PREFACE

Dear Conference Participants,

Welcome to COBRA 2012 - the Royal Institution of Chartered Surveyors annual international construction, building, and real estate research conference - hosted by the Arizona State University. The theme of this year's conference is the integration of academia and industry professional, working together to provide solutions, efficiency, and innovation to our industry.

The conference returns to the United States this year and promises to be another successful program. We have 200 papers, a diversity of research and themes, and authors from 32 different countries. This is a true sign of global collaboration of the best researchers, students, and experts. I have been attending the Cobra conference since its inception and have seen it grow. What makes this conference exciting and unique is the following:

- Industry and researcher collaboration
- Law Stream
- RICS workshops and roundtable with panelist
- Particularly high level of PhD Student involvement

The venue of Las Vegas and the Monte Carlo Hotel makes this year's conference especially enjoyable. The atmosphere of the location will provide a memorable experience for all, let us reacquaint ourselves with old friends and help us make new ones. In the last three years COBRA has made stops in Cape Town, South Africa; Paris, France; and Manchester, UK. Las Vegas will continue the tradition of excellent venues.

Every paper within these proceedings was peer reviewed and selected based on the quality of research. I want to take time to thank all the reviewers that made this possible. As the editors we couldn't have done this alone. I would like to give special recognition to those individuals that made this conference possible: Dr. Paul Chynoweth with the University of Salford for the Law Stream/CIB W113, Dr. Charles Egbu and Dr. Kenneth Sullivan for the CIB W117 support, Dr. Monty Sutrisna for the doctoral stream, Dr. Tsunemi Watanabe and Dr. Syed Ahmed for their keynote addresses, and the RICS Team (Jenny and Danielle) for their support. A special thank you to my staff (Ms. Sylvia Romero, Johnny, Catie, and Kailey) that worked countless hours on organizing the papers and the reviews and with the help of our doctoral students (Jacob, Jake, Kristen, Brian, Anthony, and Dhaval); I am very fortunate to have an excellent team and couldn't have done this alone.

Dr. Dean Kashiwagi
Conference Chair

Danielle Blair, Conference Logistics Coordinator
Rohan Verma, Webmaster

REVIEW COMMITTEE

All papers submitted to COBRA 2012 were subjected to a double-blind review process. Reviewers volunteered their expertise from a multitude of prestigious universities, all representing the innovative contributions made to continuing research and development in the Built Environment education community. The conference organizers wish to extend their gratitude to the following members of the review committee for their efforts to make this publication a success.

KEYNOTE SPEAKERS

Topic: TOWARD HIGH PERFORMANCE THROUGH COMPETITION IN THE CONSTRUCTION INDUSTRY IN JAPAN

The Japanese construction industry is now making many reform efforts to keep its high performance through enhancing its competitiveness. The objectives of this presentation are to compare essences of public bidding reforms in Japan with principles of the Best Value Approach and to discuss future of public bidding.

Presented by: Dr. Tsunemi Watanabe, Kochi University of Technology (KUT), School of Management

Watanabe received B. Eng. and M. Eng. from Hokkaido University and PhD from the Johns Hopkins University in the field of environmental systems engineering. At the University of Tokyo in 1991, his main research changed to construction management, particularly public bidding. In 1997 at KUT, his focus in education, research, and outreach activities are in the field of construction and local environmental management. He is the current president of Geo Risk Society in Japan, a chairperson of the international alliance subcommittee of the construction management committee of the Japan Society of Civil Engineers (JSCE), and a member of the committee of quality assurance through application and improvement of the comprehensive evaluation method (CEM) in the Ministry of land, Infrastructure, Transport, and Tourism (MLIT).

Topic: HOW CONSTRUCTION MANAGEMENT RESEARCH CAN IMMEDIATELY IMPACT INDUSTRY PRACTICE TO IMPROVE PERFORMANCE AND VALUE

A focus on the global perspective of R&D expenditures in different industries and compare that to R&D expenditure in the Construction industry. Obstacles and bottlenecks in developing a research culture in the academic environment will be highlighted, suggested steps and procedures will be discussed to bridge the gap between academic research and the construction industry needs and requirements.

Presented by: Dr. Syed Ahmed, East Carolina University,
Department of College of Technology and Computer Science

Ahmed is a professor and chair of the Dept. of CM in the College of TCS at ECU.He began his career as a trainee engineer at McDonald Layton and Company in Islamabad, Pakistan. He subsequently held positions at Capital Development Authority in Islamabad, CRSS-AMC Construction Managers in Atlanta, Ga., Georgia Institute of Technology in Atlanta, Hong Kong Polytechnic University in Hong Kong, and at Florida International University in Miami. Ahmed holds a B.S. in civil engineering from the University of Engineering and Technology in Lahore, Pakistan, and M.S. and PhD in civil engineering, majoring in construction management from the Georgia Institute of Technology. He has over 25 years of international experience in teaching, research and consulting in Pakistan, Hong Kong, USA, Mexico, and Jamaica. His areas of interest/expertise are construction scheduling, quality and risk management, project controls, construction safety, construction procurement, and construction education and information technology.

KEYNOTE SPEAKERS

Topic: THE FUTURE OF ACADEMIC RESEARCH

Future research must integrate industry and academia efforts. Academic researchers must be experts. New concepts and technology must be simple, easy to understand, and have dominant value to be able to overcome the resistance to change and absorb the cost of change. Research to change the industry requires visionary industry partners who need and are committed to change and who share the risk and cost of change.

Presented by:
Dean Kashiwagi, Arizona State University,
School of Sustainable Engineering and the Built Environment

Kashiwagi is a professor at Arizona State University's School of Sustainable Engineering and the Built Environment, Director/Creator of PBSRG, and CIB W117 coordinator. He is the renowned world expert in the best value research. His credits include the cration of the IMT, PIPS and PIRMS processes. The technology has been tested over 1000 times totalling $4.7 Billion ($2.9 Billion in construction projects and $1.8 Billion in non-construction projects) with a 98% success rate since 1994. His work has reached beyond the U.S. to the Netherlands, Botswana (Africa) and Malaysia. His is a Fulbright Scholar. Prior to ASU Kashiwagi served in the US Airforce as an Officer Major and Engineer. He is currently a licensed professional engineer in seven states. Also he is an established author in the best value, risk management, performance measurement, and information measurement theory (25 books, 37 journals, and over 160 conference proceedings).

SPECIAL KEYNOTE ADDRESS BY RICS:

John Pierce
FRICS, Regional Manager, Latin America and the Caribbean
Turner Construction Company, New York, NY USA

With 29 years professional experience, Pierce utilizes his background in construction to serve clients in corporate real estate, private property development and the public sector.

RICS PANELISTS

Moderator: Simon Taylor, CEO
Questant Inc.
Taylor has over 25 years of international project consultancy experience at a senior level. Taylor also teaches Construction Management and Computer Applications at Pratt University in New York, and is a former chair of RICS Americas, and continues to chair the Project Controls and Construction Management professional group in the Americas.

Jeff D. Baize, CEO
Brookhurst Development
Baize is the Founder and CEO of Brookhurst Development Corporation, a national development firm that specializes in public-private partnerships ("P3s") since 1996. He has written numerous articles, including School Facilities Planning: A Guide to Laws and Procedures for Funding, Siting, Design and Construction (Solano Press) wherein he authored the section on public school development using private funding. Baize holds a Bachelor of Architecture and MBA degrees, both conferred at the University of Texas where he was also a faculty member teaching real estate development and finance.

Ryan Brady, Regional Commercial Director
Faithful+Gould's PPP Technical Advisory
Brady is a Regional Commercial Director for the Faithful+Gould's PPP Technical Advisory practice for North America. He has provided services on PPPs including technical due diligence, commercial and risk advisory, Independent Certifier, construction monitoring and program management to Lenders, Public Governments and Investors for multiple projects in North America and Europe. Brady worked extensively on PPP and Private Finance Initiative projects throughout England, Scotland and Ireland in technical advisory roles for new projects and in transaction advisory roles for secondary market acquisitions. He holds a BA from Northern Arizona University and an MBA from Arizona State University.

Stephen B. Pearlman, Founding Partner
Inglesino, Pearlman, Wyciskala & Taylor, LLC
Pearlman is a founding partner of the law firm Inglesino, Pearlman, Wyciskala & Taylor, LLC, of Parsippany, New Jersey. In his quarter century of practicing law, Pearlman has closed over $10 billion par amount of financings, primarily in the areas of public, project, redevelopment, and renewable energy finance. He has acted as bond counsel, as well as transaction, underwriters', finance, project, and borrower's counsel over that term. Several pieces of New Jersey legislation have been drafted by Pearlman and enacted by the State Legislature, resulting in either expanded financing opportunities, and/or cost savings initiatives for local government.

Communication skills in ADR: Theory adding value

ORC du Preez[1] and Prof. JJP Verster [2]

[1] Department Quantity Surveying,
University of the Free State, Bloemfontein 9301,
South Africa

Email: DuPreezorc@ufs.ac.za; VersterJ@ufs.ac.za

Abstract:
Communication is an essential element in the negotiation process. The fast and competitive nature of the construction industry lends itself to reliance on inherent communication skills for the facilitation of mediation and conciliation. The questions raised; are inherent communication skills sufficient to support effective negotiation; and is there a need to be familiar with the theoretical aspects of communication?
The purpose of the study is to identify the essential elements required by facilitators which may enhance effective communication. The requirements for effective communication based on standard international practice were sourced from literature, studied and applied to the South African Construction industry to identify which skills and attributes would provide the most support. Based on the findings of the literature review, a survey questionnaire was developed and distributed amongst practicing professionals and their staff/employees who are active in the industry with the view to determine the levels of the respondent's knowledge and skills relating to the identified elements and how they rate the importance of these skills and attributes to success in their practice. The research findings suggest that effective communication in mediation and conciliation will lead to more generally acceptable outcomes when the parties consider the process to have been fair and well facilitated.

Keywords:
ADR, communication, learned, requirements, theory.

1 Introduction

Communication is a primary element in the negotiation process. Brown and Marriott (1993) are of the opinion that in the past, negotiation training has not been an integral part of the education and training of professionals who have had to develop these skills and attributes on the job. This trend is starting to change and that there is an increased demand for formalised development in this regard.

Curriculums of tertiary institutions are generally saturated with subject matter pertaining to the technical and management sciences, with limited time available for the development of the "softer skills" such as communication. Some tertiary institutions address the ADR context in their curriculums in modules such as Construction Contracts Law and Professional Practice (Du Preez and Verster, 2011).

 ISBN: 978-1-84219-840-7 .

According to Brown & Marriott, (1993) communication and negotiation skills are largely influenced by personalities within the workplace and facilitators may tend to emulate their formal mentors;
According to Povey, Cattell and Michell (2006), professionals in the industry are inclined to place more emphasis on the evaluative skills of ADR than facilitation skills which promote effective negotiations.

Research conducted by Povey (2005) supports the notion that professionals rely on their inherent communication skills to facilitate mediation. This reassesses the question as to whether or not inherent communication skills are in fact sufficient to support effective negotiations; or is there a need for further education and training in the theoretical aspects of effective communication?

According to Boulle and Rycroft (1997) and Brown and Marriott (1993) referring to standard practice of mediation, mediators require a range of skills and techniques which support the applicable functions however; these skills are inherent, learned, and intuitive; or may be acquired and developed through education, training and experience. Some consider communication to be a natural or inherent skill however; Knipe, van der Walt, van Nierkerk, Burger & Nell, (2002) support the belief that communication can also be learned.

2 Negotiation

Negotiation presents itself as a method of ADR and it is also an important skill required by facilitators in order to achieve competence in all consensual methods of ADR.
According to Richbell (2008), successful negotiations require effective communication between the parties and the facilitator who ensures that the message is conveyed and received in an effective manner.
Pretorius (1993) suggests that a thorough understanding of the principles and techniques of negotiation is considered an advantage to those who facilitate ADR.
Due to limited education in negotiation skills, relatively little is known about the science and art of the subject (Pretorius, 1993). In support of this opinion, Bevan (1992) suggests that some professionals such as lawyers are self-taught however, basic theory of communication skills, attributes and processes may add value to competence in facilitation

3 Communication

De Wet (1991: 1) suggests that communication is the imparting of ideas to achieve a mutual understanding. However, in ADR messages are often interpreted by the receiver from an emotional perspective which further emphasises the need for effective communication and listening skills. This is where the skill of effective communication may have its greatest impact in the mediation process which is combined with the facilitative procedure of conciliation.
Moore (1986) is of the opinion that the extent, structure and quality of communication contribute to the successful outcomes of negotiation and as with most negotiations, communication is the central component in the negotiation process upon which, good communication skills support constructive negotiations.

 ISBN: 978-1-84219-840-7 .

The above discussions suggest that the quality of communication is dependent on the participants and facilitators and as such, communication is identified as an important skill in achieving successful negotiations. As such, the facilitator who has a good theoretical knowledge of communication skills and the application in ADR would in all probability apply this knowledge in the execution of their facilitation roles and in so doing, promote effective negotiations.

Communication is an important element in Project Management and has been identified as a Knowledge Area in the Project Management Body of Knowledge (PMBOK) (2008) however, the probability exists that communication management failure may lead to disputes (Boulle & Rycroft, 1997).

As illustrated in Figure 1, conflict invariably stems from poor communication and may inhibit the negotiation process. Ineffective communication may lead to a breakdown in the negotiation process which may result in a deadlock. This may create a challenge for the mediator who may need to creatively restructure communication to encourage the pursuit of negotiations. Poor communication skills create a negative cycle in which disputes are difficult to resolve (Richbell, 2008; Boulle & Rycroft 1997; Moore, 1986). Ineffective communication may cause a dispute to worsen and the facilitator may need to apply good communication skills in order to restore constructive communication channels (Boulle & Rycroft, 1997).

