foo      bar      foo
B

↪NaN      NaN  0.872482

[3 rows x 12 columns]

```

The result object is a `DataFrame` having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
Out [60]:
```

		D		E	
		bar	foo	bar	foo
A	B				
	one	1.120915	-0.514058	1.393057	-0.021605
		-0.338421	0.002759	0.684140	-0.551692
three	A	-0.538846	0.699535	-0.988442	0.747859
	B	-1.181568	NaN	0.961289	NaN
		NaN	0.433512	NaN	-1.064372
two	C	0.588783	NaN	-0.131830	NaN
	A	NaN	1.000985	NaN	0.064245
	B	0.158248	NaN	-0.097147	NaN
	C	NaN	0.176180	NaN	0.436241

Also, you can use `Groupby` for index and columns keywords. For detail of `Groupby`, see *Grouping with a Groupby specification*.

```
In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'),
.....:                  columns='C')
```

```
Out [61]:
```

	bar	foo
F		
2013-01-31	NaN	-0.514058
2013-02-28	NaN	0.002759
2013-03-31	NaN	0.176180
2013-04-30	-1.181568	NaN
2013-05-31	-0.338421	NaN
2013-06-30	-0.538846	NaN
2013-07-31	NaN	1.000985
2013-08-31	NaN	0.433512
2013-09-30	NaN	0.699535
2013-10-31	1.120915	NaN
2013-11-30	0.158248	NaN
2013-12-31	0.588783	NaN

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

(continues on next page)

(continued from previous page)

```
In [63]: print(table.to_string(na_rep=''))
          D          E
C         bar      foo      bar      foo
A  B
one  A  1.120915 -0.514058  1.393057 -0.021605
     B -0.338421  0.002759  0.684140 -0.551692
     C -0.538846  0.699535 -0.988442  0.747859
three A -1.181568          0.961289
     B          0.433512      -1.064372
     C  0.588783      -0.131830
two  A          1.000985          0.064245
     B  0.158248      -0.097147
     C          0.176180          0.436241
```

Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

### Adding margins

If you pass `margins=True` to `pivot_table`, special `All` columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out [64]:
          D          E
C         bar      foo      All      bar      foo      All
A  B
one  A  1.804346  1.210272  1.569879  0.179483  0.418374  0.858005
     B  0.690376  1.353355  0.898998  1.083825  0.968138  1.101401
     C  0.273641  0.418926  0.771139  1.689271  0.446140  1.422136
three A  0.794212          NaN  0.794212  2.049040          NaN  2.049040
     B          NaN  0.363548  0.363548          NaN  1.625237  1.625237
     C  3.915454          NaN  3.915454  1.035215          NaN  1.035215
two  A          NaN  0.442998  0.442998          NaN  0.447104  0.447104
     B  0.202765          NaN  0.202765  0.560757          NaN  0.560757
     C          NaN  1.819408  1.819408          NaN  0.650439  0.650439
All  1.556686  0.952552  1.246608  1.250924  0.899904  1.059389
```

## 4.5.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.

- margins: boolean, default False, Add row/column margins (subtotals)
- normalize: boolean, {'all', 'index', 'columns'}, or {0,1}, default False. Normalize by dividing all values by the sum of values.

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [67]: b = np.array([one, one, two, one, two, one], dtype=object)
In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
Out[69]:
b      one      two
c  dull shiny dull shiny
a
bar    1     0     0     1
foo    2     1     1     0
```

If crosstab receives only two Series, it will provide a frequency table.

```
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
.....:                    'C': [1, 1, np.nan, 1, 1]})
.....:

In [71]: df
Out[71]:
   A  B   C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
4  2  4  1.0

In [72]: pd.crosstab(df.A, df.B)
Out[72]:
B  3  4
A
1  1  0
2  1  3
```

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

```
In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
In [75]: pd.crosstab(foo, bar)
Out[75]:
col_0  d  e
```

(continues on next page)

(continued from previous page)

```
row_0
a      1  0
b      0  1
```

## Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```
In [76]: pd.crosstab(df.A, df.B, normalize=True)
Out [76]:
B      3      4
A
1  0.2  0.0
2  0.2  0.6
```

`normalize` can also normalize values within each row or within each column:

```
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out [77]:
B      3      4
A
1  0.5  0.0
2  0.5  1.0
```

`crosstab` can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out [78]:
B      3      4
A
1  1.0  NaN
2  1.0  2.0
```

## Adding Margins

Finally, one can also add margins or normalize this output.

```
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True,
.....:               margins=True)
.....:
Out [79]:
B      3      4  All
A
1   0.25  0.0  0.25
2   0.25  0.5  0.75
All  0.50  0.5  1.00
```

## 4.5.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out [81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.
→95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.
→0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [83]: c
Out [83]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]]
```

New in version 0.20.0.

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

## 4.5.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” `DataFrame`, for example a column in a `DataFrame` (a `Series`) which has  $k$  distinct values, can derive a `DataFrame` containing  $k$  columns of 1s and 0s using `get_dummies()`:

```
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})

In [85]: pd.get_dummies(df['key'])
Out [85]:
   a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')

In [87]: dummies
Out [87]:
   key_a  key_b  key_c
0      0      1      0
1      0      1      0
```

(continues on next page)

(continued from previous page)

```

2      1      0      0
3      0      0      1
4      1      0      0
5      0      1      0

```

```
In [88]: df[['data1']].join(dummies)
```

```

////////////////////////////////////
↪
   data1  key_a  key_b  key_c
0      0      0      1      0
1      1      0      1      0
2      2      1      0      0
3      3      0      0      1
4      4      1      0      0
5      5      0      1      0

```

This function is often used along with discretization functions like `cut`:

```
In [89]: values = np.random.randn(10)
```

```
In [90]: values
```

```
Out [90]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29   ,
        0.0824, -0.0558,  0.5366])
```

```
In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]
```

```
In [92]: pd.get_dummies(pd.cut(values, bins))
```

```
Out [92]:
   (0.0, 0.2]  (0.2, 0.4]  (0.4, 0.6]  (0.6, 0.8]  (0.8, 1.0]
0            0            0            1            0            0
1            0            0            0            0            0
2            0            0            0            0            0
3            0            0            0            0            0
4            1            0            0            0            0
5            0            0            0            0            0
6            0            0            0            0            0
7            1            0            0            0            0
8            0            0            0            0            0
9            0            0            1            0            0

```

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a `DataFrame`. By default all categorical variables (categorical in the statistical sense, those with *object* or *categorical* dtype) are encoded as dummy variables.

```
In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                    'C': [1, 2, 3]})
.....:
```

```
In [94]: pd.get_dummies(df)
```

```
Out [94]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

```

All non-object columns are included untouched in the output. You can control the columns that are encoded with the

columns keyword.

```
In [95]: pd.get_dummies(df, columns=['A'])
```

```
Out [95]:
```

	B	C	A_a	A_b
0	c	1	1	0
1	c	2	0	1
2	b	3	1	0

Notice that the B column is still included in the output, it just hasn't been encoded. You can drop B before calling `get_dummies` if you don't want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `'_'` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')
```

```
In [97]: simple
```

```
Out [97]:
```

	C	new_prefix_a	new_prefix_b	new_prefix_b	new_prefix_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

```
In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])
```

```
In [99]: from_list
```

```
Out [99]:
```

	C	from_A_a	from_A_b	from_B_b	from_B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

```
In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})
```

```
In [101]: from_dict
```

```
Out [101]:
```

	C	from_A_a	from_A_b	from_B_b	from_B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

New in version 0.18.0.

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```
In [102]: s = pd.Series(list('abcaa'))
```

```
In [103]: pd.get_dummies(s)
```

```
Out [103]:
```

	a	b	c
0	1	0	0

(continues on next page)

(continued from previous page)

```

1 0 1 0
2 0 0 1
3 1 0 0
4 1 0 0

In [104]: pd.get_dummies(s, drop_first=True)
Out[104]:
↪
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0

```

When a column contains only one level, it will be omitted in the result.

```

In [105]: df = pd.DataFrame({'A': list('aaaa'), 'B': list('ababc')})

In [106]: pd.get_dummies(df)
Out[106]:
   A_a  B_a  B_b  B_c
0     1    1    0    0
1     1    0    1    0
2     1    1    0    0
3     1    0    1    0
4     1    0    0    1

In [107]: pd.get_dummies(df, drop_first=True)
Out[107]:
↪
   B_b  B_c
0     0    0
1     1    0
2     0    0
3     1    0
4     0    1

```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```

In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})

In [109]: pd.get_dummies(df, dtype=bool).dtypes
Out[109]:
B          float64
A_a         bool
A_b         bool
A_c         bool
dtype: object

```

New in version 0.23.0.

## 4.5.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```

In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [111]: x
Out[111]:
0      A
1      A
2     NaN
3      B
4    3.14
5     inf
dtype: object

In [112]: labels, uniques = pd.factorize(x)

In [113]: labels
Out[113]: array([ 0,  0, -1,  1,  2,  3])

In [114]: uniques
Out[114]: Index(['A', 'B', 3.14, inf],
dtype='object')

```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

**Note:** The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```

In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2,  2, -1,  3,  0,  1]),
 Index([3.14, inf, u'A', u'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))

```

**Note:** If you just want to handle one column as a categorical variable (like R's `factor`), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on *Categorical*, see the *Categorical introduction* and the API documentation.

## 4.5.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```

In [115]: np.random.seed([3, 1415])

In [116]: n = 20

In [117]: cols = np.array(['key', 'row', 'item', 'col'])

In [118]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4))
.....:                               // [2, 1, 2, 1]).astype(str))

```

(continues on next page)

(continued from previous page)

```

.....:
In [119]: df.columns = cols

In [120]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix('val'))

In [121]: df
Out [121]:
   key  row  item  col  val0  val1
0  key0 row3  item1 col3  0.81  0.04
1  key1 row2  item1 col2  0.44  0.07
2  key1 row0  item1 col0  0.77  0.01
3  key0 row4  item0 col2  0.15  0.59
4  key1 row0  item2 col1  0.81  0.64
5  key1 row2  item2 col4  0.13  0.88
6  key2 row4  item1 col3  0.88  0.39
..   ...   ...   ...   ...   ...   ...
13 key0 row4  item1 col4  0.24  0.46
14 key1 row3  item2 col3  0.28  0.11
15 key0 row3  item1 col1  0.31  0.23
16 key0 row0  item2 col3  0.86  0.01
17 key0 row4  item0 col3  0.64  0.21
18 key2 row2  item2 col0  0.13  0.45
19 key0 row2  item0 col4  0.37  0.70

[20 rows x 6 columns]

```

## Pivoting with Single Aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

---

**Note:** col col0 col1 col2 col3 col4 row row0 0.77 0.605 NaN 0.860 0.65 row2 0.13 NaN 0.395 0.500 0.25 row3 NaN 0.310 NaN 0.545 NaN row4 NaN 0.100 0.395 0.760 0.24

---

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```

In [122]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean')
.....:
Out [122]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN  0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24

```

Note that we can also replace the missing values by using the `fill_value` parameter.

```

In [123]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean', fill_value=0)

```

(continues on next page)

(continued from previous page)

```

.....:
Out [123]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  0.000  0.860  0.65
row2  0.13  0.000  0.395  0.500  0.25
row3  0.00  0.310  0.000  0.545  0.00
row4  0.00  0.100  0.395  0.760  0.24

```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```

In [124]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='sum', fill_value=0)
.....:
Out [124]:
col  col0  col1  col2  col3  col4
row
row0  0.77  1.21  0.00  0.86  0.65
row2  0.13  0.00  0.79  0.50  0.50
row3  0.00  0.31  0.00  1.09  0.00
row4  0.00  0.10  0.79  1.52  0.24

```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```

In [125]: df.pivot_table(index='row', columns='col', fill_value=0, aggfunc='size')
Out [125]:
col  col0  col1  col2  col3  col4
row
row0     1     2     0     1     1
row2     1     0     2     1     2
row3     0     1     0     2     0
row4     0     1     2     2     1

```

### Pivoting with Multiple Aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and `mean`, we can pass in a list to the `aggfunc` argument.

```

In [126]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc=['mean', 'sum'])
.....:
Out [126]:
      mean
col  col0  col1  col2  col3  col4  sum
row
row0  0.77  0.605  NaN  0.860  0.65  0.77  1.21  NaN  0.86  0.65
row2  0.13  NaN  0.395  0.500  0.25  0.13  NaN  0.79  0.50  0.50
row3  NaN  0.310  NaN  0.545  NaN  NaN  0.31  NaN  1.09  NaN
row4  NaN  0.100  0.395  0.760  0.24  NaN  0.10  0.79  1.52  0.24

```

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```

In [127]: df.pivot_table(
.....:     values=['val0', 'val1'], index='row', columns='col', aggfunc=['mean'])

```

(continues on next page)

(continued from previous page)

```
.....:
Out [127]:
      mean
      val0
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65  0.01  0.745  NaN  0.010  0.02
row2  0.13   NaN  0.395  0.500  0.25  0.45   NaN  0.34  0.440  0.79
row3   NaN  0.310   NaN  0.545   NaN   NaN  0.230   NaN  0.075   NaN
row4   NaN  0.100  0.395  0.760  0.24   NaN  0.070  0.42  0.300  0.46
```

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [128]: df.pivot_table(
.....:     values=['val0'], index='row', columns=['item', 'col'], aggfunc=['mean'])
.....:
Out [128]:
      mean
      val0
item item0          item1          item2
col  col2  col3  col4  col0  col1  col2  col3  col4  col0  col1  col3  col4
row
row0  NaN  NaN  NaN  0.77  NaN  NaN  NaN  NaN  NaN  NaN  0.605  0.86  0.65
row2  0.35  NaN  0.37  NaN  NaN  0.44  NaN  NaN  0.13  NaN  0.50  0.13
row3   NaN  NaN  NaN  NaN  0.31  NaN  0.81  NaN  NaN  NaN  NaN  0.28  NaN
row4  0.15  0.64  NaN  NaN  0.10  0.64  0.88  0.24  NaN  NaN  NaN  NaN  NaN
```

## 4.6 Working with Text Data

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [2]: s.str.lower()
```

```
Out [2]:
0      a
1      b
2      c
3     aaba
4     baca
5      NaN
6     caba
7     dog
8     cat
dtype: object
```

```
In [3]: s.str.upper()
```

```

=====
→
0      A
1      B
2      C
```

(continues on next page)

(continued from previous page)

```

3    AABA
4    BACA
5     NaN
6    CABA
7     DOG
8     CAT
dtype: object

```

```
In [4]: s.str.len()
```

```

\-----/
↪
0     1.0
1     1.0
2     1.0
3     4.0
4     4.0
5     NaN
6     4.0
7     3.0
8     3.0
dtype: float64

```

```
In [5]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])
```

```
In [6]: idx.str.strip()
```

```
Out [6]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

```
In [7]: idx.str.lstrip()
```

```

\-----/Out [7]: Index(['jack
↪', 'jill ', 'jesse ', 'frank'], dtype='object')

```

```
In [8]: idx.str.rstrip()
```

```

\-----/
↪Index([' jack', 'jill', ' jesse', 'frank'], dtype='object')

```

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(np.random.randn(3, 2),
...:                      columns=[' Column A ', ' Column B '], index=range(3))
...:
```

```
In [10]: df
```

```
Out [10]:
```

```

   Column A   Column B
0   0.469112 -0.282863
1  -1.509059 -1.135632
2   1.212112 -0.173215

```

Since `df.columns` is an Index object, we can use the `.str` accessor

```
In [11]: df.columns.str.strip()
```

```
Out [11]: Index(['Column A', 'Column B'], dtype='object')
```

```
In [12]: df.columns.str.lower()
```

```

\-----/Out [12]: Index([' column a ',
↪ ' column b '], dtype='object')

```

(continues on next page)

(continued from previous page)

```

0          A
1          B
2          C
3    XX-XX ba
4    XX-XX ca
5
6          NaN
7    XX-XX BA
8      XX-XX
9    XX-XX t
dtype: object

```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of \$:

```

# Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])

# This does what you'd naively expect:
In [26]: dollars.str.replace('$', '')
Out [26]:
0          12
1         -10
2    10,000
dtype: object

# But this doesn't:
In [27]: dollars.str.replace('-$', '-')
\\Out [27]:
0          12
1         -$10
2    $10,000
dtype: object

# We need to escape the special character (for >1 len patterns)
In [28]: dollars.str.replace(r'\$', '-')
\\Out [28]:
↪
0          12
1         -10
2    $10,000
dtype: object

```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

# These lines are equivalent
In [29]: dollars.str.replace(r'\$', '-')
Out [29]:
0          12
1         -10
2    $10,000
dtype: object

In [30]: dollars.str.replace('-$', '-', regex=False)

```

(continues on next page)

(continued from previous page)

```
8      XX-XX
9      XX-XX t
dtype: object
```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```
In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
-----
ValueError: case and flags cannot be set when pat is a compiled regex
```

## 4.6.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

### Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])
In [42]: s.str.cat(sep=',')
Out [42]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```
In [43]: s.str.cat()
Out [43]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])
In [45]: t.str.cat(sep=',')
Out [45]: 'a,b,d'

In [46]: t.str.cat(sep=',', na_rep='-')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out [46]: 'a,b,-,d'
```

### Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling `Series` (or `Index`).

```
In [47]: s.str.cat(['A', 'B', 'C', 'D'])
Out [47]:
0      aA
1      bB
2      cC
3      dD
dtype: object
```

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])

In [55]: s
Out [55]:
0    a
1    b
2    c
3    d
dtype: object

In [56]: u
Out [56]:
1    b
3    d
0    a
2    c
dtype: object

In [57]: s.str.cat(u)
Out [57]:
0    ab
1    bd
2    ca
3    dc
dtype: object

In [58]: s.str.cat(u, join='left')
Out [58]:
0    aa
1    bb
2    cc
3    dd
dtype: object
```

**Warning:** If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [59]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4])

In [60]: s
Out [60]:
0    a
1    b
2    c
3    d
dtype: object
```

(continues on next page)

(continued from previous page)

```

In [61]: v
\\Out [61]:
-1    z
 0    a
 1    b
 3    d
 4    e
dtype: object

In [62]: s.str.cat(v, join='left', na_rep='-')
→
 0    aa
 1    bb
 2    c-
 3    dd
dtype: object

In [63]: s.str.cat(v, join='outer', na_rep='-')
→
-1    -z
 0    aa
 1    bb
 2    c-
 3    dd
 4    -e
dtype: object

```

The same alignment can be used when others is a DataFrame:

```

In [64]: f = d.loc[[3, 2, 1, 0], :]

In [65]: s
Out [65]:
 0    a
 1    b
 2    c
 3    d
dtype: object

In [66]: f
\\Out [66]:
      0 1
3    d d
2  NaN c
1    b b
0    a a

In [67]: s.str.cat(f, join='left', na_rep='-')
→
 0    aaa
 1    bbb
 2    c-c
 3    ddd

```

(continues on next page)

If using `join='right'` on a list-like of `others` that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [73]: u.loc[[3]]
Out [73]:
3      d
dtype: object

In [74]: v.loc[[-1, 0]]
\\Out [74]:
-1     z
 0     a
dtype: object

In [75]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join='right', na_rep='-')
\\Out [75]:
-1    --z
 0    a-a
 3    dd-
dtype: object
```

### 4.6.3 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan,
.....:                  'CABA', 'dog', 'cat'])
.....:

In [77]: s.str[0]
Out [77]:
0      A
1      B
2      C
3      A
4      B
5      NaN
6      C
7      d
8      c
dtype: object

In [78]: s.str[1]
\\Out [78]:
→
0      NaN
1      NaN
2      NaN
3      a
4      a
5      NaN
6      A
7      o
8      a
dtype: object
```

## 4.6.4 Extracting Substrings

### Extract first match in each subject (extract)

**Warning:** In version 0.18.0, `extract` gained the `expand` argument. When `expand=False` it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When `expand=True` it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user. `expand=True` is the default since version 0.23.0.

The `extract` method accepts a [regular expression](#) with at least one capture group.

Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'([ab])(\d)', expand=False)
Out [79]:
```

	0	1
0	a	1
1	b	2
2	NaN	NaN

Elements that do not match return a row filled with `NaN`. Thus, a `Series` of messy strings can be “converted” into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The dtype of the result is always `object`, even if no match is found and the result only contains `NaN`.

Named groups like

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'(?P<letter>[ab])(?P<digit>\d)',
.....:                                             expand=False)
.....:
Out [80]:
```

	letter	digit
0	a	1
1	b	2
2	NaN	NaN

and optional groups like

```
In [81]: pd.Series(['a1', 'b2', '3']).str.extract(r'([ab])?(\d)', expand=False)
Out [81]:
```

	0	1
0	a	1
1	b	2
2	NaN	3

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a `DataFrame` with one column if `expand=True`.

```
In [82]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out [82]:
```

	0
0	1
1	2
2	NaN

It returns a Series if `expand=False`.

```
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out [83]:
0      1
1      2
2     NaN
dtype: object
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if `expand=True`.

```
In [84]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])

In [85]: s
Out [85]:
A11    a1
B22    b2
C33    c3
dtype: object

In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out [86]:
letter
0      A
1      B
2      C
```

It returns an Index if `expand=False`.

```
In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out [87]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if `expand=True`.

```
In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out [88]:
letter  1
0      A  11
1      B  22
2      C  33
```

It raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of `extract (expand=False)` (input subject in first column, number of groups in regex in first row)

	1 group	>1 group
Index	Index	ValueError
Series	Series	DataFrame

### Extract all matches in each subject (`extractall`)

New in version 0.18.0.

Unlike `extract` (which returns only the first match),

```
In [89]: s = pd.Series(["ala2", "b1", "c1"], index=["A", "B", "C"])

In [90]: s
Out[90]:
A    ala2
B     b1
C     c1
dtype: object

In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'

In [92]: s.str.extract(two_groups, expand=True)
Out[92]:
   letter digit
A      a      1
B      b      1
C      c      1
```

the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```
In [93]: s.str.extractall(two_groups)
Out[93]:
   match letter digit
A 0      a      1
  1      a      2
B 0      b      1
C 0      c      1
```

When each subject string in the Series has exactly one match,

```
In [94]: s = pd.Series(['a3', 'b3', 'c2'])

In [95]: s
Out[95]:
0    a3
1    b3
2    c2
dtype: object
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [96]: extract_result = s.str.extract(two_groups, expand=True)

In [97]: extract_result
Out[97]:
   letter digit
0      a      3
1      b      3
2      c      2

In [98]: extractall_result = s.str.extractall(two_groups)

In [99]: extractall_result
```

(continues on next page)

(continued from previous page)

**Out [99]:**

```

      letter digit
match
0 0      a      3
1 0      b      3
2 0      c      2

```

**In [100]:** `extractall_result.xs(0, level="match")`

```

////////////////////////////////////
↪
      letter digit
0      a      3
1      b      3
2      c      2

```

Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a `Series.str.extractall` with a default index (starts from 0).

New in version 0.19.0.

**In [101]:** `pd.Index(["ala2", "b1", "c1"]).str.extractall(two_groups)`**Out [101]:**

```

      letter digit
match
0 0      a      1
  1      a      2
1 0      b      1
2 0      c      1

```

**In [102]:** `pd.Series(["ala2", "b1", "c1"]).str.extractall(two_groups)`

```

////////////////////////////////////
↪
      letter digit
match
0 0      a      1
  1      a      2
1 0      b      1
2 0      c      1

```

## 4.6.5 Testing for Strings that Match or Contain a Pattern

You can check whether elements contain a pattern:

**In [103]:** `pattern = r'[0-9][a-z]'`**In [104]:** `pd.Series(['1', '2', '3a', '3b', '03c']).str.contains(pattern)`**Out [104]:**

```

0    False
1    False
2     True
3     True
4     True
dtype: bool

```

Or whether elements match a pattern:

```
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
Out [105]:
0    False
1    False
2     True
3     True
4    False
dtype: bool
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered `True` or `False`:

```
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat
↪'])
In [107]: s4.str.contains('A', na=False)
Out [107]:
0     True
1    False
2    False
3     True
4    False
5    False
6     True
7    False
8    False
dtype: bool
```

## 4.6.6 Creating Indicator Variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])
In [109]: s.str.get_dummies(sep='|')
Out [109]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

New in version 0.18.1.

```
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])
In [111]: idx.str.get_dummies(sep='|')
Out [111]:
MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
            codes=[[1, 1, 0, 1], [0, 1, 0, 0], [0, 0, 0, 1]],
            names=['a', 'b', 'c'])
```

See also `get_dummies()`.

## 4.6.7 Method Summary

Method	Description
<code>cat()</code>	Concatenate strings
<code>split()</code>	Split strings on delimiter
<code>rsplit()</code>	Split strings on delimiter working from the end of the string
<code>get()</code>	Index into each element (retrieve i-th element)
<code>join()</code>	Join strings in each element of the Series with passed separator
<code>get_dummies()</code>	Split strings on the delimiter returning DataFrame of dummy variables
<code>contains()</code>	Return boolean array if each string contains pattern/regex
<code>replace()</code>	Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence
<code>repeat()</code>	Duplicate values ( <code>s.str.repeat(3)</code> equivalent to <code>x * 3</code> )
<code>pad()</code>	Add whitespace to left, right, or both sides of strings
<code>center()</code>	Equivalent to <code>str.center</code>
<code>ljust()</code>	Equivalent to <code>str.ljust</code>
<code>rjust()</code>	Equivalent to <code>str.rjust</code>
<code>zfill()</code>	Equivalent to <code>str.zfill</code>
<code>wrap()</code>	Split long strings into lines with length less than a given width
<code>slice()</code>	Slice each string in the Series
<code>slice_replace()</code>	Replace slice in each string with passed value
<code>count()</code>	Count occurrences of pattern
<code>startswith()</code>	Equivalent to <code>str.startswith(pat)</code> for each element
<code>endswith()</code>	Equivalent to <code>str.endswith(pat)</code> for each element
<code>findall()</code>	Compute list of all occurrences of pattern/regex for each string
<code>match()</code>	Call <code>re.match</code> on each element, returning matched groups as list
<code>extract()</code>	Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group
<code>extractall()</code>	Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group
<code>len()</code>	Compute string lengths
<code>strip()</code>	Equivalent to <code>str.strip</code>
<code>rstrip()</code>	Equivalent to <code>str.rstrip</code>
<code>lstrip()</code>	Equivalent to <code>str.lstrip</code>
<code>partition()</code>	Equivalent to <code>str.partition</code>
<code>rpartition()</code>	Equivalent to <code>str.rpartition</code>
<code>lower()</code>	Equivalent to <code>str.lower</code>
<code>upper()</code>	Equivalent to <code>str.upper</code>
<code>find()</code>	Equivalent to <code>str.find</code>
<code>rfind()</code>	Equivalent to <code>str.rfind</code>
<code>index()</code>	Equivalent to <code>str.index</code>
<code>rindex()</code>	Equivalent to <code>str.rindex</code>
<code>capitalize()</code>	Equivalent to <code>str.capitalize</code>
<code>swapcase()</code>	Equivalent to <code>str.swapcase</code>
<code>normalize()</code>	Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>
<code>translate()</code>	Equivalent to <code>str.translate</code>
<code>isalnum()</code>	Equivalent to <code>str.isalnum</code>
<code>isalpha()</code>	Equivalent to <code>str.isalpha</code>

Continued on next page

Table 2 – continued from previous page

Method	Description
<code>isdigit()</code>	Equivalent to <code>str.isdigit</code>
<code>isspace()</code>	Equivalent to <code>str.isspace</code>
<code>islower()</code>	Equivalent to <code>str.islower</code>
<code>isupper()</code>	Equivalent to <code>str.isupper</code>
<code>istitle()</code>	Equivalent to <code>str.istitle</code>
<code>isnumeric()</code>	Equivalent to <code>str.isnumeric</code>
<code>isdecimal()</code>	Equivalent to <code>str.isdecimal</code>

## 4.7 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

**Note:** The choice of using `NaN` internally to denote missing data was largely for simplicity and performance reasons. It differs from the `MaskedArray` approach of, for example, `scikits.timeseries`. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

See the *cookbook* for some advanced strategies.

### 4.7.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While `NaN` is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python `None` will arise and we wish to also consider that “missing” or “not available” or “NA”.

**Note:** If you want to consider `inf` and `-inf` to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
...:                      columns=['one', 'two', 'three'])
...:

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:
   one      two      three four  five
a  0.469112 -0.282863 -1.509059 bar   True
c -1.135632  1.212112 -0.173215 bar  False
e  0.119209 -1.044236 -0.861849 bar   True
f -2.104569 -0.494929  1.071804 bar  False
h  0.721555 -0.706771 -1.039575 bar   True

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
```

(continues on next page)

(continued from previous page)

```
Out [6]:
```

	one	two	three	four	five
a	0.469112	-0.282863	-1.509059	bar	True
b	NaN	NaN	NaN	NaN	NaN
c	-1.135632	1.212112	-0.173215	bar	False
d	NaN	NaN	NaN	NaN	NaN
e	0.119209	-1.044236	-0.861849	bar	True
f	-2.104569	-0.494929	1.071804	bar	False
g	NaN	NaN	NaN	NaN	NaN
h	0.721555	-0.706771	-1.039575	bar	True

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
```

```
Out [7]:
```

```
a    0.469112
b         NaN
c   -1.135632
d         NaN
e    0.119209
f   -2.104569
g         NaN
h    0.721555
Name: one, dtype: float64
```

```
In [8]: pd.isna(df2['one'])
```

```

////////////////////////////////////
↪
a    False
b     True
c    False
d     True
e    False
f    False
g     True
h    False
Name: one, dtype: bool
```

```
In [9]: df2['four'].notna()
```

```

////////////////////////////////////
↪
a     True
b    False
c     True
d    False
e     True
f     True
g    False
h     True
Name: four, dtype: bool
```

```
In [10]: df2.isna()
```

```

////////////////////////////////////
↪
   one  two  three  four  five
a  False  True  True  True  True
b  True   True  True  True  True
c  False  True  True  True  True
d  True   True  True  True  True
e  False  True  True  True  True
f  False  True  True  True  True
g  True   True  True  True  True
h  False  True  True  True  True
```

(continues on next page)

(continued from previous page)

```

a False False False False False
b  True  True  True  True  True
c False False False False False
d  True  True  True  True  True
e False False False False False
f False False False False False
g  True  True  True  True  True
h False False False False False

```

**Warning:** One has to be mindful that in Python (and NumPy), the nan 's don't compare equal, but None 's **do**. Note that pandas/NumPy uses the fact that `np.nan != np.nan`, and treats None like `np.nan`.

```

In [11]: None == None                                     # noqa: E711
Out[11]: True

In [12]: np.nan == np.nan
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[12]: False

```

So as compared to above, a scalar equality comparison versus a None/`np.nan` doesn't provide useful information.

```

In [13]: df2['one'] == np.nan
Out[13]:
a    False
b    False
c    False
d    False
e    False
f    False
g    False
h    False
Name: one, dtype: bool

```

## Integer Dtypes and Missing Data

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see *Support for integer NA* for more). Pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```

In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0      1
1      2
2     NaN
3      4
dtype: Int64

```

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See *Nullable Integer Data Type* for more.

## Datetimes

For `datetime64[ns]` types, `NaT` represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (`datetime64[ns]`). pandas objects provide compatibility between `NaT` and `NaN`.

```
In [15]: df2 = df.copy()

In [16]: df2['timestamp'] = pd.Timestamp('20120101')

In [17]: df2
Out[17]:
```

	one	two	three	four	five	timestamp
a	0.469112	-0.282863	-1.509059	bar	True	2012-01-01
c	-1.135632	1.212112	-0.173215	bar	False	2012-01-01
e	0.119209	-1.044236	-0.861849	bar	True	2012-01-01
f	-2.104569	-0.494929	1.071804	bar	False	2012-01-01
h	0.721555	-0.706771	-1.039575	bar	True	2012-01-01

```
In [18]: df2.loc[['a', 'c', 'h'], ['one', 'timestamp']] = np.nan

In [19]: df2
Out[19]:
```

	one	two	three	four	five	timestamp
a	NaN	-0.282863	-1.509059	bar	True	NaT
c	NaN	1.212112	-0.173215	bar	False	NaT
e	0.119209	-1.044236	-0.861849	bar	True	2012-01-01
f	-2.104569	-0.494929	1.071804	bar	False	2012-01-01
h	NaN	-0.706771	-1.039575	bar	True	NaT

```
In [20]: df2.get_dtype_counts()
//////////
↔
float64      3
object       1
bool         1
datetime64[ns] 1
dtype: int64
```

## Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use `NaN` regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])

In [22]: s.loc[0] = None

In [23]: s
Out[23]:
```

0	NaN
1	2.0
2	3.0

```
dtype: float64
```

Likewise, datetime containers will always use `NaT`.

For object containers, pandas will use the value given:

```
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0      None
1       NaN
2         c
dtype: object
```

### Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [28]: a
Out[28]:
      one      two
a      NaN -0.282863
c      NaN  1.212112
e  0.119209 -1.044236
f -2.104569 -0.494929
h -2.104569 -0.706771

In [29]: b
////////////////////////////////////
↪
      one      two      three
a      NaN -0.282863 -1.509059
c      NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h      NaN -0.706771 -1.039575

In [30]: a + b
////////////////////////////////////
↪
      one      three      two
a      NaN      NaN -0.565727
c      NaN      NaN  2.424224
e  0.238417      NaN -2.088472
f -4.209138      NaN -0.989859
h      NaN      NaN -1.413542
```

The descriptive statistics and computational methods discussed in the *data structure overview* (and listed *here* and *here*) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
```

```
Out [31]:
```

```
   one      two      three
a   NaN -0.282863 -1.509059
c   NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h   NaN -0.706771 -1.039575
```

```
In [32]: df['one'].sum()
```

```

```

```
In [34]: df.cumsum()
```

```
↪
   one      two      three
a   NaN -0.282863 -1.509059
c   NaN  0.929249 -1.682273
e  0.119209 -0.114987 -2.544122
f -1.985361 -0.609917 -1.472318
h   NaN -1.316688 -2.511893
```

```
In [35]: df.cumsum(skipna=False)
```

```
↪
   one      two      three
a  NaN -0.282863 -1.509059
c  NaN  0.929249 -1.682273
e  NaN -0.114987 -2.544122
f  NaN -0.609917 -1.472318
h  NaN -1.316688 -2.511893
```

## 4.7.2 Sum/Prod of Empties/Nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in `numpy`; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See *v0.22.0 whatsnew* for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
```

```
Out [36]: 0.0
```

(continues on next page)

(continued from previous page)

```
In [37]: pd.Series([]).sum()
\\Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0

In [39]: pd.Series([]).prod()
\\Out[39]: 1.0
```

### 4.7.3 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
```

	one	two	three
a	NaN	-0.282863	-1.509059
c	NaN	1.212112	-0.173215
e	0.119209	-1.044236	-0.861849
f	-2.104569	-0.494929	1.071804
h	NaN	-0.706771	-1.039575

```
In [41]: df.groupby('one').mean()
\\Out[41]:
```

	two	three
one		
-2.104569	-0.494929	1.071804
0.119209	-1.044236	-0.861849

See the groupby section [here](#) for more information.

### Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

### 4.7.4 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

#### Replace NA with a scalar value

```
In [42]: df2
Out[42]:
```

	one	two	three	four	five	timestamp
a	NaN	-0.282863	-1.509059	bar	True	NaT
c	NaN	1.212112	-0.173215	bar	False	NaT
e	0.119209	-1.044236	-0.861849	bar	True	2012-01-01
f	-2.104569	-0.494929	1.071804	bar	False	2012-01-01
h	NaN	-0.706771	-1.039575	bar	True	NaT

(continues on next page)

(continued from previous page)

**In [43]:** df2.fillna(0)

```

////////////////////////////////////
↪
      one      two      three four   five      timestamp
a  0.000000 -0.282863 -1.509059  bar   True           0
c  0.000000  1.212112 -0.173215  bar  False          0
e  0.119209 -1.044236 -0.861849  bar   True  2012-01-01 00:00:00
f -2.104569 -0.494929  1.071804  bar  False  2012-01-01 00:00:00
h  0.000000 -0.706771 -1.039575  bar   True           0

```

**In [44]:** df2['one'].fillna('missing')

```

////////////////////////////////////
↪
a      missing
c      missing
e      0.119209
f      -2.10457
h      missing
Name: one, dtype: object

```

### Fill gaps forward or backward

Using the same filling arguments as *reindexing*, we can propagate non-NA values forward or backward:

**In [45]:** df**Out [45]:**

```

      one      two      three
a      NaN -0.282863 -1.509059
c      NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h      NaN -0.706771 -1.039575

```

**In [46]:** df.fillna(method='pad')

```

////////////////////////////////////
↪
      one      two      three
a      NaN -0.282863 -1.509059
c      NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h -2.104569 -0.706771 -1.039575

```

### Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the *limit* keyword:

**In [47]:** df**Out [47]:**

```

      one      two      three
a      NaN -0.282863 -1.509059
c      NaN  1.212112 -0.173215
e      NaN         NaN         NaN
f      NaN         NaN         NaN
h      NaN -0.706771 -1.039575

```

**In [48]:** df.fillna(method='pad', limit=1)

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
   one      two      three
a  NaN -0.282863 -1.509059
c  NaN  1.212112 -0.173215
e  NaN  1.212112 -0.173215
f  NaN      NaN      NaN
h  NaN -0.706771 -1.039575

```

To remind you, these are the available filling methods:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

#### 4.7.5 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```

In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list('ABC'))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
Out [53]:
      A         B         C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3      NaN  0.577046 -1.715002
4      NaN      NaN -1.157892
5 -1.344312      NaN      NaN
6 -0.109050  1.643563      NaN
7  0.357021 -0.674600      NaN
8 -0.968914 -1.294524  0.413738
9  0.276662 -0.472035 -0.013960

In [54]: dff.fillna(dff.mean())
////////////////////////////////////
↪
      A         B         C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690

```

(continues on next page)

(continued from previous page)

```
Empty DataFrame
Columns: [one, two, three]
Index: []

In [59]: df.dropna(axis=1)
\\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳
      two     three
a -0.282863 -1.509059
c  1.212112 -0.173215
e  0.000000  0.000000
f  0.000000  0.000000
h -0.706771 -1.039575

In [60]: df['one'].dropna()
\\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined *in the API*.

### 4.7.7 Interpolation

New in version 0.21.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
Out [61]:
2000-01-31    0.469112
2000-02-29         NaN
2000-03-31         NaN
2000-04-28         NaN
2000-05-31         NaN
2000-06-30         NaN
2000-07-31         NaN
...
2007-10-31   -3.305259
2007-11-30   -5.485119
2007-12-31   -6.854968
2008-01-31   -7.809176
2008-02-29   -6.346480
2008-03-31   -8.089641
2008-04-30   -8.916232
Freq: BM, Length: 100, dtype: float64

In [62]: ts.count()
\\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳61

In [63]: ts.interpolate().count()
\\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳100
```

(continues on next page)

(continued from previous page)

```
dtype: float64
In [67]: ts2.interpolate(method='time')
//.....
↳
2000-01-31    0.469112
2000-02-29    0.273272
2002-07-31   -5.689738
2005-01-31   -7.095568
2008-04-30   -8.916232
dtype: float64
```

For a floating-point index, use `method='values'`:

```
In [68]: ser
Out [68]:
0.0    0.0
1.0    NaN
10.0   10.0
dtype: float64

In [69]: ser.interpolate()
//.....\Out [69]:
0.0    0.0
1.0    5.0
10.0   10.0
dtype: float64

In [70]: ser.interpolate(method='values')
//.....
↳
0.0    0.0
1.0    1.0
10.0   10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```
In [71]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:

In [72]: df
Out [72]:
   A     B
0  1.0  0.25
1  2.1   NaN
2  NaN   NaN
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

In [73]: df.interpolate()
//.....
↳
   A     B
0  1.0  0.25
```

(continues on next page)

(continued from previous page)

1	2.1	1.50
2	3.4	2.75
3	4.7	4.00
4	5.6	12.20
5	6.8	14.40

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You'll want to consult the full [scipy interpolation documentation](#) and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.

```
In [74]: df.interpolate(method='barycentric')
```

```
Out [74]:
```

	A	B
0	1.00	0.250
1	2.10	-7.660
2	3.53	-4.515
3	4.70	4.000
4	5.60	12.200
5	6.80	14.400

```
In [75]: df.interpolate(method='pchip')
```

```

////////////////////////////////////
→
      A          B
0  1.00000  0.25000
1  2.10000  0.672808
2  3.43454  1.928950
3  4.70000  4.000000
4  5.60000  12.200000
5  6.80000  14.400000

```

```
In [76]: df.interpolate(method='akima')
```

```

////////////////////////////////////
→
      A          B
0  1.000000  0.250000
1  2.100000 -0.873316
2  3.406667  0.320034
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000

```

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [86]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [87]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [88]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [89]: interp_s[49:51]
Out[89]:
49.00    0.471410
49.25    0.476841
49.50    0.481780
49.75    0.485998
50.00    0.489266
50.25    0.491814
50.50    0.493995
50.75    0.495763
51.00    0.497074
dtype: float64
```

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit

For a DataFrame, you can specify individual values by column:

```
In [103]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})

In [104]: df.replace({'a': 0, 'b': 5}, 100)
Out[104]:
```

	a	b
0	100	100
1	1	6
2	2	7
3	3	8
4	4	9

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [105]: ser.replace([1, 2, 3], method='pad')
Out[105]:
```

0	0.0
1	0.0
2	0.0
3	0.0
4	4.0

dtype: float64

## 4.7.9 String/Regular Expression Replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\'` == `'\\'`. You should [read about them](#) if this is unclear.

Replace the `'.'` with `NaN` (`str -> str`):

```
In [106]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}

In [107]: df = pd.DataFrame(d)

In [108]: df.replace('.', np.nan)
Out[108]:
```

	a	b	c
0	0	a	a
1	1	b	b
2	2	NaN	NaN
3	3	NaN	d

Now do it with a regular expression that removes surrounding whitespace (`regex -> regex`):

```
In [109]: df.replace(r'\s*\.\s*', np.nan, regex=True)
Out[109]:
```

	a	b	c
0	0	a	a
1	1	b	b
2	2	NaN	NaN
3	3	NaN	d

Replace a few different values (`list -> list`):

```
In [110]: df.replace(['a', '.'], ['b', np.nan])
Out[110]:
   a  b  c
0  0  b  b
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

list of regex -> list of regex:

```
In [111]: df.replace([r'\.', r'(a)'], ['dot', '\1stuff'], regex=True)
Out[111]:
   a  b  c
0  0 {stuff {stuff
1  1  b  b
2  2  dot  NaN
3  3  dot  d
```

Only search in column 'b' (dict -> dict):

```
In [112]: df.replace({'b': '.'}, {'b': np.nan})
Out[112]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [113]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
Out[113]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [114]: df.replace({'b': {'b': r''}}, regex=True)
Out[114]:
   a  b  c
0  0  a  a
1  1  b  b
2  2  . NaN
3  3  .  d
```

Alternatively, you can pass the nested dictionary like so:

```
In [115]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[115]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [116]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\lty'}, regex=True)
Out [116]:
   a  b  c
0  0  a  a
1  1  b  b
2  2  .ty NaN
3  3  .ty  d
```

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [117]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out [117]:
   a  b  c
0  0 NaN NaN
1  1 NaN NaN
2  2 NaN NaN
3  3 NaN  d
```

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [118]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out [118]:
   a  b  c
0  0 NaN NaN
1  1 NaN NaN
2  2 NaN NaN
3  3 NaN  d
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

## 4.7.10 Numeric Replacement

`replace()` is similar to `fillna()`.

```
In [119]: df = pd.DataFrame(np.random.randn(10, 2))
In [120]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
In [121]: df.replace(1.5, np.nan)
Out [121]:
      0      1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
```

(continues on next page)

(continued from previous page)

```

4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9      NaN      NaN

```

Replacing more than one value is possible by passing a list.

```
In [122]: df00 = df.iloc[0, 0]
```

```
In [123]: df.replace([1.5, df00], [np.nan, 'a'])
```

```
Out [123]:
      0      1
0      a -1.02141
1  0.432396 -0.32358
2  0.423825  0.79918
3  1.26261  0.751965
4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.0608
7  0.591667 -0.183257
8  1.01985  -1.48247
9      NaN      NaN

```

```
In [124]: df[1].dtype
```

```

////////////////////////////////////
↪dtype('float64')

```

You can also operate on the DataFrame in place:

```
In [125]: df.replace(1.5, np.nan, inplace=True)
```

**Warning:** When replacing multiple bool or datetime64 objects, the first argument to replace (to\_replace) must match the type of the value being replaced. For example,

```

>>> s = pd.Series([True, False, True])
>>> s.replace({'a string': 'new value', True: False}) # raises
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

```

will raise a TypeError because one of the dict keys is not of the correct type for replacement.

However, when replacing a *single* object such as,

```
In [126]: s = pd.Series([True, False, True])
```

```
In [127]: s.replace('a string', 'another string')
```

```
Out [127]:
0      True
1     False
2      True
dtype: bool

```

the original NDFrame object will be returned untouched. We're working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See [GH6354](#) for more details.

## Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we've established some "casting rules". When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

data type	Cast to
integer	float
boolean	object
float	no cast
object	no cast

For example:

```
In [128]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [129]: s > 0
Out[129]:
0    True
2    True
4    True
6    True
7    True
dtype: bool

In [130]: (s > 0).dtype
\\Out[130]:
↳dtype('bool')
```

```
In [131]: crit = (s > 0).reindex(list(range(8)))

In [132]: crit
Out[132]:
0    True
1    NaN
2    True
3    NaN
4    True
5    NaN
6    True
7    True
dtype: object

In [133]: crit.dtype
\\Out[133]:
↳dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```
In [134]: reindexed = s.reindex(list(range(8))).fillna(0)

In [135]: reindexed[crit]
-----
ValueError                                Traceback (most recent call last)
```

(continues on next page)

(continued from previous page)

```
<ipython-input-135-0dac417a4890> in <module>
----> 1 reindexed[crit]

/pandas/pandas/core/series.py in __getitem__(self, key)
    906         key = list(key)
    907
--> 908         if com.is_bool_indexer(key):
    909             key = check_bool_indexer(self.index, key)
    910

/pandas/pandas/core/common.py in is_bool_indexer(key)
    122         if not lib.is_bool_array(key):
    123             if isna(key).any():
--> 124                 raise ValueError(na_msg)
    125             return False
    126         return True

ValueError: cannot index with vector containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```
In [136]: reindexed[crit.fillna(False)]
Out[136]:
0    0.126504
2    0.696198
4    0.697416
6    0.601516
7    0.003659
dtype: float64

In [137]: reindexed[crit.fillna(True)]
Out[137]:
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64
```

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

```
In [138]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")

In [139]: s
Out[139]:
0    0
1    1
2    NaN
3    3
4    4
dtype: Int64
```

See *Nullable Integer Data Type* for more.

## 4.8 Categorical Data

This is an introduction to pandas categorical data type, including a short comparison with R's `factor`.

*Categoricals* are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (*categories*; *levels* in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. 'strongly agree' vs 'agree' or 'first observation' vs. 'second observation'), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in *categories* or *np.nan*. Order is defined by the order of *categories*, not lexical order of the values. Internally, the data structure consists of a *categories* array and an integer array of *codes* which point to the real value in the *categories* array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see *here*.
- The lexical order of a variable is not the same as the logical order ("one", "two", "three"). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see *here*.
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the *API docs on categoricals*.

### 4.8.1 Object Creation

#### Series Creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [2]: s
Out[2]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]
```

By converting an existing Series or column to a category dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [4]: df["B"] = df["A"].astype('category')

In [5]: df
```

(continues on next page)

(continued from previous page)

```

Out [5]:
   A B
0  a a
1  b b
2  c c
3  a a

```

By using special functions, such as `cut()`, which groups data into discrete bins. See the *example on tiling* in the docs.

```

In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})
In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
In [9]: df.head(10)
Out [9]:
   value  group
0     65  60 - 69
1     49  40 - 49
2     56  50 - 59
3     43  40 - 49
4     43  40 - 49
5     91  90 - 99
6     32  30 - 39
7     87  80 - 89
8     36  30 - 39
9      8   0 - 9

```

By passing a `pandas.Categorical` object to a `Series` or assigning it to a `DataFrame`.

```

In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"],
.....:                             ordered=False)
.....:
In [11]: s = pd.Series(raw_cat)
In [12]: s
Out [12]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b, c, d]
In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [14]: df["B"] = raw_cat
In [15]: df
Out [15]:
   A    B
0  a  NaN
1  b   b

```

(continues on next page)

(continued from previous page)

```
2 c c
3 a NaN
```

Categorical data has a specific *category dtype*:

```
In [16]: df.dtypes
Out [16]:
A      object
B      category
dtype: object
```

## DataFrame Creation

Similar to the previous section where a single column was converted to categorical, all columns in a `DataFrame` can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the `DataFrame` constructor:

```
In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out [18]:
A      category
B      category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df['A']
Out [19]:
0      a
1      b
2      c
3      a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df['B']
Out [20]:
Out:
////////////////////////////////////Out
↪
0      b
1      c
2      c
3      d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

New in version 0.23.0.

Analogously, all columns in an existing `DataFrame` can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
```

(continues on next page)

(continued from previous page)

```
In [23]: df_cat.dtypes
Out [23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out [24]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]
```

```
In [25]: df_cat['B']
Out [25]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

## Controlling Behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `'category'`, use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype

In [27]: s = pd.Series(["a", "b", "c", "a"])

In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"],
.....:                                     ordered=True)
.....:

In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out [30]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b < c < d]
```

(continued from previous page)

```

0    a
1    b
2    c
3    a
dtype: object

In [41]: s2 = s.astype('category')

In [42]: s2
Out [42]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [43]: s2.astype(str)
Out [43]:
0    a
1    b
2    c
3    a
dtype: object

In [44]: np.asarray(s2)
Out [44]:
array(['a', 'b', 'c', 'a'], dtype=object)

```

---

**Note:** In contrast to R's *factor* function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

---

---

**Note:** In contrast to R's *factor* function, there is currently no way to assign/change labels at creation time. Use *categories* to change the categories after creation time.

---

## 4.8.2 CategoricalDtype

Changed in version 0.21.0.

A categorical's type is fully described by

1. *categories*: a sequence of unique values and no missing values
2. *ordered*: a boolean

This information can be stored in a `CategoricalDtype`. The *categories* argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```
In [45]: from pandas.api.types import CategoricalDtype
```

(continues on next page)

(continued from previous page)

```
In [55]: df.describe()
Out [55]:
      cat  s
count    3  3
unique    2  2
top       c  c
freq     2  2

In [56]: df["cat"].describe()
\\Out [56]:
↪
count    3
unique    2
top       c
freq     2
Name: cat, dtype: object
```

### 4.8.4 Working with categories

Categorical data has a *categories* and a *ordered* property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [58]: s.cat.categories
Out [58]: Index(['a', 'b', 'c'], dtype='object')
In [59]: s.cat.ordered
\\Out [59]: False
```

It's also possible to pass in the categories in a specific order:

```
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"],
    ...:                             categories=["c", "b", "a"]))
In [61]: s.cat.categories
Out [61]: Index(['c', 'b', 'a'], dtype='object')
In [62]: s.cat.ordered
\\Out [62]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

**Note:** The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```
In [63]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd')))
```

(continues on next page)

(continued from previous page)

```

In [64]: s
Out [64]:
0    b
1    a
2    b
3    c
dtype: category
Categories (4, object): [a, b, c, d]

# categories
In [65]: s.cat.categories
Out [65]:
\\Out [65]:
↪Index(['a', 'b', 'c', 'd'], dtype='object')

# uniques
In [66]: s.unique()
Out [66]:
\\Out [66]:
↪
[b, a, c]
Categories (3, object): [b, a, c]

```

## Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```

In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [68]: s
Out [68]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [70]: s
Out [70]:
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out [72]:
0    1
1    2

```

(continues on next page)

(continued from previous page)

```

2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

In [74]: s
Out[74]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]

```

---

**Note:** In contrast to R's *factor*, categorical data can have categories of other types than string.

---

---

**Note:** Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

---

Categories must be unique or a `ValueError` is raised:

```

In [75]: try:
.....:     s.cat.categories = [1, 1, 1]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories must be unique

```

Categories must also not be NaN or a `ValueError` is raised:

```

In [76]: try:
.....:     s.cat.categories = [1, 2, np.nan]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories cannot be null

```

## Appending new categories

Appending categories can be done by using the `add_categories()` method:

```

In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
\\Out[79]:

```

(continues on next page)

(continued from previous page)

```

0    x
1    y
2    z
3    x
dtype: category
Categories (4, object): [x, y, z, 4]

```

## Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```

In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out [81]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]

```

## Removing unused categories

Removing unused categories can also be done:

```

In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"],
....:                               categories=["a", "b", "c", "d"]))
....:

In [83]: s
Out [83]:
0    a
1    b
2    a
dtype: category
Categories (4, object): [a, b, c, d]

In [84]: s.cat.remove_unused_categories()
Out [84]:
↪
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]

```

## Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a *new* object.

```
In [95]: s.cat.as_ordered()
Out [95]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a < b < c]

In [96]: s.cat.as_unordered()
Out [96]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a, b, c]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
In [99]: s
Out [99]:
0      1
1      2
2      3
3      1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [100]: s.sort_values(inplace=True)
In [101]: s
Out [101]:
1      2
2      3
0      1
3      1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [102]: s.min(), s.max()
Out [102]:
(2, 1)
```

## Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old

categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)

In [105]: s
Out[105]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
\\Out[108]:
↪ (2, 1)
```

**Note:** Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

**Note:** If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

### Multi Column Sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

```
In [109]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'),
.....:                                     categories=['e', 'a', 'b'],
.....:                                     ordered=True),
.....:                       'B': [1, 2, 1, 2, 2, 1, 2, 1]})

In [110]: dfs.sort_values(by=['A', 'B'])
```

(continues on next page)

(continued from previous page)

**Out [110]:**

```

   A  B
2  e  1
3  e  2
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2

```

Reordering the categories changes a future sort.

```
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])
```

```
In [112]: dfs.sort_values(by=['A', 'B'])
```

**Out [112]:**

```

   A  B
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
2  e  1
3  e  2

```

## 4.8.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered==True` and the *categories* are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

---

**Note:** Any “non-equality” comparisons of categorical data with a Series, `np.array`, list or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

---

```
In [113]: cat = pd.Series([1, 2, 3]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:
```

```
In [114]: cat_base = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
```

(continues on next page)

(continued from previous page)

```

.....:
In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:

In [116]: cat
Out[116]:
0    1
1    2
2    3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base
Out[117]:
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [118]: cat_base2
Out[118]:
0    2
1    2
2    2
dtype: category
Categories (1, int64): [2]

```

Comparing to a categorical with the same categories and ordering or to a scalar works:

```

In [119]: cat > cat_base
Out[119]:
0    True
1   False
2   False
dtype: bool

In [120]: cat > 2
Out[120]:
0    True
1   False
2   False
dtype: bool

```

Equality comparisons work with any list-like object of same length and scalars:

```

In [121]: cat == cat_base
Out[121]:
0   False
1    True
2   False
dtype: bool

```

(continues on next page)

(continued from previous page)

```

In [122]: cat == np.array([1, 2, 3])
\\Out[122]:
0    True
1    True
2    True
dtype: bool

In [123]: cat == 2
\\
↪
0    False
1     True
2    False
dtype: bool

```

This doesn't work because the categories are not the same:

```

In [124]: try:
.....:     cat > cat_base2
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Comparisons can only be made between identical datatypes (e.g.
↪are different lengths

```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```

In [125]: base = np.array([1, 2, 3])

In [126]: try:
.....:     cat > base
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray
↪'.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
\\
↪array([False, False, False], dtype=bool)

```

When you compare two unordered categoricals with the same categories, the order is not considered:

```

In [128]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)

In [129]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)

In [130]: c1 == c2
Out[130]: array([ True,  True], dtype=bool)

```

## 4.8.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

`Series` methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"],
.....:                               categories=["c", "a", "b", "d"]))
.....:

In [132]: s.value_counts()
Out[132]:
c    2
b    1
a    1
d    0
dtype: int64
```

`Groupby` will also show “unused” categories:

```
In [133]: cats = pd.Categorical(["a", "b", "b", "b", "c", "c", "c"],
.....:                           categories=["a", "b", "c", "d"])
.....:

In [134]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})

In [135]: df.groupby("cats").mean()
Out[135]:
      values
cats
a         1.0
b         2.0
c         4.0
d         NaN

In [136]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [137]: df2 = pd.DataFrame({"cats": cats2,
.....:                       "B": ["c", "d", "c", "d"],
.....:                       "values": [1, 2, 3, 4]})
.....:

In [138]: df2.groupby(["cats", "B"]).mean()
Out[138]:
      values
cats B
a    c     1.0
     d     2.0
b    c     3.0
     d     4.0
c    c     NaN
     d     NaN
```

Pivot tables:

```
In [139]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])
```

```
In [140]: df = pd.DataFrame({"A": raw_cat,
.....:                      "B": ["c", "d", "c", "d"],
.....:                      "values": [1, 2, 3, 4]})
.....:
```

```
In [141]: pd.pivot_table(df, values='values', index=['A', 'B'])
```

```
Out[141]:
      values
```

A	B	values
a	c	1
	d	2
b	c	3
	d	4

## 4.8.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in *categories* can be assigned.

### Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the `category` dtype is preserved.

```
In [142]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
```

```
In [143]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"],
.....:                      dtype="category", index=idx)
.....:
```

```
In [144]: values = [1, 2, 2, 2, 3, 4, 5]
```

```
In [145]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
```

```
In [146]: df.iloc[2:4, :]
```

```
Out[146]:
      cats  values
j      b         2
k      b         2
```

```
In [147]: df.iloc[2:4, :].dtypes
```

```
Out[147]:
cats      category
values    int64
dtype: object
```

```
In [148]: df.loc["h":"j", "cats"]
```

```
Out[148]:
h      a
i      b
j      b
Name: cats, dtype: category
```

(continues on next page)

(continued from previous page)

```
Categories (3, object): [a, b, c]
```

```
In [149]: df[df["cats"] == "b"]
```

```

////////////////////////////////////
→
  cats  values
i     b      2
j     b      2
k     b      2

```

An example where the category type is not preserved is if you take one single row: the resulting `Series` is of dtype `object`:

```
# get the complete "h" row as a Series
```

```
In [150]: df.loc["h", :]
```

```
Out [150]:
```

```

cats      a
values    1
Name: h, dtype: object

```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```
In [151]: df.iat[0, 0]
```

```
Out [151]: 'a'
```

```
In [152]: df["cats"].cat.categories = ["x", "y", "z"]
```

```
In [153]: df.at["h", "cats"] # returns a string
```

```
Out [153]: 'x'
```

---

**Note:** This is in contrast to R’s `factor` function, where `factor(c(1,2,3))[1]` returns a single value `factor`.

---

To get a single value `Series` of type `category`, you pass in a list with a single value:

```
In [154]: df.loc[["h"], "cats"]
```

```
Out [154]:
```

```

h      x
Name: cats, dtype: category
Categories (3, object): [x, y, z]

```

## String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [155]: str_s = pd.Series(list('aabb'))
```

```
In [156]: str_cat = str_s.astype('category')
```

```
In [157]: str_cat
```

```
Out [157]:
```

```

0      a
1      a
2      b

```

(continues on next page)

(continued from previous page)

```

3      b
dtype: category
Categories (2, object): [a, b]

In [158]: str_cat.str.contains("a")
Out[158]:
0      True
1      True
2     False
3     False
dtype: bool

In [159]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))

In [160]: date_cat = date_s.astype('category')

In [161]: date_cat
Out[161]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]

In [162]: date_cat.dt.day
Out[162]:
0      1
1      2
2      3
3      4
4      5
dtype: int64

```

---

**Note:** The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a Series of that type (and not of type `category`!).

---

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type `category` will be equal:

```

In [163]: ret_s = str_s.str.contains("a")

In [164]: ret_cat = str_cat.str.contains("a")

In [165]: ret_s.dtype == ret_cat.dtype
Out[165]: True

In [166]: ret_s == ret_cat
Out[166]:

```

(continues on next page)

(continued from previous page)

```

h    a    1
i    a    1
j    a    2
k    a    2
l    a    1
m    a    1
n    a    1

In [176]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"],
.....:                                             categories=["a", "b", "c"])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
////////////////////////////////////
↪Cannot set a Categorical with another, without identical categories

```

Assigning a Categorical to parts of a column of other types will use the values:

```

In [177]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [178]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [179]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [180]: df
Out[180]:
   a  b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [181]: df.dtypes
Out[181]:
a    object
b    object
dtype: object

```

## Merging

You can concat two DataFrames containing categorical data together, but the categories of these categoricals need to be the same:

```

In [182]: cat = pd.Series(["a", "b"], dtype="category")

In [183]: vals = [1, 2]

In [184]: df = pd.DataFrame({"cats": cat, "vals": vals})

In [185]: res = pd.concat([df, df])

In [186]: res
Out[186]:

```

(continues on next page)

(continued from previous page)

```

   cats  vals
0     a     1
1     b     2
0     a     1
1     b     2

In [187]: res.dtypes
Out[187]:
cats     category
vals     int64
dtype: object

```

In this case the categories are not the same, and therefore an error is raised:

```

In [188]: df_different = df.copy()

In [189]: df_different["cats"].cat.categories = ["c", "d"]

In [190]: try:
.....:     pd.concat([df, df_different])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:

```

The same applies to `df.append(df_different)`.

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

## Unioning

New in version 0.19.0.

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```

In [191]: from pandas.api.types import union_categoricals

In [192]: a = pd.Categorical(["b", "c"])

In [193]: b = pd.Categorical(["a", "b"])

In [194]: union_categoricals([a, b])
Out[194]:
[b, c, a, b]
Categories (3, object): [b, c, a]

```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexicographically sorted, use `sort_categories=True` argument.

```

In [195]: union_categoricals([a, b], sort_categories=True)
Out[195]:
[b, c, a, b]
Categories (3, object): [a, b, c]

```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [196]: a = pd.Categorical(["a", "b"], ordered=True)
In [197]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [198]: union_categoricals([a, b])
Out[198]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [199]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [200]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [201]: union_categoricals([a, b], ignore_order=True)
Out[201]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [202]: a = pd.Series(["b", "c"], dtype='category')
In [203]: b = pd.Series(["a", "b"], dtype='category')
In [204]: union_categoricals([a, b])
Out[204]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [205]: c1 = pd.Categorical(["b", "c"])
In [206]: c2 = pd.Categorical(["a", "b"])
In [207]: c1
Out[207]:
[b, c]
Categories (2, object): [b, c]
# "b" is coded to 0
```

(continues on next page)

(continued from previous page)

```

In [208]: c1.codes
Out[208]: array([0, 1], dtype=int8)

In [209]: c2
Out[209]:
↪
[a, b]
Categories (2, object): [a, b]

# "b" is coded to 1
In [210]: c2.codes
Out[210]:
↪array([0, 1], dtype=int8)

In [211]: c = union_categoricals([c1, c2])

In [212]: c
Out[212]:
[b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [213]: c.codes
Out[213]: array([0, 1, 2, 1,
↪0], dtype=int8)

```

## Concatenation

This section describes concatenations specific to `category` dtype. See *Concatenating objects* for general description.

By default, `Series` or `DataFrame` concatenation which contains the same categories results in `category` dtype, otherwise results in `object` dtype. Use `.astype` or `union_categoricals` to get category result.

```

# same categories
In [214]: s1 = pd.Series(['a', 'b'], dtype='category')

In [215]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [216]: pd.concat([s1, s2])
Out[216]:
0    a
1    b
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]

# different categories
In [217]: s3 = pd.Series(['b', 'c'], dtype='category')

In [218]: pd.concat([s1, s3])
Out[218]:
0    a

```

(continues on next page)

(continued from previous page)

```
1    b
0    b
1    c
dtype: object
```

```
In [219]: pd.concat([s1, s3]).astype('category')
Out[219]:
0    a
1    b
0    b
1    c
dtype: category
Categories (3, object): [a, b, c]
```

```
In [220]: union_categoricals([s1.array, s3.array])
Out[220]:
[a, b, b, c]
Categories (3, object): [a, b, c]
```

Following table summarizes the results of `Categoricals` related concatenations.

arg1	arg2	result
category	category (identical categories)	category
category	category (different categories, both not ordered)	object (dtype is inferred)
category	category (different categories, either one is ordered)	object (dtype is inferred)
category	not category	object (dtype is inferred)

## 4.8.9 Getting Data In/Out

You can write data that contains `category` dtypes to a `HDFStore`. See [here](#) for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to `category` and assign the right categories and categories ordering.

```
In [221]: import io

In [222]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories
In [223]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [224]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [225]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})

In [226]: csv = io.StringIO()

In [227]: df.to_csv(csv)

In [228]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))
```

(continues on next page)

(continued from previous page)

```

In [229]: df2.dtypes
Out [229]:
Unnamed: 0      int64
cats           object
vals           int64
dtype: object

In [230]: df2["cats"]
Out [230]:
↪
0      very good
1         good
2         good
3      very good
4      very good
5         bad
Name: cats, dtype: object

# Redo the category
In [231]: df2["cats"] = df2["cats"].astype("category")

In [232]: df2["cats"].cat.set_categories(["very bad", "bad", "medium",
.....:                                  "good", "very good"],
.....:                                  inplace=True)
.....:

In [233]: df2.dtypes
Out [233]:
Unnamed: 0      int64
cats           category
vals           int64
dtype: object

In [234]: df2["cats"]
Out [234]:
↪
0      very good
1         good
2         good
3      very good
4      very good
5         bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

```

The same holds for writing to a SQL database with `to_sql`.

#### 4.8.10 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data section*.

Missing values should **not** be included in the Categorical's `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical's `codes`, missing values will always have a code of `-1`.

```
In [235]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")
```

```
# only two categories
```

```
In [236]: s
```

```
Out [236]:
```

```
0      a
1      b
2     NaN
3      a
dtype: category
Categories (2, object): [a, b]
```

```
In [237]: s.cat.codes
```

```
Out [237]:
0      0
1      1
2     -1
3      0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [238]: s = pd.Series(["a", "b", np.nan], dtype="category")
```

```
In [239]: s
```

```
Out [239]:
```

```
0      a
1      b
2     NaN
dtype: category
Categories (2, object): [a, b]
```

```
In [240]: pd.isna(s)
```

```
Out [240]:
0      False
1      False
2       True
dtype: bool
```

```
In [241]: s.fillna("a")
```

```
Out [241]:
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]
```

#### 4.8.11 Differences to R's *factor*

The following differences to R's factor functions can be observed:

- R's *levels* are named *categories*.
- R's *levels* are always of type string, while *categories* in pandas can be of any dtype.

- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's `factor` function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its `levels` (pandas' `categories`). Pandas does not allow `NaN` categories, but missing values can still be in the `values`.

## 4.8.12 Gotchas

### Memory Usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object dtype` is a constant times the length of the data.

```
In [242]: s = pd.Series(['foo', 'bar'] * 1000)

# object dtype
In [243]: s.nbytes
Out[243]: 16000

# category dtype
In [244]: s.astype('category').nbytes
Out[244]: 2016
```

---

**Note:** If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object dtype` representation.

```
In [245]: s = pd.Series(['foo%04d' % i for i in range(2000)])

# object dtype
In [246]: s.nbytes
Out[246]: 16000

# category dtype
In [247]: s.astype('category').nbytes
Out[247]: 20000
```

### *Categorical* is not a *numpy* array

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new `dtype`:

```
In [248]: try:
.....:     np.dtype("category")
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type "category" not understood
```

(continues on next page)

(continued from previous page)

```
In [249]: dtype = pd.Categorical(["a"]).dtype
In [250]: try:
.....:     np.dtype(dtype)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type not understood
```

Dtype comparisons work:

```
In [251]: dtype == np.str_
Out[251]: False

In [252]: np.str_ == dtype
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[252]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [253]: hasattr(pd.Series(['a'], dtype='category'), 'cat')
Out[253]: True

In [254]: hasattr(pd.Series(['a']), 'cat')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[254]: False
```

Using NumPy functions on a Series of type category should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [255]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))

In [256]: try:
.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categorical cannot perform the operation sum
```

**Note:** If such a function works, please file a bug at <https://github.com/pandas-dev/pandas!>

## dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a *Series* of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

```
In [257]: df = pd.DataFrame({"a": [1, 2, 3, 4],
.....:                      "b": ["a", "b", "c", "d"],
.....:                      "cats": pd.Categorical([1, 2, 3, 2])})
.....:

In [258]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[258]:
```

(continues on next page)

(continued from previous page)

```

0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object

```

```
In [259]: df.apply(lambda col: col.dtype, axis=0)
```

```

////////////////////////////////////
↪
a          int64
b          object
cats      category
dtype: object

```

## Categorical Index

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements. See the *advanced indexing docs* for a more detailed explanation.

Setting the index will create a `CategoricalIndex`:

```
In [260]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])
```

```
In [261]: strings = ["a", "b", "c", "d"]
```

```
In [262]: values = [4, 2, 3, 1]
```

```
In [263]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)
```

```
In [264]: df.index
```

```
Out [264]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False,
↪ dtype='category')
```

```
# This now sorts by the categories order
```

```
In [265]: df.sort_index()
```

```

////////////////////////////////////
↪
  strings  values
4         d         1
2         b         2
3         c         3
1         a         4

```

## Side Effects

Constructing a `Series` from a `Categorical` will not copy the input `Categorical`. This means that changes to the `Series` will in most cases change the original `Categorical`:

```
In [266]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
```

```
In [267]: s = pd.Series(cat, name="cat")
```

```
In [268]: cat
```

(continues on next page)

(continued from previous page)

```
Out [268]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

```
In [269]: s.iloc[0:2] = 10
```

```
In [270]: cat
```

```
Out [270]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

```
In [271]: df = pd.DataFrame(s)
```

```
In [272]: df["cat"].cat.categories = [1, 2, 3, 4, 5]
```

```
In [273]: cat
```

```
Out [273]:
[5, 5, 3, 5]
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse Categoricals:

```
In [274]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
```

```
In [275]: s = pd.Series(cat, name="cat", copy=True)
```

```
In [276]: cat
```

```
Out [276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

```
In [277]: s.iloc[0:2] = 10
```

```
In [278]: cat
```

```
Out [278]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

---

**Note:** This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. `np.array([1, 2, 3, 4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a", "b", "c", "a"])`) will not.

---

## 4.9 Nullable Integer Data Type

New in version 0.24.0.

---

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

---

In *Working with missing data*, we saw that pandas primarily uses NaN to represent missing data. Because NaN is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not

matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

Pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an *extension types* implemented within pandas. It is not the default dtype for integers, and will not be inferred; you must explicitly pass the dtype into `array()` or `Series`:

```
In [1]: arr = pd.array([1, 2, np.nan], dtype=pd.Int64Dtype())

In [2]: arr
Out [2]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy's 'int64' dtype):

```
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out [3]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

This array can be stored in a `DataFrame` or `Series` like any NumPy array.

```
In [4]: pd.Series(arr)
Out [4]:
0      1
1      2
2     NaN
dtype: Int64
```

You can also pass the list-like object to the `Series` constructor with the dtype.

```
In [5]: s = pd.Series([1, 2, np.nan], dtype="Int64")

In [6]: s
Out [6]:
0      1
1      2
2     NaN
dtype: Int64
```

By default (if you don't specify dtype), NumPy is used, and you'll end up with a `float64` dtype `Series`:

```
In [7]: pd.Series([1, 2, np.nan])
Out [7]:
0      1.0
1      2.0
2     NaN
dtype: float64
```

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and and the data will be coerced to another dtype if needed.

```
# arithmetic
In [8]: s + 1
Out [8]:
```

(continues on next page)

(continued from previous page)

```

0      2
1      3
2     NaN
dtype: Int64

# comparison
In [9]: s == 1
\\Out [9]:
0      True
1     False
2     False
dtype: bool

# indexing
In [10]: s.iloc[1:3]
\\Out [10]:
→
1      2
2     NaN
dtype: Int64

# operate with other dtypes
In [11]: s + s.iloc[1:3].astype('Int8')
\\Out [11]:
→
0     NaN
1      4
2     NaN
dtype: Int64

# coerce when needed
In [12]: s + 0.01
\\Out [12]:
→
0     1.01
1     2.01
2     NaN
dtype: float64

```

These dtypes can operate as part of DataFrame.

```

In [13]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})

In [14]: df
Out [14]:
   A  B  C
0  1  1  a
1  2  1  a
2 NaN  3  b

In [15]: df.dtypes
\\Out [15]:
A      Int64
B      int64
C      object
dtype: object

```

```

In [3]: ts = pd.Series(np.random.randn(1000),
...:                  index=pd.date_range('1/1/2000', periods=1000))
...:
In [4]: ts = ts.cumsum()
In [5]: ts.plot()
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e601f438>

```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On `DataFrame`, `plot()` is a convenience to plot all of the columns with labels:

```

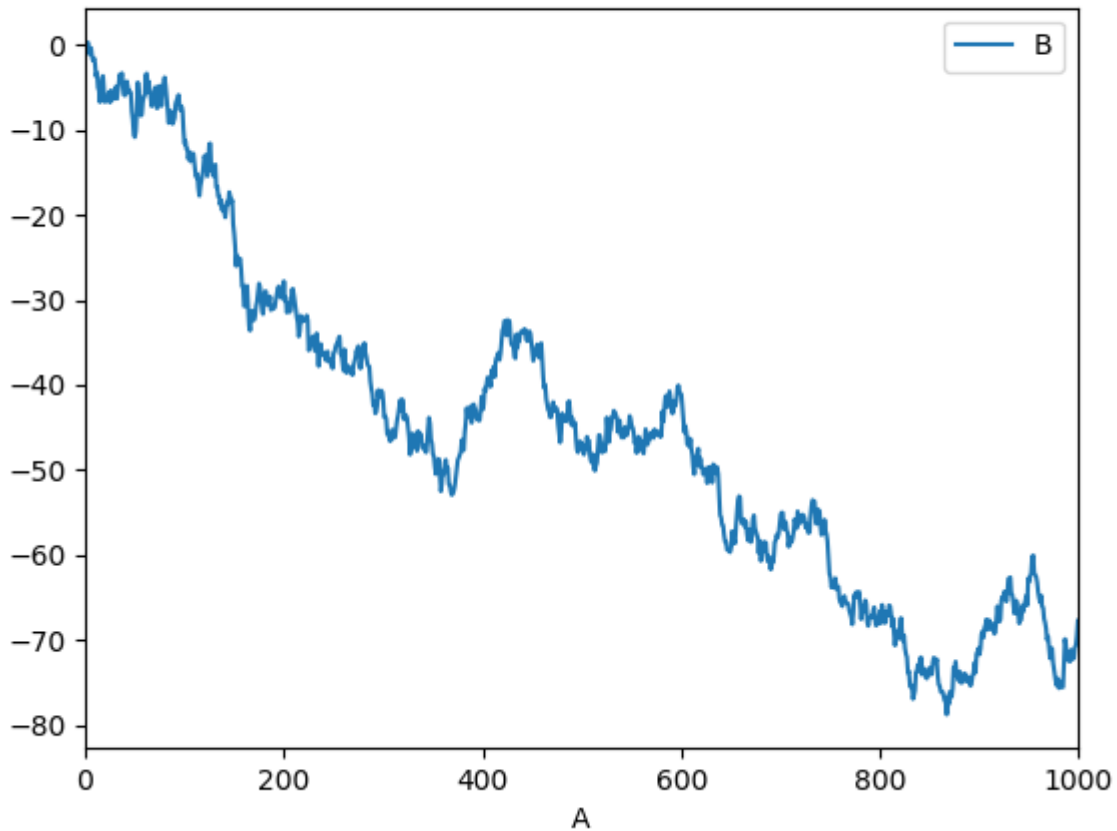

In [6]: df = pd.DataFrame(np.random.randn(1000, 4),
...:                      index=ts.index, columns=list('ABCD'))
...:
In [7]: df = df.cumsum()
In [8]: plt.figure();
In [9]: df.plot();

```

You can plot one column versus another using the *x* and *y* keywords in `plot()`:

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [11]: df3['A'] = pd.Series(list(range(len(df))))
In [12]: df3.plot(x='A', y='B')
Out [12]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a0e2f1f60>
```

---

**Note:** For more formatting and styling options, see *formatting* below.

---

### 4.10.2 Other Plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `'bar'` or `'barh'` for bar plots
- `'hist'` for histogram
- `'box'` for boxplot
- `'kde'` or `'density'` for density plots
- `'area'` for area plots
- `'scatter'` for scatter plots
- `'hexbin'` for hexagonal bin plots
- `'pie'` for pie plots

For example, a bar plot can be created the following way:

```
In [13]: plt.figure();
```

```
In [14]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [15]: df = pd.DataFrame()
```

```
In [16]: df.plot.<TAB> # noqa: E225, E999
```

```
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist     df.plot.line     ↵
↳df.plot.scatter
df.plot.bar       df.plot.box       df.plot.hexbin   df.plot.kde      df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*

- *Lag Plot*
- *Autocorrelation Plot*
- *Bootstrap Plot*
- *RadViz*

Plots may also be adorned with *errorbars* or *tables*.

## Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();
```

```
In [18]: df.iloc[5].plot.bar()
```

```
Out[18]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1e5a5400>
```

```
In [19]: plt.axhline(0, color='k');
```

Calling a `DataFrame`'s `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
In [21]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [23]: df2.plot.barh(stacked=True);
```

## Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [24]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.
↳randn(1000),
      ....:                  'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])
      ....:

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5)
Out [26]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1c2a3898>
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [27]: plt.figure();
```

```
In [28]: df4.plot.hist(stacked=True, bins=20)
```

```
Out [28]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1c1cb5f8>
```

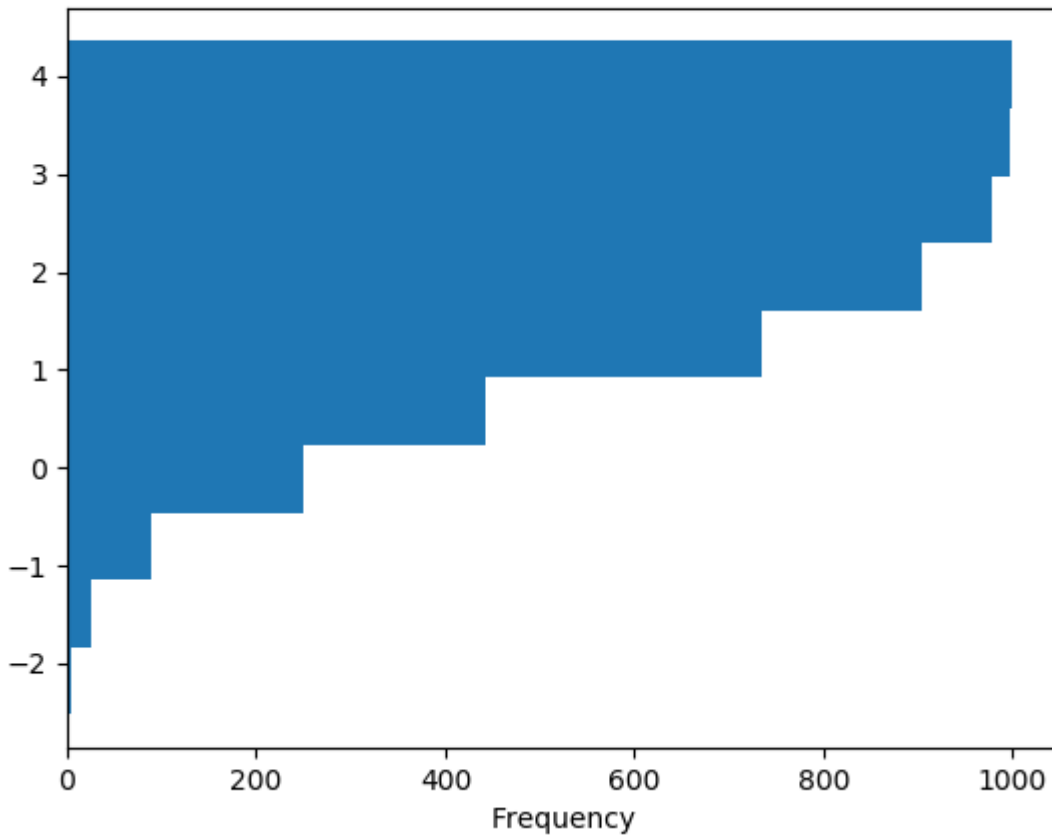

You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();
```

```
In [30]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
```

```
Out [30]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e515afd0>
```

See the [hist](#) method and the [matplotlib hist](#) documentation for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [31]: plt.figure();
```

```
In [32]: df['A'].diff().hist()
```

```
Out [32]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e4eeb5f8>
```

`DataFrame.hist()` plots the histograms of the columns on multiple subplots:

```
In [33]: plt.figure()
Out[33]: <Figure size 640x480 with 0 Axes>

In [34]: df.diff().hist(color='k', alpha=0.5, bins=50)
Out[34]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f79e5246e10>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7f79e5dab0b8>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7f79e6062320>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7f79e6046588>]],
      dtype=object)
```

The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))
```

```
In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
```

```
Out [36]:
```

```
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f79e52ae320>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7f79e5280da0>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x7f79e4e75048>,
         <matplotlib.axes._subplots.AxesSubplot object at 0x7f79e4dc92b0>]],
      dtype=object)
```

## Box Plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
```

```
In [38]: df.plot.box()
```

```
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e69666a0>
```

Boxplot can be colored by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the boxes, whiskers, medians and caps colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [39]: color = {'boxes': 'DarkGreen', 'whiskers': 'DarkOrange',
.....:           'medians': 'DarkBlue', 'caps': 'Gray'}
.....:

In [40]: df.plot.box(color=color, sym='r+')
Out [40]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e6961160>
```

Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out [41]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e5df4fd0>
```

See the `boxplot` method and the `matplotlib boxplot` documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [42]: df = pd.DataFrame(np.random.rand(10, 5))
```

```
In [43]: plt.figure();
```

```
In [44]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
In [46]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [47]: plt.figure();
In [48]: bp = df.boxplot(by='X')
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
In [50]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [51]: df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A', 'B', 'A', 'B', 'A', 'B'])
In [52]: plt.figure();
In [53]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

**Warning:** The default changed from 'dict' to 'axes' in version 0.19.0.

In `boxplot`, the return type can be controlled by the `return_type`, keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<code>return_type=</code>	Faceted	Output type
None	No	axes
None	Yes	2-D ndarray of axes
'axes'	No	axes
'axes'	Yes	Series of axes
'dict'	No	dict of artists
'dict'	Yes	Series of dicts of artists
'both'	No	namedtuple
'both'	Yes	Series of namedtuples

`Groupby.boxplot` always returns a `Series` of `return_type`.

```

In [54]: np.random.seed(1234)

In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))

In [56]: df_box['g'] = np.random.choice(['A', 'B'], size=50)

In [57]: df_box.loc[df_box['g'] == 'B', 1] += 3

In [58]: bp = df_box.boxplot(by='g')

```

The subplots above are split by the numeric columns first, then the value of the `g` column. Below the subplots are first split by the value of `g`, then by the numeric columns.

```

In [59]: bp = df_box.groupby('g').boxplot()

```

## Area Plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains *NaN*, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [61]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [62]: df.plot.area(stacked=False);
```

## Scatter Plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [64]: df.plot.scatter(x='a', y='b');
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [65]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
```

```
In [66]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [67]: df.plot.scatter(x='a', y='b', c='c', s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the `DataFrame` as the bubble size.

```
In [68]: df.plot.scatter(x='a', y='b', s=df['c'] * 200);
```

See the `scatter` method and the [matplotlib scatter](#) documentation for more.

### Hexagonal Bin Plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
```

```
In [70]: df['b'] = df['b'] + np.arange(1000)
```

```
In [71]: df.plot.hexbin(x='a', y='b', gridsize=25)
```

```
Out [71]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79dfc44588>
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each  $(x, y)$  point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each  $(x, y)$  point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [72]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [73]: df['b'] = df['b'] + np.arange(1000)
In [74]: df['z'] = np.random.uniform(0, 3, 1000)
In [75]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)
Out[75]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79dfb61518>
```

See the `hexbin` method and the `matplotlib hexbin` documentation for more.

## Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [76]: series = pd.Series(3 * np.random.rand(4),
.....:                      index=['a', 'b', 'c', 'd'], name='series')
.....:

In [77]: series.plot.pie(figsize=(6, 6))
Out [77]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79dfb06518>
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with *DataFrame* requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [78]: df = pd.DataFrame(3 * np.random.rand(4, 2),
.....:                    index=['a', 'b', 'c', 'd'], columns=['x', 'y'])
.....:
```

```
In [79]: df.plot.pie(subplots=True, figsize=(8, 4))
```

```
Out [79]:
```

```
array([<matplotlib.axes._subplots.AxesSubplot object at 0x7f79dfac7748>,
```

(continues on next page)

(continued from previous page)

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7f79dfa83eb8>],  
dtype=object)
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [80]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],  
.....:                 autopct='%0.2f', fontsize=20, figsize=(6, 6))  
.....:  
.....:  
Out [80]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79dfa05908>
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [81]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
```

```
In [82]: series.plot.pie(figsize=(6, 6))
```

```
Out [82]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79df9c3ef0>
```

See the [matplotlib pie](#) documentation for more.

### 4.10.3 Plotting with Missing Data

Pandas tries to be pragmatic about plotting `DataFrames` or `Series` that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

Plot Type	NaN Handling
Line	Leave gaps at NaNs
Line (stacked)	Fill 0's
Bar	Fill 0's
Scatter	Drop NaNs
Histogram	Drop NaNs (column-wise)
Box	Drop NaNs (column-wise)
Area	Fill 0's
KDE	Drop NaNs (column-wise)
Hexbin	Drop NaNs
Pie	Fill 0's

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

#### 4.10.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a *Series* or *DataFrame* as an argument.

##### Scatter Matrix Plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [83]: from pandas.plotting import scatter_matrix

In [84]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [85]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
Out[85]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f79df932780>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df9579e8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df902c50>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df8aaeb8>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7f79df8dc160>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df8843c8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df82d2e8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df856588>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7f79df8565c0>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df7a8a20>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df7d1c88>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df778ef0>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7f79df72a198>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df753400>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df6fb668>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f79df6a48d0>]], dtype=object)
```

## Density Plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [86]: ser = pd.Series(np.random.randn(1000))
```

```
In [87]: ser.plot.kde()
```

```
Out[87]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79df56e6d8>
```

## Parallel Coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the [Wikipedia entry](#) for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [92]: from pandas.plotting import parallel_coordinates

In [93]: data = pd.read_csv('data/iris.data')

In [94]: plt.figure()
Out[94]: <Figure size 640x480 with 0 Axes>

In [95]: parallel_coordinates(data, 'Name')
Out[95]: <matplotlib.axes._subplots.
↳AxesSubplot at 0x7f79dfc8fac8>
```

## Lag Plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [96]: from pandas.plotting import lag_plot

In [97]: plt.figure()
Out[97]: <Figure size 640x480 with 0 Axes>

In [98]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [99]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [100]: lag_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e62f7e48>
```

### Autocorrelation Plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [101]: from pandas.plotting import autocorrelation_plot
In [102]: plt.figure()
Out[102]: <Figure size 640x480 with 0 Axes>
In [103]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
In [104]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
In [105]: autocorrelation_plot(data)
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1e1f9f98>
```

### Bootstrap Plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [106]: from pandas.plotting import bootstrap_plot
In [107]: data = pd.Series(np.random.rand(1000))
In [108]: bootstrap_plot(data, size=50, samples=500, color='grey')
Out[108]: <Figure size 640x480 with 6 Axes>
```

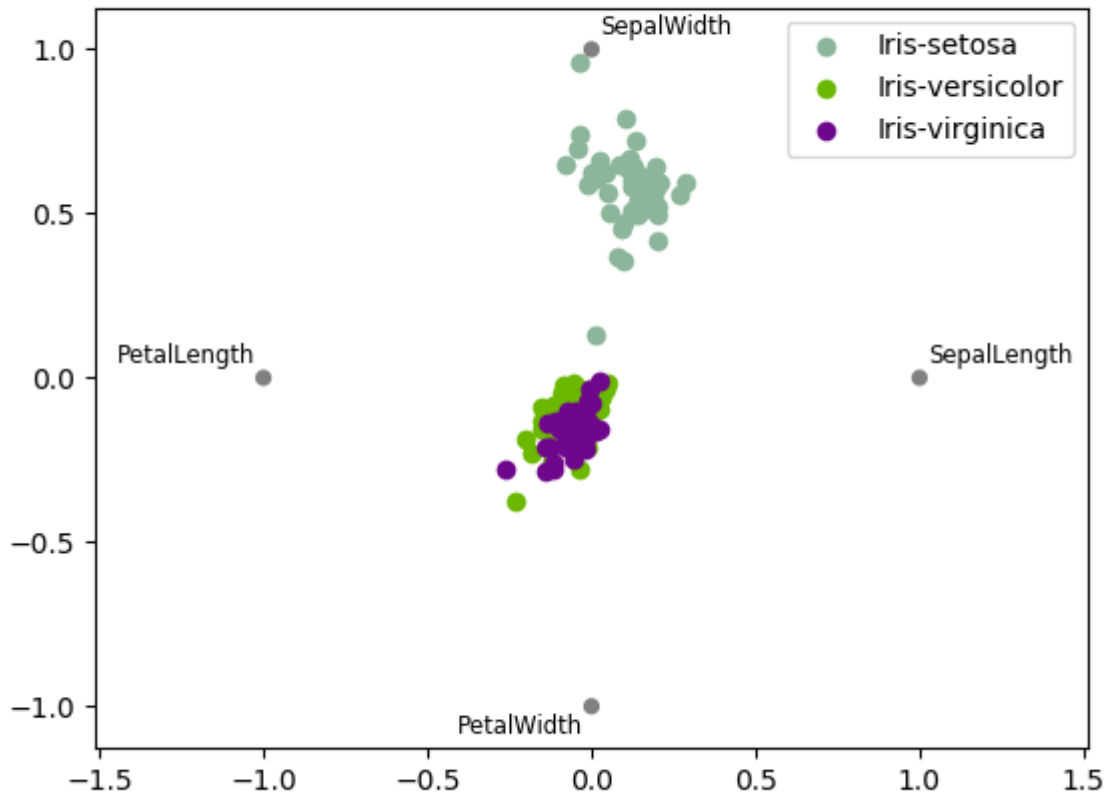

## RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs to it will be colored differently. See the R package [Radviz](#) for more information.

**Note:** The “Iris” dataset is available [here](#).

```
In [109]: from pandas.plotting import radviz
In [110]: data = pd.read_csv('data/iris.data')
In [111]: plt.figure()
Out[111]: <Figure size 640x480 with 0 Axes>
In [112]: radviz(data, 'Name')
Out[112]: <matplotlib.axes._subplots.
↳AxesSubplot at 0x7f79e431aef0>
```

## 4.10.5 Plot Formatting

### Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

### General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [113]: plt.figure();
In [114]: ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. *line*, *bar*, *scatter*) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

### Controlling the Legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [115]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                      index=ts.index, columns=list('ABCD'))
.....:

In [116]: df = df.cumsum()

In [117]: df.plot(legend=False)
Out[117]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e4f23828>
```

## Scales

You may pass `logy` to get a log-scale Y axis.

```
In [118]: ts = pd.Series(np.random.randn(1000),
.....:                  index=pd.date_range('1/1/2000', periods=1000))
.....:

In [119]: ts = np.exp(ts.cumsum())

In [120]: ts.plot(logy=True)
Out [120]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e647b048>
```

See also the `logx` and `loglog` keyword arguments.

### Plotting on a Secondary Y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [121]: df.A.plot()
Out [121]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79e6152b70>

In [122]: df.B.plot(secondary_y=True, style='g')
Out [122]:
↪<matplotlib.axes._subplots.AxesSubplot at 0x7f79e588a780>
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>

In [124]: ax = df.plot(secondary_y=['A', 'B'])

In [125]: ax.set_ylabel('CD scale')
Out[125]: Text(0, 0.5, 'CD scale')

In [126]: ax.right_ax.set_ylabel('AB scale')
Out[126]: Text(0, 0.5, 'AB scale')
```

### Suppressing Tick Resolution Adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [129]: plt.figure()
Out[129]: <Figure size 640x480 with 0 Axes>

In [130]: df.A.plot()
////////////////////////////////////Out[130]: <matplotlib.axes._subplots.
↪AxesSubplot at 0x7f79e56263c8>
```

If you have more than one plot that needs to be suppressed, the use method in `pandas.plotting.plot_params` can be used in a *with statement*:

```
In [133]: plt.figure()
Out[133]: <Figure size 640x480 with 0 Axes>

In [134]: with pd.plotting.plot_params.use('x_compat', True):
.....:     df.A.plot(color='r')
.....:     df.B.plot(color='g')
.....:     df.C.plot(color='b')
.....:
```

### Automatic Date Tick Adjustment

New in version 0.20.0.

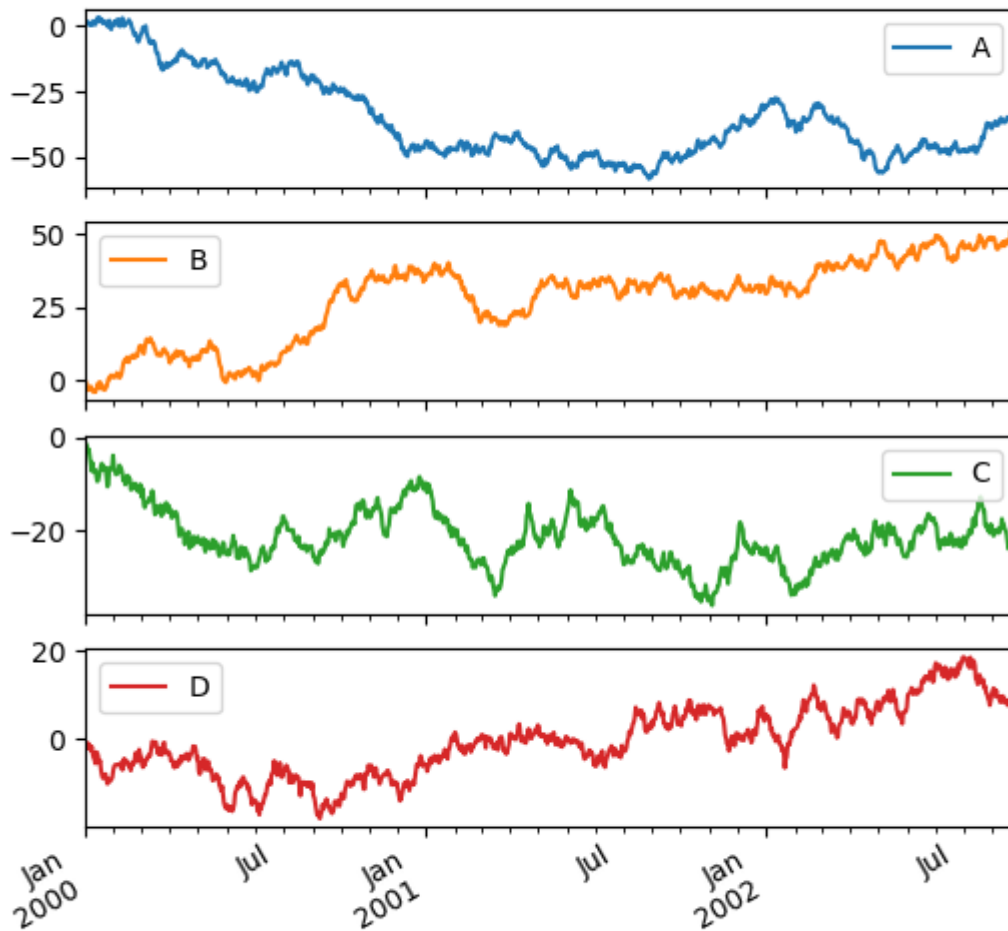

`TimeDeltaIndex` now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib documentation](#) for more.

### Subplots

Each `Series` in a `DataFrame` can be plotted on a different axis with the `subplots` keyword:

```
In [135]: df.plot(subplots=True, figsize=(6, 6));
```

### Using Layout and Targeting Multiple Axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by `rows x columns` specified by `layout` must be larger than the number of required subplots. If `layout` can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [136]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [137]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [138]: fig, axes = plt.subplots(4, 4, figsize=(6, 6))
```

```
In [139]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
```

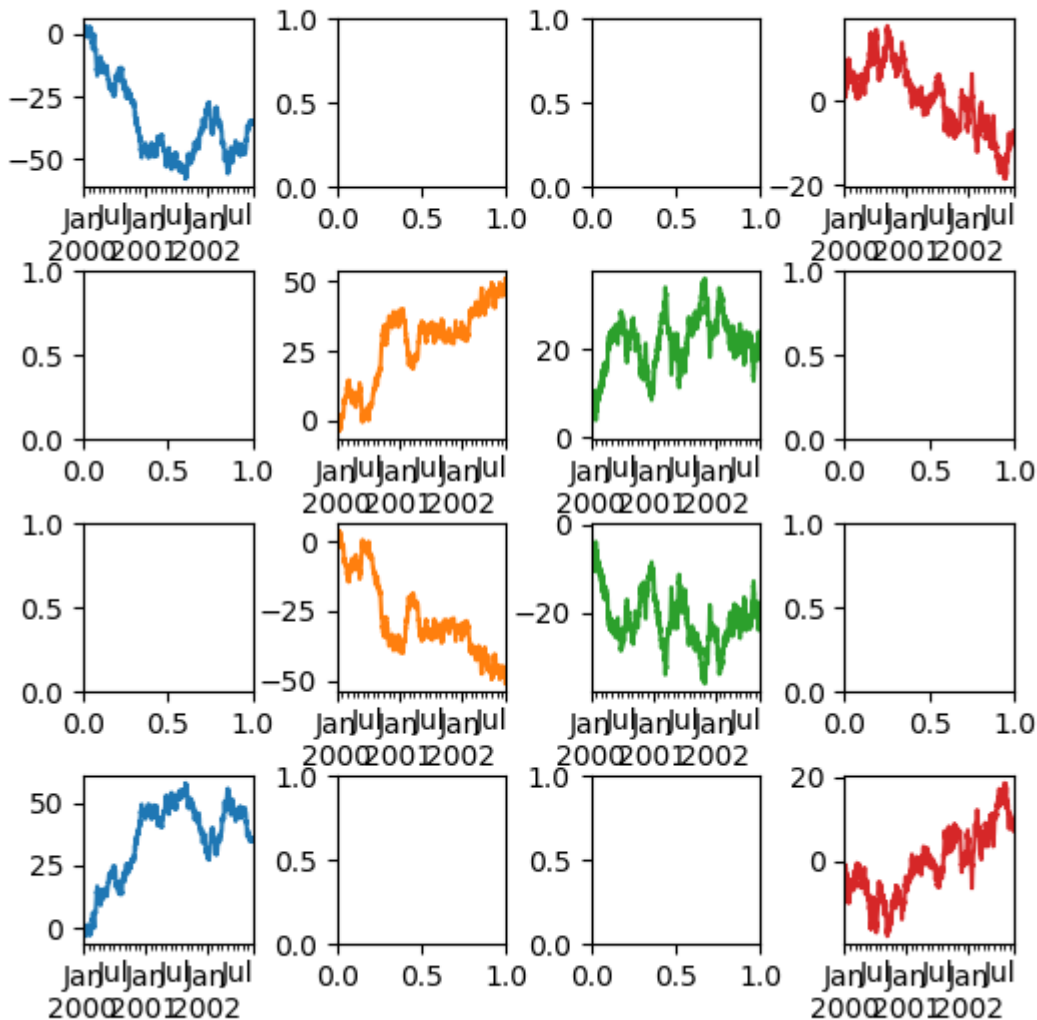

```
In [140]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
```

(continues on next page)

(continued from previous page)

```
In [141]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [142]: df.plot(subplots=True, ax=target1, legend=False, sharex=False,
→sharey=False);
In [143]: (-df).plot(subplots=True, ax=target2, legend=False,
.....:                sharex=False, sharey=False);
.....:
```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```
In [144]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [145]: df['A'].plot(ax=axes[0, 0]);
```

(continues on next page)

(continued from previous page)

```

In [146]: axes[0, 0].set_title('A');
In [147]: df['B'].plot(ax=axes[0, 1]);
In [148]: axes[0, 1].set_title('B');
In [149]: df['C'].plot(ax=axes[1, 0]);
In [150]: axes[1, 0].set_title('C');
In [151]: df['D'].plot(ax=axes[1, 1]);
In [152]: axes[1, 1].set_title('D');

```

### Plotting With Error Bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting

## Plotting Tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [162]: fig, ax = plt.subplots(1, 1)
In [163]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])
In [164]: ax.get_xaxis().set_visible(False) # Hide Ticks
In [165]: df.plot(table=True, ax=ax)
Out[165]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79de483400>
```

Also, you can pass a different `DataFrame` or `Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [166]: fig, ax = plt.subplots(1, 1)
In [167]: ax.get_xaxis().set_visible(False) # Hide Ticks
In [168]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[168]: <matplotlib.axes._subplots.AxesSubplot at 0x7f79de417320>
```

There also exists a helper function `pandas.plotting.table`, which creates a table from *DataFrame* or *Series*, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib.table` has.

```
In [169]: from pandas.plotting import table

In [170]: fig, ax = plt.subplots(1, 1)

In [171]: table(ax, np.round(df.describe(), 2),
.....:         loc='upper right', colWidths=[0.2, 0.2, 0.2])
.....:
Out[171]: <matplotlib.table.Table at 0x7f79de34e2e8>

In [172]: df.plot(ax=ax, ylim=(0, 2), legend=None)
Out[172]: <matplotlib.axes._
↳subplots.AxesSubplot at 0x7f79de395940>
```

**Note:** You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

## Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib [colormap](#) or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the `cubehelix` colormap, we can pass `colormap='cubehelix'`.

```
In [173]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
```

```
In [174]: df = df.cumsum()
```

```
In [175]: plt.figure()
```

```
Out [175]: <Figure size 640x480 with 0 Axes>
```

(continues on next page)

(continued from previous page)

```
In [176]: df.plot(colormap='cubehelix')
Out[176]: <matplotlib.axes._subplots.
AxesSubplot at 0x7f79de2cbf28>
```

Alternatively, we can pass the colormap itself:

```
In [177]: from matplotlib import cm
In [178]: plt.figure()
Out[178]: <Figure size 640x480 with 0 Axes>
In [179]: df.plot(colormap=cm.cubehelix)
Out[179]: <matplotlib.axes._subplots.
AxesSubplot at 0x7f79de0edba8>
```

Colormaps can also be used other plot types, like bar charts:

```
In [180]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [181]: dd = dd.cumsum()
In [182]: plt.figure()
Out[182]: <Figure size 640x480 with 0 Axes>
In [183]: dd.plot.bar(colormap='Greens')
Out[183]: <matplotlib.axes._subplots.
AxesSubplot at 0x7f79ddf972e8>
```

Parallel coordinates charts:

```
In [184]: plt.figure()
Out[184]: <Figure size 640x480 with 0 Axes>

In [185]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
Out[185]: <matplotlib.axes._subplots.
AxesSubplot at 0x7f79dddf6a20>
```

#### 4.10.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. `Series` and `DataFrame` objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [188]: price = pd.Series(np.random.randn(150).cumsum(),
.....:                    index=pd.date_range('2000-1-1', periods=150, freq='B'))
.....:
```

```
In [189]: ma = price.rolling(20).mean()
```

```
In [190]: mstd = price.rolling(20).std()
```

```
In [191]: plt.figure()
```

```
Out[191]: <Figure size 640x480 with 0 Axes>
```

```
In [192]: plt.plot(price.index, price, 'k')
```

```
Out[192]: [matplotlib.lines.Line2D at 0x7f79e4e0a5c0]
```

(continues on next page)

(continued from previous page)

```

In [193]: plt.plot(ma.index, ma, 'b')
////////////////////////////////////
↪ [<matplotlib.lines.Line2D at 0x7f7a275d2198>]

In [194]: plt.fill_between(mstd.index, ma - 2 * mstd, ma + 2 * mstd,
.....:                    color='b', alpha=0.2)
.....:
.....:
////////////////////////////////////
↪ [<matplotlib.collections.PolyCollection at 0x7f79e4ba0fd0>]

```

#### 4.10.7 Trellis plotting interface

**Warning:** The `rplot` trellis plotting interface has been **removed**. Please use external packages like [seaborn](#) for similar but more refined functionality and refer to our 0.18.1 documentation [here](#) for how to convert to using it.

## 4.11 Computational tools

### 4.11.1 Statistical Functions

#### Percent Change

`Series`, `DataFrame`, and `Panel` all have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

```
In [2]: ser.pct_change()
```

```
Out [2]:
0      NaN
1   -1.602976
2    4.334938
3   -0.247456
4   -2.067345
5   -1.142903
6   -1.688214
7   -9.759729
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [4]: df.pct_change( periods=3)
```

```
Out [4]:
      0      1      2      3
0     NaN     NaN     NaN     NaN
1     NaN     NaN     NaN     NaN
2     NaN     NaN     NaN     NaN
3  -0.218320 -1.054001  1.987147 -0.510183
4  -0.439121 -1.816454  0.649715 -4.822809
5  -0.127833 -3.042065 -5.866604 -1.776977
6  -2.596833 -1.959538 -2.111697 -3.798900
7  -0.117826 -2.169058  0.036094 -0.067696
8   2.492606 -1.357320 -1.205802 -1.558697
9  -1.012977  2.324558 -1.003744 -0.371806
```

#### Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))
```

```
In [6]: s2 = pd.Series(np.random.randn(1000))
```

```
In [7]: s1.cov(s2)
```

```
Out [7]: 0.00068010881743108204
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the `DataFrame`, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which

is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5),
...:                         columns=['a', 'b', 'c', 'd', 'e'])
...:
In [9]: frame.cov()
Out[9]:
         a         b         c         d         e
a  1.000882 -0.003177 -0.002698 -0.006889  0.031912
b -0.003177  1.024721  0.000191  0.009212  0.000857
c -0.002698  0.000191  0.950735 -0.031743 -0.005087
d -0.006889  0.009212 -0.031743  1.002983 -0.047952
e  0.031912  0.000857 -0.005087 -0.047952  1.042487
```

DataFrame.cov also supports an optional min\_periods keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [11]: frame.loc[frame.index[:5], 'a'] = np.nan
In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [13]: frame.cov()
Out[13]:
         a         b         c
a  1.123670 -0.412851  0.018169
b -0.412851  1.154141  0.305260
c  0.018169  0.305260  1.301149

In [14]: frame.cov(min_periods=12)
///////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
         a         b         c
a  1.123670      NaN  0.018169
b         NaN  1.154141  0.305260
c  0.018169  0.305260  1.301149
```

### Correlation

Correlation may be computed using the *corr()* method. Using the *method* parameter, several methods for computing correlations are provided:

Method name	Description
pearson (default)	Standard correlation coefficient
kendall	Kendall Tau correlation coefficient
spearman	Spearman rank correlation coefficient

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above

correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman's rank correlation coefficient

**Note:** Please see the *caveats* associated with this method of calculating correlation matrices in the *covariance section*.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5),
.....:                        columns=['a', 'b', 'c', 'd', 'e'])
.....:

In [16]: frame.iloc[:,2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: 0.013479040400098794

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.0072898851595406371

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
```

	a	b	c	d	e
a	1.000000	0.013479	-0.049269	-0.042239	-0.028525
b	0.013479	1.000000	-0.020433	-0.011139	0.005654
c	-0.049269	-0.020433	1.000000	0.018587	-0.054269
d	-0.042239	-0.011139	0.018587	1.000000	-0.017060
e	-0.028525	0.005654	-0.054269	-0.017060	1.000000

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
Out[23]:
```

	a	b	c
a	1.000000	-0.121111	0.069544
b	-0.121111	1.000000	0.051742
c	0.069544	0.051742	1.000000

```
In [24]: frame.corr(min_periods=12)
Out[24]:
```

	a	b	c
a	1.000000	NaN	0.069544
b	NaN	1.000000	0.051742
c	0.069544	0.051742	1.000000

New in version 0.24.0.

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```
# histogram intersection
In [25]: def histogram_intersection(a, b):
.....:     return np.minimum(np.true_divide(a, a.sum()),
.....:                       np.true_divide(b, b.sum())).sum()
.....:

In [26]: frame.corr(method=histogram_intersection)
Out [26]:
```

	a	b	c
a	1.000000	-6.404882	-2.058431
b	-6.404882	1.000000	-19.255743
c	-2.058431	-19.255743	1.000000

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```
In [27]: index = ['a', 'b', 'c', 'd', 'e']

In [28]: columns = ['one', 'two', 'three', 'four']

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)
Out [31]:
```

one	-0.125501
two	-0.493244
three	0.344056
four	0.004183

```
dtype: float64

In [32]: df2.corrwith(df1, axis=1)
Out [32]:
```

a	-0.675817
b	0.458296
c	0.190809
d	-0.186275
e	NaN

```
dtype: float64
```

## Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```
In [33]: s = pd.Series(np.random.randn(5), index=list('abcde'))

In [34]: s['d'] = s['b'] # so there's a tie

In [35]: s.rank()
```

(continues on next page)

(continued from previous page)

```
Out [35]:
a    5.0
b    2.5
c    1.0
d    2.5
e    4.0
dtype: float64
```

`rank()` is also a `DataFrame` method and can rank either the rows (`axis=0`) or the columns (`axis=1`). `NaN` values are excluded from the ranking.

```
In [36]: df = pd.DataFrame(np.random.randn(10, 6))
```

```
In [37]: df[4] = df[2][:5] # some ties
```

```
In [38]: df
```

```
Out [38]:
      0         1         2         3         4         5
0 -0.904948 -1.163537 -1.457187  0.135463 -1.457187  0.294650

8 -0.547231  0.664402 -0.519424 -0.073254          NaN -1.263544
9 -0.250277 -0.237428 -1.056443  0.419477          NaN  1.375064
```

```
In [39]: df.rank(1)
```

```

////////////////////////////////////
↪
      0         1         2         3         4         5
0  4.0  3.0  1.5  5.0  1.5  6.0
1  2.0  6.0  4.5  1.0  4.5  3.0
2  1.0  6.0  3.5  5.0  3.5  2.0
3  4.0  5.0  1.5  3.0  1.5  6.0
4  5.0  3.0  1.5  4.0  1.5  6.0
5  1.0  2.0  5.0  3.0  NaN  4.0
6  4.0  5.0  3.0  1.0  NaN  2.0
7  2.0  5.0  3.0  4.0  NaN  1.0
8  2.0  5.0  3.0  4.0  NaN  1.0
9  2.0  3.0  1.0  4.0  NaN  5.0
```

`rank` optionally takes a parameter `ascending` which by default is `true`; when `false`, data is reverse-ranked, with larger values assigned a smaller rank.

`rank` supports different tie-breaking methods, specified with the `method` parameter:

- `average` : average rank of tied group
- `min` : lowest rank in the group
- `max` : highest rank in the group
- `first` : ranks assigned in the order they appear in the array

## 4.11.2 Window Functions

For working with data, a number of window functions are provided for computing common *window* or *rolling* statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and kurtosis.

The `rolling()` and `expanding()` functions can be used directly from `DataFrameGroupBy` objects, see the *groupby docs*.

---

**Note:** The API for window statistics is quite similar to the way one works with `GroupBy` objects, see the documentation *here*.

---

We work with `rolling`, `expanding` and `exponentially weighted data` through the corresponding objects, `Rolling`, `Expanding` and `EWM`.

```
In [40]: s = pd.Series(np.random.randn(1000),
.....:                 index=pd.date_range('1/1/2000', periods=1000))
.....:

In [41]: s = s.cumsum()

In [42]: s
Out[42]:
2000-01-01    -0.268824
2000-01-02    -1.771855
2000-01-03    -0.818003
2000-01-04    -0.659244
2000-01-05    -1.942133
2000-01-06    -1.869391
2000-01-07     0.563674
.....
2002-09-20   -68.233054
2002-09-21   -66.765687
2002-09-22   -67.457323
2002-09-23   -69.253182
2002-09-24   -70.296818
2002-09-25   -70.844674
2002-09-26   -72.475016
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on `Series` and `DataFrame`.

```
In [43]: r = s.rolling(window=60)

In [44]: r
Out[44]: Rolling [window=60,center=False,axis=0]
```

These object provide tab-completion of the available methods and properties.

```
In [14]: r.<TAB>                                     # noqa: E225, E999
r.agg      r.apply      r.count      r.exclusions  r.max      r.median      r.
↪name      r.skew      r.sum
r.aggregate  r.corr      r.cov      r.kurt      r.mean      r.min      r.
↪quantile  r.std      r.var
```

Generally these methods all have the same interface. They all accept the following arguments:

- window: size of moving window
- min\_periods: threshold of non-null data points to require (otherwise result is NA)
- center: boolean, whether to set the labels at the center (default is False)

We can then call methods on these rolling objects. These return like-indexed objects:

```
In [45]: r.mean()
Out [45]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05      NaN
2000-01-06      NaN
2000-01-07      NaN
...
2002-09-20  -62.694135
2002-09-21  -62.812190
2002-09-22  -62.914971
2002-09-23  -63.061867
2002-09-24  -63.213876
2002-09-25  -63.375074
2002-09-26  -63.539734
Freq: D, Length: 1000, dtype: float64
```

```
In [46]: s.plot(style='k--')
Out [46]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a25f891d0>

In [47]: r.mean().plot(style='k')
Out [47]:
<matplotlib.axes._subplots.AxesSubplot at 0x7f7a25f891d0>
```

They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame's columns:

```
In [48]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                    index=pd.date_range('1/1/2000', periods=1000),
.....:                    columns=['A', 'B', 'C', 'D'])
.....:

In [49]: df = df.cumsum()

In [50]: df.rolling(window=60).sum().plot(subplots=True)
Out[50]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x7f7a1c1e26d8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f7a1c1f2940>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f7a1c202a58>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f7a1c212b70>],
      dtype=object)
```

## Method Summary

We provide a number of common statistical functions:

Method	Description
<code>count()</code>	Number of non-null observations
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values
<code>median()</code>	Arithmetic median of values
<code>min()</code>	Minimum
<code>max()</code>	Maximum
<code>std()</code>	Bessel-corrected sample standard deviation
<code>var()</code>	Unbiased variance
<code>skew()</code>	Sample skewness (3rd moment)
<code>kurt()</code>	Sample kurtosis (4th moment)
<code>quantile()</code>	Sample quantile (value at %)
<code>apply()</code>	Generic apply
<code>cov()</code>	Unbiased covariance (binary)
<code>corr()</code>	Correlation (binary)

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argu-

ment should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [51]: def mad(x):
...:     return np.fabs(x - x.mean()).mean()
...:

In [52]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[52]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1c1cf8d0>
```

## Rolling Windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according to the `win_type`. The following methods are available:

Method	Description
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- `boxcar`

- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

```
In [53]: ser = pd.Series(np.random.randn(10),
.....:                  index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [54]: ser.rolling(window=5, win_type='triang').mean()
```

```
Out [54]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05    -1.037870
2000-01-06    -0.767705
2000-01-07    -0.383197
2000-01-08    -0.395513
2000-01-09    -0.558440
2000-01-10    -0.672416
Freq: D, dtype: float64
```

Note that the boxcar window is equivalent to `mean()`.

```
In [55]: ser.rolling(window=5, win_type='boxcar').mean()
```

```
Out [55]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN

2000-01-05    -0.841164
2000-01-06    -0.779948
2000-01-07    -0.565487
2000-01-08    -0.502815
2000-01-09    -0.553755
2000-01-10    -0.472211
Freq: D, dtype: float64
```

```
In [56]: ser.rolling(window=5).mean()
```

```
////////////////////////////////////
```

```
↪
```

(continues on next page)

(continued from previous page)

```

2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05    -0.841164
2000-01-06    -0.779948
2000-01-07    -0.565487
2000-01-08    -0.502815
2000-01-09    -0.553755
2000-01-10    -0.472211
Freq: D, dtype: float64

```

For some windowing functions, additional parameters must be specified:

```

In [57]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out [57]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05    -1.309989
2000-01-06    -1.153000
2000-01-07     0.606382
2000-01-08    -0.681101
2000-01-09    -0.289724
2000-01-10    -0.996632
Freq: D, dtype: float64

```

**Note:** For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

## Time-aware Rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```

In [58]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00',
.....:                                           periods=5,
.....:                                           freq='s'))
.....:

In [59]: dft
Out [59]:

```

(continues on next page)

	Description	Default for
closed		
right	close right endpoint	time-based windows
left	close left endpoint	
both	close both endpoints	fixed windows
neither	open endpoints	

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [70]: df = pd.DataFrame({'x': 1},
.....:                      index=[pd.Timestamp('20130101 09:00:01'),
.....:                               pd.Timestamp('20130101 09:00:02'),
.....:                               pd.Timestamp('20130101 09:00:03'),
.....:                               pd.Timestamp('20130101 09:00:04'),
.....:                               pd.Timestamp('20130101 09:00:06')])
.....:

In [71]: df["right"] = df.rolling('2s', closed='right').x.sum() # default

In [72]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [73]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [74]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [75]: df
Out[75]:
```

	x	right	both	left	neither
2013-01-01 09:00:01	1	1.0	1.0	NaN	NaN
2013-01-01 09:00:02	1	2.0	2.0	1.0	1.0
2013-01-01 09:00:03	1	2.0	3.0	2.0	1.0
2013-01-01 09:00:04	1	2.0	3.0	2.0	1.0
2013-01-01 09:00:06	1	1.0	2.0	1.0	NaN

Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

### Time-aware Rolling vs. Resampling

Using `.rolling()` with a time-based index is quite similar to *resampling*. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

(continued from previous page)

```
In [80]: df2 = df[:20]

In [81]: df2.rolling(window=5).corr(df2['B'])

[20 rows x 4 columns]

## Computing rolling pairwise covariances and correlations

**Warning:** Prior to version 0.20.0 if `pairwise=True` was passed, a `Panel` would be returned. This will now return a 2-level `MultiIndexed DataFrame`, see the [whatsnew here](#).

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a `MultiIndexed DataFrame` whose `index` are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

**Note:** Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for *caveats* associated with this method of calculating covariance and correlation matrices.

```
In [82]: covs = (df[['B', 'C', 'D']].rolling(window=50)
.....:              .cov(df[['A', 'B', 'C']], pairwise=True))
.....:

In [83]: covs.loc['2002-09-22:']

           C  0.743113  0.124683  1.000000 -0.719088
...
...           ...           ...           ...           ...
2002-09-25 B  0.075157  1.000000  0.064399 -0.164179
           C  0.731888  0.064399  1.000000 -0.704686
           D -0.739160 -0.164179 -0.704686  1.000000
2002-09-26 A  1.000000  0.087756  0.727792 -0.736562
           B  0.087756  1.000000  0.079913 -0.179477
           C  0.727792  0.079913  1.000000 -0.692303
           D -0.736562 -0.179477 -0.692303  1.000000

```

```
[20 rows x 4 columns]
```

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```
In [86]: correls.unstack(1)[('A', 'C')].plot()
```

```
Out [86]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f5ede48>
```

### 4.11.3 Aggregation

Once the `Rolling`, `Expanding` or `EWM` objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the *aggregating API*, *groupby API*, and *resample API*.

```
In [87]: dfa = pd.DataFrame(np.random.randn(1000, 3),
.....:                      index=pd.date_range('1/1/2000', periods=1000),
.....:                      columns=['A', 'B', 'C'])
.....:
```

```
In [88]: r = dfa.rolling(window=60, min_periods=1)
```

```
In [89]: r
```

```
Out [89]: Rolling [window=60,min_periods=1,center=False,axis=0]
```

We can aggregate by passing a function to the entire `DataFrame`, or select a `Series` (or multiple `Series`) via standard `__getitem__`.

```
In [90]: r.aggregate(np.sum)
```

```
Out [90]:
```

	A	B	C
2000-01-01	-0.289838	-0.370545	-1.284206
2000-01-02	-0.216612	-1.675528	-1.169415

(continues on next page)

2002-09-26  5.093787  -7.074515

```

```
[1000 rows x 2 columns]
```

As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

### Applying multiple functions

With windowed Series you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```
In [93]: r['A'].agg([np.sum, np.mean, np.std])
```

```
Out [93]:
```

	sum	mean	std
2000-01-01	-0.289838	-0.289838	NaN
2000-01-02	-0.216612	-0.108306	0.256725
2000-01-03	1.154661	0.384887	0.873311
2000-01-04	2.969393	0.742348	1.009734
2000-01-05	4.690630	0.938126	0.977914
2000-01-06	3.880630	0.646772	1.128883
2000-01-07	4.001957	0.571708	1.049487
...	...	...	...
2002-09-20	2.652493	0.044208	1.164919
2002-09-21	0.844497	0.014075	1.148231
2002-09-22	2.860036	0.047667	1.132051
2002-09-23	3.510163	0.058503	1.134296
2002-09-24	6.524983	0.108750	1.144204
2002-09-25	6.409626	0.106827	1.142913
2002-09-26	5.093787	0.084896	1.151416

```
[1000 rows x 3 columns]
```

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [94]: r.agg([np.sum, np.mean])
```

```
Out [94]:
```

```
[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.

### Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [95]: r.agg({'A': np.sum, 'B': lambda x: np.std(x, ddof=1)})
```

```
Out [95]:
```

	A	B
2000-01-01	-0.289838	NaN
2000-01-02	-0.216612	0.660747
2000-01-03	1.154661	0.689929
2000-01-04	2.969393	1.072199
2000-01-05	4.690630	0.939657
2000-01-06	3.880630	0.966848
2000-01-07	4.001957	1.240137
...	...	...
2002-09-20	2.652493	1.114814
2002-09-21	0.844497	1.113220
2002-09-22	2.860036	1.113208
2002-09-23	3.510163	1.132381
2002-09-24	6.524983	1.080963
2002-09-25	6.409626	1.082911
2002-09-26	5.093787	1.136199

```
[1000 rows x 2 columns]
```

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object

```
In [96]: r.agg({'A': 'sum', 'B': 'std'})
```

```
Out [96]:
```

	A	B
2000-01-01	-0.289838	NaN
2000-01-02	-0.216612	0.660747
2000-01-03	1.154661	0.689929
2000-01-04	2.969393	1.072199
2000-01-05	4.690630	0.939657
2000-01-06	3.880630	0.966848
2000-01-07	4.001957	1.240137
...	...	...
2002-09-20	2.652493	1.114814
2002-09-21	0.844497	1.113220
2002-09-22	2.860036	1.113208
2002-09-23	3.510163	1.132381
2002-09-24	6.524983	1.080963
2002-09-25	6.409626	1.082911
2002-09-26	5.093787	1.136199

```
[1000 rows x 2 columns]
```

Furthermore you can pass a nested dict to indicate different aggregations on different columns.

```
In [97]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
```

```
Out [97]:
```

	A		B	
	sum	std	mean	std
2000-01-01	-0.289838	NaN	-0.370545	NaN
2000-01-02	-0.216612	0.256725	-0.837764	0.660747
2000-01-03	1.154661	0.873311	-0.544672	0.689929
2000-01-04	2.969393	1.009734	-1.000819	1.072199
2000-01-05	4.690630	0.977914	-0.936403	0.939657
2000-01-06	3.880630	1.128883	-0.741283	0.966848

(continues on next page)

## Method Summary

Function	Description
<code>count()</code>	Number of non-null observations
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values
<code>median()</code>	Arithmetic median of values
<code>min()</code>	Minimum
<code>max()</code>	Maximum
<code>std()</code>	Unbiased standard deviation
<code>var()</code>	Unbiased variance
<code>skew()</code>	Unbiased skewness (3rd moment)
<code>kurt()</code>	Unbiased kurtosis (4th moment)
<code>quantile()</code>	Sample quantile (value at %)
<code>apply()</code>	Generic apply
<code>cov()</code>	Unbiased covariance (binary)
<code>corr()</code>	Correlation (binary)

Aside from not having a window parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```
In [100]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [101]: sn
Out [101]:
0    1.0
1    2.0
2    NaN
3    3.0
4    NaN
5    4.0
dtype: float64

In [102]: sn.rolling(2).max()
Out [102]:
0    NaN
1    2.0
2    NaN
3    NaN
4    NaN
5    NaN
dtype: float64

In [103]: sn.rolling(2, min_periods=1).max()
Out [103]:
0    1.0
1    2.0
2    3.0
3    3.0
4    4.0
5    4.0
dtype: float64
```

(continues on next page)

(continued from previous page)

```
0    1.0
1    2.0
2    2.0
3    3.0
4    3.0
5    4.0
dtype: float64
```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with expanding, use `fillna()`:

```
In [104]: sn.expanding().sum()
Out [104]:
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5   10.0
dtype: float64

In [105]: sn.cumsum()
Out [105]:
0    1.0
1    3.0
2    NaN
3    6.0
4    NaN
5   10.0
dtype: float64

In [106]: sn.cumsum().fillna(method='ffill')
Out [106]:
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5   10.0
dtype: float64
```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the `mean()` output for the previous time series dataset:

```
In [107]: s.plot(style='k--')
Out [107]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f49d080>

In [108]: s.expanding().mean().plot(style='k')
Out [108]:
<matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f49d080>
```

### 4.11.5 Exponentially Weighted Windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

Function	Description
<code>mean()</code>	EW moving average
<code>var()</code>	EW moving variance
<code>std()</code>	EW moving standard deviation
<code>corr()</code>	EW moving correlation
<code>cov()</code>	EW moving covariance

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where  $x_t$  is the input,  $y_t$  is the result and the  $w_i$  are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights  $w_i =$

$(1 - \alpha)^i$  which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

---

**Note:** These equations are sometimes written in terms of  $\alpha' = 1 - \alpha$ , e.g.

$$y_t = \alpha' y_{t-1} + (1 - \alpha')x_t.$$

---

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of  $1 - \alpha$  we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which shows the equivalence of the above two variants for infinite series. When `adjust=True` we have  $y_0 = x_0$  and from the last representation above we have  $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$ , therefore there is an assumption that  $x_0$  is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have  $0 < \alpha \leq 1$ , and while since version 0.18.0 it has been possible to pass  $\alpha$  directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{-\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span:  $c = (s - 1)/2$ .
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:

```
In [109]: s.plot(style='k--')
Out[109]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f423780>

In [110]: s.ewm(span=20).mean().plot(style='k')
Out[110]:
<matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f423780>
```

EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}.$$

(For  $w_i = 1$ , this reduces to the usual  $N/(N - 1)$  factor, with  $N = t + 1$ .) See [Weighted Sample Variance](#) on Wikipedia for further details.

## 4.12 Group By: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.
- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.
- Some combination of the above: `GroupBy` will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a `DataFrame` function on each group. The name `GroupBy` should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of `GroupBy` functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.

### 4.12.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
In [1]: df = pd.DataFrame([('bird', 'Falconiformes', 389.0),
...:                      ('bird', 'Psittaciformes', 24.0),
...:                      ('mammal', 'Carnivora', 80.2),
...:                      ('mammal', 'Primates', np.nan),
...:                      ('mammal', 'Carnivora', 58)],
...:                      index=['falcon', 'parrot', 'lion', 'monkey', 'leopard'],
...:                      columns=('class', 'order', 'max_speed'))
...:

In [2]: df
Out[2]:
```

	class	order	max_speed
falcon	bird	Falconiformes	389.0
parrot	bird	Psittaciformes	24.0
lion	mammal	Carnivora	80.2
monkey	mammal	Primates	NaN
leopard	mammal	Carnivora	58.0

```
# default is axis=0
In [3]: grouped = df.groupby('class')

In [4]: grouped = df.groupby('order', axis='columns')

In [5]: grouped = df.groupby(['class', 'order'])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label  $\rightarrow$  group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

---

**Note:** A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name, a `ValueError` will be raised.

---

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...:                           'foo', 'bar', 'foo', 'foo'],
...:                      'B': ['one', 'one', 'two', 'three',
...:                           'two', 'two', 'one', 'three'],
...:                      'C': np.random.randn(8),
...:                      'D': np.random.randn(8)})
...:
```

(continues on next page)

(continued from previous page)

```
In [7]: df
Out[7]:
```

	A	B	C	D
0	foo	one	0.469112	-0.861849
1	bar	one	-0.282863	-2.104569
2	foo	two	-1.509059	-0.494929
3	bar	three	-1.135632	1.071804
4	foo	two	1.212112	0.721555
5	bar	two	-0.173215	-0.706771
6	foo	one	0.119209	-1.039575
7	foo	three	-1.044236	0.271860

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [8]: grouped = df.groupby('A')
In [9]: grouped = df.groupby(['A', 'B'])
```

New in version 0.24.

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```
In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
Out[12]:
```

	C	D
A		
bar	-1.591710	-1.739537
foo	-0.752861	-1.402938

These will split the DataFrame on its index (rows). We could also split by the columns:

```
In [13]: def get_letter_type(letter):
.....:     if letter.lower() in 'aeiou':
.....:         return 'vowel'
.....:     else:
.....:         return 'consonant'
.....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
```

(continues on next page)

(continued from previous page)

```

1      1
2      2
3      3
dtype: int64

In [19]: grouped.last()
\\Out [19]:
1      10
2      20
3      30
dtype: int64

In [20]: grouped.sum()
\\Out [20]:
1      11
2      22
3      33
dtype: int64

```

Note that **no splitting occurs** until it's needed. Creating the GroupBy object only verifies that you've passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

## GroupBy sorting

By default the group keys are sorted during the groupby operation. You may however pass `sort=False` for potential speedups:

```

In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})

In [22]: df2.groupby(['X']).sum()
Out [22]:
   Y
X
A   7
B   3

In [23]: df2.groupby(['X'], sort=False).sum()
\\Out [23]:
   Y
X
B   3
A   7

```

Note that groupby will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by groupby() below are in the order they appeared in the original DataFrame:

```

In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})

In [25]: df3.groupby(['X']).get_group('A')

```

## GroupBy with MultiIndex

With *hierarchically-indexed data*, it's quite natural to group by one of the levels of the hierarchy.

Let's create a Series with a two-level MultiIndex.

```
In [35]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:
```

```
In [36]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

```
In [37]: s = pd.Series(np.random.randn(8), index=index)
```

```
In [38]: s
```

```
Out [38]:
```

```

first second
bar    one   -0.919854
      two   -0.042379
baz    one    1.247642
      two   -0.009920
foo    one    0.290213
      two    0.495767
qux    one    0.362949
      two    1.548106
dtype: float64

```

We can then group by one of the levels in `s`.

```
In [39]: grouped = s.groupby(level=0)
```

```
In [40]: grouped.sum()
```

```
Out [40]:
```

```

first
bar   -0.962232
baz    1.237723

```

(continues on next page)

(continued from previous page)

```
foo    bop    1.023898
qux    bop    0.000895
dtype: float64
```

More on the `sum` function and aggregation later.

## Grouping DataFrame with Index Levels and Columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [46]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [47]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [48]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                      'B': np.arange(8)},
.....:                      index=index)
.....:

In [49]: df
Out[49]:
```

first	second	A	B
bar	one	1	0
	two	1	1
baz	one	1	2
	two	1	3
foo	one	2	4
	two	2	5
qux	one	3	6
	two	3	7

The following example groups `df` by the second index level and the A column.

```
In [50]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[50]:
```

second	A	B
one	1	2
	2	4
	3	6
two	1	4
	2	5
	3	7

Index levels may also be specified by name.

```
In [51]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[51]:
```

second	A	B
one	1	2

(continues on next page)

(continued from previous page)

```

      2  4
      3  6
two   1  4
      2  5
      3  7

```

New in version 0.20.

Index level names may be specified as keys directly to `groupby`.

```

In [52]: df.groupby(['second', 'A']).sum()
Out [52]:
      B
second A
one     1  2
        2  4
        3  6
two     1  4
        2  5
        3  7

```

### DataFrame column selection in GroupBy

Once you have created the `GroupBy` object from a `DataFrame`, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a `DataFrame`, you can do:

```

In [53]: grouped = df.groupby(['A'])
In [54]: grouped_C = grouped['C']
In [55]: grouped_D = grouped['D']

```

This is mainly syntactic sugar for the alternative and much more verbose:

```

In [56]: df['C'].groupby(df['A'])
Out [56]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f7a1c1319e8>

```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

## 4.12.2 Iterating through groups

With the `GroupBy` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```

In [57]: grouped = df.groupby('A')

In [58]: for name, group in grouped:
...:     print(name)
...:     print(group)
...:
bar
   A      B      C      D
1 bar  one  0.254161  1.511763
3 bar three 0.215897 -0.990582

```

(continues on next page)

(continued from previous page)

```

5 bar two -0.077118 1.211526
foo
  A      B      C      D
0 foo one -0.575247 1.346061
2 foo two -1.143704 1.627081
4 foo two 1.193555 -0.441652
6 foo one -0.408530 0.268520
7 foo three -0.862495 0.024580

```

In the case of grouping by multiple keys, the group name will be a tuple:

```

In [59]: for name, group in df.groupby(['A', 'B']):
...:     print(name)
...:     print(group)
...:
('bar', 'one')
  A      B      C      D
1 bar one 0.254161 1.511763
('bar', 'three')
  A      B      C      D
3 bar three 0.215897 -0.990582
('bar', 'two')
  A      B      C      D
5 bar two -0.077118 1.211526
('foo', 'one')
  A      B      C      D
0 foo one -0.575247 1.346061
6 foo one -0.408530 0.268520
('foo', 'three')
  A      B      C      D
7 foo three -0.862495 0.02458
('foo', 'two')
  A      B      C      D
2 foo two -1.143704 1.627081
4 foo two 1.193555 -0.441652

```

See *Iterating through groups*.

### 4.12.3 Selecting a group

A single group can be selected using `get_group()`:

```

In [60]: grouped.get_group('bar')
Out[60]:
  A      B      C      D
1 bar one 0.254161 1.511763
3 bar three 0.215897 -0.990582
5 bar two -0.077118 1.211526

```

Or for an object grouped on multiple columns:

```

In [61]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[61]:
  A      B      C      D
1 bar one 0.254161 1.511763

```

## 4.12.4 Aggregation

Once the `GroupBy` object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the *aggregating API*, *window functions API*, and *resample API*.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [62]: grouped = df.groupby('A')

In [63]: grouped.aggregate(np.sum)
Out [63]:
```

	C	D
A		
bar	0.392940	1.732707
foo	-1.796421	2.824590

```
In [64]: grouped = df.groupby(['A', 'B'])

In [65]: grouped.aggregate(np.sum)
Out [65]:
```

A	B	C	D
bar	one	0.254161	1.511763
	three	0.215897	-0.990582
	two	-0.077118	1.211526
foo	one	-0.983776	1.614581
	three	-0.862495	0.024580
	two	0.049851	1.185429

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a *MultiIndex* by default, though this can be changed by using the `as_index` option:

```
In [66]: grouped = df.groupby(['A', 'B'], as_index=False)

In [67]: grouped.aggregate(np.sum)
Out [67]:
```

	A	B	C	D
0	bar	one	0.254161	1.511763
1	bar	three	0.215897	-0.990582
2	bar	two	-0.077118	1.211526
3	foo	one	-0.983776	1.614581
4	foo	three	-0.862495	0.024580
5	foo	two	0.049851	1.185429

```
In [68]: df.groupby('A', as_index=False).sum()
Out [68]:
```

	A	C	D
0	bar	0.392940	1.732707
1	foo	-1.796421	2.824590

Note that you could use the `reset_index` `DataFrame` function to achieve the same result as the column names are stored in the resulting `MultiIndex`:

```
In [69]: df.groupby(['A', 'B']).sum().reset_index()
Out [69]:
```

A	B	C	D
bar	one	0.254161	1.511763
	three	0.215897	-0.990582
	two	-0.077118	1.211526
foo	one	-0.983776	1.614581
	three	-0.862495	0.024580
	two	0.049851	1.185429

(continues on next page)

(continued from previous page)

```

0 bar one 0.254161 1.511763
1 bar three 0.215897 -0.990582
2 bar two -0.077118 1.211526
3 foo one -0.983776 1.614581
4 foo three -0.862495 0.024580
5 foo two 0.049851 1.185429

```

Another simple aggregation example is to compute the size of each group. This is included in `GroupBy` as the `size` method. It returns a `Series` whose index are the group names and whose values are the sizes of each group.

```
In [70]: grouped.size()
```

```
Out [70]:
```

```

A B
bar one 1
     three 1
     two 1
foo one 2
     three 1
     two 2
dtype: int64

```

```
In [71]: grouped.describe()
```

```
Out [71]:
```

```

      C      ...      D
↪
count      mean      std      min      25%      ...      min      25%      50%      ↪

```

```
[6 rows x 16 columns]
```

**Note:** Aggregation functions **will not** return the groups that you are aggregating over if they are named *columns*, when `as_index=True`, the default. The grouped columns will be the **indices** of the returned object.

Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named *columns*.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

Function	Description
<code>mean()</code>	Compute mean of groups
<code>sum()</code>	Compute sum of group values
<code>size()</code>	Compute group sizes
<code>count()</code>	Compute count of group
<code>std()</code>	Standard deviation of groups
<code>var()</code>	Compute variance of groups
<code>sem()</code>	Standard error of the mean of groups
<code>describe()</code>	Generates descriptive statistics
<code>first()</code>	Compute first of group values
<code>last()</code>	Compute last of group values
<code>nth()</code>	Take <i>nth</i> value, or a subset if <i>n</i> is a list
<code>min()</code>	Compute min of group values
<code>max()</code>	Compute max of group values

The aggregating functions above will exclude NA values. Any function which reduces a *Series* to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

### Applying multiple functions at once

With grouped *Series* you can also pass a list or dict of functions to do aggregation with, outputting a *DataFrame*:

```
In [72]: grouped = df.groupby('A')
In [73]: grouped['C'].agg([np.sum, np.mean, np.std])
Out [73]:
```

	sum	mean	std
A			
bar	0.392940	0.130980	0.181231
foo	-1.796421	-0.359284	0.912265

On a grouped *DataFrame*, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [74]: grouped.agg([np.sum, np.mean, np.std])
Out [74]:
```

	C			D		
	sum	mean	std	sum	mean	std
A						
bar	0.392940	0.130980	0.181231	1.732707	0.577569	1.366330
foo	-1.796421	-0.359284	0.912265	2.824590	0.564918	0.884785

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a *Series* like this:

```
In [75]: (grouped['C'].agg([np.sum, np.mean, np.std])
.....:                .rename(columns={'sum': 'foo',
.....:                                'mean': 'bar',
.....:                                'std': 'baz'}))
Out [75]:
```

	foo	bar	baz
A			

(continues on next page)

(continued from previous page)

```
bar 0.392940 0.130980 0.181231
foo -1.796421 -0.359284 0.912265
```

For a grouped DataFrame, you can rename in a similar manner:

```
In [76]: (grouped.agg([np.sum, np.mean, np.std])
.....:             .rename(columns={'sum': 'foo',
.....:                             'mean': 'bar',
.....:                             'std': 'baz'}))
.....:
Out[76]:
```

	C			D		
	foo	bar	baz	foo	bar	baz
A						
bar	0.392940	0.130980	0.181231	1.732707	0.577569	1.366330
foo	-1.796421	-0.359284	0.912265	2.824590	0.564918	0.884785

### Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [77]: grouped.agg({'C': np.sum,
.....:                'D': lambda x: np.std(x, ddof=1)})
.....:
Out[77]:
```

	C	D
A		
bar	0.392940	1.366330
foo	-1.796421	0.884785

The function names can also be strings. In order for a string to be valid it must be either implemented on `GroupBy` or available via *dispatching*:

```
In [78]: grouped.agg({'C': 'sum', 'D': 'std'})
Out[78]:
```

	C	D
A		
bar	0.392940	1.366330
foo	-1.796421	0.884785

**Note:** If you pass a dict to `aggregate`, the ordering of the output columns is non-deterministic. If you want to be sure the output columns will be in a specific order, you can use an `OrderedDict`. Compare the output of the following two commands:

```
In [79]: from collections import OrderedDict
In [80]: grouped.agg({'D': 'std', 'C': 'mean'})
Out[80]:
```

	D	C
A		
bar	1.366330	0.130980
foo	0.884785	-0.359284

(continues on next page)

(continued from previous page)

```
In [81]: grouped.agg(OrderedDict([('D', 'std'), ('C', 'mean')]))
//////////////////////////////////////////////////
↪
           D          C
A
bar  1.366330  0.130980
foo  0.884785 -0.359284
```

## Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```
In [82]: df.groupby('A').sum()
Out [82]:
           C          D
A
bar  0.392940  1.732707
foo -1.796421  2.824590

In [83]: df.groupby(['A', 'B']).mean()
//////////////////////////////////////////////////
↪
           C          D
A  B
bar one    0.254161  1.511763
   three  0.215897 -0.990582
   two   -0.077118  1.211526
foo one   -0.491888  0.807291
   three -0.862495  0.024580
   two    0.024925  0.592714
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

### 4.12.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the *second* chunk.

For example, suppose we wished to standardize the data within each group:

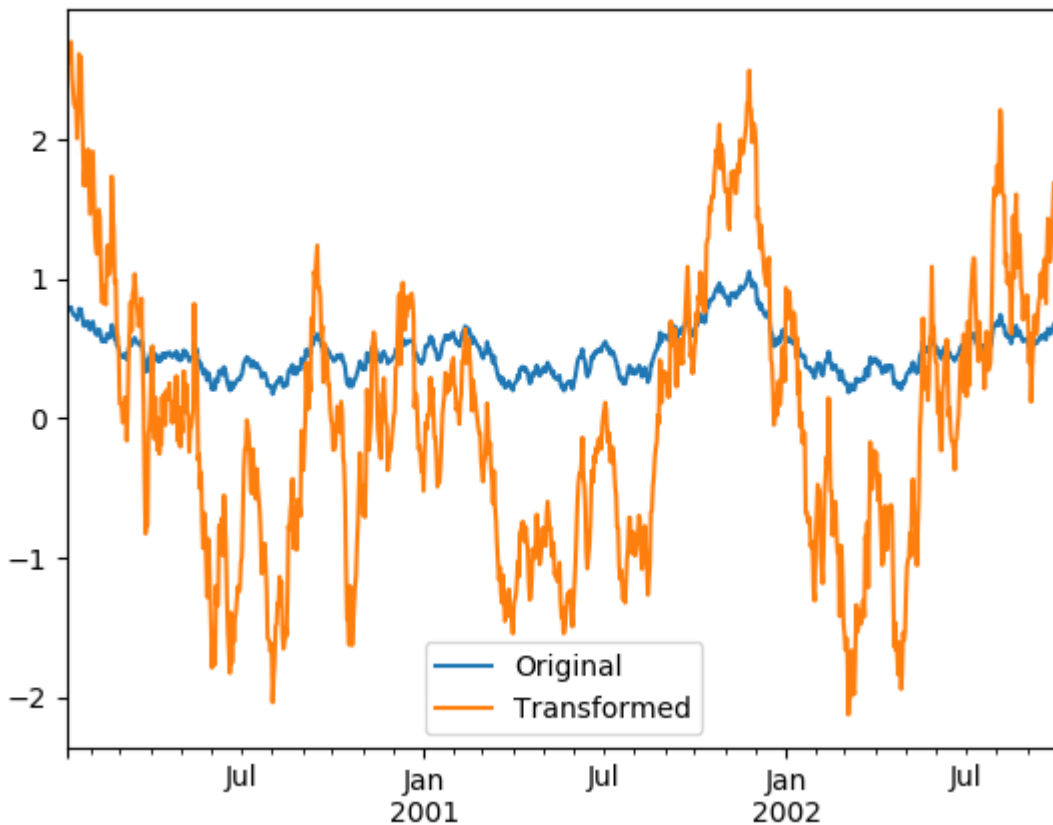

(continued from previous page)

```
dtype: float64
In [95]: grouped_trans.std()
Out [95]:
-----
→
2000    1.0
2001    1.0
2002    1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```
In [96]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})
In [97]: compare.plot()
Out [97]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a1c174be0>
```

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [98]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out [98]:
2000-01-08    0.623893
2000-01-09    0.623893
```

## New syntax to window and resample operations

New in version 0.18.1.

Working with the resample, expanding or rolling operations on the groupby level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [115]: df_re = pd.DataFrame({'A': [1] * 10 + [5] * 10,
.....:                        'B': np.arange(20)})
```

(continues on next page)

(continued from previous page)

```

.....:
In [116]: df_re
Out[116]:
   A  B
0  1  0
1  1  1
2  1  2
3  1  3
4  1  4
5  1  5
6  1  6
.. .. ..
13 5 13
14 5 14
15 5 15
16 5 16
17 5 17
18 5 18
19 5 19

[20 rows x 2 columns]

In [117]: df_re.groupby('A').rolling(4).B.mean()
\\//////////////////////////////////////////////////////////////////////////////////////////////////
↳
A
1  0      NaN
1  1      NaN
2  2      NaN
3  3      1.5
4  4      2.5
5  5      3.5
6  6      4.5
...
5 13     11.5
14 14     12.5
15 15     13.5
16 16     14.5
17 17     15.5
18 18     16.5
19 19     17.5
Name: B, Length: 20, dtype: float64

```

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

```

In [118]: df_re.groupby('A').expanding().sum()
Out[118]:
   A    B
A
1  0  1.0  0.0
1  1  2.0  1.0
2  2  3.0  3.0
3  3  4.0  6.0
4  4  5.0 10.0

```

(continues on next page)

(continued from previous page)

```

```
[16 rows x 2 columns]
```

## 4.12.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [122]: sf = pd.Series([1, 1, 2, 3, 3, 3])

In [123]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[123]:
3      3
4      3
5      3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [124]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})

In [125]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[125]:
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [126]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[126]:
   A  B
0 NaN NaN
1 NaN NaN
2 2.0  b
3 3.0  b
4 4.0  b
5 5.0  b
6 NaN NaN
7 NaN NaN
```

For `DataFrames` with multiple columns, filters should explicitly specify a column as the filter criterion.

```
In [127]: dff['C'] = np.arange(8)

In [128]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[128]:
   A  B  C
2  2  b  2
3  3  b  3
4  4  b  4
5  5  b  5
```

**Note:** Some functions when applied to a `groupby` object will act as a **filter** on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not

affect these transformation methods.

For example: `head`, `tail`.

```
In [129]: dff.groupby('B').head(2)
Out[129]:
   A B C
0  0 a  0
1  1 a  1
2  2 b  2
3  3 b  3
6  6 c  6
7  7 c  7
```

### 4.12.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [130]: grouped = df.groupby('A')
In [131]: grouped.agg(lambda x: x.std())
Out[131]:
           C           D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, `GroupBy` now has the ability to “dispatch” method calls to the groups:

```
In [132]: grouped.std()
Out[132]:
           C           D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [133]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
.....:                        index=pd.date_range('1/1/2000', periods=1000),
.....:                        columns=['A', 'B', 'C'])
.....:

In [134]: tsdf.iloc[::2] = np.nan

In [135]: grouped = tsdf.groupby(lambda x: x.year)

In [136]: grouped.fillna(method='pad')
Out[136]:
           A           B           C
```

(continues on next page)

(continued from previous page)

```

2002-09-26  1.123162  0.354660  1.128135

[1000 rows x 3 columns]

```

In this example, we chopped the collection of time series into yearly chunks then independently called *fillna* on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```
In [137]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
```

```
In [138]: g = pd.Series(list('abababab'))
```

```
In [139]: gb = s.groupby(g)
```

```
In [140]: gb.nlargest(3)
```

```
Out[140]:
a  4  19.0
   0   9.0
   2   7.0
b  1   8.0
   3   5.0
   7   3.3
dtype: float64
```

```
In [141]: gb.nsmallest(3)
```

```

\-----\
↪
a  6   4.2
   2   7.0
   0   9.0
b  5   1.0
   7   3.3
   3   5.0
dtype: float64

```

## 4.12.8 Flexible `apply`

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want `GroupBy` to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```

In [142]: df
Out[142]:
   A      B      C      D
0  foo   one -0.575247  1.346061
1  bar   one  0.254161  1.511763
2  foo   two -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo   two  1.193555 -0.441652
5  bar   two -0.077118  1.211526
6  foo   one -0.408530  0.268520
7  foo  three -0.862495  0.024580

In [143]: grouped = df.groupby('A')

# could also just call .describe()
In [144]: grouped['C'].apply(lambda x: x.describe())
Out[144]:
A
bar  count      3.000000
     mean      0.130980
     std      0.181231
     min     -0.077118
     25%      0.069390
     50%      0.215897
     75%      0.235029
     ...
foo  mean     -0.359284
     std      0.912265
     min     -1.143704
     25%     -0.862495
     50%     -0.575247
     75%     -0.408530
     max      1.193555
Name: C, Length: 16, dtype: float64

```

The dimension of the returned result can also change:

```

In [145]: grouped = df.groupby('A')['C']

In [146]: def f(group):
.....:     return pd.DataFrame({'original': group,
.....:                          'demeaned': group - group.mean()})
.....:

In [147]: grouped.apply(f)
Out[147]:
   original  demeaned
0 -0.575247 -0.215962
1  0.254161  0.123181
2 -1.143704 -0.784420
3  0.215897  0.084917
4  1.193555  1.552839
5 -0.077118 -0.208098
6 -0.408530 -0.049245
7 -0.862495 -0.503211

```

`apply` on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

## 4.12.9 Other useful features

### Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```
In [155]: df
Out [155]:
```

	A	B	C	D
0	foo	one	-0.575247	1.346061
1	bar	one	0.254161	1.511763
2	foo	two	-1.143704	1.627081
3	bar	three	0.215897	-0.990582
4	foo	two	1.193555	-0.441652
5	bar	two	-0.077118	1.211526
6	foo	one	-0.408530	0.268520
7	foo	three	-0.862495	0.024580

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [156]: df.groupby('A').std()
Out [156]:
```

A	C	D
bar	0.181231	1.366330
foo	0.912265	0.884785

Note that `df.groupby('A').colname.std().colname` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

**Note:** Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```
In [157]: from decimal import Decimal

In [158]: df_dec = pd.DataFrame(
.....:     {'id': [1, 2, 1, 2],
.....:      'int_column': [1, 2, 3, 4],
.....:      'dec_column': [Decimal('0.50'), Decimal('0.15'),
.....:                   Decimal('0.25'), Decimal('0.40')]
.....:     }
.....: )
.....:

# Decimal columns can be sum'd explicitly by themselves...
In [159]: df_dec.groupby(['id'])[['dec_column']].sum()
Out [159]:
dec_column
```

(continues on next page)

(continued from previous page)

```

id
1      0.75
2      0.55

# ...but cannot be combined with standard data types or they will be excluded
In [160]: df_dec.groupby(['id'])[['int_column', 'dec_column']].sum()
Out[160]:
int_column
id
1          4
2          6

# Use .agg function to aggregate over standard and "nuisance" data types
# at the same time
In [161]: df_dec.groupby(['id']).agg({'int_column': 'sum', 'dec_column': 'sum'})
Out[161]:
int_column dec_column
id
1          4          0.75
2          6          0.55

```

## Handling of (un)observed Categorical values

When using a `Categorical` grouper (as a single grouper, or as part of multiple groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```

In [162]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                             categories=['a', 'b']),
.....:                               observed=False).count()
Out[162]:
a    3
b    0
dtype: int64

```

Show only the observed values:

```

In [163]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                             categories=['a', 'b']),
.....:                               observed=True).count()
Out[163]:
a    3
dtype: int64

```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```

In [164]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                             categories=['a', 'b']),
.....:                               observed=False).count()

```

(continues on next page)

(continued from previous page)

```
In [165]: s.index.dtype
Out [165]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

## NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

## Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [166]: data = pd.Series(np.random.randn(100))
In [167]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])
In [168]: data.groupby(factor).mean()
Out [168]:
(-2.645, -0.523]    -1.362896
(-0.523, 0.0296]   -0.260266
(0.0296, 0.654]    0.361802
(0.654, 2.21]     1.073801
dtype: float64
```

## Grouping with a Grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [169]: import datetime

In [170]: df = pd.DataFrame({'Branch': 'A A A A A A B'.split(),
.....:                      'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
.....:                      'Quantity': [1, 3, 5, 1, 8, 1, 9, 3],
.....:                      'Date': [
.....:                          datetime.datetime(2013, 1, 1, 13, 0),
.....:                          datetime.datetime(2013, 1, 1, 13, 5),
.....:                          datetime.datetime(2013, 10, 1, 20, 0),
.....:                          datetime.datetime(2013, 10, 2, 10, 0),
.....:                          datetime.datetime(2013, 10, 1, 20, 0),
.....:                          datetime.datetime(2013, 10, 2, 10, 0),
.....:                          datetime.datetime(2013, 12, 2, 12, 0),
.....:                          datetime.datetime(2013, 12, 2, 14, 0)]
.....:                      })

In [171]: df
Out [171]:
   Branch Buyer  Quantity          Date
0     A    Carl         1 2013-01-01
1     A   Mark         3 2013-01-01
2     A   Carl         5 2013-10-01
3     A   Carl         1 2013-10-02
4     A    Joe         8 2013-10-01
5     A    Joe         1 2013-10-02
6     A    Joe         9 2013-12-02
7     B   Carl         3 2013-12-02
```

(continues on next page)

(continued from previous page)

0	A	Carl	1	2013-01-01	13:00:00
1	A	Mark	3	2013-01-01	13:05:00
2	A	Carl	5	2013-10-01	20:00:00
3	A	Carl	1	2013-10-02	10:00:00
4	A	Joe	8	2013-10-01	20:00:00
5	A	Joe	1	2013-10-02	10:00:00
6	A	Joe	9	2013-12-02	12:00:00
7	B	Carl	3	2013-12-02	14:00:00

Groupby a specific column with the desired frequency. This is like resampling.

```

In [172]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
Out[172]:
         Date Buyer  Quantity
2013-01-31 Carl     1
                Mark     3
2013-10-31 Carl     6
                Joe      9
2013-12-31 Carl     3
                Joe      9

```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```

In [173]: df = df.set_index('Date')
In [174]: df['Date'] = df.index + pd.offsets.MonthEnd(2)
In [175]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
Out[175]:
         Date Buyer  Quantity
2013-02-28 Carl     1
                Mark     3
2014-02-28 Carl     9
                Joe    18

In [176]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
\\\
↳
         Date Buyer  Quantity
2013-01-31 Carl     1
                Mark     3
2014-01-31 Carl     9
                Joe    18

```

Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```

In [177]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [178]: df
Out[178]:

```

(continues on next page)

```
# nth(0) is the same as g.first()
In [187]: g.nth(0, dropna='any')
Out[187]:
   B
A
1  4.0
5  6.0

In [188]: g.first()
Out[188]:
   B
A
1  4.0
5  6.0

# nth(-1) is the same as g.last()
In [189]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
Out[189]:
↪
   B
A
1  4.0
5  6.0

In [190]: g.last()
↪
   B
A
1  4.0
5  6.0

In [191]: g.B.nth(0, dropna='all')
↪
A
1    4.0
5    6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [192]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [193]: g = df.groupby('A', as_index=False)
In [194]: g.nth(0)
Out[194]:
   A  B
0  1 NaN
2  5  6.0

In [195]: g.nth(-1)
Out[195]:
   A  B
1  1  4.0
2  5  6.0
```

## Enumerate groups

New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [203]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])
```

```
In [204]: dfg
```

```
Out [204]:
```

```
   A
0  a
1  a
2  a
3  b
4  b
5  a
```

```
In [205]: dfg.groupby('A').ngroup()
```

```
Out [205]:
```

```
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64
```

```
In [206]: dfg.groupby('A').ngroup(ascending=False)
```

```
Out [206]:
```

```
→
```

```
0    1
1    1
2    1
3    0
4    0
5    1
dtype: int64
```

## Plotting

`Groupby` also works with some plotting methods. For example, suppose we suspect that some features in a `DataFrame` may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [207]: np.random.seed(1234)
```

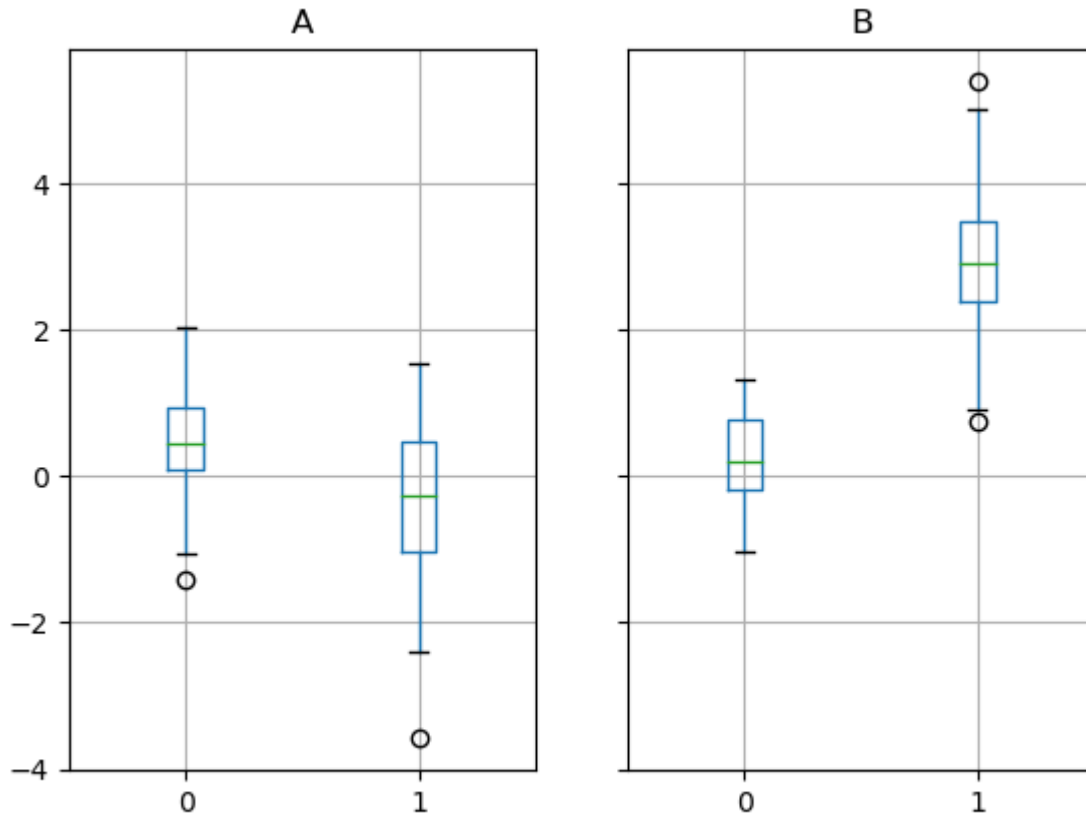

```
In [208]: df = pd.DataFrame(np.random.randn(50, 2))
```

```
In [209]: df['g'] = np.random.choice(['A', 'B'], size=50)
```

```
In [210]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [211]: df.groupby('g').boxplot()
Out [211]:
A      AxesSubplot(0.1,0.15;0.363636x0.75)
B      AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

## Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We'd like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```
In [212]: n = 1000

In [213]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                      'Product': np.random.choice(['Product_1',
.....:                                                    'Product_2'], n),
.....:                      'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....:                      'Quantity': np.random.randint(1, 10, size=n)})
.....:

In [214]: df.head(2)
Out[214]:
```

	Store	Product	Revenue	Quantity
0	Store_2	Product_1	26.12	1
1	Store_2	Product_1	28.86	1

Now, to find prices per store/product, we can simply do:

```
In [215]: (df.groupby(['Store', 'Product'])
.....:       .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....:       .unstack().round(2))
.....:
Out[215]:
```

Product	Product_1	Product_2
Store		
Store_1	6.82	7.05
Store_2	6.30	6.64

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
In [216]: def mean(groupby):
.....:       return groupby.mean()
.....:

In [217]: df.groupby(['Store', 'Product']).pipe(mean)
Out[217]:
```

		Revenue	Quantity
Store	Product		
Store_1	Product_1	34.622727	5.075758
	Product_2	35.482815	5.029630
Store_2	Product_1	32.972837	5.237589
	Product_2	34.684360	5.224000

where `mean` takes a `GroupBy` object and finds the mean of the Revenue and Quantity columns respectively for each Store-Product combination. The `mean` function can be any function that takes in a `GroupBy` object; the `.pipe` will pass the `GroupBy` object as a parameter into the function you specify.

## 4.12.10 Examples

### Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

(continued from previous page)

```
'2018-01-01 02:00:00'],
dtype='datetime64[ns]', freq='H')
```

### Manipulating and converting date times with timezone information

```
In [6]: dti = dti.tz_localize('UTC')

In [7]: dti
Out [7]:
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
              '2018-01-01 02:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert('US/Pacific')
↪
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
              '2017-12-31 18:00:00-08:00'],
              dtype='datetime64[ns, US/Pacific]', freq='H')
```

### Resampling or converting a time series to a particular frequency

```
In [9]: idx = pd.date_range('2018-01-01', periods=5, freq='H')

In [10]: ts = pd.Series(range(len(idx)), index=idx)

In [11]: ts
Out [11]:
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64

In [12]: ts.resample('2H').mean()
↪
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64
```

### Performing date and time arithmetic with absolute or relative time increments

```
In [13]: friday = pd.Timestamp('2018-01-05')

In [14]: friday.day_name()
Out [14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta('1 day')

In [16]: saturday.day_name()
Out [16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
```

(continues on next page)

(continued from previous page)

```
In [17]: monday = friday + pd.offsets.BDay()
```

```
In [18]: monday.day_name()
```

```
Out [18]: 'Monday'
```

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

### 4.13.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

Concept	Scalar Class	Array Class	pandas Data Type	Primary Creation Method
Date times	Timestamp	DatetimeIndex	datetime64[ns] or datetime64[ns, tz]	to_datetime or date_range
Time deltas	Timedelta	TimedeltaIndex	timedelta64[ns]	to_timedelta or timedelta_range
Time spans	Period	PeriodIndex	period[freq]	Period or period_range
Date offsets	DateOffset	None	None	DateOffset

For time series data, it's conventional to represent the time component in the index of a *Series* or *DataFrame* so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range('2000', freq='D', periods=3))
```

```
Out [19]:
```

```
2000-01-01    0
2000-01-02    1
2000-01-03    2
Freq: D, dtype: int64
```

However, *Series* and *DataFrame* can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range('2000', freq='D', periods=3))
```

```
Out [20]:
```

```
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
```

*Series* and *DataFrame* have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as object data.