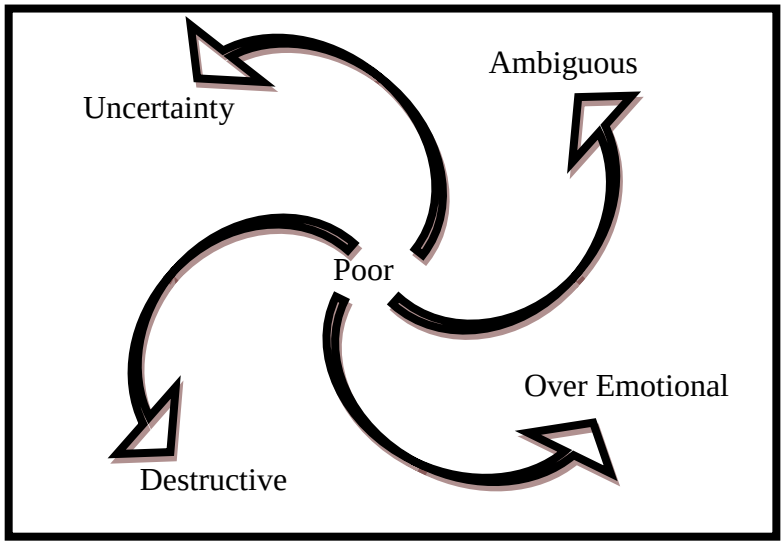

Figure 1: Unproductive communication
(Source:Adapted from: Boulle & Rycroft, 1997)

A theoretical knowledge of communication in ADR may assist in identifying the problem areas in order to restore effective communication. As illustrated in Figure 2, a positive approach should continue producing outcomes for effective mediation.

 ISBN: 978-1-84219-840-7 .

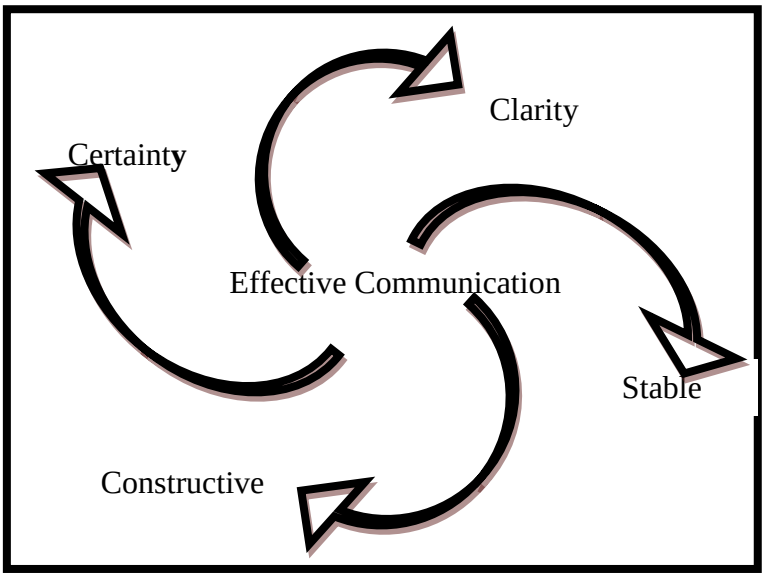

Figure 2: Productive communication
(Source:Adapted from: Boulle & Rycroft, 1997)

The question is raised as to the extent to which these communication skills are natural, inherent, learned or acquired by experience?

3.1 Active listening

In order to receive and convey the message without distorting it, the facilitator would be required to be an active listener (Moore, 1986). Active listening supports effective communication which assists parties to better hear and understand a communiqué (Brown & Marriott, 1993).

Active listening is an important element in effective communication and it is a skill which is progressively developed and is used as a tool by facilitators to identify the emotional status of the parties. It is an essential component in the communication process whereby the receiver of the communiqué listens attentively in order to analyse the conveyor's emotions in the message and to reiterate the message for confirmation (Moore, 1986).

Active listening underlies the communication process in ADR of which the facilitator requires a good understanding. Active listening is a skill which is vital to the communication process and addresses various important factors inter alia:

- Parties speak without interruptions to allow full explanation of their dispute and expressing emotions.
- Parties are assured that they have been heard.
- Emphasis on the individual demonstrates the acceptability of expression and develops a better understanding of the concerns based on both the verbal and non-verbal message.
- Helps the speaker to identify his/her own emotions.

- The mediator can better understand, summarize and analyse the parties' concerns.
- Creates a situation where the facilitator can absorb the message, verify and integrate it into an extension of the negotiation process. (Boulle & Rycroft 1997: 153-154; Brown & Marriott, 1993; Moore, 1986).

In view of the above, the facilitator may therefore need to be aware of the parties' capabilities of absorbing the messages because a distraught disposition may hamper a person's ability to actively listen.

The objective of active listening in the negotiation process is to create a mutual understanding by clarifying uncertainties, summarising facts, concerns and feelings, acknowledging the message and reiterating to facilitate a better understanding of concerns, feelings and emotions. By displaying an understanding of the parties' feelings and emotions and receipt of the facts, may assure parties that a concerted effort is being made to resolve the dispute (Boulle & Rycroft, 1997; Brown & Marriott, 1993, & Moore, 1986:).
Figure 3 below illustrates the extent of the skills and attributes required for the effective application of active listening.

REQUIREMENTS FOR ACTIVE LISTENING

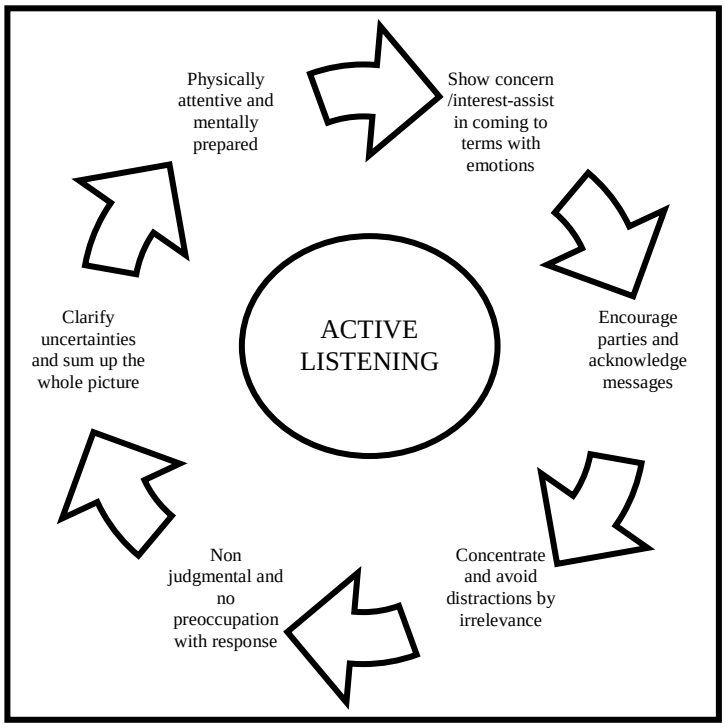

Figure 3: Requirements for active listening
Source: Adapted from: (Moore, 1986; Boulle & Rycroft, 1997).

Boulle and Rycroft (1997) suggest that there are three categories of skills which promote active listening which assures the parties in the negotiation process:

- Physical attention is displayed by interest and encouragement where face-to-face, relaxed and direct eye contact is suggested.
- A display of full comprehension is noted by minimal encouragement, occasional questions, reframing and summarizing notes.
- Reflecting and summarizing the whole picture.

In addition to active listening, communication in ADR is supported by various elements pertaining to the psychological element addressed in facilitation. The intention is to prepare the parties psychologically for the evaluative part of mediation. Considering the extent of the skill of active listening relating to effective communication, practicing professionals may need to be familiar with the theory to support effective application.

3.2 Paralanguage

Paralanguage refers to the "tones" or "effects" used to emphasize messages. Awareness of these effects will assist the mediator to better assess the mood (Boulle and Rycroft, 1997; De Wet, 1991,). Paralanguage may be less complicated to identify however; it may pose a challenge to address, especially in an emotional situation.

The identification of the psychological state of the parties may assist the mediator in directing negotiations to suit the mood of the negotiators. The approach to the negotiations may need to be adjusted as the mood changes. Apart from being aware of the paralanguage of the disputing parties, the mediators may consider managing their own (Bevan, 1992).

3.3 Non-verbal communication

"The most important thing in communication is to hear what isn't being said" (Drucker, 2001).

In addition to paralanguage, the skill of identifying non-verbal communication was considered important in achieving competence in the facilitation of ADR in so far as the emotional state of the parties can be detected and according to De Wet (1991), non-verbal messages may contradict, complement or accentuate verbal messages. As a form of self improvement, it is preferred that non-verbal messages complement verbal messages.
As with verbal messages, body language should also be used appropriately and in a positive sense bearing in mind that body language varies between different cultures (Boulle and Rycroft, 1997).

Non-verbal communication can be used to send both positive and negative messages and the facilitator would do well to recognize and appropriately react to these non-verbal messages. The identification of non-verbal messages plays an important role in communication. These messages can portray the parties underlying feelings such as status, anxiety or lack of confidence. In addition to this, it can be used to threaten, show authority or even show encouragement (Boulle and Rycroft, 1997; Brown and Marriott, 1993 and Moore, 1986).

 ISBN: 978-1-84219-840-7 .

It is important that the facilitator be alert to these non-verbal messages however; the mediator should also be conscious of his/her own non-verbal messages so as to be perceived by the parties to have an unbiased and positive attitude As the mediator would be observant to identify the body language of the parties, careful consideration should be given not to display any feelings such as irritation or impatience in the form of body language (Boulle and Rycroft:1997).

3.4 Being silent

As with verbal and non-verbal communication, being silent represents a form of communication. Boulle and Rycroft (1997) and Brown and Marriott (1993) suggest that silence can be manipulative to those who may be uncomfortable with it. In a situation such as this, the uncomfortable party may be forced into a decision. However, in the positive sense this may provide the moment of silence to reflect and the parties may consider propositions. Being silent was identified as a technique used by facilitators in a positive sense however, the negative application may need to be identified.

4 Attributes

Attributes were identified as being essential elements relating to effective application of facilitator skills and professionals may find that being aware of these assists in the art of the application.

Some may find that they are naturally equipped with inherent qualities which are considered an asset in the application of facilitation skills however; these qualities have to be demonstrated by the facilitator and are referred to as attributes and are generally known as ‘soft’ skills.
According to the Oxford English Dictionary, (2002) an attribute defined is a “characteristic quality”; a distinct feature which makes a person different from others. Authors (Brown and Marriott, 1993 and Boulle and Rycroft, 1997) are of the opinion that attributes may be learned and developed with experience however, Bevan (1992) bases his identification of the attributes on personality types.

Brown and Marriott (1993) suggest that attributes relate to psychological and personality traits whereas the Oxford English Dictionary (2002) defines psychological traits as the mental characteristics or the attitude of a person. Characters may therefore be formed and influenced by an individual’s surroundings however; attributes may be generally learned and developed though practice and experience.

4.1 Impartiality

Boule and Rycroft (1997) believe impartiality relates to even-handedness, objectivity and fairness to the parties during the dispute. Finsen (2005) suggests that although under obligation, it is a matter of professional honour for the principal agent to be fair and impartial to both parties. In view of these requirements, impartiality may be learned or developed with experience.

4.2 Empathy

Empathy reflects an awareness and respect for the parties' concerns (Brown and Marriott, 1993). Empathy refers to comprehension by the facilitator has on the thoughts, perceptions and feelings of the parties and responding to them in a sympathetic way (Boulle and Rycroft, 1997). Butler and Finsen (1993) are of the opinion that empathy would encourage the parties to respond and explain their situation better however; this should be applied in an even-handed manner.

5 Discussion

Active listening goes beyond merely audibly receiving a message in order to conveying it; it develops an understanding of each other's views and intentions. Boule and Rycroft (1997) are of the opinion that the ability to listen is not just a passive exercise. Although listening skills can be learned, the inherent ability to listen actively may add value to the active listening process.

Due to the rarity of being gifted with inherent communication skills, theoretical communication skills are required by facilitating practitioners Furthermore, people may be inclined to overestimate the extent of their skills when doing a self evaluation. Practitioners who have limited practice in communication skills may lack the natural inherent skills, would in all probability benefit form a better theoretical knowledge to support effective communications.

Povey (2005) indicates that mediators in the South African Construction industry are inclined to unilaterally resolve a dispute for the parties, which suggests that success rates in mediation are not in essence related to effective facilitation and communication skills as reflected in the study.

Although practitioners are inclined to rely on their inherent negotiation and communication skills when facilitating ADR, the application of various personal attributes which relate to ADR practitioners may add value if considered, developed and applied effectively. As such, a theoretical knowledge may assist the effective application when facilitating.

6 Research Methodology

A literature review was conducted to identify the requirements for effective communication based on international standard practice of ADR, followed by a mixed method study which employed self-response questionnaires to determine the level of the practioners' theoretical knowledge relating to communication in ADR practice in the South African construction industry. One hundred questionnaires were distributed with a twenty eight per cent response. Respondents were requested to rate the importance of and their knowledge, skills and attributes relating to communication in ADR. Experience was rated according to the number of actual interventions.