```
In [21]: pd.Series(pd.period_range('1/1/2011', freq='M', periods=3))
```

```
Out [21]:
0    2011-01
1    2011-02
2    2011-03
dtype: period[M]
```

```
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
```

```
Out [22]:
0    <DateOffset>
1    <2 * DateOffsets>
dtype: object
```

```
In [23]: pd.Series(pd.date_range('1/1/2011', freq='M', periods=3))
```

```
Out [23]:
0    2011-01-31
1    2011-02-28
2    2011-03-31
dtype: datetime64[ns]
```

Lastly, pandas represents null date times, time deltas, and time spans as NaT which is useful for representing missing or null date like values and behaves similar as np.nan does for float data.

```
In [24]: pd.Timestamp(pd.NaT)
```

```
Out [24]: NaT
```

```
In [25]: pd.Timedelta(pd.NaT)
```

```
Out [25]: NaT
```

```
In [26]: pd.Period(pd.NaT)
```

```
Out [26]: NaT
```

```
# Equality acts as np.nan would
```

```
In [27]: pd.NaT == pd.NaT
```

```
Out [27]: False
```

### 4.13.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
```

```
Out [28]: Timestamp('2012-05-01 00:00:00')
```

```
In [29]: pd.Timestamp('2012-05-01')
```

```
Out [29]: Timestamp('2012-05-01 00:00:00')
```

```
In [30]: pd.Timestamp(2012, 5, 1)
```

```
Out [30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by Period can be specified explicitly, or inferred from datetime string format.

For example:

```
In [31]: pd.Period('2011-01')
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period('2012-05', freq='D')
Out[32]: Period('2012-05-01', 'D')
```

*Timestamp* and *Period* can serve as an index. Lists of *Timestamp* and *Period* are automatically coerced to *DatetimeIndex* and *PeriodIndex* respectively.

```
In [33]: dates = [pd.Timestamp('2012-05-01'),
.....:             pd.Timestamp('2012-05-02'),
.....:             pd.Timestamp('2012-05-03')]
.....:

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [37]: ts
Out[37]:
2012-05-01    0.469112
2012-05-02   -0.282863
2012-05-03   -1.509059
dtype: float64

In [38]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')

In [42]: ts
Out[42]:
2012-01   -1.135632
2012-02    1.212112
2012-03   -0.173215
Freq: M, dtype: float64
```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of *Timestamp* and sequences of timestamps using instances of *DatetimeIndex*. For regular time spans, pandas uses *Period* objects for scalar values and *PeriodIndex* for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

### 4.13.3 Converting to Timestamps

To convert a *Series* or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a *Series*, this returns a *Series* (with the same index), while a list-like is converted to a *DatetimeIndex*:

```
In [43]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out [43]:
0    2009-07-31
1    2010-01-10
2             NaT
dtype: datetime64[ns]

In [44]: pd.to_datetime(['2005/11/23', '2010.12.31'])
Out [44]:
DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out [45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)

In [46]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out [46]:
DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

**Warning:** You see in the above example that `dayfirst` isn't strict, so if a date can't be parsed with the day being first it will be parsed as if `dayfirst` were `False`.

If you pass a single string to `to_datetime`, it returns a single *Timestamp*. *Timestamp* can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime('2010/11/12')
Out [47]: Timestamp('2010-11-12 00:00:00')

In [48]: pd.Timestamp('2010/11/12')
Out [48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the *DatetimeIndex* constructor directly:

```
In [49]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'])
Out [49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype=
↳ 'datetime64[ns]', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], freq='infer')
Out [50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype=
↳ 'datetime64[ns]', freq='2D')
```

## Providing a Format Argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the [Python datetime documentation](#).

## Assembling Datetime from Multiple DataFrame Columns

New in version 0.18.1.

You can also pass a `DataFrame` of integer or string columns to assemble into a `Series` of `Timestamps`.

```
In [53]: df = pd.DataFrame({'year': [2015, 2016],
.....:                    'month': [2, 3],
.....:                    'day': [4, 5],
.....:                    'hour': [2, 3]})

In [54]: pd.to_datetime(df)
Out[54]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [55]: pd.to_datetime(df[['year', 'month', 'day']])
Out[55]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- **required:** year, month, day
- **optional:** hour, minute, second, millisecond, microsecond, nanosecond

## Invalid Data

The default behavior, `errors='raise'`, is to raise when unparseable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparseable:

```
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

```
In [62]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')
```

```
In [63]: stamps
```

```
Out [63]:
```

```
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
              dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [64]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
```

```
Out [64]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

### Using the `origin` Parameter

New in version 0.20.0.

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [65]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
```

```
Out [65]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
→ 'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [66]: pd.to_datetime([1, 2, 3], unit='D')
```

```
Out [66]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
→ 'datetime64[ns]', freq=None)
```

## 4.13.4 Generating Ranges of Timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [67]: dates = [datetime.datetime(2012, 5, 1),
.....:             datetime.datetime(2012, 5, 2),
.....:             datetime.datetime(2012, 5, 3)]
.....:
```

```
# Note the frequency information
```

```
In [68]: index = pd.DatetimeIndex(dates)
```

```
In [69]: index
```

```
Out [69]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
→ 'datetime64[ns]', freq=None)
```

```
# Automatically converted to DatetimeIndex
```

```
In [70]: index = pd.Index(dates)
```

```
In [71]: index
```

```
Out [71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
→ 'datetime64[ns]', freq=None)
```

(continued from previous page)

```
dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```
In [80]: pd.date_range(start, end, freq='BM')
```

```
Out[80]:
```

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')
```

```
In [81]: pd.date_range(start, end, freq='W')
```

```

////////////////////////////////////
↪
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
               '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
               '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
               '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
               '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
               '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
               '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
               '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07',
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
               '2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30',
               '2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
               '2012-01-01'],
              dtype='datetime64[ns]', freq='W-SUN')
```

```
In [82]: pd.bdate_range(end=end, periods=20)
```

```

////////////////////////////////////
↪
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
               '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
               '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
              dtype='datetime64[ns]', freq='B')
```

```
In [83]: pd.bdate_range(start=start, periods=20)
```

```

////////////////////////////////////
↪
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
               '2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',
               '2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',
               '2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],
              dtype='datetime64[ns]', freq='B')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced dates from `start` to `end` inclusively, with `periods` number of elements in the resulting `DatetimeIndex`:

```
In [84]: pd.date_range('2018-01-01', '2018-01-05', periods=5)
Out [84]:
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05'],
              dtype='datetime64[ns]', freq=None)

In [85]: pd.date_range('2018-01-01', '2018-01-05', periods=10)
////////////////////////////////////
↪
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
              '2018-01-01 21:20:00', '2018-01-02 08:00:00',
              '2018-01-02 18:40:00', '2018-01-03 05:20:00',
              '2018-01-03 16:00:00', '2018-01-04 02:40:00',
              '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Custom Frequency Ranges

**Warning:** This functionality was originally exclusive to `cdate_range`, which is deprecated as of version 0.21.0 in favor of `bdate_range`. Note that `cdate_range` only utilizes the `weekmask` and `holidays` parameters when custom business day, 'C', is passed as the frequency string. Support has been expanded with `bdate_range` to work with any custom frequency string.

New in version 0.21.0.

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [86]: weekmask = 'Mon Wed Fri'

In [87]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [88]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out [88]:
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
              '2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',
              '2011-01-24', '2011-01-26',
              ...
              '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
              '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
              '2011-12-28', '2011-12-30'],
              dtype='datetime64[ns]', length=154, freq='C')

In [89]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
////////////////////////////////////
↪
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
              '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
              '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
              dtype='datetime64[ns]', freq='CBMS')
```

**See also:**

*Custom Business Days*

### 4.13.5 Timestamp Limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [90]: pd.Timestamp.min
Out [90]: Timestamp('1677-09-21 00:12:43.145225')

In [91]: pd.Timestamp.max
Out [91]: Timestamp('2262-04-11
↪23:47:16.854775807')
```

**See also:**

*Representing Out-of-Bounds Spans*

### 4.13.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

**See also:**

*Reindexing methods*

---

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

---

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [92]: rng = pd.date_range(start, end, freq='BM')

In [93]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [94]: ts.index
Out [94]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')

In [95]: ts[:5].index
```

(continues on next page)

(continued from previous page)

```

New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [109]: dft2 = pd.DataFrame(np.random.randn(20, 1),
.....:                        columns=['A'],
.....:                        index=pd.MultiIndex.from_product(
.....:                            [pd.date_range('20130101', periods=10, freq='12H'),
.....:                             ['a', 'b']]))
.....:
```

```
In [110]: dft2
```

```
Out [110]:
```

```

                A
2013-01-01 00:00:00 a -0.298694

```

### Slice vs. Exact Match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a Series object with a minute resolution index:

```

In [115]: series_minute = pd.Series([1, 2, 3],
.....:                               pd.DatetimeIndex(['2011-12-31 23:59:00',
.....:                                                    '2012-01-01 00:00:00',
.....:                                                    '2012-01-01 00:02:00']))
.....:

In [116]: series_minute.index.resolution
Out[116]: 'minute'

```

A timestamp string less accurate than a minute gives a Series object.

```

In [117]: series_minute['2011-12-31 23']
Out[117]:
2011-12-31 23:59:00    1
dtype: int64

```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

(continued from previous page)

```
In [128]: series_monthly['2011-12'] # returns Series
Out[128]:
2011-12-01    1
dtype: int64
```

## Exact Indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
In [129]: dft[datetime.datetime(2013, 1, 1):datetime.datetime(2013, 2, 28)]
Out[129]:
          A
2013-01-01 00:00:00  0.276232

### 4.13.8 Time/Date Components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

Property	Description
year	The year of the datetime
month	The month of the datetime
day	The days of the datetime
hour	The hour of the datetime
minute	The minutes of the datetime
second	The seconds of the datetime
microsecond	The microseconds of the datetime
nanosecond	The nanoseconds of the datetime
date	Returns datetime.date (does not contain timezone information)
time	Returns datetime.time (does not contain timezone information)
timetz	Returns datetime.time as local time with timezone information
dayofyear	The ordinal day of year
weekofyear	The week ordinal of the year
week	The week ordinal of the year
dayofweek	The number of the day of the week with Monday=0, Sunday=6
weekday	The number of the day of the week with Monday=0, Sunday=6
weekday_name	The name of the day in a week (ex: Friday)
quarter	Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.
days_in_month	The number of days in the month of the datetime
is_month_start	Logical indicating if first day of month (defined by frequency)
is_month_end	Logical indicating if last day of month (defined by frequency)
is_quarter_start	Logical indicating if first day of quarter (defined by frequency)
is_quarter_end	Logical indicating if last day of quarter (defined by frequency)
is_year_start	Logical indicating if first day of year (defined by frequency)
is_year_end	Logical indicating if last day of year (defined by frequency)
is_leap_year	Logical indicating if the date belongs to a leap year

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on *.dt accessors*.

### 4.13.9 DateOffset Objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment datetimes by 24 hours, while a `DateOffset` day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (`Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` ([relativedelta documentation](#)) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the `apply` method can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [139]: ts = pd.Timestamp('2016-10-30 00:00:00', tz='Europe/Helsinki')
```

(continues on next page)

(continued from previous page)

```
# Respects absolute time
In [140]: ts + pd.Timedelta(days=1)
Out [140]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [141]: ts + pd.DateOffset(days=1)
Out [141]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [142]: friday = pd.Timestamp('2018-01-05')

In [143]: friday.day_name()
Out [143]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [144]: two_business_days = 2 * pd.offsets.BDay()

In [145]: two_business_days.apply(friday)
Out [145]: Timestamp('2018-01-09 00:00:00')

In [146]: friday + two_business_days
Out [146]: Timestamp('2018-01-09 00:00:00')

In [147]: (friday + two_business_days).day_name()
Out [147]: 'Tuesday'
```

Most DateOffsets have associated frequencies strings, or offset aliases, that can be passed into freq keyword arguments. The available date offsets and associated frequency strings can be found below:

Date Offset	Frequency String	Description
<i>DateOffset</i>	None	Generic offset class, defaults to 1 calendar day
<i>BDay</i> or <i>BusinessDay</i>	'B'	business day (weekday)
<i>CDay</i> or <i>CustomBusinessDay</i>	'C'	custom business day
<i>Week</i>	'W'	one week, optionally anchored on a day of the week
<i>WeekOfMonth</i>	'WOM'	the x-th day of the y-th week of each month
<i>LastWeekOfMonth</i>	'LWOM'	the x-th day of the last week of each month
<i>MonthEnd</i>	'M'	calendar month end
<i>MonthBegin</i>	'MS'	calendar month begin
<i>BMonthEnd</i> or <i>BusinessMonthEnd</i>	'BM'	business month end
<i>BMonthBegin</i> or <i>BusinessMonthBegin</i>	'BMS'	business month begin
<i>CBMonthEnd</i> or <i>CustomBusinessMonthEnd</i>	'CBM'	custom business month end

Continued on next page

Table 3 – continued from previous page

Date Offset	Frequency String	Description
<i>CBMonthBegin</i> or <i>CustomBusinessMonthBegin</i>	'CBMS'	custom business month begin
<i>SemiMonthEnd</i>	'SM'	15th (or other day_of_month) and calendar month end
<i>SemiMonthBegin</i>	'SMS'	15th (or other day_of_month) and calendar month begin
<i>QuarterEnd</i>	'Q'	calendar quarter end
<i>QuarterBegin</i>	'QS'	calendar quarter begin
<i>BQuarterEnd</i>	'BQ'	business quarter end
<i>BQuarterBegin</i>	'BQS'	business quarter begin
<i>FY5253Quarter</i>	'REQ'	retail (aka 52-53 week) quarter
<i>YearEnd</i>	'A'	calendar year end
<i>YearBegin</i>	'AS' or 'BYS'	calendar year begin
<i>BYearEnd</i>	'BA'	business year end
<i>BYearBegin</i>	'BAS'	business year begin
<i>FY5253</i>	'RE'	retail (aka 52-53 week) year
<i>Easter</i>	None	Easter holiday
<i>BusinessHour</i>	'BH'	business hour
<i>CustomBusinessHour</i>	'CBHr'	custom business hour
<i>Day</i>	'D'	one absolute day
<i>Hour</i>	'H'	one hour
<i>Minute</i>	'T' or 'min'	one minute
<i>Second</i>	'S'	one second
<i>Milli</i>	'L' or 'ms'	one millisecond
<i>Micro</i>	'U' or 'us'	one microsecond
<i>Nano</i>	'N'	one nanosecond

DateOffsets additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [148]: ts = pd.Timestamp('2018-01-06 00:00:00')

In [149]: ts.day_name()
Out[149]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [150]: offset = pd.offsets.BusinessHour(start='09:00')

# Bring the date to the closest offset date (Monday)
In [151]: offset.rollforward(ts)
Out[151]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [152]: ts + offset
Out[152]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

(continued from previous page)

```
In [169]: d - pd.offsets.Week(normalize=True)
Out[169]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing YearEnd with the specific ending month:

```
In [170]: d + pd.offsets.YearEnd()
Out[170]: Timestamp('2008-12-31 09:00:00')

In [171]: d + pd.offsets.YearEnd(month=6)
Out[171]: Timestamp('2009-06-30 09:00:00')
```

### Using Offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

```
In [172]: rng = pd.date_range('2012-01-01', '2012-01-03')

In [173]: s = pd.Series(rng)

In [174]: rng
Out[174]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype=
->'datetime64[ns]', freq='D')

In [175]: rng + pd.DateOffset(months=2)
Out[175]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]',
->freq='D')

In [176]: s + pd.DateOffset(months=2)
Out[176]:
0    2012-03-01
1    2012-03-02
2    2012-03-03
dtype: datetime64[ns]

In [177]: s - pd.DateOffset(months=2)
Out[177]:
0    2011-11-01
1    2011-11-02
2    2011-11-03
dtype: datetime64[ns]
```

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the *Timedelta* section for more examples.

```
In [178]: s - pd.offsets.Day(2)
Out[178]:
0    2011-12-30
1    2011-12-31
2    2012-01-01
dtype: datetime64[ns]

In [179]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))
```

(continues on next page)

(continued from previous page)

```

In [180]: td
Out[180]:
0    3 days
1    3 days
2    3 days
dtype: timedelta64[ns]

In [181]: td + pd.offsets.Minute(15)
Out[181]:
0    3 days 00:15:00
1    3 days 00:15:00
2    3 days 00:15:00
dtype: timedelta64[ns]

```

Note that some offsets (such as `BQuarterEnd`) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```

In [182]: rng + pd.offsets.BQuarterEnd()
Out[182]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype=
↳ 'datetime64[ns]', freq='D')

```

## Custom Business Days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```

In [183]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [184]: holidays = ['2012-05-01',
.....:                 datetime.datetime(2013, 5, 1),
.....:                 np.datetime64('2014-05-01')]
.....:

In [185]: bday_egypt = pd.offsets.CustomBusinessDay(holidays=holidays,
.....:                                             weekmask=weekmask_egypt)
.....:

In [186]: dt = datetime.datetime(2013, 4, 30)

In [187]: dt + 2 * bday_egypt
Out[187]: Timestamp('2013-05-05 00:00:00')

```

Let's map to the weekday names:

```

In [188]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [189]: pd.Series(dts.weekday, dts).map(
.....:     pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split()))
.....:
Out[189]:

```

(continues on next page)

(continued from previous page)

```

2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object

```

Holiday calendars can be used to provide the list of holidays. See the *holiday calendar* section for more information.

```

In [190]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [191]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [192]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [193]: dt + bday_us
Out[193]: Timestamp('2014-01-21 00:00:00')

```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```

In [194]: bmth_us = pd.offsets.CustomBusinessMonthBegin(
.....:     calendar=USFederalHolidayCalendar())
.....:

# Skip new years
In [195]: dt = datetime.datetime(2013, 12, 17)

In [196]: dt + bmth_us
Out[196]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [197]: pd.date_range(start='20100101', end='20120101', freq=bmth_us)
Out[197]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
              '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
              '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
              '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
              '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
              dtype='datetime64[ns]', freq='CBMS')

```

**Note:** The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

## Business Hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment

Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [198]: bh = pd.offsets.BusinessHour()

In [199]: bh
Out[199]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [200]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[200]: 4

In [201]: pd.Timestamp('2014-08-01 10:00') + bh
Out[201]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [202]: pd.Timestamp('2014-08-01 08:00') + bh
Out[202]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [203]: pd.Timestamp('2014-08-01 16:00') + bh
Out[203]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [204]: pd.Timestamp('2014-08-01 16:30') + bh
Out[204]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [205]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(2)
Out[205]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [206]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(-3)
Out[206]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

```
In [207]: bh = pd.offsets.BusinessHour(start='11:00', end=datetime.time(20, 0))

In [208]: bh
Out[208]: <BusinessHour: BH=11:00-20:00>

In [209]: pd.Timestamp('2014-08-01 13:00') + bh
Out[209]: Timestamp('2014-08-01 14:00:00')

In [210]: pd.Timestamp('2014-08-01 09:00') + bh
Out[210]: Timestamp('2014-08-01 12:00:00')

In [211]: pd.Timestamp('2014-08-01 18:00') + bh
```

(continues on next page)

Alias	Description
B	business day frequency
C	custom business day frequency
D	calendar day frequency
W	weekly frequency
M	month end frequency
SM	semi-month end frequency (15th and end of month)
BM	business month end frequency
CBM	custom business month end frequency
MS	month start frequency
SMS	semi-month start frequency (1st and 15th)
BMS	business month start frequency
CBMS	custom business month start frequency
Q	quarter end frequency
BQ	business quarter end frequency
QS	quarter start frequency
BQS	business quarter start frequency
A, Y	year end frequency
BA, BY	business year end frequency
AS, YS	year start frequency
BAS, BYS	business year start frequency
BH	business hour frequency
H	hourly frequency
T, min	minutely frequency
S	secondly frequency
L, ms	milliseconds
U, us	microseconds
N	nanoseconds

## Combining Aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [230]: pd.date_range(start, periods=5, freq='B')
Out [230]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
              '2011-01-07'],
              dtype='datetime64[ns]', freq='B')

In [231]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
////////////////////////////////////
↔
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
              '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```
In [232]: pd.date_range(start, periods=10, freq='2h20min')
Out [232]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
              '2011-01-01 04:40:00', '2011-01-01 07:00:00',
```

(continues on next page)

(continued from previous page)

```

        '2011-01-01 09:20:00', '2011-01-01 11:40:00',
        '2011-01-01 14:00:00', '2011-01-01 16:20:00',
        '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
        dtype='datetime64[ns]', freq='140T')

In [233]: pd.date_range(start, periods=10, freq='1D10U')
//////////////////////////////////////
↪
DatetimeIndex([          '2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
                '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
                '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
                '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
                '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
                dtype='datetime64[ns]', freq='86400000010U')

```

### Anchored Offsets

For some frequencies you can specify an anchoring suffix:

Alias	Description
W-SUN	weekly frequency (Sundays). Same as 'W'
W-MON	weekly frequency (Mondays)
W-TUE	weekly frequency (Tuesdays)
W-WED	weekly frequency (Wednesdays)
W-THU	weekly frequency (Thursdays)
W-FRI	weekly frequency (Fridays)
W-SAT	weekly frequency (Saturdays)
(B)Q(S)-DEC	quarterly frequency, year ends in December. Same as 'Q'
(B)Q(S)-JAN	quarterly frequency, year ends in January
(B)Q(S)-FEB	quarterly frequency, year ends in February
(B)Q(S)-MAR	quarterly frequency, year ends in March
(B)Q(S)-APR	quarterly frequency, year ends in April
(B)Q(S)-MAY	quarterly frequency, year ends in May
(B)Q(S)-JUN	quarterly frequency, year ends in June
(B)Q(S)-JUL	quarterly frequency, year ends in July
(B)Q(S)-AUG	quarterly frequency, year ends in August
(B)Q(S)-SEP	quarterly frequency, year ends in September
(B)Q(S)-OCT	quarterly frequency, year ends in October
(B)Q(S)-NOV	quarterly frequency, year ends in November

Continued on next page

Table 4 – continued from previous page

Alias	Description
(B)A(S)-DEC	annual frequency, anchored end of December. Same as 'A'
(B)A(S)-JAN	annual frequency, anchored end of January
(B)A(S)-FEB	annual frequency, anchored end of February
(B)A(S)-MAR	annual frequency, anchored end of March
(B)A(S)-APR	annual frequency, anchored end of April
(B)A(S)-MAY	annual frequency, anchored end of May
(B)A(S)-JUN	annual frequency, anchored end of June
(B)A(S)-JUL	annual frequency, anchored end of July
(B)A(S)-AUG	annual frequency, anchored end of August
(B)A(S)-SEP	annual frequency, anchored end of September
(B)A(S)-OCT	annual frequency, anchored end of October
(B)A(S)-NOV	annual frequency, anchored end of November

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

### Anchored Offset Semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When `n` is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved  $|n| - 1$  additional steps forwards or backwards.

```
In [234]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=1)
Out[234]: Timestamp('2014-02-01 00:00:00')
```

```
In [235]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=1)
Out[235]: Timestamp('2014-01-31 00:00:00')
```

```
In [236]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=1)
Out[236]: Timestamp('2014-01-01 00:00:00')
```

```
In [237]: pd.Timestamp('2014-01-02') - pd.offsets.MonthEnd(n=1)
Out[237]: Timestamp('2013-12-31 00:00:00')
```

```
In [238]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=4)
Out[238]: Timestamp('2014-05-01 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [239]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=4)
\\Out[239]: Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved  $|n|$  points forwards or backwards.

```
In [240]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=1)
Out[240]: Timestamp('2014-02-01 00:00:00')
```

```
In [241]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=1)
\\Out[241]: Timestamp('2014-02-28 00:00:00')
```

```
In [242]: pd.Timestamp('2014-01-01') - pd.offsets.MonthBegin(n=1)
\\Out[242]: Timestamp('2013-12-01 00:00:00')
```

```
In [243]: pd.Timestamp('2014-01-31') - pd.offsets.MonthEnd(n=1)
\\Out[243]: Timestamp('2013-12-31 00:00:00')
```

```
In [244]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=4)
\\Out[244]: Timestamp('2014-05-01 00:00:00')
```

```
In [245]: pd.Timestamp('2014-01-31') - pd.offsets.MonthBegin(n=4)
\\Out[245]: Timestamp('2013-10-01 00:00:00')
```

For the case when  $n=0$ , the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [246]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=0)
Out[246]: Timestamp('2014-02-01 00:00:00')
```

```
In [247]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=0)
\\Out[247]: Timestamp('2014-01-31 00:00:00')
```

```
In [248]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=0)
\\Out[248]: Timestamp('2014-01-01 00:00:00')
```

```
In [249]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=0)
\\Out[249]: Timestamp('2014-01-31 00:00:00')
```

### Holidays / Holiday Calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

## Shifting / Lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [270]: ts = pd.Series(range(len(rng)), index=rng)
```

```
In [271]: ts = ts[:5]
```

```
In [272]: ts.shift(1)
```

```
Out [272]:
2012-01-01    NaN
2012-01-02     0.0
2012-01-03     1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*:

```
In [273]: ts.shift(5, freq=pd.offsets.BDay())
```

```
Out [273]:
2012-01-06     0
2012-01-09     1
2012-01-10     2
Freq: B, dtype: int64
```

```
In [274]: ts.shift(5, freq='BM')
```

```
Out [274]:
2012-05-31     0
2012-05-31     1
2012-05-31     2
Freq: D, dtype: int64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```
In [275]: ts.tshift(5, freq='D')
```

```
Out [275]:
2012-01-06     0
2012-01-07     1
2012-01-08     2
Freq: D, dtype: int64
```

Note that with `tshift`, the leading entry is no longer `NaN` because the data is not being realigned.

## Frequency Conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [276]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * pd.offsets.BDay())
```

```
In [277]: ts = pd.Series(np.random.randn(3), index=dr)
```

```
In [278]: ts
```

(continues on next page)

(continued from previous page)

```
Out [278]:
2010-01-01    1.494522
2010-01-06   -0.778425
2010-01-11   -0.253355
Freq: 3B, dtype: float64
```

```
In [279]: ts.asfreq(pd.offsets.BDay())
```

```

////////////////////////////////////
↔
2010-01-01    1.494522
2010-01-04         NaN
2010-01-05         NaN
2010-01-06   -0.778425
2010-01-07         NaN
2010-01-08         NaN
2010-01-11   -0.253355
Freq: B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [280]: ts.asfreq(pd.offsets.BDay(), method='pad')
```

```
Out [280]:
2010-01-01    1.494522
2010-01-04    1.494522
2010-01-05    1.494522
2010-01-06   -0.778425
2010-01-07   -0.778425
2010-01-08   -0.778425
2010-01-11   -0.253355
Freq: B, dtype: float64
```

### Filling Forward / Backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the *missing data section*.

### Converting to Python Datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

#### 4.13.11 Resampling

**Warning:** The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the *whatsnew docs* for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some *cookbook examples* for some advanced strategies.

Starting in version 0.18.1, the `resample()` function can be used directly from `DataFrameGroupBy` objects, see the *groupby docs*.

---

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion *here*.

---

## Basics

```
In [281]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [282]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [283]: ts.resample('5Min').sum()
Out [283]:
2012-01-01    25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via *dispatching* is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [284]: ts.resample('5Min').mean()
Out [284]:
2012-01-01    251.03
Freq: 5T, dtype: float64

In [285]: ts.resample('5Min').ohlc()
Out [285]:
                open  high  low  close
2012-01-01    308    460    9    205

In [286]: ts.resample('5Min').max()
Out [286]:
2012-01-01    460
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to `'left'` or `'right'` to specify which end of the interval is closed:

```
In [287]: ts.resample('5Min', closed='right').mean()
Out [287]:
2011-12-31 23:55:00    308.000000
2012-01-01 00:00:00    250.454545
Freq: 5T, dtype: float64

In [288]: ts.resample('5Min', closed='left').mean()
Out [288]:
2012-01-01    251.03
Freq: 5T, dtype: float64
```

Parameters like `label` and `loffset` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval. `loffset` performs a time adjustment on the output labels.

```
In [289]: ts.resample('5Min').mean() # by default label='left'
Out [289]:
2012-01-01    251.03
Freq: 5T, dtype: float64

In [290]: ts.resample('5Min', label='left').mean()
Out [290]:
2012-01-01    251.03
Freq: 5T, dtype: float64

In [291]: ts.resample('5Min', label='left', loffset='1s').mean()
Out [291]:
2012-01-01 00:00:01    251.03
dtype: float64
```

**Note:** The default values for `label` and `closed` is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

```
In [292]: rng2 = pd.date_range('1/1/2012', end='3/31/2012', freq='D')
In [293]: ts2 = pd.Series(range(len(rng2)), index=rng2)

# default: label='right', closed='right'
In [294]: ts2.resample('M').max()
Out [294]:
2012-01-31    30
2012-02-29    59
2012-03-31    90
Freq: M, dtype: int64

# default: label='left', closed='left'
In [295]: ts2.resample('SM').max()
Out [295]:
2011-12-31    13
2012-01-15    29
2012-01-31    44
2012-02-15    58
2012-02-29    73
2012-03-15    89
2012-03-31    90
Freq: SM-15, dtype: int64

In [296]: ts2.resample('SM', label='right', closed='right').max()
Out [296]:
2012-01-15    14.0
2012-01-31    30.0
2012-02-15    45.0
2012-02-29    59.0
2012-03-15    74.0
2012-03-31    90.0
2012-04-15     NaN
```

(continues on next page)

(continued from previous page)

```
Freq: SM-15, dtype: float64
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`.

`kind` can be set to 'timestamp' or 'period' to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

`convention` can be set to 'start' or 'end' when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

## Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```
# from secondly to every 250 milliseconds
In [297]: ts[:2].resample('250L').asfreq()
Out [297]:
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250     NaN
2012-01-01 00:00:00.500     NaN
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

```
In [298]: ts[:2].resample('250L').ffill()
\
↔
2012-01-01 00:00:00.000    308
2012-01-01 00:00:00.250    308
2012-01-01 00:00:00.500    308
2012-01-01 00:00:00.750    308
2012-01-01 00:00:01.000    204
Freq: 250L, dtype: int64
```

```
In [299]: ts[:2].resample('250L').ffill(limit=2)
\
↔
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250    308.0
2012-01-01 00:00:00.500    308.0
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

## Sparse Resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [300]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [301]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [302]: ts.resample('3T').sum()
Out[302]:
2014-01-01 00:00:00    0
2014-01-01 00:03:00    0
2014-01-01 00:06:00    0
2014-01-01 00:09:00    0
2014-01-01 00:12:00    0
2014-01-01 00:15:00    0
2014-01-01 00:18:00    0
..
2014-04-09 23:42:00    0
2014-04-09 23:45:00    0
2014-04-09 23:48:00    0
2014-04-09 23:51:00    0
2014-04-09 23:54:00    0
2014-04-09 23:57:00    0
2014-04-10 00:00:00    99
Freq: 3T, Length: 47521, dtype: int64
```

We can instead only resample those groups where we have points as follows:

```
In [303]: from functools import partial
In [304]: from pandas.tseries.frequencies import to_offset
In [305]: def round(t, freq):
.....:     freq = to_offset(freq)
.....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
.....:
In [306]: ts.groupby(partial(round, freq='3T')).sum()
Out[306]:
2014-01-01    0
2014-01-02    1
2014-01-03    2
2014-01-04    3
2014-01-05    4
2014-01-06    5
2014-01-07    6
..
2014-04-04    93
2014-04-05    94
2014-04-06    95
2014-04-07    96
2014-04-08    97
2014-04-09    98
2014-04-10    99
Length: 100, dtype: int64
```

## Aggregation

Similar to the *aggregating API*, *groupby API*, and the *window functions API*, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```
In [307]: df = pd.DataFrame(np.random.randn(1000, 3),
.....:                      index=pd.date_range('1/1/2012', freq='S', periods=1000),
.....:                      columns=['A', 'B', 'C'])
.....:

In [308]: r = df.resample('3T')

In [309]: r.mean()
Out [309]:
```

	A	B	C
2012-01-01 00:00:00	-0.033823	-0.121514	-0.081447
2012-01-01 00:03:00	0.056909	0.146731	-0.024320
2012-01-01 00:06:00	-0.058837	0.047046	-0.052021
2012-01-01 00:09:00	0.063123	-0.026158	-0.066533
2012-01-01 00:12:00	0.186340	-0.003144	0.074752
2012-01-01 00:15:00	-0.085954	-0.016287	-0.050046

We can select a specific column or columns using standard getitem.

```
In [310]: r['A'].mean()
Out [310]:
```

2012-01-01 00:00:00	-0.033823
2012-01-01 00:03:00	0.056909
2012-01-01 00:06:00	-0.058837
2012-01-01 00:09:00	0.063123
2012-01-01 00:12:00	0.186340
2012-01-01 00:15:00	-0.085954

```
Freq: 3T, Name: A, dtype: float64

In [311]: r[['A', 'B']].mean()
///////////////////////////////////////
↪
```

	A	B
2012-01-01 00:00:00	-0.033823	-0.121514
2012-01-01 00:03:00	0.056909	0.146731
2012-01-01 00:06:00	-0.058837	0.047046
2012-01-01 00:09:00	0.063123	-0.026158
2012-01-01 00:12:00	0.186340	-0.003144
2012-01-01 00:15:00	-0.085954	-0.016287

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [312]: r['A'].agg([np.sum, np.mean, np.std])
Out [312]:
```

	sum	mean	std
2012-01-01 00:00:00	-6.088060	-0.033823	1.043263
2012-01-01 00:03:00	10.243678	0.056909	1.058534
2012-01-01 00:06:00	-10.590584	-0.058837	0.949264
2012-01-01 00:09:00	11.362228	0.063123	1.028096
2012-01-01 00:12:00	33.541257	0.186340	0.884586
2012-01-01 00:15:00	-8.595393	-0.085954	1.035476

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [313]: r.agg([np.sum, np.mean])
Out [313]:
```

	A		B		C	
	sum	mean	sum	mean	sum	mean
2012-01-01 00:00:00	-6.088060	-0.033823	-21.872530	-0.121514	-14.660515	-0.081447
2012-01-01 00:03:00	10.243678	0.056909	26.411633	0.146731	-4.377642	-0.024320
2012-01-01 00:06:00	-10.590584	-0.058837	8.468289	0.047046	-9.363825	-0.052021
2012-01-01 00:09:00	11.362228	0.063123	-4.708526	-0.026158	-11.975895	-0.066533
2012-01-01 00:12:00	33.541257	0.186340	-0.565895	-0.003144	13.455299	0.074752
2012-01-01 00:15:00	-8.595393	-0.085954	-1.628689	-0.016287	-5.004580	-0.050046

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```
In [314]: r.agg({'A': np.sum,
.....:         'B': lambda x: np.std(x, ddof=1)})
Out [314]:
```

	A	B
2012-01-01 00:00:00	-6.088060	1.001294
2012-01-01 00:03:00	10.243678	1.074597
2012-01-01 00:06:00	-10.590584	0.987309
2012-01-01 00:09:00	11.362228	0.944953
2012-01-01 00:12:00	33.541257	1.095025
2012-01-01 00:15:00	-8.595393	1.035312

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [315]: r.agg({'A': 'sum', 'B': 'std'})
Out [315]:
```

	A	B
2012-01-01 00:00:00	-6.088060	1.001294
2012-01-01 00:03:00	10.243678	1.074597
2012-01-01 00:06:00	-10.590584	0.987309
2012-01-01 00:09:00	11.362228	0.944953
2012-01-01 00:12:00	33.541257	1.095025
2012-01-01 00:15:00	-8.595393	1.035312

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [316]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
Out [316]:
```

	A		B	
	sum	std	mean	std
2012-01-01 00:00:00	-6.088060	1.043263	-0.121514	1.001294
2012-01-01 00:03:00	10.243678	1.058534	0.146731	1.074597
2012-01-01 00:06:00	-10.590584	0.949264	0.047046	0.987309
2012-01-01 00:09:00	11.362228	1.028096	-0.026158	0.944953
2012-01-01 00:12:00	33.541257	0.884586	-0.003144	1.095025
2012-01-01 00:15:00	-8.595393	1.035476	-0.016287	1.035312

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can be passed to the `on` keyword.

(continued from previous page)

```
In [324]: pd.Period('2012-1-1 19:00', freq='5H')
\-----/
↪Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different freq (span).

```
In [325]: p = pd.Period('2012', freq='A-DEC')
```

```
In [326]: p + 1
Out[326]: Period('2013', 'A-DEC')
```

```
In [327]: p - 3
\-----/
Out[327]: Period('2009', 'A-DEC')
```

```
In [328]: p = pd.Period('2012-01', freq='2M')
```

```
In [329]: p + 2
Out[329]: Period('2012-05', '2M')
```

```
In [330]: p - 1
\-----/
Out[330]: Period('2011-11', '2M')
```

```
In [331]: p == pd.Period('2012-01', freq='3M')
\-----/
↪-----
IncompatibleFrequency                                Traceback (most recent call last)
<ipython-input-331-4b67dc0b596c> in <module>
----> 1 p == pd.Period('2012-01', freq='3M')

/pandas/pandas/_libs/tslibs/period.pyx in pandas._libs.tslibs.period._Period.__
↪richcmp__()

IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)
```

If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

```
In [332]: p = pd.Period('2014-07-01 09:00', freq='H')
```

```
In [333]: p + pd.offsets.Hour(2)
Out[333]: Period('2014-07-01 11:00', 'H')
```

```
In [334]: p + datetime.timedelta(minutes=120)
\-----/
Out[334]: Period('2014-07-01 11:00', 'H')
```

```
In [335]: p + np.timedelta64(7200, 's')
\-----/
Out[335]: ↪
↪Period('2014-07-01 11:00', 'H')
```

```
In [1]: p + pd.offsets.Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)
```

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

```
In [336]: p = pd.Period('2014-07', freq='M')
```

```
In [337]: p + pd.offsets.MonthEnd(3)
```

```
Out [337]: Period('2014-10', 'M')
```

```
In [1]: p + pd.offsets.MonthBegin(3)
```

```
Traceback
```

```
...
```

```
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

```
In [338]: pd.Period('2012', freq='A-DEC') - pd.Period('2002', freq='A-DEC')
```

```
Out [338]: <10 * YearEnds: month=12>
```

## PeriodIndex and period\_range

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

```
In [339]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')
```

```
In [340]: prng
```

```
Out [340]:
```

```
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
             '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
             '2012-01'],
            dtype='period[M]', freq='M')
```

The `PeriodIndex` constructor can also be used directly:

```
In [341]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
```

```
Out [341]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of `Period` which has multiplied span.

```
In [342]: pd.period_range(start='2014-01', freq='3M', periods=4)
```

```
Out [342]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]',
                       ↪ freq='3M')
```

If start or end are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```
In [343]: pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                        .....: end=pd.Period('2017Q2', freq='Q'), freq='M')
                        .....:
```

```
Out [343]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]',
                       ↪ freq='M')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```
In [344]: ps = pd.Series(np.random.randn(len(prng)), prng)
```

```
In [345]: ps
```

(continues on next page)

(continued from previous page)

```

Out [345]:
2011-01    -2.916901
2011-02     0.514474
2011-03     1.346470
2011-04     0.816397
2011-05     2.258648

Freq: M, dtype: float64

```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [346]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
```

```
In [347]: idx
```

```
Out [347]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')
```

```
In [348]: idx + pd.offsets.Hour(2)
```

```

////////////////////////////////////
↪
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')
```

```
In [349]: idx = pd.period_range('2014-07', periods=5, freq='M')
```

```
In [350]: idx
```

```
Out [350]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'], dtype=
↪ 'period[M]', freq='M')
```

```
In [351]: idx + pd.offsets.MonthEnd(3)
```

```

////////////////////////////////////
↪ PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'], dtype=
↪ 'period[M]', freq='M')
```

PeriodIndex has its own dtype named period, refer to *Period Dtypes*.

## Period Dtypes

New in version 0.19.0.

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```
In [352]: pi = pd.period_range('2016-01-01', periods=3, freq='M')
In [353]: pi
Out [353]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]', freq='M')
In [354]: pi.dtype
Out [354]:
period[M]
```

The period dtype can be used in `.astype(...)`. It allows one to change the `freq` of a `PeriodIndex` like `.asfreq()` and convert a `DatetimeIndex` to `PeriodIndex` like `to_period()`:

```
# change monthly freq to daily freq
In [355]: pi.astype('period[D]')
Out [355]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]',
freq='D')

# convert to DatetimeIndex
In [356]: pi.astype('datetime64[ns]')
Out [356]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]',
freq='MS')

# convert to PeriodIndex
In [357]: dti = pd.date_range('2011-01-01', freq='M', periods=3)
In [358]: dti
Out [358]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'], dtype='datetime64[ns]',
freq='M')
In [359]: dti.astype('period[M]')
Out [359]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

## PeriodIndex Partial String Indexing

You can pass in dates and strings to `Series` and `DataFrame` with `PeriodIndex`, in the same manner as `DatetimeIndex`. For details, refer to *DatetimeIndex Partial String Indexing*.

```
In [360]: ps['2011-01']
Out [360]: -2.9169013294054507

In [361]: ps[datetime.datetime(2011, 12, 25):]
Out [361]:
2011-12    2.261385
2012-01   -0.329583
Freq: M, dtype: float64

In [362]: ps['10/31/2011':'12/31/2011']
Out [362]:
2011-10    0.056780
2011-11    0.197035
2011-12    2.261385
Freq: M, dtype: float64
```

(continued from previous page)

```

2013-01-01 10:53 -0.266928
2013-01-01 10:54  0.327742

2013-01-01 11:59	-0.685496

```

[120 rows x 1 columns]

```

## Frequency Conversion and Resampling with `PeriodIndex`

The frequency of `Period` and `PeriodIndex` can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```

In [368]: p = pd.Period('2011', freq='A-DEC')
In [369]: p
Out [369]: Period('2011', 'A-DEC')

```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```

In [370]: p.asfreq('M', how='start')
Out [370]: Period('2011-01', 'M')

In [371]: p.asfreq('M', how='end')
Out [371]: Period('2011-12', 'M')

```

The shorthands 's' and 'e' are provided for convenience:

```
In [372]: p.asfreq('M', 's')
Out[372]: Period('2011-01', 'M')

In [373]: p.asfreq('M', 'e')
Out[373]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```
In [374]: p = pd.Period('2011-12', freq='M')

In [375]: p.asfreq('A-NOV')
Out[375]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [376]: p = pd.Period('2012Q1', freq='Q-DEC')

In [377]: p.asfreq('D', 's')
Out[377]: Period('2012-01-01', 'D')

In [378]: p.asfreq('D', 'e')
Out[378]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:

```
In [379]: p = pd.Period('2011Q4', freq='Q-MAR')

In [380]: p.asfreq('D', 's')
Out[380]: Period('2011-01-01', 'D')

In [381]: p.asfreq('D', 'e')
Out[381]: Period('2011-03-31', 'D')
```

### 4.13.13 Converting Between Representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [382]: rng = pd.date_range('1/1/2012', periods=5, freq='M')

In [383]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [384]: ts
Out[384]:
2012-01-31    1.931253
2012-02-29   -0.184594
2012-03-31    0.249656
```

(continues on next page)

for `dateutil` is provided for compatibility with other applications e.g. if you use `dateutil` in other Python packages.

## Working with Time Zones

By default, pandas objects are time zone unaware:

```
In [402]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')
In [403]: rng.tz is None
Out[403]: True
```

To supply the time zone, you can use the `tz` keyword to `date_range` and other functions. Dateutil time zone strings are distinguished from pytz time zones by starting with `dateutil/`.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS timezones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```
In [404]: import dateutil

# pytz
In [405]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                             tz='Europe/London')
.....:

In [406]: rng_pytz.tz
Out[406]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [407]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                                 tz='dateutil/Europe/London')
.....:

In [408]: rng_dateutil.tz
Out[408]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [409]: rng_utc = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                             tz=dateutil.tz.tzutc())
.....:

In [410]: rng_utc.tz
Out[410]: tzutc()
```

Note that the UTC timezone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other timezones explicitly first, which gives you more control over which time zone is used:

```
In [411]: import pytz

# pytz
In [412]: tz_pytz = pytz.timezone('Europe/London')

In [413]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
```

(continues on next page)

(continued from previous page)

```

.....:
.....:
In [414]: rng_pytz.tz == tz_pytz
Out[414]: True

# dateutil
In [415]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [416]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:
.....:
.....:
Out[417]: rng_dateutil.tz == tz_dateutil
Out[417]: True

```

Timestamps, like Python's `datetime.datetime` object can be either time zone naive or time zone aware. Naive time series and `DatetimeIndex` objects can be *localized* using `tz_localize`:

```

In [418]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [419]: ts_utc = ts.tz_localize('UTC')

In [420]: ts_utc
Out[420]:
2012-03-06 00:00:00+00:00    0.326152
2012-03-07 00:00:00+00:00    0.455487
2012-03-08 00:00:00+00:00   -0.173426
2012-03-09 00:00:00+00:00    0.832223
2012-03-10 00:00:00+00:00   -0.166404
2012-03-11 00:00:00+00:00   -0.918468
2012-03-12 00:00:00+00:00    0.076835
2012-03-13 00:00:00+00:00    0.039694
2012-03-14 00:00:00+00:00   -1.246487
2012-03-15 00:00:00+00:00   -0.146705
2012-03-16 00:00:00+00:00   -1.392724
2012-03-17 00:00:00+00:00    0.523910
2012-03-18 00:00:00+00:00    1.578829
2012-03-19 00:00:00+00:00    0.654179
2012-03-20 00:00:00+00:00   -1.130643
Freq: D, dtype: float64

```

Again, you can explicitly construct the timezone object first. You can use the `tz_convert` method to convert pandas objects to convert tz-aware data to another time zone:

```

In [421]: ts_utc.tz_convert('US/Eastern')
Out[421]:
2012-03-05 19:00:00-05:00    0.326152
2012-03-06 19:00:00-05:00    0.455487
2012-03-07 19:00:00-05:00   -0.173426
2012-03-08 19:00:00-05:00    0.832223
2012-03-09 19:00:00-05:00   -0.166404
2012-03-10 19:00:00-05:00   -0.918468
2012-03-11 20:00:00-04:00    0.076835
2012-03-12 20:00:00-04:00    0.039694
2012-03-13 20:00:00-04:00   -1.246487

```

(continues on next page)

(continued from previous page)

```

2012-03-14 20:00:00-04:00    -0.146705
2012-03-15 20:00:00-04:00    -1.392724
2012-03-16 20:00:00-04:00     0.523910
2012-03-17 20:00:00-04:00     1.578829
2012-03-18 20:00:00-04:00     0.654179
2012-03-19 20:00:00-04:00    -1.130643
Freq: D, dtype: float64

```

**Warning:** Be wary of conversions between libraries. For some zones `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual timezones than for 'standard' zones like US/Eastern.

**Warning:** Be aware that a timezone definition across versions of timezone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** It is incorrect to pass a timezone directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=timezone('US/Eastern'))`). Instead, the datetime needs to be localized using the `localize` method on the timezone.

Under the hood, all timestamps are stored in UTC. Scalar values from a `DatetimeIndex` with a time zone will have their fields (day, hour, minute) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```

In [422]: rng_eastern = rng_utc.tz_convert('US/Eastern')

In [423]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')

In [424]: rng_eastern[5]
Out[424]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')

In [425]: rng_berlin[5]
Out[425]:
↳Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')

In [426]: rng_eastern[5] == rng_berlin[5]
Out[426]:
↳True

```

Like `Series`, `DataFrame`, and `DatetimeIndex`; `Timestamp` objects can be converted to other time zones using `tz_convert`:

```

In [427]: rng_eastern[5]
Out[427]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')

In [428]: rng_berlin[5]
Out[428]:
↳Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')

```

(continues on next page)

(continued from previous page)

```
In [429]: rng_eastern[5].tz_convert('Europe/Berlin')
\\\Out [429]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin')
```

Localization of Timestamp functions just like DatetimeIndex and Series:

```
In [430]: rng[5]
Out [430]: Timestamp('2012-03-11 00:00:00', freq='D')

In [431]: rng[5].tz_localize('Asia/Shanghai')
\\\Out [431]: Timestamp('2012-03-11 00:00:00+0800', tz='Asia/Shanghai')
```

Operations between Series in different time zones will yield UTC Series, aligning the data on the UTC timestamps:

```
In [432]: eastern = ts_utc.tz_convert('US/Eastern')

In [433]: berlin = ts_utc.tz_convert('Europe/Berlin')

In [434]: result = eastern + berlin

In [435]: result
Out [435]:
2012-03-06 00:00:00+00:00    0.652304

\\\Out [436]: DatetimeIndex(['2012-03-06 00:00:00+00:00', '2012-03-07 00:00:00+00:00',
                '2012-03-08 00:00:00+00:00', '2012-03-09 00:00:00+00:00',
                '2012-03-10 00:00:00+00:00', '2012-03-11 00:00:00+00:00',
                '2012-03-12 00:00:00+00:00', '2012-03-13 00:00:00+00:00',
                '2012-03-14 00:00:00+00:00', '2012-03-15 00:00:00+00:00',
                '2012-03-16 00:00:00+00:00', '2012-03-17 00:00:00+00:00',
                '2012-03-18 00:00:00+00:00', '2012-03-19 00:00:00+00:00',
                '2012-03-20 00:00:00+00:00'],
                dtype='datetime64[ns, UTC]', freq='D')
```

To remove timezone from tz-aware DatetimeIndex, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove timezone holding local time representations. `tz_convert(None)` will remove timezone after converting to UTC time.

This will fail as there are ambiguous times

```
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try_
↳ using the 'ambiguous' argument
```

Infer the ambiguous times

```
In [443]: rng_hourly_eastern = rng_hourly.tz_localize('US/Eastern', ambiguous='infer')

In [444]: rng_hourly_eastern.to_list()
Out [444]:
[Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0500', tz='US/Eastern'),
 Timestamp('2011-11-06 02:00:00-0500', tz='US/Eastern'),
 Timestamp('2011-11-06 03:00:00-0500', tz='US/Eastern')]
```

In addition to ‘infer’, there are several other arguments supported. Passing an array-like of bools or 0s/1s where True represents a DST hour and False a non-DST hour, allows for distinguishing more than one DST transition (e.g., if you have multiple records in a database each with their own DST transition). Or passing ‘NaT’ will fill in transition times with not-a-time values. These methods are available in the DatetimeIndex constructor as well as tz\_localize.

```
In [445]: rng_hourly_dst = np.array([1, 1, 0, 0, 0])

In [446]: rng_hourly.tz_localize('US/Eastern', ambiguous=rng_hourly_dst).to_list()
Out [446]:
[Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),

## Nonexistent Times when Localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times. The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- 'raise': Raises a `pytz.NonExistentTimeError` (the default behavior)
- 'NaT': Replaces nonexistent times with `NaT`
- 'shift\_forward': Shifts nonexistent times forward to the closest real time
- 'shift\_backward': Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [453]: dti = pd.date_range(start='2015-03-29 02:30:00', periods=3, freq='H')
```

```
# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to `NaT` or shift the times.

```
In [454]: dti
Out [454]:

              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

## TZ Aware Dtypes

Series/DatetimeIndex with a timezone **naive** value are represented with a dtype of `datetime64[ns]`.

```
In [459]: s_naive = pd.Series(pd.date_range('20130101', periods=3))
```

```
In [460]: s_naive
```

```
Out[460]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
dtype: datetime64[ns]
```

Series/DatetimeIndex with a timezone **aware** value are represented with a dtype of `datetime64[ns, tz]`.

```
In [461]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))
```

```
In [462]: s_aware
```

```
Out[462]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
```

(continues on next page)

(continued from previous page)

```
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series can be manipulated via the `.dt` accessor, see [here](#).

For example, to localize and convert a naive stamp to timezone aware.

```
In [463]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[463]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Further more you can `.astype(...)` timezone aware (and naive). This operation is effectively a localize AND convert on a naive stamp, and a convert on an aware stamp.

```
# localize and convert a naive timezone
In [464]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[464]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
In [465]: s_aware.astype('datetime64[ns]')
\
↪
0 2013-01-01 05:00:00
1 2013-01-02 05:00:00
2 2013-01-03 05:00:00
dtype: datetime64[ns]

# convert to a new timezone
In [466]: s_aware.astype('datetime64[ns, CET]')
\
↪
0 2013-01-01 06:00:00+01:00
1 2013-01-02 06:00:00+01:00
2 2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a Series, returns a NumPy array of the data. NumPy does not currently support timezones (even though it is *printing* in the local timezone!), therefore an object array of Timestamps is returned for timezone aware data:

```
In [467]: s_naive.to_numpy()
Out[467]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [468]: s_aware.to_numpy()
\
↪
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern', freq='D'),
```

(continues on next page)

(continued from previous page)

```
Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern', freq='D'),
Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern', freq='D')],
↳dtype=object)
```

By converting to an object array of Timestamps, it preserves the timezone information. For example, when converting back to a Series:

```
In [469]: pd.Series(s_aware.to_numpy())
Out [469]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array of objects, you can specify the `dtype` argument:

```
In [470]: s_aware.to_numpy(dtype='datetime64[ns]')
Out [470]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

## 4.14 Time Deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

`Timedelta` is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 4.14.1 Parsing

You can construct a `Timedelta` scalar through various arguments:

```
In [1]: import datetime

# strings
In [2]: pd.Timedelta('1 days')
Out [2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 00:00:00')
Out [3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta('1 days 2 hours')
Out [4]:
↳Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta('-1 days 2 min 3us')
Out [5]:
↳Timedelta('-2 days +23:57:59.999997')
```

(continues on next page)

(continued from previous page)

```

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
\\
↳Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit='d')
\\
↳Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
\\
↳Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, 'ms'))
\\
↳Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta('-1us')
\\
↳Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta('nan')
\\
↳NaT

In [12]: pd.Timedelta('nat')
\\
↳NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta('P0DT0H1M0S')
\\
↳Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta('P0DT0H0M0.000000123S')
\\
↳Timedelta('0 days 00:00:00.000000')

```

New in version 0.23.0: Added constructor for [ISO 8601 Duration strings](#)

*DateOffsets* (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out [15]: Timedelta('0 days 00:00:02')

```

Further, operations among the scalars yield another scalar *Timedelta*.

```

In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) + \
.....: pd.Timedelta('00:00:00.000123')
.....:
Out [16]: Timedelta('2 days 00:00:02.000123')

```

## to\_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a `Timedelta` type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a `TimedeltaIndex`.

You can parse a single string to a `Timedelta`:

```
In [17]: pd.to_timedelta('1 days 06:05:01.00003')
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta('15.5us')
Out[18]: Timedelta('0 days 00:00:00.000015')
```

or a list/array of strings:

```
In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
                        dtype='timedelta64[ns]', freq=None)
```

The `unit` keyword argument specifies the unit of the `Timedelta`:

```
In [20]: pd.to_timedelta(np.arange(5), unit='s')
Out[20]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
                        dtype='timedelta64[ns]', freq=None)

In [21]: pd.to_timedelta(np.arange(5), unit='d')
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                        dtype='timedelta64[ns]', freq=None)
```

## Timedelta limitations

Pandas represents `Timedeltas` in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the `Timedelta` limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224')

In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days
                23:47:16.854775')
```

## 4.14.2 Operations

You can operate on `Series/DataFrames` and construct `timedelta64[ns]` Series through subtraction operations on `datetime64[ns]` Series, or `Timestamps`.

```
In [24]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])

In [26]: df = pd.DataFrame({'A': s, 'B': td})
```

(continues on next page)

(continued from previous page)

**In [27]:** df**Out [27]:**

```

      A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

```

**In [28]:** df['C'] = df['A'] + df['B']**In [29]:** df**Out [29]:**

```

      A      B      C
0 2012-01-01 0 days 2012-01-01
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05

```

**In [30]:** df.dtypes

A      datetime64[ns]
B      timedelta64[ns]
C      datetime64[ns]
dtype: object

```

**In [31]:** s - s.max()

```

////////////////////////////////////
↪
0      -2 days
1      -1 days
2         0 days
dtype: timedelta64[ns]

```

**In [32]:** s - datetime.datetime(2011, 1, 1, 3, 5)

```

////////////////////////////////////
↪
0      364 days 20:55:00
1      365 days 20:55:00
2      366 days 20:55:00
dtype: timedelta64[ns]

```

**In [33]:** s + datetime.timedelta(minutes=5)

```

////////////////////////////////////
↪
0      2012-01-01 00:05:00
1      2012-01-02 00:05:00
2      2012-01-03 00:05:00
dtype: datetime64[ns]

```

**In [34]:** s + pd.offsets.Minute(5)

```

////////////////////////////////////
↪
0      2012-01-01 00:05:00
1      2012-01-02 00:05:00
2      2012-01-03 00:05:00
dtype: datetime64[ns]

```

(continues on next page)

(continued from previous page)

```
In [44]: datetime.timedelta(minutes=5) + s
//////////////////////////////////////////////////
↪
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```
In [45]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')
In [46]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))
In [47]: df = pd.DataFrame({'A': A, 'B': B})
```

```
In [48]: df
Out[48]:
          A          B
0 -1 days +23:54:55 -1 days
1  0 days 23:54:55 -1 days
2  1 days 23:54:55 -1 days
```

```
In [49]: df.min()
//////////////////////////////////////////////////
↪
A    -1 days +23:54:55
B    -1 days +00:00:00
dtype: timedelta64[ns]
```

```
In [50]: df.min(axis=1)
//////////////////////////////////////////////////
↪
0    -1 days
1    -1 days
2    -1 days
dtype: timedelta64[ns]
```

```
In [51]: df.idxmin()
//////////////////////////////////////////////////
↪
A    0
B    0
dtype: int64
```

```
In [52]: df.idxmax()
//////////////////////////////////////////////////
↪
A    2
B    0
dtype: int64
```

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```
In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')
```

(continues on next page)

(continued from previous page)

```
In [54]: df.min(axis=1).min()
\\Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
\\Out[55]:
↪ 'A'

In [56]: df.min(axis=1).idxmin()
\\Out[56]:
↪ 0
```

You can fillna on timedeltas. Integers will be interpreted as seconds. You can pass a timedelta to get a particular value.

```
In [57]: y.fillna(0)
Out[57]:
0    0 days
1    0 days
2    1 days
dtype: timedelta64[ns]

In [58]: y.fillna(10)
\\Out[58]:
0    0 days 00:00:10
1    0 days 00:00:10
2    1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
\\Out[59]:
↪
0    -1 days +00:00:05
1    -1 days +00:00:05
2     1 days 00:00:00
dtype: timedelta64[ns]
```

You can also negate, multiply and use abs on Timedeltas:

```
In [60]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')

In [61]: td1
Out[61]: Timedelta('-2 days +21:59:57')

In [62]: -1 * td1
\\Out[62]: Timedelta('1 days 02:00:03')

In [63]: - td1
\\Out[63]:
↪ Timedelta('1 days 02:00:03')

In [64]: abs(td1)
\\Out[64]:
↪ Timedelta('1 days 02:00:03')
```

(continued from previous page)

```

'1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
'1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
'1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
'1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
'1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
'1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
'1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
'1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
'1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
'1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
'1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
'1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
'1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
'1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
'2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
~/.../venv/lib/python3.8/site-packages/pandas/timedeltas.py:100:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
               '7 days 15:00:00', '9 days 20:00:00'],
               dtype='timedelta64[ns]', freq='53H')

```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced timedeltas from start to end inclusively, with periods number of elements in the resulting TimedeltaIndex:

```

In [105]: pd.timedelta_range('0 days', '4 days', periods=5)
Out [105]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
->'timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range('0 days', '4 days', periods=10)
~/.../venv/lib/python3.8/site-packages/pandas/timedeltas.py:100:
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
               '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
               '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
               '4 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)

```

## Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```

In [107]: s = pd.Series(np.arange(100),
.....:                  index=pd.timedelta_range('1 days', periods=100, freq='h'))
.....:

In [108]: s
Out [108]:
1 days 00:00:00    0
1 days 01:00:00    1

```

(continues on next page)

(continued from previous page)

```

1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
..
4 days 21:00:00   93
4 days 22:00:00   94
4 days 23:00:00   95
5 days 00:00:00   96
5 days 01:00:00   97
5 days 02:00:00   98
5 days 03:00:00   99
Freq: H, Length: 100, dtype: int64

```

Selections work similarly, with coercion on string-likes and slices:

```

In [109]: s['1 day':'2 day']
Out [109]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
..
2 days 17:00:00   41
2 days 18:00:00   42
2 days 19:00:00   43
2 days 20:00:00   44
2 days 21:00:00   45
2 days 22:00:00   46
2 days 23:00:00   47
Freq: H, Length: 48, dtype: int64

```

```
In [110]: s['1 day 01:00:00']
```

```

////////////////////////////////////
↪1

```

```
In [111]: s[pd.Timedelta('1 day 1h')]
```

```

////////////////////////////////////
↪1

```

Furthermore you can use partial string selection and the range will be inferred:

```
In [112]: s['1 day':'1 day 5 hours']
```

```

Out [112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64

```

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the axis parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let's see some examples.

```
[2]: import pandas as pd
import numpy as np

np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
              axis=1)
df.iloc[0, 2] = np.nan
```

Here's a boring example of rendering a DataFrame, without any (visible) styles:

```
[3]: df.style
[3]: <pandas.io.formats.style.Styler at 0x7f90173d31d0>
```

*Note:* The `DataFrame.style` attribute is a property that returns a `Styler` object. `Styler` has a `_repr_html_` method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the `.render()` method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we've done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the `.render` method.

```
[4]: df.style.highlight_null().render().split('\n')[:10]
[4]: ['<style type="text/css" >',
'    #T_4492268a_27fc_11e9_882e_538142ed2710row0_col2 {',
'        background-color: red;',
'    }</style><table id="T_4492268a_27fc_11e9_882e_538142ed2710" ><thead>    <tr>
↪ <th class="blank level0" ></th>        <th class="col_heading level0 col0" >
↪ A</th>        <th class="col_heading level0 col1" >B</th>        <th class="col_
↪ heading level0 col2" >C</th>        <th class="col_heading level0 col3" >D</th>
↪ <th class="col_heading level0 col4" >E</th>    </tr></thead><tbody>',
'        <tr>',
'            <th id="T_4492268a_27fc_11e9_882e_538142ed2710level0_row0"
↪ class="row_heading level0 row0" >0</th>+',
'            <td id="T_4492268a_27fc_11e9_882e_538142ed2710row0_col0"
↪ class="data row0 col0" >1</td>+',
'            <td id="T_4492268a_27fc_11e9_882e_538142ed2710row0_col1"
↪ class="data row0 col1" >1.32921</td>+',
'            <td id="T_4492268a_27fc_11e9_882e_538142ed2710row0_col2"
↪ class="data row0 col2" >nan</td>+',
'            <td id="T_4492268a_27fc_11e9_882e_538142ed2710row0_col3"
↪ class="data row0 col3" >-0.31628</td>']
```

The `row0_col2` is the identifier for that particular cell. We've also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn't collide with the styling from another within the same notebook or page (you can set the `uuid` if you'd like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let's write a simple style function that will color negative numbers red and positive numbers black.

```
[5]: def color_negative_red(val):
      """
      Takes a scalar and returns a string with
      the css property `color: red` for negative
      strings, black otherwise.
      """
      color = 'red' if val < 0 else 'black'
      return 'color: %s' % color
```

In this case, the cell's style depends only on it's own value. That means we should use the `Styler.applymap` method which works elementwise.

```
[6]: s = df.style.applymap(color_negative_red)
      s
[6]: <pandas.io.formats.style.Styler at 0x7f901418d438>
```

Notice the similarity with the standard `df.applymap`, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can't use `.applymap` anymore since that operated elementwise. Instead, we'll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we'll see that something like `highlight_max` is already defined on `Styler` so you wouldn't need to write this yourself.

```
[7]: def highlight_max(s):
      '''
      highlight the maximum in a Series yellow.
      '''
      is_max = s == s.max()
      return ['background-color: yellow' if v else '' for v in is_max]
```

```
[8]: df.style.apply(highlight_max)
[8]: <pandas.io.formats.style.Styler at 0x7f8ff98928d0>
```

In this case the input is a `Series`, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
[9]: df.style.\
      applymap(color_negative_red).\
      apply(highlight_max)
[9]: <pandas.io.formats.style.Styler at 0x7f8ff9892550>
```

Above we used `Styler.apply` to pass in each column one at a time.

Debugging Tip: If you're having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let's try that

next.

We'll rewrite our `highlight_max` to handle either `Series` (from `.apply(axis=0 or 1)`) or `DataFrames` (from `.apply(axis=None)`). We'll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.

```
[10]: def highlight_max(data, color='yellow'):
      '''
      highlight the maximum in a Series or DataFrame
      '''
      attr = 'background-color: {}'.format(color)
      if data.ndim == 1: # Series from .apply(axis=0) or axis=1
          is_max = data == data.max()
          return [attr if v else '' for v in is_max]
      else: # from .apply(axis=None)
          is_max = data == data.max().max()
          return pd.DataFrame(np.where(is_max, attr, ''),
                              index=data.index, columns=data.columns)
```

When using `Styler.apply(func, axis=None)`, the function must return a `DataFrame` with the same index and column labels.

```
[11]: df.style.apply(highlight_max, color='darkorange', axis=None)
```

```
[11]: <pandas.io.formats.style.Styler at 0x7f8ff985d9e8>
```

## Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- `Styler.applymap(func)` for elementwise styles
- `Styler.apply(func, axis=0)` for columnwise styles
- `Styler.apply(func, axis=1)` for rowwise styles
- `Styler.apply(func, axis=None)` for tablewise styles

And crucially the input and output shapes of `func` must match. If `x` is the input then `func(x).shape == x.shape`.

### 4.15.2 Finer Control: Slicing

Both `Styler.apply`, and `Styler.applymap` accept a `subset` keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a `DataFrame`.

- A scalar is treated as a column label
- A list (or series or numpy array)
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one.

```
[12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
```

```
[12]: <pandas.io.formats.style.Styler at 0x7f8ff982d828>
```

For row and column slicing, any valid indexer to `.loc` will work.

```
[13]: df.style.applymap(color_negative_red,
                        subset=pd.IndexSlice[2:5, ['B', 'D']])
```

```
[13]: <pandas.io.formats.style.Styler at 0x7f8ff985d860>
```

Only label-based slicing is supported right now, not positional.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

### 4.15.3 Finer Control: Display Values

We distinguish the *display* value from the *actual* value in `Styler`. To control the display value, the text is printed in each cell, use `Styler.format`. Cells can be formatted according to a *format spec string* or a callable that takes a single value and returns a string.

```
[14]: df.style.format("{:.2%}")
```

```
[14]: <pandas.io.formats.style.Styler at 0x7f8ff985def0>
```

Use a dictionary to format specific columns.

```
[15]: df.style.format({'B': "{:0<4.0f}", 'D': '{:+.2f}'})
```

```
[15]: <pandas.io.formats.style.Styler at 0x7f8ff983e940>
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```
[16]: df.style.format({'B': lambda x: "±{:.2f}".format(abs(x))})
```

```
[16]: <pandas.io.formats.style.Styler at 0x7f8ff983ecf8>
```

### 4.15.4 Builtin Styles

Finally, we expect certain styling functions to be common enough that we've included a few "built-in" to the `Styler`, so you don't have to write them yourself.

```
[17]: df.style.highlight_null(null_color='red')
```

```
[17]: <pandas.io.formats.style.Styler at 0x7f8ff983e828>
```

You can create "heatmaps" with the `background_gradient` method. These require `matplotlib`, and we'll use `Seaborn` to get a nice colormap.

```
[18]: import seaborn as sns
```

```
cm = sns.light_palette("green", as_cmap=True)
```

```
s = df.style.background_gradient(cmap=cm)
```

```
s
```

```
/opt/conda/envs/pandas/lib/python3.6/site-packages/matplotlib/colors.py:512:
↳RuntimeWarning: invalid value encountered in less
  xa[xa < 0] = -1
```

```
[18]: <pandas.io.formats.style.Styler at 0x7f8ff983eac8>
```

`Styler.background_gradient` takes the keyword arguments `low` and `high`. Roughly speaking these extend the range of your data by `low` and `high` percent so that when we convert the colors, the colormap's entire range isn't used. This is useful so that you can actually read the text still.

```
[19]: # Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')
```

```
[19]: <pandas.io.formats.style.Styler at 0x7f8fe9868be0>
```

```
[20]: # Compress the color range
(df.loc[:4]
 .style
 .background_gradient(cmap='viridis', low=.5, high=0)
 .highlight_null('red'))
```

```
[20]: <pandas.io.formats.style.Styler at 0x7f8fe9868908>
```

There's also `.highlight_min` and `.highlight_max`.

```
[21]: df.style.highlight_max(axis=0)
```

```
[21]: <pandas.io.formats.style.Styler at 0x7f8ff983eef0>
```

Use `Styler.set_properties` when the style doesn't actually depend on the values.

```
[22]: df.style.set_properties(**{'background-color': 'black',
                              'color': 'lawngreen',
                              'border-color': 'white'})
```

```
[22]: <pandas.io.formats.style.Styler at 0x7f8fe9868b00>
```

### Bar charts

You can include “bar charts” in your DataFrame.

```
[23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
```

```
[23]: <pandas.io.formats.style.Styler at 0x7f8ff983ea58>
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here's how you can change the above with the new `align='mid'` option:

```
[24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

```
[24]: <pandas.io.formats.style.Styler at 0x7f8fe979f128>
```

The following example aims to give a highlight of the behavior of the new align options:

```
[25]: import pandas as pd
from IPython.display import HTML

# Test series
test1 = pd.Series([-100, -60, -30, -20], name='All Negative')
```

(continues on next page)

(continued from previous page)

```

test2 = pd.Series([10,20,50,100], name='All Positive')
test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

head = """
<table>
  <thead>
    <th>Align</th>
    <th>All Negative</th>
    <th>All Positive</th>
    <th>Both Neg and Pos</th>
  </thead>
  </tbody>

"""

aligns = ['left','zero','mid']
for align in aligns:
    row = "<tr><th>{}</th>".format(align)
    for serie in [test1,test2,test3]:
        s = serie.copy()
        s.name=''
        row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                                color=['#d65f5f', '#5fba7d',
                                                                '#5fba7d', '#d65f5f'],
                                                                width=100).render())
    row += '\n'
    head += row

head+= """
</tbody>
</table>"""

HTML(head)

```

```
[25]: <IPython.core.display.HTML object>
```

### 4.15.5 Sharing Styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df2.style.set`

```
[26]: df2 = -df
style1 = df.style.applymap(color_negative_red)
style1
```

```
[26]: <pandas.io.formats.style.Styler at 0x7f8fe979fa90>
```

```
[27]: style2 = df2.style
style2.use(style1.export())
style2
```

```
[27]: <pandas.io.formats.style.Styler at 0x7f8fe97c3390>
```

Notice that you're able share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

## 4.15.6 Other Options

You’ve seen a few methods for data-driven styling. `Styler` also provides a few other options for styles that don’t depend on the data.

- precision
- captions
- table-wide styles
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the `Styler` constructor when building many styled `DataFrames` that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

### Precision

You can control the precision of floats using pandas’ regular `display.precision` option.

```
[28]: with pd.option_context('display.precision', 2):
      html = (df.style
              .applymap(color_negative_red)
              .apply(highlight_max))
      html
```

```
[28]: <pandas.io.formats.style.Styler at 0x7f8fe979f940>
```

Or through a `set_precision` method.

```
[29]: df.style\
      .applymap(color_negative_red)\
      .apply(highlight_max)\
      .set_precision(2)
```

```
[29]: <pandas.io.formats.style.Styler at 0x7f8fe97b34e0>
```

Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you’d prefer to round from the start.

### Captions

Regular table captions can be added in a few ways.

```
[30]: df.style.set_caption('Colormaps, with a caption.')\
      .background_gradient(cmap=cm)
```

```
[30]: <pandas.io.formats.style.Styler at 0x7f8fe97c3a90>
```

### Table Styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like `:hover` can only be used this way.

```
[31]: from IPython.display import HTML

def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "%s" % hover_color)])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                               ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]
html = (df.style.set_table_styles(styles)
        .set_caption("Hover to highlight. "))
html
```

```
[31]: <pandas.io.formats.style.Styler at 0x7f8fe979fe10>
```

`table_styles` should be a list of dictionaries. Each dictionary should have the `selector` and `props` keys. The value for `selector` should be a valid CSS selector. Recall that all the styles are already attached to an `id`, unique to each `Styler`. This selector is in addition to that `id`. The value for `props` should be a list of tuples of ('attribute', 'value').

`table_styles` are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that *builds on top* the tools here.

### Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```
[32]: df.style.hide_index()
```

```
[32]: <pandas.io.formats.style.Styler at 0x7f8fe97c34a8>
```

```
[33]: df.style.hide_columns(['C', 'D'])
```

```
[33]: <pandas.io.formats.style.Styler at 0x7f8fe97c39e8>
```

### CSS Classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a `MultiIndex`
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
  - `level<k>` where `k` is the level in a `MultiIndex`
- Column label cells include
  - `col_heading`
  - `col<n>` where `n` is the numeric position of the column
  - `level<k>` where `k` is the level in a `MultiIndex`

- Blank cells include `blank`
- Data cells include `data`

## Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn't great; this is intended for summary DataFrames
- You can only style the *values*, not the index or columns
- You can only apply styles, you can't insert new HTML entities

Some of these will be addressed in the future.

## Terms

- Style function: a function that's passed into `Styler.apply` or `Styler.applymap` and returns values like `'css attribute: value'`
- Builtin style functions: style functions that are methods on `Styler`
- table style: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

## 4.15.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```
[34]: from IPython.html import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
                                           as_cmap=True)
    )
```

```
<pandas.io.formats.style.Styler at 0x7f8fe979f860>
```

```
[35]: def magnify():
    return [dict(selector="th",
                props=[("font-size", "4pt")]),
            dict(selector="td",
                props=[('padding', "0em 0em")]),
            dict(selector="th:hover",
                props=[("font-size", "12pt")]),
            dict(selector="tr:hover td:hover",
                props=[('max-width', '200px'),
                      ('font-size', '12pt')])
    ]
```

```
[36]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

bigdf.style.background_gradient(cmap, axis=1)\
    .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\
    .set_caption("Hover to magnify")\
    .set_precision(2)\
    .set_table_styles(magnify())

[36]: <pandas.io.formats.style.Styler at 0x7f8fe979f2b0>
```

## 4.15.8 Export to Excel

*New in version 0.20.0*

Experimental: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their {top, right, bottom, left variants}
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
  - number-format

```
[37]: df.style.\
    applymap(color_negative_red).\
    apply(highlight_max).\
    to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:

	A	B	C	D	E	F
1		A	B	C	D	E
2	0	1	1.329212		-0.31628	-0.99081
3	1	2	-1.070816	-1.438713	0.564417	0.295722
4	2	3	-1.626404	0.219565	0.678805	1.889273
5	3	4	0.961538	0.104011	-0.481165	0.850229
6	4	5	1.453425	1.057737	0.165562	0.515018
7	5	6	-1.336936	0.562861	1.392855	-0.063328
8	6	7	0.121668	1.207603	-0.00204	1.627796
9	7	8	0.354493	1.037528	-0.385684	0.519818
10	8	9	1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

### 4.15.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll [link](#) to it.

#### Subclassing

If the default template doesn’t quite suit your needs, you can subclass `Styler` and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```
[38]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
      from IPython.display import HTML
      from pandas.io.formats.style import Styler
```

We’ll use the following template:

```
[39]: with open("templates/myhtml.tpl") as f:
      print(f.read())

{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of `Styler` that knows about it.

```
[40]: class MyStyler(Styler):
      env = Environment(
          loader=ChoiceLoader([
              FileSystemLoader("templates"), # contains ours
              Styler.loader, # the default
```

(continues on next page)

(continued from previous page)

```

    ])
)
template = env.get_template("myhtml.tpl")

```

Notice that we include the original loader in our environment's loader. That's because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It's `__init__` takes a `DataFrame`.

```
[41]: MyStyler(df)
```

```
[41]: <__main__.MyStyler at 0x7f8fe978a198>
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```
[42]: HTML(MyStyler(df).render(table_title="Extending Example"))
```

```
[42]: <IPython.core.display.HTML object>
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```
[43]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
EasyStyler(df)
```

```
[43]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at
↳0x7f8felled400>
```

Here's the template structure:

```
[44]: with open("templates/template_structure.html") as f:
      structure = f.read()
```

```
HTML(structure)
```

```
[44]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](#) for more details.

## 4.16 Options and Settings

### 4.16.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd
```

```
In [2]: pd.options.display.max_rows
```

```
Out[2]: 15
```

```
In [3]: pd.options.display.max_rows = 999
```

(continues on next page)

(continued from previous page)

```
In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

**Note:** Developers can check out [pandas/core/config.py](#) for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
.....:     pd.get_option("column")
.....: except KeyError as e:
.....:     print(e)
.....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

## 4.16.2 Getting and Setting Options

As described above, `get_option()` and `set_option()` are available from the `pandas` namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)
```

(continues on next page)

(continued from previous page)

```
In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

**Note:** The option 'mode.sim\_interactive' is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It's also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the *with* block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
.....:     print(pd.get_option("display.max_rows"))
.....:     print(pd.get_option("display.max_columns"))
.....:
10
5

In [21]: print(pd.get_option("display.max_rows"))
\\\\\\\\60

In [22]: print(pd.get_option("display.max_columns"))
\\\\\\\\\\\\\\\\0
```

### 4.16.3 Setting Startup Options in python/ipython Environment

Using startup scripts for the python/ipython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [ipython documentation](#). An example startup script for pandas is displayed below:

```
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

## 4.16.4 Frequently Used Options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [24]: pd.set_option('max_rows', 7)
```

```
In [25]: df
```

```
Out [25]:
```

```
      0         1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771
```

```
In [26]: pd.set_option('max_rows', 5)
```

```
In [27]: df
```

```
Out [27]:
```

```
      0         1
0  0.469112 -0.282863
1 -1.509059 -1.135632
..     ...     ...
5 -0.494929  1.071804
6  0.721555 -0.706771
```

```
[7 rows x 2 columns]
```

```
In [28]: pd.reset_option('max_rows')
```

`display.expand_frame_repr` allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

```
In [29]: df = pd.DataFrame(np.random.randn(5, 10))
```

```
In [30]: pd.set_option('expand_frame_repr', True)
```

```
In [31]: df
```

```
Out [31]:
```

```
      0         1         2         3         4         5         6         7         8         9
↪  8         9
0 -1.039575  0.271860 -0.424972  0.567020  0.276232 -1.087401 -0.673690  0.113648 -1.478427  0.524988

display.max\_info\_rows: `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

```
In [55]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

```

### 4.16.5 Available Options

	Option	Default	Function
display.chop_threshold	None		If set to a float value, all float values smaller than the given threshold will be displayed.
display.colheader_justify	right		Controls the justification of column headers. used by DataFrameFormatter.
display.column_space	12		No description available.
display.date_dayfirst	False		When True, prints and parses dates with the day first, eg 20/01/2005
display.date_yearfirst	False		When True, prints and parses dates with the year first, eg 2005/01/20
display.encoding	UTF-8		Defaults to the detected encoding of the console. Specifies the encoding to be used for file I/O.
display.expand_frame_repr	True		Whether to print out the full DataFrame repr for wide DataFrames across multiple lines.
display.float_format	None		The callable should accept a floating point number and return a string with the desired format.
display.large_repr	truncate		For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated version.
display.latex.repr	False		Whether to produce a latex DataFrame representation for jupyter frontends that support it.
display.latex.escape	True		Escapes special characters in DataFrames, when using the to_latex method.
display.latex.longtable	False		Specifies if the to_latex method of a DataFrame uses the longtable format.
display.latex.multicolumn	True		Combines columns when using a MultiIndex
display.latex.multicolumn_format	'l'		Alignment of multicolumn labels
display.latex.multiprow	False		Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by a horizontal line.
display.max_columns	0 or 20		max_rows and max_columns are used in __repr__() methods to decide if to_string() should be used.
display.max_colwidth	50		The maximum width in characters of a column in the repr of a pandas data structure.
display.max_info_columns	100		max_info_columns is used in DataFrame.info method to decide if per column information should be displayed.
display.max_info_rows	1690785		df.info() will usually show null-counts for each column. For large frames this can be a lot of output.
display.max_rows	60		This sets the maximum number of rows pandas should output when printing out various objects.
display.max_seq_items	100		when pretty-printing a long sequence, no more than max_seq_items will be printed. 100 is a reasonable default.
display.memory_usage	True		This specifies if the memory usage of a DataFrame should be displayed when the df.memory_usage() method is called.
display.multi_sparse	True		"Sparsify" MultiIndex display (don't display repeated elements in outer levels within a group).
display.notebook_repr_html	True		When True, IPython notebook will use html representation for pandas objects (if it is available).
display.pprint_nest_depth	3		Controls the number of nested levels to process when pretty-printing
display.precision	6		Floating point output precision in terms of number of places after the decimal, for repr.
display.show_dimensions	truncate		Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, the dimensions will be truncated.
display.width	80		Width of the display in characters. In case python/IPython is running in a terminal the width is determined by the terminal width.
display.html.table_schema	False		Whether to publish a Table Schema representation for frontends that support it.
display.html.border	1		A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr.
display.html.use_mathjax	True		When True, Jupyter notebook will process table contents using MathJax, rendering mathematical symbols.
io.excel.xls.writer	xlwt		The default Excel writer engine for 'xls' files.
io.excel.xlsm.writer	openpyxl		The default Excel writer engine for 'xlsm' files. Available options: 'openpyxl' (the default), 'xlwt'.
io.excel.xlsx.writer	openpyxl		The default Excel writer engine for 'xlsx' files.
io.hdf.default_format	None		default format writing format, if None, then put will default to 'fixed' and append will default to 'append'.
io.hdf.dropna_table	True		drop ALL nan rows when appending to a table
io.parquet.engine	None		The engine to use as a default for parquet reading and writing. If None then try 'pyarrow', 'fastparquet'.
mode.chained_assignment	warn		Controls SettingWithCopyWarning: 'raise', 'warn', or None. Raise an exception on chained assignment.
mode.sim_interactive	False		Whether to simulate interactive mode for purposes of testing.
mode.use_inf_as_na	False		True means treat None, NaN, -INF, INF as NA (old way), False means None and NaN are distinct.
compute.use_bottleneck	True		Use the bottleneck library to accelerate computation if it is installed.
compute.use_numexpr	True		Use the numexpr library to accelerate computation if it is installed.
plotting.matplotlib.register_converters	True		Register custom converters with matplotlib. Set to False to de-register.

### 4.16.6 Number Formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [79]: import numpy as np

In [80]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [81]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [82]: s / 1.e3
Out[82]:
a    -236.866u
b     846.974u
c    -685.597u
d     609.099u
e    -303.961u
dtype: float64

In [83]: s / 1.e6
Out[83]:
a    -236.866n
b     846.974n
c    -685.597n
d     609.099n
e    -303.961n
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

### 4.16.7 Unicode Formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```
In [84]: df = pd.DataFrame({'u': ['UK', u''], 'u': ['Alice', u'']})

In [85]: df
Out[85]:
0  UK  Alice
1
```

```
>>> df = pd.DataFrame({'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
   名前  国籍
0  Alice  UK
1   しのぶ  日本
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [86]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [87]: df
Out[87]:
```

```
0    UK  Alice
1
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
```

```
>>> df
   名前  国籍
0  Alice  UK
1   しのぶ  日本
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [88]: df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
```

```
In [89]: df
Out[89]:
```

```
   a    b
0  xxx  yyy
1   ¡¡  ¡¡
```

```
>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
```

```
>>> df
   a    b
0  xxx  yyy
1   ¡¡  ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
```

```
In [91]: df
Out[91]:
```

```
   a    b
0  xxx  yyy
1   ¡¡  ¡¡
```

```
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)
>>> df
   a  b
0  xxx yyy
1  ii  ii
```

### 4.16.8 Table Schema Display

New in version 0.20.0.

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [92]: pd.set_option('display.html.table_schema', True)
```

Only `'display.max_rows'` are serialized and published.

## 4.17 Enhancing Performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrames` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

### 4.17.1 Cython (Writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to `cython`.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an [example from the Cython documentation](#) but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

#### Pure python

We have a `DataFrame` to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
...:                       'b': np.random.randn(1000),
...:                       'N': np.random.randint(100, 1000, (1000)),
...:                       'x': 'x'})
...:

In [2]: df
Out[2]:
```

	a	b	N	x
0	0.469112	-0.218470	585	x
1	-0.282863	-0.061645	841	x
2	-1.509059	-0.723780	251	x

(continues on next page)

(continued from previous page)

```

3   -1.135632  0.551225  972  x
4    1.212112 -0.497767  181  x
5   -0.173215  0.837519  458  x
6    0.119209  1.103245  159  x
..      ...      ...      ...  ..
993  0.131892  0.290162  190  x
994  0.342097  0.215341  931  x
995 -1.512743  0.874737  374  x
996  0.933753  1.120790  246  x
997 -0.308013  0.198768  157  x
998 -0.079915  1.757555  977  x
999 -1.010589 -1.115680  770  x

[1000 rows x 4 columns]

```

Here's the function in pure Python:

```

In [3]: def f(x):
...:     return x * (x - 1)
...:

In [4]: def integrate_f(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f(a + i * dx)
...:     return s * dx
...:

```

We achieve our result by using apply (row-wise):

```

In [7]: %timeit df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 174 ms per loop

```

But clearly this isn't fast enough for us. Let's take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:

```

In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1) #_
↪noqa E999
    672216 function calls (667196 primitive calls) in 0.190 seconds

Ordered by: internal time
List reduced from 219 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
    1000    0.097    0.000    0.139    0.000  <ipython-input-4-c2a74e076cf0>
↪:1(integrate_f)
    552423    0.043    0.000    0.043    0.000  <ipython-input-3-c138bdd570e3>:1(f)
     3000    0.006    0.000    0.033    0.000  base.py:4341(get_value)
     3000    0.003    0.000    0.038    0.000  series.py:865(__getitem__)

```

By far the majority of time is spent inside either `integrate_f` or `f`, hence we'll concentrate our efforts cythonizing these two functions.

**Note:** In Python 2 replacing the range with its generator counterpart (`xrange`) would mean the range line would

vanish. In Python 3 `range` is already a generator.

## Plain Cython

First we're going to need to import the Cython magic function to ipython:

```
In [6]: %load_ext Cython
```

Now, let's simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython
...: def f_plain(x):
...:     return x * (x - 1)
...: def integrate_f_plain(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_plain(a + i * dx)
...:     return s * dx
...:
```

**Note:** If you're having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.

## Adding type

We get another huge improvement simply by providing type information:

```
In [8]: %%cython
...: cdef double f_typed(double x) except? -2:
...:     return x * (x - 1)
...: cpdef double integrate_f_typed(double a, double b, int N):
...:     cdef int i
...:     cdef double s, dx
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_typed(a + i * dx)
...:     return s * dx
...:
```

```
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we're talking! It's now over ten times faster than the original python implementation, and we haven't *really* modified the code. Let's have another look at what's eating up time:

```
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']),
↳axis=1)
119791 function calls (114771 primitive calls) in 0.054 seconds

Ordered by: internal time
List reduced from 216 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
  3000    0.006    0.000    0.034    0.000  base.py:4341(get_value)
     1    0.003    0.003    0.051    0.051  {pandas._libs.reduction.reduce}
  3000    0.003    0.000    0.039    0.000  series.py:865(__getitem__)
  9264    0.003    0.000    0.006    0.000  {built-in method builtins.getattr}
```

## Using ndarray

It's calling series... a lot! It's creating a Series from each row, and getting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
.....: cimport numpy as np
.....: import numpy as np
.....: cdef double f_typed(double x) except? -2:
.....:     return x * (x - 1)
.....: cpdef double integrate_f_typed(double a, double b, int N):
.....:     cdef int i
.....:     cdef double s, dx
.....:     s = 0
.....:     dx = (b - a) / N
.....:     for i in range(N):
.....:         s += f_typed(a + i * dx)
.....:     return s * dx
.....: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_
↳b,
.....:                                           np.ndarray col_N):
.....:     assert (col_a.dtype == np.float
.....:           and col_b.dtype == np.float and col_N.dtype == np.int)
.....:     cdef Py_ssize_t i, n = len(col_N)
.....:     assert (len(col_a) == len(col_b) == n)
.....:     cdef np.ndarray[double] res = np.empty(n)
.....:     for i in range(len(col_a)):
.....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
.....:     return res
.....:
```

The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

**Warning:** You can **not** pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df['a'].to_numpy(),
                  df['b'].to_numpy(),
                  df['N'].to_numpy())
```

**Note:** Loops like this would be *extremely* slow in Python, but in Cython looping over NumPy arrays is *fast*.

```
In [4]: %timeit apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
1000 loops, best of 3: 1.25 ms per loop
```

We've gotten another big improvement. Let's check again where the time is spent:

```
In [11]: %prun -l 4 apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
197 function calls in 0.002 seconds

Ordered by: internal time
List reduced from 53 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
→ 1      0.001    0.001    0.001    0.001    {built-in method _cython_magic_
62b00698d71527c516fe264bd42a374f.apply_integrate_f}
  3      0.000    0.000    0.000    0.000    managers.py:934(get)
  3      0.000    0.000    0.001    0.000    frame.py:2893(__getitem__)
  3      0.000    0.000    0.000    0.000    managers.py:963(iget)
```

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

## More advanced techniques

There is still hope for improvement. Here's an example of using some more advanced Cython techniques:

```
In [12]: %%cython
....: cimport cython
....: cimport numpy as np
....: import numpy as np
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....: @cython.boundscheck(False)
....: @cython.wraparound(False)
....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
```

(continues on next page)

(continued from previous page)

```

.....:                                     np.ndarray[double] col_b,
.....:                                     np.ndarray[int] col_N):
.....:     cdef int i, n = len(col_N)
.....:     assert len(col_a) == len(col_b) == n
.....:     cdef np.ndarray[double] res = np.empty(n)
.....:     for i in range(n):
.....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
.....:     return res
.....:
.....:

```

```

In [4]: %timeit apply_integrate_f_wrap(df['a'].values, df['b'].values, df['N'].values)
1000 loops, best of 3: 987 us per loop

```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn't checked. For more about `boundscheck` and `wraparound`, see the Cython docs on [compiler directives](#).

## 4.17.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a *dynamic jit-compiler*, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included `pycc` tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

---

**Note:** You will need to install Numba. This is easy with `conda`, by using: `conda install numba`, see [installing using miniconda](#).

---

---

**Note:** As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

---

### Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```

import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):

```

(continues on next page)

(continued from previous page)

```

s = 0
dx = (b - a) / N
for i in range(N):
    s += f_plain(a + i * dx)
return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].values, df['b'].values,
                                     df['N'].values)
    return pd.Series(result, index=df.index, name='result')

```

Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```

In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop

```

In this example, using Numba was faster than Cython.

## Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```

import numba

def double_every_value_nonumba(x):
    return x * 2

@numba.vectorize
def double_every_value_withnumba(x): # noqa E501
    return x * 2

```

```

# Custom function without numba
In [5]: %timeit df['coll_doubled'] = df.a.apply(double_every_value_nonumba) # noqa_
↳E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['coll_doubled'] = df.a * 2
1000 loops, best of 3: 233 us per loop

```

(continues on next page)

(continued from previous page)

```
# Custom function with numba
In [7]: %timeit (df['coll_doubled'] = double_every_value_withnumba(df.a.values)
1000 loops, best of 3: 145 us per loop
```

## Caveats

---

**Note:** Numba will execute on any function, but can only accelerate certain classes of functions.

---

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn't know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the [Numba troubleshooting page](#).

Read more in the [Numba docs](#).

### 4.17.3 Expression Evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

---

**Note:** To benefit from using `eval()` you need to install `numexpr`. See the *recommended dependencies section* for more details.

---

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame` objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

---

**Note:** You should not use `eval()` for simple expressions or for expressions involving small `DataFrames`. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol' Python. A good rule of thumb is to only use `eval()` when you have a `DataFrame` with more than 10,000 rows.

---

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

---

**Note:** The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

---

## Supported Syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (`<<`) and right shift (`>>`) operators, e.g., `df + 2 * pi / s`  
`** 4 % 42 - the_golden_ratio`

- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4` or `not df_bool`
- list and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: *sin, cos, exp, log, expm1, log1p, sqrt, sinh, cosh, tanh, arcsin, arccos, arctan, arccosh, arcsinh, arctanh, abs, arctan2* and *log10*.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
  - `is/is not` operations
  - `if` expressions
  - `lambda` expressions
  - list/set/dict comprehensions
  - Literal dict and set expressions
  - `yield` expressions
  - Generator expressions
  - Boolean expressions consisting of only scalar values
- Statements
  - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

## eval() Examples

`pandas.eval()` works well with expressions containing large arrays.

First let's create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in
↳ range(4)]
```

Now let's compare adding them together using plain ol' Python versus `eval()`:

```
In [15]: %timeit df1 + df2 + df3 + df4
20.5 ms +- 4.11 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
6.98 ms +- 627 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let's do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
170 ms +- 2.77 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
12.2 ms +- 1.49 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`eval()` also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))
```

```
In [20]: %timeit df1 + df2 + df3 + df4 + s
86.8 ms +- 2.44 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
7.51 ms +- 333 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

---

**Note:** Operations such as

```
1 and 2 # would parse to 1 & 2, but should evaluate to 2
3 or 4 # would parse to 3 | 4, but should evaluate to 3
~1 # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

---

### The `DataFrame.eval` method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])
```

```
In [23]: df.eval('a + b')
```

```
Out[23]:
0    -0.246747
1     0.867786
2    -1.626063
3    -1.134978
4    -1.027798
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

New in version 0.18.0.

The `inplace` keyword determines whether this assignment will be performed on the original `DataFrame` or return a copy with the new column.

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas - if your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [25]: df.eval('c = a + b', inplace=True)
```

```
In [26]: df.eval('d = a + b + c', inplace=True)
```

```
In [27]: df.eval('a = 1', inplace=True)
```

```
In [28]: df
```

```
Out [28]:
```

```
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

When `inplace` is set to `False`, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
```

```
Out [29]:
```

```
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

```
In [30]: df.eval('e = a - c', inplace=False)
```

```
////////////////////////////////////
↪
   a  b  c  d  e
0  1  5  5 10 -4
1  1  6  7 14 -6
2  1  7  9 18 -8
3  1  8 11 22 -10
4  1  9 13 26 -12
```

```
In [31]: df
```

```
////////////////////////////////////
↪
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

New in version 0.18.0.

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval("""
.....: c = a + b
.....: d = a + b + c
.....: a = 1""", inplace=False)
.....:
Out [32]:
   a  b  c  d
0  1  5  6 12
1  1  6  7 14
2  1  7  8 16
3  1  8  9 18
4  1  9 10 20
```

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [34]: df['c'] = df.a + df.b

In [35]: df['d'] = df.a + df.b + df.c

In [36]: df['a'] = 1

In [37]: df
Out [37]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

New in version 0.18.0.

The `query` method gained the `inplace` keyword which determines whether the query modifies the original frame.

```
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [39]: df.query('a > 2')
Out [39]:
   a  b
3  3  8
4  4  9

In [40]: df.query('a > 2', inplace=True)

In [41]: df
Out [41]:
   a  b
3  3  8
4  4  9
```

**Warning:** Unlike with `eval`, the default value for `inplace` for `query` is `False`. This is consistent with prior versions of pandas.

## Local Variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the @ character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))
```

```
In [43]: newcol = np.random.randn(len(df))
```

```
In [44]: df.eval('b + @newcol')
```

```
Out[44]:
```

```
0    -0.173926
1     2.493083
2    -0.881831
3    -0.691045
4     1.334703
dtype: float64
```

```
In [45]: df.query('b < @newcol')
```

```
Out[45]:
   a      b
0  0.863987 -0.115998
2 -2.621419 -1.297879
```

If you don't prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()
```

```
In [47]: df.query('@a < a')
```

```
Out[47]:
```

```
   a      b
0  0.863987 -0.115998
```

```
In [48]: df.loc[a < df.a] # same as the previous expression
```

```
Out[48]:
   a      b
0  0.863987 -0.115998
```

With `pandas.eval()` you cannot use the @ prefix *at all*, because it isn't defined in that context. pandas will let you know this if you try to use @ in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2
```

```
In [50]: pd.eval('@a + b')
```

```
Traceback (most recent call last):

File "/pandas/pandas/core/computation/eval.py", line 153, in _check_for_locals
    raise SyntaxError(msg)

File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls,
please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval('a + b')
Out [51]: 3
```

### **pandas.eval() Parsers**

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0) '
In [53]: x = pd.eval(expr, parser='python')
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
In [56]: np.all(x == y)
Out [56]: True
```

The same expression can be “anded” together with the word `and` as well:

```
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0) '
In [58]: x = pd.eval(expr, parser='python')
In [59]: expr_with_ands = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'
In [60]: y = pd.eval(expr_with_ands, parser='pandas')
In [61]: np.all(x == y)
Out [61]: True
```

The `and` and `or` operators here have the same precedence that they would in vanilla Python.

### **pandas.eval() Backends**

There's also the option to make `eval()` operate identical to plain ol' Python.

---

**Note:** Using the 'python' engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

---

You can see this by using `pandas.eval()` with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python

```
In [62]: %timeit df1 + df2 + df3 + df4
16.9 ms +- 1.18 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [63]: %timeit pd.eval('df1 + df2 + df3 + df4', engine='python')
18.1 ms +- 1.04 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

### `pandas.eval()` Performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

---

**Note:** Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a DataFrame with 3 columns each containing floating point values generated using `numpy.random.randn()`.

### Technical Minutia Regarding Expression Evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60 characters in length. Second, we can't pass object arrays to `numexpr` thus string comparisons must be evaluated in Python space.

The upshot is that this *only* applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame({'strings': np.repeat(list('cba'), 3),
.....:                    'nums': np.repeat(range(3), 3)})
.....:
```

```
In [65]: df
```

```
Out [65]:
  strings  nums
0        c    0
1        c    0
2        c    0
3        b    1
4        b    1
5        b    1
6        a    2
7        a    2
8        a    2
```

```
In [66]: df.query('strings == "a" and nums == 1')
```

```

////////////////////////////////////
↪
Empty DataFrame
```

(continues on next page)

(continued from previous page)

```
Columns: [strings, nums]
Index: []
```

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that *can* be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

## 4.18 Sparse data structures

**Note:** The `SparsePanel` class has been removed in 0.19.0

We have implemented “sparse” versions of `Series` and `DataFrame`. These are not sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (`NaN` / missing value, though any value can be chosen) is omitted. A special `SparseIndex` object tracks where data has been “sparsified”. This will make much more sense with an example. All of the standard pandas data structures have a `to_sparse` method:

```
In [1]: ts = pd.Series(np.random.randn(10))
```

```
In [2]: ts[2:-2] = np.nan
```

```
In [3]: sts = ts.to_sparse()
```

```
In [4]: sts
```

```
Out [4]:
```

```
0    0.469112
1   -0.282863
2         NaN
3         NaN
4         NaN
5         NaN
6         NaN
7         NaN
8   -0.861849
9   -2.104569
dtype: Sparse[float64, nan]
BlockIndex
Block locations: array([0, 8], dtype=int32)
Block lengths: array([2, 2], dtype=int32)
```

The `to_sparse` method takes a `kind` argument (for the sparse index, see below) and a `fill_value`. So if we had a mostly zero `Series`, we could convert it to sparse with `fill_value=0`:

```
In [5]: ts.fillna(0).to_sparse(fill_value=0)
```

```
Out [5]:
```

```
0    0.469112
1   -0.282863
2    0.000000
3    0.000000
4    0.000000
```

(continues on next page)

(continued from previous page)

```
6          NaN
7          NaN
8   -0.861849
9   -2.104569
dtype: float64
```

### 4.18.1 Sparse Accessor

New in version 0.24.0.

Pandas provides a `.sparse` accessor, similar to `.str` for string data, `.cat` for categorical data, and `.dt` for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```
In [12]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int]")

In [13]: s.sparse.density
Out[13]: 0.5

In [14]: s.sparse.fill_value
Out[14]: 0
```

This accessor is available only on data with `SparseDtype`, and on the `Series` class itself for creating a `Series` with sparse data from a `scipy COO` matrix with.

### 4.18.2 SparseArray

`SparseArray` is the base layer for all of the sparse indexed data structures. It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```
In [15]: arr = np.random.randn(10)

In [16]: arr[2:5] = np.nan

In [17]: arr[7:8] = np.nan

In [18]: sparr = pd.SparseArray(arr)

In [19]: sparr
Out[19]:
[-1.95566352972, -1.6588664276, nan, nan, nan, 1.15893288864, 0.145297113733, nan, 0.
 →606027190513, 1.33421134013]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

Like the indexed objects (`SparseSeries`, `SparseDataFrame`), a `SparseArray` can be converted back to a regular ndarray by calling `to_dense`:

```
In [20]: sparr.to_dense()
Out[20]:
array([-1.9557, -1.6589,      nan,      nan,      nan,  1.1589,  0.1453,
        nan,  0.606 ,  1.3342])
```

It raises if any value cannot be coerced to specified dtype.

```
In [1]: ss = pd.Series([1, np.nan, np.nan]).to_sparse()
Out [1]:
0    1.0
1    NaN
2    NaN
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)

In [2]: ss.astype(np.int64)
Out [2]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

### 4.18.5 Sparse Calculation

You can apply NumPy *ufuncs* to SparseArray and get a SparseArray as a result.

```
In [35]: arr = pd.SparseArray([1., np.nan, np.nan, -2., np.nan])

In [36]: np.abs(arr)
Out [36]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The *ufunc* is also applied to *fill\_value*. This is needed to get the correct dense result.

```
In [37]: arr = pd.SparseArray([1., -1, -1, -2., -1], fill_value=-1)

In [38]: np.abs(arr)
Out [38]:
[1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)

In [39]: np.abs(arr).to_dense()
Out [39]:
array([ 1.,  1.,  1.,  2.,  1.])
```

### 4.18.6 Interaction with scipy.sparse

#### SparseDataFrame

New in version 0.20.0.

Pandas supports creating sparse dataframes directly from `scipy.sparse` matrices.

```
In [40]: from scipy.sparse import csr_matrix
```

(continues on next page)

(continued from previous page)

```

In [41]: arr = np.random.random(size=(1000, 5))

In [42]: arr[arr < .9] = 0

In [43]: sp_arr = csr_matrix(arr)

In [44]: sp_arr
Out [44]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
      with 517 stored elements in Compressed Sparse Row format>

In [45]: sdf = pd.SparseDataFrame(sp_arr)

In [46]: sdf
Out [46]:
      0  1  2  3  4
0  0.956380 NaN NaN NaN NaN
1      NaN NaN NaN NaN NaN
2      NaN NaN NaN NaN NaN
3      NaN NaN NaN NaN NaN
4  0.999552 NaN NaN 0.956153 NaN
5      NaN NaN NaN NaN NaN
6  0.913638 NaN NaN NaN NaN
..     ... ..     ...     ... ..
993     NaN NaN NaN NaN NaN
994     NaN NaN NaN NaN NaN
995     NaN NaN NaN 0.998834 NaN
996     NaN NaN NaN NaN NaN
997     NaN NaN NaN NaN NaN
998     NaN NaN 0.95659 NaN NaN
999     NaN NaN NaN NaN NaN

[1000 rows x 5 columns]

```

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed. To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use the `SparseDataFrame.to_coo()` method:

```

In [47]: sdf.to_coo()
Out [47]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
      with 517 stored elements in COOrdinate format>

```

## SparseSeries

A `SparseSeries.to_coo()` method is implemented for transforming a `SparseSeries` indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.

```

In [48]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [49]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
      ...:                                   (1, 2, 'a', 1),
      ...:                                   (1, 1, 'b', 0),

```

(continues on next page)

(continued from previous page)

```

\[\]
↪[(1, 1), (1, 2), (2, 1)]

```

```

In [57]: columns

```

```

\[\]
↪[('a', 0), ('a', 1), ('b', 0), ('b', 1)]

```

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

```

In [58]: A, rows, columns = ss.to_coo(row_levels=['A', 'B', 'C'],
.....:                               column_levels=['D'],
.....:                               sort_labels=False)
.....:

```

```

In [59]: A

```

```

Out[59]:

```

```

<3x2 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>

```

```

In [60]: A.todense()

```

```

\[\]
↪
matrix([[ 3.,  0.],
        [ 1.,  3.],
        [ 0.,  0.]])

```

```

In [61]: rows

```

```

\[\]
↪[(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

```

```

In [62]: columns

```

```

\[\]
↪[0, 1]

```

A convenience method `SparseSeries.from_coo()` is implemented for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`.

```

In [63]: from scipy import sparse

```

```

In [64]: A = sparse.coo_matrix((([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
.....:                          shape=(3, 4))
.....:

```

```

In [65]: A

```

```

Out[65]:

```

```

<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>

```

```

In [66]: A.todense()

```

```

\[\]
↪
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])

```

The default behaviour (with `dense_index=False`) simply returns a `SparseSeries` containing only the non-null entries.

```
In [67]: ss = pd.SparseSeries.from_coo(A)
```

```
In [68]: ss
```

```
Out [68]:
```

```
0 2 1.0
   3 2.0
1 0 3.0
dtype: Sparse[float64, nan]
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```
In [69]: ss_dense = pd.SparseSeries.from_coo(A, dense_index=True)
```

```
In [70]: ss_dense
```

```
Out [70]:
```

```
0 0 NaN
   1 NaN
   2 1.0
   3 2.0
1 0 3.0
   1 NaN
   2 NaN
   3 NaN
2 0 NaN
   1 NaN
   2 NaN
   3 NaN
dtype: Sparse[float64, nan]
BlockIndex
Block locations: array([2], dtype=int32)
Block lengths: array([3], dtype=int32)
```

## 4.19 Frequently Asked Questions (FAQ)

### 4.19.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see *the list of options*), specifies if the DataFrame's memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```
In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
...:             'complex128', 'object', 'bool']
...:
...:

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}
```

(continues on next page)

(continued from previous page)

```

In [4]: df = pd.DataFrame(data)

In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64                5000 non-null int64
float64              5000 non-null float64
datetime64[ns]      5000 non-null datetime64[ns]
timedelta64[ns]     5000 non-null timedelta64[ns]
complex128           5000 non-null complex128
object               5000 non-null object
bool                 5000 non-null bool
categorical          5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳object(1), timedelta64[ns](1)
memory usage: 289.1+ KB

```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```

In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64                5000 non-null int64
float64              5000 non-null float64
datetime64[ns]      5000 non-null datetime64[ns]
timedelta64[ns]     5000 non-null timedelta64[ns]
complex128           5000 non-null complex128
object               5000 non-null object
bool                 5000 non-null bool
categorical          5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳object(1), timedelta64[ns](1)
memory usage: 425.6 KB

```

By default the display option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a `Series` with an index represented by column names and memory usage of each column shown in bytes. For the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```

In [8]: df.memory_usage()
Out [8]:
Index                80
int64                40000
float64              40000
datetime64[ns]      40000
timedelta64[ns]     40000

```

(continues on next page)

(continued from previous page)

```

complex128      80000
object          40000
bool            5000
categorical     10920
dtype: int64

```

```
# total memory usage of dataframe
```

```
In [9]: df.memory_usage().sum()
```

```

////////////////////////////////////
↪296000

```

By default the memory usage of the DataFrame's index is shown in the returned Series, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)
```

```
Out [10]:
```

```

int64          40000
float64        40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128     80000
object         40000
bool           5000
categorical    10920
dtype: int64

```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also *Categorical Memory Usage*.

## 4.19.2 Using If/Truth Statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```

>>> if pd.Series([False, True, False]):
...     pass

```

Should it be `True` because it's not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```

>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().

```

You need to explicitly choose what you want to do with the DataFrame, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```
>>> if pd.Series([False, True, False]) is not None:
...     print("I was not None")
I was not None
```

Below is how to check if any of the values are True:

```
>>> if pd.Series([False, True, False]).any():
...     print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()
Out[11]: True

In [12]: pd.Series([False]).bool()
Out[12]: False

In [13]: pd.DataFrame([[True]]).bool()
Out[13]: True

In [14]: pd.DataFrame([[False]]).bool()
Out[14]: False
```

## Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.

```
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See *boolean comparisons* for more examples.

## Using the `in` operator

Using the Python `in` operator on a `Series` tests for membership in the index, not membership among the values.

```
In [15]: s = pd.Series(range(5), index=list('abcde'))

In [16]: 2 in s
Out[16]: False

In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and `Series` are dict-like. To test for membership in the values, use the method `isin()`:

```
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c     True
d    False
e    False
dtype: bool

In [19]: s.isin([2]).any()
Out[19]:
↪ True
```

For DataFrames, likewise, `in` applies to the column axis, testing for membership in the list of column names.

### 4.19.3 NaN, Integer NA values and NA type promotions

#### Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A *masked array* solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value `NaN` (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

#### Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [20]: s = pd.Series([1, 2, 3, 4, 5], index=list('abcde'))

In [21]: s
Out[21]:
a    1
b    2
c    3
d    4
e    5
dtype: int64

In [22]: s.dtype
Out[22]: dtype('int64')

In [23]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])
```

(continues on next page)

## NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

Typeclass	Promotion dtype for storing NAs
<code>floating</code>	no change
<code>object</code>	no change
<code>integer</code>	cast to <code>float64</code>
<code>boolean</code>	cast to <code>object</code>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than  $2^{53}$ . Some explanation for the motivation is in the next section.

## Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

Typeclass	Dtypes
<code>numpy.floating</code>	<code>float16</code> , <code>float32</code> , <code>float64</code> , <code>float128</code>
<code>numpy.integer</code>	<code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code>
<code>numpy.unsignedinteger</code>	<code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code>
<code>numpy.object_</code>	<code>object_</code>
<code>numpy.bool_</code>	<code>bool_</code>
<code>numpy.character</code>	<code>string_</code> , <code>unicode_</code>

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean *mask* denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

### 4.19.4 Differences with NumPy

For `Series` and `DataFrame` objects, `var()` normalizes by  $N-1$  to produce unbiased estimates of the sample variance, while NumPy’s `var` normalizes by  $N$ , which measures the variance of the sample. Note that `cov()` normalizes by  $N-1$  in both pandas and NumPy.

### 4.19.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of `DataFrame` objects shared among threads, we recommend holding locks inside the threads where

the data copying occurs.

See [this link](#) for more information.

### 4.19.6 Byte-Ordering Issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like::

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order *before* passing it to Series or DataFrame constructors using something similar to the following:

```
In [32]: x = np.array(list(range(10)), '>i4') # big endian
In [33]: newx = x.byteswap().newbyteorder() # force native byteorder
In [34]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.

## 4.20 Cookbook

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 4.20.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...:                      'BBB': [10, 20, 30, 40],
...:                      'CCC': [100, 50, -30, -50]})
...:

In [2]: df
Out[2]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
```

(continues on next page)

(continued from previous page)

```
2    6    30   -30
3    7    40   -50
```

**if-then...**

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, 'BBB'] = -1
```

```
In [4]: df
```

```
Out [4]:
```

```
   AAA  BBB  CCC
0     4   10  100
1     5   -1   50
2     6   -1  -30
3     7   -1  -50
```

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555
```

```
In [6]: df
```

```
Out [6]:
```

```
   AAA  BBB  CCC
0     4   10  100
1     5  555  555
2     6  555  555
3     7  555  555
```

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000
```

```
In [8]: df
```

```
Out [8]:
```

```
   AAA  BBB  CCC
0     4 2000 2000
1     5  555  555
2     6  555  555
3     7  555  555
```

Or use pandas where after you've set up a mask

```
In [9]: df_mask = pd.DataFrame({'AAA': [True] * 4,
...:                           'BBB': [False] * 4,
...:                           'CCC': [True, False] * 2})
...:
```

```
In [10]: df.where(df_mask, -1000)
```

```
Out [10]:
```

```
   AAA  BBB  CCC
0     4 -1000 2000
1     5 -1000 -1000
2     6 -1000  555
3     7 -1000 -1000
```

if-then-else using numpy's where()

```
In [11]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [12]: df
Out[12]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [13]: df['logic'] = np.where(df['AAA'] > 5, 'high', 'low')

In [14]: df
Out[14]:
   AAA  BBB  CCC  logic
0     4   10  100   low
1     5   20   50   low
2     6   30  -30  high
3     7   40  -50  high
```

## Splitting

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [16]: df
Out[16]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [17]: df[df.AAA <= 5]
Out[17]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50

In [18]: df[df.AAA > 5]
Out[18]:
   AAA  BBB  CCC
2     6   30  -30
3     7   40  -50
```

## Building Criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [20]: df
Out[20]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

... and (without assignment returns a Series)

```
In [21]: df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']
Out[21]:
0    4
1    5
Name: AAA, dtype: int64
```

... or (without assignment returns a Series)

```
In [22]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']
Out[22]:
0    4
1    5
2    6
3    7
Name: AAA, dtype: int64
```

... or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1

In [24]: df
Out[24]:
   AAA  BBB  CCC
0  0.1   10  100
1  5.0   20   50
2  0.1   30  -30
3  0.1   40  -50
```

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [26]: df
Out[26]:
   AAA  BBB  CCC
0    4   10  100
```

(continues on next page)

(continued from previous page)

```
1    5    20    50
2    6    30   -30
3    7    40   -50
```

```
In [27]: aValue = 43.0
```

```
In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
```

```
Out[28]:
```

```
   AAA  BBB  CCC
1     5   20   50
0     4   10  100
2     6   30  -30
3     7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:
```

```
In [30]: df
```

```
Out[30]:
```

```
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

```
In [31]: Crit1 = df.AAA <= 5.5
```

```
In [32]: Crit2 = df.BBB == 10.0
```

```
In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

... Or it can be done with a list of dynamically built criteria

```
In [35]: import functools
```

```
In [36]: CritList = [Crit1, Crit2, Crit3]
```

```
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
```

```
In [38]: df[AllCrit]
```

```
Out[38]:
```

```
   AAA  BBB  CCC
0     4   10  100
```

## 4.20.2 Selection

## DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:
```

```
In [40]: df
```

```
Out [40]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

```
In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
```

```
Out [41]:
   AAA  BBB  CCC
0    4   10  100
2    6   30  -30
```

Use `loc` for label-oriented slicing and `iloc` positional slicing

```
In [42]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]},
.....:                    index=['foo', 'bar', 'boo', 'kar'])
.....:
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```
In [43]: df.loc['bar':'kar'] # Label
```

```
Out [43]:
   AAA  BBB  CCC
bar    5   20   50
boo    6   30  -30
kar    7   40  -50
```

```
# Generic
```

```
In [44]: df.iloc[0:3]
```

```
Out [44]:
   AAA  BBB  CCC
foo    4   10  100
bar    5   20   50
boo    6   30  -30
```

```
In [45]: df.loc['bar':'kar']
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
      AAA  BBB  CCC
bar    5   20   50
boo    6   30  -30
kar    7   40  -50

```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```

In [46]: data = {'AAA': [4, 5, 6, 7],
.....:          'BBB': [10, 20, 30, 40],
.....:          'CCC': [100, 50, -30, -50]}
.....:

In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4]) # Note index starts at 1.

In [48]: df2.iloc[1:3] # Position-oriented
Out[48]:
      AAA  BBB  CCC
2     5   20   50
3     6   30  -30

In [49]: df2.loc[1:3] # Label-oriented
////////////////////////////////////Out[49]:
      AAA  BBB  CCC
1     4   10  100
2     5   20   50
3     6   30  -30

```

Using inverse operator (~) to take the complement of a mask

```

In [50]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [51]: df
Out[51]:
      AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
////////////////////////////////////Out[52]:
↪
      AAA  BBB  CCC
1     5   20   50
3     7   40  -50

```

## Panels

Extend a panel frame by transposing, adding a new dimension, and transposing back to the original dimensions

```
In [53]: rng = pd.date_range('1/1/2013', periods=100, freq='D')
In [54]: data = np.random.randn(100, 4)
In [55]: cols = ['A', 'B', 'C', 'D']
In [56]: df1 = pd.DataFrame(data, rng, cols)
In [57]: df2 = pd.DataFrame(data, rng, cols)
In [58]: df3 = pd.DataFrame(data, rng, cols)
In [59]: pf = pd.Panel({'df1': df1, 'df2': df2, 'df3': df3})
In [60]: pf
Out[60]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 4 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to D
In [61]: pf.loc[:, :, 'F'] = pd.DataFrame(data, rng, cols)
In [62]: pf
Out[62]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 5 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to F
```

Mask a panel by using `np.where` and then reconstructing the panel with the new masked values

## New Columns

Efficiently and dynamically creating new columns using `applymap`

```
In [63]: df = pd.DataFrame({'AAA': [1, 2, 1, 3],
.....:                    'BBB': [1, 1, 2, 2],
.....:                    'CCC': [2, 1, 3, 1]})
.....:
In [64]: df
Out[64]:
   AAA  BBB  CCC
0    1    1    2
1    2    1    1
2    1    2    3
3    3    2    1
In [65]: source_cols = df.columns  # Or some subset would work too
In [66]: new_cols = [str(x) + "_cat" for x in source_cols]
In [67]: categories = {1: 'Alpha', 2: 'Beta', 3: 'Charlie'}
```

(continues on next page)

(continued from previous page)

```
In [68]: df[new_cols] = df[source_cols].applymap(categories.get)
```

```
In [69]: df
```

```
Out [69]:
```

	AAA	BBB	CCC	AAA_cat	BBB_cat	CCC_cat
0	1	1	2	Alpha	Alpha	Beta
1	2	1	1	Beta	Alpha	Alpha
2	1	2	3	Alpha	Beta	Charlie
3	3	2	1	Charlie	Beta	Alpha

Keep other columns when using min() with groupby

```
In [70]: df = pd.DataFrame({'AAA': [1, 1, 1, 2, 2, 2, 3, 3],
.....:                      'BBB': [2, 1, 3, 4, 5, 1, 2, 3]})
.....:
```

```
In [71]: df
```

```
Out [71]:
```

	AAA	BBB
0	1	2
1	1	1
2	1	3
3	2	4
4	2	5
5	2	1
6	3	2
7	3	3

Method 1 : idxmin() to get the index of the minimums

```
In [72]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
```

```
Out [72]:
```

	AAA	BBB
1	1	1
5	2	1
6	3	2

Method 2 : sort then take first of each

```
In [73]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
```

```
Out [73]:
```

	AAA	BBB
0	1	1
1	2	1
2	3	2

Notice the same results, with the exception of the index.

### 4.20.3 MultiIndexing

The *multiindexing* docs.

Creating a MultiIndex from a labeled frame

```

In [74]: df = pd.DataFrame({'row': [0, 1, 2],
.....:                    'One_X': [1.1, 1.1, 1.1],
.....:                    'One_Y': [1.2, 1.2, 1.2],
.....:                    'Two_X': [1.11, 1.11, 1.11],
.....:                    'Two_Y': [1.22, 1.22, 1.22]})
.....:

In [75]: df
Out[75]:
   row  One_X  One_Y  Two_X  Two_Y
0    0    1.1    1.2    1.11  1.22
1    1    1.1    1.2    1.11  1.22
2    2    1.1    1.2    1.11  1.22

# As Labelled Index
In [76]: df = df.set_index('row')

In [77]: df
Out[77]:
      One_X  One_Y  Two_X  Two_Y
row
0         1.1    1.2    1.11  1.22
1         1.1    1.2    1.11  1.22
2         1.1    1.2    1.11  1.22

# With Hierarchical Columns
In [78]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_'))
.....:                                         for c in df.columns])
.....:

In [79]: df
Out[79]:
      One      Two
      X      Y      X      Y
row
0     1.1  1.2  1.11  1.22
1     1.1  1.2  1.11  1.22
2     1.1  1.2  1.11  1.22

# Now stack & Reset
In [80]: df = df.stack(0).reset_index(1)

In [81]: df
Out[81]:
   level_1      X      Y
row
0        One  1.10  1.20
0        Two  1.11  1.22
1        One  1.10  1.20
1        Two  1.11  1.22
2        One  1.10  1.20
2        Two  1.11  1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [82]: df.columns = ['Sample', 'All_X', 'All_Y']

In [83]: df

```

(continues on next page)

(continued from previous page)

```

Out [83]:
   Sample  All_X  All_Y
row
0     One    1.10    1.20
0     Two    1.11    1.22
1     One    1.10    1.20
1     Two    1.11    1.22
2     One    1.10    1.20
2     Two    1.11    1.22

```

## Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```

In [84]: cols = pd.MultiIndex.from_tuples([(x, y) for x in ['A', 'B', 'C']
.....:                                     for y in ['O', 'I']])
.....:

In [85]: df = pd.DataFrame(np.random.randn(2, 6), index=['n', 'm'], columns=cols)

In [86]: df
Out [86]:
           A           I           B           I           C           I
n  1.920906 -0.388231 -2.314394  0.665508  0.402562  0.399555
m -1.765956  0.850423  0.388054  0.992312  0.744086 -0.739776

In [87]: df = df.div(df['C'], level=1)

In [88]: df
Out [88]:
           A           I           B           I           C           I
n  4.771702 -0.971660 -5.749162  1.665625  1.0  1.0
m -2.373321 -1.149568  0.521518 -1.341367  1.0  1.0

```

## Slicing

Slicing a MultiIndex with xs

```

In [89]: coords = [('AA', 'one'), ('AA', 'six'), ('BB', 'one'), ('BB', 'two'),
.....:               ('BB', 'six')]
.....:

In [90]: index = pd.MultiIndex.from_tuples(coords)

In [91]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ['MyData'])

In [92]: df
Out [92]:
           MyData
AA one         11
   six         22
BB one         33

```

(continues on next page)

(continued from previous page)

```
two      44
six      55
```

To take the cross section of the 1st level and 1st axis the index:

```
# Note : level and axis are optional, and default to zero
In [93]: df.xs('BB', level=0, axis=0)
Out [93]:
      MyData
one      33
two      44
six      55
```

... and now the 2nd level of the 1st axis.

```
In [94]: df.xs('six', level=1, axis=0)
Out [94]:
      MyData
AA      22
BB      55
```

Slicing a MultiIndex with xs, method #2

```
In [95]: import itertools

In [96]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'],
....:                                  ['Comp', 'Math', 'Sci']))
....:

In [97]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))

In [98]: indx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])

In [99]: cols = pd.MultiIndex.from_tuples(headr)      # Notice these are un-named

In [100]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]

In [101]: df = pd.DataFrame(data, indx, cols)

In [102]: df
Out [102]:
      Exams      Labs

## Expanding Data

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval

## Splitting

Splitting a frame

Create a list of dataframes, split using a delineation based on logic included in rows.

```
In [156]: df = pd.DataFrame(data={'Case': ['A', 'A', 'A', 'B', 'A', 'A', 'B', 'A',
.....:                                'A'],
.....:                            'Data': np.random.randn(9)})
.....:
```

```
In [157]: dfs = list(zip(*df.groupby((1 * (df['Case'] == 'B')).cumsum()
.....:                               .rolling(window=3, min_periods=1).median()))[-1]
.....:
```

```
In [158]: dfs[0]
```

```
Out [158]:
```

	Case	Data
0	A	0.174068
1	A	-0.439461
2	A	-0.741343
3	B	-0.079673

```
In [159]: dfs[1]
```

```
Out [159]:
```

	Case	Data
4	A	-0.922875
5	A	0.303638
6	B	-0.917368

```
In [160]: dfs[2]
```

```
Out [160]:
```

	Case	Data
7	A	-1.624062
8	A	-0.758514

## Pivot

The *Pivot* docs.

Partial sums and subtotals

```

In [161]: df = pd.DataFrame(data={'Province': ['ON', 'QC', 'BC', 'AL', 'AL', 'MN', 'ON'
↵'],
.....:                               'City': ['Toronto', 'Montreal', 'Vancouver',
.....:                                       'Calgary', 'Edmonton', 'Winnipeg',
.....:                                       'Windsor'],
.....:                               'Sales': [13, 6, 16, 8, 4, 3, 1]})
.....:

In [162]: table = pd.pivot_table(df, values=['Sales'], index=['Province'],
.....:                             columns=['City'], aggfunc=np.sum, margins=True)
.....:

In [163]: table.stack('City')
Out[163]:

```

Province	City	Sales
AL	All	12.0

.....:                                     '2008', '2008', '2009', '2009', '2009'],
.....:                       'Class': ['algebra', 'stats', 'bio', 'algebra',
.....:                                   'algebra', 'stats', 'stats', 'algebra',
.....:                                   'bio', 'bio'],
.....:                       'Participated': ['yes', 'yes', 'yes', 'yes', 'no',
.....:                                         'yes', 'yes', 'yes', 'yes', 'yes'],
.....:                       'Passed': ['yes' if x > 50 else 'no' for x in grades],
.....:                       'Employed': [True, True, True, False,
.....:                                     False, False, False, True, True, False],
.....:                       'Grade': grades})
.....:

In [166]: df.groupby('ExamYear').agg({'Participated': lambda x: x.value_counts()['yes'
↵'],
.....:                               'Passed': lambda x: sum(x == 'yes')},

```

(continues on next page)

(continued from previous page)

```

.....:
.....:          'Employed': lambda x: sum(x),
.....:          'Grade': lambda x: sum(x) / len(x)}
.....:
Out [166]:

```

ExamYear	Participated	Passed	Employed	Grade
2007	3	2	3	74.000000
2008	3	3	0	68.500000
2009	3	2	2	60.666667

### Plot pandas DataFrame with year over year data

To create year and month cross tabulation:

```

In [167]: df = pd.DataFrame({'value': np.random.randn(36)},
.....:                      index=pd.date_range('2011-01-01', freq='M', periods=36))
.....:

In [168]: pd.pivot_table(df, index=df.index.month, columns=df.index.year,
.....:                   values='value', aggfunc='sum')
.....:
Out [168]:

```

	2011	2012	2013
1	-0.560859	0.120930	0.516870
2	-0.589005	-0.210518	0.343125

## 4.20.6 Timeseries

Between times

Using indexer between time

Constructing a datetime range that excludes weekends and includes only certain times

Vectorized Lookup

Aggregation and plotting time series

Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series.  
How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency

Calculate the first day of the month for each entry in a DatetimeIndex

```

In [185]: dates = pd.date_range('2000-01-01', periods=5)

In [186]: dates.to_period(freq='M').to_timestamp()
Out[186]:
DatetimeIndex(['2000-01-01', '2000-01-01', '2000-01-01', '2000-01-01',
                '2000-01-01'],
              dtype='datetime64[ns]', freq=None)

```

## Resampling

The *Resample* docs.

Using Grouper instead of TimeGrouper for time grouping of values

Time grouping with some missing values

Valid frequency arguments to Grouper

Grouping using a MultiIndex

Using TimeGrouper and another grouping to create subgroups, then apply a custom function

Resampling with custom periods

Resample intraday frame without adding new days

Resample minute data

Resample with groupby

## 4.20.7 Merge

The *Concat* docs. The *Join* docs.

Append two dataframes with overlapping index (emulate R rbind)

```
In [187]: rng = pd.date_range('2000-01-01', periods=6)
In [188]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C'
↪])
In [189]: df2 = df1.copy()
```

Depending on df construction, `ignore_index` may be needed

```
In [190]: df = df1.append(df2, ignore_index=True)
In [191]: df
Out[191]:
```

	A	B	C
0	-0.480676	-1.305282	-0.212846

```

	Area	Bins	Test_0_L	Data_L	Test_1_L	Test_0_R	Data_R	Test_1_R
0	A	110	0	-0.378914	-1	1	-1.032527	0
1	A	160	0	-1.402816	-1	1	0.715333	0
2	A	160	1	0.715333	0	2	-0.091438	1
3	C	40	0	1.608418	-1	1	0.753207	0

How to set the index and join

KDB like asof join

Join with a criteria based on the values

Using searchsorted to merge based on values inside a range

## 4.20.8 Plotting

The *Plotting* docs.

Make Matplotlib look like R

Setting x-axis major and minor labels

Plotting multiple charts in an ipython notebook

Creating a multi-line plot

Plotting a heatmap

Annotate a time-series plot

Annotate a time-series plot #2

Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter

Boxplot for each quartile of a stratifying variable

```
In [196]: df = pd.DataFrame(
.....:     {'stratifying_var': np.random.uniform(0, 100, 20),
.....:      'price': np.random.normal(100, 5, 20)})
.....:
In [197]: df['quartiles'] = pd.qcut(
.....:     df['stratifying_var'],
.....:     4,
.....:     labels=['0-25%', '25-50%', '50-75%', '75-100%'])
.....:
In [198]: df.boxplot(column='price', by='quartiles')
Out [198]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7a0f451438>
```

### 4.20.9 Data In/Out

Performance comparison of SQL vs HDF5

#### CSV

The *CSV* docs

[read\\_csv](#) in action

[appending to a csv](#)

[Reading a csv chunk-by-chunk](#)

[Reading only certain rows of a csv chunk-by-chunk](#)

[Reading the first few lines of a frame](#)

[Reading a file that is compressed but not by gzip/bz2 \(the native compressed formats which read\\_csv understands\). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here](#)

[Inferring dtypes from a file](#)

[Dealing with bad lines](#)

Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

## Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [199]: for i in range(3):
.....:     data = pd.DataFrame(np.random.randn(10, 4))
.....:     data.to_csv('file_{}.csv'.format(i))
.....:

In [200]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [201]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [202]: import glob

In [203]: import os

In [204]: files = glob.glob('file_*.csv')

In [205]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*` (...) functions described in the *io docs*.

## Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [206]: i = pd.date_range('20000101', periods=10000)

In [207]: df = pd.DataFrame({'year': i.year, 'month': i.month, 'day': i.day})

In [208]: df.head()
Out[208]:
   year  month  day
0  2000     1    1
1  2000     1    2
2  2000     1    3
3  2000     1    4
4  2000     1    5

In [209]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y
↪ %m%d')
.....: ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'],
.....:                                           x['month'], x['day']), axis=1)
.....: ds.head()
.....: %timeit pd.to_datetime(ds)
.....:
```

(continues on next page)

(continued from previous page)

```
In [214]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns

In [215]: pd.read_csv(StringIO(data), sep=';', index_col=0,
.....:                header=12, parse_dates=True, names=columns)
.....:

Out [215]:
```

	Param1	Param2	Param4	Param5
date				
1990-01-01 00:00:00	1	1	2	3
1990-01-01 01:00:00	5	3	4	5
1990-01-01 02:00:00	9	5	6	7
1990-01-01 03:00:00	13	7	8	9
1990-01-01 04:00:00	17	9	10	11
1990-01-01 05:00:00	21	11	12	13

## SQL

The *SQL* docs

Reading from databases with SQL

## Excel

The *Excel* docs

Reading from a filelike handle

Modifying formatting in XlsxWriter output

## HTML

Reading HTML tables from a server that cannot handle the default request header

## HDFStore

The *HDFStores* docs

Simple Queries with a Timestamp Index

Managing heterogeneous data using a linked multiple table hierarchy

Merging on-disk tables with millions of rows

Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. [See here](#)

Creating a store chunk-by-chunk from a csv file

Appending to a store, while creating a unique index

Large Data work flows

Reading in a sequence of files, then providing a global unique index to a store while appending

Groupby on a HDFStore with low group density

Groupby on a HDFStore with high group density

Hierarchical queries on a HDFStore

Counting with a HDFStore

Troubleshoot HDFStore exceptions

Setting min\_itemsize with strings

Using ptrepack to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [216]: df = pd.DataFrame(np.random.randn(8, 3))

In [217]: store = pd.HDFStore('test.h5')

In [218]: store.put('df', df)

# you can store an arbitrary Python object via pickle
In [219]: store.get_storer('df').attrs.my_attribute = {'A': 10}

In [220]: store.get_storer('df').attrs.my_attribute
Out[220]: {'A': 10}
```

## Binary Files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);
}
```

(continues on next page)

(continued from previous page)

```

return 0;
}

```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```

names = 'count', 'avg', 'scale'

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
              align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))

```

**Note:** The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas' IO facilities.

## 4.20.10 Computation

Numerical integration (sample-based) of a time series

### Correlation

Often it's useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from *DataFrame*. *corr()*. This can be achieved by passing a boolean mask to *where* as follows:

```

In [221]: df = pd.DataFrame(np.random.random(size=(100, 5)))
In [222]: corr_mat = df.corr()
In [223]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool), k=-1)
In [224]: corr_mat.where(mask)
Out[224]:

```

	0	1	2	3	4
0	NaN	NaN	NaN	NaN	NaN
1	0.100443	NaN	NaN	NaN	NaN
2	0.012441	-0.068965	NaN	NaN	NaN
3	0.009641	0.078722	-0.067531	NaN	NaN
4	-0.065089	-0.156980	-0.004463	0.075126	NaN

The *method* argument within *DataFrame.corr* can accept a callable in addition to the named correlation types. Here we compute the *distance correlation* matrix for a *DataFrame* object.

```

In [225]: def distcorr(x, y):
.....:     n = len(x)
.....:     a = np.zeros(shape=(n, n))
.....:     b = np.zeros(shape=(n, n))

```

(continues on next page)

(continued from previous page)

```

.....:
In [226]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [227]: df.corr(method=distcorr)
Out[227]:
   0    1    2
0  1.0  NaN  NaN
1  NaN  1.0  NaN
2  NaN  NaN  1.0

```

## 4.20.11 Timedeltas

The *Timedeltas* docs.

Using timedeltas

```

In [228]: import datetime

In [229]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [230]: s - s.max()
Out[230]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]

In [231]: s.max() - s
Out[231]:
0    2 days
1    1 days
2    0 days
dtype: timedelta64[ns]

In [232]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[232]:
0    364 days 20:55:00
1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]

In [233]: s + datetime.timedelta(minutes=5)
Out[233]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]

In [234]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[234]:
0    -365 days +03:05:00

```

(continues on next page)

(continued from previous page)

```
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]
```

```
In [235]: datetime.timedelta(minutes=5) + s
```

```
////////////////////////////////////
→
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]
```

### Adding and subtracting deltas and dates

```
In [236]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])
```

```
In [237]: df = pd.DataFrame({'A': s, 'B': deltas})
```

```
In [238]: df
```

```
Out [238]:
      A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
```

```
In [239]: df['New Dates'] = df['A'] + df['B']
```

```
In [240]: df['Delta'] = df['A'] - df['New Dates']
```

```
In [241]: df
```

```
Out [241]:
      A      B  New Dates  Delta
0 2012-01-01 0 days 2012-01-01 0 days
1 2012-01-02 1 days 2012-01-03 -1 days
2 2012-01-03 2 days 2012-01-05 -2 days
```

```
In [242]: df.dtypes
```

```
////////////////////////////////////
→
A      datetime64[ns]
B      timedelta64[ns]
New Dates  datetime64[ns]
Delta      timedelta64[ns]
dtype: object
```

### Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [243]: y = s - s.shift()
```

```
In [244]: y
```

```
Out [244]:
0      NaT
1   1 days
2   1 days
dtype: timedelta64[ns]
```

(continues on next page)

(continued from previous page)

```
In [245]: y[1] = np.nan

In [246]: y
Out[246]:
0      NaT
1      NaT
2      1 days
dtype: timedelta64[ns]
```

## 4.20.12 Aliasing Axis Names

To globally provide aliases for axis names, one can define these 2 functions:

```
In [247]: def set_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES[alias] = axis
.....:
```

```
In [248]: def clear_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES.pop(alias, None)
.....:
```

```
In [249]: set_axis_alias(pd.DataFrame, 'columns', 'myaxis2')

In [250]: df2 = pd.DataFrame(np.random.randn(3, 2), columns=['c1', 'c2'],
.....:                        index=['i1', 'i2', 'i3'])
.....:

In [251]: df2.sum(axis='myaxis2')
Out[251]:
i1    -0.842809
i2    -2.136732
i3    -0.596719
dtype: float64

In [252]: clear_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

## 4.20.13 Creating Example Data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [253]: def expand_grid(data_dict):
.....:     rows = itertools.product(*data_dict.values())
.....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
.....:

In [254]: df = expand_grid({'height': [60, 70],
```

(continues on next page)

(continued from previous page)

```
.....:          'weight': [100, 140, 180],  
.....:          'sex': ['Male', 'Female']})  
.....:
```

In [255]: df

Out [255]:

	height	weight	sex
0	60	100	Male
1	60	100	Female
2	60	140	Male
3	60	140	Female
4	60	180	Male
5	60	180	Female
6	70	100	Male
7	70	100	Female
8	70	140	Male
9	70	140	Female
10	70	180	Male
11	70	180	Female

## PANDAS ECOSYSTEM

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. This is encouraging because it means pandas is not only helping users to handle their data tasks but also that it provides a better starting point for developers to build powerful and more focused data tools. The creation of libraries that complement pandas' functionality also allows pandas development to remain focused around its original requirements.

This is an inexhaustive list of projects that build on pandas in order to provide tools in the PyData space. For a list of projects that depend on pandas, see the [libraries.io usage page for pandas](#) or [search pypi for pandas](#).

We'd like to make it easier for users to find these projects, if you know of other substantial projects that you feel should be on this list, please let us know.

### 5.1 Statistics and Machine Learning

#### 5.1.1 Statsmodels

Statsmodels is the prominent Python “statistics and econometrics library” and it has a long-standing special relationship with pandas. Statsmodels provides powerful statistics, econometrics, analysis and modeling functionality that is out of pandas' scope. Statsmodels leverages pandas objects as the underlying data container for computation.

#### 5.1.2 sklearn-pandas

Use pandas DataFrames in your [scikit-learn](#) ML pipeline.

#### 5.1.3 Featuretools

Featuretools is a Python library for automated feature engineering built on top of pandas. It excels at transforming temporal and relational datasets into feature matrices for machine learning using reusable feature engineering “primitives”. Users can contribute their own primitives in Python and share them with the rest of the community.

### 5.2 Visualization

#### 5.2.1 Altair

Altair is a declarative statistical visualization library for Python. With Altair, you can spend more time understanding your data and its meaning. Altair's API is simple, friendly and consistent and built on top of the powerful Vega-Lite

JSON specification. This elegant simplicity produces beautiful and effective visualizations with a minimal amount of code. Altair works with Pandas DataFrames.

### 5.2.2 Bokeh

Bokeh is a Python interactive visualization library for large datasets that natively uses the latest web technologies. Its goal is to provide elegant, concise construction of novel graphics in the style of Protovis/D3, while delivering high-performance interactivity over large data to thin clients.

### 5.2.3 seaborn

Seaborn is a Python visualization library based on `matplotlib`. It provides a high-level, dataset-oriented interface for creating attractive statistical graphics. The plotting functions in seaborn understand pandas objects and leverage pandas grouping operations internally to support concise specification of complex visualizations. Seaborn also goes beyond matplotlib and pandas with the option to perform statistical estimation while plotting, aggregating across observations and visualizing the fit of statistical models to emphasize patterns in a dataset.

### 5.2.4 yhat/ggpy

Hadley Wickham's `ggplot2` is a foundational exploratory visualization package for the R language. Based on “The Grammar of Graphics” it provides a powerful, declarative and extremely general way to generate bespoke plots of any kind of data. It's really quite incredible. Various implementations to other languages are available, but a faithful implementation for Python users has long been missing. Although still young (as of Jan-2014), the `yhat/ggpy` project has been progressing quickly in that direction.

### 5.2.5 IPython Vega

IPython Vega leverages Vega to create plots within Jupyter Notebook.

### 5.2.6 Plotly

Plotly's Python API enables interactive figures and web shareability. Maps, 2D, 3D, and live-streaming graphs are rendered with WebGL and D3.js. The library supports plotting directly from a pandas DataFrame and cloud-based collaboration. Users of `matplotlib`, `ggplot for Python`, and `Seaborn` can convert figures into interactive web-based plots. Plots can be drawn in IPython Notebooks, edited with R or MATLAB, modified in a GUI, or embedded in apps and dashboards. Plotly is free for unlimited sharing, and has `cloud`, `offline`, or `on-premise` accounts for private use.

### 5.2.7 QtPandas

Spun off from the main pandas library, the `qtpandas` library enables DataFrame visualization and manipulation in PyQt4 and PySide applications.

## 5.3 IDE

### 5.3.1 IPython

IPython is an interactive command shell and distributed computing environment. IPython tab completion works with Pandas methods and also attributes like DataFrame columns.

### 5.3.2 Jupyter Notebook / Jupyter Lab

Jupyter Notebook is a web application for creating Jupyter notebooks. A Jupyter notebook is a JSON document containing an ordered list of input/output cells which can contain code, text, mathematics, plots and rich media. Jupyter notebooks can be converted to a number of open standard output formats (HTML, HTML presentation slides, LaTeX, PDF, ReStructuredText, Markdown, Python) through ‘Download As’ in the web interface and `jupyter convert` in a shell.

Pandas DataFrames implement `_repr_html_` and `__repr_latex` methods which are utilized by Jupyter Notebook for displaying (abbreviated) HTML or LaTeX tables. LaTeX output is properly escaped. (Note: HTML tables may or may not be compatible with non-HTML Jupyter output formats.)

See *Options and Settings* and *Available Options* for `pandas display . settings`.

### 5.3.3 quantopian/qgrid

qgrid is “an interactive grid for sorting and filtering DataFrames in IPython Notebook” built with SlickGrid.

### 5.3.4 Spyder

Spyder is a cross-platform PyQt-based IDE combining the editing, analysis, debugging and profiling functionality of a software development tool with the data exploration, interactive execution, deep inspection and rich visualization capabilities of a scientific environment like MATLAB or Rstudio.

Its *Variable Explorer* allows users to view, manipulate and edit pandas `Index`, `Series`, and `DataFrame` objects like a “spreadsheet”, including copying and modifying values, sorting, displaying a “heatmap”, converting data types and more. Pandas objects can also be renamed, duplicated, new columns added, copied/pasted to/from the clipboard (as TSV), and saved/loaded to/from a file. Spyder can also import data from a variety of plain text and binary files or the clipboard into a new pandas DataFrame via a sophisticated import wizard.

Most pandas classes, methods and data attributes can be autocompleted in Spyder’s *Editor* and *IPython Console*, and Spyder’s *Help pane* can retrieve and render Numpydoc documentation on pandas objects in rich text with Sphinx both automatically and on-demand.

## 5.4 API

### 5.4.1 pandas-datareader

`pandas-datareader` is a remote data access library for pandas (PyPI:`pandas-datareader`). It is based on functionality that was located in `pandas.io.data` and `pandas.io.wb` but was split off in v0.19. See more in the [pandas-datareader docs](#):

The following data feeds are available:

- [Google Finance](#)
- [Tiingo](#)
- [Morningstar](#)
- [IEX](#)
- [Robinhood](#)
- [Enigma](#)
- [Quandl](#)
- [FRED](#)
- [Fama/French](#)
- [World Bank](#)
- [OECD](#)
- [Eurostat](#)
- [TSP Fund Data](#)
- [Nasdaq Trader Symbol Definitions](#)
- [Stooq Index Data](#)
- [MOEX Data](#)

### 5.4.2 [quandl/Python](#)

Quandl API for Python wraps the Quandl REST API to return Pandas DataFrames with timeseries indexes.

### 5.4.3 [pydatastream](#)

PyDatastream is a Python interface to the [Thomson Dataworks Enterprise \(DWE/Datastream\)](#) SOAP API to return indexed Pandas DataFrames or Panels with financial data. This package requires valid credentials for this API (non free).

### 5.4.4 [pandaSDMX](#)

pandaSDMX is a library to retrieve and acquire statistical data and metadata disseminated in [SDMX 2.1](#), an ISO-standard widely used by institutions such as statistics offices, central banks, and international organisations. pandaSDMX can expose datasets and related structural metadata including data flows, code-lists, and data structure definitions as pandas Series or MultiIndexed DataFrames.

### 5.4.5 [fredapi](#)

fredapi is a Python interface to the [Federal Reserve Economic Data \(FRED\)](#) provided by the Federal Reserve Bank of St. Louis. It works with both the FRED database and ALFRED database that contains point-in-time data (i.e. historic data revisions). fredapi provides a wrapper in Python to the FRED HTTP API, and also provides several convenient methods for parsing and analyzing point-in-time data from ALFRED. fredapi makes use of pandas and returns data in a Series or DataFrame. This module requires a FRED API key that you can obtain for free on the FRED website.

## 5.5 Domain Specific

### 5.5.1 Geopandas

Geopandas extends pandas data objects to include geographic information which support geometric operations. If your work entails maps and geographical coordinates, and you love pandas, you should take a close look at Geopandas.

### 5.5.2 xarray

xarray brings the labeled data power of pandas to the physical sciences by providing N-dimensional variants of the core pandas data structures. It aims to provide a pandas-like and pandas-compatible toolkit for analytics on multi-dimensional arrays, rather than the tabular data for which pandas excels.

## 5.6 Out-of-core

### 5.6.1 Blaze

Blaze provides a standard API for doing computations with various in-memory and on-disk backends: NumPy, Pandas, SQLAlchemy, MongoDB, PyTables, PySpark.

### 5.6.2 Dask

Dask is a flexible parallel computing library for analytics. Dask provides a familiar `DataFrame` interface for out-of-core, parallel and distributed computing.

### 5.6.3 Dask-ML

Dask-ML enables parallel and distributed machine learning using Dask alongside existing machine learning libraries like Scikit-Learn, XGBoost, and TensorFlow.

### 5.6.4 Odo

Odo provides a uniform API for moving data between different formats. It uses pandas own `read_csv` for CSV IO and leverages many existing packages such as PyTables, h5py, and pymongo to move data between non pandas formats. Its graph based approach is also extensible by end users for custom formats that may be too specific for the core of odo.

### 5.6.5 Ray

Pandas on Ray is an early stage DataFrame library that wraps Pandas and transparently distributes the data and computation. The user does not need to know how many cores their system has, nor do they need to specify how to distribute the data. In fact, users can continue using their previous Pandas notebooks while experiencing a considerable speedup from Pandas on Ray, even on a single machine. Only a modification of the import statement is needed, as we demonstrate below. Once you've changed your import statement, you're ready to use Pandas on Ray just like you would Pandas.

```
# import pandas as pd
import ray.dataframe as pd
```

## 5.6.6 Vaex

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. Vaex is a python library for Out-of-Core DataFrames (similar to Pandas), to visualize and explore big tabular datasets. It can calculate statistics such as mean, sum, count, standard deviation etc, on an N-dimensional grid up to a billion ( $10^9$ ) objects/rows per second. Visualization is done using histograms, density plots and 3d volume rendering, allowing interactive exploration of big data. Vaex uses memory mapping, zero memory copy policy and lazy computations for best performance (no memory wasted).

- `vaex.from_pandas`
- `vaex.to_pandas_df`

## 5.7 Data validation

### 5.7.1 Engarde

Engarde is a lightweight library used to explicitly state your assumptions about your datasets and check that they're *actually* true.

## 5.8 Extension Data Types

Pandas provides an interface for defining *extension types* to extend NumPy's type system. The following libraries implement that interface to provide types not found in NumPy or pandas, which work well with pandas' data containers.

### 5.8.1 cyberpandas

Cyberpandas provides an extension type for storing arrays of IP Addresses. These arrays can be stored inside pandas' Series and DataFrame.

## 5.9 Accessors

A directory of projects providing *extension accessors*. This is for users to discover new accessors and for library authors to coordinate on the namespace.

Library	Accessor	Classes
<code>cyberpandas</code>	<code>ip</code>	<code>Series</code>
<code>pdvega</code>	<code>vgplot</code>	<code>Series, DataFrame</code>

## API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in `pandas.*` namespace are public.

Some subpackages are public which include `pandas.errors`, `pandas.plotting`, and `pandas.testing`. Public functions in `pandas.io` and `pandas.tseries` submodules are mentioned in the documentation. `pandas.api.types` subpackage holds some public functions related to data types in pandas.

**Warning:** The `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

## 6.1 Input/Output

### 6.1.1 Pickling

---

`read_pickle(path[, compression])` Load pickled pandas object (or any object) from file.

---

#### `pandas.read_pickle`

`pandas.read_pickle(path, compression='infer')`  
Load pickled pandas object (or any object) from file.

**Warning:** Loading pickled data received from untrusted sources can be unsafe. See [here](#).

#### Parameters

**path** [str] File path where the pickled object will be loaded.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, xz or zip if path ends in '.gz', '.bz2', '.xz', or '.zip' respectively, and no decompression otherwise. Set to None for no decompression.

New in version 0.20.0.

#### Returns

**unpickled** [same type as object stored in file]

See also:

**DataFrame.to\_pickle** Pickle (serialize) DataFrame object to file.

**Series.to\_pickle** Pickle (serialize) Series object to file.

**read\_hdf** Read HDF5 file into a DataFrame.

**read\_sql** Read SQL query or database table into a DataFrame.

**read\_parquet** Load a parquet object, returning a DataFrame.

## Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> pd.to_pickle(original_df, "./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

## 6.1.2 Flat File

<code>read_table(filepath_or_buffer[, sep, ...])</code>	(DEPRECATED) Read general delimited file into DataFrame.
<code>read_csv(filepath_or_buffer[, sep, ...])</code>	Read a comma-separated values (csv) file into DataFrame.
<code>read_fwf(filepath_or_buffer[, colspecs, ...])</code>	Read a table of fixed-width formatted lines into DataFrame.
<code>read_msgpack(path_or_buf[, encoding, iterator])</code>	Load msgpack pandas object from the specified file path

## pandas.read\_table

`pandas.read_table` (*filepath\_or\_buffer*, *sep=False*, *delimiter=None*, *header='infer'*, *names=None*, *index\_col=None*, *usecols=None*, *squeeze=False*, *prefix=None*, *mangle\_dupe\_cols=True*, *dtype=None*, *engine=None*, *converters=None*, *true\_values=None*, *false\_values=None*, *skipinitialspace=False*, *skiprows=None*, *skipfooter=0*, *nrows=None*, *na\_values=None*, *keep\_default\_na=True*, *na\_filter=True*, *verbose=False*, *skip\_blank\_lines=True*, *parse\_dates=False*, *infer\_datetime\_format=False*, *keep\_date\_col=False*, *date\_parser=None*, *dayfirst=False*, *iterator=False*, *chunksize=None*, *compression='infer'*, *thousands=None*, *decimal=b'.'*, *lineterminator=None*, *quotechar='\"'*, *quoting=0*, *doublequote=True*, *escapechar=None*, *comment=None*, *encoding=None*, *dialect=None*, *tupleize\_cols=None*, *error\_bad\_lines=True*, *warn\_bad\_lines=True*, *delim\_whitespace=False*, *low\_memory=True*, *memory\_map=False*, *float\_precision=None*)

Read general delimited file into DataFrame.

Deprecated since version 0.24.0.

Use `pandas.read_csv()` instead, passing `sep='\t'` if necessary.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**sep** [str, default '\t' (tab-stop)] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

**delimiter** [str, default None] Alias for `sep`.

**header** [int, list of int, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int, sequence or bool, optional] Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to not use the first column as the index (row names).

**usecols** [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, optional] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

**mangle\_dupe\_cols** [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{'c', 'python'}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, optional] Values to consider as True.

**false\_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na\_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: `'', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'`.

**keep\_default\_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is True, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is True, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as False, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [bool, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter*=False can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse\_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify *date\_parser* to be a partially-applied `pandas.to_datetime()` with `utc=True`. See *Parsing a CSV with mixed Timezones* for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [bool, default False] If True and *parse\_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep\_date\_col** [bool, default False] If True and *parse\_dates* specifies combining multiple columns then keep the original columns.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call *date\_parser* in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse\_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse\_dates* into a single array and pass that; and 3) call *date\_parser* once for each row using one or more strings (corresponding to the columns defined by *parse\_dates*) as arguments.

- dayfirst** [bool, default False] DD/MM format dates, international and European format.
- iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.
- chunksize** [int, optional] Return TextFileReader object for iteration. See the [IO Tools docs](#) for more information on `iterator` and `chunksize`.
- compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and *filepath\_or\_buffer* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.
- New in version 0.18.1: support for 'zip' and 'xz' compression.
- thousands** [str, optional] Thousands separator.
- decimal** [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).
- lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.
- quotechar** [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.
- quoting** [int or csv.QUOTE\_\* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).
- doublequote** [bool, default True] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements `INSIDE` a field as a single `quotechar` element.
- escapechar** [str (length 1), optional] One-character string used to escape other characters.
- comment** [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in 'a,b,c' being treated as the header.
- encoding** [str, optional] Encoding to use for UTF when reading/writing (ex. 'utf-8'). [List of Python standard encodings](#).
- dialect** [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.
- tupleize\_cols** [bool, default False] Leave a list of tuples on columns as is (default is to convert to a `MultiIndex` on the columns).
- Deprecated since version 0.21.0: This argument will be removed and will always convert to `MultiIndex`
- error\_bad\_lines** [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these "bad lines" will be dropped from the `DataFrame` that is returned.
- warn\_bad\_lines** [bool, default True] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each "bad line" will be output.

**delim\_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or ' ') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

**low\_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

**memory\_map** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float\_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round\_trip* for the round-trip converter.

### Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

### See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

### Examples

```
>>> pd.read_table('data.csv') # doctest: +SKIP
```

## pandas.read\_csv

`pandas.read_csv` (*filepath\_or\_buffer*, *sep*=' ', *delimiter*=None, *header*='infer', *names*=None, *index\_col*=None, *usecols*=None, *squeeze*=False, *prefix*=None, *mangle\_dupe\_cols*=True, *dtype*=None, *engine*=None, *converters*=None, *true\_values*=None, *false\_values*=None, *skipinitialspace*=False, *skiprows*=None, *skipfooter*=0, *nrows*=None, *na\_values*=None, *keep\_default\_na*=True, *na\_filter*=True, *verbose*=False, *skip\_blank\_lines*=True, *parse\_dates*=False, *infer\_datetime\_format*=False, *keep\_date\_col*=False, *date\_parser*=None, *dayfirst*=False, *iterator*=False, *chunks*=None, *compression*='infer', *thousands*=None, *decimal*='.', *lineterminator*=None, *quotechar*='"', *quoting*=0, *doublequote*=True, *escapechar*=None, *comment*=None, *encoding*=None, *dialect*=None, *tupelize\_cols*=None, *error\_bad\_lines*=True, *warn\_bad\_lines*=True, *delim\_whitespace*=False, *low\_memory*=True, *memory\_map*=False, *float\_precision*=None)

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**sep** [str, default ‘,’] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

**delimiter** [str, default `None`] Alias for `sep`.

**header** [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int, sequence or bool, optional] Column to use as the row labels of the `DataFrame`. If a sequence is given, a `MultiIndex` is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to not use the first column as the index (row names).

**usecols** [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from `data` with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [bool, default `False`] If the parsed data only contains one column then return a `Series`.

**prefix** [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

**mangle\_dupe\_cols** [bool, default `True`] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’… ‘X’. Passing in `False` will cause data to be overwritten if there are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{ 'c', 'python' }, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, optional] Values to consider as True.

**false\_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na\_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

**keep\_default\_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is True, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is True, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as False, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [bool, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter*=False can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse\_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. { 'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See *Parsing a CSV with mixed Timezones* for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep\_date\_col** [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**iterator** [bool, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, optional] Return `TextFileReader` object for iteration. See the [IO Tools docs](#) for more information on `iterator` and `chunksize`.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and `filepath_or_buffer` is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for 'zip' and 'xz' compression.

**thousands** [str, optional] Thousands separator.

**decimal** [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

**lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote** [bool, default True] When quotechar is specified and quoting is not QUOTE\_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

**escapechar** [str (length 1), optional] One-character string used to escape other characters.

**comment** [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip\_blank\_lines=True), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if comment='#', parsing #empty\na,b,c\n1,2,3 with header=0 will result in 'a,b,c' being treated as the header.

**encoding** [str, optional] Encoding to use for UTF when reading/writing (ex. 'utf-8'). [List of Python standard encodings](#) .

**dialect** [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

**tupleize\_cols** [bool, default False] Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns).

Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

**error\_bad\_lines** [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

**warn\_bad\_lines** [bool, default True] If error\_bad\_lines is False, and warn\_bad\_lines is True, a warning for each “bad line” will be output.

**delim\_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the *delimiter* parameter.

New in version 0.18.1: support for the Python parser.

**low\_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the *dtype* parameter. Note that the entire file is read into a single DataFrame regardless, use the *chunksizes* or *iterator* parameter to return the data in chunks. (Only valid with C parser).

**memory\_map** [bool, default False] If a filepath is provided for *filepath\_or\_buffer*, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float\_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round\_trip* for the round-trip converter.

## Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

## Examples

```
>>> pd.read_csv('data.csv') # doctest: +SKIP
```

## pandas.read\_fwf

`pandas.read_fwf` (*filepath\_or\_buffer*, *colspecs='infer'*, *widths=None*, *infer\_nrows=100*, *\*\*kwds*)

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the [online docs for IO Tools](#).

### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**colspecs** [list of tuple (int, int) or 'infer'. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[ ). String value 'infer' can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via `skiprows` (default='infer').

**widths** [list of int, optional] A list of field widths which can be used instead of 'colspecs' if the intervals are contiguous.

**infer\_nrows** [int, default 100] The number of rows to consider when letting the parser determine the *colspecs*.

New in version 0.24.0.

**\*\*kwds** [optional] Optional keyword arguments can be passed to `TextFileReader`.

### Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

## Examples

```
>>> pd.read_fwf('data.csv') # doctest: +SKIP
```

## pandas.read\_msgpack

`pandas.read_msgpack` (*path\_or\_buf*, *encoding='utf-8'*, *iterator=False*, *\*\*kwargs*)  
Load msgpack pandas object from the specified file path

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

### Parameters

- path\_or\_buf** [string File path, BytesIO like or string]
- encoding** [Encoding for decoding msgpack str type]
- iterator** [boolean, if True, return an iterator to the unpacker] (default is False)

### Returns

- obj** [same type as object stored in file]

## 6.1.3 Clipboard

---

<code>read_clipboard([sep])</code>	Read text from clipboard and pass to <code>read_csv</code> .
------------------------------------	--

---

## pandas.read\_clipboard

`pandas.read_clipboard` (*sep='\s+'*, *\*\*kwargs*)  
Read text from clipboard and pass to `read_csv`. See `read_csv` for the full argument list

### Parameters

- sep** [str, default '\s+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

### Returns

- parsed** [DataFrame]

## 6.1.4 Excel

---

<code>read_excel(io[, sheet_name, header, names, ...])</code>	Read an Excel file into a pandas DataFrame.
<code>ExcelFile.parse([sheet_name, header, names, ...])</code>	Parse specified sheet(s) into a DataFrame

---

## pandas.read\_excel

`pandas.read_excel` (*io*, *sheet\_name=0*, *header=0*, *names=None*, *index\_col=None*, *parse\_cols=None*, *usecols=None*, *squeeze=False*, *dtype=None*, *engine=None*, *converters=None*, *true\_values=None*, *false\_values=None*, *skiprows=None*, *nrows=None*, *na\_values=None*, *keep\_default\_na=True*, *verbose=False*, *parse\_dates=False*, *date\_parser=None*, *thousands=None*, *comment=None*, *skip\_footer=0*, *skip\_footer=0*, *convert\_float=True*, *mangle\_dupe\_cols=True*, *\*\*kwds*)  
Read an Excel file into a pandas DataFrame.

Support both *xls* and *xlsx* file extensions from a local filesystem or URL. Support an option to read a single sheet or a list of sheets.

### Parameters

**io** [str, file descriptor, pathlib.Path, ExcelFile or xlr.Book] The string could be a URL. Valid URL schemes include http, ftp, s3, gcs, and file. For file URLs, a host is expected. For instance, a local file could be /path/to/workbook.xlsx.

**sheet\_name** [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.

Available cases:

- Defaults to 0: 1st sheet as a *DataFrame*
- 1: 2nd sheet as a *DataFrame*
- "Sheet1": Load sheet with name "Sheet1"
- [0, 1, "Sheet5"]: Load first, second and sheet named "Sheet5" as a dict of *DataFrame*
- None: All sheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed *DataFrame*. If a list of integers is passed those row positions will be combined into a *MultiIndex*. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index\_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the *DataFrame*. Pass None if there is no such column. If a list is passed, those columns will be combined into a *MultiIndex*. If a subset of data is selected with *usecols*, *index\_col* is based on the subset.

**parse\_cols** [int or list, default None] Alias of *usecols*.

Deprecated since version 0.21.0: Use *usecols* instead.

**usecols** [int, str, list-like, or callable default None] Return a subset of the columns. \* If None, then parse all columns. \* If int, then indicates last column to be parsed.

Deprecated since version 0.24.0: Pass in a list of int instead from 0 to *usecols* inclusive.

- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. "A:E" or "A,C,E:F"). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.

New in version 0.24.0.

- If callable, then evaluate each column name against it and parse the column if the callable returns *True*.

New in version 0.24.0.

**squeeze** [bool, default False] If the parsed data only contains one column then return a *Series*.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use *object* to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

New in version 0.20.0.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Acceptable values are None or xlrd.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true\_values** [list, default None] Values to consider as True.

New in version 0.19.0.

**false\_values** [list, default None] Values to consider as False.

New in version 0.19.0.

**skiprows** [list-like] Rows to skip at the beginning (0-indexed).

**nrows** [int, default None] Number of rows to parse.

New in version 0.23.0.

**na\_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep\_default\_na** [bool, default True] If na\_values are specified and keep\_default\_na is False the default NaN values are overridden, otherwise they’re appended to.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**parse\_dates** [bool, list-like, or dict, default False] The behavior is as follows:

- bool. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {{ ‘foo’ : [1, 3] }} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`

Note: A fast-path exists for iso8601-formatted dates.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**thousands** [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

**comment** [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

**skip\_footer** [int, default 0] Alias of *skipfooter*.

Deprecated since version 0.23.0: Use *skipfooter* instead.

**skipfooter** [int, default 0] Rows at the end to skip (0-indexed).

**convert\_float** [bool, default True] Convert integral floats to int (i.e., 1.0 → 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

**mangle\_dupe\_cols** [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**\*\*kwargs** [optional] Optional keyword arguments can be passed to `TextFileReader`.

### Returns

**DataFrame or dict of DataFrames** DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

### See also:

**to\_excel** Write DataFrame to an Excel file.

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

### Examples

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0) # doctest: +SKIP
   Name  Value
0  string1    1
1  string2    2
2  #Comment    3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
...               sheet_name='Sheet3') # doctest: +SKIP
   Unnamed: 0  Name  Value
0           0  string1    1
1           1  string2    2
2           2  #Comment    3
```

Index and header can be specified via the `index_col` and `header` arguments

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None) # doctest: +SKIP
   0      1      2
0 NaN      Name  Value
1 0.0  string1    1
2 1.0  string2    2
3 2.0  #Comment    3
```

Column types are inferred but can be explicitly specified

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               dtype={'Name': str, 'Value': float}) # doctest: +SKIP
   Name  Value
0  string1  1.0
1  string2  2.0
2  #Comment  3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               na_values=['string1', 'string2']) # doctest: +SKIP
   Name  Value
0     NaN     1
1     NaN     2
2  #Comment     3
```

Comment lines in the excel input file can be skipped using the *comment* kwarg

```
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#') # doctest: +SKIP
   Name  Value
0  string1  1.0
1  string2  2.0
2     None  NaN
```

## pandas.ExcelFile.parse

`ExcelFile.parse` (*sheet\_name=0, header=0, names=None, index\_col=None, usecols=None, squeeze=False, converters=None, true\_values=None, false\_values=None, skiprows=None, nrows=None, na\_values=None, parse\_dates=False, date\_parser=None, thousands=None, comment=None, skipfooter=0, convert\_float=True, mangle\_dupe\_cols=True, \*\*kwargs*)

Parse specified sheet(s) into a DataFrame

Equivalent to `read_excel(ExcelFile, ...)` See the `read_excel` docstring for more info on accepted parameters

`ExcelWriter`(*path[, engine, date\_format, ...]*)

Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx.