Quantitative measures were used to determine the respondents' level of importance, knowledge and skill relating to the various attributes in the form of self assessment questions whereupon qualitative data was collected and through the process of triangulation, was used to verify the findings of the research, upon which the present situation in the construction industry was recorded. Qualitative data was used to identify the current situation in the industry.

 ISBN: 978-1-84219-840-7 .

The results of the questionnaire analysis were illustrated in graphical format comparing the relevant elements relating to the required theoretical knowledge.
Due to the extent of the target population of architects, engineers, quantity surveyors and construction project managers, the sample group was limited to professionals who currently manage or are employed in practices in the Construction industry. In addition to this, the responses were grouped as follows: 30 years, 30-40 years and over 40 years. This was to identify the areas of knowledge received.
The net effect of the sampling strategy is that the findings of the study will not be able to be generalized to the entire South African Construction industry, but will serve as a means of identifying areas for future research.

7 Findings

Respondents were generally of the opinion that they applied communication skills in ADR without giving it much thought, thus suggesting that they are equipped with the application requirements in the form of inherent skills and attributes. The respondents rated themselves very high in regard to their knowledge, skills and attributes in communication and negotiation of which communication is a primary element. The knowledge levels are rated above 70% with skills and attributes slightly lower. Negotiation is generally rated lower than communication in spite of communication forming the main function of negotiation.

Figure 4 is a graphical presentation of the respondents' skills relating to the effective application of communication upon which active listening was rated as being very important above 90%.

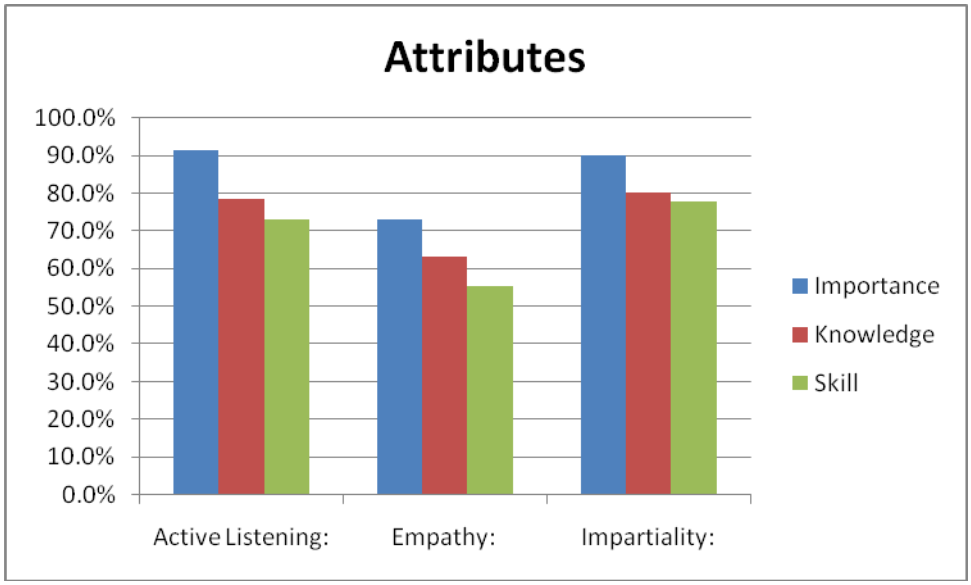

Figure 4: Respondents'analysis of the importance, knowledge and skills of the attributes. Source: Author's diagram

At a glance, the illustrated findings of the research suggest that professionals in the Construction industry consider the relevant attributes and skills supporting communication to be important and have assessed themselves to be knowledgable of

and skilled in the requirements for effective application however, the findings of the quantitative resarch does not correllate with that of the qualitative research. In spite of the escalated self analysis which suggests the probability of response bias, the lack of theoretical knowledge was displayed in the literature review and interviews. Secondary data indicates that tertiary institutions do not include an in depth study of the ADR skills and attributes in their curriculums, suggesting that the escalated self analysis is based on perceived inherent qualities.

An interviewee, an architect by profession, was of the opinion that few people have the skills to resolve a dispute within minutes of walking into a room. This suggests that effective communication skills and supporting attributes are rarely inherent but rather developed over time.

Based on the findings of the qualitative research, respondents are of the opinion that there is a need for education and training in communication skills and attributes for effective application of ADR. Furthermore, understanding and empathy is regarded as a "waste of time because we are running a business". There was generally a lack of regard as to the importance of empathy in the application of communication skills and this was also reflected in the quantitive analysis.

The results of the age group analysis are reflected in Table 1 below. It is interesting to note that empathy correlates with the qualitative research to a certain degree

Table 1. Results of the age group analysis (%)
(Source: Author's own table)

	Knowledge			**Skill**			**Attributes**			**Experience**		
	< 30	**30-40**	**40 >**	**< 30**	**30-40**	**40 >**	**< 30**	**30-40**	**40 >**	**< 30**	**30-40**	**40 >**
Communication	63	86.7	78.6	63.3	63.3	72.9	60.3	66.7	76	50	53.3	62.9
Negotiation	63	73.3	78.6	53.3	56.7	68.6	53.3	73.3	71	47	50	60
	Importance			**Knowledge**			**Skills**			**Experience**		
Active listening	80	100	92.9	63.3	86.7	81.4	60	80	76	40	43.3	67.1
Empathy	53	76.7	80	40	76.7	67.1	30	66.7	61	27	40	60
Impartiality	77	96.7	92.9	63.3	80	87.1	66.7	83.3	80	37	43.3	70

The additional analysis where responses were divided into age groups is a clear indication of the reponse bias in so far as experience in the skills and attributes is rated somewhat lower than that of knowledge and skills. Although respondents are aware of the importance of communication skills, experience is somewhat lacking.It is interesting to note that the 30-40 year age group have higher knowledge ratings than the under 30 and over 40 year groups.

8 Conclusion

Respondents assessed themselves to be knowledgable and skilled in both communication and negotiation including the attributes relating to the effecive application of ADR. The graphical presentation of the results of the quantitative data relating to the effective application of communication in ADR in the construction industry suggests that the response was not reliable in relation to the qualitative data gathered from the findings of the literature review and the interviews conducted.

In spite of the probability of response bias, the qualitative research indicated that there is a need for increased emphasis to be placed on the importance of the theoretical knowledge relating to communication in ADR, which professionals may refer to in the process of gaining experience on the job.

Based on the architect's opinion addressed in the findings, it is suggested that the industry should not be totally reliant on inherent communication skills but rather that these skills should be developed though formal training and development programmes.

8 Recommendations

It is recommended that professionals in the Construction industry take heed not to underestimate the importance of a sound theoretical knowledge of communication skills in the application of ADR.
It is further recommended that based on the importance of the communication skills in ADR practice, tertiary institutions consider including communication skills in their curriculums.
Institutions should provide opportunities for professionals in the industry to update their knowledge of communication skills in the form of Continuous Professional Development and that emphasis should be placed on the advantages of the theoretical knowledge.

Complex Multiple Party Disputes: Throw Out the Standard Mediation Model

John Jozwick, Esq.[1] and Sam Barakat, Esq.[2]

Abstract:
Mediation of complex construction disputes that involve multiple issues (whether multiple changes, claims, disputes, delays, or defects) may include the Owner, Prime Contractor, Multiple Subcontractors, Suppliers, Architects, and Engineers. Each of these parties may have Attorneys, Experts, and Insurance or Surety Claim Adjusters who will be involved in the mediation. These types of disputes require that the standard mediation model of a pre-mediation exchange of positions, joint session, and then caucus sessions with all parties present be changed. The success of complex, multiple party construction disputes requires that the Mediator begin mediation before any joint session, if a joint session is ever convened. Complex multiple party mediation process is actually more cost effective when the Mediator is able to meet with each of the parties individually or in combination with other parties throughout the mediation process without allowing other parties to sit and wait idle in caucus rooms. This allows the Mediator to find common party interests and needs, where there are champions to help the cause, and where the key divergent positions and personalities may lie in a more controlled, efficient, and cost effective manner.

1 Introduction

Much of the literature discussing multi-party mediation of complex disputes stems from the mediation of international nation disputes including Bosnia in 1994 and several regional conflicts in Africa (Angola and Liberia) and South America. The lessons learned from these international conflicts now being applied throughout the mediation community include concepts of "leverage" and understanding similar alignments with conflicting agendas. Leverage is the concept of finding coalitions and groups that can be aligned to provide weight to move the mediation process towards resolution. The concept of conflicting agendas arises when multiple parties may have similar but not identical alignments commonly found in multiple party negotiations. Additionally, due to the number of parties, alignment of interests, and trust issues from years of war, border, and territory disputes, teams of Mediators worked together depending on the parties and issues being discussed. Complex multi-party mediation in the commercial

and construction dispute areas are likewise now starting to use Co-Mediators for specific issues or parties involved in the conflict.

Mediation has evolved from a two party dispute resolution mechanism to one involving multiple parties, aligned interests with possible conflicting agendas, use of leverage, and use of Co-Mediators. These changes in the mediation process are reasons why a Mediator in a multi-party construction dispute must change the typical mediation process template to adapt to the needs of complex multi-party mediation.

2 Traditional Mediation Rules

When considering the level of sophistication in multi-party mediation, it should be noted that while mediation rules and procedures allow for a flexible process, little guidance is given on how to modify a mediation when multiple parties are involved. Ultimately, the procedure is left up to the skill and creativity of the Mediator and parties to devise a process to fit the needs of the mediation (AAA, FINRA, JAMS, NAR, and WIPA).

It is critical that the Mediator of a multi-party complex mediation take control of the process, the parties, and the attorneys. This does not mean that the overall process cannot remain flexible and adapt to the needs of a particular dispute. However, multi-party mediations require additional time to prepare and develop the negotiation issues, may require multiple mini-mediations within the mediation, may require assistance with Co-Mediators, and may need time to find leverage alliances with parties. The Mediator needs to manage these dynamics and not succumb to the varied interests and desires of the participants who think they have a better way to run the mediation.

3 Developing Techniques To Handle Multi-Party Mediations

As noted above, the Mediator's first task is to understand that controlling the process is critical. Scheduling, management, organization, and clear agreements for the process must be the Mediator's priority.

It is also important for the Mediator to assess who may be aligned, who may become champions and can provide leverage to assist in moving the process to settlement. Similarly, the Mediator needs to assess who will be negative influences or seek to avoid the process and the conflict. Managing negative influencers is critical to obtaining a successful outcome, and is a key reason the Mediator must rely on leverage, alignments, and champions to assist in the process. Further, depending on these multi-party dynamics the lead Mediator may seek Co-Mediator assistance. As discussed below, Co-Mediation can be beneficial to a mediation when the mediation involves different personalities, skills, technical issues, and cultures.

Multi-party mediation is a process that can cause a significant amount of wasted time if parties, attorneys, and experts are waiting for their turn to speak with the Mediator. The wasted time generates mistrust and a frustration that significant fees are being incurred without progress to a settlement (even if progress is being made overall with the other participants towards resolution). Process control and management must continue throughout the mediation.

Getting the parties into the same ballpark for the mediation defines the out of bounds and the playing field for the mediation. The more parties there are to a mediation the more opinions exist for what each party desires in a settlement and where they think settlement and contribution should lie. As a result, it is sometimes helpful to have the participants define the boundaries of the dispute playing field and continue to re-define and narrow the field for settlement as the mediation proceeds.

4 Initial Pre-Mediation Conference

Typically, a Mediator conducts a pre-mediation conference to introduce him/herself, calendar the mediation session and location, and discuss the schedule for submittal of pre-mediation statements without substantive discussion into negotiation.

While establishing a rapport with the participants and building a level of trust is imperative for the mediation process, with multi-parties and complex issues, the initial trust building takes more time. Used wisely, the initial pre-mediation conference and time before any joint session is held can be used so that the Mediator can begin to build trust, understand the dispute, and sense the interpersonal dynamics that may be involved.

The Mediator should ask the participants to briefly explain the dispute, how they each relate to the dispute, and what the parties' perspective is regarding the dispute. This overview allows the Mediator to immediately start gaining a better understanding of the overall dispute, the issues that may be involved, and to start appreciating the interpersonal dynamics to leverage relationships. It also allows the parties to start building the trust relationship with the Mediator. Finally, it allows each party to speak and be heard by the others so that everyone listens to each other's reality of the conflict.

Depending on the dispute and comments made in the pre-mediation conference, the Mediator can begin discussion of a mediation schedule. It may be prudent for the Mediator to first conference with each participant separately, and then reconvene for another pre-mediation conference to set the mediation schedule. This allows the Mediator to build relationships with the participants individually, gain a deeper understanding of the issues in conflict, formulate leverage alignments in the conflict, and determine if Co-Mediators would be beneficial.

5 The Scheduling Conference

The scheduling conference is when the Mediator is ready to set the joint session and initial caucus sessions, now understanding the dynamics of the conflict. The conference will establish the schedule and content for exchange of mediation statements (including confidential Mediator eyes only statements).

This conference is important for the Mediator to take control of the process by establishing how the joint session will be conducted, including who shall attend, and the time schedule for the joint session. It should be clearly expressed what will occur and what the goal(s) of the joint session is/are through party presentations and in consensus development of the conflict issues that need to be addressed.

 ISBN: 978-1-84219-840-7 .

The Mediator should also schedule the first rounds of caucus sessions based upon the initial pre-mediation conference call and individual party meetings, identifying the parties or groups of parties that the Mediator desires to speak with first. By only scheduling necessary parties for each caucus session, wasted and unproductive time can be minimized. Further, the logistics of having numerous meeting and caucus rooms is eased.