## pandas.ExcelWriter

`class pandas.ExcelWriter` (*path, engine=None, date\_format=None, datetime\_format=None, mode='w', \*\*engine\_kwargs*)

Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx. See `DataFrame.to_excel` for typical usage.

### Parameters

**path** [string] Path to xls or xlsx file.

**engine** [string (optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>.writer`. NOTE: can only be passed as a keyword argument.

**date\_format** [string, default None] Format string for dates written into Excel files (e.g. 'YYYY-MM-DD')

**datetime\_format** [string, default None] Format string for datetime objects written into Excel files (e.g. 'YYYY-MM-DD HH:MM:SS')

**mode** [{ 'w' or 'a' }, default 'w'] File mode to use (write or append).

.. versionadded:: 0.24.0

## Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

## Examples

Default usage:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet1')
...     df2.to_excel(writer, sheet_name='Sheet2')
```

You can set the date format or datetime format:

```
>>> with ExcelWriter('path_to_file.xlsx',
...                 date_format='YYYY-MM-DD',
...                 datetime_format='YYYY-MM-DD HH:MM:SS') as writer:
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```
>>> with ExcelWriter('path_to_file.xlsx', mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet3')
```

## Attributes

None	
------	--

## Methods

None	
------	--

## 6.1.5 JSON

---

*read\_json*([path\_or\_buf, orient, typ, dtype, ...]) Convert a JSON string to pandas object.

---

## pandas.read\_json

`pandas.read_json` (*path\_or\_buf=None, orient=None, typ='frame', dtype=True, convert\_axes=True, convert\_dates=True, keep\_default\_dates=True, numpy=False, precise\_float=False, date\_unit=None, encoding=None, lines=False, chunksize=None, compression='infer'*)

Convert a JSON string to pandas object.

### Parameters

**path\_or\_buf** [a valid JSON string or file-like, default: None] The string could be a URL. Valid URL schemes include http, ftp, s3, gcs, and file. For file URLs, a host is expected. For instance, a local file could be `file://localhost/path/to/table.json`

**orient** [string,] Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orients is:

- 'split': dict like {index -> [index], columns -> [columns], data -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index': dict like {index -> {column -> value}}
- 'columns': dict like {column -> {index -> value}}
- 'values': just the values array

The allowed and default values depend on the value of the *typ* parameter.

- when `typ == 'series'`,
  - allowed orients are {'split', 'records', 'index'}
  - default is 'index'
  - The Series index must be unique for orient 'index'.
- when `typ == 'frame'`,
  - allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
  - default is 'columns'
  - The DataFrame index must be unique for orients 'index' and 'columns'.
  - The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

New in version 0.23.0: 'table' as an allowed value for the *orient* argument

**typ** [type of object to recover (series or frame), default 'frame']

**dtype** [boolean or dict, default True] If True, infer dtypes, if a dict of column to dtype, then use those, if False, then don't infer dtypes at all, applies only to the data.

**convert\_axes** [boolean, default True] Try to convert the axes to the proper dtypes.

**convert\_dates** [boolean, default True] List of columns to parse for dates; If True, then try to parse datelike columns default is True; a column label is datelike if

- it ends with '\_at',
- it ends with '\_time',

- it begins with 'timestamp',
- it is 'modified', or
- it is 'date'

**keep\_default\_dates** [boolean, default True] If parsing dates, then parse the default datelike columns

**numpy** [boolean, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

**precise\_float** [boolean, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality

**date\_unit** [string, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

**encoding** [str, default is 'utf-8'] The encoding to use to decode py3 bytes.

New in version 0.19.0.

**lines** [boolean, default False] Read the file as a json object per line.

New in version 0.19.0.

**chunksize** [integer, default None] Return JsonReader object for iteration. See the [line-delimited json docs](#) for more information on `chunksize`. This can only be passed if `lines=True`. If this is None, the file will be read into memory all at once.

New in version 0.21.0.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip or xz if `path_or_buf` is a string ending in '.gz', '.bz2', '.zip', or '.xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.21.0.

### Returns

**result** [Series or DataFrame, depending on the value of `typ`.]

### See also:

`DataFrame.to_json`

### Notes

Specific to `orient='table'`, if a `DataFrame` with a literal `Index` name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the `Index` name to `None`. This is because `index` is also used by `DataFrame.to_json()` to denote a missing `Index` name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with 'level\_'.

## Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]]}'
>>> pd.read_json(_, orient='split')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
>>> pd.read_json(_, orient='index')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
>>> pd.read_json(_, orient='records')
   col 1 col 2
0      a    b
1      c    d
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                       {"name": "col 1", "type": "string"},
                       {"name": "col 2", "type": "string"}],
            "primaryKey": "index",
            "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
            {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

---

`json_normalize(data[, record_path, meta, ...])`

Normalize semi-structured JSON data into a flat table.

`build_table_schema(data[, index, ...])`

Create a Table schema from data.

---

## pandas.io.json.json\_normalize

`pandas.io.json.json_normalize` (*data*, *record\_path*=None, *meta*=None, *meta\_prefix*=None, *record\_prefix*=None, *errors*='raise', *sep*='.')

Normalize semi-structured JSON data into a flat table.

(continued from previous page)

```

...                                     ['info', 'governor'])
>>> result
   name  population  info.governor  state  shortname
0   Dade      12345    Rick Scott  Florida         FL
1  Broward     40000    Rick Scott  Florida         FL
2  Palm Beach  60000    Rick Scott  Florida         FL
3   Summit      1234    John Kasich  Ohio          OH
4  Cuyahoga     1337    John Kasich  Ohio          OH

```

```

>>> data = {'A': [1, 2]}
>>> json_normalize(data, 'A', record_prefix='Prefix.')
Prefix.0
0         1
1         2

```

## pandas.io.json.build\_table\_schema

`pandas.io.json.build_table_schema` (*data*, *index=True*, *primary\_key=None*, *version=True*)

Create a Table schema from *data*.

### Parameters

**data** [Series, DataFrame]

**index** [bool, default True] Whether to include `data.index` in the schema.

**primary\_key** [bool or None, default True] column names to designate as the primary key. The default *None* will set *primaryKey* to the index level or levels if the index is unique.

**version** [bool, default True] Whether to include a field `pandas_version` with the version of pandas that generated the schema.

### Returns

**schema** [dict]

## Notes

See `_as_json_table_type` for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the *any* dtype, and use the *enum* field constraint to list the allowed values. The *ordered* attribute is included in an *ordered* field.

## Examples

```

>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'},
{'name': 'A', 'type': 'integer'},

```

(continues on next page)

(continued from previous page)

```
{'name': 'B', 'type': 'string'},
{'name': 'C', 'type': 'datetime'}],
'pandas_version': '0.20.0',
'primaryKey': ['idx']}
```

## 6.1.6 HTML

<code>read_html(io[, match, flavor, header, ...])</code>	Read HTML tables into a list of DataFrame objects.
--	--

### pandas.read\_html

`pandas.read_html` (*io*, *match*='.+', *flavor*=None, *header*=None, *index\_col*=None, *skiprows*=None, *attrs*=None, *parse\_dates*=False, *tupleize\_cols*=None, *thousands*=' ', *encoding*=None, *decimal*='.', *converters*=None, *na\_values*=None, *keep\_default\_na*=True, *displayed\_only*=True)

Read HTML tables into a list of DataFrame objects.

#### Parameters

- io** [str or file-like] A URL, a file-like object, or a raw string containing HTML. Note that `lxml` only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.
- match** [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to `‘.+’` (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and `lxml`.
- flavor** [str or None, container of strings] The parsing engine to use. `‘bs4’` and `‘html5lib’` are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use `lxml` to parse and if that fails it falls back on `bs4 + html5lib`.
- header** [int or list-like or None, optional] The row (or list of rows for a *MultiIndex*) to use to make the columns headers.
- index\_col** [int or list-like or None, optional] The column (or list of columns) to use to create the index.
- skiprows** [int or list-like or slice or None, optional] 0-based. Number of rows to skip after parsing the column integer. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.
- attrs** [dict or None, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to `lxml` or Beautiful Soup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the `‘id’` HTML tag attribute is a valid HTML attribute for any HTML tag as per [this document](#).

```
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found [here](#). A working draft of the HTML 5 spec can be found [here](#). It contains the latest information on table attributes for the modern web.

**parse\_dates** [bool, optional] See `read_csv()` for more details.

**tupleize\_cols** [bool, optional] If `False` try to parse multiple header rows into a `MultiIndex`, otherwise return raw tuples. Defaults to `False`.

Deprecated since version 0.21.0: This argument will be removed and will always convert to `MultiIndex`

**thousands** [str, optional] Separator to use to parse thousands. Defaults to `','`.

**encoding** [str or None, optional] The encoding used to decode the web page. Defaults to `None`. ‘None’ preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

**decimal** [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

New in version 0.19.0.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

New in version 0.19.0.

**na\_values** [iterable, default None] Custom NA values

New in version 0.19.0.

**keep\_default\_na** [bool, default True] If `na_values` are specified and `keep_default_na` is `False` the default NaN values are overridden, otherwise they’re appended to

New in version 0.19.0.

**displayed\_only** [bool, default True] Whether elements with “display: none” should be parsed

New in version 0.23.0.

## Returns

**dfs** [list of DataFrames]

## See also:

`pandas.read_csv`

## Notes

Before using this function you should read the *gotchas about the HTML parsing libraries*.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for “table data”. This function attempts to properly

handle `colspan` and `rowspan` attributes. If the function has a `<thead>` argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>` elements into the header).

New in version 0.21.0.

Similar to `read_csv()` the `header` argument is applied **after** `skiprows` is applied.

This function will *always* return a list of `DataFrame` or it will fail, e.g., it will *not* return an empty list.

## Examples

See the `read_html` documentation in the *IO* section of the docs for some examples of reading in HTML tables.

### 6.1.7 HDFStore: PyTables (HDF5)

<code>read_hdf(path_or_buf[, key, mode])</code>	Read from the store, close it if we opened it.
<code>HDFStore.put(key, value[, format, append])</code>	Store object in HDFStore
<code>HDFStore.append(key, value[, format, ...])</code>	Append to Table in file.
<code>HDFStore.get(key)</code>	Retrieve pandas object stored in file
<code>HDFStore.select(key[, where, start, stop, ...])</code>	Retrieve pandas object stored in file, optionally based on where criteria
<code>HDFStore.info()</code>	Print detailed information on the store.
<code>HDFStore.keys()</code>	Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore.
<code>HDFStore.groups()</code>	return a list of all the top-level nodes (that are not themselves a pandas storage object)
<code>HDFStore.walk([where])</code>	Walk the pytables group hierarchy for pandas objects

#### pandas.read\_hdf

`pandas.read_hdf(path_or_buf, key=None, mode='r', **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria

#### Parameters

**path\_or\_buf** [string, buffer or path object] Path to the file to open, or an open `pandas.HDFStore` object. Supports any object implementing the `__fspath__` protocol. This includes `pathlib.Path` and `py._path.local.LocalPath` objects.

New in version 0.19.0: support for `pathlib`, `py.path`.

New in version 0.21.0: support for `__fspath__` protocol.

**key** [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

**mode** [{'r', 'r+', 'a'}, optional] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is 'r'.

**where** [list, optional] A list of Term (or convertible) objects.

**start** [int, optional] Row number to start selection.

**stop** [int, optional] Row number to stop selection.

- columns** [list, optional] A list of columns names to return.
- iterator** [bool, optional] Return an iterator object.
- chunksize** [int, optional] Number of rows to include in an iteration when using an iterator.
- errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the `errors` argument for `open()` for a full list of options.
- \*\*kwargs** Additional keyword arguments passed to `HDFStore`.

#### Returns

- item** [object] The selected object. Return type depends on the object stored.

#### See also:

`pandas.DataFrame.to_hdf` Write a HDF file from a DataFrame.

`pandas.HDFStore` Low-level access to HDF files.

#### Examples

```
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

### pandas.HDFStore.put

`HDFStore.put` (*key, value, format=None, append=False, \*\*kwargs*)  
Store object in `HDFStore`

#### Parameters

- key** [object]
- value** [{Series, DataFrame, Panel}]
- format** ['fixed(f)|table(t)', default is 'fixed']
- fixed(f)** [Fixed format] Fast writing/reading. Not-appendable, nor searchable
- table(t)** [Table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data
- append** [boolean, default False] This will force Table format, append the input data to the existing.
- data\_columns** [list of columns to create as data columns, or True to] use all columns. See [here](#)  
# noqa
- encoding** [default None, provide an encoding for strings]
- dropna** [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna\_table'

## pandas.HDFStore.append

`HDFStore.append` (*key*, *value*, *format=None*, *append=True*, *columns=None*, *dropna=None*, *\*\*kwargs*)  
Append to Table in file. Node must already exist and be Table format.

### Parameters

**key** [object]

**value** [{Series, DataFrame, Panel}]

**format** ['table' is the default]

**table(t)** [table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

**append** [boolean, default True, append the input data to the] existing

**data\_columns** [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [here](#).

**min\_itemsize** [dict of columns that specify minimum string sizes]

**nan\_rep** [string to use as string nan representation]

**chunksize** [size to chunk the writing]

**expectedrows** [expected TOTAL row size of this table]

**encoding** [default None, provide an encoding for strings]

**dropna** [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna\_table'

### Notes

Does *not* check if data being appended overlaps with existing data in the table, so be careful

## pandas.HDFStore.get

`HDFStore.get` (*key*)  
Retrieve pandas object stored in file

### Parameters

**key** [object]

### Returns

**obj** [same type as object stored in file]

## pandas.HDFStore.select

`HDFStore.select` (*key*, *where=None*, *start=None*, *stop=None*, *columns=None*, *iterator=False*, *chunk-size=None*, *auto\_close=False*, *\*\*kwargs*)  
Retrieve pandas object stored in file, optionally based on where criteria

### Parameters

**key** [object]

**where** [list of Term (or convertible) objects, optional]  
**start** [integer (defaults to None), row number to start selection]  
**stop** [integer (defaults to None), row number to stop selection]  
**columns** [a list of columns that if not None, will limit the return] columns  
**iterator** [boolean, return an iterator, default False]  
**chunksize** [nrows to include in iteration, return an iterator]  
**auto\_close** [boolean, should automatically close the store when] finished, default is False

**Returns**

The selected object

**pandas.HDFStore.info**

`HDFStore.info()`

Print detailed information on the store.

New in version 0.21.0.

**pandas.HDFStore.keys**

`HDFStore.keys()`

Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore. These are ABSOLUTE path-names (e.g. have the leading '/')

**pandas.HDFStore.groups**

`HDFStore.groups()`

return a list of all the top-level nodes (that are not themselves a pandas storage object)

**pandas.HDFStore.walk**

`HDFStore.walk(`*where*`=')`

Walk the pytables group hierarchy for pandas objects

This generator will yield the group path, subgroups and pandas object names for each group. Any non-pandas PyTables objects that are not a group will be ignored.

The *where* group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

New in version 0.24.0.

**Parameters**

**where** [str, optional] Group where to start walking. If not supplied, the root group is used.

**Yields**

**path** [str] Full path to a group (without trailing '/')

**groups** [list of str] names of the groups contained in *path*

**leaves** [list of str] names of the pandas objects contained in *path*

## 6.1.8 Feather

`read_feather(path[, columns, use_threads])` Load a feather-format object from the file path

---

### pandas.read\_feather

`pandas.read_feather(path, columns=None, use_threads=True)`

Load a feather-format object from the file path

#### Parameters

**path** [string file path, or file-like object]

**columns** [sequence, default None] If not provided, all columns are read

**nthreads** [int, default 1]

Number of CPU threads to use when reading to pandas.DataFrame

**use\_threads** [bool, default True]

Whether to parallelize reading using multiple threads

#### Returns

type of object stored in file

## 6.1.9 Parquet

`read_parquet(path[, engine, columns])` Load a parquet object from the file path, returning a DataFrame.

---

### pandas.read\_parquet

`pandas.read_parquet(path, engine='auto', columns=None, **kwargs)`

Load a parquet object from the file path, returning a DataFrame.

#### Parameters

**path** [string] File path

**columns** [list, default=None] If not None, only these columns will be read from the file.

**engine** [{ 'auto', 'pyarrow', 'fastparquet' }, default 'auto'] Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

**kwargs are passed to the engine**

#### Returns

DataFrame

## 6.1.10 SAS

---

<code>read_sas(filepath_or_buffer[, format, ...])</code>	Read SAS files stored as either XPORT or SAS7BDAT format files.
--	---

---

## pandas.read\_sas

`pandas.read_sas` (*filepath\_or\_buffer*, *format=None*, *index=None*, *encoding=None*, *chunksize=None*, *iterator=False*)  
 Read SAS files stored as either XPORT or SAS7BDAT format files.

### Parameters

- filepath\_or\_buffer** [string or file-like object] Path to the SAS file.
- format** [string { 'xport', 'sas7bdat' } or None] If None, file format is inferred from file extension. If 'xport' or 'sas7bdat', uses the corresponding format.
- index** [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.
- encoding** [string, default is None] Encoding for text data. If None, text data are stored as raw bytes.
- chunksize** [int] Read file *chunksize* lines at a time, returns iterator.
- iterator** [bool, defaults to False] If True, returns an iterator for reading the file incrementally.

### Returns

**DataFrame if iterator=False and chunksize=None, else SAS7BDATReader or XportReader**

## 6.1.11 SQL

---

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.

---

## 6.1.12 Google BigQuery

---

<code>read_gbq(query[, project_id, index_col, ...])</code>	Load data from Google BigQuery.
--	---------------------------------

---

## pandas.read\_gbq

`pandas.read_gbq` (*query*, *project\_id=None*, *index\_col=None*, *col\_order=None*, *reauth=False*, *auth\_local\_webserver=False*, *dialect=None*, *location=None*, *configuration=None*, *credentials=None*, *private\_key=None*, *verbose=None*)  
 Load data from Google BigQuery.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

### Parameters

- query** [str] SQL-Like Query to return data values.

**project\_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

**index\_col** [str, optional] Name of result column to use for index in results DataFrame.

**col\_order** [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.

**reauth** [boolean, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

**auth\_local\_webserver** [boolean, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**dialect** [str, default 'legacy'] Note: The default value is changing to 'standard' in a future version.

SQL syntax dialect to use. Value can be one of:

'**legacy**' Use BigQuery's legacy SQL dialect. For more information see [BigQuery Legacy SQL Reference](#).

'**standard**' Use BigQuery's standard SQL, which is compliant with the SQL 2011 standard. For more information see [BigQuery Standard SQL Reference](#).

Changed in version 0.24.0.

**location** [str, optional] Location where the query job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of any datasets used in the query.

*New in version 0.5.0 of pandas-gbq.*

**configuration** [dict, optional] Query config parameters for job processing. For example:

```
configuration = {'query': {'useQueryCache': False}}
```

For more information see [BigQuery REST API Reference](#).

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

*New in version 0.8.0 of pandas-gbq.*

New in version 0.24.0.

**private\_key** [str, deprecated] Deprecated in pandas-gbq version 0.8.0. Use the `credentials` parameter and `google.oauth2.service_account.Credentials.from_service_account_info()` or `google.oauth2.service_account.Credentials.from_service_account_file()` instead.

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

**verbose** [None, deprecated] Deprecated in pandas-gbq version 0.4.0. Use the [logging module](#) to adjust verbosity instead.

### Returns

**df: DataFrame** DataFrame representing results of query.

See also:

`pandas_gbq.read_gbq` This function in the pandas-gbq library.

`pandas.DataFrame.to_gbq` Write a DataFrame to Google BigQuery.

### 6.1.13 STATA

---

`read_stata(filepath_or_buffer[, ...])` Read Stata file into DataFrame.

---

#### **pandas.read\_stata**

`pandas.read_stata` (*filepath\_or\_buffer*, *convert\_dates=True*, *convert\_categoricals=True*, *encoding=None*, *index\_col=None*, *convert\_missing=False*, *preserve\_dtypes=True*, *columns=None*, *order\_categoricals=True*, *chunksize=None*, *iterator=False*)  
 Read Stata file into DataFrame.

#### **Parameters**

**filepath\_or\_buffer** [string or file-like object] Path to .dta file or object implementing a binary read() functions.

**convert\_dates** [boolean, defaults to True] Convert date variables to DataFrame time values.

**convert\_categoricals** [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.

**encoding** [string, None or encoding] Encoding used to parse the files. None defaults to latin-1.

**index\_col** [string, optional, default: None] Column to set as index.

**convert\_missing** [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

**preserve\_dtypes** [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

**columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

**order\_categoricals** [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

**chunksize** [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

**iterator** [boolean, default False] Return StataReader object.

#### **Returns**

**DataFrame or StataReader**

See also:

`pandas.io.stata.StataReader` Low-level reader for Stata data files.

`pandas.DataFrame.to_stata` Export Stata data files.

## Examples

Read a Stata dta file:

```
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     do_something(chunk)
```

<code>StataReader.data(**kwargs)</code>	(DEPRECATED) Reads observations from Stata file, converting them into a dataframe
<code>StataReader.data_label()</code>	Returns data label of Stata file
<code>StataReader.value_labels()</code>	Returns a dict, associating each variable name a dict, associating each value its corresponding label
<code>StataReader.variable_labels()</code>	Returns variable labels as a dict, associating each variable name with corresponding label
<code>StataWriter.write_file()</code>	

## pandas.io.stata.StataReader.data

`StataReader.data(**kwargs)`

Reads observations from Stata file, converting them into a dataframe

Deprecated since version This: is a legacy method. Use `read` in new code.

### Parameters

- convert\_dates** [boolean, defaults to True] Convert date variables to DataFrame time values.
- convert\_categoricals** [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.
- index\_col** [string, optional, default: None] Column to set as index.
- convert\_missing** [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by `StataMissingValue` objects.
- preserve\_dtypes** [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).
- columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.
- order\_categoricals** [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

### Returns

**DataFrame**

**pandas.io.stata.StataReader.data\_label**

`StataReader.data_label()`  
Returns data label of Stata file

**pandas.io.stata.StataReader.value\_labels**

`StataReader.value_labels()`  
Returns a dict, associating each variable name a dict, associating each value its corresponding label

**pandas.io.stata.StataReader.variable\_labels**

`StataReader.variable_labels()`  
Returns variable labels as a dict, associating each variable name with corresponding label

**pandas.io.stata.StataWriter.write\_file**

`StataWriter.write_file()`

## 6.2 General functions

### 6.2.1 Data manipulations

<code>melt(frame[, id_vars, value_vars, var_name, ...])</code>	Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.
<code>pivot(data[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(data[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>crosstab(index, columns[, values, rownames, ...])</code>	Compute a simple cross-tabulation of two (or more) factors.
<code>cut(x, bins[, right, labels, retbins, ...])</code>	Bin values into discrete intervals.
<code>qcut(x, q[, labels, retbins, precision, ...])</code>	Quantile-based discretization function.
<code>merge(left, right[, how, on, left_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>merge_ordered(left, right[, on, left_on, ...])</code>	Perform merge with optional filling/interpolation designed for ordered data like time series data.
<code>merge_asof(left, right[, on, left_on, ...])</code>	Perform an asof merge.
<code>concat(objs[, axis, join, join_axes, ...])</code>	Concatenate pandas objects along a particular axis with optional set logic along the other axes.
<code>get_dummies(data[, prefix, prefix_sep, ...])</code>	Convert categorical variable into dummy/indicator variables
<code>factorize(values[, sort, order, ...])</code>	Encode the object as an enumerated type or categorical variable.
<code>unique(values)</code>	Hash table-based unique.
<code>wide_to_long(df, stubnames, i, j[, sep, suffix])</code>	Wide panel to long format.

## pandas.melt

`pandas.melt` (*frame*, *id\_vars=None*, *value\_vars=None*, *var\_name=None*, *value\_name='value'*, *col\_level=None*)

Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id\_vars*), while all other columns, considered measured variables (*value\_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

### Parameters

**frame** [DataFrame]

**id\_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

**value\_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id\_vars*.

**var\_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

**value\_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

**col\_level** [int or string, optional] If columns are a MultiIndex then use this level to melt.

### See also:

`DataFrame.melt`, `pivot_table`, `DataFrame.pivot`

### Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                   'B': {0: 1, 1: 3, 2: 5},
...                   'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
3  a         C      2
4  b         C      4
5  c         C      6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
  A myVarname myValname
0 a          B          1
1 b          B          3
2 c          B          5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A B C
   D E F
0 a 1 2
1 b 3 4
2 c 5 6
```

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
  A variable  value
0 a          B      1
1 b          B      3
2 c          B      5
```

```
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
  (A, D) variable_0 variable_1  value
0      a          B          E      1
1      b          B          E      3
2      c          B          E      5
```

## pandas.pivot

pandas.**pivot** (*data*, *index=None*, *columns=None*, *values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

### Parameters

**data** [DataFrame]

**index** [string or object, optional] Column to use to make new frame’s index. If None, uses existing index.

**columns** [string or object] Column to use to make new frame’s columns.

**values** [string, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

### Returns

**DataFrame** Returns reshaped DataFrame.

### Raises

**ValueError:** When there are any *index*, *columns* combinations with multiple values. `DataFrame.pivot_table` when you need to aggregate.

See also:

**`DataFrame.pivot_table`** Generalization of pivot that can handle duplicate values for one index/column pair.

**`DataFrame.unstack`** Pivot based on the index values instead of a column.

## Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

## Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A  B  C  A  B  C
foo
one  1  2  3  x  y  z
two  4  5  6  q  w  t
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
```

(continues on next page)

(continued from previous page)

```
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

## pandas.pivot\_table

`pandas.pivot_table` (*data*, *values=None*, *index=None*, *columns=None*, *aggfunc='mean'*, *fill\_value=None*, *margins=False*, *dropna=True*, *margins\_name='All'*)

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

### Parameters

**data** [DataFrame]

**values** [column to aggregate, optional]

**index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

**columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

**aggfunc** [function, list of functions, dict, default `numpy.mean`] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions

**fill\_value** [scalar, default `None`] Value to replace missing values with

**margins** [boolean, default `False`] Add all row / columns (e.g. for subtotal / grand totals)

**dropna** [boolean, default `True`] Do not include columns whose entries are all `NaN`

**margins\_name** [string, default `'All'`] Name of the row / column that will contain the totals when margins is `True`.

### Returns

**table** [DataFrame]

See also:

**DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.

### Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                          "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                          "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                          "small", "large", "small", "small",
...                          "large"],
...                    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A  B  C  D  E
0  foo one small 1 2
1  foo one large 2 4
2  foo one large 2 5
3  foo two small 3 5
4  foo two small 3 6
5  bar one large 4 6
6  bar one small 5 8
7  bar two small 6 9
8  bar two large 7 9
```

This first example aggregates values by taking the sum.

```
>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                     columns=['C'], aggfunc=np.sum)
>>> table
C          large  small
A  B
bar one         4      5
   two         7      6
foo one         4      1
   two        NaN      6
```

We can also fill missing values using the *fill\_value* parameter.

```
>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                     columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C          large  small
A  B
bar one         4      5
   two         7      6
foo one         4      1
   two          0      6
```

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                     aggfunc={'D': np.mean,
...                               'E': np.mean})
>>> table
          D          E
A  C      mean      mean
bar large 5.500000 7.500000
```

(continues on next page)

(continued from previous page)

small	5.500000	8.500000
foo large	2.000000	4.500000
small	2.333333	4.333333

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                       aggfunc={'D': np.mean,
...                                 'E': [min, max, np.mean]})
>>> table
```

		D		E	
		mean	max	mean	min
A	C				
bar	large	5.500000	9	7.500000	6
	small	5.500000	9	8.500000	8
foo	large	2.000000	5	4.500000	4
	small	2.333333	6	4.333333	2

## pandas.crosstab

`pandas.crosstab` (*index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins\_name='All', dropna=True, normalize=False*)

Compute a simple cross-tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed

### Parameters

**index** [array-like, Series, or list of arrays/Series] Values to group by in the rows

**columns** [array-like, Series, or list of arrays/Series] Values to group by in the columns

**values** [array-like, optional] Array of values to aggregate according to the factors. Requires *aggfunc* be specified.

**rownames** [sequence, default None] If passed, must match number of row arrays passed

**colnames** [sequence, default None] If passed, must match number of column arrays passed

**aggfunc** [function, optional] If specified, requires *values* be specified as well

**margins** [boolean, default False] Add row/column margins (subtotals)

**margins\_name** [string, default 'All'] Name of the row / column that will contain the totals when margins is True.

New in version 0.21.0.

**dropna** [boolean, default True] Do not include columns whose entries are all NaN

**normalize** [boolean, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.

- If passed 'all' or *True*, will normalize over all values.
- If passed 'index' will normalize over each row.
- If passed 'columns' will normalize over each column.
- If margins is *True*, will also normalize margin values.

New in version 0.18.1.

## Returns

`crosstab` [DataFrame]

## Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren't overlapping indexes an empty DataFrame will be returned.

## Examples

```
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
...              "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
...              "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
...              "shiny", "dull", "shiny", "shiny", "shiny"],
...              dtype=object)
```

```
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
... # doctest: +NORMALIZE_WHITESPACE
b   one      two
c   dull shiny dull shiny
a
bar   1      2   1      0
foo   2      2   1      2
```

```
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> crosstab(foo, bar) # 'c' and 'f' are not represented in the data,
                       # and will not be shown in the output because
                       # dropna is True by default. Set 'dropna=False'
                       # to preserve categories with no data
... # doctest: +SKIP
col_0  d  e
row_0
a      1  0
b      0  1
```

```
>>> crosstab(foo, bar, dropna=False) # 'c' and 'f' are not represented
                                       # in the data, but they still will be counted
                                       # and shown in the output
... # doctest: +SKIP
col_0  d  e  f
row_0
a      1  0  0
b      0  1  0
c      0  0  0
```

## pandas.cut

`pandas.cut` (*x*, *bins*, *right=True*, *labels=None*, *retbins=False*, *precision=3*, *include\_lowest=False*, *duplicates='raise'*)  
Bin values into discrete intervals.

Use *cut* when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, *cut* could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

### Parameters

**x** [array-like] The input array to be binned. Must be 1-dimensional.

**bins** [int, sequence of scalars, or pandas.IntervalIndex] The criteria to bin by.

- **int** : Defines the number of equal-width bins in the range of *x*. The range of *x* is extended by .1% on each side to include the minimum and maximum values of *x*.
- **sequence of scalars** : Defines the bin edges allowing for non-uniform width. No extension of the range of *x* is done.
- **IntervalIndex** : Defines the exact bins to be used. Note that IntervalIndex for *bins* must be non-overlapping.

**right** [bool, default True] Indicates whether *bins* includes the rightmost edge or not. If *right* == True (the default), then the *bins* [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when *bins* is an IntervalIndex.

**labels** [array or bool, optional] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when *bins* is an IntervalIndex.

**retbins** [bool, default False] Whether to return the bins or not. Useful when *bins* is provided as a scalar.

**precision** [int, default 3] The precision at which to store and display the bins labels.

**include\_lowest** [bool, default False] Whether the first interval should be left-inclusive or not.

**duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.23.0.

### Returns

**out** [pandas.Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of *x*. The type depends on the value of *labels*.

- **True (default)** : returns a Series for Series *x* or a pandas.Categorical for all other inputs. The values stored within are Interval dtype.
- **sequence of scalars** : returns a Series for Series *x* or a pandas.Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- **False** : returns an ndarray of integers.

**bins** [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when *retbins=True*. For scalar or sequence *bins*, this is an ndarray with the computed bins. If set *duplicates=drop*, *bins* will drop non-unique bin. For an IntervalIndex *bins*, this is equal to *bins*.

See also:

**qcut** Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

**pandas.Categorical** Array type for storing data that come from a fixed set of values.

**Series** One-dimensional array with axis labels (including time series).

**pandas.IntervalIndex** Immutable Index implementing an ordered, sliceable set.

## Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or pandas.Categorical object.

## Examples

Discretize into three equal-sized bins.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
... # doctest: +ELLIPSIS
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
```

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
... # doctest: +ELLIPSIS
([(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3.    , 5.    , 7.    ])
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical's categories are *labels* and is ordered.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
...         3, labels=["bad", "medium", "good"])
[bad, good, medium, medium, good, bad]
Categories (3, object): [bad < medium < good]
```

labels=False implies you just want the bins back.

```
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
... # doctest: +ELLIPSIS
a    (1.992, 4.667]
b    (1.992, 4.667]
c    (4.667, 7.333]
d    (7.333, 10.0]
e    (7.333, 10.0]
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ...
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
... # doctest: +ELLIPSIS
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    4.0
 dtype: float64, array([0, 2, 4, 6, 8]))
```

Use `drop` optional when bins is not unique

```
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True,
...         right=False, duplicates='drop')
... # doctest: +ELLIPSIS
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    3.0
 dtype: float64, array([0, 2, 4, 6, 8]))
```

Passing an `IntervalIndex` for `bins` results in those categories exactly. Notice that values not covered by the `IntervalIndex` are set to `NaN`. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0, 1], NaN, (2, 3], (4, 5]]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5]]
```

## pandas.qcut

`pandas.qcut` (*x*, *q*, *labels=None*, *retbins=False*, *precision=3*, *duplicates='raise'*)

Quantile-based discretization function. Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

### Parameters

**x** [1d ndarray or Series]

**q** [integer or array of quantiles] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles

**labels** [array or boolean, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins.

**retbins** [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.

**precision** [int, optional] The precision at which to store and display the bins labels

**duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise `ValueError` or drop non-uniques.

New in version 0.20.0.

### Returns

- out** [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.
- bins** [ndarray of floats] Returned only if *retbins* is True.

### Notes

Out of bounds values will be NA in the resulting Categorical object

### Examples

```
>>> pd.qcut(range(5), 4)
... # doctest: +ELLIPSIS
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
... # doctest: +SKIP
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

## pandas.merge

`pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)`

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

### Parameters

- left** [DataFrame]
- right** [DataFrame or named Series] Object to merge with.
- how** [{'left', 'right', 'outer', 'inner'}] Type of merge to be performed.
- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

**on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left\_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right\_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left\_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right\_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as `left_index`.

**sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

**suffixes** [tuple of (str, str), default ('\_x', '\_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

**copy** [bool, default True] If False, avoid copy if possible.

**indicator** [bool or str, default False] If True, adds a column to output DataFrame called “\_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left\_only” for observations whose merge key only appears in ‘left’ DataFrame, “right\_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate** [str, optional] If specified, checks if merge is of specified type.

- “one\_to\_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one\_to\_many” or “1:m”: check if merge keys are unique in left dataset.
- “many\_to\_one” or “m:1”: check if merge keys are unique in right dataset.
- “many\_to\_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

### Returns

**DataFrame** A DataFrame of the two merged objects.

See also:

*merge\_ordered* Merge with optional filling/interpolation.

*merge\_asof* Merge on nearest keys.

*DataFrame.join* Similar method using indices.

## Notes

Support for specifying index levels as the *on*, *left\_on*, and *right\_on* parameters was added in version 0.23.0  
 Support for merging named Series objects was added in version 0.24.0

## Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0  foo     1
1  bar     2
2  baz     3
3  foo     5
>>> df2
   rkey  value
0  foo     5
1  bar     6
2  baz     7
3  foo     8
```

Merge `df1` and `df2` on the `lkey` and `rkey` columns. The value columns have the default suffixes, `_x` and `_y`, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames `df1` and `df2` with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames `df1` and `df2`, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
   Index(['value'], dtype='object')
```

## pandas.merge\_ordered

`pandas.merge_ordered` (*left*, *right*, *on=None*, *left\_on=None*, *right\_on=None*, *left\_by=None*, *right\_by=None*, *fill\_method=None*, *suffixes=('\_x', '\_y')*, *how='outer'*)

Perform merge with optional filling/interpolation designed for ordered data like time series data. Optionally perform group-wise merge (see examples)

### Parameters

**left** [DataFrame]

**right** [DataFrame]

**on** [label or list] Field names to join on. Must be found in both DataFrames.

**left\_on** [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns

**right\_on** [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left\_on docs

**left\_by** [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame

**right\_by** [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame

**fill\_method** [{ 'ffill', None }, default None] Interpolation method for data

**suffixes** [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'outer']

- left: use only keys from left frame (SQL: left outer join)
- right: use only keys from right frame (SQL: right outer join)
- outer: use union of keys from both frames (SQL: full outer join)
- inner: use intersection of keys from both frames (SQL: inner join)

New in version 0.19.0.

### Returns

**merged** [DataFrame] The output type will be the same as 'left', if it is a subclass of DataFrame.

### See also:

`merge`, `merge_asof`

### Examples

```
>>> A
   key  lvalue group
0    a        1    a
1    c        2    a
2    e        3    a
3    a        1    b
4    c        2    b
5    e        3    b

>>> B
   key  rvalue
0    b        1
1    c        2
2    d        3
```

```
>>> merge_ordered(A, B, fill_method='ffill', left_by='group')
  group key  lvalue  rvalue
0     a  a         1     NaN
1     a  b         1     1.0
2     a  c         2     2.0
3     a  d         2     3.0
4     a  e         3     3.0
5     b  a         1     NaN
6     b  b         1     1.0
7     b  c         2     2.0
8     b  d         2     3.0
9     b  e         3     3.0
```

## pandas.merge\_asof

`pandas.merge_asof` (*left*, *right*, *on=None*, *left\_on=None*, *right\_on=None*, *left\_index=False*, *right\_index=False*, *by=None*, *left\_by=None*, *right\_by=None*, *suffixes=('\_x', '\_y')*, *tolerance=None*, *allow\_exact\_matches=True*, *direction='backward'*)

Perform an asof merge. This is similar to a left-join except that we match on nearest key rather than equal keys.

Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The `direction` parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

New in version 0.19.0.

### Parameters

**left** [DataFrame]

**right** [DataFrame]

**on** [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or `left_on/right_on` must be given.

**left\_on** [label] Field name to join on in left DataFrame.

**right\_on** [label] Field name to join on in right DataFrame.

**left\_index** [boolean] Use the index of the left DataFrame as the join key.

New in version 0.19.2.

**right\_index** [boolean] Use the index of the right DataFrame as the join key.

New in version 0.19.2.

**by** [column name or list of column names] Match on these columns before performing merge operation.

**left\_by** [column name] Field names to match on in the left DataFrame.

New in version 0.19.2.

**right\_by** [column name] Field names to match on in the right DataFrame.

New in version 0.19.2.

**suffixes** [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively.

**tolerance** [integer or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

**allow\_exact\_matches** [boolean, default True]

- If True, allow matching with the same 'on' value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don't match the same 'on' value (i.e., strictly less-than / strictly greater-than)

**direction** ['backward' (default), 'forward', or 'nearest'] Whether to search for prior, subsequent, or closest matches.

New in version 0.20.0.

### Returns

**merged** [DataFrame]

### See also:

*merge, merge\_ordered*

### Examples

```
>>> left = pd.DataFrame({'a': [1, 5, 10], 'left_val': ['a', 'b', 'c']})
>>> left
   a left_val
0  1         a
1  5         b
2 10         c
```

```
>>> right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...                       'right_val': [1, 2, 3, 6, 7]})
>>> right
   a right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7
```

```
>>> pd.merge_asof(left, right, on='a')
   a left_val right_val
0  1         a         1
1  5         b         3
2 10         c         7
```

```
>>> pd.merge_asof(left, right, on='a', allow_exact_matches=False)
   a left_val right_val
0  1         a        NaN
1  5         b         3.0
2 10         c         7.0
```

```
>>> pd.merge_asof(left, right, on='a', direction='forward')
   a left_val right_val
0  1         a         1.0
1  5         b         6.0
2 10         c         NaN
```

```
>>> pd.merge_asof(left, right, on='a', direction='nearest')
   a left_val right_val
0  1         a         1
1  5         b         6
2 10         c         7
```

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c']}, index=[1, 5, 10])
>>> left
   left_val
1         a
5         b
10        c
```

```
>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7]},
...                       index=[1, 2, 3, 6, 7])
>>> right
   right_val
1           1
2           2
3           3
6           6
7           7
```

```
>>> pd.merge_asof(left, right, left_index=True, right_index=True)
   left_val right_val
1         a         1
5         b         3
10        c         7
```

Here is a real-world times-series example

```
>>> quotes
   time ticker  bid  ask
0 2016-05-25 13:30:00.023  GOOG  720.50  720.93
1 2016-05-25 13:30:00.023  MSFT  51.95  51.96
2 2016-05-25 13:30:00.030  MSFT  51.97  51.98
3 2016-05-25 13:30:00.041  MSFT  51.99  52.00
4 2016-05-25 13:30:00.048  GOOG  720.50  720.93
5 2016-05-25 13:30:00.049  AAPL  97.99  98.01
6 2016-05-25 13:30:00.072  GOOG  720.50  720.88
7 2016-05-25 13:30:00.075  MSFT  52.01  52.03
```

```
>>> trades
      time ticker  price  quantity
0 2016-05-25 13:30:00.023  MSFT   51.95     75
1 2016-05-25 13:30:00.038  MSFT   51.95    155
2 2016-05-25 13:30:00.048  GOOG  720.77    100
3 2016-05-25 13:30:00.048  GOOG  720.92    100
4 2016-05-25 13:30:00.048  AAPL   98.00    100
```

By default we are taking the asof of the quotes

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker')
      time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95    155  51.97  51.98
2 2016-05-25 13:30:00.048  GOOG  720.77    100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100    NaN    NaN
```

We only asof within 2ms between the quote time and the trade time

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker',
...               tolerance=pd.Timedelta('2ms'))
      time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95    155    NaN    NaN
2 2016-05-25 13:30:00.048  GOOG  720.77    100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100    NaN    NaN
```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. However *prior* data will propagate forward

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker',
...               tolerance=pd.Timedelta('10ms'),
...               allow_exact_matches=False)
      time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75    NaN    NaN
1 2016-05-25 13:30:00.038  MSFT   51.95    155  51.97  51.98
2 2016-05-25 13:30:00.048  GOOG  720.77    100    NaN    NaN
3 2016-05-25 13:30:00.048  GOOG  720.92    100    NaN    NaN
4 2016-05-25 13:30:00.048  AAPL   98.00    100    NaN    NaN
```

## pandas.concat

`pandas.concat` (*objs*, *axis=0*, *join='outer'*, *join\_axes=None*, *ignore\_index=False*, *keys=None*, *levels=None*, *names=None*, *verify\_integrity=False*, *sort=None*, *copy=True*)

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

### Parameters

**objs** [a sequence or mapping of Series, DataFrame, or Panel objects] If a dict is passed, the sorted keys will be used as the *keys* argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised

**axis** [{0/'index', 1/'columns'}, default 0] The axis to concatenate along

**join** [{'inner', 'outer'}, default 'outer'] How to handle indexes on other axis(es)

**join\_axes** [list of Index objects] Specific indexes to use for the other  $n - 1$  axes instead of performing inner/outer set logic

**ignore\_index** [boolean, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ...,  $n - 1$ . This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

**keys** [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level

**levels** [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys

**names** [list, default None] Names for the levels in the resulting hierarchical index

**verify\_integrity** [boolean, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation

**sort** [boolean, default None] Sort non-concatenation axis if it is not already aligned when *join* is 'outer'. The current default of sorting is deprecated and will change to not-sorting in a future version of pandas.

Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

This has no effect when `join='inner'`, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

**copy** [boolean, default True] If False, do not copy data unnecessarily

### Returns

**concatenated** [object, type of objs] When concatenating all Series along the index (`axis=0`), a Series is returned. When *objs* contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (`axis=1`), a DataFrame is returned.

### See also:

*Series.append*, *DataFrame.append*, *DataFrame.join*, *DataFrame.merge*

### Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

## Examples

Combine two Series.

```
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to `True`.

```
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2',])
s1 0    a
   1    b
s2 0    c
   1    d
dtype: object
```

Label the index keys you create with the `names` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...           names=['Series name', 'Row ID'])
Series name  Row ID
s1          0      a
           1      b
s2          0      c
           1      d
dtype: object
```

Combine two DataFrame objects with identical columns.

```
>>> df1 = pd.DataFrame(['a', 1], ['b', 2]),
...                   columns=['letter', 'number'])
>>> df1
  letter  number
0     a         1
1     b         2
>>> df2 = pd.DataFrame(['c', 3], ['d', 4]),
...                   columns=['letter', 'number'])
>>> df2
  letter  number
0     c         3
1     d         4
>>> pd.concat([df1, df2])
  letter  number
```

(continues on next page)

(continued from previous page)

0	a	1
1	b	2
0	c	3
1	d	4

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```
>>> df3 = pd.DataFrame([['c', 3, 'cat'], ['d', 4, 'dog']],
...                     columns=['letter', 'number', 'animal'])
>>> df3
  letter  number animal
0      c         3   cat
1      d         4   dog
>>> pd.concat([df1, df3], sort=False)
  letter  number animal
0      a         1   NaN
1      b         2   NaN
0      c         3   cat
1      d         4   dog
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing inner to the join keyword argument.

```
>>> pd.concat([df1, df3], join="inner")
  letter  number
0      a         1
1      b         2
0      c         3
1      d         4
```

Combine DataFrame objects horizontally along the x axis by passing in axis=1.

```
>>> df4 = pd.DataFrame(['bird', 'polly'], ['monkey', 'george'],
...                     columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
  letter  number animal  name
0      a         1   bird  polly
1      b         2  monkey  george
```

Prevent the result from including duplicate index values with the verify\_integrity option.

```
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
  0
a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
  0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: ['a']
```

## pandas.get\_dummies

`pandas.get_dummies` (*data*, *prefix=None*, *prefix\_sep='\_'*, *dummy\_na=False*, *columns=None*, *sparse=False*, *drop\_first=False*, *dtype=None*)

Convert categorical variable into dummy/indicator variables

### Parameters

**data** [array-like, Series, or DataFrame]

**prefix** [string, list of strings, or dict of strings, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, *prefix* can be a dictionary mapping column names to prefixes.

**prefix\_sep** [string, default '\_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with *prefix*.

**dummy\_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.

**columns** [list-like, default None] Column names in the DataFrame to be encoded. If *columns* is None then all the columns with *object* or *category* dtype will be converted.

**sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a *SparseArray* (True) or a regular NumPy array (False).

**drop\_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

New in version 0.18.0.

**dtype** [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

New in version 0.23.0.

### Returns

**dummies** [DataFrame]

### See also:

`Series.str.get_dummies`

### Examples

```
>>> s = pd.Series(list('abca'))
```

```
>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
```

```
>>> s1 = ['a', 'b', np.nan]
```

```
>>> pd.get_dummies(s1)
   a  b
0  1  0
```

(continues on next page)

(continued from previous page)

```
1 0 1
2 0 0
```

```
>>> pd.get_dummies(s1, dummy_na=True)
   a  b  NaN
0  1  0    0
1  0  1    0
2  0  0    1
```

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'],
...                    'C': [1, 2, 3]})
```

```
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1         1         0         0         1         0
1  2         0         1         1         0         0
2  3         1         0         0         0         1
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')))
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')), drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
   a  b  c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

## pandas.factorize

pandas.**factorize** (*values*, *sort=False*, *order=None*, *na\_sentinel=-1*, *size\_hint=None*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function *pandas.factorize()*, and as a method *Series.factorize()* and *Index.factorize()*.

### Parameters

**values** [sequence] A 1-D sequence. Sequences that aren't pandas objects are coerced to ndarrays before factorization.

**sort** [bool, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

**order** Deprecated since version 0.23.0: This parameter has no effect and is deprecated.

**na\_sentinel** [int, default -1] Value to mark “not found”.

**size\_hint** [int, optional] Hint to the hashtable sizer.

### Returns

**labels** [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.

**uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

---

### See also:

**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

### Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

## pandas.unique

`pandas.unique` (*values*)

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than `numpy.unique`. Includes NA values.

### Parameters

**values** [1d array-like]

### Returns

**unique values.**

- If the input is an Index, the return is an Index
- If the input is a Categorical dtype, the return is a Categorical
- If the input is a Series/ndarray, the return will be an ndarray

**See also:**

*pandas.Index.unique, pandas.Series.unique*

## Examples

```
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])
```

```
>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101'),
...                       pd.Timestamp('20160101')]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...                       pd.Timestamp('20160101', tz='US/Eastern')]))
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
      dtype=object)
```

```
>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...                     pd.Timestamp('20160101', tz='US/Eastern')]))
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
...           dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
>>> pd.unique(list('baabc'))
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                   categories=list('abc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                   categories=list('abc'),
...                                   ordered=True)))
[b, a, c]
Categories (3, object): [a < b < c]
```

An array of tuples

```
>>> pd.unique([('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')])
array([('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
```

## pandas.wide\_to\_long

`pandas.wide_to_long(df, stubnames, i, j, sep=',', suffix='\d+')`

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2, ..., B-suffix1, B-suffix2, ... You specify what you want to call this suffix in the resulting long format with *j* (for example *j*='year')

Each row of these wide variables are assumed to be uniquely identified by *i* (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

### Parameters

**df** [DataFrame] The wide-format DataFrame

**stubnames** [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.

**i** [str or list-like] Column(s) to use as id variable(s)

**j** [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.

**sep** [str, default “”] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying `sep='-'`

New in version 0.20.0.

**suffix** [str, default ‘\d+’] A regular expression capturing the wanted suffixes. ‘\d+’ captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class ‘\D+’. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying `suffix='(!?one|two)'`

New in version 0.20.0.

Changed in version 0.23.0: When all suffixes are numeric, they are cast to int64/float64.

### Returns

**DataFrame** A DataFrame that contains each stub name as a variable, with new index (i, j)

### Notes

All extra variables are left untouched. This simply uses `pandas.melt` under the hood, but is hard-coded to “do the right thing” in a typical case.

### Examples

```
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
...                   "A1980" : {0 : "d", 1 : "e", 2 : "f"},
...                   "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
...                   "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
...                   "X"      : dict(zip(range(3), np.random.randn(3)))
...                   })
>>> df["id"] = df.index
>>> df
   A1970 A1980  B1970  B1980         X  id
0      a      d    2.5    3.2 -1.085631  0
1      b      e    1.2    1.3  0.997345  1
2      c      f    0.7    0.1  0.282978  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
... # doctest: +NORMALIZE_WHITESPACE
           X  A      B
id year
0  1970 -1.085631  a  2.5
1  1970  0.997345  b  1.2
2  1970  0.282978  c  0.7
0  1980 -1.085631  d  3.2
1  1980  0.997345  e  1.3
2  1980  0.282978  f  0.1
```

With multiple id columns

```

>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   birth  famid  ht1  ht2
0      1      1  2.8  3.4
1      2      1  2.9  3.8
2      3      1  2.2  2.9
3      1      2  2.0  3.2
4      2      2  1.8  2.8
5      3      2  1.9  2.4
6      1      3  2.2  3.3
7      2      3  2.3  3.4
8      3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
      ht
famid birth age
1      1      1  2.8
      2      2  3.4
      2      1  2.9
      2      2  3.8
      3      1  2.2
      2      2  2.9
2      1      1  2.0
      2      2  3.2
      2      1  1.8
      2      2  2.8
      3      1  1.9
      2      2  2.4
3      1      1  2.2
      2      2  3.3
      2      1  2.3
      2      2  3.4
      3      1  2.1
      2      2  2.9

```

Going from long back to wide just takes some creative use of *unstack*

```

>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
   famid  birth  ht1  ht2
0      1      1  2.8  3.4
1      1      2  2.9  3.8
2      1      3  2.2  2.9
3      2      1  2.0  3.2
4      2      2  1.8  2.8
5      2      3  1.9  2.4
6      3      1  2.2  3.3
7      3      2  2.3  3.4
8      3      3  2.1  2.9

```

Less wily column names are also handled

```

>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(quarterly)-2010': np.random.rand(3),
...                   'A(quarterly)-2011': np.random.rand(3),
...                   'B(quarterly)-2010': np.random.rand(3),
...                   'B(quarterly)-2011': np.random.rand(3),
...                   'X' : np.random.randint(3, size=3)})
>>> df['id'] = df.index
>>> df # doctest: +NORMALIZE_WHITESPACE, +ELLIPSIS
   A(quarterly)-2010  A(quarterly)-2011  B(quarterly)-2010  ...
0          0.548814          0.544883          0.437587  ...
1          0.715189          0.423655          0.891773  ...
2          0.602763          0.645894          0.963663  ...

   X  id
0  0   0
1  1   1
2  1   2

```

```

>>> pd.wide_to_long(df, ['A(quarterly)', 'B(quarterly)'], i='id',
...                 j='year', sep='-')
... # doctest: +NORMALIZE_WHITESPACE
   X  A(quarterly)  B(quarterly)
id year
0  2010  0          0.548814      0.437587
1  2010  1          0.715189      0.891773
2  2010  1          0.602763      0.963663
0  2011  0          0.544883      0.383442
1  2011  1          0.423655      0.791725
2  2011  1          0.645894      0.528895

```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`

```

>>> stubnames = sorted(
...     set([match[0] for match in df.columns.str.findall(
...         r'[A-B]\(.*\)']).values if match != [] ])
... )
>>> list(stubnames)
['A(quarterly)', 'B(quarterly)']

```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```

>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   birth  famid  ht_one  ht_two
0      1      1      2.8      3.4
1      2      1      2.9      3.8
2      3      1      2.2      2.9
3      1      2      2.0      3.2
4      2      2      1.8      2.8
5      3      2      1.9      2.4
6      1      3      2.2      3.3
7      2      3      2.3      3.4
8      3      3      2.1      2.9

```

```

>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
                        sep='_', suffix='\w')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
      ht
famid birth age
1      1    one  2.8
      two  3.4
      2    one  2.9
      two  3.8
      3    one  2.2
      two  2.9
2      1    one  2.0
      two  3.2
      2    one  1.8
      two  2.8
      3    one  1.9
      two  2.4
3      1    one  2.2
      two  3.3
      2    one  2.3
      two  3.4
      3    one  2.1
      two  2.9

```

## 6.2.2 Top-level missing data

<code>isna(obj)</code>	Detect missing values for an array-like object.
<code>isnull(obj)</code>	Detect missing values for an array-like object.
<code>notna(obj)</code>	Detect non-missing values for an array-like object.
<code>notnull(obj)</code>	Detect non-missing values for an array-like object.

### pandas.isna

`pandas.isna(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaT in object arrays, NaT in datetimelike).

#### Parameters

**obj** [scalar or array-like] Object to check for null or missing values.

#### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

#### See also:

**notna** Boolean inverse of `pandas.isna`.

**Series.isna** Detect missing values in a Series.

**DataFrame.isna** Detect missing values in a DataFrame.

**Index.isna** Detect missing values in an Index.

### Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None fly
>>> pd.isna(df)
   0    1    2
0  False False False
1  False  True False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

## pandas.isnull

pandas.**isnull** (*obj*)

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

**obj** [scalar or array-like] Object to check for null or missing values.

**Returns**

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

**notna** Boolean inverse of pandas.isna.

**Series.isna** Detect missing values in a Series.

**DataFrame.isna** Detect missing values in a DataFrame.

**Index.isna** Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None fly
>>> pd.isna(df)
   0    1    2
```

(continues on next page)

(continued from previous page)

```
0 False False False
1 False True False
```

```
>>> pd.isna(df[1])
0 False
1 True
Name: 1, dtype: bool
```

## pandas.notna

pandas.**notna** (*obj*)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

### Parameters

**obj** [array-like or object value] Object to check for *not* null or *non*-missing values.

### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

**isna** Boolean inverse of pandas.notna.

**Series.notna** Detect valid values in a Series.

**DataFrame.notna** Detect valid values in a DataFrame.

**Index.notna** Detect valid values in an Index.

## Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None fly
>>> pd.notna(df)
   0    1    2
0  True  True  True
1  True False  True
```

```
>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

## pandas.notnull

pandas.**notnull** (*obj*)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

### Parameters

**obj** [array-like or object value] Object to check for *not* null or *non*-missing values.

### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

**isna** Boolean inverse of pandas.notna.

**Series.notna** Detect valid values in a Series.

**DataFrame.notna** Detect valid values in a DataFrame.

**Index.notna** Detect valid values in an Index.

## Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0 ant  bee cat
1 dog None fly
>>> pd.notna(df)
   0    1    2
0 True  True True
1 True False True
```

```
>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

### 6.2.3 Top-level conversions

`to_numeric(arg[, errors, downcast])`

Convert argument to a numeric type.

---

#### **pandas.to\_numeric**

`pandas.to_numeric(arg, errors='raise', downcast=None)`

Convert argument to a numeric type.

The default return dtype is *float64* or *int64* depending on the data supplied. Use the *downcast* parameter to obtain other dtypes.

#### **Parameters**

**arg** [list, tuple, 1-d array, or Series]

**errors** [{ 'ignore', 'raise', 'coerce' }, default 'raise']

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaN
- If 'ignore', then invalid parsing will return the input

**downcast** [{ 'integer', 'signed', 'unsigned', 'float' }, default None] If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:

- 'integer' or 'signed': smallest signed int dtype (min.: np.int8)
- 'unsigned': smallest unsigned int dtype (min.: np.uint8)
- 'float': smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the 'errors' input.

In addition, downcasting will only occur if the size of the resulting data's dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

New in version 0.19.0.

### Returns

**ret** [numeric if parsing succeeded.] Return type depends on input. Series if Series, otherwise ndarray

### See also:

***pandas.DataFrame.astype*** Cast argument to a specified dtype.

***pandas.to\_datetime*** Convert argument to datetime.

***pandas.to\_timedelta*** Convert argument to timedelta.

***numpy.ndarray.astype*** Cast a numpy array to a specified type.

### Examples

Take separate series and convert to numeric, coercing when told to

```
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0    1
1    2
2   -3
```

(continues on next page)

(continued from previous page)

```

dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1     1.0
2      2
3     -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
0    NaN
1     1.0
2     2.0
3    -3.0
dtype: float64

```

## 6.2.4 Top-level dealing with datetimelike

<code>to_datetime(arg[, errors, dayfirst, ...])</code>	Convert argument to datetime.
<code>to_timedelta(arg[, unit, box, errors])</code>	Convert argument to timedelta.
<code>date_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex.
<code>bdate_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex, with business day as the default frequency
<code>period_range([start, end, periods, freq, name])</code>	Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency
<code>timedelta_range([start, end, periods, freq, ...])</code>	Return a fixed frequency TimedeltaIndex, with day as the default frequency
<code>infer_freq(index[, warn])</code>	Infer the most likely frequency given the input index.

### pandas.to\_datetime

`pandas.to_datetime` (*arg*, *errors*='raise', *dayfirst*=False, *yearfirst*=False, *utc*=None, *box*=True, *format*=None, *exact*=True, *unit*=None, *infer\_datetime\_format*=False, *origin*='unix', *cache*=False)

Convert argument to datetime.

#### Parameters

**arg** [integer, float, string, datetime, list, tuple, 1-d array, Series] New in version 0.18.1: or DataFrame/dict-like

**errors** [{ 'ignore', 'raise', 'coerce' }, default 'raise']

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaT
- If 'ignore', then invalid parsing will return the input

**dayfirst** [boolean, default False] Specify a date parse order if *arg* is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: *dayfirst*=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

**yearfirst** [boolean, default False] Specify a date parse order if *arg* is str or its list-likes.

- If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.

- If both `dayfirst` and `yearfirst` are `True`, `yearfirst` is preceded (same as `dateutil`).

Warning: `yearfirst=True` is not strict, but will prefer to parse with year first (this is a known bug, based on `dateutil` behavior).

New in version 0.16.1.

**utc** [boolean, default `None`] Return UTC `DatetimeIndex` if `True` (converting any tz-aware `datetime.datetime` objects as well).

**box** [boolean, default `True`]

- If `True` returns a `DatetimeIndex` or `Index`-like object
- If `False` returns `ndarray` of values.

**format** [string, default `None`] `strftime` to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds.

**exact** [boolean, `True` by default]

- If `True`, require an exact format match.
- If `False`, allow the format to match anywhere in the target string.

**unit** [string, default ‘ns’] unit of the arg (`D,s,ms,us,ns`) denote the unit, which is an integer or float number. This will be based off the origin. Example, with `unit='ms'` and `origin='unix'` (the default), this would calculate the number of milliseconds to the unix epoch start.

**infer\_datetime\_format** [boolean, default `False`] If `True` and no `format` is given, attempt to infer the format of the datetime strings, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

**origin** [scalar, default is ‘unix’] Define the reference date. The numeric values would be parsed as number of units (defined by `unit`) since this reference date.

- If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.
- If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If `Timestamp` convertible, origin is set to `Timestamp` identified by origin.

New in version 0.20.0.

**cache** [boolean, default `False`] If `True`, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.23.0.

## Returns

**ret** [datetime if parsing succeeded.] Return type depends on input:

- list-like: `DatetimeIndex`
- Series: Series of `datetime64` dtype
- scalar: `Timestamp`

In case when it is not possible to return designated types (e.g. when any element of input is before `Timestamp.min` or after `Timestamp.max`) return will have `datetime.datetime` type (or corresponding array/Series).

See also:

**pandas.DataFrame.astype** Cast argument to a specified dtype.

**pandas.to\_timedelta** Convert argument to timedelta.

## Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```
>>> df = pd.DataFrame({'year': [2015, 2016],
                       'month': [2, 3],
                       'day': [4, 5]})
>>> pd.to_datetime(df)
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the [timestamp limitations](#), passing `errors='ignore'` will return the original input instead of raising any exception.

Passing `errors='coerce'` will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing `infer_datetime_format=True` can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```
>>> s = pd.Series(['3/11/2000', '3/12/2000', '3/13/2000']*1000)
```

```
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

**Warning:** For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```
>>> pd.to_datetime([1, 2, 3], unit='D',
                   origin=pd.Timestamp('1960-01-01'))
0    1960-01-02
1    1960-01-03
2    1960-01-04
```

## pandas.to\_timedelta

`pandas.to_timedelta` (*arg*, *unit='ns'*, *box=True*, *errors='raise'*)

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

### Parameters

**arg** [str, timedelta, list-like or Series] The data to be converted to timedelta.

**unit** [str, default 'ns'] Denotes the unit of the arg. Possible values: ('Y', 'M', 'W', 'D', 'days', 'day', 'hours', hour, 'hr', 'h', 'm', 'minute', 'min', 'minutes', 'T', 'S', 'seconds', 'sec', 'second', 'ms', 'milliseconds', 'millisecond', 'milli', 'millis', 'L', 'us', 'microseconds', 'microsecond', 'micro', 'micros', 'U', 'ns', 'nanoseconds', 'nano', 'nanos', 'nanosecond', 'N').

**box** [bool, default True]

- If True returns a Timedelta/TimedeltaIndex of the results.
- If False returns a numpy.timedelta64 or numpy.darray of values of dtype timedelta64[ns].

**errors** [{ 'ignore', 'raise', 'coerce' }, default 'raise']

- If 'raise', then invalid parsing will raise an exception.
- If 'coerce', then invalid parsing will be set as NaT.
- If 'ignore', then invalid parsing will return the input.

### Returns

**timedelta64 or numpy.array of timedelta64** Output type returned if parsing succeeded.

See also:

**DataFrame.astype** Cast argument to a specified dtype.

**to\_datetime** Convert argument to datetime.

## Examples

Parsing a single string to a Timedelta:

```
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015')
```

Parsing a list or array of strings:

```
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
                dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the *unit* keyword argument:

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02',
                '00:00:03', '00:00:04'],
                dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

Returning an ndarray by using the ‘box’ keyword argument:

```
>>> pd.to_timedelta(np.arange(5), box=False)
array([0, 1, 2, 3, 4], dtype='timedelta64[ns]')
```

## pandas.date\_range

`pandas.date_range` (*start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, \*\*kwargs*)

Return a fixed frequency DatetimeIndex.

### Parameters

- start** [str or datetime-like, optional] Left bound for generating dates.
- end** [str or datetime-like, optional] Right bound for generating dates.
- periods** [integer, optional] Number of periods to generate.
- freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See [here](#) for a list of frequency aliases.
- tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong\_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- name** [str, default None] Name of the resulting DatetimeIndex.
- closed** [{None, ‘left’, ‘right’}, optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).
- \*\*kwargs** For compatibility. Has no effect on the result.

### Returns

**rng** [DatetimeIndex]

See also:

**`pandas.DatetimeIndex`** An immutable container for datetimes.

**`pandas.timedelta_range`** Return a fixed frequency `TimedeltaIndex`.

**`pandas.period_range`** Return a fixed frequency `PeriodIndex`.

**`pandas.interval_range`** Return a fixed frequency `IntervalIndex`.

## Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

## Examples

### Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```
>>> pd.date_range(start='1/1/2018', periods=8)
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
              '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
              '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Other Parameters

Changed the `freq` (frequency) to 'M' (month end frequency).

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31', '2018-04-30',
              '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

*freq* can also be specified as an Offset object.

```
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

Specify *tz* to set the timezone.

```
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
              '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
              '2018-01-05 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

*closed* controls whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='left'* to exclude *end* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='right'* to exclude *start* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

## pandas.bdate\_range

`pandas.bdate_range` (*start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=None, \*\*kwargs*)

Return a fixed frequency DatetimeIndex, with business day as the default frequency

### Parameters

**start** [string or datetime-like, default None] Left bound for generating dates.

**end** [string or datetime-like, default None] Right bound for generating dates.

**periods** [integer, default None] Number of periods to generate.

**freq** [string or DateOffset, default 'B' (business daily)] Frequency strings can have multiples, e.g. '5H'.

**tz** [string or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**name** [string, default None] Name of the resulting DatetimeIndex.

**weekmask** [string or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to 'Mon Tue Wed Thu Fri'.

New in version 0.21.0.

**holidays** [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.

New in version 0.21.0.

**closed** [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None).

**\*\*kwargs** For compatibility. Has no effect on the result.

## Returns

**DatetimeIndex**

## Notes

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see [this link](#).

## Examples

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-08'],
              dtype='datetime64[ns]', freq='B')
```

## pandas.period\_range

`pandas.period_range` (*start=None, end=None, periods=None, freq=None, name=None*)

Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency

### Parameters

**start** [string or period-like, default None] Left bound for generating periods

**end** [string or period-like, default None] Right bound for generating periods

**periods** [integer, default None] Number of periods to generate

**freq** [string or DateOffset, optional] Frequency alias. By default the freq is taken from `start` or `end` if those are Period objects. Otherwise, the default is "D" for daily frequency.

**name** [string, default None] Name of the resulting PeriodIndex

### Returns

**prng** [PeriodIndex]

### Notes

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see [this link](#).

### Examples

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05',
            '2017-06', '2017-06', '2017-07', '2017-08', '2017-09',
            '2017-10', '2017-11', '2017-12', '2018-01'],
            dtype='period[M]', freq='M')
```

If `start` or `end` are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the `period_range` constructor.

```
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
...                 end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

## pandas.timedelta\_range

`pandas.timedelta_range` (*start=None, end=None, periods=None, freq=None, name=None, closed=None*)

Return a fixed frequency TimedeltaIndex, with day as the default frequency

### Parameters

**start** [string or timedelta-like, default None] Left bound for generating timedeltas

**end** [string or timedelta-like, default None] Right bound for generating timedeltas

**periods** [integer, default None] Number of periods to generate

**freq** [string or DateOffset, default 'D'] Frequency strings can have multiples, e.g. '5H'

**name** [string, default None] Name of the resulting TimedeltaIndex

**closed** [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

### Returns

**rng** [TimedeltaIndex]

### Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting TimedeltaIndex will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

## Examples

```
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the `TimedeltaIndex`. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='6H')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                '5 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

## pandas.infer\_freq

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

### Parameters

**index** [DatetimeIndex or TimedeltaIndex] if passed a Series will use the values of the series (NOT THE INDEX)

**warn** [boolean, default True]

### Returns

**freq** [string or None] None if no discernible frequency TypeError if the index is not datetime-like ValueError if there are less than three values.

## 6.2.5 Top-level dealing with intervals

---

`interval_range([start, end, periods, freq, ...])`      Return a fixed frequency IntervalIndex

---

## pandas.interval\_range

pandas.**interval\_range** (*start=None, end=None, periods=None, freq=None, name=None, closed='right'*)

Return a fixed frequency IntervalIndex

### Parameters

**start** [numeric or datetime-like, default None] Left bound for generating intervals

**end** [numeric or datetime-like, default None] Right bound for generating intervals

**periods** [integer, default None] Number of periods to generate

**freq** [numeric, string, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or '5H' for datetime-like. Default is 1 for numeric and 'D' for datetime-like.

**name** [string, default None] Name of the resulting IntervalIndex

**closed** [{ 'left', 'right', 'both', 'neither' }, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

### Returns

**rng** [IntervalIndex]

See also:

**IntervalIndex** An Index of intervals that are all closed on the same side.

### Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have periods linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see [this link](#).

### Examples

Numeric `start` and `end` is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right', dtype='interval[int64]')
```

Additionally, datetime-like input is also supported.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                  end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
              (2017-01-03, 2017-01-04]],
              closed='right', dtype='interval[datetime64[ns]]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
              closed='right', dtype='interval[float64]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a DateOffset.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                  periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
              (2017-03-01, 2017-04-01]],
              closed='right', dtype='interval[datetime64[ns]]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
              closed='right',
              dtype='interval[float64]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
              closed='both', dtype='interval[int64]')
```

## 6.2.6 Top-level evaluation

`eval(expr[, parser, engine, truediv, ...])`

Evaluate a Python expression as a string using various backends.

### pandas.eval

`pandas.eval` (*expr*, *parser*='pandas', *engine*=None, *truediv*=True, *local\_dict*=None, *global\_dict*=None, *resolvers*=(), *level*=0, *target*=None, *inplace*=False)

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: +, -, \*, /, \*\*, %, // (python engine only) along with the following boolean operations: | (or), & (and), and ~ (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. *Series* and *DataFrame* objects are supported and behave as they would with plain ol' Python evaluation.

#### Parameters

**expr** [str or unicode] The expression to evaluate. This string cannot contain any Python `statements`, only Python `expressions`.

**parser** [string, default 'pandas', {'pandas', 'python'}] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the *enhancing performance* documentation for more details.

**engine** [string or None, default 'numexpr', {'python', 'numexpr'}] The engine used to evaluate the expression. Supported engines are

- `None` : tries to use `numexpr`, falls back to `python`
- `'numexpr'` : This default engine evaluates pandas objects using `numexpr` for large speed ups in complex expressions with large frames.
- `'python'` : Performs operations as if you had `eval`'d in top level python. This engine is generally not that useful.

More backends may be available in the future.

**truediv** [bool, optional] Whether to use true division, like in Python `>= 3`

**local\_dict** [dict or None, optional] A dictionary of local variables, taken from `locals()` by default.

**global\_dict** [dict or None, optional] A dictionary of global variables, taken from `globals()` by default.

**resolvers** [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

**level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

**target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then `target` must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

**inplace** [bool, default False] If `target` is provided, and the expression mutates `target`, whether to modify `target` inplace. Otherwise, return a copy of `target` with the mutation.

### Returns

**ndarray, numeric scalar, DataFrame, Series**

### Raises

**ValueError** There are many instances where such an error can be raised:

- `target=None`, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

```
a = b + 1 a + 2
```

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of `a + 2`.

- `inplace=True`, but the expression is missing item assignment.
- Item assignment is provided, but the `target` does not support string item assignment.
- Item assignment is provided and `inplace=False`, but the `target` does not support the `.copy()` method

### See also:

`pandas.DataFrame.query`, `pandas.DataFrame.eval`

## Notes

The `dtype` of any objects involved in an arithmetic `%` operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.

## 6.2.7 Hashing

---

<code>util.hash_array(vals[, encoding, hash_key, ...])</code>	Given a 1d array, return an array of deterministic integers.
<code>util.hash_pandas_object(obj[, index, ...])</code>	Return a data hash of the Index/Series/DataFrame

---

### pandas.util.hash\_array

`pandas.util.hash_array(vals, encoding='utf8', hash_key=None, categorize=True)`

Given a 1d array, return an array of deterministic integers.

New in version 0.19.2.

#### Parameters

**vals** [ndarray, Categorical]

**encoding** [string, default 'utf8'] encoding for data & key when strings

**hash\_key** [string key to encode, default to `_default_hash_key`]

**categorize** [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

#### Returns

**1d uint64 numpy array of hash values, same length as the vals**

### pandas.util.hash\_pandas\_object

`pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key=None, categorize=True)`

Return a data hash of the Index/Series/DataFrame

New in version 0.19.2.

#### Parameters

**index** [boolean, default True] include the index in the hash (if Series/DataFrame)

**encoding** [string, default 'utf8'] encoding for data & key when strings

**hash\_key** [string key to encode, default to `_default_hash_key`]

**categorize** [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

#### Returns

**Series of uint64, same length as the object**

## 6.2.8 Testing

`test([extra_args])`

---

### pandas.test

`pandas.test` (*extra\_args=None*)

## 6.3 Series

### 6.3.1 Constructor

`Series([data, index, dtype, name, copy, ...])`      One-dimensional ndarray with axis labels (including time series).

---

### pandas.Series

**class** `pandas.Series` (*data=None, index=None, dtype=None, name=None, copy=False, fast-path=False*)

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, \*,) align values based on their associated index values—they need not be the same length. The result index will be the sorted union of the two indexes.

#### Parameters

**data** [array-like, Iterable, dict, or scalar value] Contains data stored in Series.

Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

**index** [array-like or Index (1d)] Values must be hashable and have the same length as *data*. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.

**dtype** [str, numpy.dtype, or ExtensionDtype, optional] dtype for the output Series. If not specified, this will be inferred from *data*. See the *user guide* for more usages.

**copy** [bool, default False] Copy input data.

#### Attributes

<code>T</code>	Return the transpose, which is by definition self.
<code>array</code>	The ExtensionArray of the data backing this Series or Index.
<code>asobject</code>	Return object Series which contains boxed values.