As alluded to by Crocker, Hampson, and Aall, control of the process is needed to "herd the cats," to control the masses and move them in a somewhat organized fashion into the mediation process (Crocker, et.al. 1999 and 2001). Shaping the process and establishing clear rules and boundaries of the initial stages of the mediation set the tone of how the overall mediation will proceed.

The simple act of carefully planning the mediation process, initial schedule, setting rules for the joint session, and organizing the opening rounds of caucus sessions sets a framework of control and trust that the Mediator is ready and able to move the process to resolution. And, this is before any negotiation or issue development has even taken place.

6 Joint Session Consideration

When scheduling the date and location for the preliminary joint session, consideration should be given to scheduling the order and length of time for each presentation. Some Mediators may feel that joint sessions are not needed and would rather proceed directly to caucus and negotiation. However, a joint session is important to let the parties have a safe environment to each provide their perspective on the dispute issues. The presentations can be cathartic and open dialog. They can also be emotional and appear to take the mediation steps backward from settlement (but necessary to move forward). It is important that parties have an opportunity to speak and be heard regarding the dispute and what their perspective is; not just to the Mediator but to the other participants.

7 Joint Session Opening Statements And Consensus Building

The joint session of a multi-party/complex dispute mediation is a time for the parties to describe their reality of the dispute to the Mediator and to the other participants. The time needed for presentations is obviously longer with multi-party/complex dispute joint sessions; hence the need when scheduling the preliminary joint session to set the order and length of time for each presentation. In fact, depending on the number of parties and complexity of the issues in dispute, the Mediator may devote the entire joint session to only opening statements and the consensus building on what issues need to be discussed and resolved to settle the dispute.

Again, it is important that the Mediator maintain control of the process. The Mediator needs to acknowledge the parties and their positions, while explaining that the parties' differences can either allow them to agree or agree to disagree. The key question that the parties need to answer after opening statements is whether they are committed to working to a resolution despite the differences between them. If they would rather agree to disagree, the parties need to understand that at mediation they have the opportunity to

shape the resolution. To agree to disagree, and continue towards litigation requires that they all weigh the risks of proceeding to trial and forfeiting the opportunity of a reasonable negotiation.

Setting the tone at the preliminary joint session also requires that the Mediator begin changing any preconceived settlement expectation of "what I want" to "what I need" or "what is reasonable" to resolve the dispute. A flipchart or whiteboard allows the Mediator to have a place and a time to list, prioritize or frame issues and groups of issues with dialog and open communication from the participants. This subtle technique of writing allows time for the parties to talk about the dispute and issues; it opens communication, which is most likely something that has broken down as a result of the dispute. Getting the parties to identify key issues begins the process of communicating with each other and the Mediator to move the dialog towards settlement discussions and what might be reasonable terms and issues to reach settlement.

The preliminary joint session is critical. It is a time when communication lines are re-opened and the participants can begin to understand why it is that other parties see the dispute differently. By the end of the joint session, the Mediator should have identified not only the issues involved in the dispute that will need to be discussed, but also have confirmed the follow-on sessions. These sessions should be arranged to meet with common alliances, those with common issues, and those where the Mediator can begin to work with the parties with leverage towards a settlement. An example may be seen in a construction dispute involving an owner, prime contractor, and multiple subcontractors. It may be necessary to meet with all the subcontractors as a common alliance. Maybe meeting with the owner and prime contractor will allow for a settlement that the prime contractor can then take back to the group of subcontractors. Again, the preliminary joint session and dialog allows the Mediator to appreciate the dynamics of the dispute and where to form bargaining positions.

As the joint session begins the process of communicating and framing the dispute from the perspectives of the participants, a good technique to use is to also frame the dispute in terms of settlement ranges. Some might think it is much too early to discuss settlement ranges. However, the transition from "what I want" to "what is a reasonable settlement" needs to take place. Obtaining a dispute range helps the parties to think about the "reasonable settlement" range and continues to build consensus before actual settlement offers are exchanged. A suggested technique is the use of polling / ballots.

8 Polling / Ballots

The use of ballots during mediation and with different groups/participants can be a very helpful tool to obtain input from the participants, while at the same time letting each party understand where the collective wisdom lies (Kichaven 2008). At the preliminary joint session, a poll relating to the overall dispute can be obtained from every individual participant, including the parties, attorneys, experts, asking "If you were to predict a successful and reasonable settlement number to resolve this matter what would it be?" The responses will give the Mediator an average settlement number as well as a range for where the participants think settlement will occur. The range lets the group see what the collective opinion is regarding the range for settlement negotiations rather each party

staying focused on only what they may want. Research has shown that the collective guess of a group can be very accurate and better than the vast majority of individual guesses (Surowiecki 2004).

Later on, when meeting with multi-defendants, a different type of ballot can be taken to seek input on the percentage of fault by each defendant and the percentage of financial responsibility (Kichaven 2008). This allows multi-defendants to consider respective liability, but also the financial resources available to make an offer to settle the matter (which may include consideration of insurance, contract indemnity provisions, limitations of liability, etc.).

Mediators should tap the collective wisdom of the group. Ballots should be filled out anonymously and independently to elicit the greatest number of individual predictions. The results should be tabulated by the Mediator and discussed. The average(s) will give the prediction of settlement and the individual ballot entries will provide the range. A narrow range will illustrate that the collective group view is fairly consistent in defining the settlement area. Remember, the collective wisdom of the crowd will be superior to the insights of any one individual when attempting to come to a consensus settlement (Surowiecki 2004). The opportunity to harness that collective wisdom should not be overlooked. The ballot process, whether polling the overall range of settlement to defining possible pro-rata sharing of contribution, provides valuable information to the group and to the Mediator.

9 Should There Be Co-Mediators

As discussed above, a team of Mediators may be appropriate in certain multi-party mediations (Crocker, et.al. 2001). Consideration should be given to the need to separately handle different groups of plaintiffs and/or defendants where Co-Mediators can better facilitate the separate groups. Thus, while there is always focus on the global settlement between the plaintiff side and the defendant side, multiple defendants or multiple plaintiffs typically need to mediate the details of any settlement offer or settlement recovery among themselves. Additionally, the addition of Co-Mediators with different styles, technical skills, professional experience, and cultures can be beneficial.

10 Reconvene Joint Sessions And Caucuses For Leverage

As the mediation process evolves, it may be necessary to revise and distribute caucus schedules. Be willing to reconvene joint sessions to discuss progress or impasses with the collective group. Re-poll the participants to find out if the settlement range is getting narrower, or if there has been any changes in the predicted settlement. In the event that the polling reveals a widening range of settlement, the Mediator has data to show that something has to change if the parties want to resolve the dispute.

The concept of leverage cannot be overstated when involved in multi-party mediations. Mediators should take advantage of leveraging alliances in joint sessions and caucuses to find champions in moving the dispute to resolution. Similarly, Mediators should be cognizant of negative influencers and destructive parties so that they can be leveraged by others and motivated to keep the process moving.

 ISBN: 978-1-84219-840-7 .

11 Mediation Agreement

The mediation agreement in a multi-party negotiation is absolutely critical. The resolution must be memorialized in detail, including the identification of monetary sums and payment terms, to the identification of who is paying. Additionally, terms regarding release of claims, confidentiality, indemnification, waiver of subrogation claims, and dismissal terms for any underlying litigation or arbitration should be set forth along with how the parties are to pay their own or each other's fees and costs.

Mediation agreements should be drafted immediately to ensure the settlement is memorialized. The mediation agreement should be read by all parties and the Mediator should remain available to answer questions. Before parties sign the agreement, they should be asked if they understand the terms and whether or not they are satisfied with the terms. So long as answered affirmatively, all parties and their counsel should sign the mediation agreement. To the extent that any changes or modifications need to be made in the drafting of the mediation agreement, those changes should be initialed by all parties and counsel. The original mediation agreement should be left with the Mediator, while copies of the mediation agreement should be distributed to all parties and their counsel.

12 Additional Considerations - Insurance Coverage

When mediating a multi-party/multi-issue complex construction dispute, the issue of insurance and surety coverage will most likely be involved. Obtain an understanding of coverage, reservations of right, limitations of liability, subrogation, Owner or Contractor Controlled Insurance Programs (OCIP/CCIP), Sub-Guard protection, performance and/or payment bonds, and/or letters of guarantee. While mediation focuses on the overall dispute and a settlement number, in multi-party dispute matters, the source and limits of proceeds is equally important. It does nothing to agree to a settlement number and not have available revenue sources.

13 Additional Considerations - Fees And Costs

It is also vital that the Mediator discuss the issue of fees and costs from the initial stages of the mediation. In a multi-party dispute, typically the parties do not all have equal share of the settlement, nor do they have equal share of the Mediator's time. The parties need to understand and agree how attorney, expert, even Mediator fees and costs are to be divided. If left to the end of the mediation, when the overall dispute has reached an agreement, the issue of fees and costs can unravel an otherwise successful mediation.

The mediation agreement should detail how the parties are to pay their own or each other's attorney, expert, fees and costs associated with the mediation, as well as how payment of Mediator fees and costs shall be paid. The payment of fees and costs is an area that cannot be overlooked and at times is a critical component of the mediation.

14 Conclusion

Multiple party mediations require that the standard mediation model of a pre-mediation exchange of positions, joint session, and caucus sessions with all parties present be changed. Engagement and commencement of the mediation needs to begin prior to the typical joint session. Scheduling, organization, and management of the mediation process requires that the parties and the Mediator understand that the mediation is a series of steps over time that rarely can be concluded in a single day joint session and caucuses.

Abstract:
The value of mediation has been widely acknowledged worldwide, as evidenced by the number of jurisdictions in which the courts enforce obligations on parties to negotiate and adopt mediation to settle construction disputes. In most contexts, voluntary uptake of the process is low, however, and research into prospective client perceptions is particularly valuable. The principal aim then of this paper is to explore construction participants' awareness, attitudes and experiences relative to mediation, based upon a questionnaire survey of small and medium-sized contracting firms in Scotland. While the bulk of respondents had no direct experience of mediation and felt unable to offer comments on key characteristics of the process, the findings suggest that a sophisticated appreciation of mediation at the client base level may remain illusive in Scotland. Similarly, few firms reported having any policies regarding mediation use and training in, or educational exposure to the process. Nonetheless, a small measure of generally successful mediation activity was charted in our study. This suggests that mediation is currently underused in the sector and increased efforts to promote the process to construction firms through such vehicles as publicity, training, contractual embedding and court promotion are needed.

Keywords:
Attitudes, Contractors, Mediation, Scotland.

1 Introduction

Proponents argue that mediation is a cheaper, quicker, and altogether more harmonious method of dispute resolution than traditional, adversarial methods. Despite evidence of modest growth in the use of mediation within Scottish civil disputes generally (Clark & Dawson, 2007; Clark, 2009), and evidence of the growing use of construction mediation in other jurisdictions such as England and Wales (see Gould et al, 2009), little evidence can be gleaned from the literature regarding construction mediation in Scotland.

The Scottish construction lawyers work we have undertaken has confirmed mediation as a suitable forum for such disputes, the opinion being it can be effective across the spectrum of

construction disputes irrespective of the relationships involved or dispute type (Agapiou & Clark, 2010; Agapiou & Clark, 2011). In most contexts, voluntary uptake of the process is low, however, and research into prospective client perceptions is particularly valuable. In particular, it can be questioned as to whether Scottish construction industry participants share the generally upbeat opinion of mediation expressed by their legal advisors. Indeed, one issue that arose from the previous study was the possibility of clients' unwillingness to engage in the mediation process.

The construction industry has long been painted as a macho, adversarial environment in which hard bargaining and tough reputations may be commonplace. Against this backdrop, we might pose the question then whether construction participants are willing to shift away from traditional approaches to dispute resolution to mediatory techniques, which may strike of a softer, more harmonious note? If they are, what are the drivers towards the adoption of mediation, and if not what are the barriers to change? The principal aim then of this paper was to fill a gap in the literature and chart Scottish construction participants' (specifically the contractor and subcontractor communities') awareness, attitudes and experiences relative to mediation.

2 Related Research

The first major survey into dispute resolution in the UK [England and Wales] construction industry was conducted in 1994 (Gould, 1999). The research found that less than 30 % of the respondents had actually been involved in an ADR process and that the UK construction industry lacked an understanding of the principles of ADR. A second survey by Gould (Gould, 1999) reported an increase in mediation experiences but concluded that 'formal mediation', defined by Gould (1999) as a 'private, informal process in which parties are assisted by one or more third parties in their efforts towards settlement', was rarely employed. Brooker and Lavers' research (Brooker & Lavers 2000) into the processes, perceptions and predictions regarding dispute resolution in the UK construction industry, found that, on balance, negative experience with dispute resolution related to arbitration and litigation, while all other dispute resolution processes produced positive results. Negotiation produced the greatest level of positive experience, closely followed by mediation. Respondents from both UK surveys predicted that, of the dispute resolution processes in the UK, the use of adjudication would make the most significant increase in the UK construction industry over ADR processes such as mediation or expert determination. In a follow-up analysis, Brooker's study (Brooker, 2009) of the use of mediation to resolve construction disputes at the Technology and Construction Court in England would seem to indicate a significant steer from the judiciary on when construction cases are deemed appropriate for the process of mediation. It would seem from the analysis, '*that most cases at the TCC are identified as suitable, particularly if they involve small sums compared to litigation and where there is uncertainty about factual and legal issues'.*

More recently, Gould et al (2009) have investigated the use of mediation in UK construction disputes in which parties involved in litigation at the Technology and Construction Courts in London, Birmingham and Bristol were asked how they settled their disputes, and in particular their experiences with mediation during litigation. The aim of the research was to establish under what circumstances mediation offers an effective and efficient alternative to litigation, as well as to determine whether and at what stage the court could or should encourage mediation.

The results of the survey showed that 35% of those cases that settled after commencing litigation in the TCC used mediation. The vast majority were undertaken as a result of the parties' own initiative, with the parties also agreeing the identity of their mediator. From this

survey, Gould et al (2009) also concluded that successful mediations were undertaken throughout the litigation timetable, and that cost savings attributed to successful mediations were also significant.

In South Africa, research into ADR in the construction industry includes Schindler's (1989) research into the role of mediation and arbitration as dispute resolution mechanisms in the construction industry and Barth's (1991) investigation into the suitability of arbitration as a dispute settling mechanism in the construction industry. Schindler's (1989) research focused on the awareness, experience, attitudes and perceptions of architects, engineers and contractors to mediation and arbitration. Schindler (1989) concluded that these participants did not have much experience in mediation and yet had negative attitudes and perceptions about the process. Barth (1991), in investigating the suitability of arbitration as a dispute settling mechanism in the construction industry, found that mediation was considered a more suitable dispute settling mechanism than litigation or arbitration by the industry participants (including attorneys). Watson (1996) analysed 44 different disputes with a view to establishing the effectiveness of the different dispute resolution processes utilised. Watson (1996) found that 85 % of the cases were resolved through the mediation process at a fraction of the cost and in a fraction of the time involved in a number of arbitrations on similar issues. Povey's (Povey, 2005) survey of mediation practice in the South African construction industry was a notable addition to the empirical evidence, replicating much of the approaches in previous research for a different context. From the survey, Povey (2005) found that that the practice of mediation in the South African industry was not consistent with the accepted principles of the process, that mediators did not as a matter of course assist parties in determining their own settlement, and that mediation activities centred mainly on the collection of information on the dispute by the mediator, as well as the formulation of a solution by the mediator. The respondents to the survey also revealed that mediators' knowledge and use of specific mediation process skills and techniques was inadequate.

There is evidence of growing disenchantment with statutory adjudication particularly in the construction industry, both because of its perceived unpredictability and also because of the increasing role that appeals to the courts seem to be playing in the adjudication process (Kennedy et al, 2010): could mediation be a viable and cost effective option to adjudication and litigation? It is then a very interesting question to ask whether the attitudes of construction industry stakeholders in Scotland creates a real limit to what could be implemented by a government that seeks to promote alternative approaches to the dispute resolution as part of its civil justice reform agenda . We anticipate that the outcome of this research will provide fresh stimulus to the current debate on mediation and further baseline data on the attitudes and perceptions of a wider spectrum of stakeholders on the utility of mediation to resolve construction disputes in Scotland.

3 Primary Data Collection and Analysis

Against this backdrop, this paper focuses on the utility of mediation as a process of dispute resolution within the sphere of Scottish construction disputes, as well as the role of construction participants within the process. It builds upon recent research on the experiences, attitudes and perceptions of Scottish lawyers to mediation in construction disputes (Agapiou & Clark, 2010; Agapiou & Clark, 2011; Agapiou, 2011).

The research is based upon a questionnaire survey of Scottish construction industry contractors and sub-contractors' attitudes towards, and experiences of mediation. An understanding of the views of construction industry participants towards mediation was essential to establish whether it had taken root in Scotland as part of the dispute resolution landscape.

A search in the literature did not produce any widely-based analysis of construction participants' opinions on mediation in Scotland. Research into the subject of mediation, as a dispute resolution mechanism for use in the construction industry has, received some attention in other common law jurisdictions, such as England, South Africa, New Zealand and Australia. Such research has generally aimed at establishing the perceptions, attitudes and experiences of industry participants towards mediation as alternative dispute resolution mechanisms. The questionnaire survey was deployed to build a better picture of the understanding of mediation, its various streams and whether these were being used or were at least being considered for use in the resolution of construction disputes in the Scottish context. The decision was made to survey both contractors and subcontractors to ascertain whether views were consistent between the two-part of the industry in Scotland or, if there was variation, how it manifested itself. Both sections of the industry have aspects unique to themselves and so the questionnaire had to be tailored to suit these differences. Two forms were produced with the same question themes and where possible use of exactly the same questions. We utilised Survey Monkey to gauge the views of participants relative to mediation. The quantitative data was processed and analysed using the SPSS 9.0 software package.

4 Research Findings

In this paper we offer a snapshot of recent survey research conducted with Scottish construction industry participants (mainly small contractors and subcontractors) on their attitudes and experiences relative to mediation. The findings discussed below are based on the survey responses and 63 contractors and subcontractors (hereinafter 'clients') conducted in 2011. Using a membership list of contractors and subcontractors provided by the Scottish Building Federation (SBF), comprising mainly small and medium sized construction firms, we collected responses from 63 firms, representing a response rate of around 18%.

4.1 Knowledge levels

The survey first sought to establish basic awareness levels of mediation throughout the Scottish construction industry base. Around 80% of respondents professed awareness of mediation. While this seems high, given the decades of publicity and promotion afforded to mediation, the finding that one in five respondents had apparently not heard of the process may be surprising. Furthermore, we might speculate that a significant proportion of those who did not respond to the survey were also unaware of the process. It is also worth noting that although the research method did not allow us to ask respondents what they thought that mediation entailed, given that relatively few respondents had practical experience of mediation or felt able to comment on its merit and disadvantages, we might surmise that there is a general lack of any sophisticated appreciation of the process at the industry user level. Those that had awareness of mediation had gathered information on the process from a wide variety of sources including the press/media, professional bodies, lawyers, colleagues and mediation organisations.

4.2 Policies on mediation use

In contrast to the widespread mediation pledges, for example, by public bodies, large commercial entities and Scottish law firms to make use of mediation in resolving disputes, only a small minority of respondents (19%) said that their firm had a policy or practice to consider mediation. A small number (13%) in fact had a policy or practice never to mediate, while in the main respondents had no firm policy or practice as regards mediation use. Such findings are not surprising given the limited experience that the bulk of respondents had with mediation.

4.3 Training and education

In sharp contrast to the high levels of construction lawyers who had received training or education in mediation, our survey found that industry participants in the main (88%) had no such educational exposure to the process. A smattering of respondents had received training either at university/college or through external training courses. Respondents representing contractors and subcontractors may emanate from a wide variety of professional and non-professional backgrounds and the limited reported exposure to educational exposure to mediation holds few surprises.

4.4 Mediation experience

The first and most striking aspect of the survey is that the vast majority of respondents (around two thirds) had no direct experience of mediation. From our survey we tracked 37 cases in which mediation had taken place. The most common types of dispute mediation were change to scope of work and payment (both 11 cases). Other reported cases included delay, professional negligence and damages. Change to scope of work and payment were also considered by respondents to be the two most amenable dispute types for mediation. More research is needed to ascertain what sorts of construction disputes may by their nature comport better with mediation, and why. We are currently exploring such matters in follow up interview work. Despite the very modest levels of take up, in general the mediations that did occur, can be considered to have been a success. Settlement rates were respectable and generally in line with levels reported elsewhere. From the reported cases, some 24 settled (65%) with another 5 (14%) partially settling. We were unable to record what later outcomes occurred in respect of cases that did not settle at mediation, but there exists significant anecdotal evidence in the field that mediations which are not successful often proceed to resolve shortly afterwards at an earlier juncture that would otherwise be the case. Aside from positive results relative to settlement, parties also seemed generally satisfied with the mediation process, in terms of such factors as speed, cost, the mediator and outcomes produced, although the data discerned a small measure of dissatisfaction with the costs time involved in the process. The findings here generally replicate, however, the positive evidence gleaned in the Scottish construction field from our recent study of construction lawyers (Agapiou and Clark, 2011). Given reported concerns over mediation's lack of coercive power, when compared to formal adjudicated outcomes which may carry with them the full force of law (at least on a temporary basis), it is notable that the majority of agreements reached at mediation recorded in the study were reportedly complied with. This finding may be of little surprise given the growing evidence of durability of agreements reached in mediation in Scotland (see eg Ross and Bain, 2010; Samuel 2002 (high levels – 90% and 100% respectively- of mediated settlements recorded adhered to without further enforcement action in the Sheriff Court Small Claims context). Evidence regarding the common adherence to mediated outcomes is often attributed to the fact that active participation in mediation by parties may lead to increased 'ownership' of settlements produced (McEwen and Maiman, 1984).

In terms of why parties mediated disputes, a whole range of reasons were cited, which mirrored commonly painted advantages of the process, the most prevalent being saving costs and time, seeking continuation of the business relationship, finding a creative agreement, the low value of the dispute at hand and assessing the risk of continuing the dispute.

Few parties had declined offers to mediate their disputes, but for those that did, factors which dissuaded them from mediating including the costs of mediation itself, a belief in the strength of their legal case, the idea that negotiation could settle the matter and a jaundiced view that the other side would not mediate in good faith.

Echoing this, failed mediations were typically blamed on the failure of opponents to compromise, with some evidence of tactical use and disputes having become too personal to settle amicably. It is difficult to discern from the findings the extent that lawyer intransigence to the process acted as a barrier to mediation or successful outcomes therein (although 40% of respondents to the question suggested that they had experienced being told by the lawyer not to mediate) . There is substantial evidence, however, of lawyer resistance towards, and cultural barriers towards mediation within legal circles (Clark 2012, chap. 2). Moreover, as discussed further below, a significant number of respondents suggested that ignorance and hostility towards mediation may remain ripe within the Scottish construction law fraternity.

4.5 Attitudes on mediation

Respondents were then asked to respond to a number of statements about mediation on a scale ranging from strongly agree to strongly disagree. Many respondents particularly those with no direct experience of the process, felt unable to offer such views. Nonetheless 25 respondents (40%) provided their perspectives on a range of key policy and practice issues surrounding mediation. Some of the main findings in this respect are discussed here. Table 1 illustrates the frequency and percentage response of respondents' attitudes to dispute resolution and mediation.

The vast majority of those that responded to this section were in favour of some sort of institutional pushing of mediation to put wind in its sails. For example, 76% strongly or somewhat agreed that judges should refer more cases to mediation. Similarly, 76% strongly or somewhat agreed that rendering mediation a mandatory first step in court litigation procedures was an attractive proposition with 71% favouring the widespread use of mediation clauses in contracts. While such findings favouring mandatory referral to mediation may at first blush seem surprising, it needs to be remembered that a compulsory form of extra-judicial forms of dispute resolution (adjudication) is already prevalent within the construction field. Moves towards compulsory referral to mediation, either through contractual embedding or court promotion, also chime with recently expressed views that mandating the process may be necessary to expedite the use of mediation, at least at the outset until levels of acceptance thereto increase (Peters 2010; Clark 2012, chapter 5). Generally speaking the senior judiciary in Scotland (save in the employment sphere, where there exists a recently established judicial mediation scheme in employment tribunals) has done little to suggest an appetite for more robust court promotion of the mediation (see Clark 2008), although it remains to be seen whether the current Scottish government's long awaited legislative response to the recent Gill review into civil justice (Gill 2009)will enhance the prospects of increased court initiation of the process taking place.

In terms of who should mediate disputes the respondents were no less unequivocal. Very few, a mere 4% felt that lawyers made the best mediators, with a whopping 88% stating that in their view those with industry experience as construction professionals were preferred. While more nuanced findings shall be ascertained on this issue by the authors in follow up interview work, the bare opinions expressed here provide food for thought. Such matters tie into the longstanding debate regarding the identity of the rightful inheritors of the mediator's crown.

While there is significant debate surrounding whether lawyers are the most appropriate professionals to act as mediators (Clark 2012, chapter 4), whether subject matter expertise in the area of dispute is an essential tool in the mediator's kit bag is also a moot issue.

It is hardly surprising that construction professionals, used as they are to adjudicators with significant subject matter expertise, should demand the same from their mediators. Respondents also seemed to favour more directive or evaluative styles of mediation that is contemplated by

 ISBN: 978-1-84219-840-7 .

the general, facilitative mediation discourse in the UK. Some 46% of respondents views that mediators should offer their own opinions on the merits of the dispute at hand.

With regard to other means of resolving construction disputes, a mixed bag of responses was revealed. Despite the recent push to re-launch Scotland as a centre for arbitration excellence, few respondents (20%) thought the process well suited to the resolution of construction disputes. Litigation fared even worse with only 12% of respondents viewing that it passed muster. This somewhat jaundiced view of traditional forms of dispute resolution were shared by our respondents to our survey of Scottish construction lawyers, albeit that the lawyers were more dismissive of arbitration than litigation. Adjudication, the default process of dispute resolution in many standard contracts, which attracted high levels of praise in our recent survey of construction lawyers (with some 84% stating that the process was well suited to the resolution of construction disputes), did not so fare so well with our client respondents with only 25% viewing it in a similar positive light to the lawyers. At first glance, this seems a striking contradiction.

Obviously the current work is a small study and the findings must be viewed with caution but this negative general appraisal of adjudication chimes with recently voiced judicial concerns (Macob Civil Engineering Ltd v. Morrison Construction Ltd[1]; William Verry (Glazing Systems) Ltd v. Furlong Homes Ltd[2]) about the unsuitability of the process for handling more complex matters and anecdotal tales of poor quality adjudicators. A significant number of respondents (47%) did view however that the prominent place enjoyed by adjudication in the construction dispute resolution landscape blocked out scope for increased mediation use. The unestablished nature of mediation may perhaps thus mean that it often fails to comport with the general *modus operandi* of clients and their lawyers in terms of dispute resolution pathways.