---

Continued on next page

Table 26 – continued from previous page

<i>at</i>	Access a single value for a row/column label pair.
<i>axes</i>	Return a list of the row axis labels.
<i>base</i>	Return the base object if the memory of the underlying data is shared.
<i>blocks</i>	(DEPRECATED) Internal property, property synonym for <code>as_blocks()</code> .
<i>data</i>	Return the data pointer of the underlying data.
<i>dtype</i>	Return the dtype object of the underlying data.
<i>dtypes</i>	Return the dtype object of the underlying data.
<i>flags</i>	
<i>ftype</i>	Return if the data is sparsedense.
<i>ftypes</i>	Return if the data is sparsedense.
<i>hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>iat</i>	Access a single value for a row/column pair by integer position.
<i>iloc</i>	Purely integer-location based indexing for selection by position.
<i>imag</i>	Return imag value of vector.
<i>index</i>	The index (axis labels) of the Series.
<i>is_copy</i>	Return the copy.
<i>is_monotonic</i>	Return boolean if values in the object are monotonic_increasing.
<i>is_monotonic_decreasing</i>	Return boolean if values in the object are monotonic_decreasing.
<i>is_monotonic_increasing</i>	Return boolean if values in the object are monotonic_increasing.
<i>is_unique</i>	Return boolean if values in the object are unique.
<i>itemsize</i>	Return the size of the dtype of the item of the underlying data.
<i>ix</i>	A primarily label-location based indexer, with integer position fallback.
<i>loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>name</i>	Return name of the Series.
<i>nbytes</i>	Return the number of bytes in the underlying data.
<i>ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>real</i>	Return the real value of vector.
<i>shape</i>	Return a tuple of the shape of the underlying data.
<i>size</i>	Return the number of elements in the underlying data.
<i>strides</i>	Return the strides of the underlying data.
<i>values</i>	Return Series as ndarray or ndarray-like depending on the dtype.

**pandas.Series.T****Series.T**

Return the transpose, which is by definition self.

## pandas.Series.array

### Series.array

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

#### Returns

**array** [ExtensionArray] An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

#### See also:

**Index.to\_numpy** Similar method that always returns a NumPy array.

**Series.to\_numpy** Similar method that always returns a NumPy array.

#### Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

#### Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

## pandas.Series.asobject

### Series.asobject

Return object Series which contains boxed values.

Deprecated since version 0.23.0: Use `astype(object)` instead.

*this is an internal non-public method*

## pandas.Series.at

### Series.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**KeyError** When label does not exist in DataFrame

#### See also:

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

### **pandas.Series.axes**

#### **Series.axes**

Return a list of the row axis labels.

### **pandas.Series.base**

#### **Series.base**

Return the base object if the memory of the underlying data is shared.

### **pandas.Series.blocks**

#### **Series.blocks**

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

### **pandas.Series.data**

#### **Series.data**

Return the data pointer of the underlying data.

### **pandas.Series.dtype**

#### **Series.dtype**

Return the dtype object of the underlying data.

### **pandas.Series.dtypes**

#### **Series.dtypes**

Return the dtype object of the underlying data.

### **pandas.Series.flags**

#### **Series.flags**

### **pandas.Series.ftype**

#### **Series.ftype**

Return if the data is sparse/dense.

### **pandas.Series.ftypes**

#### **Series.ftypes**

Return if the data is sparse/dense.

## pandas.Series.hasnans

### Series.hasnans

Return if I have any nans; enables various perf speedups.

## pandas.Series.iat

### Series.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**IndexError** When integer position is out of bounds

#### See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.loc** Access a group of rows and columns by label(s).

**DataFrame.iloc** Access a group of rows and columns by integer position(s).

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.Series.iloc

### Series.iloc

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at ref:*Selection by Position <indexing.integer>*.

**See also:**

**`DataFrame.iat`** Fast integer location scalar accessor.

**`DataFrame.loc`** Purely label-location based indexer for selection by label.

**`Series.iloc`** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
   a    b    c    d
0   1    2    3    4
1  100  200  300  400
2 1000 2000 3000 4000
```

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
```

(continues on next page)

(continued from previous page)

```
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a  b  c  d
0   1  2  3  4
1 100 200 300 400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a  b  c  d
0   1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a  b  c  d
0   1  2  3  4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the `DataFrame` being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a  b  c  d
0   1  2  3  4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0   2  4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a  b  c
1 100 200 300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

### **pandas.Series.imag**

`Series.imag`

Return imag value of vector.

### **pandas.Series.index**

`Series.index`

The index (axis labels) of the Series.

### **pandas.Series.is\_copy**

`Series.is_copy`

Return the copy.

### **pandas.Series.is\_monotonic**

`Series.is_monotonic`

Return boolean if values in the object are monotonic\_increasing.

New in version 0.19.0.

#### **Returns**

`is_monotonic` [boolean]

### **pandas.Series.is\_monotonic\_decreasing**

`Series.is_monotonic_decreasing`

Return boolean if values in the object are monotonic\_decreasing.

New in version 0.19.0.

#### **Returns**

`is_monotonic_decreasing` [boolean]

### pandas.Series.is\_monotonic\_increasing

#### Series.is\_monotonic\_increasing

Return boolean if values in the object are monotonic\_increasing.

New in version 0.19.0.

#### Returns

**is\_monotonic** [boolean]

### pandas.Series.is\_unique

#### Series.is\_unique

Return boolean if values in the object are unique.

#### Returns

**is\_unique** [boolean]

### pandas.Series.itemsize

#### Series.itemsize

Return the size of the dtype of the item of the underlying data.

### pandas.Series.ix

#### Series.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.

.ix[] supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

.ix is the most general indexer and will support any of the inputs in .loc and .iloc. .ix also supports floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use .iloc or .loc.

See more at *Advanced Indexing*.

### pandas.Series.loc

#### Series.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].

- A slice object with labels, e.g. 'a': 'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

### Raises

**KeyError:** when any items are not found

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
```

	max_speed	shield
cobra	1	2
viper	4	5
sidewinder	7	8

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using [ [] ] returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

	max_speed	shield
viper	4	5
sidewinder	7	8

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra      1
viper      4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
      max_speed  shield
sidewinder      7      8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
      max_speed  shield
sidewinder      7      8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
      max_speed
sidewinder      7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
      max_speed  shield
sidewinder      7      8
```

### Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
      max_speed  shield
cobra           1      2
viper           4     50
sidewinder       7     50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
      max_speed  shield
cobra         10     10
viper          4     50
sidewinder      7     50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
      max_speed  shield
cobra         30     10
```

(continues on next page)

(continued from previous page)

viper	30	50
sidewinder	30	50

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
```

	max_speed	shield
cobra	30	10
viper	0	0
sidewinder	0	0

### Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
```

	max_speed	shield
7	1	2
8	4	5
9	7	8

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
```

	max_speed	shield
7	1	2
8	4	5
9	7	8

### Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
```

		max_speed	shield
cobra	mark i	12	2
	mark ii	0	4
sidewinder	mark i	10	20
	mark ii	1	4
viper	mark ii	7	1
	mark iii	16	36

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
      max_speed  shield
mark i         12     2
mark ii        0     4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
      max_speed  shield
cobra mark ii    0     4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
      max_speed  shield
cobra  mark i    12     2
      mark ii    0     4
sidewinder mark i  10    20
      mark ii    1     4
viper  mark ii   7     1
      mark iii  16    36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):(viper', 'mark ii')]
      max_speed  shield
cobra  mark i    12     2
      mark ii    0     4
sidewinder mark i  10    20
      mark ii    1     4
viper  mark ii   7     1
```

## pandas.Series.name

`Series.name`

Return name of the Series.

### **pandas.Series.nbytes**

`Series.nbytes`

Return the number of bytes in the underlying data.

### **pandas.Series.ndim**

`Series.ndim`

Number of dimensions of the underlying data, by definition 1.

### **pandas.Series.real**

`Series.real`

Return the real value of vector.

### **pandas.Series.shape**

`Series.shape`

Return a tuple of the shape of the underlying data.

### **pandas.Series.size**

`Series.size`

Return the number of elements in the underlying data.

### **pandas.Series.strides**

`Series.strides`

Return the strides of the underlying data.

### **pandas.Series.values**

`Series.values`

Return Series as ndarray or ndarray-like depending on the dtype.

<p><b>Warning:</b> We recommend using <code>Series.array</code> or <code>Series.to_numpy()</code>, depending on whether you need a reference to the underlying data or a NumPy array.</p>
---

#### **Returns**

**arr** [numpy.ndarray or ndarray-like]

#### **See also:**

**`Series.array`** Reference to the underlying data.

**`Series.to_numpy`** A NumPy array representing the underlying data.

## Examples

```
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```
>>> pd.Series(list('aabc')).astype('category').values
[a, a, b, c]
Categories (3, object): [a, b, c]
```

Timezone aware datetime data is converted to UTC:

```
>>> pd.Series(pd.date_range('20130101', periods=3,
...                          tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
      '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

empty	
timetuple	

## Methods

<i>abs()</i>	Return a Series/DataFrame with absolute numeric value of each element.
<i>add(other[, level, fill_value, axis])</i>	Addition of series and other, element-wise (binary operator <i>add</i> ).
<i>add_prefix(prefix)</i>	Prefix labels with string <i>prefix</i> .
<i>add_suffix(suffix)</i>	Suffix labels with string <i>suffix</i> .
<i>agg(func[, axis])</i>	Aggregate using one or more operations over the specified axis.
<i>aggregate(func[, axis])</i>	Aggregate using one or more operations over the specified axis.
<i>align(other[, join, axis, level, copy, ...])</i>	Align two objects on their axes with the specified join method for each axis Index.
<i>all([axis, bool_only, skipna, level])</i>	Return whether all elements are True, potentially over an axis.
<i>any([axis, bool_only, skipna, level])</i>	Return whether any element is True, potentially over an axis.
<i>append(to_append[, ignore_index, ...])</i>	Concatenate two or more Series.
<i>apply(func[, convert_dtype, args])</i>	Invoke function on values of Series.
<i>argmax([axis, skipna])</i>	(DEPRECATED) Return the row label of the maximum value.
<i>argmin([axis, skipna])</i>	(DEPRECATED) Return the row label of the minimum value.
<i>argsort([axis, kind, order])</i>	Overrides ndarray.argsort.

Continued on next page

Table 27 – continued from previous page

<code>as_blocks([copy])</code>	(DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.
<code>as_matrix([columns])</code>	(DEPRECATED) Convert the frame to its Numpy-array representation.
<code>asfreq(freq[, method, how, normalize, ...])</code>	Convert TimeSeries to specified frequency.
<code>asof(where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>astype(dtype[, copy, errors])</code>	Cast a pandas object to a specified dtype <i>dtype</i> .
<code>at_time(time[, asof, axis])</code>	Select values at particular time of day (e.g.
<code>autocorr([lag])</code>	Compute the lag-N autocorrelation.
<code>between(left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left &lt;= series &lt;= right</code> .
<code>between_time(start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool()</code>	Return the bool of a single element PandasObject.
<code>cat</code>	alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code>
<code>clip([lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>clip_lower(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values below a given threshold.
<code>clip_upper(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values above a given threshold.
<code>combine(other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <i>func</i> .
<code>combine_first(other)</code>	Combine Series values, choosing the calling Series's values first.
<code>compound([axis, skipna, level])</code>	Return the compound percentage of the values for the requested axis.
<code>compress(condition, *args, **kwargs)</code>	(DEPRECATED) Return selected slices of an array along given axis as a Series.
<code>convert_objects([convert_dates, ...])</code>	(DEPRECATED) Attempt to infer better dtype for object columns.
<code>copy([deep])</code>	Make a copy of this object's indices and data.
<code>corr(other[, method, min_periods])</code>	Compute correlation with <i>other</i> Series, excluding missing values.
<code>count([level])</code>	Return number of non-NA/null observations in the Series.
<code>cov(other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>cummax([axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin([axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod([axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum([axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.

Continued on next page

Table 27 – continued from previous page

<code>describe([percentiles, include, exclude])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>diff([periods])</code>	First discrete difference of element.
<code>div(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>truediv</i> ).
<code>divide(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>truediv</i> ).
<code>divmod(other[, level, fill_value, axis])</code>	Integer division and modulo of series and other, element-wise (binary operator <i>divmod</i> ).
<code>dot(other)</code>	Compute the dot product between the Series and the columns of other.
<code>drop([labels, axis, index, columns, level, ...])</code>	Return Series with specified index labels removed.
<code>drop_duplicates([keep, inplace])</code>	Return Series with duplicate values removed.
<code>droplevel(level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna([axis, inplace])</code>	Return a new Series with missing values removed.
<code>dt</code>	alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code>
<code>duplicated([keep])</code>	Indicate duplicate Series values.
<code>eq(other[, level, fill_value, axis])</code>	Equal to of series and other, element-wise (binary operator <i>eq</i> ).
<code>equals(other)</code>	Test whether two objects contain the same elements.
<code>ewm([com, span, halflife, alpha, ...])</code>	Provides exponential weighted functions.
<code>expanding([min_periods, center, axis])</code>	Provides expanding transformations.
<code>factorize([sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>ffill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna([value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter([items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.
<code>first(offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>first_valid_index()</code>	Return index for first non-NA/null value.
<code>floordiv(other[, level, fill_value, axis])</code>	Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).
<code>from_array(arr[, index, name, dtype, copy, ...])</code>	Construct Series from array.
<code>from_csv(path[, sep, parse_dates, header, ...])</code>	(DEPRECATED) Read CSV file.
<code>ge(other[, level, fill_value, axis])</code>	Greater than or equal to of series and other, element-wise (binary operator <i>ge</i> ).
<code>get(key[, default])</code>	Get item from object for given key (DataFrame column, Panel slice, etc.).
<code>get_dtype_counts()</code>	Return counts of unique dtypes in this object.
<code>get_ftype_counts()</code>	(DEPRECATED) Return counts of unique ftypes in this object.
<code>get_value(label[, takeable])</code>	(DEPRECATED) Quickly retrieve single value at passed index label.
<code>get_values()</code>	Same as <code>values</code> (but handles sparseness conversions); is a view.

Continued on next page

Table 27 – continued from previous page

<code>groupby([by, axis, level, as_index, sort, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>gt(other[, level, fill_value, axis])</code>	Greater than of series and other, element-wise (binary operator <i>gt</i> ).
<code>head([n])</code>	Return the first <i>n</i> rows.
<code>hist([by, ax, grid, xlabelsize, xrot, ...])</code>	Draw histogram of the input series using matplotlib.
<code>idxmax([axis, skipna])</code>	Return the row label of the maximum value.
<code>idxmin([axis, skipna])</code>	Return the row label of the minimum value.
<code>infer_objects()</code>	Attempt to infer better dtypes for object columns.
<code>interpolate([method, axis, limit, inplace, ...])</code>	Interpolate values according to different methods.
<code>isin(values)</code>	Check whether <i>values</i> are contained in Series.
<code>isna()</code>	Detect missing values.
<code>isnull()</code>	Detect missing values.
<code>item()</code>	Return the first element of the underlying data as a python scalar.
<code>items()</code>	Lazily iterate over (index, value) tuples.
<code>iteritems()</code>	Lazily iterate over (index, value) tuples.
<code>keys()</code>	Alias for index.
<code>kurt([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>kurtosis([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>last(offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>last_valid_index()</code>	Return index for last non-NA/null value.
<code>le(other[, level, fill_value, axis])</code>	Less than or equal to of series and other, element-wise (binary operator <i>le</i> ).
<code>lt(other[, level, fill_value, axis])</code>	Less than of series and other, element-wise (binary operator <i>lt</i> ).
<code>mad([axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>map(arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>mask(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is True.
<code>max([axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>mean([axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>median([axis, skipna, level, numeric_only])</code>	Return the median of the values for the requested axis.
<code>memory_usage([index, deep])</code>	Return the memory usage of the Series.
<code>min([axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>mod(other[, level, fill_value, axis])</code>	Modulo of series and other, element-wise (binary operator <i>mod</i> ).
<code>mode([dropna])</code>	Return the mode(s) of the dataset.
<code>mul(other[, level, fill_value, axis])</code>	Multiplication of series and other, element-wise (binary operator <i>mul</i> ).
<code>multiply(other[, level, fill_value, axis])</code>	Multiplication of series and other, element-wise (binary operator <i>mul</i> ).

Continued on next page

Table 27 – continued from previous page

<code>ne(other[, level, fill_value, axis])</code>	Not equal to of series and other, element-wise (binary operator <i>ne</i> ).
<code>nlargest([n, keep])</code>	Return the largest <i>n</i> elements.
<code>nonzero()</code>	(DEPRECATED) Return the <i>integer</i> indices of the elements that are non-zero.
<code>notna()</code>	Detect existing (non-missing) values.
<code>notnull()</code>	Detect existing (non-missing) values.
<code>nsmallest([n, keep])</code>	Return the smallest <i>n</i> elements.
<code>nunique([dropna])</code>	Return number of unique elements in the object.
<code>pct_change([periods, fill_method, limit, freq])</code>	Percentage change between the current and a prior element.
<code>pipe(func, *args, **kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>plot</code>	alias of <code>pandas.plotting._core.SeriesPlotMethods</code>
<code>pop(item)</code>	Return item and drop from frame.
<code>pow(other[, level, fill_value, axis])</code>	Exponential power of series and other, element-wise (binary operator <i>pow</i> ).
<code>prod([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values for the requested axis.
<code>product([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values for the requested axis.
<code>ptp([axis, skipna, level, numeric_only])</code>	(DEPRECATED) Returns the difference between the maximum value and the
<code>put(*args, **kwargs)</code>	Applies the <i>put</i> method to its <i>values</i> attribute if it has one.
<code>quantile([q, interpolation])</code>	Return value at the given quantile.
<code>radd(other[, level, fill_value, axis])</code>	Addition of series and other, element-wise (binary operator <i>radd</i> ).
<code>rank([axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through n) along axis.
<code>ravel([order])</code>	Return the flattened underlying data as an ndarray.
<code>rdiv(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ).
<code>rdivmod(other[, level, fill_value, axis])</code>	Integer division and modulo of series and other, element-wise (binary operator <i>rdivmod</i> ).
<code>reindex([index])</code>	Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>reindex_axis(labels[, axis])</code>	(DEPRECATED) Conform Series to new index with optional filling logic.
<code>reindex_like(other[, method, copy, limit, ...])</code>	Return an object with matching indices as other object.
<code>rename([index])</code>	Alter Series index labels or name.
<code>rename_axis([mapper, index, columns, axis, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(order)</code>	Rearrange index levels using input order.
<code>repeat(repeats[, axis])</code>	Repeat elements of a Series.
<code>replace([to_replace, value, inplace, limit, ...])</code>	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>resample(rule[, how, axis, fill_method, ...])</code>	Resample time-series data.
<code>reset_index([level, drop, name, inplace])</code>	Generate a new DataFrame or Series with the index reset.

Continued on next page

Table 27 – continued from previous page

<code>rfloordiv</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Integer division of series and other, element-wise (binary operator <code>rfloordiv</code> ).
<code>rmod</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Modulo of series and other, element-wise (binary operator <code>rmod</code> ).
<code>rmul</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Multiplication of series and other, element-wise (binary operator <code>rmul</code> ).
<code>rolling</code> ( <code>window</code> [, <code>min_periods</code> , <code>center</code> , ...])	Provides rolling window calculations.
<code>round</code> ([ <code>decimals</code> ])	Round each value in a Series to the given number of decimals.
<code>rpow</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Exponential power of series and other, element-wise (binary operator <code>rpow</code> ).
<code>rsub</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Subtraction of series and other, element-wise (binary operator <code>rsub</code> ).
<code>rtruediv</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Floating division of series and other, element-wise (binary operator <code>rtruediv</code> ).
<code>sample</code> ([ <code>n</code> , <code>frac</code> , <code>replace</code> , <code>weights</code> , ...])	Return a random sample of items from an axis of object.
<code>searchsorted</code> ( <code>value</code> [, <code>side</code> , <code>sorter</code> ])	Find indices where elements should be inserted to maintain order.
<code>select</code> ( <code>crit</code> [, <code>axis</code> ])	(DEPRECATED) Return data corresponding to axis labels matching criteria.
<code>sem</code> ([ <code>axis</code> , <code>skipna</code> , <code>level</code> , <code>ddof</code> , <code>numeric_only</code> ])	Return unbiased standard error of the mean over requested axis.
<code>set_axis</code> ( <code>labels</code> [, <code>axis</code> , <code>inplace</code> ])	Assign desired index to given axis.
<code>set_value</code> ( <code>label</code> , <code>value</code> [, <code>takeable</code> ])	(DEPRECATED) Quickly set single value at passed label.
<code>shift</code> ([ <code>periods</code> , <code>freq</code> , <code>axis</code> , <code>fill_value</code> ])	Shift index by desired number of periods with an optional time <code>freq</code> .
<code>skew</code> ([ <code>axis</code> , <code>skipna</code> , <code>level</code> , <code>numeric_only</code> ])	Return unbiased skew over requested axis Normalized by N-1.
<code>slice_shift</code> ([ <code>periods</code> , <code>axis</code> ])	Equivalent to <code>shift</code> without copying data.
<code>sort_index</code> ([ <code>axis</code> , <code>level</code> , <code>ascending</code> , ...])	Sort Series by index labels.
<code>sort_values</code> ([ <code>axis</code> , <code>ascending</code> , <code>inplace</code> , ...])	Sort by the values.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.SparseAccessor</code>
<code>squeeze</code> ([ <code>axis</code> ])	Squeeze 1 dimensional axis objects into scalars.
<code>std</code> ([ <code>axis</code> , <code>skipna</code> , <code>level</code> , <code>ddof</code> , <code>numeric_only</code> ])	Return sample standard deviation over requested axis.
<code>str</code>	alias of <code>pandas.core.strings.StringMethods</code>
<code>sub</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Subtraction of series and other, element-wise (binary operator <code>sub</code> ).
<code>subtract</code> ( <code>other</code> [, <code>level</code> , <code>fill_value</code> , <code>axis</code> ])	Subtraction of series and other, element-wise (binary operator <code>sub</code> ).
<code>sum</code> ([ <code>axis</code> , <code>skipna</code> , <code>level</code> , <code>numeric_only</code> , ...])	Return the sum of the values for the requested axis.
<code>swapaxes</code> ( <code>axis1</code> , <code>axis2</code> [, <code>copy</code> ])	Interchange axes and swap values axes appropriately.
<code>swaplevel</code> ([ <code>i</code> , <code>j</code> , <code>copy</code> ])	Swap levels <code>i</code> and <code>j</code> in a MultiIndex.
<code>tail</code> ([ <code>n</code> ])	Return the last <code>n</code> rows.
<code>take</code> ( <code>indices</code> [, <code>axis</code> , <code>convert</code> , <code>is_copy</code> ])	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard</code> ([ <code>excel</code> , <code>sep</code> ])	Copy object to the system clipboard.

Continued on next page

Table 27 – continued from previous page

<code>to_csv(*args, **kwargs)</code>	Write object to a comma-separated values (csv) file.
<code>to_dense()</code>	Return dense representation of NDFrame (as opposed to sparse).
<code>to_dict([into])</code>	Convert Series to {label -> value} dict or dict-like object.
<code>to_excel(excel_writer[, sheet_name, na_rep, ...])</code>	Write object to an Excel sheet.
<code>to_frame([name])</code>	Convert Series to DataFrame.
<code>to_hdf(path_or_buf, key, **kwargs)</code>	Write the contained data to an HDF5 file using HDF-Store.
<code>to_json([path_or_buf, orient, date_format, ...])</code>	Convert the object to a JSON string.
<code>to_latex([buf, columns, col_space, header, ...])</code>	Render an object to a LaTeX tabular environment table.
<code>to_list()</code>	Return a list of the values.
<code>to_msgpack([path_or_buf, encoding])</code>	Serialize object to input file path using msgpack format.
<code>to_numpy([dtype, copy])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>to_period([freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>to_pickle(path[, compression, protocol])</code>	Pickle (serialize) object to file.
<code>to_sparse([kind, fill_value])</code>	Convert Series to SparseSeries.
<code>to_sql(name, con[, schema, if_exists, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_string([buf, na_rep, float_format, ...])</code>	Render a string representation of the Series.
<code>to_timestamp([freq, how, copy])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>to_xarray()</code>	Return an xarray object from the pandas object.
<code>tolist()</code>	Return a list of the values.
<code>transform(func[, axis])</code>	Call <code>func</code> on self producing a Series with transformed values and that has the same axis length as self.
<code>transpose(*args, **kwargs)</code>	Return the transpose, which is by definition self.
<code>truediv(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>truediv</i> ).
<code>truncate([before, after, axis, copy])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift([periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(tz[, axis, level, copy])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(tz[, axis, level, copy, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unique()</code>	Return unique values of Series object.
<code>unstack([level, fill_value])</code>	Unstack, a.k.a.
<code>update(other)</code>	Modify Series in place using non-NA values from passed Series.
<code>valid([inplace])</code>	(DEPRECATED) Return Series without null values.
<code>value_counts([normalize, sort, ascending, ...])</code>	Return a Series containing counts of unique values.
<code>var([axis, skipna, level, ddof, numeric_only])</code>	Return unbiased variance over requested axis.
<code>view([dtype])</code>	Create a new view of the Series.

Continued on next page

Table 27 – continued from previous page

<code>where(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is False.
<code>xs(key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

**pandas.Series.abs**`Series.abs()`

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns****abs** Series/DataFrame containing the absolute value of each element.**See also:****numpy.absolute** Calculate the absolute value element-wise.**Notes**For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .**Examples**

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
```

(continues on next page)

(continued from previous page)

```

... })
>>> df
   a    b    c
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a    b    c
1   5   20   50
0   4   10  100
2   6   30  -30
3   7   40  -50

```

### pandas.Series.add

`Series.add` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Addition of series and other, element-wise (binary operator *add*).

Equivalent to `series + other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level

#### Returns

**result** [Series]

#### See also:

`Series.radd`

#### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN

```

(continues on next page)

(continued from previous page)

```
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.add\_prefix

`Series.add_prefix` (*prefix*)

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

### Parameters

**prefix** [str] The string to add before each label.

### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

### See also:

**`Series.add_suffix`** Suffix row labels with string *suffix*.

**`DataFrame.add_suffix`** Suffix column labels with string *suffix*.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1     3
1      2     4
2      3     5
3      4     6
```

### pandas.Series.add\_suffix

`Series.add_suffix` (*suffix*)

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

#### Parameters

**suffix** [str] The string to add after each label.

#### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

**`Series.add_prefix`** Prefix row labels with string *prefix*.

**`DataFrame.add_prefix`** Prefix column labels with string *prefix*.

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0       1     3
1       2     4
2       3     5
3       4     6
```

## pandas.Series.agg

`Series.agg` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

### See also:

**Series.apply** Invoke function on a Series.

**Series.transform** Transform function producing a Series with like indexes.

### Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

## pandas.Series.aggregate

`Series.aggregate` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

### See also:

**Series.apply** Invoke function on a Series.

**Series.transform** Transform function producing a Series with like indexes.

## Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

## pandas.Series.align

`Series.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`

Align two objects on their axes with the specified join method for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{ 'outer', 'inner', 'left', 'right' }, default 'outer']

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

**copy** [boolean, default True] Always returns new objects. If `copy=False` and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series `pad` / `ffill`: propagate last valid observation forward to next valid `backfill` / `bfill`: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [{0 or 'index'}, default 0] Filling axis, method and limit

**broadcast\_axis** [{0 or 'index'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

### Returns

**(left, right)** [(Series, type of other)] Aligned objects

## pandas.Series.all

`Series.all` (*axis=0, bool\_only=None, skipna=True, level=None, \*\*kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**scalar or Series** If level is specified, then, Series is returned; otherwise, scalar is returned.

### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
```

(continues on next page)

(continued from previous page)

```
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

## DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0    True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

## pandas.Series.any

`Series.any` (*axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**scalar or Series** If level is specified, then, Series is returned; otherwise, scalar is returned.

### See also:

**numpy.any** Numpy version of this method.

**Series.any** Return whether any element is True.

**Series.all** Return whether all elements are True.

**DataFrame.any** Return whether any element is True over requested axis.

**DataFrame.all** Return whether all elements are True over requested axis.

## Examples

### Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

### DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A     True
B     True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1  False  2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1  False  0
```

```
>>> df.any(axis='columns')
0    True
1   False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame().any()
Series([], dtype: bool)
```

## pandas.Series.append

`Series.append(to_append, ignore_index=False, verify_integrity=False)`  
Concatenate two or more Series.

### Parameters

**to\_append** [Series or list/tuple of Series]

**ignore\_index** [boolean, default False] If True, do not use the index labels.

New in version 0.19.0.

**verify\_integrity** [boolean, default False] If True, raise Exception on creating index with duplicates

### Returns

**appended** [Series]

### See also:

**concat** General function to concatenate DataFrame, Series or Panel objects.

## Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

## Examples

```
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3,4,5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64
```

```
>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `ignore_index` set to `True`:

```
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `verify_integrity` set to `True`:

```
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

## pandas.Series.apply

`Series.apply(func, convert_dtype=True, args=(), **kwargs)`  
Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

### Parameters

**func** [function] Python function or NumPy ufunc to apply.

**convert\_dtype** [bool, default True] Try to find better dtype for elementwise function results.  
If False, leave as dtype=object.

**args** [tuple] Positional arguments passed to func after the series value.

**\*\*kwargs** Additional keyword arguments passed to func.

### Returns

**Series or DataFrame** If func returns a Series object the result will be a DataFrame.

### See also:

**Series.map** For element-wise operations.

**Series.agg** Only perform aggregating type operations.

**Series.transform** Only perform transforming type operations.

### Examples

Create a series with typical summer temperatures for each city.

```
>>> s = pd.Series([20, 21, 12],
...               index=['London', 'New York', 'Helsinki'])
>>> s
London      20
New York    21
Helsinki    12
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```
>>> def square(x):
...     return x ** 2
>>> s.apply(square)
London      400
New York    441
Helsinki    144
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```
>>> s.apply(lambda x: x ** 2)
London      400
New York    441
Helsinki    144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```
>>> s.apply(subtract_custom_value, args=(5,))
London      15
New York    16
Helsinki     7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London      95
New York    96
Helsinki    87
dtype: int64
```

Use a function from the Numpy library.

```
>>> s.apply(np.log)
London      2.995732
New York    3.044522
Helsinki    2.484907
dtype: float64
```

## pandas.Series.argmax

`Series.argmax` (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the maximum value.

Deprecated since version 0.21.0.

The current behaviour of ‘`Series.argmax`’ is deprecated, use ‘`idxmax`’ instead. The behavior of ‘`argmax`’ will be corrected to return the positional maximum in the future. For now, use ‘`series.values.argmax`’ or ‘`np.argmax(np.array(values))`’ to get the position of the maximum row.

If multiple values equal the maximum, the first row label with that value is returned.

### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmax`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**idxmax** [Index of maximum of values.]

### Raises

**ValueError** If the Series is empty.

See also:

**numpy.argmax** Return indices of the maximum values along the given axis.

**DataFrame.idxmax** Return index of first occurrence of maximum over requested axis.

**Series.idxmin** Return index *label* of the first occurrence of minimum of values.

## Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

## Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...               index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If `skipna` is `False` and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmax(skipna=False)
nan
```

## pandas.Series.argmax

**Series.argmax** (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the minimum value.

Deprecated since version 0.21.0.

The current behaviour of ‘Series.argmax’ is deprecated, use ‘idxmin’ instead. The behavior of ‘argmin’ will be corrected to return the positional minimum in the future. For now, use ‘series.values.argmax’ or ‘np.argmax(np.array(values))’ to get the position of the minimum row.

If multiple values equal the minimum, the first row label with that value is returned.

### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmin`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**idxmin** [Index of minimum of values.]

#### Raises

**ValueError** If the Series is empty.

#### See also:

**numpy.argmax** Return indices of the minimum values along the given axis.

**DataFrame.idxmin** Return index of first occurrence of minimum over requested axis.

**Series.idxmax** Return index *label* of the first occurrence of maximum of values.

#### Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

#### Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...                index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If `skipna` is `False` and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmin(skipna=False)
nan
```

### pandas.Series.argsort

**Series.argsort** (*axis=0, kind='quicksort', order=None*)

Overrides `ndarray.argsort`. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

#### Parameters

**axis** [int] Has no effect but is accepted for compatibility with numpy.

**kind** [{‘mergesort’, ‘quicksort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See `np.sort` for more information. ‘mergesort’ is the only stable algorithm

**order** [None] Has no effect but is accepted for compatibility with numpy.

#### Returns

**argsorted** [Series, with -1 indicated where nan values are present]

**See also:**

`numpy.ndarray.argsort`

### **pandas.Series.as\_blocks**

`Series.as_blocks` (*copy=True*)

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)**

**Parameters**

**copy** [boolean, default True]

**Returns**

**values** [a dict of dtype -> Constructor Types]

### **pandas.Series.as\_matrix**

`Series.as_matrix` (*columns=None*)

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

**Parameters**

**columns** [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

**Returns**

**values** [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

**See also:**

`DataFrame.values`

### **Notes**

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `'values'`.

## pandas.Series.asfreq

`Series.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

### Parameters

**freq** [DateOffset object, or string]

**method** [{ 'backfill'/'bfill', 'pad'/'ffill' }, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill

**how** [{ 'start', 'end' }, default end] For PeriodIndex only, see `PeriodIndex.asfreq`

**normalize** [bool, default False] Whether to reset output index to midnight

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

### Returns

**converted** [same type as caller]

### See also:

*reindex*

### Notes

To learn more about the frequency strings, please see [this link](#).

### Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.iasfreq(freq='30S')
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30   NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill value.

```
>>> df.iasfreq(freq='30S', fill_value=9.0)
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.iasfreq(freq='30S', method='bfill')
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

## pandas.Series.asof

`Series.asof` (*where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`)

New in version 0.19.0: For `DataFrame`

If there is no good value, NaN is returned for a `Series` or a `Series` of NaN values for a `DataFrame`

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default `None`] For `DataFrame`, if not `None`, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame**

- scalar : when *self* is a `Series` and *where* is a scalar

- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

**See also:**

***merge\_asof*** Perform an asof merge. Similar to left join.

**Notes**

Dates are assumed to be sorted. Raises if this is not the case.

**Examples**

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                   index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                           '2018-02-27 09:02:00',
...                                           '2018-02-27 09:03:00',
...                                           '2018-02-27 09:04:00',
...                                           '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
           a    b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

## pandas.Series.astype

`Series.astype(dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype dtype.

### Parameters

**dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

**errors** [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise`: allow exceptions to be raised
- `ignore`: suppress exceptions. On error return original object

New in version 0.20.0.

**kwargs** [keyword arguments to pass on to the constructor]

### Returns

**casted** [same type as caller]

### See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to a numeric type.

**numpy.ndarray.astype** Cast a numpy array to a specified type.

### Examples

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

## pandas.Series.at\_time

`Series.at_time` (*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or string]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

**values\_at\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

See also:

**between\_time** Select values between particular times of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_at\_time** Get just the index locations for values at particular time of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

	A
2018-04-09 00:00:00	1
2018-04-09 12:00:00	2
2018-04-10 00:00:00	3
2018-04-10 12:00:00	4

```
>>> ts.at_time('12:00')
```

	A
2018-04-09 12:00:00	2
2018-04-10 12:00:00	4

## pandas.Series.autocorr

`Series.autocorr(lag=1)`

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

### Parameters

**lag** [int, default 1] Number of lags to apply before performing autocorrelation.

### Returns

**float** The Pearson correlation between self and self.shift(lag).

### See also:

**Series.corr** Compute the correlation between two Series.

**Series.shift** Shift index by desired number of periods.

**DataFrame.corr** Compute pairwise correlation of columns.

**DataFrame.corrwith** Compute pairwise correlation between rows or columns of two DataFrame objects.

## Notes

If the Pearson correlation is not well defined return 'NaN'.

## Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr() # doctest: +ELLIPSIS
0.10355...
>>> s.autocorr(lag=2) # doctest: +ELLIPSIS
-0.99999...
```

If the Pearson correlation is not well defined, then 'NaN' is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

## pandas.Series.between

`Series.between` (*left, right, inclusive=True*)

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing *True* wherever the corresponding Series element is between the boundary values *left* and *right*. NA values are treated as *False*.

### Parameters

**left** [scalar] Left boundary.

**right** [scalar] Right boundary.

**inclusive** [bool, default True] Include boundaries.

### Returns

**Series** Each element will be a boolean.

### See also:

***Series.gt*** Greater than of series and other.

***Series.lt*** Less than of series and other.

### Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

### Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0    True
1    False
2    True
3    False
4    False
dtype: bool
```

With *inclusive* set to *False* boundary values are excluded:

```
>>> s.between(1, 4, inclusive=False)
0    True
1    False
2    False
3    False
```

(continues on next page)

(continued from previous page)

```
4    False
dtype: bool
```

*left* and *right* can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0    False
1     True
2     True
3    False
dtype: bool
```

### pandas.Series.between\_time

`Series.between_time` (*start\_time*, *end\_time*, *include\_start=True*, *include\_end=True*, *axis=None*)  
Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting *start\_time* to be later than *end\_time*, you can get the times that are *not* between the two times.

#### Parameters

- start\_time** [datetime.time or string]
- end\_time** [datetime.time or string]
- include\_start** [boolean, default True]
- include\_end** [boolean, default True]
- axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

#### Returns

- values\_between\_time** [same type as caller]

#### Raises

- TypeError** If the index is not a *DatetimeIndex*

#### See also:

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_between\_time** Get just the index locations for values between particular times of the day.

### Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

A

(continues on next page)

(continued from previous page)

```

2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

```

```

>>> ts.between_time('0:15', '0:45')
A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3

```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```

>>> ts.between_time('0:45', '0:15')
A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4

```

### pandas.Series.bfill

`Series.bfill` (*axis=None, inplace=False, limit=None, downcast=None*)  
 Synonym for `DataFrame.fillna()` with `method='bfill'`.

### pandas.Series.bool

`Series.bool()`

Return the bool of a single element `PandasObject`.

This must be a boolean scalar value, either `True` or `False`. Raise a `ValueError` if the `PandasObject` does not have exactly 1 element, or that element is not boolean

### pandas.Series.cat

`Series.cat()`

Accessor object for categorical properties of the Series values.

Be aware that assigning to `categories` is an inplace operation, while all methods return new categorical data per default (but can be called with `inplace=True`).

#### Parameters

**data** [Series or CategoricalIndex]

#### Examples

```

>>> s.cat.categories
>>> s.cat.categories = list('abc')
>>> s.cat.rename_categories(list('cab'))
>>> s.cat.reorder_categories(list('cab'))
>>> s.cat.add_categories(['d', 'e'])
>>> s.cat.remove_categories(['d'])
>>> s.cat.remove_unused_categories()

```

(continues on next page)

(continued from previous page)

```
>>> s.cat.set_categories(list('abcde'))
>>> s.cat.as_ordered()
>>> s.cat.as_unordered()
```

## pandas.Series.clip

`Series.clip` (*lower=None, upper=None, axis=None, inplace=False, \*args, \*\*kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

### Parameters

**lower** [float or array\_like, default None] Minimum threshold value. All values below this threshold will be set to it.

**upper** [float or array\_like, default None] Maximum threshold value. All values above this threshold will be set to it.

**axis** [int or string axis name, optional] Align object with lower and upper along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**Series or DataFrame** Same type as calling object with the values outside the clip boundaries replaced

## Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

### pandas.Series.clip\_lower

`Series.clip_lower` (*threshold*, *axis=None*, *inplace=False*)

Trim values below a given threshold.

Deprecated since version 0.24.0: Use `clip(lower=threshold)` instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

#### Parameters

**threshold** [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should be 2-D and the same shape as *self* for *axis=None*, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align *self* with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

#### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

## Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
1  3  4
2  5  6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

### pandas.Series.clip\_upper

`Series.clip_upper` (*threshold*, *axis=None*, *inplace=False*)

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

#### Parameters

**threshold** [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should be 2-D and the same shape as *self* for *axis=None*, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align object with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

#### Returns

**Series or DataFrame** Original data with values trimmed.

**See also:**

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

### Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
3    2
4    1
dtype: int64
```

## pandas.Series.combine

`Series.combine` (*other, func, fill\_value=None*)

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill\_value* is assumed when value is missing at some index from one of the two objects being combined.

### Parameters

**other** [Series or scalar] The value(s) to be combined with the *Series*.

**func** [function] Function that takes two scalars as inputs and returns an element.

**fill\_value** [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

### Returns

**Series** The result of combining the Series with the other object.

### See also:

***Series.combine\_first*** Combine Series values, choosing the calling Series' values first.

## Examples

Consider 2 Datasets *s1* and *s2* containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
```

(continues on next page)

(continued from previous page)

```
>>> s2
falcon    345.0
eagle     200.0
duck       30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck      NaN
eagle     200.0
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set `fill_value=0`, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck      30.0
eagle     200.0
falcon    345.0
dtype: float64
```

### pandas.Series.combine\_first

`Series.combine_first` (*other*)

Combine Series values, choosing the calling Series's values first.

#### Parameters

**other** [Series] The value(s) to be combined with the *Series*.

#### Returns

**Series** The result of combining the Series with the other object.

**See also:**

***Series.combine*** Perform elementwise operation on two Series using a given function.

#### Notes

Result index will be the union of the two indexes.

#### Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0    1.0
1    4.0
dtype: float64
```

### pandas.Series.compound

`Series.compound` (*axis=None, skipna=None, level=None*)

Return the compound percentage of the values for the requested axis.

#### Parameters

**axis** [int (0)] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**compounded** [scalar or Series (if level specified)]

### pandas.Series.compress

`Series.compress` (*condition, \*args, \*\*kwargs*)

Return selected slices of an array along given axis as a Series.

Deprecated since version 0.24.0.

#### See also:

`numpy.ndarray.compress`

### pandas.Series.convert\_objects

`Series.convert_objects` (*convert\_dates=True, convert\_numeric=False, convert\_timedeltas=True, copy=True*)

Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

#### Parameters

**convert\_dates** [boolean, default True] If True, convert to date where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**convert\_numeric** [boolean, default False] If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

**convert\_timedeltas** [boolean, default True] If True, convert to timedelta where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**copy** [boolean, default True] If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.

#### Returns

**converted** [same as input object]

#### See also:

**`to_datetime`** Convert argument to datetime.

**`to_timedelta`** Convert argument to timedelta.

**`to_numeric`** Convert argument to numeric type.

## pandas.Series.copy

`Series.copy (deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

### Parameters

**`deep`** [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

### Returns

**`copy`** [Series, DataFrame or Panel] Object type matches caller.

## Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

## Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

**Shallow copy versus default (deep) copy:**

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

## pandas.Series.corr

`Series.corr` (*other*, *method*='pearson', *min\_periods*=None)  
Compute correlation with *other* Series, excluding missing values.

### Parameters

**other** [Series]

**method** [{‘pearson’, ‘kendall’, ‘spearman’} or callable]

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarray** and returning a float .. versionadded:: 0.24.0

**min\_periods** [int, optional] Minimum number of observations needed to have a valid result

### Returns

**correlation** [float]

### Examples

```
>>> histogram_intersection = lambda a, b: np.minimum(a, b
... ).sum().round(decimals=1)
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```

## pandas.Series.count

`Series.count` (*level=None*)

Return number of non-NA/null observations in the Series.

### Parameters

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series

### Returns

**nobs** [int or Series (if level specified)]

## pandas.Series.cov

`Series.cov` (*other, min\_periods=None*)

Compute covariance with Series, excluding missing values.

### Parameters

**other** [Series]

**min\_periods** [int, optional] Minimum number of observations needed to have a valid result

### Returns

**covariance** [float]

**Normalized by N-1 (unbiased estimator).**

## pandas.Series.cummax

`Series.cummax` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs**: Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummax** [scalar or Series]

### See also:

**`core.window.Expanding.max`** Similar functionality but ignores NaN values.

**`Series.max`** Return the maximum over Series axis.

**`Series.cummax`** Return cumulative maximum over Series axis.

**`Series.cummin`** Return cumulative minimum over Series axis.

**`Series.cumsum`** Return cumulative sum over Series axis.

**`Series.cumprod`** Return cumulative product over Series axis.

## Examples

### Series

```

>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64

```

By default, NA values are ignored.

```

>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64

```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

### pandas.Series.cummin

`Series.cummin` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**cummin** [scalar or Series]

See also:

***core.window.Expanding.min*** Similar functionality but ignores NaN values.

***Series.min*** Return the minimum over Series axis.

***Series.cummax*** Return cumulative maximum over Series axis.

***Series.cummin*** Return cumulative minimum over Series axis.

***Series.cumsum*** Return cumulative sum over Series axis.

***Series.cumprod*** Return cumulative product over Series axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
      A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
      A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

### pandas.Series.cumprod

`Series.cumprod` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**cumprod** [scalar or Series]

See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**Series.prod** Return the product over Series axis.

**Series.cummax** Return cumulative maximum over Series axis.

**Series.cummin** Return cumulative minimum over Series axis.

**Series.cumsum** Return cumulative sum over Series axis.

**Series.cumprod** Return cumulative product over Series axis.

### Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A  B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.Series.cumsum

`Series.cumsum` (*axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs**: Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumsum** [scalar or Series]

### See also:

***core.window.Expanding.sum*** Similar functionality but ignores NaN values.

***Series.sum*** Return the sum over Series axis.

***Series.cummax*** Return cumulative maximum over Series axis.

***Series.cummin*** Return cumulative minimum over Series axis.

***Series.cumsum*** Return cumulative sum over Series axis.

***Series.cumprod*** Return cumulative product over Series axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

### pandas.Series.describe

`Series.describe` (*percentiles=None, include=None, exclude=None*)

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

#### Parameters

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.

- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default) : The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

### Returns

**Series or DataFrame** Summary statistics of the Series or Dataframe provided.

See also:

**DataFrame.count** Count number of non-NA/null observations.

**DataFrame.max** Maximum of the values in the object.

**DataFrame.min** Minimum of the values in the object.

**DataFrame.mean** Mean of the values.

**DataFrame.std** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

### Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

## Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count                3
unique                2
top      2010-01-01 00:00:00
freq                2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
           numeric
count         3.0
mean          2.0
std           1.0
min           1.0
25%           1.5
50%           2.0
75%           2.5
max           3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top             f        NaN      c
freq            1        NaN      1
mean            NaN        2.0    NaN
std             NaN        1.0    NaN
min             NaN        1.0    NaN
25%            NaN        1.5    NaN
50%            NaN        2.0    NaN
75%            NaN        2.5    NaN
max             NaN        3.0    NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%       1.5
50%       2.0
75%       2.5
max        3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%       1.5
50%       2.0
75%       2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique      3
top        c
freq       1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count           3
unique          3
```

(continues on next page)

(continued from previous page)

top	f
freq	1

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
           categorical  object
count              3      3
unique             3      3
top               f      c
freq              1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
           categorical  numeric
count              3      3.0
unique             3      NaN
top               f      NaN
freq              1      NaN
mean              NaN      2.0
std               NaN      1.0
min               NaN      1.0
25%               NaN      1.5
50%               NaN      2.0
75%               NaN      2.5
max               NaN      3.0
```

## pandas.Series.diff

`Series.diff` (*periods=1*)

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

### Parameters

**periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.

### Returns

**diffed** [Series]

**See also:**

***Series.pct\_change*** Percent change over given number of periods.

***Series.shift*** Shift index by desired number of periods with an optional time freq.

***DataFrame.diff*** First discrete difference of object.

## Examples

Difference with previous row

```
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0    NaN
1    0.0
2    1.0
3    1.0
4    2.0
5    3.0
dtype: float64
```

Difference with 3rd previous row

```
>>> s.diff( periods=3)
0    NaN
1    NaN
2    NaN
3    2.0
4    4.0
5    6.0
dtype: float64
```

Difference with following row

```
>>> s.diff( periods=-1)
0    0.0
1   -1.0
2   -1.0
3   -2.0
4   -3.0
5    NaN
dtype: float64
```

## pandas.Series.div

`Series.div` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

`Series.rtruediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.divide

`Series.divide` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rtruediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0

```

(continues on next page)

(continued from previous page)

```

b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.divmod

`Series.divmod` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Integer division and modulo of series and other, element-wise (binary operator *divmod*).

Equivalent to `series divmod other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.rdivmod`

#### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64

```

(continues on next page)

(continued from previous page)

```

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.dot

`Series.dot` (*other*)

Compute the dot product between the Series and the columns of *other*.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using *self @ other* in Python  $\geq 3.5$ .

### Parameters

**other** [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

### Returns

**scalar, Series or numpy.ndarray** Return the dot product of the Series and *other* if *other* is a Series, the Series of the dot product of Series and each rows of *other* if *other* is a DataFrame or a `numpy.ndarray` between the Series and each columns of the `numpy` array.

### See also:

**DataFrame.dot** Compute the matrix product with the DataFrame.

**Series.mul** Multiplication of series and other, element-wise.

### Notes

The Series and *other* has to share the same index if *other* is a Series or a DataFrame.

### Examples

```

>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other

```

(continues on next page)

(continued from previous page)

```

8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])

```

## pandas.Series.drop

`Series.drop` (*labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise'*)

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

### Parameters

**labels** [single label or list-like] Index labels to drop.

**axis** [0, default 0] Redundant for application on Series.

**index, columns** [None] Redundant for application on Series, but index can be used instead of labels.

New in version 0.21.0.

**level** [int or level name, optional] For MultiIndex, level for which the labels will be removed.

**inplace** [bool, default False] If True, do operation inplace and return None.

**errors** [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

### Returns

**dropped** [pandas.Series]

### Raises

**KeyError** If none of the labels are found in the index.

**See also:**

**`Series.reindex`** Return only specified index labels of Series.

**`Series.dropna`** Return series without null values.

**`Series.drop_duplicates`** Return Series with duplicate values removed.

**`DataFrame.drop`** Drop specified labels from rows or columns.

## Examples

```
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A    0
B    1
C    2
dtype: int64
```

#### Drop labels B en C

```
>>> s.drop(labels=['B', 'C'])
A    0
dtype: int64
```

#### Drop 2nd level label in MultiIndex Series

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                      codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                             [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...               index=midx)
>>> s
lama    speed    45.0
        weight   200.0
        length    1.2
cow     speed    30.0
        weight   250.0
        length    1.5
falcon  speed   320.0
        weight    1.0
        length    0.3
dtype: float64
```

```
>>> s.drop(labels='weight', level=1)
lama    speed    45.0
        length    1.2
cow     speed    30.0
        length    1.5
falcon  speed   320.0
        length    0.3
dtype: float64
```

### pandas.Series.drop\_duplicates

`Series.drop_duplicates` (*keep='first', inplace=False*)

Return Series with duplicate values removed.

#### Parameters

**keep** [{'first', 'last', False}, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

**inplace** [boolean, default False] If True, performs operation inplace and returns None.

**Returns****deduplicated** [Series]**See also:****Index.drop\_duplicates** Equivalent method on Index.**DataFrame.drop\_duplicates** Equivalent method on DataFrame.**Series.duplicated** Related method on Series, indicating duplicate Series values.**Examples**

Generate an Series with duplicated entries.

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...               name='animal')
>>> s
0    lama
1     cow
2    lama
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```
>>> s.drop_duplicates()
0    lama
1     cow
3  beetle
5   hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```
>>> s.drop_duplicates(keep='last')
1     cow
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

The value `False` for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to `True` performs the operation inplace and returns `None`.

```
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1     cow
3  beetle
5   hippo
Name: animal, dtype: object
```

**pandas.Series.droplevel**

`Series.droplevel` (*level*, *axis=0*)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

**Parameters**

**level** [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

**axis** [{0 or 'index', 1 or 'columns'}, default 0]

**Returns**

**DataFrame.droplevel()**

**Examples**

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

**pandas.Series.dropna**

`Series.dropna` (*axis=0, inplace=False, \*\*kwargs*)

Return a new Series with missing values removed.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

**Parameters**

**axis** [{0 or 'index'}, default 0] There is only one axis to drop values from.

**inplace** [bool, default False] If True, do operation inplace and return None.

**\*\*kwargs** Not in use.

**Returns**

**Series** Series with NA entries dropped from it.

**See also:**

**`Series.isna`** Indicate missing values.

**`Series.notna`** Indicate existing (non-missing) values.

**`Series.fillna`** Replace missing values.

**`DataFrame.dropna`** Drop rows or columns which contain NA values.

**`Index.dropna`** Drop missing indices.

**Examples**

```
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0    1.0
1    2.0
2     NaN
dtype: float64
```

Drop NA values from a Series.

```
>>> ser.dropna()
0    1.0
1    2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```
>>> ser.dropna(inplace=True)
>>> ser
0    1.0
1    2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0     NaN
```

(continues on next page)

(continued from previous page)

```

1      2
2      NaT
3
4      None
5      I stay
dtype: object
>>> ser.dropna()
1      2
3
5      I stay
dtype: object

```

## pandas.Series.dt

`Series.dt()`

Accessor object for datetimelike properties of the Series values.

### Examples

```

>>> s.dt.hour
>>> s.dt.second
>>> s.dt.quarter

```

Returns a Series indexed like the original Series. Raises `TypeError` if the Series does not contain datetimelike values.

## pandas.Series.duplicated

`Series.duplicated(keep='first')`

Indicate duplicate Series values.

Duplicated values are indicated as `True` values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

### Parameters

**keep** [{ 'first', 'last', False }, default 'first']

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

### Returns

`pandas.core.series.Series`

See also:

***Index.duplicated*** Equivalent method on `pandas.Index`.

***DataFrame.duplicated*** Equivalent method on `pandas.DataFrame`.

***Series.drop\_duplicates*** Remove duplicate values from Series.

## Examples

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True:

```
>>> animals.duplicated(keep=False)
0     True
1    False
2     True
3    False
4     True
dtype: bool
```

## pandas.Series.eq

`Series.eq` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Equal to of series and other, element-wise (binary operator *eq*).

Equivalent to `series == other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

Series.None

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

**pandas.Series.equals**

Series.equals (*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

**Parameters**

**other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

**Returns**

**bool** True if all elements are the same in both objects, False otherwise.

**See also:**

**Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**assert\_series\_equal** Return True if left and right Series are equal, False otherwise.

**assert\_frame\_equal** Return True if left and right DataFrames are equal, False otherwise.

**numpy.array\_equal** Return True if two arrays have the same shape and elements, False otherwise.

## Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

## Examples

```
>>> df = pd.DataFrame({'1': [10], '2': [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({'1': [10], '2': [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({'1.0': [10], '2.0': [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({'1': [10.0], '2': [20.0]})
>>> different_data_type
   1  2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

## pandas.Series.ewm

`Series.ewm` (*com=None, span=None, halflife=None, alpha=None, min\_periods=0, adjust=True, ignore\_na=False, axis=0*)

Provides exponential weighted functions.

New in version 0.18.0.

### Parameters

**com** [float, optional] Specify decay in terms of center of mass,  $\alpha = 1/(1 + com)$ , for  $com \geq 0$

**span** [float, optional] Specify decay in terms of span,  $\alpha = 2/(span + 1)$ , for  $span \geq 1$

**halflife** [float, optional] Specify decay in terms of half-life,  $\alpha = 1 - \exp(\log(0.5)/halflife)$ , for  $halflife > 0$

**alpha** [float, optional] Specify smoothing factor  $\alpha$  directly,  $0 < \alpha \leq 1$

New in version 0.18.0.

**min\_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

**adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average)

**ignore\_na** [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior

### Returns

a Window sub-classed for the particular operation

See also:

**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

### Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When `adjust` is True (default), weighted averages are calculated using weights  $(1-\alpha)^{(n-1)}$ ,  $(1-\alpha)^{(n-2)}$ , ...,  $1-\alpha$ , 1.

**When `adjust` is False, weighted averages are calculated recursively as:** `weighted_average[0] = arg[0]`; `weighted_average[i] = (1-alpha)*weighted_average[i-1] + alpha*arg[i]`.

When `ignore_na` is False (default), weights are based on absolute positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are  $(1-\alpha)^2$  and 1 (if `adjust` is True), and  $(1-\alpha)^2$  and  $\alpha$  (if `adjust` is False).

When `ignore_na` is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are  $1-\alpha$  and 1 (if `adjust` is True), and  $1-\alpha$  and  $\alpha$  (if `adjust` is False).

More details can be found at <http://pandas.pydata.org/pandas-docs/stable/computation.html#exponentially-weighted-windows>

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
      B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

## pandas.Series.expanding

`Series.expanding` (*min\_periods=1, center=False, axis=0*)

Provides expanding transformations.

New in version 0.18.0.

### Parameters

**min\_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

**center** [bool, default False] Set the labels at the center of the window.

**axis** [int or str, default 0]

### Returns

**a Window sub-classed for the particular operation**

**See also:**

***rolling*** Provides rolling window calculations.

***ewm*** Provides exponential weighted functions.

## Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
```

(continues on next page)

(continued from previous page)

```
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

## pandas.Series.factorize

`Series.factorize` (*sort=False, na\_sentinel=-1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

### Parameters

**sort** [boolean, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

**na\_sentinel** [int, default -1] Value to mark “not found”.

### Returns

**labels** [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.

**uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

---

### See also:

**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

## Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
```

(continues on next page)

(continued from previous page)

```
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### pandas.Series.ffill

`Series.ffi11` (*axis=None, inplace=False, limit=None, downcast=None*)  
Synonym for `DataFrame.fillna()` with `method='ffill'`.

### pandas.Series.fillna

`Series.fillna` (*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, \*\*kwargs*)  
Fill NA/NaN values using the specified method.

**Parameters**

**value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**axis** [{0 or 'index'}]

**inplace** [boolean, default False] If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

**filled** [Series]

**See also:**

***interpolate*** Fill NaN values using interpolation.

*reindex, asfreq*

**Examples**

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0  NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0 NaN  1
2  NaN  1.0 NaN  5
3  NaN  3.0 NaN  4
```

## pandas.Series.filter

`Series.filter` (*items=None, like=None, regex=None, axis=None*)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

### Parameters

**items** [list-like] List of axis to restrict to (must not all be present).

**like** [string] Keep axis where “arg in col == True”.

**regex** [string (regular expression)] Keep axis with `re.search(regex, col) == True`.

**axis** [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

### Returns

same type as input object

### See also:

`DataFrame.loc`

### Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

## Examples

```
>>> df = pd.DataFrame(np.array([[1,2,3], [4,5,6]]),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one two three
rabbit  4  5   6
```

## pandas.Series.first

`Series.first` (*offset*)

Convenience method for subsetting initial periods of time series data based on a date offset.

### Parameters

**offset** [string, DateOffset, dateutil.relativedelta]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

**See also:**

***last*** Select final periods of time series based on a date offset.

***at\_time*** Select values at a particular time of the day.

***between\_time*** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
      A
2018-04-09  1
2018-04-11  2
```

(continues on next page)

(continued from previous page)

```
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
      A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

### pandas.Series.first\_valid\_index

`Series.first_valid_index()`  
Return index for first non-NA/null value.

#### Returns

**scalar** [type of index]

#### Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

### pandas.Series.floordiv

`Series.floordiv(other, level=None, fill_value=None, axis=0)`  
Integer division of series and other, element-wise (binary operator *floordiv*).

Equivalent to `series // other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.rfloordiv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.from\_array

**classmethod** `Series.from_array` (*arr*, *index=None*, *name=None*, *dtype=None*, *copy=False*, *fastpath=False*)

Construct Series from array.

Deprecated since version 0.23.0: Use `pd.Series(..)` constructor instead.

### pandas.Series.from\_csv

**classmethod** `Series.from_csv` (*path*, *sep=''*, *parse\_dates=True*, *header=None*, *index\_col=0*, *encoding=None*, *infer\_datetime\_format=False*)

Read CSV file.

Deprecated since version 0.21.0: Use `pandas.read_csv()` instead.

It is preferable to use the more powerful `pandas.read_csv()` for most general purposes, but `from_csv` makes for an easy roundtrip to and from a file (the exact counterpart of `to_csv`), especially with a time Series.

This method only differs from `pandas.read_csv()` in some defaults:

- *index\_col* is 0 instead of None (take first column as index by default)
- *header* is None instead of 0 (the first row is not used as the column names)
- *parse\_dates* is True instead of False (try parsing the index as datetime by default)

With `pandas.read_csv()`, the option `squeeze=True` can be used to return a Series like `from_csv`.

#### Parameters

**path** [string file path or file handle / StringIO]

**sep** [string, default ‘,'] Field delimiter

**parse\_dates** [boolean, default True] Parse dates. Different default from `read_table`

**header** [int, default None] Row to use as header (skip prior rows)

**index\_col** [int or sequence, default 0] Column to use for index. If a sequence is given, a `MultiIndex` is used. Different default from `read_table`

**encoding** [string, optional] a string representing the encoding to use if the contents are non-ascii, for python versions prior to 3

**infer\_datetime\_format** [boolean, default False] If True and `parse_dates` is True for a column, try to infer the datetime format based on the first datetime string. If the format can be inferred, there often will be a large parsing speed-up.

**Returns**

**y** [Series]

**See also:**

`read_csv`

**pandas.Series.ge**

`Series.ge` (*other, level=None, fill\_value=None, axis=0*)

Greater than or equal to of series and other, element-wise (binary operator *ge*).

Equivalent to `series >= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

`Series.None`

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d     NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.get

`Series.get(key, default=None)`

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

### Parameters

**key** [object]

### Returns

**value** [same type as items contained in object]

## pandas.Series.get\_dtype\_counts

`Series.get_dtype_counts()`

Return counts of unique dtypes in this object.

### Returns

**dtype** [Series] Series with the count of columns with each dtype.

### See also:

**dtypes** Return the dtypes in this object.

## Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

### pandas.Series.get\_ftype\_counts

`Series.get_ftype_counts()`

Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

#### Returns

**dtype** [Series] Series with the count of columns with each type and sparsity (dense/sparse)

#### See also:

**ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.

### Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

### pandas.Series.get\_value

`Series.get_value(label, takeable=False)`

Quickly retrieve single value at passed index label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

#### Parameters

**label** [object]

**takeable** [interpret the index as indexers, default False]

#### Returns

**value** [scalar value]

## pandas.Series.get\_values

`Series.get_values()`

Same as `values` (but handles sparseness conversions); is a view.

## pandas.Series.groupby

`Series.groupby` (*by=None, axis=0, level=None, as\_index=True, sort=True, group\_keys=True, squeeze=False, observed=False, \*\*kwargs*)

Group DataFrame or Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

### Parameters

**by** [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted a (single) key.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

**level** [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

**as\_index** [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

**sort** [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

**group\_keys** [bool, default True] When calling `apply`, add group keys to index to identify pieces.

**squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

**\*\*kwargs** Optional, only accepts keyword argument 'mutated' and is passed to groupby.

### Returns

**DataFrameGroupBy or SeriesGroupBy** Depends on the calling object and returns groupby object that contains information about the groups.

### See also:

**resample** Convenience method for frequency conversion and resampling of time series.

## Notes

See the [user guide](#) for more.

## Examples

```

>>> df = pd.DataFrame({'Animal' : ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                   'Max Speed' : [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon    380.0
1  Falcon    370.0
2  Parrot     24.0
3  Parrot     26.0
>>> df.groupby(['Animal']).mean()
      Max Speed
Animal
Falcon    375.0
Parrot     25.0

```

## Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```

>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Capitve', 'Wild', 'Capitve', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed' : [390., 350., 30., 20.]},
...                   index=index)
>>> df
      Max Speed
Animal Type
Falcon Capitve    390.0
       Wild      350.0
Parrot Capitve     30.0
       Wild      20.0
>>> df.groupby(level=0).mean()
      Max Speed
Animal
Falcon    370.0
Parrot     25.0
>>> df.groupby(level=1).mean()
      Max Speed
Type
Capitve    210.0
Wild      185.0

```

## pandas.Series.gt

Series **.gt** (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Greater than of series and other, element-wise (binary operator *gt*).

Equivalent to `series > other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

**Parameters****other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level**Returns****result** [Series]**See also:**

Series.None

**Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

**pandas.Series.head**Series.head(*n*=5)Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

**Parameters****n** [int, default 5] Number of rows to select.**Returns****obj\_head** [same type as caller] The first *n* rows of the caller object.

See also:

`DataFrame.tail` Returns the last  $n$  rows.

### Examples

```
>>> df = pd.DataFrame({'animal':['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1     bee
2   falcon
3     lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the first 5 lines

```
>>> df.head()
   animal
0  alligator
1     bee
2   falcon
3     lion
4  monkey
```

Viewing the first  $n$  lines (three in this case)

```
>>> df.head(3)
   animal
0  alligator
1     bee
2   falcon
```

### pandas.Series.hist

`Series.hist` (*by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, \*\*kwargs*)

Draw histogram of the input series using matplotlib.

#### Parameters

**by** [object, optional] If passed, then used to form histograms for separate groups

**ax** [matplotlib axis object] If not passed, uses `gca()`

**grid** [boolean, default True] Whether to show axis grid lines

**xlabelsize** [int, default None] If specified changes the x-axis label size

**xrot** [float, default None] rotation of x axis labels

**ylabelsize** [int, default None] If specified changes the y-axis label size

**yrot** [float, default None] rotation of y axis labels

**figsize** [tuple, default None] figure size in inches by default

**bins** [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**bins** [integer, default 10] Number of histogram bins to be used

**\*\*kwargs** [keywords] To be passed to the actual plotting function

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

### pandas.Series.idxmax

`Series.idxmax` (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

#### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmax`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**idxmax** [Index of maximum of values.]

#### Raises

**ValueError** If the Series is empty.

See also:

`numpy.argmax` Return indices of the maximum values along the given axis.

`DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.

`Series.idxmin` Return index *label* of the first occurrence of minimum of values.

#### Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

#### Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...               index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmax(skipna=False)
nan
```

### pandas.Series.idxmin

`Series.idxmin` (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

#### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmin`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**idxmin** [Index of minimum of values.]

#### Raises

**ValueError** If the Series is empty.

#### See also:

`numpy.argmax` Return indices of the minimum values along the given axis.

`DataFrame.idxmin` Return index of first occurrence of minimum over requested axis.

`Series.idxmax` Return index *label* of the first occurrence of maximum of values.

#### Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

## Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...                 index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmin(skipna=False)
nan
```

## pandas.Series.infer\_objects

`Series.infer_objects()`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

### Returns

**converted** [same type as input object]

**See also:**

***to\_datetime*** Convert argument to datetime.

***to\_timedelta*** Convert argument to timedelta.

***to\_numeric*** Convert argument to numeric type.

## Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A      int64
dtype: object
```

## pandas.Series.interpolate

`Series.interpolate` (*method='linear', axis=0, limit=None, inplace=False, limit\_direction='forward', limit\_area=None, downcast=None, \*\*kwargs*)  
Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

### Parameters

**method** [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interpId`. Both 'polynomial' and 'spline' require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=4)`. These use the numerical values of the index.
- 'krogh', 'piecewise\_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from\_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise\_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from\_derivatives' which replaces 'piecewise\_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{'forward', 'backward', 'both'}, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.21.0.

**downcast** [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

### Returns

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values

### See also:

**fillna** Fill missing values using different methods.

**scipy.interpolate.Akima1DInterpolator** Piecewise cubic polynomials (Akima interpolator).

**scipy.interpolate.BPoly.from\_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interpld** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

### Notes

The 'krogh', 'piecewise\_polynomial', 'spline', 'pchip' and 'akima' methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

### Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
1    single_one
```

(continues on next page)

(continued from previous page)

```

2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0,  np.nan, -1.0,  1.0),
...                   (np.nan,  2.0,  np.nan,  np.nan),
...                   (2.0,  3.0,  np.nan,  9.0),
...                   (np.nan,  4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0  NaN -1.0  1.0
1  NaN  2.0  NaN  NaN
2  2.0  3.0  NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0  NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

## pandas.Series.isin

Series.**isin** (*values*)

Check whether *values* are contained in Series.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.

### Parameters

**values** [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

New in version 0.18.1: Support for values as a set.

### Returns

**isin** [Series (bool dtype)]

### Raises

#### TypeError

- If *values* is a string

**See also:**

**DataFrame.isin** Equivalent method on DataFrame.

## Examples

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
...               'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0    True
1    True
2    True
3    False
4    True
5    False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```
>>> s.isin(['lama'])
0    True
1    False
2    True
3    False
4    True
```

(continues on next page)

(continued from previous page)

```
5    False
Name: animal, dtype: bool
```

## pandas.Series.isna

`Series.isna()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

### See also:

**`Series.isnull`** Alias of `isna`.

**`Series.notna`** Boolean inverse of `isna`.

**`Series.dropna`** Omit axes labels with missing values.

**`isna`** Top-level `isna`.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25         Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
```

(continues on next page)

(continued from previous page)

```
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

## pandas.Series.isnull

`Series.isnull()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

***Series.isnull*** Alias of `isna`.

***Series.notna*** Boolean inverse of `isna`.

***Series.dropna*** Omit axes labels with missing values.

***isna*** Top-level `isna`.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

### pandas.Series.item

Series.**item**()

Return the first element of the underlying data as a python scalar.

### pandas.Series.items

Series.**items**()

Lazily iterate over (index, value) tuples.

### pandas.Series.iteritems

Series.**iteritems**()

Lazily iterate over (index, value) tuples.

### pandas.Series.keys

Series.**keys**()

Alias for index.

### pandas.Series.kurt

Series.**kurt** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

#### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**kurt** [scalar or Series (if level specified)]

**pandas.Series.kurtosis**

`Series.kurtosis` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**kurt** [scalar or Series (if level specified)]

**pandas.Series.last**

`Series.last` (*offset*)

Convenience method for subsetting final periods of time series data based on a date offset.

**Parameters**

**offset** [string, DateOffset, dateutil.relativedelta]

**Returns**

**subset** [same type as caller]

**Raises**

**TypeError** If the index is not a *DatetimeIndex*

**See also:**

**first** Select initial periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
           A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

## pandas.Series.last\_valid\_index

`Series.last_valid_index()`  
Return index for last non-NA/null value.

### Returns

**scalar** [type of index]

### Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

## pandas.Series.le

`Series.le(other, level=None, fill_value=None, axis=0)`  
Less than or equal to of series and other, element-wise (binary operator *le*).

Equivalent to `series <= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

Series.None

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

**pandas.Series.lt**

Series.lt (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Less than of series and other, element-wise (binary operator *lt*).

Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

Series.None

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.mad

`Series.mad` (*axis=None, skipna=None, level=None*)

Return the mean absolute deviation of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**mad** [scalar or Series (if level specified)]

## pandas.Series.map

`Series.map` (*arg, na\_action=None*)

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a dict or a *Series*.

### Parameters

**arg** [function, dict, or Series] Mapping correspondence.

**na\_action** [{None, 'ignore'}, default None] If 'ignore', propagate NaN values, without passing them to the mapping correspondence.

**Returns**

**Series** Same index as caller.

**See also:**

**Series.apply** For applying more complex functions on a Series.

**DataFrame.apply** Apply a function row-/column-wise.

**DataFrame.applymap** Apply a function elementwise on a whole DataFrame.

**Notes**

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a dict subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

**Examples**

```
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0      cat
1      dog
2      NaN
3  rabbit
dtype: object
```

`map` accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. `defaultdict`):

```
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0  kitten
1  puppy
2      NaN
3      NaN
dtype: object
```

It also accepts a function:

```
>>> s.map('I am a {}'.format)
0      I am a cat
1      I am a dog
2      I am a nan
3  I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```
>>> s.map('I am a {}'.format, na_action='ignore')
0      I am a cat
1      I am a dog
2                NaN
3      I am a rabbit
dtype: object
```

## pandas.Series.mask

`Series.mask` (*cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try\_cast=False*, *raise\_on\_error=None*)  
 Replace values where the condition is True.

### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

### See also:

**DataFrame.where()** Return an object of same shape as self.

## Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True

## pandas.Series.max

`Series.max` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**max** [scalar or Series (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

### Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

## pandas.Series.mean

Series.**mean** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the mean of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**mean** [scalar or Series (if level specified)]

## pandas.Series.median

`Series.median` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the median of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**median** [scalar or Series (if level specified)]

## pandas.Series.memory\_usage

`Series.memory_usage` (*index=True, deep=False*)

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of *object* dtype.

### Parameters

**index** [bool, default True] Specifies whether to include the memory usage of the Series index.

**deep** [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned value.

### Returns

**int** Bytes of memory consumed.

### See also:

`numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.

`DataFrame.memory_usage` Bytes consumed by a DataFrame.

## Examples

```
>>> s = pd.Series(range(3))
>>> s.memory_usage()
104
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```
>>> s.memory_usage(index=False)
24
```

The memory footprint of *object* values is ignored by default:

```
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
96
>>> s.memory_usage(deep=True)
212
```

## pandas.Series.min

`Series.min` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**min** [scalar or Series (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

## pandas.Series.mod

`Series.mod` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Modulo of series and other, element-wise (binary operator *mod*).

Equivalent to `series % other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

See also:

*Series.rmod*

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.mode

`Series.mode` (*dropna=True*)

Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

### Parameters

**dropna** [boolean, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

### Returns

**modes** [Series (sorted)]

## pandas.Series.mul

`Series.mul` (*other, level=None, fill\_value=None, axis=0*)

Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rmul`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.multiply

`Series.multiply` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

`Series.rmul`

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

**pandas.Series.ne**

`Series.ne` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Not equal to of series and other, element-wise (binary operator *ne*).

Equivalent to `series != other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

`Series.None`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.nlargest

`Series.nlargest` ( $n=5$ ,  $keep='first'$ )

Return the largest  $n$  elements.

### Parameters

**n** [int, default 5] Return this many descending sorted values.

**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of  $n$  elements:

- **first**: take the first occurrences based on the index order
- **last**: take the last occurrences based on the index order
- **all** [keep all occurrences. This can result in a Series of] size larger than  $n$ .

### Returns

**Series** The  $n$  largest values in the Series, sorted in decreasing order.

**See also:**

**`Series.nsmallest`** Get the  $n$  smallest elements.

**`Series.sort_values`** Sort Series by values.

**`Series.head`** Return the first  $n$  rows.

### Notes

Faster than `.sort_values(ascending=False).head(n)` for small  $n$  relative to the size of the Series object.

## Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives        434000
Brunei          434000
Iceland         337000
Nauru            11300
Tuvalu          11300
Anguilla        11300
Monserat         5200
dtype: int64
```

The  $n$  largest elements where  $n=5$  by default.

```
>>> s.nlargest()
France         65000000
Italy          59000000
Malta           434000
Maldives        434000
Brunei          434000
dtype: int64
```

The  $n$  largest elements where  $n=3$ . Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France         65000000
Italy          59000000
Malta           434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France         65000000
Italy          59000000
Brunei          434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France         65000000
Italy          59000000
Malta           434000
Maldives        434000
Brunei          434000
dtype: int64
```

## pandas.Series.nonzero

`Series.nonzero()`

Return the *integer* indices of the elements that are non-zero.

Deprecated since version 0.24.0: Please use `.to_numpy().nonzero()` as a replacement.

This method is equivalent to calling `numpy.nonzero` on the series data. For compatibility with NumPy, the return value is the same (a tuple with an array of indices for each dimension), but it will always be a one-item tuple because series only have one dimension.

### See also:

`numpy.nonzero`

### Examples

```
>>> s = pd.Series([0, 3, 0, 4])
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
1    3
3    4
dtype: int64
```

```
>>> s = pd.Series([0, 3, 0, 4], index=['a', 'b', 'c', 'd'])
# same return although index of s is different
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
b    3
d    4
dtype: int64
```

## pandas.Series.notna

`Series.notna()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

### See also:

**Series.notnull** Alias of `notna`.

**Series.isna** Boolean inverse of `notna`.

**Series.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT Alfred     None
1  6.0 1939-05-27 Batman  Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2     NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

## pandas.Series.notnull

`Series.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

**`Series.notnull`** Alias of `notna`.

**`Series.isna`** Boolean inverse of `notna`.

**Series.dropna** Omit axes labels with missing values.

**notna** Top-level notna.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born   name   toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25         Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

## pandas.Series.nsmallest

Series.**nsmallest** ( $n=5$ , *keep='first'*)

Return the smallest  $n$  elements.

### Parameters

**n** [int, default 5] Return this many ascending sorted values.

**keep** [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of  $n$  elements:

- **first** : take the first occurrences based on the index order
- **last** : take the last occurrences based on the index order
- **all** [keep all occurrences. This can result in a Series of] size larger than  $n$ .

## Returns

**Series** The  $n$  smallest values in the Series, sorted in increasing order.

## See also:

**Series.nlargest** Get the  $n$  largest elements.

**Series.sort\_values** Sort Series by values.

**Series.head** Return the first  $n$  rows.

## Notes

Faster than `.sort_values().head(n)` for small  $n$  relative to the size of the Series object.

## Examples

```

>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru            11300
Tuvalu           11300
Anguilla         11300
Monserat         5200
dtype: int64

```

The  $n$  largest elements where  $n=5$  by default.

```

>>> s.nsmallest()
Monserat         5200
Nauru            11300
Tuvalu           11300
Anguilla         11300
Iceland          337000
dtype: int64

```

The  $n$  smallest elements where  $n=3$ . Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```

>>> s.nsmallest(3)
Monserat         5200
Nauru            11300
Tuvalu           11300
dtype: int64

```

The  $n$  smallest elements where  $n=3$  and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Monserat      5200
Anguilla      11300
Tuvalu        11300
dtype: int64
```

The  $n$  smallest elements where  $n=3$  with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Monserat      5200
Nauru         11300
Tuvalu        11300
Anguilla      11300
dtype: int64
```

### pandas.Series.nunique

`Series.nunique` (*dropna=True*)

Return number of unique elements in the object.

Excludes NA values by default.

#### Parameters

**dropna** [boolean, default True] Don't include NaN in the count.

#### Returns

**nunique** [int]

### pandas.Series.pct\_change

`Series.pct_change` (*periods=1, fill\_method='pad', limit=None, freq=None, \*\*kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

#### Parameters

**periods** [int, default 1] Periods to shift for forming percent change.

**fill\_method** [str, default 'pad'] How to handle NAs before computing percent changes.

**limit** [int, default None] The number of consecutive NAs to fill before stopping.

**freq** [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or BDay()).

**\*\*kwargs** Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

#### Returns

**chg** [Series or DataFrame] The same type as the calling object.

**See also:**

**`Series.diff`** Compute the difference of two elements in a Series.

**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

## Examples

### Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0      NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change( periods=2)
0      NaN
1      NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

	FR	GR	IT
--	----	----	----

(continues on next page)

(continued from previous page)

1980-01-01	4.0405	1.7246	804.74
1980-02-01	4.0963	1.7482	810.01
1980-03-01	4.3149	1.8519	860.13

```
>>> df.pct_change()
              FR          GR          IT
1980-01-01      NaN          NaN          NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
              2016          2015          2014
GOOG  1769950    1500923    1371819
APPL  30586265   40912316   41403351
```

```
>>> df.pct_change(axis='columns')
              2016          2015          2014
GOOG      NaN -0.151997 -0.086016
APPL      NaN  0.337604  0.012002
```

## pandas.Series.pipe

`Series.pipe` (*func*, \*args, \*\*kwargs)  
Apply func(self, \*args, \*\*kwargs).

### Parameters

**func** [function] function to apply to the NDFrame. *args*, and *kwargs* are passed into *func*. Alternatively a (callable, *data\_keyword*) tuple where *data\_keyword* is a string indicating the keyword of callable that expects the NDFrame.

**args** [iterable, optional] positional arguments passed into *func*.

**kwargs** [mapping, optional] a dictionary of keyword arguments passed into *func*.

### Returns

**object** [the return type of *func*.]

### See also:

*DataFrame.apply*, *DataFrame.applymap*, *Series.map*

### Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

## pandas.Series.plot

`Series.plot` (*kind='line', ax=None, figsize=None, use\_index=True, title=None, grid=None, legend=False, style=None, logx=False, logy=False, loglog=False, xticks=None, yticks=None, xlim=None, ylim=None, rot=None, fontsize=None, colormap=None, table=False, yerr=None, xerr=None, label=None, secondary\_y=False, \*\*kws*)

Make plots of Series using matplotlib / pylab.

*New in version 0.17.0:* Each plot kind has a corresponding method on the `Series.plot` accessor: `s.plot(kind='line')` is equivalent to `s.plot.line()`.