In terms of other barriers to mediation's growth, respondents saw both a lack of awareness of mediation (63% strongly agreed or somewhat agreed) and a negative perception of the process (50% strongly agreed or somewhat agreed) existing within the construction industry as stifling mediation's promise. Interestingly they suggested that construction lawyers similarly may act as roadblocks to mediation's journey in the construction sector by dint of their ignorance of the process (43%) and negative perceptions of it (42%). Although the possibility of socially desired responses cannot be ruled out, respondents were generally keen to play down, however, any notion that the supposed macho, adversarial environment of the Scottish construction sector militated against a role for mediation therein. In this sense, only 16% of respondents agreed with the statement that *"If I participated in mediation more often my standing amongst colleagues would suffer".*

Table 1: Breakdown of frequency and percentage response of respondents' attitudes to mediation

Attitudes	Strongly agree	Somewhat agree	Somewhat disagree	Strongly disagree	Don't know	Response Count

[1] Macob Civil Engineering Ltd v Morrison Construction Ltd [2000] 75 Con LR 101
[2] William Verry (Glazing Systems) Ltd v Furlong Homes Ltd [2005] EWHC 138 (TCC),

If I participated more often in mediation my standing amongst colleagues would suffer	0 0%	4 16%	6 24%	12 48%	3 12%	25
Mediation is inappropriate where there is a power imbalance between the parties	2 8%	13 52%	5 20%	4 16%	1 4%	25
Judges should refer more cases to mediation	7 28%	12 48%	3 12%	3 12%	0 00%	25
Making mediation a mandatory first step in the construction industry would be a positive development	6 24%	13 52%	4 16%	2 8%	0 0%	25
Lawyers make the best mediators	0 0%	1 4%	15 60%	5 20%	4 16%	25
Those with substantial knowledge of the area of dispute make the best mediators	9 36%	13 52%	1 4%	1 4%	1 4%	25
Litigation is generally well adapted to the needs and practices of the construction community	0 0%	3 12%	10 40%	8 32%	4 16%	25
Arbitration is generally well adapted to the needs and practices of the construction community	0 0%	5 20%	10 40%	4 16%	6 24%	25
Adjudication is generally well adapted to the needs and practices of the construction community	2 8.3%	4 16.7%	13 54.2%	1 4.2%	4 16.7%	24
Default to adjudication in many construction disputes renders mediation obsolete	0 0%	10 41.7%	7 29.2%	2 8.3%	5 20.8%	24
Mediation suffers from a lack of coercive power	1 4.3%	11 47.8%	5 21.7%	4 17.4%	2 8.7%	23
Mediation is an opportunity for lawyers to offer further services to their clients	2 8.7%	12 52.2%	5 20.8%	6 25%	4 16.7%	23
Lawyers will lose money if mediation grows	0 0%	9 37.5%	23 46%	16 32%	8 16%	24
Suggesting mediation to an opponent is a sign of weakness	0 0%	3 12.5%	10 41.7%	10 41.7%	1 4.2%	24
Construction contracts should contain a mediation clause	2 8.3%	15 62.5%	5 20.8%	1 4.2%	1 4.2%	24
A barrier to mediation's development in Scotland is its negative perception among construction industry participants	2 8.3%	10 41.7%	6 25%	2 8.3%	4 16.7%	24
A barrier to mediation's development in Scotland is its negative perception among lawyers	1 4.2%	9 37.5%	5 20.8%	3 12.5%	6 25%	24

Mediation training should be compulsory for lawyers	3 12.5%	11 45.8%	5 20.8%	2 8.3%	3 12.5%	24
There is a lack of awareness regarding mediation amongst the legal fraternity in Scotland	1 4.3%	9 39.1%	5 21.7%	1 4.3%	7 30.4%	23
There is a lack of awareness regarding mediation amongst the Scottish construction industry	4 16.7%	11 45.8%	4 16.7%	2 8.3%	3 12.5%	24
Mediation is of more utility in low value disputes	1 4.2%	7 29.2%	10 41.7%	4 16.7%	2 8.3%	24
Mediators should offer their opinion on the merits of the dispute before them to the parties involved	3 12.5%	8 33.3%	6 25%	2 8.3%	5 20.8%	24

5 Conclusion

This is a modest study and a first foray into client research in the area. Further research is required to shed more significant light on the findings unearthed here. In short, however, we can note that at the industry user level, and in respect of smaller firms at least, mediation may remain largely unnoticed, its potential unrealised. Take up is low and sophisticated awareness of the process and the benefits it can reap for participants scant. Much effort thus far has been expended selling mediation to lawyers through educational drives, conferences, seminars and training. Such endeavours targeting undoubted key players in mediation's progress is useful and continuing evidence of the same can be seen, for example, through the recent Law Society of Scotland's, 'Embedding ADR in Civil Justice' conference.[3] Much more needs to be done on the ground in repeating and escalating such efforts for the client base, however.

This is particularly true because in line with evidence worldwide, as our study suggests, when parties do try mediation, they generally enjoy it and often settle their cases. Much research has also suggested that parties (clients and their lawyers) often become repeat players in the process and champions for its cause. Crossing the Rubicon is the hard part. While lawyers may often act as gatekeepers to dispute resolution methods by dint of their traditional dominance in the lawyer-client relationship, recent evidence suggests that clients may be increasingly wrestling control back from their legal advisors in such matters (Clark, 2012, chap. 2) and thus direct selling of mediation to the client base may be of increasing importance to help inform their dispute settlement deliberations.

Further institutional scaffolding that may help to expedite use of mediation in the Scottish construction sector such as court promotion, professional rules mandating discussion and consideration of the process and contractual embedding remain largely absent in Scotland.

There remains much ambivalence from legal professional in Scotland (and the mediation community itself for that matter) regarding the extent that participation in mediation should be any sense propelled through arm twisting (Clark and Dawson, 2007; Agapiou and Clark, 2011). Nonetheless our survey suggests that the appetite for stiffer measures to drag parties into the mediation process may be stronger amongst the client base, at least for those who have had successful experiences within the process.

Abstract:

Purpose - Although it is the favoured choice to settle construction disputes in Kuwait, mediation has been rarely used due to some barriers (cultural difficulties and lack of awareness of mediation). This paper explores the deciding factors to use mediation with construction projects disputes, plus the barriers to mediation. Also, this paper presents the findings of what ADR strategies are currently been implemented by different organisations in Kuwait, to avoid litigation. Finally, elimination instruments to the barriers were revealed in this study.

Design/methodology/approach - Two sets of interviews were conducted in Kuwait, with 27 workers in the construction industry, to explore the preferred form of ADR, to identify the main reasons, in terms of culture and awareness aspects, for not adopting the existing ADR forms in construction disputes.

Findings - Mediation and conciliation roles are exist in Kuwait, these regulations were designed for the purpose of avoiding litigation by different organisations. Interviewed workers preferred resorting to mediation in order to settle construction disputes. However, a number of barriers to mediation were explored. The barriers to mediation are found to be, mainly, lack of awareness and another six cultural aspects.

Research limitations/implications - Confidentiality nature of disputes, especially in the Kuwaiti/Arabic culture, was the significant concern of the respondents. Additionally, preparing preliminary sessions due to the low level of knowledge in ADR gave an additional challenge to this research. Finally, translating the interviews' questions from English to Arabic and translating the results from Arabic to English during the transcription and analysis periods, needed extra time and efforts than normal research's transcription and analysis.

Originality/value - The paper provides original data on the practice and barriers to mediation in the construction industry of Kuwait.

Alternative dispute resolution ADR, Awareness, Barriers, Kuwait construction industry KCI, Culture, Mediation.

1 Introduction

Litigation as a formal way of dispute resolution is time consuming, costly, adversarial and damages, if not destroys, relationships and reputations. Construction law researchers revealed many alternative forms to litigation and arbitration, also in Kuwait different organisations prepared regulations for different forms of alternative dispute resolution. Although two forms of alternative dispute resolution ADR (mediation and conciliation) exist in two different documents produced by two bodies in Kuwait, these ADR guidance are rarely been used because of some barriers. A two-stage interview survey was conducted in Kuwait to investigate the need for ADR in the construction industry and the preferred form of ADR by industry and the reasons of preferring the named form. Furthermore, the causes of the delay of employing the existing forms of ADR in construction industry were under focus.

The cultural and knowledge barriers to employing different ADR forms in Kuwait were explored during the conducted interviews. Different themes from the open ended questions were found. In addition, several suggestions to eliminate these barriers were recommended from the interviewees.

As a part of an ongoing PhD which explores the possibility of implementing different forms of ADR to settle construction disputes in Kuwait, this study highlights the barriers to employing the existing forms of ADR in settling construction disputes. In particular, barriers to the use of mediation were researched through two sets of interviews conducted in Kuwait with 27 specialists in the construction industry of Kuwait from different sectors. The interviewees' perspectives provide a representation view and were picked randomly. All 27 interviewees, in both stages, were chosen randomly from different sectors based on their experience in the construction industry as well as their familiarity with construction disputes in the private sector.

Briefly, findings of this study can be summarised under two main headings: lack of awareness in mediation; and cultural concerns to use mediation. These matters were found to be the main barriers to the employment of mediation in order to resolve construction disputes in Kuwait. Afterwards, the resolutions to these barriers to mediation were indicated in this brief study.

1.1 Aim and objectives of this study

This paper arises out of a PhD study seeking to improve dispute resolution in the Kuwaiti construction industry. The main aim of the paper is to explore the barriers to ADR in the Kuwaiti construction industry, which has been achieved through the following objectives are as follows.

- To explore the requirements of Kuwaiti construction industry (KCI) in terms of resolving construction disputes in Kuwait.
- To identify the barriers to ADR in KCI.
- To recognise ways to overcome the identified barriers.

- To identify and explore good practice and the role of ADR (mediation).

The mentioned objectives, of this paper, are the vital objectives of the whole PhD research, which are concentrating on the data collection and analysis chapters of the mentioned PhD.

1.2 Research limitations/difficulties

Respondents to such studies are difficult to be found, particularly in Kuwait, where the culture makes them keep their conflicts and disputes to the highest level of confidentiality. In which, small number of respondents who have got the desire to be interviewed replied to both interview stages' calls. Some respondents, because of confidentiality, have not answered every question that was asked in the interview. Some other interviewees declined to mention their project's titles, furthermore, some wished to remain anonymous. All respondents and the company names have thus remained confidential in this study, due to the commercial sensitivity of the subject.

Because of the low level of knowledge and lack of awareness in ADR, a preliminary session for the actual interviewees was used to ensure that they understood the concept and principles of ADR and the aim of the whole session was to ensure non-bias and reliable data to eliminate the possibilities of unreliable outcomes. To ensure true judgement of the outcomes after the explanation session which was based on literature and been given before each interview, both interviews' questions and the above mentioned session was prepared by the authors and translated, from English to Arabic, with the assistant of independent expert. Additionally, during the transcription and analysis periods, translation (from Arabic to English) was a must. Translation in the transcription period was conducted directly by the authors and was checked by an independent body.

2 ADR forms in Kuwait

Cheung (1999) states that alternative dispute resolutions arose in the last two decades as a response to the high cost and lengthy process associated with arbitration and litigation. However, ADR procedures tend to be relatively informal, but their range is very wide (Uff 2005). In the United Kingdom different types of ADR mechanisms have been used in order to amicably resolve disputes in construction projects, such as conciliation, mediation, mini-trails and adjudication.

A review of the literature in Kuwait, in depth, proved that there are amicable alternative dispute resolution ADR regulations already in existence. These were prepared by: Kuwait Chamber of Commerce and Industry (KCCI) issued a document called (Nedham Al-Tawfeeq w Al-Tahkeem Al-Tejari: Conciliation and Commercial Arbitration System); and Kuwait Lawyers Association (KBAR) issued (Al-La'eha Al-Ejra'eyah w Al-Nedham Al-Asasi: The Procedural List and The Basic System). In addition, Kuwait Society of Engineers (KSE) which established a department called 'Kuwait Mediation and International Arbitration Chamber - under construction' they are preparing to issue a document called (Qawaed Al-Wasatta w Al-Tahkim Al-Ekhteyari fi Al-Masharie Al-Handasia: Regulations of Mediation and Optional Arbitration in Engineering Projects).

2.1 Conciliation

The Arabic translation of conciliation is "Al-Tawfeeq". Conciliation, as a commercial alternative dispute resolution in Kuwait has been provided by Kuwait Commercial

Arbitration Centre which was established on the 14th of November 2000 as an accredited centre in KCCI. Although this document does not give the conciliator(s) in Kuwait the right to produce binding decisions, conciliator(s) can contribute towards convergence of views. To have the ability to consult The Kuwait Commercial Arbitration Centre, to use conciliation as a type of alternative dispute resolution, there needs to be the following clause included in the contract.

"Any dispute arises upon this contract to be referred to the conciliation in accordance to the provisions contained in the Conciliation and commercial arbitration system of Kuwait commercial arbitration centre".

In addition to having this clause in the contract, to resort to conciliation, the disputants should have the desire to settle their dispute amicably and agree about conciliation. Agreeing to participate in the ADR processes is the most important movement towards choosing conciliation. This was found to be the main reason to why the usage of this and other types of ADR was poor. This conclusion was based on the interviews which will be discussed soon. The procedure of 'conciliation' in Kuwait is found to apply the conciliation regulations of the United Nations Commission on International Trade Law (UNCITRAL). The board of the centre forms an executive committee out of five members, which nominates the conciliation body in accordance with clause 14 of the previously mentioned document. The conciliation body contains either one member or more, who can be selected from the committee itself or externally, to conciliate in the dispute.