### Parameters

**data** [Series]

**kind** [str]

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot

**ax** [matplotlib axes object] If not passed, uses `gca()`

**figsize** [a tuple (width, height) in inches]

**use\_index** [boolean, default True] Use index as ticks for x axis

**title** [string or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

**grid** [boolean, default None (matlab style default)] Axis grid lines

**legend** [False/True/'reverse'] Place legend on axis subplots

**style** [list or dict] matplotlib line style per column

**logx** [boolean, default False] Use log scaling on x axis

**logy** [boolean, default False] Use log scaling on y axis

**loglog** [boolean, default False] Use log scaling on both x and y axes

**xticks** [sequence] Values to use for the xticks

**yticks** [sequence] Values to use for the yticks

**xlim** [2-tuple/list]

**ylim** [2-tuple/list]

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots)

**fontsize** [int, default None] Font size for xticks and yticks

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [boolean, optional] If True, plot colorbar (only relevant for 'scatter' and 'hexbin' plots)

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**table** [boolean, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib's default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [same types as yerr.]

**label** [label argument to provide to plot]

**secondary\_y** [boolean or sequence of ints, default False] If True then y-axis will be on the right

**mark\_right** [boolean, default True] When using a secondary\_y axis, automatically mark the column labels with "(right)" in the legend

**\*\*\*kwds** [keywords] Options to pass to matplotlib plotting method

**Returns**

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

**Notes**

- See matplotlib documentation online for more on this subject
- If *kind* = 'bar' or 'barh', you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.Series.pop**`Series.pop` (*item*)Return item and drop from frame. Raise `KeyError` if not found.**Parameters****item** [str] Column label to be popped**Returns****popped** [Series]**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon  bird    389.0
1  parrot  bird     24.0
2   lion  mammal    80.5
3  monkey  mammal     NaN
```

```
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
   name  max_speed
0  falcon    389.0
1  parrot    24.0
2   lion    80.5
3  monkey     NaN
```

**pandas.Series.pow**`Series.pow` (*other*, *level=None*, *fill\_value=None*, *axis=0*)Exponential power of series and other, element-wise (binary operator *pow*).Equivalent to `series ** other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rpow`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

### pandas.Series.prod

`Series.prod`(*axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

#### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**prod** [scalar or Series (if level specified)]

**Examples**

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Series.product**

`Series.product` (*axis=None, skipna=None, level=None, numeric\_only=None, min\_count=0, \*\*kwargs*)

Return the product of the values for the requested axis.

**Parameters**

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**prod** [scalar or Series (if level specified)]

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.Series.ptp

`Series.ptp` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

**Returns the difference between the maximum value and the** minimum value in the object. This is the equivalent of the `numpy.ndarray` method `ptp`.

Deprecated since version 0.24.0: Use `numpy.ptp` instead

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**ptp** [scalar or Series (if level specified)]

## pandas.Series.put

`Series.put` (*\*args, \*\*kwargs*)

Applies the `put` method to its `values` attribute if it has one.

**See also:**

`numpy.ndarray.put`

## pandas.Series.quantile

`Series.quantile` ( $q=0.5$ ,  $interpolation='linear'$ )

Return value at the given quantile.

### Parameters

**q** [float or array-like, default 0.5 (50% quantile)]  $0 \leq q \leq 1$ , the quantile(s) to compute

**interpolation** [{ 'linear', 'lower', 'higher', 'midpoint', 'nearest' }] New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points  $i$  and  $j$ :

- linear:  $i + (j - i) * fraction$ , where  $fraction$  is the fractional part of the index surrounded by  $i$  and  $j$ .
- lower:  $i$ .
- higher:  $j$ .
- nearest:  $i$  or  $j$  whichever is nearest.
- midpoint:  $(i + j) / 2$ .

### Returns

**quantile** [float or Series] if  $q$  is an array, a Series will be returned where the index is  $q$  and the values are the quantiles.

### See also:

`core.window.Rolling.quantile`, `numpy.percentile`

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25    1.75
0.50    2.50
0.75    3.25
dtype: float64
```

## pandas.Series.radd

`Series.radd` ( $other$ ,  $level=None$ ,  $fill\_value=None$ ,  $axis=0$ )

Addition of series and other, element-wise (binary operator `radd`).

Equivalent to `other + series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.add`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rank

`Series.rank` (*axis=0, method='average', numeric\_only=None, na\_option='keep', ascending=True, pct=False*)

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] index to direct ranking

**method** [{ 'average', 'min', 'max', 'first', 'dense' }]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups

**numeric\_only** [boolean, default None] Include only float, int, boolean data. Valid only for DataFrame or Panel objects

**na\_option** [{'keep', 'top', 'bottom'}]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

**ascending** [boolean, default True] False for ranks by high (1) to low (N)

**pct** [boolean, default False] Computes percentage rank of data

#### Returns

**ranks** [same type as caller]

### pandas.Series.ravel

`Series.ravel` (*order='C'*)

Return the flattened underlying data as an ndarray.

#### See also:

`numpy.ndarray.ravel`

### pandas.Series.rdiv

`Series.rdiv` (*other, level=None, fill\_value=None, axis=0*)

Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.truediv`

### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.rdivmod

`Series.rdivmod` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Integer division and modulo of series and other, element-wise (binary operator *rdivmod*).

Equivalent to `other.divmod` series, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.divmod`

#### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0

```

(continues on next page)

(continued from previous page)

```

d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.reindex

`Series.reindex` (*index=None, \*\*kwargs*)

Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

### Parameters

**index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest' }] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

**limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series with changed index.**

### See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

DataFrame.reindex supports two calling conventions

- (index=index\_labels, columns=column\_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200,200,404,404,301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df
```

	http_status	response_time
Firefox	200	0.04
Chrome	200	0.02
Safari	404	0.07
IE10	404	0.08
Konqueror	301	1.00

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)
```

	http_status	response_time
Safari	404.0	0.07
Iceweasel	NaN	NaN
Comodo Dragon	NaN	NaN
IE10	404.0	0.08
Chrome	200.0	0.02

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
      http_status  response_time
Safari           404             0.07
Iceweasel         0             0.00
Comodo Dragon     0             0.00
IE10              404             0.08
Chrome            200             0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
      http_status  response_time
Safari           404             0.07
Iceweasel        missing         missing
Comodo Dragon    missing         missing
IE10              404             0.08
Chrome            200             0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
      http_status  user_agent
Firefox          200         NaN
Chrome           200         NaN
Safari           404         NaN
IE10              404         NaN
Konqueror        301         NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
      http_status  user_agent
Firefox          200         NaN
Chrome           200         NaN
Safari           404         NaN
IE10              404         NaN
Konqueror        301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
      prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
      prices
2009-12-29    NaN
```

(continues on next page)

(continued from previous page)

2009-12-30	NaN
2009-12-31	NaN
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
           prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

### pandas.Series.reindex\_axis

`Series.reindex_axis` (*labels, axis=0, \*\*kwargs*)

Conform Series to new index with optional filling logic.

Deprecated since version 0.21.0: Use `Series.reindex` instead.

### pandas.Series.reindex\_like

`Series.reindex_like` (*other, method=None, copy=True, limit=None, tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

#### Parameters

**other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series or DataFrame** Same type as caller, but with changed indices on each axis.

### See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

### Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

### Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                    [31, 87.8, 'high'],
...                    [22, 71.6, 'medium'],
...                    [35, 95, 'medium']],
...                    columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                    index=pd.date_range(start='2014-02-12',
...                                       end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12      24.3             75.7      high
2014-02-13      31.0             87.8      high
2014-02-14      22.0             71.6    medium
2014-02-15      35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                    [30, 'low'],
...                    [35.1, 'medium']],
...                   columns=['temp_celsius', 'windspeed'],
...                   index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                           '2014-02-15']))
```

```
>>> df2
      temp_celsius windspeed
2014-02-12      28.0      low
2014-02-13      30.0      low
2014-02-15      35.1  medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit windspeed
2014-02-12      28.0              NaN      low
2014-02-13      30.0              NaN      low
2014-02-14         NaN              NaN      NaN
2014-02-15      35.1              NaN  medium
```

## pandas.Series.rename

`Series.rename` (*index=None, \*\*kwargs*)

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

Alternatively, change `Series.name` with a scalar value.

See the *user guide* for more.

### Parameters

**index** [scalar, hashable sequence, dict-like or function, optional] dict-like or functions are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.

**copy** [bool, default True] Also copy underlying data

**inplace** [bool, default False] Whether to return a new Series. If True then value of copy is ignored.

**level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

### Returns

**renamed** [Series (new object)]

**See also:**

`Series.rename_axis`

## Examples

```

>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0    1
1    2
4    3
dtype: int64
>>> s.rename({1: 3, 2: 5}) # mapping, changes labels
0    1
3    2
5    3
dtype: int64

```

## pandas.Series.rename\_axis

`Series.rename_axis` (*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

### Parameters

**mapper** [scalar, list-like, optional] Value to set the axis name attribute.

**index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

### Returns

**Series, DataFrame, or None** The same type as the caller or None if *inplace* is True.

### See also:

**Series.rename** Alter Series index labels or name.

**DataFrame.rename** Alter DataFrame index labels or name.

**Index.rename** Set new names on index.

## Notes

Prior to version 0.21.0, `rename_axis` could also be used to change the axis *labels* by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use `rename` instead.

`DataFrame.rename_axis` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

## Examples

### Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2    monkey
dtype: object
```

### DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
```

(continues on next page)

(continued from previous page)

dog	4	0
cat	4	0
monkey	2	2

**MultiIndex**

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']),
...                                       names=['type', 'name'])
>>> df
```

limbs		num_legs	num_arms
type	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

```
>>> df.rename_axis(index={'type': 'class'})
```

limbs		num_legs	num_arms
class	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

```
>>> df.rename_axis(columns=str.upper)
```

LIMBS		num_legs	num_arms
type	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

**pandas.Series.reorder\_levels****Series.reorder\_levels** (*order*)

Rearrange index levels using input order.

May not drop or duplicate levels.

**Parameters****order** [list of int representing new level order] (reference level by number or key)**Returns****type of caller (new object)****pandas.Series.repeat****Series.repeat** (*repeats, axis=None*)

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

**Parameters**

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

**axis** [None] Must be `None`. Has no effect but is accepted for compatibility with numpy.

### Returns

**repeated\_series** [Series] Newly created Series with repeated elements.

### See also:

**Index.repeat** Equivalent function for Index.

**numpy.repeat** Similar method for `numpy.ndarray`.

### Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
0    a
1    b
1    b
2    c
2    c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
1    b
1    b
2    c
2    c
2    c
dtype: object
```

### pandas.Series.replace

`Series.replace` (*to\_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)

Replace values given in *to\_replace* with *value*.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

#### Parameters

**to\_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to\_replace* will be replaced with *value*
  - str: string exactly matching *to\_replace* will be replaced with *value*

- regex: regexs matching *to\_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to\_replace* and *value* are both lists, they **must** be the same length.
  - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:
  - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default None] Value to replace any values matching *to\_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

**limit** [int, default None] Maximum size gap to forward or backward fill.

**regex** [bool or same types as *to\_replace*, default False] Whether to interpret *to\_replace* and/or *value* as regular expressions. If this is True then *to\_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to\_replace* must be *None*.

**method** [{'pad', 'ffill', 'bfill', None}] The method to use when for replacement, when *to\_replace* is a scalar, list or tuple and *value* is *None*.

Changed in version 0.23.0: Added to DataFrame.

## Returns

**Series** Object after replacement.

**Raises****AssertionError**

- If *regex* is not a `bool` and *to\_replace* is not `None`.

**TypeError**

- If *to\_replace* is a `dict` and *value* is not a `list`, `dict`, `ndarray`, or `Series`
- If *to\_replace* is `None` and *regex* is not compilable into a regular expression or is a `list`, `dict`, `ndarray`, or `Series`.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to\_replace* does not match the type of the value being replaced

**ValueError**

- If a `list` or an `ndarray` is passed to *to\_replace* and *value* but they are not the same length.

**See also:**

***Series.fillna*** Fill NA values.

***Series.where*** Replace values based on boolean condition.

***Series.str.replace*** Simple string replacement.

**Notes**

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When `dict` is used as the *to\_replace* value, it is like `key(s)` in the `dict` are the *to\_replace* part and `value(s)` in the `dict` are the *value* parameter.

**Examples****Scalar ‘to\_replace’ and ‘value’**

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

**List-like 'to\_replace'**

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

**dict-like 'to\_replace'**

```
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2    2  7  c
3    3  8  d
4    4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1    1    6  b
2    2    7  c
3    3    8  d
4    4    9  e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e
```

**Regular expression ‘to\_replace’**

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={'r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple bool or datetime64 objects, the data types in the *to\_replace* parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the *to\_replace* parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the *to\_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0      10
1     None
2     None
3        b
4     None
dtype: object
```

When *value=None* and *to\_replace* is a scalar, list or tuple, *replace* uses the *method* parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0      10
1      10
2      10
3        b
4        b
dtype: object
```

## pandas.Series.resample

`Series.resample` (*rule*, *how=None*, *axis=0*, *fill\_method=None*, *closed=None*, *label=None*, *convention='start'*, *kind=None*, *loffset=None*, *limit=None*, *base=0*, *on=None*, *level=None*)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

### Parameters

**rule** [str] The offset string or object representing target conversion.

**how** [str] Method for down/re-sampling, default to 'mean' for downsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

**fill\_method** [str, default None] Filling method for upsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`

**closed** [{‘right’, ‘left’}, default None] Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**label** [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

**kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a *DateTimeIndex* or ‘period’ to convert it to a *PeriodIndex*. By default the input representation is retained.

**loffset** [timedelta, default None] Adjust the resampled time labels.

**limit** [int, default None] Maximum size gap when reindexing with *fill\_method*.

Deprecated since version 0.18.0.

**base** [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

**on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

**level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

New in version 0.19.0.

## Returns

### Resampler object

See also:

***groupby*** Group by mapping, function, label, or list of labels.

***Series.resample*** Resample a Series.

***DataFrame.resample*** Resample a DataFrame.

## Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

## Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
```

(continues on next page)

(continued from previous page)

```

2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64

```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```

>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```

>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```

>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64

```

Upsample the series into 30 second bins.

```

>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64

```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```

>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1

```

(continues on next page)

(continued from previous page)

```
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                           freq='Q',
...                                           periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
```

(continues on next page)

(continued from previous page)

```

2018Q4      4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03      1.0
2018-04      NaN
2018-05      NaN
2018-06      2.0
2018-07      NaN
2018-08      NaN
2018-09      3.0
2018-10      NaN
2018-11      NaN
2018-12      4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10     50  2018-01-07
1     11     60  2018-01-14
2      9     40  2018-01-21
3     13    100  2018-01-28
4     14     50  2018-02-04
5     18    100  2018-02-11
6     17     40  2018-02-18
7     19     50  2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                       ['morning',
...                                                       'afternoon']])
>>> df2
           price  volume
2000-01-01 morning     10     50
           afternoon    11     60
2000-01-02 morning      9     40

```

(continues on next page)

(continued from previous page)

```

                afternoon    13    100
2000-01-03 morning         14     50
                afternoon    18    100
2000-01-04 morning         17     40
                afternoon    19     50
>>> df2.resample('D', level=0).sum()
                price  volume
2000-01-01         21    110
2000-01-02         22    140
2000-01-03         32    150
2000-01-04         36     90

```

### pandas.Series.reset\_index

`Series.reset_index` (*level=None, drop=False, name=None, inplace=False*)

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

#### Parameters

**level** [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

**drop** [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

**name** [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when `drop` is True.

**inplace** [bool, default False] Modify the Series in place (do not create a new object).

#### Returns

**Series or DataFrame** When `drop` is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When `drop` is True, a Series is returned. In either case, if `inplace=True`, no value is returned.

#### See also:

**DataFrame.reset\_index** Analogous function for DataFrame.

#### Examples

```

>>> s = pd.Series([1, 2, 3, 4], name='foo',
...               index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))

```

Generate a DataFrame with default index.

```

>>> s.reset_index()
   idx  foo
0    a    1
1    b    2

```

(continues on next page)

(continued from previous page)

```
2  c  3
3  d  4
```

To specify the name of the new column use *name*.

```
>>> s.reset_index(name='values')
   idx  values
0    a      1
1    b      2
2    c      3
3    d      4
```

To generate a new Series with the default set *drop* to True.

```
>>> s.reset_index(drop=True)
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set *inplace* to True. Note that it also requires *drop=True*.

```
>>> s.reset_index(inplace=True, drop=True)
>>> s
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

The *level* parameter is interesting for Series with a multi-level index.

```
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...           np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
...     range(4), name='foo',
...     index=pd.MultiIndex.from_arrays(arrays,
...                                     names=['a', 'b']))
```

To remove a specific level from the Index, use *level*.

```
>>> s2.reset_index(level='a')
   a  foo
b
one bar  0
two bar  1
one baz  2
two baz  3
```

If *level* is not set, all levels are removed from the Index.

```
>>> s2.reset_index()
   a  b  foo
0  bar one  0
```

(continues on next page)

(continued from previous page)

1	bar	two	1
2	baz	one	2
3	baz	two	3

**pandas.Series.rfloordiv**

`Series.rfloordiv` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Integer division of series and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

**Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

`Series.floordiv`

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rmod

`Series.rmod` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Modulo of series and other, element-wise (binary operator *rmod*).

Equivalent to `other % series`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.mod`

### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.rmul

`Series.rmul` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Multiplication of series and other, element-wise (binary operator *rmul*).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.mul`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rolling

`Series.rolling` (*window*, *min\_periods=None*, *center=False*, *win\_type=None*, *on=None*, *axis=0*, *closed=None*)

Provides rolling window calculations.

New in version 0.18.0.

### Parameters

**window** [int, or offset] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

**min\_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min\_periods* will default to 1. Otherwise, *min\_periods* will default to the size of the window.

**center** [bool, default False] Set the labels at the center of the window.

**win\_type** [str, default None] Provide a window type. If *None*, all points are evenly weighted. See the notes below for further information.

**on** [str, optional] For a DataFrame, column on which to calculate the rolling window, rather than the index

**axis** [int or str, default 0]

**closed** [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

### Returns

a **Window or Rolling** sub-classed for the particular operation

### See also:

**expanding** Provides expanding transformations.

**ewm** Provides exponential weighted functions.

### Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized `win_types` are:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)

- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

### Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  1.0
2  2.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                    index = [pd.Timestamp('20130101 09:00:00'),
...                              pd.Timestamp('20130101 09:00:02'),
...                              pd.Timestamp('20130101 09:00:03'),
...                              pd.Timestamp('20130101 09:00:05'),
...                              pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

## pandas.Series.round

`Series.round` (*decimals=0, \*args, \*\*kwargs*)

Round each value in a Series to the given number of decimals.

### Parameters

**decimals** [int] Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.

### Returns

Series object

### See also:

`numpy.around`, `DataFrame.round`

## pandas.Series.rpow

`Series.rpow` (*other, level=None, fill\_value=None, axis=0*)

Exponential power of series and other, element-wise (binary operator *rpow*).

Equivalent to `other ** series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

*Series.pow*

**Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

**pandas.Series.rsub**

`Series.rsub` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Subtraction of series and other, element-wise (binary operator *rsub*).

Equivalent to `other - series`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

**Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

**Returns**

**result** [Series]

**See also:**

*Series.sub*

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.rtruediv

`Series.rtruediv` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.truediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0

```

(continues on next page)

(continued from previous page)

```

b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.sample

`Series.sample` (*n=None*, *frac=None*, *replace=False*, *weights=None*, *random\_state=None*, *axis=None*)

Return a random sample of items from an axis of object.

You can use *random\_state* for reproducibility.

#### Parameters

**n** [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

**frac** [float, optional] Fraction of axis items to return. Cannot be used with *n*.

**replace** [bool, default False] Sample with or without replacement.

**weights** [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

**random\_state** [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

**axis** [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

#### Returns

**Series or DataFrame** A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

## Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

	num_legs	num_wings	num_specimen_seen
falcon	2	2	10
dog	4	0	2
spider	8	0	1
fish	0	0	8

Extract 3 random elements from the Series `df['num_legs']`: Note that we use `random_state` to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
```

Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon     2         2                 10
fish       0         0                 8
```

## pandas.Series.searchsorted

`Series.searchsorted` (*value*, *side='left'*, *sorter=None*)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

**Returns**

**int or array of int** A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

**See also:**

`numpy.searchsorted`

**Notes**

Binary search is used to find the required insertion points.

**Examples**

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                       'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

**pandas.Series.select**

`Series.select` (*crit*, *axis=0*)

Return data corresponding to axis labels matching criteria.

Deprecated since version 0.21.0: Use `df.loc[df.index.map(crit)]` to select via labels

### Parameters

**crit** [function] To be called on each index (label). Should return True or False

**axis** [int]

### Returns

**selection** [same type as caller]

## pandas.Series.sem

`Series.sem` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

### Parameters

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

### Returns

**sem** [scalar or Series (if level specified)]

## pandas.Series.set\_axis

`Series.set_axis` (*labels, axis=0, inplace=None*)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

### Parameters

**labels** [list-like, Index] The values for the new index.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

**inplace** [boolean, default None] Whether to return a new `%(klass)s` instance.

**Warning:** `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

**Returns**

**renamed** [% (klass)s or None] An object of same type as caller if inplace=False, None otherwise.

**See also:**

**DataFrame.rename\_axis** Alter the name of the index or columns.

**Examples****Series**

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

**DataFrame**

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
  A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
  I  II
0  1  4
1  2  5
2  3  6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

## pandas.Series.set\_value

`Series.set_value` (*label, value, takeable=False*)

Quickly set single value at passed label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

If label is not contained, a new object is created with the label placed at the end of the result index.

### Parameters

**label** [object] Partial indexing with MultiIndex not allowed

**value** [object] Scalar value

**takeable** [interpret the index as indexers, default False]

### Returns

**series** [Series] If label is contained, will be reference to calling Series, otherwise a new object

## pandas.Series.shift

`Series.shift` (*periods=1, freq=None, axis=0, fill\_value=None*)

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the *freq*.

### Parameters

**periods** [int] Number of periods to shift. Can be positive or negative.

**freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

### Returns

**Series** Copy of input object, shifted.

**See also:****Index.shift** Shift values of Index.**DatetimeIndex.shift** Shift values of DatetimeIndex.**PeriodIndex.shift** Shift values of PeriodIndex.**tshift** Shift the time index, using the index's frequency if available.**Examples**

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                    'Col2': [13, 23, 18, 33, 48],
...                    'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0   NaN   NaN   NaN
1   NaN   NaN   NaN
2   NaN   NaN   NaN
3  10.0  13.0  17.0
4  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   NaN  10.0  13.0
1   NaN  20.0  23.0
2   NaN  15.0  18.0
3   NaN  30.0  33.0
4   NaN  45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

**pandas.Series.skew****Series.skew** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased skew over requested axis Normalized by N-1.

**Parameters****axis** [{index (0)}] Axis for the function to be applied on.**skipna** [bool, default True] Exclude NA/null values when computing the result.**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**skew** [scalar or Series (if level specified)]

**pandas.Series.slice\_shift**

`Series.slice_shift` (*periods=1, axis=0*)

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

**periods** [int] Number of periods to move, can be positive or negative

**Returns**

**shifted** [same type as caller]

**Notes**

While the *slice\_shift* is faster than *shift*, you may pay for it later during alignment.

**pandas.Series.sort\_index**

`Series.sort_index` (*axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na\_position='last', sort\_remaining=True*)

Sort Series by index labels.

Returns a new Series sorted by label if *inplace* argument is `False`, otherwise updates the original series and returns `None`.

**Parameters**

**axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.

**level** [int, optional] If not `None`, sort on values in specified index level(s).

**ascending** [bool, default `true`] Sort ascending vs. descending.

**inplace** [bool, default `False`] If `True`, perform operation in-place.

**kind** [{`'quicksort'`, `'mergesort'`, `'heapsort'`}, default `'quicksort'`] Choice of sorting algorithm. See also `numpy.sort()` for more information. `'mergesort'` is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{`'first'`, `'last'`}, default `'last'`] If `'first'` puts NaNs at the beginning, `'last'` puts NaNs at the end. Not implemented for MultiIndex.

**sort\_remaining** [bool, default `True`] If `true` and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

**Returns**

**pandas.Series** The original Series sorted by the labels

**See also:**

**DataFrame.sort\_index** Sort DataFrame by the index.

**DataFrame.sort\_values** Sort DataFrame by the value.

**Series.sort\_values** Sort Series by the value.

## Examples

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

### Sort Descending

```
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

### Sort Inplace

```
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
dtype: object
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN    d
1.0    c
2.0    b
3.0    a
dtype: object
```

### Specify index level to sort

```
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                    'baz', 'baz', 'bar', 'bar']),
...          np.array(['two', 'one', 'two', 'one',
...                    'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar one    8
baz one    6
foo one    4
qux one    2
```

(continues on next page)

(continued from previous page)

```
bar two 7
baz two 5
foo two 3
qux two 1
dtype: int64
```

Does not sort by remaining levels when sorting by levels

```
>>> s.sort_index(level=1, sort_remaining=False)
qux one 2
foo one 4
baz one 6
bar one 8
qux two 1
foo two 3
baz two 5
bar two 7
dtype: int64
```

### pandas.Series.sort\_values

`Series.sort_values` (*axis=0*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na\_position='last'*)

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

#### Parameters

**axis** [{0 or 'index'}, default 0] Axis to direct sorting. The value 'index' is accepted for compatibility with `DataFrame.sort_values`.

**ascending** [bool, default True] If True, sort values in ascending order, otherwise descending.

**inplace** [bool, default False] If True, perform operation in-place.

**kind** [{'quicksort', 'mergesort' or 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. 'mergesort' is the only stable algorithm.

**na\_position** [{'first' or 'last'}, default 'last'] Argument 'first' puts NaNs at the beginning, 'last' puts NaNs at the end.

#### Returns

**Series** Series ordered by values.

See also:

**Series.sort\_index** Sort by the Series indices.

**DataFrame.sort\_values** Sort DataFrame by the values along either axis.

**DataFrame.sort\_index** Sort DataFrame by indices.

## Examples

```
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0      NaN
1      1.0
2      3.0
3     10.0
4      5.0
dtype: float64
```

### Sort values ascending order (default behaviour)

```
>>> s.sort_values(ascending=True)
1      1.0
2      3.0
4      5.0
3     10.0
0      NaN
dtype: float64
```

### Sort values descending order

```
>>> s.sort_values(ascending=False)
3     10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

### Sort values inplace

```
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3     10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

### Sort values putting NAs first

```
>>> s.sort_values(na_position='first')
0      NaN
1      1.0
2      3.0
4      5.0
3     10.0
dtype: float64
```

### Sort a series of strings

```
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0      z
```

(continues on next page)

(continued from previous page)

```

1    b
2    d
3    a
4    c
dtype: object

```

```

>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object

```

## pandas.Series.squeeze

`Series.squeeze` (*axis=None*)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

New in version 0.20.0.

### Returns

**DataFrame, Series, or scalar** The projection after squeezing *axis* or all the axes.

**See also:**

***Series.iloc*** Integer-location based indexing for selecting scalars.

***DataFrame.iloc*** Integer-location based indexing for selecting Series.

***Series.to\_frame*** Inverse of `DataFrame.squeeze` for a single-column DataFrame.

## Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```

>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64

```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

### pandas.Series.std

`Series.std` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**std** [scalar or Series (if level specified)]

### pandas.Series.str

`Series.str()`

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

#### Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

### pandas.Series.sub

`Series.sub` (*other, level=None, fill\_value=None, axis=0*)

Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rsub`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.subtract

`Series.subtract` (*other, level=None, fill\_value=None, axis=0*)

Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rsub`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.sum

`Series.sum` (*axis=None, skipna=None, level=None, numeric\_only=None, min\_count=0, \*\*kwargs*)

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**sum** [scalar or Series (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

### Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm      6
cold      8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

## pandas.Series.swapaxes

Series.**swapaxes** (*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

### Returns

**y** [same as input]

## pandas.Series.swaplevel

Series.**swaplevel** (*i=-2*, *j=-1*, *copy=True*)

Swap levels *i* and *j* in a MultiIndex.

### Parameters

**i, j** [int, string (can be mixed)] Level of index to be swapped. Can pass level name as string.

### Returns

**swapped** [Series]

.. **versionchanged:: 0.18.1** The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.

## pandas.Series.tail

Series.**tail** (*n=5*)

Return the last *n* rows.

This function returns last  $n$  rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

#### Parameters

**n** [int, default 5] Number of rows to select.

#### Returns

**type of caller** The last  $n$  rows of the caller object.

#### See also:

**DataFrame.head** The first  $n$  rows of the caller object.

### Examples

```
>>> df = pd.DataFrame({'animal':['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3      lion
4   monkey
5   parrot
6    shark
7   whale
8    zebra
```

#### Viewing the last 5 lines

```
>>> df.tail()
   animal
4   monkey
5   parrot
6    shark
7   whale
8    zebra
```

#### Viewing the last $n$ lines (three in this case)

```
>>> df.tail(3)
   animal
6    shark
7   whale
8    zebra
```

### pandas.Series.take

`Series.take` (*indices*, *axis=0*, *convert=None*, *is\_copy=True*, *\*\*kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

**indices** [array-like] An array of ints indicating which positions to take.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

**convert** [bool, default True] Whether to convert negative indices into positive ones. For example, `-1` would map to the `len(axis) - 1`. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

**is\_copy** [bool, default True] Whether to return a copy of the original object or not.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

**Returns**

**taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by labels.

**DataFrame.iloc** Select a subset of a DataFrame by positions.

**numpy.take** Take elements from an array along an axis.

**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird    389.0
2  parrot   bird     24.0
3   lion  mammal     80.5
1  monkey  mammal      NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon   bird    389.0
1  monkey  mammal      NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
```

(continues on next page)

(continued from previous page)

2	bird	24.0
3	mammal	80.5
1	mammal	NaN

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
      name  class  max_speed
1  monkey  mammal         NaN
3    lion  mammal         80.5
```

### pandas.Series.to\_clipboard

`Series.to_clipboard` (*excel=True, sep=None, \*\*kwargs*)

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

#### Parameters

**excel** [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

**sep** [str, default '\t'] Field delimiter.

**\*\*kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

**DataFrame.to\_csv** Write a DataFrame to a comma-separated values (csv) file.

**read\_clipboard** Read text from clipboard and pass to `read_table`.

#### Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `gtk` or `PyQt4` modules)
- Windows : none
- OS X : none

#### Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
```

(continues on next page)

(continued from previous page)

```
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

## pandas.Series.to\_csv

`Series.to_csv(*args, **kwargs)`

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

### Parameters

**path\_or\_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string.

Changed in version 0.24.0: Was previously named “path” for Series.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na\_rep** [str, default ‘’] Missing data representation.

**float\_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index\_label=False* for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.

**compression** [str, default ‘infer’] Compression mode among the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If ‘infer’ and *path\_or\_buf* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression).

Changed in version 0.24.0: ‘infer’ option added and set to default.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE\_MINIMAL. If you have set a *float\_format* then floats are converted to strings and thus csv.QUOTE\_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default `''`] String of length 1. Character used to quote fields.

**line\_terminator** [string, optional] The newline character or character sequence to use in the output file. Defaults to `os.linesep`, which depends on the OS in which this method is called (`'n'` for linux, `'rn'` for Windows, i.e.).

Changed in version 0.24.0.

**chunksize** [int or None] Rows to write at a time.

**tupleize\_cols** [bool, default False] Write MultiIndex columns as a list of tuples (if True) or in the new, expanded format, where each MultiIndex column is a row in the CSV (if False).

Deprecated since version 0.21.0: This argument will be removed and will always write each row of the multi-index as a separate row in the CSV file.

**date\_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of *quotechar* inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

**decimal** [str, default `'.'`] Character recognized as decimal separator. E.g. use `','` for European data.

### Returns

**None or str** If `path_or_buf` is None, returns the resulting csv format as a string. Otherwise returns None.

### See also:

**`read_csv`** Load a CSV file into a DataFrame.

**`to_excel`** Load an Excel file into a DataFrame.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

### `pandas.Series.to_dense`

`Series.to_dense()`

Return dense representation of NDFrame (as opposed to sparse).

### `pandas.Series.to_dict`

`Series.to_dict(into=<class 'dict'>)`

Convert Series to {label -> value} dict or dict-like object.

#### Parameters

**into** [class, default dict] The collections.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

### Returns

**value\_dict** [collections.Mapping]

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<type 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

### pandas.Series.to\_excel

`Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep="", float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)`

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet\_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

### Parameters

**excel\_writer** [str or ExcelWriter object] File path or existing ExcelWriter.

**sheet\_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

**na\_rep** [str, default ''] Missing data representation.

**float\_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

**columns** [sequence or list of str, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

- startrow** [int, default 0] Upper left cell row to dump data frame.
- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge\_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf\_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze\_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
- New in version 0.20.0..

**See also:**

- `to_csv`** Write DataFrame to a comma-separated values (csv) file.
- `ExcelWriter`** Class for writing DataFrame objects into excel sheets.
- `read_excel`** Read an Excel file into a pandas DataFrame.
- `read_csv`** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

## pandas.Series.to\_frame

`Series.to_frame` (*name=None*)  
Convert Series to DataFrame.

### Parameters

**name** [object, default None] The passed name should substitute for the series name (if it has one).

### Returns

**data\_frame** [DataFrame]

## pandas.Series.to\_hdf

`Series.to_hdf` (*path\_or\_buf, key, \*\*kwargs*)  
Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

### Parameters

**path\_or\_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**format** [{ 'fixed', 'table' }, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.

- `'table'`: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

**append** [bool, default False] For Table formats, append the input data to the existing.

**data\_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via Data Columns*. Applicable only to `format='table'`.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{`'zlib'`, `'lzo'`, `'bzip2'`, `'blosc'`}, default `'zlib'`] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: `'blosc:blosclz'`): {`'blosc:blosclz'`, `'blosc:lz4'`, `'blosc:lz4hc'`, `'blosc:snappy'`, `'blosc:zlib'`, `'blosc:zstd'`}. Specifying a compression library which is not available issues a `ValueError`.

**fletcher32** [bool, default False] If applying compression use the fletcher32 checksum.

**dropna** [bool, default False] If true, ALL nan rows will not be written to store.

**errors** [str, default `'strict'`] Specifies how encoding and decoding errors are to be handled. See the `errors` argument for `open()` for a full list of options.

See also:

**DataFrame.read\_hdf** Read from HDF file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_feather** Write out feather-format for DataFrames.

**DataFrame.to\_csv** Write out to a csv file.

## Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
```

(continues on next page)

(continued from previous page)

```
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

## pandas.Series.to\_json

`Series.to_json` (*path\_or\_buf=None, orient=None, date\_format=None, double\_precision=10, force\_ascii=True, date\_unit='ms', default\_handler=None, lines=False, compression='infer', index=True*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

### Parameters

**path\_or\_buf** [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

**orient** [string] Indication of expected JSON string format.

- Series
  - default is 'index'
  - allowed values are: {'split', 'records', 'index', 'table'}
- DataFrame
  - default is 'columns'
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}
- The format of the JSON string
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ... , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array
  - 'table' : dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like `orient='records'`.

Changed in version 0.20.0.

**date\_format** [[None, 'epoch', 'iso']] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

**double\_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force\_ascii** [bool, default True] Force encoded string to be ASCII.

**date\_unit** [string, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

**default\_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

New in version 0.19.0.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is 'split' or 'table'.

New in version 0.23.0.

#### See also:

`read_json`

#### Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                   index=[ 'row 1', 'row 2'],
...                   columns=[ 'col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[[{"a", "b"}, {"c", "d"}]'
```

#### Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
            "primaryKey": "index",
            "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
            {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

### pandas.Series.to\_latex

`Series.to_latex` (*buf=None*, *columns=None*, *col\_space=None*, *header=True*, *index=True*, *na\_rep='NaN'*, *formatters=None*, *float\_format=None*, *sparsify=None*, *index\_names=True*, *bold\_rows=False*, *column\_format=None*, *longtable=None*, *escape=None*, *encoding=None*, *decimal='.'*, *multicolumn=None*, *multicolumn\_format=None*, *multirow=None*)

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

#### Parameters

- buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.
- columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- col\_space** [int, optional] The minimum width of each column.
- header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- na\_rep** [str, default 'NaN'] Missing data representation.
- formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- float\_format** [str, optional] Format string for floating point numbers.
- sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.
- index\_names** [bool, default True] Prints the names of the indexes.
- bold\_rows** [bool, default False] Make the row labels bold in the output.
- column\_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

**longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'ascii' on Python 2 and 'utf-8' on Python 3.

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe. .. versionadded:: 0.18.0

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module. .. versionadded:: 0.20.0

**multicolumn\_format** [str, default 'l'] The alignment for multicolumns, similar to *column\_format*. The default will be read from the config module. .. versionadded:: 0.20.0

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module. .. versionadded:: 0.20.0

### Returns

**str or None** If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

### See also:

**DataFrame.to\_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to\_html** Render a DataFrame as an HTML table.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\begin{tabular}{lll}\n\toprule\n      name & mask & weapon
\\\\\n\midrule\n  Raphael & red & sai \\\\\n Donatello &
purple & bo staff \\\\\n\bottomrule\n\end{tabular}\n'
```

### pandas.Series.to\_list

**Series.to\_list()**

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

### See also:

`numpy.ndarray.tolist`

### pandas.Series.to\_msgpack

`Series.to_msgpack` (*path\_or\_buf=None, encoding='utf-8', \*\*kwargs*)  
Serialize object to input file path using msgpack format.

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

#### Parameters

- path** [string File path, buffer-like, or None] if None, return generated string
- append** [bool whether to append to an existing msgpack] (default is False)
- compress** [type of compressor (zlib or blosc), default to None (no) compression]

### pandas.Series.to\_numpy

`Series.to_numpy` (*dtype=None, copy=False*)  
A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

#### Parameters

- dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`
- copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

#### Returns

`numpy.ndarray`

See also:

**`Series.array`** Get the actual data stored within.

**`Index.array`** Get the actual data stored within.

**`DataFrame.to_numpy`** Similar method for DataFrame.

### Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an `ExtensionArray`, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

## Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
... # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

## pandas.Series.to\_period

`Series.to_period` (*freq=None, copy=True*)

Convert Series from `DatetimeIndex` to `PeriodIndex` with desired frequency (inferred from index if not passed).

### Parameters

**freq** [string, default]

### Returns

**ts** [Series with `PeriodIndex`]

## pandas.Series.to\_pickle

`Series.to_pickle` (*path, compression='infer', protocol=4*)

Pickle (serialize) object to file.

### Parameters

**path** [str] File path where the pickled object will be stored.

**compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

**protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST\_PROTOCOL (see [?] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python >=3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST\_PROTOCOL.

New in version 0.21.0.

**See also:**

**`read_pickle`** Load pickled pandas object (or any object) from file.

**`DataFrame.to_hdf`** Write DataFrame to an HDF5 file.

**`DataFrame.to_sql`** Write DataFrame to a SQL database.

**`DataFrame.to_parquet`** Write a DataFrame to the binary parquet format.

**Examples**

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

**pandas.Series.to\_sparse**

`Series.to_sparse` (*kind='block', fill\_value=None*)  
Convert Series to SparseSeries.

**Parameters**

**kind** [{‘block’, ‘integer’}]

**fill\_value** [float, defaults to NaN (missing)]

### Returns

**sp** [SparseSeries]

## pandas.Series.to\_sql

`Series.to_sql` (*name*, *con*, *schema=None*, *if\_exists='fail'*, *index=True*, *index\_label=None*, *chunk-size=None*, *dtype=None*, *method=None*)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

### Parameters

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### Raises

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

**See also:**

`read_sql` Read a DataFrame from a table.

**Notes**

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

**References**

[?], [?]

**Examples**

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.Series.to\_string

`Series.to_string` (*buf=None, na\_rep='NaN', float\_format=None, header=True, index=True, length=False, dtype=False, name=False, max\_rows=None*)

Render a string representation of the Series.

#### Parameters

- buf** [StringIO-like, optional] buffer to write to
- na\_rep** [string, optional] string representation of NAN to use, default 'NaN'
- float\_format** [one-parameter function, optional] formatter function to apply to columns' elements if they are floats default None
- header** [boolean, default True] Add the Series header (index name)
- index** [bool, optional] Add index (row) labels, default True
- length** [boolean, default False] Add the Series length
- dtype** [boolean, default False] Add the Series dtype
- name** [boolean, default False] Add the Series name if not None
- max\_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.

#### Returns

- formatted** [string (if not buffer passed)]

### pandas.Series.to\_timestamp

`Series.to_timestamp` (*freq=None, how='start', copy=True*)

Cast to DatetimeIndex of timestamps, at *beginning* of period.

#### Parameters

- freq** [string, default frequency of PeriodIndex] Desired frequency
- how** [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end

#### Returns

```
ts [Series with DatetimeIndex]
```

## pandas.Series.to\_xarray

`Series.to_xarray()`

Return an xarray object from the pandas object.

### Returns

**xarray.DataArray or xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

### See also:

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

### Notes

See the [xarray docs](#)

### Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                    columns=['name', 'class', 'max_speed',
...                              'num_legs'])
>>> df
   name  class  max_speed  num_legs
0  falcon  bird     389.0         2
1  parrot  bird      24.0         2
2   lion  mammal     80.5         4
3  monkey  mammal      NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:      (index: 4)
Coordinates:
  * index        (index) int64 0 1 2 3
Data variables:
  name           (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class          (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed      (index) float64 389.0 24.0 80.5 nan
  num_legs       (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5,  nan])
Coordinates:
  * index      (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot', 'falcon',
...                                       'parrot'],
...                               'speed': [350, 18, 361, 15]}).set_index(['date',
...                                                                      'animal'])
>>> df_multiindex
```

date	animal	speed
2018-01-01	falcon	350
	parrot	18
2018-01-02	falcon	361
	parrot	15

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

### pandas.Series.tolist

`Series.tolist()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**See also:**

`numpy.ndarray.tolist`

### pandas.Series.transform

`Series.transform(func, axis=0, *args, **kwargs)`

Call `func` on self producing a Series with transformed values and that has the same axis length as self.

New in version 0.20.0.

#### Parameters

**func** [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to `Series.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**Series** A Series that must have the same length as self.

### Raises

**ValueError** [If the returned Series has a different length than self.]

### See also:

***Series.agg*** Only perform aggregating type operations.

***Series.apply*** Invoke function on a Series.

### Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

### pandas.Series.transpose

**Series.t.transpose** (\*args, \*\*kwargs)

Return the transpose, which is by definition self.

### pandas.Series.truediv

Series.**truediv** (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.rtruediv`

#### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.truncate

Series.**truncate** (*before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

### Parameters

- before** [date, string, int] Truncate all rows before this index value.
- after** [date, string, int] Truncate all rows after this index value.
- axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.
- copy** [boolean, default is True,] Return a copy of the truncated section.

### Returns

**type of caller** The truncated Series or DataFrame.

### See also:

**DataFrame.loc** Select a subset of a DataFrame by label.

**DataFrame.iloc** Select a subset of a DataFrame by position.

### Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

### Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                   'B': ['f', 'g', 'h', 'i', 'j'],
...                   'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o
```

```
>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A B
1  a f
2  b g
3  c h
4  d i
5  e j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

### pandas.Series.tshift

Series.**tshift** (*periods=1, freq=None, axis=0*)

Shift the time index, using the index's frequency if available.

#### Parameters

**periods** [int] Number of periods to move, can be positive or negative

**freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')

**axis** [int or basestring] Corresponds to the axis that contains the Index

**Returns**

**shifted** [NDFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred\_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

**pandas.Series.tz\_convert**

`Series.tz_convert(tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

**Parameters**

**tz** [string or pytz.timezone object]

**axis** [the axis to convert]

**level** [int, str, default None] If axis ia a MultiIndex, convert a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

**Raises**

**TypeError** If the axis is tz-naive.

**pandas.Series.tz\_localize**

`Series.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

**Parameters**

**tz** [string or pytz.timezone object]

**axis** [the axis to localize]

**level** [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**Series or DataFrame** Same type as the input.

### Raises

**TypeError** If the TimeSeries is tz-aware and tz is not None.

## Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

## pandas.Series.unique

`Series.unique()`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

### Returns

**ndarray or ExtensionArray** The unique values returned as a NumPy array. In case of an extension-array backed Series, a new *ExtensionArray* of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

**See also:**

**unique** Top-level unique method for any 1-d array-like object.

**Index.unique** Return Index with unique values from an Index object.

## Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                           ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

## pandas.Series.unstack

`Series.unstack` (*level=-1, fill\_value=None*)

Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame. The level involved will automatically get sorted.

### Parameters

**level** [int, string, or list of these, default last level] Level(s) to unstack, can pass level name

**fill\_value** [replace NaN with this value if the unstack produces] missing values

New in version 0.18.0.

### Returns

**unstacked** [DataFrame]

### Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...               index=pd.MultiIndex.from_product(['one', 'two'], ['a', 'b']))
>>> s
one  a    1
     b    2
two  a    3
     b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
     a  b
one  1  2
two  3  4
```

```
>>> s.unstack(level=0)
      one  two
a      1   3
b      2   4
```

## pandas.Series.update

Series.**update** (*other*)

Modify Series in place using non-NA values from passed Series. Aligns on index.

### Parameters

**other** [Series]

### Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If *other* contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

## pandas.Series.valid

`Series.valid` (*inplace=False*, *\*\*kwargs*)

Return Series without null values.

Deprecated since version 0.23.0: Use `Series.dropna()` instead.

## pandas.Series.value\_counts

`Series.value_counts` (*normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

### Parameters

**normalize** [boolean, default False] If True then the object returned will contain the relative frequencies of the unique values.

**sort** [boolean, default True] Sort by values.

**ascending** [boolean, default False] Sort in ascending order.

**bins** [integer, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

**dropna** [boolean, default True] Don't include counts of NaN.

### Returns

**counts** [Series]

### See also:

**`Series.count`** Number of non-NA elements in a Series.

**`DataFrame.count`** Number of non-NA elements in a DataFrame.

### Examples

```

>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64

```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```

>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64

```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]    2
(3.0, 4.0]      1
dtype: int64
```

**dropna**

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0      2
NaN      1
4.0      1
2.0      1
1.0      1
dtype: int64
```

**pandas.Series.var**

`Series.var` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

**Parameters**

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**var** [scalar or Series (if level specified)]

**pandas.Series.view**

`Series.view` (*dtype=None*)

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

**Parameters**

**dtype** [data type] Data type object or one of their string representations.

**Returns**

**Series** A new Series object as a view of the same data in memory.

**See also:**

`numpy.ndarray.view` Equivalent numpy function to create a new view of the same data in memory.

**Notes**

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified dtype) will try using `float64` and may fail if the original data type size in bytes is not the same.

**Examples**

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0    -2
1    -1
2     0
3     1
4     2
dtype: int8
```

The 8 bit signed integer representation of `-1` is `0b11111111`, but the same bytes represent `255` if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2     0
3     1
4     2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0   -128
1     -1
2      0
3      1
4      2
dtype: int8
```

## pandas.Series.where

`Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)`

Replace values where the condition is False.

### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

### See also:

`DataFrame.mask()` Return an object of same shape as self.

### Notes

The `where` method is an application of the if-then idiom. For each element in the calling `DataFrame`, if `cond` is `True` the element is used; otherwise the corresponding element from the `DataFrame` `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

### pandas.Series.xs

Series.**xs** (*key, axis=0, level=None, drop\_level=True*)  
Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

### Parameters

- key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.
- level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- drop\_level** [bool, default True] If False, returns object with same levels as self.

### Returns

**Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.

### See also:

**DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.

**DataFrame.iloc** Purely integer-location based indexing for selection by position.

### Notes

*xs* can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

### Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
```

			num_legs	num_wings
class	animal	locomotion		
mammal	cat	walks	4	0
	dog	walks	4	0
	bat	flies	2	2
bird	penguin	walks	2	2

#### Get values at specified index

```
>>> df.xs('mammal')
          num_legs  num_wings
animal locomotion
cat     walks      4          0
dog     walks      4          0
bat     flies      2          2
```

#### Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
           num_legs  num_wings
locomotion
walks           4           0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
           num_legs  num_wings
class locomotion
mammal walks           4           0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
           num_legs  num_wings
animal
penguin           2           2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal  cat    walks      0
         dog    walks      0
         bat    flies      2
bird    penguin walks      2
Name: num_wings, dtype: int64
```

## 6.3.2 Attributes

### Axes

<i>Series.index</i>	The index (axis labels) of the Series.
<i>Series.array</i>	The ExtensionArray of the data backing this Series or Index.
<i>Series.values</i>	Return Series as ndarray or ndarray-like depending on the dtype.
<i>Series.dtype</i>	Return the dtype object of the underlying data.
<i>Series.ftype</i>	Return if the data is sparsedense.
<i>Series.shape</i>	Return a tuple of the shape of the underlying data.
<i>Series.nbytes</i>	Return the number of bytes in the underlying data.
<i>Series.ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>Series.size</i>	Return the number of elements in the underlying data.
<i>Series.strides</i>	Return the strides of the underlying data.
<i>Series.itemsize</i>	Return the size of the dtype of the item of the underlying data.
<i>Series.base</i>	Return the base object if the memory of the underlying data is shared.

Continued on next page

Table 29 – continued from previous page

<code>Series.T</code>	Return the transpose, which is by definition self.
<code>Series.memory_usage([index, deep])</code>	Return the memory usage of the Series.
<code>Series.hasnans</code>	Return if I have any nans; enables various perf speedups.
<code>Series.flags</code>	
<code>Series.empty</code>	
<code>Series.dtypes</code>	Return the dtype object of the underlying data.
<code>Series.ftypes</code>	Return if the data is sparsedense.
<code>Series.data</code>	Return the data pointer of the underlying data.
<code>Series.is_copy</code>	Return the copy.
<code>Series.name</code>	Return name of the Series.
<code>Series.put(*args, **kwargs)</code>	Applies the <code>put</code> method to its <code>values</code> attribute if it has one.

### pandas.Series.empty

`Series.empty`

### 6.3.3 Conversion

<code>Series.astype(dtype[, copy, errors])</code>	Cast a pandas object to a specified dtype <code>dtype</code> .
<code>Series.infer_objects()</code>	Attempt to infer better dtypes for object columns.
<code>Series.convert_objects([convert_dates, ...])</code>	(DEPRECATED) Attempt to infer better dtype for object columns.
<code>Series.copy([deep])</code>	Make a copy of this object's indices and data.
<code>Series.bool()</code>	Return the bool of a single element PandasObject.
<code>Series.to_numpy([dtype, copy])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>Series.to_period([freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>Series.to_timestamp([freq, how, copy])</code>	Cast to datetimeindex of timestamps, at <i>beginning</i> of period.
<code>Series.to_list()</code>	Return a list of the values.
<code>Series.get_values()</code>	Same as <code>values</code> (but handles sparseness conversions); is a view.
<code>Series.__array__([dtype])</code>	Return the values as a NumPy array.

### pandas.Series.\_\_array\_\_

`Series.__array__ (dtype=None)`  
Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

#### Parameters

**dtype** [str or `numpy.dtype`, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

#### Returns

**numpy.ndarray** The values in the series converted to a `numpy.ndarray` with the specified `dtype`.

See also:

**pandas.array** Create a new array from data.

**Series.array** Zero-copy view to the array backing the Series.

**Series.to\_numpy** Series method for similar behavior.

## Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]") # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

## 6.3.4 Indexing, iteration

<code>Series.get(key[, default])</code>	Get item from object for given key (DataFrame column, Panel slice, etc.).
<code>Series.at</code>	Access a single value for a row/column label pair.
<code>Series.iat</code>	Access a single value for a row/column pair by integer position.
<code>Series.loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>Series.iloc</code>	Purely integer-location based indexing for selection by position.
<code>Series.__iter__()</code>	Return an iterator of the values.
<code>Series.iteritems()</code>	Lazily iterate over (index, value) tuples.
<code>Series.items()</code>	Lazily iterate over (index, value) tuples.
<code>Series.keys()</code>	Alias for index.
<code>Series.pop(item)</code>	Return item and drop from frame.
<code>Series.item()</code>	Return the first element of the underlying data as a python scalar.
<code>Series.xs(key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

**pandas.Series.\_\_iter\_\_**`Series.__iter__()`

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

**6.3.5 Binary operator functions**

<code>Series.add(other[, level, fill_value, axis])</code>	Addition of series and other, element-wise (binary operator <i>add</i> ).
<code>Series.sub(other[, level, fill_value, axis])</code>	Subtraction of series and other, element-wise (binary operator <i>sub</i> ).
<code>Series.mul(other[, level, fill_value, axis])</code>	Multiplication of series and other, element-wise (binary operator <i>mul</i> ).
<code>Series.div(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>truediv</i> ).
<code>Series.truediv(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>truediv</i> ).
<code>Series.floordiv(other[, level, fill_value, axis])</code>	Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).
<code>Series.mod(other[, level, fill_value, axis])</code>	Modulo of series and other, element-wise (binary operator <i>mod</i> ).
<code>Series.pow(other[, level, fill_value, axis])</code>	Exponential power of series and other, element-wise (binary operator <i>pow</i> ).
<code>Series.radd(other[, level, fill_value, axis])</code>	Addition of series and other, element-wise (binary operator <i>radd</i> ).
<code>Series.rsub(other[, level, fill_value, axis])</code>	Subtraction of series and other, element-wise (binary operator <i>rsub</i> ).
<code>Series.rmul(other[, level, fill_value, axis])</code>	Multiplication of series and other, element-wise (binary operator <i>rmul</i> ).
<code>Series.rdiv(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ).
<code>Series.rtruediv(other[, level, fill_value, axis])</code>	Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ).
<code>Series.rfloordiv(other[, level, fill_value, ...])</code>	Integer division of series and other, element-wise (binary operator <i>rfloordiv</i> ).
<code>Series.rmod(other[, level, fill_value, axis])</code>	Modulo of series and other, element-wise (binary operator <i>rmod</i> ).
<code>Series.rpow(other[, level, fill_value, axis])</code>	Exponential power of series and other, element-wise (binary operator <i>rpow</i> ).
<code>Series.combine(other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <i>func</i> .
<code>Series.combine_first(other)</code>	Combine Series values, choosing the calling Series's values first.
<code>Series.round([decimals])</code>	Round each value in a Series to the given number of decimals.
<code>Series.lt(other[, level, fill_value, axis])</code>	Less than of series and other, element-wise (binary operator <i>lt</i> ).

Continued on next page

Table 32 – continued from previous page

<code>Series.gt(other[, level, fill_value, axis])</code>	Greater than of series and other, element-wise (binary operator <i>gt</i> ).
<code>Series.le(other[, level, fill_value, axis])</code>	Less than or equal to of series and other, element-wise (binary operator <i>le</i> ).
<code>Series.ge(other[, level, fill_value, axis])</code>	Greater than or equal to of series and other, element-wise (binary operator <i>ge</i> ).
<code>Series.ne(other[, level, fill_value, axis])</code>	Not equal to of series and other, element-wise (binary operator <i>ne</i> ).
<code>Series.eq(other[, level, fill_value, axis])</code>	Equal to of series and other, element-wise (binary operator <i>eq</i> ).
<code>Series.product([axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>Series.dot(other)</code>	Compute the dot product between the Series and the columns of other.

### 6.3.6 Function application, GroupBy & Window

<code>Series.apply(func[, convert_dtype, args])</code>	Invoke function on values of Series.
<code>Series.agg(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>Series.aggregate(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>Series.transform(func[, axis])</code>	Call <code>func</code> on self producing a Series with transformed values and that has the same axis length as self.
<code>Series.map(arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>Series.groupby([by, axis, level, as_index, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>Series.rolling(window[, min_periods, ...])</code>	Provides rolling window calculations.
<code>Series.expanding([min_periods, center, axis])</code>	Provides expanding transformations.
<code>Series.ewm([com, span, halflife, alpha, ...])</code>	Provides exponential weighted functions.
<code>Series.pipe(func, *args, **kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .

### 6.3.7 Computations / Descriptive Stats

<code>Series.abs()</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>Series.all([axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>Series.any([axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>Series.autocorr([lag])</code>	Compute the lag-N autocorrelation.
<code>Series.between(left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left &lt;= series &lt;= right</code> .
<code>Series.clip([lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>Series.clip_lower(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values below a given threshold.
<code>Series.clip_upper(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values above a given threshold.
<code>Series.corr(other[, method, min_periods])</code>	Compute correlation with <i>other</i> Series, excluding missing values.

Continued on next page

Table 34 – continued from previous page

<code>Series.count([level])</code>	Return number of non-NA/null observations in the Series.
<code>Series.cov(other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>Series.cummax([axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>Series.cummin([axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>Series.cumprod([axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>Series.cumsum([axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>Series.describe([percentiles, include, exclude])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>Series.diff([periods])</code>	First discrete difference of element.
<code>Series.factorize([sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>Series.kurt([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>Series.mad([axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>Series.max([axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>Series.mean([axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>Series.median([axis, skipna, level, ...])</code>	Return the median of the values for the requested axis.
<code>Series.min([axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>Series.mode([dropna])</code>	Return the mode(s) of the dataset.
<code>Series.nlargest([n, keep])</code>	Return the largest $n$ elements.
<code>Series.nsmallest([n, keep])</code>	Return the smallest $n$ elements.
<code>Series.pct_change([periods, fill_method, ...])</code>	Percentage change between the current and a prior element.
<code>Series.prod([axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>Series.quantile([q, interpolation])</code>	Return value at the given quantile.
<code>Series.rank([axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through $n$ ) along axis.
<code>Series.sem([axis, skipna, level, ddof, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>Series.skew([axis, skipna, level, numeric_only])</code>	Return unbiased skew over requested axis Normalized by $N-1$ .
<code>Series.std([axis, skipna, level, ddof, ...])</code>	Return sample standard deviation over requested axis.
<code>Series.sum([axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.
<code>Series.var([axis, skipna, level, ddof, ...])</code>	Return unbiased variance over requested axis.
<code>Series.kurtosis([axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>Series.unique()</code>	Return unique values of Series object.
<code>Series.nunique([dropna])</code>	Return number of unique elements in the object.
<code>Series.is_unique</code>	Return boolean if values in the object are unique.
<code>Series.is_monotonic</code>	Return boolean if values in the object are monotonic_increasing.

Continued on next page

Table 34 – continued from previous page

<code>Series.is_monotonic_increasing</code>	Return boolean if values in the object are monotonic_increasing.
<code>Series.is_monotonic_decreasing</code>	Return boolean if values in the object are monotonic_decreasing.
<code>Series.value_counts([normalize, sort, ...])</code>	Return a Series containing counts of unique values.
<code>Series.compound([axis, skipna, level])</code>	Return the compound percentage of the values for the requested axis.

### 6.3.8 Reindexing / Selection / Label manipulation

<code>Series.align(other[, join, axis, level, ...])</code>	Align two objects on their axes with the specified join method for each axis Index.
<code>Series.drop([labels, axis, index, columns, ...])</code>	Return Series with specified index labels removed.
<code>Series.droplevel(level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>Series.drop_duplicates([keep, inplace])</code>	Return Series with duplicate values removed.
<code>Series.duplicated([keep])</code>	Indicate duplicate Series values.
<code>Series.equals(other)</code>	Test whether two objects contain the same elements.
<code>Series.first(offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>Series.head([n])</code>	Return the first <i>n</i> rows.
<code>Series.idxmax([axis, skipna])</code>	Return the row label of the maximum value.
<code>Series.idxmin([axis, skipna])</code>	Return the row label of the minimum value.
<code>Series.isin(values)</code>	Check whether <i>values</i> are contained in Series.
<code>Series.last(offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>Series.reindex([index])</code>	Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>Series.reindex_like(other[, method, copy, ...])</code>	Return an object with matching indices as other object.
<code>Series.rename([index])</code>	Alter Series index labels or name.
<code>Series.rename_axis([mapper, index, columns, ...])</code>	Set the name of the axis for the index or columns.
<code>Series.reset_index([level, drop, name, inplace])</code>	Generate a new DataFrame or Series with the index reset.
<code>Series.sample([n, frac, replace, weights, ...])</code>	Return a random sample of items from an axis of object.
<code>Series.select(crit[, axis])</code>	(DEPRECATED) Return data corresponding to axis labels matching criteria.
<code>Series.set_axis(labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>Series.take(indices[, axis, convert, is_copy])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>Series.tail([n])</code>	Return the last <i>n</i> rows.
<code>Series.truncate([before, after, axis, copy])</code>	Truncate a Series or DataFrame before and after some index value.
<code>Series.where(cond[, other, inplace, axis, ...])</code>	Replace values where the condition is False.
<code>Series.mask(cond[, other, inplace, axis, ...])</code>	Replace values where the condition is True.
<code>Series.add_prefix(prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>Series.add_suffix(suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>Series.filter([items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.

### 6.3.9 Missing data handling

<code>Series.isna()</code>	Detect missing values.
<code>Series.notna()</code>	Detect existing (non-missing) values.
<code>Series.dropna([axis, inplace])</code>	Return a new Series with missing values removed.
<code>Series.fillna([value, method, axis, ...])</code>	Fill NA/NaN values using the specified method.
<code>Series.interpolate([method, axis, limit, ...])</code>	Interpolate values according to different methods.

### 6.3.10 Reshaping, sorting

<code>Series.argsort([axis, kind, order])</code>	Overrides ndarray.argsort.
<code>Series.argmin([axis, skipna])</code>	(DEPRECATED) Return the row label of the minimum value.
<code>Series.argmax([axis, skipna])</code>	(DEPRECATED) Return the row label of the maximum value.
<code>Series.reorder_levels(order)</code>	Rearrange index levels using input order.
<code>Series.sort_values([axis, ascending, ...])</code>	Sort by the values.
<code>Series.sort_index([axis, level, ascending, ...])</code>	Sort Series by index labels.
<code>Series.swaplevel([i, j, copy])</code>	Swap levels i and j in a MultiIndex.
<code>Series.unstack([level, fill_value])</code>	Unstack, a.k.a.
<code>Series.searchsorted(value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.
<code>Series.ravel([order])</code>	Return the flattened underlying data as an ndarray.
<code>Series.repeat(repeats[, axis])</code>	Repeat elements of a Series.
<code>Series.squeeze([axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>Series.view([dtype])</code>	Create a new view of the Series.

### 6.3.11 Combining / joining / merging

<code>Series.append(to_append[, ignore_index, ...])</code>	Concatenate two or more Series.
<code>Series.replace([to_replace, value, inplace, ...])</code>	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>Series.update(other)</code>	Modify Series in place using non-NA values from passed Series.

### 6.3.12 Time series-related

<code>Series.asfreq(freq[, method, how, ...])</code>	Convert TimeSeries to specified frequency.
<code>Series.asof(where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>Series.shift([periods, freq, axis, fill_value])</code>	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>Series.first_valid_index()</code>	Return index for first non-NA/null value.
<code>Series.last_valid_index()</code>	Return index for last non-NA/null value.
<code>Series.resample(rule[, how, axis, ...])</code>	Resample time-series data.
<code>Series.tz_convert(tz[, axis, level, copy])</code>	Convert tz-aware axis to target time zone.
<code>Series.tz_localize(tz[, axis, level, copy, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>Series.at_time(time[, asof, axis])</code>	Select values at particular time of day (e.g.

Continued on next page

Table 39 – continued from previous page

<code>Series.between_time(start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>Series.tshift([periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>Series.slice_shift([periods, axis])</code>	Equivalent to <i>shift</i> without copying data.

### 6.3.13 Accessors

Pandas provides dtype-specific methods under various accessors. These are separate namespaces within *Series* that only apply to specific data types.

Data Type	Accessor
Datetime, Timedelta, Period	<i>dt</i>
String	<i>str</i>
Categorical	<i>cat</i>
Sparse	<i>sparse</i>

### Datetimelike Properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

### Datetime Properties

<code>Series.dt.date</code>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
<code>Series.dt.time</code>	Returns numpy array of datetime.time.
<code>Series.dt.timetz</code>	Returns numpy array of datetime.time also containing timezone information.
<code>Series.dt.year</code>	The year of the datetime.
<code>Series.dt.month</code>	The month as January=1, December=12.
<code>Series.dt.day</code>	The days of the datetime.
<code>Series.dt.hour</code>	The hours of the datetime.
<code>Series.dt.minute</code>	The minutes of the datetime.
<code>Series.dt.second</code>	The seconds of the datetime.
<code>Series.dt.microsecond</code>	The microseconds of the datetime.
<code>Series.dt.nanosecond</code>	The nanoseconds of the datetime.
<code>Series.dt.week</code>	The week ordinal of the year.
<code>Series.dt.weekofyear</code>	The week ordinal of the year.
<code>Series.dt.dayofweek</code>	The day of the week with Monday=0, Sunday=6.
<code>Series.dt.weekday</code>	The day of the week with Monday=0, Sunday=6.
<code>Series.dt.dayofyear</code>	The ordinal day of the year.
<code>Series.dt.quarter</code>	The quarter of the date.
<code>Series.dt.is_month_start</code>	Indicates whether the date is the first day of the month.
<code>Series.dt.is_month_end</code>	Indicates whether the date is the last day of the month.
<code>Series.dt.is_quarter_start</code>	Indicator for whether the date is the first day of a quarter.
<code>Series.dt.is_quarter_end</code>	Indicator for whether the date is the last day of a quarter.

Continued on next page

Table 40 – continued from previous page

<code>Series.dt.is_year_start</code>	Indicate whether the date is the first day of a year.
<code>Series.dt.is_year_end</code>	Indicate whether the date is the last day of the year.
<code>Series.dt.is_leap_year</code>	Boolean indicator if the date belongs to a leap year.
<code>Series.dt.daysinmonth</code>	The number of days in the month.
<code>Series.dt.days_in_month</code>	The number of days in the month.
<code>Series.dt.tz</code>	Return timezone, if any.
<code>Series.dt.freq</code>	

### **pandas.Series.dt.date**

#### `Series.dt.date`

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

### **pandas.Series.dt.time**

#### `Series.dt.time`

Returns numpy array of datetime.time. The time part of the Timestamps.

### **pandas.Series.dt.timetz**

#### `Series.dt.timetz`

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

### **pandas.Series.dt.year**

#### `Series.dt.year`

The year of the datetime.

### **pandas.Series.dt.month**

#### `Series.dt.month`

The month as January=1, December=12.

### **pandas.Series.dt.day**

#### `Series.dt.day`

The days of the datetime.

### **pandas.Series.dt.hour**

#### `Series.dt.hour`

The hours of the datetime.

### **pandas.Series.dt.minute**

`Series.dt.minute`

The minutes of the datetime.

### **pandas.Series.dt.second**

`Series.dt.second`

The seconds of the datetime.

### **pandas.Series.dt.microsecond**

`Series.dt.microsecond`

The microseconds of the datetime.

### **pandas.Series.dt.nanosecond**

`Series.dt.nanosecond`

The nanoseconds of the datetime.

### **pandas.Series.dt.week**

`Series.dt.week`

The week ordinal of the year.

### **pandas.Series.dt.weekofyear**

`Series.dt.weekofyear`

The week ordinal of the year.

### **pandas.Series.dt.dayofweek**

`Series.dt.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### **Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

**`Series.dt.dayofweek`** Alias.

**`Series.dt.weekday`** Alias.

**`Series.dt.day_name`** Returns the name of the day of the week.

## Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

## pandas.Series.dt.weekday

### Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### Returns

**Series or Index** Containing integers indicating the day number.

#### See also:

**Series.dt.dayofweek** Alias.

**Series.dt.weekday** Alias.

**Series.dt.day\_name** Returns the name of the day of the week.

## Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

## pandas.Series.dt.dayofyear

### Series.dt.dayofyear

The ordinal day of the year.

## pandas.Series.dt.quarter

Series.dt.**quarter**

The quarter of the date.

## pandas.Series.dt.is\_month\_start

Series.dt.**is\_month\_start**

Indicates whether the date is the first day of the month.

### Returns

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

### See also:

**is\_month\_start** Return a boolean indicating whether the date is the first day of the month.

**is\_month\_end** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```

>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool

```

```

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])

```

## pandas.Series.dt.is\_month\_end

Series.dt.**is\_month\_end**

Indicates whether the date is the last day of the month.

### Returns

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

***is\_month\_start*** Return a boolean indicating whether the date is the first day of the month.

***is\_month\_end*** Return a boolean indicating whether the date is the last day of the month.

### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

### pandas.Series.dt.is\_quarter\_start

`Series.dt.is_quarter_start`

Indicator for whether the date is the first day of a quarter.

#### Returns

***is\_quarter\_start*** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

***quarter*** Return the quarter of the date.

***is\_quarter\_end*** Similar property for indicating the quarter start.

### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...
...
>>> df.assign(quarter=df.dates.dt.quarter,
...
...
    dates  quarter  is_quarter_start
0 2017-03-30      1             False
1 2017-03-31      1             False
2 2017-04-01      2              True
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

## pandas.Series.dt.is\_quarter\_end

### Series.dt.is\_quarter\_end

Indicator for whether the date is the last day of a quarter.

#### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...
...
>>> df.assign(quarter=df.dates.dt.quarter,
...
...
    dates  quarter  is_quarter_end
0 2017-03-30      1             False
1 2017-03-31      1              True
2 2017-04-01      2             False
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

## pandas.Series.dt.is\_year\_start

### Series.dt.is\_year\_start

Indicate whether the date is the first day of a year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**is\_year\_end** Similar property indicating the last day of the year.

### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False,  False,   True])
```

## pandas.Series.dt.is\_year\_end

### Series.dt.is\_year\_end

Indicate whether the date is the last day of the year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**`is_year_start`** Similar property indicating the start of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True,  False])
```

## pandas.Series.dt.is\_leap\_year

### Series.dt.is\_leap\_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

#### Returns

**Series or ndarray** Booleans indicating if dates belong to a leap year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True,  False,  False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
```

(continues on next page)

(continued from previous page)

```

1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool

```

**pandas.Series.dt.daysinmonth****Series.dt.daysinmonth**

The number of days in the month.

**pandas.Series.dt.days\_in\_month****Series.dt.days\_in\_month**

The number of days in the month.

**pandas.Series.dt.tz****Series.dt.tz**

Return timezone, if any.

**Returns****datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None** Returns None when the array is tz-naive.**pandas.Series.dt.freq****Series.dt.freq****Datetime Methods**

<i>Series.dt.to_period(*args, **kwargs)</i>	Cast to PeriodArray/Index at a particular frequency.
<i>Series.dt.to_pydatetime()</i>	Return the data as an array of native Python datetime objects.
<i>Series.dt.tz_localize(*args, **kwargs)</i>	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<i>Series.dt.tz_convert(*args, **kwargs)</i>	Convert tz-aware Datetime Array/Index from one time zone to another.
<i>Series.dt.normalize(*args, **kwargs)</i>	Convert times to midnight.
<i>Series.dt.strftime(*args, **kwargs)</i>	Convert to Index using specified date_format.
<i>Series.dt.round(*args, **kwargs)</i>	Perform round operation on the data to the specified <i>freq</i> .
<i>Series.dt.floor(*args, **kwargs)</i>	Perform floor operation on the data to the specified <i>freq</i> .

Continued on next page

Table 41 – continued from previous page

<code>Series.dt.ceil(*args, **kwargs)</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>Series.dt.month_name(*args, **kwargs)</code>	Return the month names of the DateTimeIndex with specified locale.
<code>Series.dt.day_name(*args, **kwargs)</code>	Return the day names of the DateTimeIndex with specified locale.

## pandas.Series.dt.to\_period

`Series.dt.to_period(*args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

### Parameters

**freq** [string or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

### Returns

**PeriodArray/Index**

### Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

### See also:

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DatetimeIndex as object.

## Examples

```
>>> df = pd.DataFrame({"y": [1,2,3]},
...                   index=pd.to_datetime(["2000-03-31 00:00:00",
...                                         "2000-05-31 00:00:00",
...                                         "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

### Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

## pandas.Series.dt.to\_pydatetime

`Series.dt.to_pydatetime()`

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

**Warning:** Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

### Returns

`numpy.ndarray` object dtype array containing native Python datetime objects.

### See also:

`datetime.datetime` Standard library value for a datetime.

### Examples

```
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas’ nanosecond precision is truncated to microseconds.

```
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000
1    2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

## pandas.Series.dt.tz\_localize

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [string, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

**ambiguous** [‘infer’, ‘NaT’, bool array, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

**errors** [{'raise', 'coerce'}, default None]

- 'raise' will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use nonexistent='raise' instead.
- 'coerce' will return NaT if the timestamp can not be converted to the specified time zone. Use nonexistent='NaT' instead.

Deprecated since version 0.24.0.

### Returns

**result** [same type as self] Array/Index converted to the specified time zone.

### Raises

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

### See also:

***DatetimeIndex.tz\_convert*** Convert tz-aware DatetimeIndex from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time: `>>> s = pd.to_datetime(pd.Series([ ... '2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00']))` `>>> s.dt.tz_localize('CET', ambiguous='infer')` 2018-10-28 01:30:00+02:00 0 2018-10-28 02:00:00+02:00 1 2018-10-28 02:30:00+02:00 2 2018-10-28 02:00:00+01:00 3 2018-10-28 02:30:00+01:00 4 2018-10-28 03:00:00+01:00 5 2018-10-28 03:30:00+01:00 6 dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.to_datetime(pd.Series([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 0 2015-03-29 03:00:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 0 2015-03-29 01:59:59.999999999+01:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 0 2015-03-29 03:30:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']

## pandas.Series.dt.tz\_convert

`Series.dt.tz_convert(*args, **kwargs)`

Convert tz-aware Datetime Array/Index from one time zone to another.

### Parameters

**tz** [string, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A `tz` of None will convert to UTC and remove the timezone information.

### Returns

**normalized** [same type as self]

### Raises

**TypeError** If Datetime Array/Index is tz-naive.

See also:

**DatetimeIndex.tz** A timezone that has a variable offset from UTC.

**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove time-zone from a tz-aware DatetimeIndex.

### Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.Series.dt.normalize

`Series.dt.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

***floor*** Floor the datetimes to the specified freq.

***ceil*** Ceil the datetimes to the specified freq.

***round*** Round the datetimes to the specified freq.

**Examples**

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                      periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

**pandas.Series.dt.strftime**

`Series.dt.strftime(*args, **kwargs)`

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#)

**Parameters**

**`date_format`** [str] Date format string (e.g. “%Y-%m-%d”).

**Returns**

**Index** Index of formatted strings

**See also:**

***to\_datetime*** Convert the given argument to datetime.

***DatetimeIndex.normalize*** Return DatetimeIndex with times to midnight.

***DatetimeIndex.round*** Round the DatetimeIndex to the specified freq.

***DatetimeIndex.floor*** Floor the DatetimeIndex to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

## pandas.Series.dt.round

`Series.dt.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.Series.dt.floor

`Series.dt.floor` (\*args, \*\*kwargs)

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,] default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.Series.dt.ceil

`Series.dt.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,] default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

#### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

#### Raises

**ValueError** if the 'freq' cannot be converted.

### Examples

#### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

#### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

### pandas.Series.dt.month\_name

`Series.dt.month_name(*args, **kwargs)`

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

#### Parameters

**locale** [str, optional] Locale determining the language in which to return the month name. Default is English locale.

#### Returns

**Index** Index of month names.

## Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

## pandas.Series.dt.day\_name

Series.dt.day\_name(\*args, \*\*kwargs)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

### Parameters

**locale** [str, optional] Locale determining the language in which to return the day name. Default is English locale.

### Returns

**Index** Index of day names.

## Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

## Period Properties

*Series.dt.qyear*

*Series.dt.start\_time*

*Series.dt.end\_time*

## pandas.Series.dt.qyear

Series.dt.qyear

## pandas.Series.dt.start\_time

Series.dt.start\_time

## **pandas.Series.dt.end\_time**

`Series.dt.end_time`

## **Timedelta Properties**

<i>Series.dt.days</i>	Number of days for each element.
<i>Series.dt.seconds</i>	Number of seconds ( $\geq 0$ and less than 1 day) for each element.
<i>Series.dt.microseconds</i>	Number of microseconds ( $\geq 0$ and less than 1 second) for each element.
<i>Series.dt.nanoseconds</i>	Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.
<i>Series.dt.components</i>	Return a Dataframe of the components of the Timedeltas.

## **pandas.Series.dt.days**

`Series.dt.days`

Number of days for each element.

## **pandas.Series.dt.seconds**

`Series.dt.seconds`

Number of seconds ( $\geq 0$  and less than 1 day) for each element.

## **pandas.Series.dt.microseconds**

`Series.dt.microseconds`

Number of microseconds ( $\geq 0$  and less than 1 second) for each element.

## **pandas.Series.dt.nanoseconds**

`Series.dt.nanoseconds`

Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.

## **pandas.Series.dt.components**

`Series.dt.components`

Return a Dataframe of the components of the Timedeltas.

**Returns**

**DataFrame**

## Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    00:00:00
1    00:00:01
2    00:00:02
3    00:00:03
4    00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0     0         0         0             0             0             0
1     0     0         0         1             0             0             0
2     0     0         0         2             0             0             0
3     0     0         0         3             0             0             0
4     0     0         0         4             0             0             0

```

## Timedelta Methods

<code>Series.dt.to_pytimedelta()</code>	Return an array of native <i>datetime.timedelta</i> objects.
<code>Series.dt.total_seconds(*args, **kwargs)</code>	Return total duration of each element expressed in seconds.

## pandas.Series.dt.to\_pytimedelta

`Series.dt.to_pytimedelta()`

Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation *timedelta*'s. This method converts a Series of pandas *Timedeltas* to *datetime.timedelta* format with the same length as the original Series.

### Returns

**a** [numpy.ndarray] 1D array containing data with *datetime.timedelta* type.

### See also:

`datetime.timedelta`

## Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]

```

```

>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(1),

```

(continues on next page)

(continued from previous page)

```
datetime.timedelta(2), datetime.timedelta(3),
datetime.timedelta(4)], dtype=object)
```

## pandas.Series.dt.total\_seconds

`Series.dt.total_seconds` (\*args, \*\*kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on `TimedeltaArray`, `TimedeltaIndex` and on `Series` containing `timedelta` values under the `.dt` namespace.

### Returns

**seconds** [[ndarray, Float64Index, Series]] When the calling object is a `TimedeltaArray`, the return type is `ndarray`. When the calling object is a `TimedeltaIndex`, the return type is a `Float64Index`. When the calling object is a `Series`, the return type is `Series` of type `float64` whose index is the same as the original.

### See also:

`datetime.timedelta.total_seconds` Standard library version of this method.

`TimedeltaIndex.components` Return a `DataFrame` with components of each `Timedelta`.

## Examples

### Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64
```

### TimedeltaIndex

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.00000000003, 345600.0],
              dtype='float64')
```

## String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<code>Series.str.capitalize()</code>	Convert strings in the Series/Index to be capitalized.
<code>Series.str.cat([others, sep, na_rep, join])</code>	Concatenate strings in the Series/Index with given separator.
<code>Series.str.center(width[, fillchar])</code>	Filling left and right side of strings in the Series/Index with an additional character.
<code>Series.str.contains(pat[, case, flags, na, ...])</code>	Test if pattern or regex is contained within a string of a Series or Index.
<code>Series.str.count(pat[, flags])</code>	Count occurrences of pattern in each string of the Series/Index.
<code>Series.str.decode(encoding[, errors])</code>	Decode character string in the Series/Index using indicated encoding.
<code>Series.str.encode(encoding[, errors])</code>	Encode character string in the Series/Index using indicated encoding.
<code>Series.str.endswith(pat[, na])</code>	Test if the end of each string element matches a pattern.
<code>Series.str.extract(pat[, flags, expand])</code>	Extract capture groups in the regex <i>pat</i> as columns in a DataFrame.
<code>Series.str.extractall(pat[, flags])</code>	For each subject string in the Series, extract groups from all matches of regular expression <i>pat</i> .
<code>Series.str.find(sub[, start, end])</code>	Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].
<code>Series.str.findall(pat[, flags])</code>	Find all occurrences of pattern or regular expression in the Series/Index.
<code>Series.str.get(i)</code>	Extract element from each component at specified position.
<code>Series.str.index(sub[, start, end])</code>	Return lowest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.join(sep)</code>	Join lists contained as elements in the Series/Index with passed delimiter.
<code>Series.str.len()</code>	Computes the length of each element in the Series/Index.
<code>Series.str.ljust(width[, fillchar])</code>	Filling right side of strings in the Series/Index with an additional character.
<code>Series.str.lower()</code>	Convert strings in the Series/Index to lowercase.
<code>Series.str.lstrip([to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.match(pat[, case, flags, na])</code>	Determine if each string matches a regular expression.
<code>Series.str.normalize(form)</code>	Return the Unicode normal form for the strings in the Series/Index.
<code>Series.str.pad(width[, side, fillchar])</code>	Pad strings in the Series/Index up to width.
<code>Series.str.partition([sep, expand])</code>	Split the string at the first occurrence of <i>sep</i> .
<code>Series.str.repeat(repeats)</code>	Duplicate each string in the Series or Index.
<code>Series.str.replace(pat, repl[, n, case, ...])</code>	Replace occurrences of pattern/regex in the Series/Index with some other string.
<code>Series.str.rfind(sub[, start, end])</code>	Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].

Continued on next page

Table 45 – continued from previous page

<code>Series.str.rindex(sub[, start, end])</code>	Return highest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.rjust(width[, fillchar])</code>	Filling left side of strings in the Series/Index with an additional character.
<code>Series.str.rpartition([sep, expand])</code>	Split the string at the last occurrence of <i>sep</i> .
<code>Series.str.rstrip([to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.slice([start, stop, step])</code>	Slice substrings from each element in the Series or Index.
<code>Series.str.slice_replace([start, stop, repl])</code>	Replace a positional slice of a string with another value.
<code>Series.str.split([pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.rsplit([pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.startswith(pat[, na])</code>	Test if the start of each string element matches a pattern.
<code>Series.str.strip([to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.swapcase()</code>	Convert strings in the Series/Index to be swapped.
<code>Series.str.title()</code>	Convert strings in the Series/Index to titlecase.
<code>Series.str.translate(table[, deletechars])</code>	Map all characters in the string through the given mapping table.
<code>Series.str.upper()</code>	Convert strings in the Series/Index to uppercase.
<code>Series.str.wrap(width, **kwargs)</code>	Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.
<code>Series.str.zfill(width)</code>	Pad strings in the Series/Index by prepending '0' characters.
<code>Series.str.isalnum()</code>	Check whether all characters in each string are alphanumeric.
<code>Series.str.isalpha()</code>	Check whether all characters in each string are alphabetic.
<code>Series.str.isdigit()</code>	Check whether all characters in each string are digits.
<code>Series.str.isspace()</code>	Check whether all characters in each string are whitespace.
<code>Series.str.islower()</code>	Check whether all characters in each string are lowercase.
<code>Series.str.isupper()</code>	Check whether all characters in each string are uppercase.
<code>Series.str.istitle()</code>	Check whether all characters in each string are titlecase.
<code>Series.str.isnumeric()</code>	Check whether all characters in each string are numeric.
<code>Series.str.isdecimal()</code>	Check whether all characters in each string are decimal.
<code>Series.str.get_dummies([sep])</code>	Split each string in the Series by <i>sep</i> and return a frame of dummy/indicator variables.

## pandas.Series.str.capitalize

`Series.str.capitalize()`

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

### Returns

Series/Index of objects

See also:

**`Series.str.lower`** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

## pandas.Series.str.cat

`Series.str.cat` (*others=None, sep=None, na\_rep=None, join=None*)

Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise. If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

### Parameters

**others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If *others* is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If *others* is None, the method returns the concatenation of all strings in the calling Series/Index.

**sep** [str, default “”] The separator between the different elements/columns. By default the empty string “” is used.

**na\_rep** [str or None, default None] Representation that is inserted for all missing values:

- If *na\_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.
- If *na\_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

**join** [{‘left’, ‘right’, ‘outer’, ‘inner’}, default None] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). If None, alignment is disabled, but this option will be removed in a future version of pandas and replaced with a default of ‘left’. To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

### Returns

**concat** [str or Series/Index of objects] If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

See also:

**split** Split each string in the Series/Index.

**join** Join lists contained as elements in the Series/Index.

### Examples

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na\_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na\_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
1    bB
2    -C
3    dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
```

(continues on next page)

(continued from previous page)

```
4    -e
2    -c
dtype: object
```

For more examples, see [here](#).

### pandas.Series.str.center

`Series.str.center` (*width*, *fillchar=' '*)

Filling left and right side of strings in the Series/Index with an additional character. Equivalent to `str.center()`.

#### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

#### Returns

**filled** [Series/Index of objects]

### pandas.Series.str.contains

`Series.str.contains` (*pat*, *case=True*, *flags=0*, *na=nan*, *regex=True*)

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

#### Parameters

**pat** [str] Character sequence or regular expression.

**case** [bool, default True] If True, case sensitive.

**flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.

**na** [default NaN] Fill value for missing values.

**regex** [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

#### Returns

**Series or Index of boolean values** A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

**See also:**

**`match`** Analogous, but stricter, relying on `re.match` instead of `re.search`.

**`Series.str.startswith`** Test if the start of each string element matches a pattern.

**`Series.str.endswith`** Same as `startswith`, but tests the end of string.

## Examples

Returning a Series of booleans using only a literal pattern.

```
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4     NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning 'house' or 'dog' when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
4      NaN
dtype: object
```

Returning any digit using regular expression.

```
>>> s1.str.contains('\d', regex=True)
0    False
1    False
2    False
3     True
4      NaN
dtype: object
```

Ensure *pat* is not a literal pattern when *regex* is set to *True*. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, *'0'* as a regex matches any character followed by a 0.

```
>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool
```

## pandas.Series.str.count

`Series.str.count` (*pat*, *flags=0*, *\*\*kwargs*)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

### Parameters

**pat** [str] Valid regular expression.

**flags** [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, [see here](#).

**\*\*kwargs** For compatibility with other string methods. Not used.

### Returns

**counts** [Series or Index] Same type as the calling object containing the integer counts.

### See also:

**re** Standard library module for regular expressions.

**str.count** Standard library version, without regular expression support.

### Notes

Some characters need to be escaped when passing in *pat*. eg. *'\$'* has a special meaning in regex and must be escaped when finding this literal character.

## Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

## pandas.Series.str.decode

`Series.str.decode(encoding, errors='strict')`

Decode character string in the Series/Index using indicated encoding. Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

### Parameters

**encoding** [str]

**errors** [str, optional]

### Returns

**decoded** [Series/Index of objects]

## pandas.Series.str.encode

`Series.str.encode(encoding, errors='strict')`

Encode character string in the Series/Index using indicated encoding. Equivalent to `str.encode()`.

### Parameters

**encoding** [str]

**errors** [str, optional]

### Returns

**encoded** [Series/Index of objects]

## pandas.Series.str.endswith

`Series.str.endswith(pat, na=nan)`

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the end of each string element.

### See also:

**`str.endswith`** Python standard library string method.

**`Series.str.startswith`** Same as `endswith`, but tests the start of string.

**`Series.str.contains`** Tests if string element contains a pattern.

## Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1   bear
2   caT
3   NaN
dtype: object
```

```
>>> s.str.endswith('t')
0     True
1    False
2    False
3     NaN
dtype: object
```

Specifying `na` to be `False` instead of `NaN`.

```
>>> s.str.endswith('t', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

## pandas.Series.str.extract

`Series.str.extract` (*pat*, *flags=0*, *expand=True*)

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

### Parameters

**pat** [string] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.

**expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

New in version 0.18.0.

### Returns

**DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and *pat* has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

**`extractall`** Returns all matches (not just the first match).

### Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0  a  1
1  b  2
2 NaN NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
   0  1
0  a  1
1  b  2
2 NaN 3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
   letter digit
0      a      1
```

(continues on next page)

(continued from previous page)

```
1      b      2
2     NaN     NaN
```

A pattern with one group will return a DataFrame with one column if `expand=True`.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
      0
0     1
1     2
2    NaN
```

A pattern with one group will return a Series if `expand=False`.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0     1
1     2
2    NaN
dtype: object
```

## pandas.Series.str.extractall

`Series.str.extractall(pat, flags=0)`

For each subject string in the Series, extract groups from all matches of regular expression `pat`. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

New in version 0.18.0.

### Parameters

**pat** [str] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

### Returns

**DataFrame** A `DataFrame` with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject `Series`. The last level is named 'match' and indexes the matches in each item of the `Series`. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used.

**See also:**

**extract** Returns first match only (not all matches).

### Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
      0
  match
A 0    1
  1    2
B 0    1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
      digit
  match
A 0      1
  1      2
B 0      1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab]) (?P<digit>\d)")
      letter digit
  match
A 0          a    1
  1          a    2
B 0          b    1
```

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
      letter digit
  match
A 0          a    1
  1          a    2
B 0          b    1
C 0         NaN    1
```

## pandas.Series.str.find

`Series.str.find` (*sub*, *start=0*, *end=None*)

Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

### Parameters

**sub** [str] Substring being searched

**start** [int] Left edge index

**end** [int] Right edge index

### Returns

**found** [Series/Index of integer values]

See also:

**rfind** Return highest indexes in each strings.

## pandas.Series.str.findall

`Series.str.findall` (*pat*, *flags=0*, *\*\*kwargs*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

### Parameters

**pat** [string] Pattern or regular expression.

**flags** [int, default 0] `re` module flags, e.g. `re.IGNORECASE` (default is 0, which means no flags).

### Returns

**Series/Index of lists of strings** All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

### See also:

**count** Count occurrences of pattern or regular expression in each string of the Series/Index.

**extractall** For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

**re.findall** The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

## Examples

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0      []
1  [Monkey]
2      []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0      []
1      []
2      []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0      []
1  [Monkey]
2      []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0    [on]
1    [on]
2     []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0    [on]
1     []
2     []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0     []
1     []
2    [b, b]
dtype: object
```

## pandas.Series.str.get

`Series.str.get(i)`

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

### Parameters

**i** [int] Position of element to extract.

### Returns

**items** [Series/Index of objects]

## Examples

```
>>> s = pd.Series(["String",
                  (1, 2, 3),
                  ["a", "b", "c"],
                  123, -456,
                  {1:"Hello", "2":"World"}])
>>> s
0          String
1          (1, 2, 3)
2          [a, b, c]
3              123
4             -456
5    {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0      t
1      2
2      b
3     NaN
4     NaN
5    Hello
dtype: object
```

```
>>> s.str.get(-1)
0      g
1      3
2      c
3     NaN
4     NaN
5     NaN
dtype: object
```

### pandas.Series.str.index

`Series.str.index` (*sub*, *start=0*, *end=None*)

Return lowest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

#### Parameters

- sub** [str] Substring being searched
- start** [int] Left edge index
- end** [int] Right edge index

#### Returns

- found** [Series/Index of objects]

**See also:**

***rindex*** Return highest indexes in each strings.

### pandas.Series.str.join

`Series.str.join` (*sep*)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

#### Parameters

- sep** [str] Delimiter to use between list entries.

#### Returns

- Series/Index: object** The list entries concatenated by intervening occurrences of the delimiter.

## Raises

**AttributeError** If the supplied Series contains neither strings nor lists.

## See also:

**str.join** Standard library version of this method.

**Series.str.split** Split strings around given separator/delimiter.

## Notes

If any of the list items is not a string object, the result of the join will be *NaN*.

## Examples

Example with a list that contains non-string elements.

```

>>> s = pd.Series(['lion', 'elephant', 'zebra'],
...                [1.1, 2.2, 3.3],
...                ['cat', np.nan, 'dog'],
...                ['cow', 4.5, 'goat'],
...                ['duck', ['swan', 'fish'], 'guppy'])
>>> s
0      [lion, elephant, zebra]
1      [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3      [cow, 4.5, goat]
4      [duck, [swan, fish], guppy]
dtype: object

```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```

>>> s.str.join('-')
0      lion-elephant-zebra
1      NaN
2      NaN
3      NaN
4      NaN
dtype: object

```

## pandas.Series.str.len

`Series.str.len()`

Computes the length of each element in the Series/Index. The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

## Returns

**Series or Index of int** A Series or Index of integer values indicating the length of each element in the Series or Index.

## See also:

**str.len** Python built-in function returning the length of an object.

**Series.size** Returns the length of the Series.

## Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```
>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo' : 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0          dog
1
2          5
3    {'foo': 'bar'}
4    [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0    3.0
1    0.0
2    NaN
3    1.0
4    4.0
5    3.0
dtype: float64
```

## pandas.Series.str.ljust

`Series.str.ljust` (*width*, *fillchar*=' ')

Filling right side of strings in the Series/Index with an additional character. Equivalent to `str.ljust()`.

### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

### Returns

**filled** [Series/Index of objects]

## pandas.Series.str.lower

`Series.str.lower` ()

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

### Returns

**Series/Index of objects**

**See also:**

**`Series.str.lower`** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

## pandas.Series.str.lstrip

`Series.str.lstrip` (*to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

Series/Index of objects

See also:

**`Series.str.strip`** Remove leading and trailing characters in Series/Index.

**`Series.str.lstrip`** Remove leading characters in Series/Index.

**`Series.str.rstrip`** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

## pandas.Series.str.match

`Series.str.match` (*pat*, *case=True*, *flags=0*, *na=nan*)

Determine if each string matches a regular expression.

### Parameters

- pat** [string] Character sequence or regular expression
- case** [boolean, default True] If True, case sensitive
- flags** [int, default 0 (no flags)] re module flags, e.g. `re.IGNORECASE`
- na** [default NaN, fill value for missing values]

### Returns

**Series/array of boolean values**

### See also:

***contains*** Analogous, but less strict, relying on `re.search` instead of `re.match`.

***extract*** Extract matched groups.

## pandas.Series.str.normalize

`Series.str.normalize` (*form*)

Return the Unicode normal form for the strings in the Series/Index. For more information on the forms, see the `unicodedata.normalize()`.

### Parameters

- form** [{ 'NFC', 'NFKC', 'NFD', 'NFKD' }] Unicode form

### Returns

**normalized** [Series/Index of objects]

## pandas.Series.str.pad

`Series.str.pad` (*width*, *side='left'*, *fillchar=' '*)

Pad strings in the Series/Index up to width.

### Parameters

- width** [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.
- side** [{ 'left', 'right', 'both' }, default 'left'] Side from which to fill resulting string.
- fillchar** [str, default ' '] Additional character for filling, default is whitespace.

**Returns**

**Series or Index of object** Returns Series or Index with minimum number of char in object.

**See also:**

**Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.

**Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.

**Series.str.center** Fills both sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.

**Series.str.zfill** Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

**Examples**

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0     caribou
1      tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0   caribou---
1   tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0   -caribou--
1   --tiger---
dtype: object
```

**pandas.Series.str.partition**

`Series.str.partition` (*sep=' '*, *expand=True*)

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

**Parameters**

**sep** [str, default whitespace] String to split on.

**pat** [str, default whitespace] Deprecated since version 0.24.0: Use *sep* instead

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality.  
If False, return Series/Index.

### Returns

**DataFrame/MultiIndex or Series/Index of objects**

See also:

**rpartition** Split the string at the last occurrence of *sep*.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1      2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1      2
0  Linda van der      Berg
1      George      Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1      2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex(levels=[['X', 'Y'], [' '], ['123', '999']],
            codes=[[0, 1], [0, 0], [0, 1]])
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

## pandas.Series.str.repeat

`Series.str.repeat` (*repeats*)

Duplicate each string in the Series or Index.

### Parameters

**repeats** [int or sequence of int] Same value for all (int) or different value per (sequence).

### Returns

**Series or Index of object** Series or Index of repeated string objects specified by input parameter repeats.

## Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1    bb
2    ccc
```

## pandas.Series.str.replace

`Series.str.replace` (*pat, repl, n=-1, case=None, flags=0, regex=True*)

Replace occurrences of pattern/regex in the Series/Index with some other string. Equivalent to `str.replace()` or `re.sub()`.

### Parameters

**pat** [string or compiled regex] String can be a character sequence or regular expression.

New in version 0.20.0: *pat* also accepts a compiled regex.

**repl** [string or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

New in version 0.20.0: *repl* also accepts a callable.

**n** [int, default -1 (all)] Number of replacements to make from start

**case** [boolean, default None]

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive
- Cannot be set if *pat* is a compiled regex

**flags** [int, default 0 (no flags)]

- re module flags, e.g. `re.IGNORECASE`
- Cannot be set if *pat* is a compiled regex

**regex** [boolean, default True]

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

### Returns

**Series or Index of object** A copy of the object with all matching occurrences of *pat* replaced by *repl*.

### Raises

#### ValueError

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

### Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

### Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is `False`, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0    <_sre.SRE_Match object; span=(0, 1), match='f'>oo
1    <_sre.SRE_Match object; span=(0, 1), match='f'>uz
2    NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0    oof 123
1    rab zab
2    NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0    tWO
1    bAR
dtype: object
```

Using a compiled regex with flags

```
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0    foo
1    bar
2    NaN
dtype: object
```

## pandas.Series.str.rfind

`Series.str.rfind(sub, start=0, end=None)`

Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

### Parameters

- sub** [str] Substring being searched
- start** [int] Left edge index

**end** [int] Right edge index

**Returns**

**found** [Series/Index of integer values]

**See also:**

**find** Return lowest indexes in each strings.

### pandas.Series.str.rindex

`Series.str.rindex` (*sub*, *start=0*, *end=None*)

Return highest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.rindex`.

**Parameters**

**sub** [str] Substring being searched

**start** [int] Left edge index

**end** [int] Right edge index

**Returns**

**found** [Series/Index of objects]

**See also:**

**index** Return lowest indexes in each strings.

### pandas.Series.str.rjust

`Series.str.rjust` (*width*, *fillchar=' '*)

Filling left side of strings in the Series/Index with an additional character. Equivalent to `str.rjust()`.

**Parameters**

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

**Returns**

**filled** [Series/Index of objects]

### pandas.Series.str.rpartition

`Series.str.rpartition` (*sep=' '*, *expand=True*)

Split the string at the last occurrence of *sep*.

This method splits the string at the last occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

**Parameters**

**sep** [str, default whitespace] String to split on.

**pat** [str, default whitespace] Deprecated since version 0.24.0: Use `sep` instead

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality.  
If False, return Series/Index.

### Returns

**DataFrame/MultiIndex or Series/Index of objects**

See also:

**partition** Split the string at the first occurrence of `sep`.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1          2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1          2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1          2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex(levels=[[ 'X', 'Y'], [ ' '], ['123', '999']],
            codes=[[0, 1], [0, 0], [0, 1]])
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([( 'X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

## pandas.Series.str.rstrip

`Series.str.rstrip` (*to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

Series/Index of objects

See also:

**Series.str.strip** Remove leading and trailing characters in Series/Index.

**Series.str.lstrip** Remove leading characters in Series/Index.

**Series.str.rstrip** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3           NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3           NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3     NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3     NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

## pandas.Series.str.slice

`Series.str.slice` (*start=None, stop=None, step=None*)

Slice substrings from each element in the Series or Index.

### Parameters

**start** [int, optional] Start position for slice operation.

**stop** [int, optional] Stop position for slice operation.

**step** [int, optional] Step size for slice operation.

### Returns

**Series or Index of object** Series or Index from sliced substring from original string object.

**See also:**

**`Series.str.slice_replace`** Replace a slice with a string.

**`Series.str.get`** Return element at position. Equivalent to `Series.str.slice(start=i, stop=i+1)` with *i* being the position.

## Examples

```
>>> s = pd.Series(["koala", "fox", "chameleon"])
>>> s
0    koala
1     fox
2  chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0      oala
1       ox
2  hameleon
dtype: object
```

```
>>> s.str.slice(stop=2)
0    ko
1   fo
2   ch
dtype: object
```

```
>>> s.str.slice(step=2)
0     kaa
1     fx
2   caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0    kl
1     f
2    cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0    kl
1     f
2    cm
dtype: object
```

### pandas.Series.str.slice\_replace

`Series.str.slice_replace` (*start=None, stop=None, repl=None*)

Replace a positional slice of a string with another value.

#### Parameters

**start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

**stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

**repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

#### Returns

**replaced** [Series or Index] Same type as the original object.

See also:

**`Series.str.slice`** Just slicing without replacement.

## Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0      a
1     ab
2    abc
3   abdc
4  abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0      X
1      X
2     Xc
3    Xdc
4   Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1    aX
2    aX
3   aXc
4  aXde
dtype: object
```

## pandas.Series.str.split

`Series.str.split` (*pat=None, n=-1, expand=False*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return `DataFrame`/`MultiIndex` expanding dimensionality.
- If `False`, return `Series`/`Index`, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

### See also:

**`Series.str.split`** Split strings around given separator/delimiter.

**`Series.str.rsplit`** Splits string around given separator/delimiter, starting from the right.

**`Series.str.join`** Join lists contained as elements in the `Series`/`Index` with passed delimiter.

**`str.split`** Standard library version for split.

**`str.rsplit`** Standard library version for rsplit.

### Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits  $> n$ , make first  $n$  splits only
- If found splits  $\leq n$ , make all splits
- If for a certain row the number of found splits  $< n$ , append `None` for padding up to  $n$  if `expand=True`

If using `expand=True`, `Series` and `Index` callers return `DataFrame` and `MultiIndex` objects, respectively.

### Examples

```
>>> s = pd.Series(["this is a regular sentence",
                  "https://docs.python.org/3/tutorial/index.html", np.nan])
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

Without the `n` parameter, the outputs of `rsplit` and `split` are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The `n` parameter can be used to limit the number of splits on the delimiter. The outputs of `split` and `rsplit` are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                          NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
0          0      1      2      3
0          this  is   a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None  None
2          NaN  NaN  NaN  NaN
4
0          sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
0          0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2          NaN      NaN
```

## pandas.Series.str.rsplit

`Series.str.rsplit` (*pat=None, n=-1, expand=False*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return `DataFrame`/`MultiIndex` expanding dimensionality.
- If `False`, return `Series`/`Index`, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

### See also:

**`Series.str.split`** Split strings around given separator/delimiter.

**`Series.str.rsplit`** Splits string around given separator/delimiter, starting from the right.

**`Series.str.join`** Join lists contained as elements in the `Series`/`Index` with passed delimiter.

**`str.split`** Standard library version for split.

**`str.rsplit`** Standard library version for rsplit.

### Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits  $> n$ , make first  $n$  splits only
- If found splits  $\leq n$ , make all splits
- If for a certain row the number of found splits  $< n$ , append `None` for padding up to  $n$  if `expand=True`

If using `expand=True`, `Series` and `Index` callers return `DataFrame` and `MultiIndex` objects, respectively.

### Examples

```
>>> s = pd.Series(["this is a regular sentence",
                  "https://docs.python.org/3/tutorial/index.html", np.nan])
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

Without the `n` parameter, the outputs of `rsplit` and `split` are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

The `n` parameter can be used to limit the number of splits on the delimiter. The outputs of `split` and `rsplit` are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...
2                                          NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
0          0      1      2      3
1  https://docs.python.org/3/tutorial/index.html  None  None  None
2          NaN  NaN  NaN  NaN
4
0  sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
0          0      1
1  https://docs.python.org/3/tutorial  index.html
2          NaN      NaN
```

## pandas.Series.str.startswith

`Series.str.startswith` (*pat*, *na=nan*)

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the start of each string element.

**See also:**

**`str.startswith`** Python standard library string method.

**`Series.str.endswith`** Same as `startswith`, but tests the end of string.

**`Series.str.contains`** Tests if string element contains a pattern.

## Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1   Bear
2    cat
3   NaN
dtype: object
```

```
>>> s.str.startswith('b')
0     True
1    False
2    False
3     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.startswith('b', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

## pandas.Series.str.strip

**`Series.str.strip`** (*to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

### Parameters

**`to_strip`** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

**Series/Index of objects**

**See also:**

**`Series.str.strip`** Remove leading and trailing characters in Series/Index.

**Series.str.lstrip** Remove leading characters in Series/Index.

**Series.str.rstrip** Remove trailing characters in Series/Index.

### Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\ \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!?\ \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

### pandas.Series.str.swapcase

**Series.str.swapcase()**

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

#### Returns

**Series/Index of objects**

**See also:**

**Series.str.lower** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

## pandas.Series.str.title

Series.str.title()

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.

### Returns

Series/Index of objects

See also:

**Series.str.lower** Converts all characters to lowercase.

**Series.str.upper** Converts all characters to uppercase.

**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.

**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.

**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

### Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
```

(continues on next page)

(continued from previous page)

```
2    This is a sentence
3                Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                LOWER
1                capitals
2    THIS IS A SENTENCE
3                sWaPcAsE
dtype: object
```

### pandas.Series.str.translate

`Series.str.translate` (*table*, *deletechars=None*)

Map all characters in the string through the given mapping table. Equivalent to standard `str.translate()`. Note that the optional argument `deletechars` is only valid if you are using python 2. For python 3, character deletion should be specified via the `table` argument.

#### Parameters

**table** [dict (python 3), str or None (python 2)] In python 3, `table` is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables. In python 2, `table` is either a string of length 256 or None. If the `table` argument is None, no translation is applied and the operation simply removes the characters in `deletechars`. `string.maketrans()` is a helper function for making translation tables.

**deletechars** [str, optional (python 2)] A string of characters to delete. This argument is only valid in python 2.

#### Returns

**translated** [Series/Index of objects]

### pandas.Series.str.upper

`Series.str.upper` ()

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

#### Returns

**Series/Index of objects**

See also:

**Series.str.lower** Converts all characters to lowercase.

**Series.str.upper** Converts all characters to uppercase.

**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.

**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.

**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3          SwApCaSe
dtype: object
```

```

0          Lower
1        Capitals
2  This is a sentence
3          Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3          sWaPcAsE
dtype: object
```

## pandas.Series.str.wrap

`Series.str.wrap` (*width*, *\*\*kwargs*)

Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

### Parameters

**width** [int] Maximum line-width

**expand\_tabs** [bool, optional] If true, tab characters will be expanded to spaces (default: True)

**replace\_whitespace** [bool, optional] If true, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True)

**drop\_whitespace** [bool, optional] If true, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True)

**break\_long\_words** [bool, optional] If true, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width. (default: True)

**break\_on\_hyphens** [bool, optional] If true, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words. (default: True)

### Returns

**wrapped** [Series/Index of objects]

### Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's stringr library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`

### Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0          line to be\nwrapped
1  another line\nto be\nwrapped
```

## pandas.Series.str.zfill

`Series.str.zfill` (*width*)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

### Parameters

**width** [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

### Returns

### Series/Index of objects

See also:

***Series.str.rjust*** Fills the left side of strings with an arbitrary character.

***Series.str.ljust*** Fills the right side of strings with an arbitrary character.

***Series.str.pad*** Fills the specified sides of strings with an arbitrary character.

***Series.str.center*** Fills both sides of strings with an arbitrary character.

### Notes

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

### Examples

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2    1000
3       10
4      NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0      0-1
1      001
2    1000
3      NaN
4      NaN
dtype: object
```

## pandas.Series.str.isalnum

`Series.str.isalnum()`

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

**Series.str.isalnum** Check whether all characters are alphanumeric.

**Series.str.isdigit** Check whether all characters are digits.

**Series.str.isdecimal** Check whether all characters are decimal.

**Series.str.isspace** Check whether all characters are whitespace.

**Series.str.islower** Check whether all characters are lowercase.

**Series.str.isupper** Check whether all characters are uppercase.

**Series.str.istitle** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isalpha

`Series.str.isalpha()`

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.isdigit

`Series.str.isdigit()`

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.

**`Series.str.isnumeric`** Check whether all characters are numeric.

**`Series.str.isalnum`** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isspace

`Series.str.isspace()`

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.

**`Series.str.isnumeric`** Check whether all characters are numeric.

**`Series.str.isdecimal`** Check whether all characters are decimal.

**`Series.str.isspace`** Check whether all characters are whitespace.

**`Series.str.islower`** Check whether all characters are lowercase.

**`Series.str.isupper`** Check whether all characters are uppercase.

**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.islower

`Series.str.islower()`

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

**`Series.str.isdecimal`** Check whether all characters are decimal.

**`Series.str.isspace`** Check whether all characters are whitespace.

**`Series.str.islower`** Check whether all characters are lowercase.

**`Series.str.isupper`** Check whether all characters are uppercase.

**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isupper

`Series.str.isupper()`

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.istitle

`Series.str.istitle()`

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.

**`Series.str.isnumeric`** Check whether all characters are numeric.

**`Series.str.isalnum`** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isnumeric

`Series.str.isnumeric()`

Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.isdecimal

`Series.str.isdecimal()`

Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.get\_dummies

`Series.str.get_dummies` (*sep*='|')

Split each string in the Series by *sep* and return a frame of dummy/indicator variables.

### Parameters

**sep** [string, default "|"] String to split on.

### Returns

**dummies** [DataFrame]

### See also:

`get_dummies`

## Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

## Categorical Accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<code>Series.cat.categories</code>	The categories of this categorical.
<code>Series.cat.ordered</code>	Whether the categories have an ordered relationship.
<code>Series.cat.codes</code>	Return Series of codes as well as the index.

## pandas.Series.cat.categories

`Series.cat.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

**Raises**

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

*rename\_categories*, *reorder\_categories*, *add\_categories*, *remove\_categories*, *remove\_unused\_categories*, *set\_categories*

**pandas.Series.cat.ordered**

`Series.cat.ordered`

Whether the categories have an ordered relationship.

**pandas.Series.cat.codes**

`Series.cat.codes`

Return Series of codes as well as the index.

<code>Series.cat.rename_categories(*args, **kwargs)</code>	Renames categories.
<code>Series.cat.reorder_categories(*args, **kwargs)</code>	Reorders categories as specified in <code>new_categories</code> .
<code>Series.cat.add_categories(*args, **kwargs)</code>	Add new categories.
<code>Series.cat.remove_categories(*args, **kwargs)</code>	Removes the specified categories.
<code>Series.cat.remove_unused_categories(*args, **kwargs)</code>	Removes categories which are not used.
<code>Series.cat.set_categories(*args, **kwargs)</code>	Sets the categories to the specified <code>new_categories</code> .
<code>Series.cat.as_ordered(*args, **kwargs)</code>	Set the Categorical to be ordered.
<code>Series.cat.as_unordered(*args, **kwargs)</code>	Set the Categorical to be unordered.

**pandas.Series.cat.rename\_categories**

`Series.cat.rename_categories(*args, **kwargs)`

Renames categories.

**Parameters**

**new\_categories** [list-like, dict-like or callable]

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0.

- `callable` : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

**Warning:** Currently, Series are considered list like. In a future version of pandas they'll be considered dict-like.

**inplace** [boolean (default: False)] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

#### Returns

**cat** [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

#### Raises

**ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

#### See also:

`reorder_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`, `set_categories`

#### Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

### pandas.Series.cat.reorder\_categories

`Series.cat.reorder_categories` (\*args, \*\*kwargs)

Reorders categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, optional] Whether or not the categorical is treated as a ordered categorical.  
If not given, do not change the ordered information.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

**cat** [Categorical with reordered categories or None if inplace.]

**Raises**

**ValueError** If the new categories do not contain all old category items or any new ones

**See also:**

*rename\_categories*, *add\_categories*, *remove\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.add\_categories

`Series.cat.add_categories(*args, **kwargs)`

Add new categories.

*new\_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

**new\_categories** [category or list-like of category] The new categories to be included.

**inplace** [boolean (default: False)] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

**cat** [Categorical with new categories added or None if inplace.]

**Raises**

**ValueError** If the new categories include old categories or do not validate as categories

**See also:**

*rename\_categories*, *reorder\_categories*, *remove\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.remove\_categories

`Series.cat.remove_categories(*args, **kwargs)`

Removes the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

**Parameters**

**removals** [category or list of categories] The categories which should be removed.

**inplace** [boolean (default: False)] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Returns**

**cat** [Categorical with removed categories or None if inplace.]

#### Raises

**ValueError** If the removals are not contained in the categories

#### See also:

*rename\_categories*, *reorder\_categories*, *add\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.remove\_unused\_categories

`Series.cat.remove_unused_categories(*args, **kwargs)`

Removes categories which are not used.

#### Parameters

**inplace** [boolean (default: False)] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

#### Returns

**cat** [Categorical with unused categories dropped or None if inplace.]

#### See also:

*rename\_categories*, *reorder\_categories*, *add\_categories*, *remove\_categories*,  
*set\_categories*

### pandas.Series.cat.set\_categories

`Series.cat.set_categories(*args, **kwargs)`

Sets the categories to the specified `new_categories`.

*new\_categories* can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not consider a S1 string equal to a single char python string.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, (default: False)] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**rename** [boolean (default: False)] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

#### Returns

**cat** [Categorical with reordered categories or None if inplace.]

### Raises

**ValueError** If `new_categories` does not validate as categories

### See also:

`rename_categories`, `reorder_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`

## pandas.Series.cat.as\_ordered

`Series.cat.as_ordered(*args, **kwargs)`

Set the Categorical to be ordered.

### Parameters

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to True

## pandas.Series.cat.as\_unordered

`Series.cat.as_unordered(*args, **kwargs)`

Set the Categorical to be unordered.

### Parameters

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to False

## Sparse Accessor

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

<code>Series.sparse.npoints</code>	The number of non- <code>fill_value</code> points.
<code>Series.sparse.density</code>	The percent of non- <code>fill_value</code> points, as decimal.
<code>Series.sparse.fill_value</code>	Elements in <code>data</code> that are <code>fill_value</code> are not stored.
<code>Series.sparse.sp_values</code>	An ndarray containing the non- <code>fill_value</code> values.

## pandas.Series.sparse.npoints

`Series.sparse.npoints`

The number of non- `fill_value` points.

### Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

### pandas.Series.sparse.density

#### Series.sparse.density

The percent of non- `fill_value` points, as decimal.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

### pandas.Series.sparse.fill\_value

#### Series.sparse.fill\_value

Elements in *data* that are *fill\_value* are not stored.

For memory savings, this should be the most common value in the array.

### pandas.Series.sparse.sp\_values

#### Series.sparse.sp\_values

An ndarray containing the non- `fill_value` values.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

*Series.sparse.from\_coo*(A[, dense\_index])

Create a SparseSeries from a `scipy.sparse.coo_matrix`.

*Series.sparse.to\_coo*([row\_levels, ...])

Create a `scipy.sparse.coo_matrix` from a SparseSeries with MultiIndex.

### pandas.Series.sparse.from\_coo

**classmethod** `sparse.from_coo` (A, dense\_index=False)

Create a SparseSeries from a `scipy.sparse.coo_matrix`.

#### Parameters

**A** [`scipy.sparse.coo_matrix`]

**dense\_index** [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original `coo_matrix`. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the `coo_matrix`.

#### Returns

s [`SparseSeries`]

## Examples

```

>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                          shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
 3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)

```

## pandas.Series.sparse.to\_coo

`sparse.to_coo` (*row\_levels=(0, ), column\_levels=(1, ), sort\_labels=False*)

Create a `scipy.sparse.coo_matrix` from a `SparseSeries` with `MultiIndex`.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the `MultiIndex` level names (or numbers).

### Parameters

**row\_levels** [tuple/list]

**column\_levels** [tuple/list]

**sort\_labels** [bool, default False] Sort the row and column labels before forming the sparse matrix.

### Returns

**y** [`scipy.sparse.coo_matrix`]

**rows** [list (row labels)]

**columns** [list (column labels)]

## Examples

```

>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],

```

(continues on next page)

(continued from previous page)

```

names=['A', 'B', 'C', 'D'])
>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
 [ 3.,  0.,  0.,  0.],
 [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]

```

### 6.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

<code>Series.plot([kind, ax, figsize, ...])</code>	Series plotting accessor and method
<code>Series.plot.area(**kwargs)</code>	Area plot.
<code>Series.plot.bar(**kwargs)</code>	Vertical bar plot.
<code>Series.plot.barh(**kwargs)</code>	Horizontal bar plot.
<code>Series.plot.box(**kwargs)</code>	Boxplot.
<code>Series.plot.density([bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.hist([bins])</code>	Histogram.
<code>Series.plot.kde([bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.line(**kwargs)</code>	Line plot.
<code>Series.plot.pie(**kwargs)</code>	Pie chart.

#### pandas.Series.plot.area

`Series.plot.area(**kwargs)`  
Area plot.

##### Parameters

**‘\*\*kwargs’** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

##### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### pandas.Series.plot.bar

`Series.plot.bar(**kws)`  
Vertical bar plot.

#### Parameters

**\*\*kws** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### pandas.Series.plot.barh

`Series.plot.barh(**kws)`  
Horizontal bar plot.

#### Parameters

**\*\*kws** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### pandas.Series.plot.box

`Series.plot.box(**kws)`  
Boxplot.

#### Parameters

**\*\*kws** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### pandas.Series.plot.density

`Series.plot.density(bw_method=None, ind=None, **kws)`  
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

#### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

#### See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

`DataFrame.plot.kde` Generate a KDE plot for a DataFrame.

#### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

### pandas.Series.plot.hist

`Series.plot.hist` (*bins=10, \*\*kwargs*)

Histogram.

#### Parameters

**bins** [integer, default 10] Number of histogram bins to be used

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

## pandas.Series.plot.kde

`Series.plot.kde` (*bw\_method=None, ind=None, \*\*kws*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kws** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

### See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

`DataFrame.plot.kde` Generate a KDE plot for a DataFrame.

## Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

## pandas.Series.plot.line

`Series.plot.line` (*\*\*kws*)

Line plot.

**Parameters**

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

**Examples**

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

**pandas.Series.plot.pie**

`Series.plot.pie(**kwargs)`

Pie chart.

**Parameters**

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

---

`Series.hist([by, ax, grid, xlabelsize, ...])` Draw histogram of the input series using matplotlib.

---

**6.3.15 Serialization / IO / Conversion**

<code>Series.to_pickle(path[, compression, protocol])</code>	Pickle (serialize) object to file.
<code>Series.to_csv(*args, **kwargs)</code>	Write object to a comma-separated values (csv) file.
<code>Series.to_dict([into])</code>	Convert Series to {label -> value} dict or dict-like object.
<code>Series.to_excel(excel_writer[, sheet_name, ...])</code>	Write object to an Excel sheet.
<code>Series.to_frame([name])</code>	Convert Series to DataFrame.
<code>Series.to_xarray()</code>	Return an xarray object from the pandas object.
<code>Series.to_hdf(path_or_buf, key, **kwargs)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>Series.to_sql(name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>Series.to_msgpack([path_or_buf, encoding])</code>	Serialize object to input file path using msgpack format.
<code>Series.to_json([path_or_buf, orient, ...])</code>	Convert the object to a JSON string.
<code>Series.to_sparse([kind, fill_value])</code>	Convert Series to SparseSeries.
<code>Series.to_dense()</code>	Return dense representation of NDFrame (as opposed to sparse).
<code>Series.to_string([buf, na_rep, ...])</code>	Render a string representation of the Series.
<code>Series.to_clipboard([excel, sep])</code>	Copy object to the system clipboard.
<code>Series.to_latex([buf, columns, col_space, ...])</code>	Render an object to a LaTeX tabular environment table.

### 6.3.16 Sparse

<code>SparseSeries.to_coo([row_levels,...])</code>	Create a <code>scipy.sparse.coo_matrix</code> from a <code>SparseSeries</code> with <code>MultiIndex</code> .
<code>SparseSeries.from_coo(A[, dense_index])</code>	Create a <code>SparseSeries</code> from a <code>scipy.sparse.coo_matrix</code> .

#### pandas.SparseSeries.to\_coo

`SparseSeries.to_coo` (`row_levels=(0,)`, `column_levels=(1,)`, `sort_labels=False`)

Create a `scipy.sparse.coo_matrix` from a `SparseSeries` with `MultiIndex`.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the `MultiIndex` level names (or numbers).

#### Parameters

**row\_levels** [tuple/list]

**column\_levels** [tuple/list]

**sort\_labels** [bool, default False] Sort the row and column labels before forming the sparse matrix.

#### Returns

**y** [`scipy.sparse.coo_matrix`]

**rows** [list (row labels)]

**columns** [list (column labels)]

#### Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
                                         names=['A', 'B', 'C', 'D'])

>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

## pandas.SparseSeries.from\_coo

**classmethod** `SparseSeries.from_coo` (*A*, *dense\_index=False*)

Create a `SparseSeries` from a `scipy.sparse.coo_matrix`.

### Parameters

**A** [`scipy.sparse.coo_matrix`]

**dense\_index** [`bool`, default `False`] If `False` (default), the `SparseSeries` index consists of only the coords of the non-null entries of the original `coo_matrix`. If `True`, the `SparseSeries` index consists of the full sorted (row, col) coordinates of the `coo_matrix`.

### Returns

**s** [`SparseSeries`]

## Examples

```

>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                          shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64''>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
 3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)

```

## 6.4 DataFrame

### 6.4.1 Constructor

`DataFrame`(*[data, index, columns, dtype, copy]*)

Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns).

## pandas.DataFrame

**class** `pandas.DataFrame` (*data=None, index=None, columns=None, dtype=None, copy=False*)

Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

### Parameters

**data** [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, or list-like objects

Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

**index** [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided

**columns** [Index or array-like] Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, ..., n) if no column labels are provided

**dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer

**copy** [boolean, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input

### See also:

**DataFrame.from\_records** Constructor from tuples, also record arrays.

**DataFrame.from\_dict** From dicts of Series, arrays, or dicts.

**DataFrame.from\_items** From sequence of (key, value) pairs pandas.read\_csv, pandas.read\_table, pandas.read\_clipboard.

### Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0      1     3
1      2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                     columns=['a', 'b', 'c'])
>>> df2
```

(continues on next page)

(continued from previous page)

	a	b	c
0	1	2	3
1	4	5	6
2	7	8	9

## Attributes

<i>T</i>	Transpose index and columns.
<i>at</i>	Access a single value for a row/column label pair.
<i>axes</i>	Return a list representing the axes of the DataFrame.
<i>blocks</i>	(DEPRECATED) Internal property, property synonym for <code>as_blocks()</code> .
<i>columns</i>	The column labels of the DataFrame.
<i>dtypes</i>	Return the dtypes in the DataFrame.
<i>empty</i>	Indicator whether DataFrame is empty.
<i>ftypes</i>	Return the ftypes (indication of sparse/dense and dtype) in DataFrame.
<i>iat</i>	Access a single value for a row/column pair by integer position.
<i>iloc</i>	Purely integer-location based indexing for selection by position.
<i>index</i>	The index (row labels) of the DataFrame.
<i>is_copy</i>	Return the copy.
<i>ix</i>	A primarily label-location based indexer, with integer position fallback.
<i>loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>ndim</i>	Return an int representing the number of axes / array dimensions.
<i>shape</i>	Return a tuple representing the dimensionality of the DataFrame.
<i>size</i>	Return an int representing the number of elements in this object.
<i>style</i>	Property returning a Styler object containing methods for building a styled HTML representation fo the DataFrame.
<i>values</i>	Return a Numpy representation of the DataFrame.

## pandas.DataFrame.T

`DataFrame.T`

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method `transpose()`.

### Parameters

**copy** [bool, default False] If True, the underlying data is copied. Otherwise (default), no copy is made if possible.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**DataFrame** The transposed DataFrame.

### See also:

`numpy.transpose` Permute the dimensions of a given array.

### Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

### Examples

#### Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
col1 1  2
col2 3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

#### Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False     0
1   Bob   8.0      True     0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0  1
name   Alice  Bob
score   9.5   8
employed False  True
kids     0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name          object
score        float64
employed      bool
kids          int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

## pandas.DataFrame.at

### DataFrame.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**KeyError** When label does not exist in DataFrame

#### See also:

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

## pandas.DataFrame.axes

`DataFrame.axes`

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

### Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

## pandas.DataFrame.blocks

`DataFrame.blocks`

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

## pandas.DataFrame.columns

`DataFrame.columns`

The column labels of the DataFrame.

## pandas.DataFrame.dtypes

`DataFrame.dtypes`

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

### Returns

**pandas.Series** The data type of each column.

**See also:**

**pandas.DataFrame.ftypes** Dtype and sparsity information.

## Examples

```

>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float          float64
int           int64
datetime      datetime64[ns]
string        object
dtype: object

```

## pandas.DataFrame.empty

### DataFrame.empty

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

### Returns

**bool** If DataFrame is empty, return True, if not return False.

### See also:

*pandas.Series.dropna*, *pandas.DataFrame.dropna*

### Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

## Examples

An example of an actual empty DataFrame. Notice the index is empty:

```

>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True

```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```

>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True

```

## pandas.DataFrame.ftypes

### DataFrame.ftypes

Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

#### Returns

**pandas.Series** The data type and indication of sparse/dense of each column.

#### See also:

**pandas.DataFrame.dtypes** Series with just dtype information.

**pandas.SparseDataFrame** Container for sparse tabular data.

## Notes

Sparse data should have the same dtypes as its dense representation.

## Examples

```
>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).ftypes
0    float64:dense
1    float64:dense
2    float64:dense
3    float64:dense
dtype: object
```

```
>>> pd.SparseDataFrame(arr).ftypes
0    float64:sparse
1    float64:sparse
2    float64:sparse
3    float64:sparse
dtype: object
```

## pandas.DataFrame.iat

### DataFrame.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**IndexError** When integer position is out of bounds

#### See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.loc** Access a group of rows and columns by label(s).

**DataFrame.iloc** Access a group of rows and columns by integer position(s).

### Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.DataFrame.iloc

### DataFrame.iloc

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [ref:Selection by Position <indexing.integer>](#).

**See also:**

**DataFrame.iat** Fast integer location scalar accessor.

**DataFrame.loc** Purely label-location based indexer for selection by label.

**Series.iloc** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
```

	a	b	c	d
0	1	2	3	4
1	100	200	300	400
2	1000	2000	3000	4000

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
```

	a	b	c	d
0	1	2	3	4

Name: 0, dtype: int64

With a list of integers.

```
>>> df.iloc[[0]]
```

	a	b	c	d
0	1	2	3	4

```
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
```

	a	b	c	d
0	1	2	3	4
1	100	200	300	400

With a *slice* object.

```
>>> df.iloc[:3]
```

	a	b	c	d
0	1	2	3	4
1	100	200	300	400
2	1000	2000	3000	4000

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
```

	a	b	c	d
0	1	2	3	4
2	1000	2000	3000	4000

With a callable, useful in method chains. The `x` passed to the `lambda` is the `DataFrame` being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the `Series` or `DataFrame`.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

## pandas.DataFrame.index

### `DataFrame.index`

The index (row labels) of the `DataFrame`.

## pandas.DataFrame.is\_copy

### `DataFrame.is_copy`

Return the copy.

## pandas.DataFrame.ix

### DataFrame.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.

.ix[] supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

.ix is the most general indexer and will support any of the inputs in .loc and .iloc. .ix also supports floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use .iloc or .loc.

See more at *Advanced Indexing*.

## pandas.DataFrame.loc

### DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

### Raises

**KeyError:** when any items are not found

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
```

	max_speed	shield
cobra	1	2
viper	4	5
sidewinder	7	8

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
max_speed  shield
viper      4      5
sidewinder 7      8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
max_speed  shield
sidewinder  7      8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
max_speed  shield
sidewinder  7      8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
max_speed
sidewinder    7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
      max_speed  shield
sidewinder      7      8
```

### Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
      max_speed  shield
cobra           1      2
viper           4     50
sidewinder      7     50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
      max_speed  shield
cobra         10     10
viper          4     50
sidewinder     7     50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
      max_speed  shield
cobra         30     10
viper         30     50
sidewinder    30     50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
      max_speed  shield
cobra         30     10
viper          0      0
sidewinder     0      0
```

### Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
7             1      2
8             4      5
9             7      8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

### Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
```

		max_speed	shield
cobra	mark i	12	2
	mark ii	0	4
sidewinder	mark i	10	20
	mark ii	1	4
viper	mark ii	7	1
	mark iii	16	36

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
   max_speed  shield
mark i       12       2
mark ii       0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield        4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield        2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [ [] ] returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
   max_speed  shield
cobra mark ii    0     4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'): 'viper']
      max_speed  shield
cobra  mark i      12     2
      mark ii     0     4
sidewinder mark i    10    20
      mark ii     1     4
viper  mark ii     7     1
      mark iii    16    36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'): ('viper', 'mark ii')]
      max_speed  shield
cobra  mark i      12     2
      mark ii     0     4
sidewinder mark i    10    20
      mark ii     1     4
viper  mark ii     7     1
```

## pandas.DataFrame.ndim

DataFrame.**ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**See also:**

**ndarray.ndim** Number of array dimensions.

### Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

## pandas.DataFrame.shape

DataFrame.**shape**

Return a tuple representing the dimensionality of the DataFrame.

**See also:**

**ndarray.shape**

## Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```

## pandas.DataFrame.size

### DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

### See also:

**ndarray.size** Number of elements in the array.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

## pandas.DataFrame.style

### DataFrame.style

Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.

### See also:

*pandas.io.formats.style.Styler*

## pandas.DataFrame.values

### DataFrame.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

### Returns

`numpy.ndarray` The values of the DataFrame.

### See also:

`DataFrame.to_numpy` Recommended alternative to this method.

`pandas.DataFrame.index` Retrieve the index labels.

`pandas.DataFrame.columns` Retrieving the column names.

### Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

### Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age': [ 3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age          int64
height       int64
weight       int64
dtype: object
>>> df.values
array([[ 3,  94,  31],
       [29, 170, 115]], dtype=int64)
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                    ('lion', 80.5, 1),
...                    ('monkey', np.nan, None)],
...                    columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
```

(continues on next page)

(continued from previous page)

```
array([[ 'parrot', 24.0, 'second'],
      [ 'lion', 80.5, 1],
      [ 'monkey', nan, None]], dtype=object)
```

**timetuple****Methods**

<code>abs()</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>add(other[, axis, level, fill_value])</code>	Addition of dataframe and other, element-wise (binary operator <i>add</i> ).
<code>add_prefix(prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>add_suffix(suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>agg(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>aggregate(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>align(other[, join, axis, level, copy, ...])</code>	Align two objects on their axes with the specified join method for each axis Index.
<code>all([axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>any([axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>append(other[, ignore_index, ...])</code>	Append rows of <i>other</i> to the end of caller, returning a new object.
<code>apply(func[, axis, broadcast, raw, reduce, ...])</code>	Apply a function along an axis of the DataFrame.
<code>applymap(func)</code>	Apply a function to a Dataframe elementwise.
<code>as_blocks(copy)</code>	(DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.
<code>as_matrix([columns])</code>	(DEPRECATED) Convert the frame to its Numpy-array representation.
<code>asfreq(freq[, method, how, normalize, ...])</code>	Convert TimeSeries to specified frequency.
<code>asof(when[, subset])</code>	Return the last row(s) without any NaNs before <i>when</i> .
<code>assign(**kwargs)</code>	Assign new columns to a DataFrame.
<code>astype(dtype[, copy, errors])</code>	Cast a pandas object to a specified dtype <i>dtype</i> .
<code>at_time(time[, asof, axis])</code>	Select values at particular time of day (e.g.
<code>between_time(start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool()</code>	Return the bool of a single element PandasObject.
<code>boxplot([column, by, ax, fontsize, rot, ...])</code>	Make a box plot from DataFrame columns.
<code>clip([lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>clip_lower(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values below a given threshold.

Continued on next page

Table 57 – continued from previous page

<code>clip_upper(threshold[, axis, inplace])</code>	(DEPRECATED) Trim values above a given threshold.
<code>combine(other, func[, fill_value, overwrite])</code>	Perform column-wise combine with another DataFrame based on a passed function.
<code>combine_first(other)</code>	Update null elements with value in the same location in <i>other</i> .
<code>compound([axis, skipna, level])</code>	Return the compound percentage of the values for the requested axis.
<code>convert_objects([convert_dates, ...])</code>	(DEPRECATED) Attempt to infer better dtype for object columns.
<code>copy([deep])</code>	Make a copy of this object's indices and data.
<code>corr([method, min_periods])</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>corrwith(other[, axis, drop, method])</code>	Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame.
<code>count([axis, level, numeric_only])</code>	Count non-NA cells for each column or row.
<code>cov([min_periods])</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>cummax([axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin([axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod([axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum([axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe([percentiles, include, exclude])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>diff([periods, axis])</code>	First discrete difference of element.
<code>div(other[, axis, level, fill_value])</code>	Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>divide(other[, axis, level, fill_value])</code>	Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>dot(other)</code>	Compute the matrix multiplication between the DataFrame and other.
<code>drop([labels, axis, index, columns, level, ...])</code>	Drop specified labels from rows or columns.
<code>drop_duplicates([subset, keep, inplace])</code>	Return DataFrame with duplicate rows removed, optionally only considering certain columns.
<code>droplevel(level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna([axis, how, thresh, subset, inplace])</code>	Remove missing values.
<code>duplicated([subset, keep])</code>	Return boolean Series denoting duplicate rows, optionally only considering certain columns.
<code>eq(other[, axis, level])</code>	Equal to of dataframe and other, element-wise (binary operator <i>eq</i> ).
<code>equals(other)</code>	Test whether two objects contain the same elements.
<code>eval(expr[, inplace])</code>	Evaluate a string describing operations on DataFrame columns.
<code>ewm([com, span, halflife, alpha, ...])</code>	Provides exponential weighted functions.

Continued on next page

Table 57 – continued from previous page

<code>expanding([min_periods, center, axis])</code>	Provides expanding transformations.
<code>ffill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna([value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter([items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.
<code>first(offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>first_valid_index()</code>	Return index for first non-NA/null value.
<code>floordiv(other[, axis, level, fill_value])</code>	Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code> ).
<code>from_csv(path[, header, sep, index_col, ...])</code>	(DEPRECATED) Read CSV file.
<code>from_dict(data[, orient, dtype, columns])</code>	Construct DataFrame from dict of array-like or dicts.
<code>from_items(items[, columns, orient])</code>	(DEPRECATED) Construct a DataFrame from a list of tuples.
<code>from_records(data[, index, exclude, ...])</code>	Convert structured or record ndarray to DataFrame.
<code>ge(other[, axis, level])</code>	Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code> ).
<code>get(key[, default])</code>	Get item from object for given key (DataFrame column, Panel slice, etc.).
<code>get_dtype_counts()</code>	Return counts of unique dtypes in this object.
<code>get_ftype_counts()</code>	(DEPRECATED) Return counts of unique ftypes in this object.
<code>get_value(index, col[, takeable])</code>	(DEPRECATED) Quickly retrieve single value at passed column and index.
<code>get_values()</code>	Return an ndarray after converting sparse values to dense.
<code>groupby([by, axis, level, as_index, sort, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>gt(other[, axis, level])</code>	Greater than of dataframe and other, element-wise (binary operator <code>gt</code> ).
<code>head([n])</code>	Return the first <i>n</i> rows.
<code>hist([column, by, grid, xlabelsize, xrot, ...])</code>	Make a histogram of the DataFrame's.
<code>idxmax([axis, skipna])</code>	Return index of first occurrence of maximum over requested axis.
<code>idxmin([axis, skipna])</code>	Return index of first occurrence of minimum over requested axis.
<code>infer_objects()</code>	Attempt to infer better dtypes for object columns.
<code>info([verbose, buf, max_cols, memory_usage, ...])</code>	Print a concise summary of a DataFrame.
<code>insert(loc, column, value[, allow_duplicates])</code>	Insert column into DataFrame at specified location.
<code>interpolate([method, axis, limit, inplace, ...])</code>	Interpolate values according to different methods.
<code>isin(values)</code>	Whether each element in the DataFrame is contained in values.
<code>isna()</code>	Detect missing values.
<code>isnull()</code>	Detect missing values.
<code>items()</code>	Iterator over (column name, Series) pairs.
<code>iteritems()</code>	Iterator over (column name, Series) pairs.
<code>iterrows()</code>	Iterate over DataFrame rows as (index, Series) pairs.
<code>itertuples([index, name])</code>	Iterate over DataFrame rows as namedtuples.
<code>join(other[, on, how, lsuffix, rsuffix, sort])</code>	Join columns of another DataFrame.

Continued on next page

Table 57 – continued from previous page

<code>keys()</code>	Get the ‘info axis’ (see Indexing for more)
<code>kurt([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0).
<code>kurtosis([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0).
<code>last(offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>last_valid_index()</code>	Return index for last non-NA/null value.
<code>le(other[, axis, level])</code>	Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i> ).
<code>lookup(row_labels, col_labels)</code>	Label-based “fancy indexing” function for DataFrame.
<code>lt(other[, axis, level])</code>	Less than of dataframe and other, element-wise (binary operator <i>lt</i> ).
<code>mad([axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>mask(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is True.
<code>max([axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>mean([axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>median([axis, skipna, level, numeric_only])</code>	Return the median of the values for the requested axis.
<code>melt([id_vars, value_vars, var_name, ...])</code>	Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.
<code>memory_usage([index, deep])</code>	Return the memory usage of each column in bytes.
<code>merge(right[, how, on, left_on, right_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>min([axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>mod(other[, axis, level, fill_value])</code>	Modulo of dataframe and other, element-wise (binary operator <i>mod</i> ).
<code>mode([axis, numeric_only, dropna])</code>	Get the mode(s) of each element along the selected axis.
<code>mul(other[, axis, level, fill_value])</code>	Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).
<code>multiply(other[, axis, level, fill_value])</code>	Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).
<code>ne(other[, axis, level])</code>	Not equal to of dataframe and other, element-wise (binary operator <i>ne</i> ).
<code>nlargest(n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in descending order.
<code>notna()</code>	Detect existing (non-missing) values.
<code>notnull()</code>	Detect existing (non-missing) values.
<code>nsmallest(n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order.
<code>nunique([axis, dropna])</code>	Count distinct observations over requested axis.
<code>pct_change([periods, fill_method, limit, freq])</code>	Percentage change between the current and a prior element.
<code>pipe(func, *args, **kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .

Continued on next page

Table 57 – continued from previous page

<code>pivot([index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table([values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>plot</code>	alias of <code>pandas.plotting._core.FramePlotMethods</code>
<code>pop(item)</code>	Return item and drop from frame.
<code>pow(other[, axis, level, fill_value])</code>	Exponential power of dataframe and other, element-wise (binary operator <code>pow</code> ).
<code>prod([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values for the requested axis.
<code>product([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values for the requested axis.
<code>quantile([q, axis, numeric_only, interpolation])</code>	Return values at the given quantile over requested axis.
<code>query(expr[, inplace])</code>	Query the columns of a DataFrame with a boolean expression.
<code>radd(other[, axis, level, fill_value])</code>	Addition of dataframe and other, element-wise (binary operator <code>radd</code> ).
<code>rank([axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through n) along axis.
<code>rdiv(other[, axis, level, fill_value])</code>	Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code> ).
<code>reindex([labels, index, columns, axis, ...])</code>	Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>reindex_axis(labels[, axis, method, level, ...])</code>	(DEPRECATED) Conform input object to new index.
<code>reindex_like(other[, method, copy, limit, ...])</code>	Return an object with matching indices as other object.
<code>rename([mapper, index, columns, axis, copy, ...])</code>	Alter axes labels.
<code>rename_axis([mapper, index, columns, axis, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(order[, axis])</code>	Rearrange index levels using input order.
<code>replace([to_replace, value, inplace, limit, ...])</code>	Replace values given in <code>to_replace</code> with <code>value</code> .
<code>resample(rule[, how, axis, fill_method, ...])</code>	Resample time-series data.
<code>reset_index([level, drop, inplace, ...])</code>	Reset the index, or a level of it.
<code>rfloordiv(other[, axis, level, fill_value])</code>	Integer division of dataframe and other, element-wise (binary operator <code>rfloordiv</code> ).
<code>rmod(other[, axis, level, fill_value])</code>	Modulo of dataframe and other, element-wise (binary operator <code>rmod</code> ).
<code>rmul(other[, axis, level, fill_value])</code>	Multiplication of dataframe and other, element-wise (binary operator <code>rmul</code> ).
<code>rolling(window[, min_periods, center, ...])</code>	Provides rolling window calculations.
<code>round([decimals])</code>	Round a DataFrame to a variable number of decimal places.
<code>rpow(other[, axis, level, fill_value])</code>	Exponential power of dataframe and other, element-wise (binary operator <code>rpow</code> ).
<code>rsub(other[, axis, level, fill_value])</code>	Subtraction of dataframe and other, element-wise (binary operator <code>rsub</code> ).

Continued on next page

Table 57 – continued from previous page

<code>rtruediv</code> ( <i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i> ])	Floating division of dataframe and <i>other</i> , element-wise (binary operator <i>rtruediv</i> ).
<code>sample</code> ( <i>n</i> , <i>frac</i> , <i>replace</i> , <i>weights</i> , ...)	Return a random sample of items from an axis of object.
<code>select</code> ( <i>crit</i> [, <i>axis</i> ])	(DEPRECATED) Return data corresponding to axis labels matching criteria.
<code>select_dtypes</code> ( <i>include</i> , <i>exclude</i> )	Return a subset of the DataFrame’s columns based on the column dtypes.
<code>sem</code> ( <i>axis</i> , <i>skipna</i> , <i>level</i> , <i>ddof</i> , <i>numeric_only</i> )	Return unbiased standard error of the mean over requested axis.
<code>set_axis</code> ( <i>labels</i> [, <i>axis</i> , <i>inplace</i> ])	Assign desired index to given axis.
<code>set_index</code> ( <i>keys</i> [, <i>drop</i> , <i>append</i> , <i>inplace</i> , ...])	Set the DataFrame index using existing columns.
<code>set_value</code> ( <i>index</i> , <i>col</i> , <i>value</i> [, <i>takeable</i> ])	(DEPRECATED) Put single value at passed column and index.
<code>shift</code> ( <i>periods</i> , <i>freq</i> , <i>axis</i> , <i>fill_value</i> )	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>skew</code> ( <i>axis</i> , <i>skipna</i> , <i>level</i> , <i>numeric_only</i> )	Return unbiased skew over requested axis Normalized by N-1.
<code>slice_shift</code> ( <i>periods</i> , <i>axis</i> )	Equivalent to <i>shift</i> without copying data.
<code>sort_index</code> ( <i>axis</i> , <i>level</i> , <i>ascending</i> , ...)	Sort object by labels (along an axis)
<code>sort_values</code> ( <i>by</i> [, <i>axis</i> , <i>ascending</i> , <i>inplace</i> , ...])	Sort by the values along either axis
<code>squeeze</code> ( <i>axis</i> )	Squeeze 1 dimensional axis objects into scalars.
<code>stack</code> ( <i>level</i> , <i>dropna</i> )	Stack the prescribed level(s) from columns to index.
<code>std</code> ( <i>axis</i> , <i>skipna</i> , <i>level</i> , <i>ddof</i> , <i>numeric_only</i> )	Return sample standard deviation over requested axis.
<code>sub</code> ( <i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i> ])	Subtraction of dataframe and <i>other</i> , element-wise (binary operator <i>sub</i> ).
<code>subtract</code> ( <i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i> ])	Subtraction of dataframe and <i>other</i> , element-wise (binary operator <i>sub</i> ).
<code>sum</code> ( <i>axis</i> , <i>skipna</i> , <i>level</i> , <i>numeric_only</i> , ...)	Return the sum of the values for the requested axis.
<code>swapaxes</code> ( <i>axis1</i> , <i>axis2</i> [, <i>copy</i> ])	Interchange axes and swap values axes appropriately.
<code>swaplevel</code> ( <i>i</i> , <i>j</i> , <i>axis</i> )	Swap levels <i>i</i> and <i>j</i> in a MultiIndex on a particular axis.
<code>tail</code> ( <i>n</i> )	Return the last <i>n</i> rows.
<code>take</code> ( <i>indices</i> [, <i>axis</i> , <i>convert</i> , <i>is_copy</i> ])	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard</code> ( <i>excel</i> , <i>sep</i> )	Copy object to the system clipboard.
<code>to_csv</code> ( <i>path_or_buf</i> , <i>sep</i> , <i>na_rep</i> , ...)	Write object to a comma-separated values (csv) file.
<code>to_dense</code> ()	Return dense representation of NDFrame (as opposed to sparse).
<code>to_dict</code> ( <i>orient</i> , <i>into</i> )	Convert the DataFrame to a dictionary.
<code>to_excel</code> ( <i>excel_writer</i> [, <i>sheet_name</i> , <i>na_rep</i> , ...])	Write object to an Excel sheet.
<code>to_feather</code> ( <i>fname</i> )	Write out the binary feather-format for DataFrames.
<code>to_gbq</code> ( <i>destination_table</i> [, <i>project_id</i> , ...])	Write a DataFrame to a Google BigQuery table.
<code>to_hdf</code> ( <i>path_or_buf</i> , <i>key</i> , ** <i>kwargs</i> )	Write the contained data to an HDF5 file using HDF-Store.
<code>to_html</code> ( <i>buf</i> , <i>columns</i> , <i>col_space</i> , <i>header</i> , ...)	Render a DataFrame as an HTML table.
<code>to_json</code> ( <i>path_or_buf</i> , <i>orient</i> , <i>date_format</i> , ...)	Convert the object to a JSON string.
<code>to_latex</code> ( <i>buf</i> , <i>columns</i> , <i>col_space</i> , <i>header</i> , ...)	Render an object to a LaTeX tabular environment table.

Continued on next page

Table 57 – continued from previous page

<code>to_msgpack([path_or_buf, encoding])</code>	Serialize object to input file path using msgpack format.
<code>to_numpy([dtype, copy])</code>	Convert the DataFrame to a NumPy array.
<code>to_panel()</code>	(DEPRECATED) Transform long (stacked) format (DataFrame) into wide (3D, Panel) format.
<code>to_parquet(fname[, engine, compression, ...])</code>	Write a DataFrame to the binary parquet format.
<code>to_period([freq, axis, copy])</code>	Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>to_pickle(path[, compression, protocol])</code>	Pickle (serialize) object to file.
<code>to_records([index, convert_datetime64, ...])</code>	Convert DataFrame to a NumPy record array.
<code>to_sparse([fill_value, kind])</code>	Convert to SparseDataFrame.
<code>to_sql(name, con[, schema, if_exists, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_stata(fname[, convert_dates, ...])</code>	Export DataFrame object to Stata dta format.
<code>to_string([buf, columns, col_space, header, ...])</code>	Render a DataFrame to a console-friendly tabular output.
<code>to_timestamp([freq, how, axis, copy])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>to_xarray()</code>	Return an xarray object from the pandas object.
<code>transform(func[, axis])</code>	Call <code>func</code> on self producing a DataFrame with transformed values and that has the same axis length as self.
<code>transpose(*args, **kwargs)</code>	Transpose index and columns.
<code>truediv(other[, axis, level, fill_value])</code>	Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>truncate([before, after, axis, copy])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift([periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(tz[, axis, level, copy])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(tz[, axis, level, copy, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unstack([level, fill_value])</code>	Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.
<code>update(other[, join, overwrite, ...])</code>	Modify in place using non-NA values from another DataFrame.
<code>var([axis, skipna, level, ddof, numeric_only])</code>	Return unbiased variance over requested axis.
<code>where(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is False.
<code>xs(key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

**pandas.DataFrame.abs**

DataFrame.**abs** ()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns**

**abs** Series/DataFrame containing the absolute value of each element.

**See also:**

`numpy.absolute` Calculate the absolute value element-wise.

**Notes**

For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .

**Examples**

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
1  5 20  50
0  4 10 100
2  6 30 -30
3  7 40 -50
```

## pandas.DataFrame.add

`DataFrame.add` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```

>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df

```

	angles	degrees
circle	0	360

(continues on next page)

(continued from previous page)

triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
```

	angles
circle	0
triangle	3
rectangle	4

```
>>> df * other
```

	angles	degrees
circle	0	NaN
triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
```

	angles	degrees
circle	0	0.0
triangle	9	0.0
rectangle	16	0.0

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

## pandas.DataFrame.add\_prefix

`DataFrame.add_prefix` (*prefix*)  
Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

### Parameters

**prefix** [str] The string to add before each label.

**Returns**

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

***Series.add\_suffix*** Suffix row labels with string *suffix*.

***DataFrame.add\_suffix*** Suffix column labels with string *suffix*.

**Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1      3
1      2      4
2      3      5
3      4      6
```

**pandas.DataFrame.add\_suffix**

`DataFrame.add_suffix` (*suffix*)  
Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

**suffix** [str] The string to add after each label.

**Returns**

**Series or DataFrame** New Series or DataFrame with updated labels.

See also:

**`Series.add_prefix`** Prefix row labels with string *prefix*.

**`DataFrame.add_prefix`** Prefix column labels with string *prefix*.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```

## pandas.DataFrame.agg

`DataFrame.agg` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a `DataFrame` or when passed to `DataFrame.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`

- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

**The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from 'numpy' aggregation functions ('mean', 'median', 'prod', 'sum', 'std', 'var'), where the default is to compute the aggregation of the flattened array, e.g., "numpy.mean(arr\_2d)" as opposed to "numpy.mean(arr\_2d, axis=0)".**

'agg' is an alias for 'aggregate'. Use the alias.

See also:

**DataFrame.apply** Perform any type of operations.

**DataFrame.transform** Perform transformation type operations.

**pandas.core.groupby.GroupBy** Perform operations over groups.

**pandas.core.resample.Resampler** Perform operations over resampled bins.

**pandas.core.window.Rolling** Perform operations over rolling window.

**pandas.core.window.Expanding** Perform operations over expanding window.

**pandas.core.window.EWM** Perform operation over exponential weighted window.

### Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

### Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum 12.0 15.0 18.0
min  1.0  2.0  3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
max  NaN  8.0
min  1.0  2.0
sum 12.0  NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

## pandas.DataFrame.aggregate

`DataFrame.aggregate` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

**The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from**

‘numpy’ aggregation functions (‘mean’, ‘median’, ‘prod’, ‘sum’, ‘std’, ‘var’), where the default is to compute the aggregation of the flattened array, e.g., “numpy.mean(arr\_2d)” as opposed to “numpy.mean(arr\_2d, axis=0)”.

‘agg’ is an alias for ‘aggregate’. Use the alias.

See also:

**DataFrame.apply** Perform any type of operations.

**DataFrame.transform** Perform transformation type operations.

**pandas.core.groupby.GroupBy** Perform operations over groups.

**pandas.core.resample.Resampler** Perform operations over resampled bins.

**pandas.core.window.Rolling** Perform operations over rolling window.

**pandas.core.window.Expanding** Perform operations over expanding window.

**pandas.core.window.EWM** Perform operation over exponential weighted window.

## Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                   [4, 5, 6],
...                   [7, 8, 9],
...                   [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A    B    C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A    B
max  NaN  8.0
min   1.0  2.0
sum  12.0 NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

## pandas.DataFrame.align

`DataFrame.align` (*other*, *join*='outer', *axis*=None, *level*=None, *copy*=True, *fill\_value*=None, *method*=None, *limit*=None, *fill\_axis*=0, *broadcast\_axis*=None)  
Align two objects on their axes with the specified join method for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{ 'outer', 'inner', 'left', 'right' }, default 'outer']

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

**copy** [boolean, default True] Always returns new objects. If *copy*=False and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series *pad* / *ffill*: propagate last valid observation forward to next valid *backfill* / *bfill*: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [{0 or 'index', 1 or 'columns'}, default 0] Filling axis, method and limit

**broadcast\_axis** [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

### Returns

(**left**, **right**) [(DataFrame, type of other)] Aligned objects

## pandas.DataFrame.all

`DataFrame.all` (*axis*=0, *bool\_only*=None, *skipna*=True, *level*=None, *\*\*kwargs*)  
Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a DataFrame axis that is False or equivalent (e.g. zero or empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

### DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2    False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0     True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

## pandas.DataFrame.any

`DataFrame.any` (*axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

### See also:

`numpy.any` Numpy version of this method.

**Series.any** Return whether any element is True.

**Series.all** Return whether all elements are True.

**DataFrame.any** Return whether any element is True over requested axis.

**DataFrame.all** Return whether all elements are True over requested axis.

## Examples

### Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

### DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A     True
B     True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1 False  2
```

```
>>> df.any(axis='columns')
0     True
1     True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
```

(continues on next page)

(continued from previous page)

```
0  True  1
1  False 0
```

```
>>> df.any(axis='columns')
0    True
1   False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

## pandas.DataFrame.append

`DataFrame.append` (*other*, *ignore\_index=False*, *verify\_integrity=False*, *sort=None*)

Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

### Parameters

**other** [DataFrame or Series/dict-like object, or list of these] The data to append.

**ignore\_index** [boolean, default False] If True, do not use the index labels.

**verify\_integrity** [boolean, default False] If True, raise `ValueError` on creating index with duplicates.

**sort** [boolean, default None] Sort columns if the columns of *self* and *other* are not aligned. The default sorting is deprecated and will change to not-sorting in a future version of pandas. Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

New in version 0.23.0.

### Returns

**appended** [DataFrame]

### See also:

**pandas.concat** General function to concatenate DataFrame, Series or Panel objects.

### Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

## Examples

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
0  5  6
1  7  8
```

With `ignore_index` set to `True`:

```
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...            ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

## pandas.DataFrame.apply

`DataFrame.apply` (*func*, *axis=0*, *broadcast=None*, *raw=False*, *reduce=None*, *result\_type=None*, *args=()*, *\*\*kwargs*)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (`axis=0`) or the DataFrame's columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

### Parameters

**func** [function] Function to apply to each column or row.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

**broadcast** [bool, optional] Only relevant for aggregation functions:

- `False` or `None` : returns a Series whose length is the length of the index or the number of columns (based on the `axis` parameter)
- `True` : results will be broadcast to the original shape of the frame, the original index and columns will be retained.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by `result_type='broadcast'`.

**raw** [bool, default False]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**reduce** [bool or None, default None] Try to apply reduction procedures. If the DataFrame is empty, `apply` will use `reduce` to determine whether the result should be a Series or a DataFrame. If `reduce=None` (the default), `apply`'s return value will be guessed by calling `func` on an empty Series (note: while guessing, exceptions raised by `func` will be ignored). If `reduce=True` a Series will always be returned, and if `reduce=False` a DataFrame will always be returned.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by `result_type='reduce'`.

**result\_type** [{'expand', 'reduce', 'broadcast', None}, default None] These only act when `axis=1` (columns):

- 'expand' : list-like results will be turned into columns.
- 'reduce' : returns a Series if possible rather than expanding list-like results. This is the opposite of 'expand'.
- 'broadcast' : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (`None`) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

**args** [tuple] Positional arguments to pass to `func` in addition to the array/series.

**\*\*kwargs** Additional keyword arguments to pass as keywords arguments to `func`.

### Returns

**applied** [Series or DataFrame]

See also:

**DataFrame.applymap** For elementwise operations.

**DataFrame.aggregate** Only perform aggregating type operations.

**DataFrame.transform** Only perform transforming type operations.

## Notes

In the current implementation `apply` calls `func` twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first column/row.

## Examples

```
>>> df = pd.DataFrame([[4, 9],] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
   A    B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a Dataframe

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0    1    2
1    1    2
2    1    2
```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

## pandas.DataFrame.applymap

`DataFrame.applymap(func)`

Apply a function to a DataFrame elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

### Parameters

**func** [callable] Python function, returns a single value from a single value.

### Returns

**DataFrame** Transformed DataFrame.

**See also:**

**DataFrame.apply** Apply a function along input axis of DataFrame.

## Notes

In the current implementation `applymap` calls `func` twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first column/row.

## Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0    1
```

(continues on next page)

(continued from previous page)

```
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Note that a vectorized version of *func* often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
   0          1
0  1.000000  4.494400
1 11.262736 20.857489
```

But it's better to avoid `applymap` in that case.

```
>>> df ** 2
   0          1
0  1.000000  4.494400
1 11.262736 20.857489
```

### pandas.DataFrame.as\_blocks

`DataFrame.as_blocks` (*copy=True*)

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)**

#### Parameters

**copy** [boolean, default True]

#### Returns

**values** [a dict of dtype -> Constructor Types]

### pandas.DataFrame.as\_matrix

`DataFrame.as_matrix` (*columns=None*)

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

#### Parameters

**columns** [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

#### Returns

**values** [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

**See also:***DataFrame.values***Notes**

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `‘.values’`.

**pandas.DataFrame.asfreq**

`DataFrame.asfreq` (*freq, method=None, how=None, normalize=False, fill\_value=None*)

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

**Parameters**

**freq** [DateOffset object, or string]

**method** [{‘backfill’/‘bfill’, ‘pad’/‘ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill

**how** [{‘start’, ‘end’}, default end] For PeriodIndex only, see `PeriodIndex.asfreq`

**normalize** [bool, default False] Whether to reset output index to midnight

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

**Returns**

**converted** [same type as caller]

**See also:***reindex***Notes**

To learn more about the frequency strings, please see [this link](#).

## Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.upsample(freq='30S')
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	NaN
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	NaN
2000-01-01 00:03:00	3.0

Upsample again, providing a fill value.

```
>>> df.upsample(freq='30S', fill_value=9.0)
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	9.0
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	9.0
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	9.0
2000-01-01 00:03:00	3.0

Upsample again, providing a method.

```
>>> df.upsample(freq='30S', method='bfill')
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	NaN
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	2.0
2000-01-01 00:02:00	2.0

## pandas.DataFrame.asof

`DataFrame.asof` (where, subset=None)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For DataFrame

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame**

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

**See also:**

***merge\_asof*** Perform an asof merge. Similar to left join.

### Notes

Dates are assumed to be sorted. Raises if this is not the case.

### Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                    '2018-02-27 09:02:00',
...                    '2018-02-27 09:03:00',
...                    '2018-02-27 09:04:00',
...                    '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                    '2018-02-27 09:04:30']))
           a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                    '2018-02-27 09:04:30']),
...          subset=['a'])
           a    b
2018-02-27 09:03:30  30.0  NaN
2018-02-27 09:04:30  40.0  NaN
```

## pandas.DataFrame.assign

`DataFrame.assign(**kwargs)`

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

### Parameters

**\*\*kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

### Returns

**DataFrame** A new DataFrame with the new columns in addition to all the existing columns.

### Notes

Assigning multiple columns within the same `assign` is possible. For Python 3.6 and above, later items in `**kwargs` may refer to newly created or modified columns in `'df'`; items are computed and assigned into `'df'` in order. For Python 3.5 and below, the order of keyword arguments is not specified, you cannot refer to newly created or modified columns. All items are computed first, and then assigned in alphabetical order.

Changed in version 0.23.0: Keyword argument order is maintained for Python 3.6 and later.

## Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                    index=['Portland', 'Berkeley'])
>>> df
```

	temp_c
Portland	17.0
Berkeley	25.0

Where the value is a callable, evaluated on *df*:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

	temp_c	temp_f
Portland	17.0	62.6
Berkeley	25.0	77.0

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

	temp_c	temp_f
Portland	17.0	62.6
Berkeley	25.0	77.0

In Python 3.6+, you can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...          temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
```

	temp_c	temp_f	temp_k
Portland	17.0	62.6	290.15
Berkeley	25.0	77.0	298.15

## pandas.DataFrame.astype

`DataFrame.astype` (*dtype*, *copy=True*, *errors='raise'*, *\*\*kwargs*)

Cast a pandas object to a specified dtype *dtype*.

### Parameters

**dtype** [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

**errors** [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise`: allow exceptions to be raised
- `ignore`: suppress exceptions. On error return original object

New in version 0.20.0.

**kwargs** [keyword arguments to pass on to the constructor]

### Returns

**casted** [same type as caller]

**See also:**

**`to_datetime`** Convert argument to datetime.

**`to_timedelta`** Convert argument to timedelta.

**`to_numeric`** Convert argument to a numeric type.

**`numpy.ndarray.astype`** Cast a numpy array to a specified type.

## Examples

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...             categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

## **pandas.DataFrame.at\_time**

`DataFrame.at_time` (*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g. 9:30AM).

**Parameters****time** [datetime.time or string]**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.**Returns****values\_at\_time** [same type as caller]**Raises****TypeError** If the index is not a *DatetimeIndex***See also:*****between\_time*** Select values between particular times of the day.***first*** Select initial periods of time series based on a date offset.***last*** Select final periods of time series based on a date offset.***DatetimeIndex.indexer\_at\_time*** Get just the index locations for values at particular time of the day.**Examples**

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

	A
2018-04-09 00:00:00	1
2018-04-09 12:00:00	2
2018-04-10 00:00:00	3
2018-04-10 12:00:00	4

```
>>> ts.at_time('12:00')
```

	A
2018-04-09 12:00:00	2
2018-04-10 12:00:00	4

**pandas.DataFrame.between\_time**

`DataFrame.between_time` (*start\_time*, *end\_time*, *include\_start=True*, *include\_end=True*,  
*axis=None*)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting *start\_time* to be later than *end\_time*, you can get the times that are *not* between the two times.

**Parameters****start\_time** [datetime.time or string]**end\_time** [datetime.time or string]**include\_start** [boolean, default True]**include\_end** [boolean, default True]**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

**values\_between\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.