Clause 18 of the document states that the party who has the desire in conciliation submits a request to the secretariat of the centre. The request must include a list of the dispute's facts together with the applicant's point of view reinforced by supporting documents. From their side, the centre's secretariat informs the other party about the conciliation request within seven days from the submission day, the other party should reply within fifteen days from the date they were informed, expressing their point of view about the dispute.

The conciliation body studies the case and then invites the disputants for a hearing; the body's main mission is convergence of views, if they agreed about the final version of settlement, then this agreement should be signed. The conciliation body must finalise its mission within three months after their first meeting, extendable to another three months (if needed) by the committee's decision. In the case of a conciliation failure, the disputant's rights would not be affected with any shown or written during the conciliation processes. Finally, the centre provides the disputants, based on their request, with a certificate which describes how the centre viewed this dispute, the reasons why the conciliation trial was failed to settle it, without expressing any comments or views about the dispute.

Some contracts include recourse to a conciliator empowered or required to express his/her provisional view on the merits of the case (Uff 2005). Cheung (1999) stated that Conciliation and Mediation are very similar in both: nature and process. However, the difference has been positioned on the degree of participation by the neutral person. Street (1992) concluded that Conciliation seems to be the preferred choice in international and European usage. Uff (2005) concludes conciliation as "a form of aided settlement in which each side present a summary of its case, in trail mode and using advocates and experts, before a tribunal composed of a senior representative of each side and natural chairman".

2.2 Mediation

Stipanowich (1997) argues that mediation "is the most popular and familiar of settlement-oriented alternatives among contractors, design professionals and attorneys", and he adds that "its popularity appears to be a direct reflection of the relatively positive experiences all these groups report with the process. Construction attorneys generally perceived mediation to be the most effective approach for achieving a wide range of goals, including reducing the cost and duration of dispute resolution", and this is depends on "where parties are able to agree to mediate after disputes arise".

"Mediation, involves a neutral person finding middle ground between the positions of the parties with the aim of achieving a negotiated solution acceptable to all parties. However, in North America and Australia mediation is pre-eminent and in Hong Kong mediation is the favoured choice" (Sayed-Gharib *et. al.* 2010; after Uff 2005; Street 1992 and Cheung 1999). A role of mediation has been provided, on January 2004, by Kuwait Lawyer's Association Arbitration Centre which is a centre at the KBAR. In the introduction of their document, the general manager of the Centre, approved that "employing ADR is not ware or brand that we should mention its advantages anymore but it is a must which been imposed by the reality of today's international commercial".

Opposite to conciliation, the mediator is not contributing to the decision, nor are they pushing any of the disputants towards a settlement. Based on the previously mentioned documents, the main role of the mediator is to neutrally propose the effective procedure(s) towards an effective settlement for the dispute, as if they could do with resorting to expert determination in some points or to resort to arbitration in others. Resorting to *Al-Wasatta*, which is the Arabic translation of mediation, should be agreed by disputant parties of any contract. Again the following clause has been proposed by the general manager of the Kuwait Lawyer's Association Arbitration Centre.

"In case of a conflict between parties upon explanation, application or implementation of this contract to be referred to the mediation process of the Lawyer's \Association Arbitration Centre in the State of Kuwait in accordance to the procedural list and the basic system of the centre".

Another future role of mediation is under preparation and will be provided by The Kuwait Mediation and International Arbitration Chamber which was established on September 2010 by KSE. The main purpose of this chamber is to initiate roles of mediation and arbitration in construction disputes of Kuwait. Similar to conciliation, resorting to mediation should be agreed between parties in all cases, which can face different types of barriers although the role of mediation exists and useful. The barriers to mediation will be discussed in details derived from interviews held in Kuwait with workers in the construction industry who had experience in solved and unsolved disputes.

2.2.1 Regulations of mediation at Kuwait society of engineers

By late 2010, the KSE had established a department called The Kuwait Mediation and International Arbitration Chamber which is still under construction, this department is aiming to issue a document called (Qawaed Al-Wasatta w Al-Tahkim Al-Ekhteyari fi Al-Masharie Al-Handasia: Regulations of Mediation and Optional Arbitration in Engineering Projects) which should be concerning the dispute resolution in construction projects in specific and all types of engineering projects in general.

The Kuwait Mediation and International Arbitration Chamber's chief revealed that the main purpose of establishing this chamber under the society of engineers in Kuwait is to decrease resorting to litigation in order to resolve construction disputes. As they have found that litigation is an impediment to a project's progress and growth, they are intending to adapt the spirit of UNCITRAL regulations to be consistent with the *Kuwaiti Civil Code*. By then they will be ready to mediate in construction disputes. He added that the chamber will train mediators in the future to fill the needs of the construction industry in Kuwait.

2.2.2 Doubts to mediators

Brooker (2007) suggests that when a mediator 'gives advice or offers opinions' for any party in the dispute, this will affect the credibility of the mediator in which risks 'alienating' the whole process. Apparently, this is the case in the Kuwaiti culture, since it is a small community, which makes finding mediators without any type of relationships with one or both parties rare, if not impossible. In this regards, interviewees in Kuwait have been asked about the mechanism of trusting a third party while resolving construction disputes in Kuwait in terms of culture.

2.3 Section 2 in brief

The above recent findings gave the PhD research a new direction, since these regulations are not well-known and not been used regularly in resolving construction disputes. The essential issue of this study is that for some reasons the above detailed forms of ADR are not widespread, however, causes of this shortage were asked in the second stage of the interviews. It is always easier to resort to either mediation or conciliation if it is printed in the contract on the bases of previous agreement between parties, however, resorting to any amicable method of ADR (e.g. mediation and/or conciliation) is always voluntary for all disputants and it is all about the conformity between parties.

In fact, it is all about agreement between parties either before the occurrence of dispute, during the contracting phase, or yet after the dispute occurred between parties. In both cases, before or after the occurrence of dispute, the construction parties are always faced with existing barriers towards ADR. Although some interviewees preferred arbitration, just because it has a binding decision, most interviewees preferred mediation as an alternative dispute resolution in construction disputes. This suits the traditional Kuwaiti culture. For this reason, in this research, barriers to mediation in construction disputes will be considered only.

3 Methodology

A set of 11 qualitative interviews, furthermore, another set of 16 qualitative interviews were conducted in Kuwait with workers in the construction industry during October to December 2009 (1st set) and November to December 2010 (2nd set). Interviewees were selected based on their experience in construction disputes based on preliminary interviews conducted in Kuwait during December 2008 to February 2009 (Sayed-Gharib *et. al.*, 2010). Face-to-face interviews are the most suitable method to collect data in Kuwait, for the sole reason that culture and the social environment in Kuwait depend on eye contact and direct conversation. That is why another stage with more detailed questions has been conducted latter on.

The first set of interviewees was selected randomly on the basis of their professionalism in construction projects and familiarity with construction disputes, regardless the sector that they were working for. Consequently, interviewees in this stage were selected from different

sectors. For this reason, this stage of interviews was broad and open not as specific as the next stage of interviews, however, in the second set of interviews, all interviewees were selected for experience in construction disputes in the Private Sector. Finding interviewees, who have had experience in construction disputes, was with the help of the KSE and the KBAR in which these two organisations have got data of different types of workers in the construction industry who have been involved in disputes previously. The interviewees, in this stage, ought to be categorised as follows: three were reported as investors in construction projects; four consultants in construction field; and a further four experienced contractors in construction projects. Others were: three lawyers experienced in construction disputes; and two experts who act as third parties (i.e. mediators, conciliators and adjudicators) in construction disputes.

The data of the interview revealed that most workers in the construction industry believe that mediation gives a better deal, compromises a solution, shows neutrality, has a non-binding agreement unless signed, is a non-adversarial method, takes a shorter time, is a confidential process, is a flexible procedure, maintains relationships and it is a voluntary process.

Although most of the interviewees agreed that mediation offers massive amounts of benefits, participants commented on the barriers to workability of mediation in construction disputes in Kuwait. The data analysis established an approach to improve employing mediation against the mentioned barriers which frustrated the implementation of mediation in spite its existence in different industries institutes of Kuwait.

3.1 Data analysis

Both sets of interview data were analysed manually by taking matching themes from interviewees' responses. Considering that different words have different synonyms, and sometimes different synonyms have got different meanings. Nonetheless, translating the data from Arabic to English, added a difficulty of different translations. (See 'Research limitations/difficulties' section below).

3.2 Broad-spectrum of the outcomes

3.2.1 First stage of interviews

- Signs of preference of mediation.
- During identifying the requirements of KCI found that there is a cultural problem and lack of understanding of ADR.
- Justification of focusing on construction disputes resolution in private sector.

3.2.2 Second stage of qualitative interviews

- Poor usage of the existing ADR forms.
- Having a preference of mediation rather than any other ADR, in order to resolve construction disputes.
- Suffers of Lack of awareness in the amicable alternative dispute resolution (mediation).

- People in Kuwait need edification of ADR and the benefits of ADR.
- Not only workers in the construction industry but the whole public of Kuwait need this type of education, because each individual will be involved in construction of at least their own house.
- Important concerns (based on culture) for instance: trust and integrity of "ordinary" third party dispute resolution process.

Specific data analysis, detailed outcomes description and discussion are specified soon, just after the research limitations/difficulties and literature review.

4 ADR not litigation or arbitration

Six interviewees, out of 27 interviews with professionals in construction industry, preferred not to resort to ADR in case of dispute in construction projects and keep the existing applicable route (five interviewees preferred arbitration and only one interviewee preferred litigation). The interviewee (a senior lawyer) who preferred litigation had doubts about the workability of voluntary nature of ADR in Kuwait, as people there do not have the will to use such process and they have got used to adversarial forms of dispute resolution. In addition, the interviewee praised the dignity, integrity and impartiality of the judicial authorities. He added "middle eastern culture trusts judicial authorities, and believes in their integrity and impartiality which makes it too difficult to trust neither a third party nor accepting the idea of ordinary person". Finally, because this respondent was interviewed in the second stage, he shared some barriers to ADR with other interviewees, which will be discussed later (see barriers to mediation below).

The other 5 interviewees, who preferred arbitration, have not refused ADR because they are not good alternatives to litigation and/or arbitration; their key reason was in preferring arbitration that 'it is binding'. In other words, they have got doubts to the success of the non-binding processes. However, they have all shown their disapproval towards the high amount of arbitrators' fees and the long time procedure of arbitration (minimum six months) in Kuwait, which is longer than litigation in some cases. Since (82%) of interviewees agreed on ADR and as the objectives of this paper are to explore and study the barriers to ADR (mediation), so the interviewees who refused resorting to ADR in construction disputes will be neglected for now.

5 Mediation in Kuwait

The 15 interviewees out of 27 (71%) who agreed on ADR, preferred mediation as an alternative to litigation and/or arbitration in construction disputes, which suits the situation in Kuwait due to different reasons (will be discussed soon). Nevertheless, they mentioned some barriers to mediation, which will be revealed later. Another 11 interviewees (29%) were distributed as follows: only one (5%) selected conciliation whereas another five (24%) had no clue what to choose, notwithstanding they have agreed about ADR. However, the five interviewees who did not decide what ADR to choose, they were not able to make a decision because of their lack of knowledge in ADR (see barriers to mediation below).

5.1 Conciliation in Kuwait

Only one expert interviewee selected conciliation because of the involvement of the third party in terms of advising the disputants, this interviewee (a lawyer/ex-consultant) had real concerns about the neutrality of the third party. In which the interviewee preferred to give the opportunity for the independent third party to express their views frankly, so both disputants can discover whether the third party is neutral or not, that was why he have not chosen mediation as the best practice

Furthermore, all interviewees have agreed about the barriers to ADR and they do believe in the same barriers to mediation with believers of mediation. The next section demonstrates the 'raison d'être' of mediation which was presented in the literature reinforced by the interviewees perspectives.

5.2 Why mediation?

Although mediation was preferable in both stages of interviews, detailed reasons of preferring mediation were asked during the second stage of interviews only. That is why only twelve interviewees out of sixteen (who decided that ADR is more convenient than litigation and/or arbitration in the second stage of interviews) will be taking into account for this section. Out of 12 interviewees only nine insisted that mediation is the most suitable form of ADR for construction dispute resolution, one preferred conciliation and two interviewees have not had any clue what sort of ADR to choose. Different factors have been argued by the interviewees (i.e. duration and cost of dispute resolution, different effects of the settlement and the nature of the process and the third party in between).

5.2.1 Shorter time

All respondents insisted that mediation saves parties' time which can be wasted through long process and routine of litigation. Two interviewees, a contractor and a consultant, declared that "actually we are looking for shorter process to settle our disputes", whilst other interviewees' opinion was not far away from that. Four interviewees (an investor, two contractors and an expert) agreed about that arbitration did not achieve the purpose that it was found for. Arbitration was found to make process shorter and faster, contrary it made it longer, slower and more expensive (the cost will be discussed below).

5.2.2 Cheaper/cost effective

Disputants are always seeking for lower costs to resolve their disputes. An investor confirmed that "Gaining money is what we are working for, and thus there is no reason to waste it in courts". Although the court's fees are very cheap comparing with the claim's amount (0.01% in best cases), the cost of lawyers are too high (50-60% of the claimed amount). In the words of an interviewed contractor "lawyers cost is an extortion". Two out of three interviewed lawyers objected about the high cost of lawyers and demonstrated that 'lawyers can be in long-term contract with firms, so they take their disputes with no extra fees, it is just the yearly agreed payment!' On the other hand, when arbitration produced to be an alternative to litigation, it was meant to be cheaper and faster as mentioned above, but in fact it became approximately equivalent to litigation in terms of cost if not more expensive, however, lawyers agreed with other respondents (100%) about the effective cost of mediation.

5.2.3 Maintaining relationships

Relationships are always an issue in any kind of conflicts. To maintain relationship (either social or business) disputants must show tolerance and forgiveness toward each other and the conflicted case in between. Nine interviewees (all contractors, consultants and investors) have had the potential to waive their rights in the sake of maintaining their relationships with other parties furthermore their reputation in the market, since it is small community. Definitely, lawyers and mediators have not had an opinion in this part simply because they have not got a right to be waived. Yet, all respondents thought that resorting to mediation offered an advantage to the construction industry, in which it keeps the favourable relations between the parties. Moreover, the mediation option preserves the disputants' reputation between other workers in the industry. Also, mediation can improve the reputation of the parties in some cases, in the sense of they are flexible in emulation to conflicts and do not go extreme in antagonism.

5.2.4 Compromising better deals/flexibility

Negotiating around a dispute most likely gives a better deal, whether parties reached an agreement or they have not. Richbell (2008) insisted that "mediation provides the opportunity for the whole story to be told" wherein disputants will have the chance to listen to each other rather than facing each other in the court or arbitration process. The best deal can be reached while going through litigation process is (Win/Lose) situation, and most likely its (Lose/Lose) situation (Sayed-Gharib *et. al.* 2010). However, because mediation is not a legal argument, both/all parties can be winners, (Win/Win) situation, since in mediation all of the disputants have to agree and say YES to the deal.

Nine interviewees, who agreed about mediation, concurred that having the negotiation opportunity with other parties, with the attendance of a neutral third party, always gives them more comfortable and stronger position in their standpoint. In addition to that, mediation process could reveal for them their own mistakes, if any.

All interviewees, even the ones who did not prefer mediation as ADR to construction disputes, believed in dealing with the dispute by mediation, definitely, results (Win/Win) situation. Not only money wise, but maintain relationships and keeping reputation can be accounted as winning matters in the case of mediation succeeding. This confirms that, the interviewees who did not agree about mediation, either did not accept as true that mediation is booming, or they did not understand what is mediation and how does it work.

Parties resort to dispute resolution in order to defend their possessions and rights. Aiming to get hold of the whole rights might cause losses in other sides of the projects itself or parts of the whole organisation. Disputants can share the (Win/Win) position by compromising a solution, assuming that achieving hundred percent solution, (Win/Lose) situation, is impossible by confrontation. 8 of the interviewees granted that mediation is all about compromising a suitable solution, which might not fit most of the disputants' desires, but it is a fair agreed solution.

5.2.5 Non-adversarial

"Move away from adversarial methods" (Ilter and Dikbas 2009) because adversarial schemes in dispute resolution irritated parties in terms of their stability in the market and relationships with other parties. Eleven interviewees believed that their organisations definitely will be effected if they had a case in the court, one of the interviewees described being in court as "a

headache". Additionally, number of interviewees preferred, in previous disputes, to neglect their rights rather than going through litigation procedures.

5.2.6 Confidential

Confidentiality is very important issue in construction disputes, since it reflects on the parties' reputations and relations with others. Reputation in construction industry is case sensitive; it can be affected by having many cases in the court, and "in fact libellous nature of litigation may perhaps damage anybody's reputation" said by an interviewed investor in construction projects. Protecting parties' reputation is all about confidentiality of the dispute resolution process. Eight respondents agreed that mediation provides the meant confidential process.

5.2.7 Non-binding

The mediation's agreement is not binding for disputants, unless they have signed an agreement, which allows the disputants to resort to litigation during the process or even after the decision was made (before signing the agreement). The non-binding nature has encouraged six respondents to prefer mediation as a trial to settle their dispute before falling into arbitration/litigation routine. Yes, some interviewees argued that this opportunity can be misused (i.e. to delay the opponent and/or to decrease their chances of winning) but mediation worth trying in which it can save massive efforts.

5.2.8 Voluntary

Although mediation is known as a voluntary process, it has been addressed as an advantage to mediation by only four interviewees in Kuwaiti construction industry. The humble percentage indicates lack of acceptance of voluntary mediation and they do prefer mandatory mediation instead which will be revealed soon.

5.2.9 Neutrality

The neutrality of an ordinary third party, not judicial body, is always a question, however, barely two of interviewees accepted that a well trained third party (mediator) is trustworthy, and these two were mediators no doubt. The low percentage can be considered as a deciding factor to mediation. There is a significant percentage of interviewees show doubt on neutrality of mediators (read doubts on neutrality below).

5.2.10 Summary

Nine deciding factors to mediation (see Figure 1) have been agreed by interviewees, the level of agreement varies due to lack of awareness on mediation, however, the short illustration brief sessions were enough for the interviewees to recognise the appropriateness of using mediation to resolve construction disputes. The deciding factors to mediation in this study were picked up from the general speech with the interviewees as themes, with consistency to the advantages of mediation in the literature. The last three factors, which had results of 50 per cent and less, were faced with some disagreement by number of interviewees. The disagreement will be discussed below as 'difficulties to use mediation'.

 ISBN: 978-1-84219-840-7 .

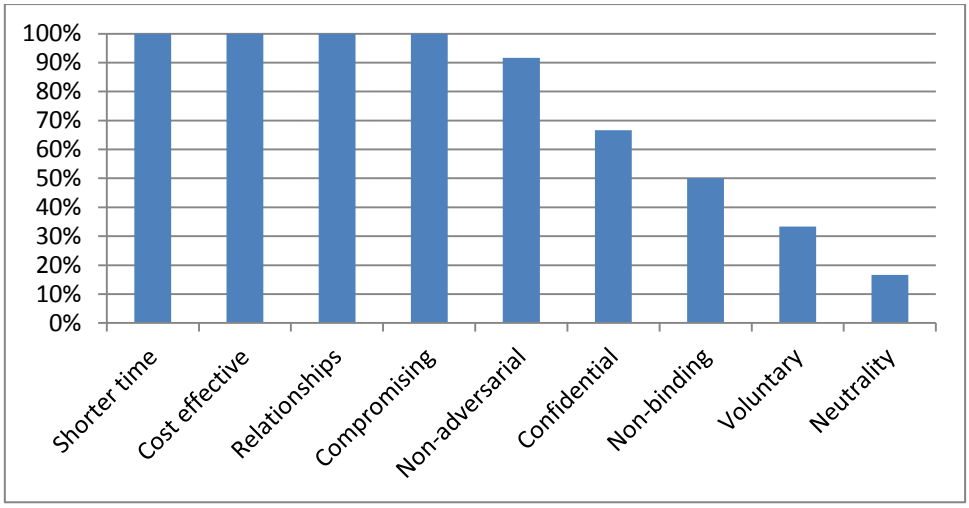

Figure 1: Deciding factors to mediation (advantages)

5.3 Recognition of appropriateness

A huge percentage of interviewees (71 per cent) agreed about the appropriateness of mediation, but due to lack of awareness about it, the usage of mediation was poor in construction disputes. The above mentioned documents conditioned resorting to ADR by certain clauses should be in the contract. Richbell (2008) concluded that 'just because the contract does not specify mediation, it does not mean parties cannot use it' parties can always agree to resolve their dispute in any form of dispute resolution, however, mediation or any other sort of ADR must be agreed in due course before it is too late. On the other hand, respondents consented that resorting to mediation, initially, sounds like an easy choice and a smooth process but in fact it is not. There are other difficulties to employ mediation in Kuwaiti construction disputes, these difficulties will be called barriers to mediation. The following sections demonstrate the Kuwaiti perspective upon the barriers to mediation in construction disputes from the interviewees' experience.

5.4 Difficulties to use mediation

Although the last three (above mentioned) advantages of mediation are common in the literature, and agreed by small percentage of the interviewees but they led the authors to a significant problem toward employing mediation. The data provided indications of difficulties to use mediation. Authors have recognised lack of approval towards ADR due to the lack of acceptance of the said advantages as advantages from large percentage of interviewees, furthermore, some other difficulties to use mediation found during the second stage of the data collection period.

5.4.1 Binding vs. Non-binding

Half of the interviewees were encouraged to prefer mediation to its non-binding nature. Despite the fact that 33 per cent claimed that the decision after mediation trail must be binding once disputants agreed to resort to mediation, no doubt, they do not know enough about mediation. Disputants always, not only workers in the construction industry, have got concerns of their opponents' intentions. The rest of the 17 per cent did not have any clue in this regards because of their lack of awareness.

In addition to the above mentioned 33 per cent of the twelve interviewees who agreed about mediation but not it is non-binding nature, there are the interviewees who have chosen arbitration for this reason which rises that percentage to 47 per cent out of the whole set of interviewees. This high percentage puts a question mark in front the non-binding nature of mediation, however, Richbell (2008) insisted that is dangerous to give the mediator the chance to recommend a binding decision for many reasons; the mediator may use or reveal confidential information given by parties, it can destroy the mediator's neutrality for one of the parties or both, and by binding decision of mediator parties abdicate the opportunity of having a (Win/Win) situation because any third party's decision can be, often, (Win/Lose) to one of the parties.

5.4.2 Mandatory vs. Voluntary

Only 33 per cent considered the voluntary nature as an advantage to mediation, while 67 per cent thought making ADR compulsory by obligating disputants to go through ADR forms before resorting to litigation/arbitration was important, however, from this huge percentage it seems that ADR got to be a mandatory clause in the contract, not an optional choice, in case of dispute, and this could be one of the causes of limited spread of mediation so far.

5.4.3 Doubts on neutrality

Nearly 17 per cent of the interviewees (mediators only) believed in the neutrality of an independent and well trained third party. Surprisingly, 42 per cent of interviewees did show lack of trust in the third party's neutrality neither integrity, on the grounds of that this third party is an ordinary person not judicial body, in addition to that Kuwait is a small country and the opportunities of knowing each other are very high. The rest of the interviewees (41%) did not comment on this part as they are not aware of the situation.

The three above revealed difficulties pave the way for barriers to mediation's widespread in resolving construction disputes of Kuwait. The early findings (barriers to mediation) will be discussed below, in details, in order to diagnose the situation and limitations of employing mediation in the construction disputes.

BARRIERS TO MEDIATION IN KUWAITI CONSTRUCTION DISPUTES FROM INTERVIEWEES PERSPECTIVE

During the second stage of interviews and after discovering, from the first stage of interviews, that the existing ADR process' in Kuwait are rarely used, number of disincentives of implementing ADR were revealed by interviewees in the second stage. The themes of disincentives were categorised based on the redundancy. Two main barriers to employing ADR were shaped; lack of awareness and cultural aspects. Moreover, six different barriers were classified under cultural barriers as the mentioned barriers are well related to the culture.

6 Lack of awareness in ADR (mediation)

6.1 Level of knowledge

Ilter (2009) pointed to the level of knowledge on mediation in the Turkish construction industry, she explored that there is a severe lack of knowledge upon mediation. Although level of knowledge is an important issue, authors discovered from the preliminary interviews

that there is major lack of awareness of mediation in the Kuwaiti construction industry. All interviewees, in both stages, (27) were asked about their knowledge or awareness of mediation. None of their responds were out of the following choices:

- Don't know about mediation, and need brief explanation about it.
- Know about mediation, but not in detail.
- Know about mediation fairly, but not used it.
- Know about mediation very well, and used it.

They have answered this question as follows in Table (1):

Table 1: level of knowledge/awareness on mediation

Respond	Frequently	Percentage
Don't know about mediation (needed brief explanation session before the interview)	**10**	**37 %**
Aware about mediation, but not in detail (procedure and process)	**8**	**30 %**
Know about mediation fairly (but never used it yet)	**5**	**18 %**
Know about mediation very well (used it at least once)	**4**	**15 %**

Although 30 per cent designates the low level of knowledge on mediation, 37 per cent is a significant indicator of lack of awareness of mediation.

6.2 Interest of improving the knowledge and usage

Sixteen interviewees, during the second stage of interviews, were asked about their need and desire to learn more about mediation. The asked questions and detailed answers are discussed below.

Q: If there is an opportunity to learn more about mediation will they go through it? Answers (in Table 2) indicate that 75 per cent have got the desire to improve their knowledge in mediation, which identify the lack of understanding of the mediation mechanism.

Table 2: workers' desire in learning more about mediation

Respond	Frequently	Percentage
Yes	**12**	**75 %**

Maybe, if needed.	**2**	**13 %**
No	**1**	**6 %**
Do not know	**1**	**6 %**

6.3 Interest of using mediation

Another question was asked to the respondents about their consideration of using mediation in resolving future disputes. The results are presented in Table 3 which shows that 63 per cent confirmed resorting to mediation in order to settle their construction disputes in future.

Table 3: Future view of resorting to mediation

Respond	Frequently	Percentage
Definitely	10	63 %
Maybe, if needed	3	19 %
No	1	6 %
Do not know	2	12 %

7 Different cultural aspects

All interviewees, in the second stage interviews, agreed about six cultural barriers to ADR (mediation in specific). Certainly, the respondents revealed on signs of the following six barriers (Figure 2 below) while answering about the advantages of mediation. In fact, views are always vary from place to place, there are some factors which can be addressed as advantages somewhere and can be disadvantages somewhere else, it depends on many aspects (i.e. Culture). So, what can be a deciding factor to use mediation in UK (for instance) can be a barrier to mediation in Kuwait. Below a brief discussion of cultural barriers which revealed by the sixteen interviewees in the second stage:

 ISBN: 978-1-84219-840-7 .

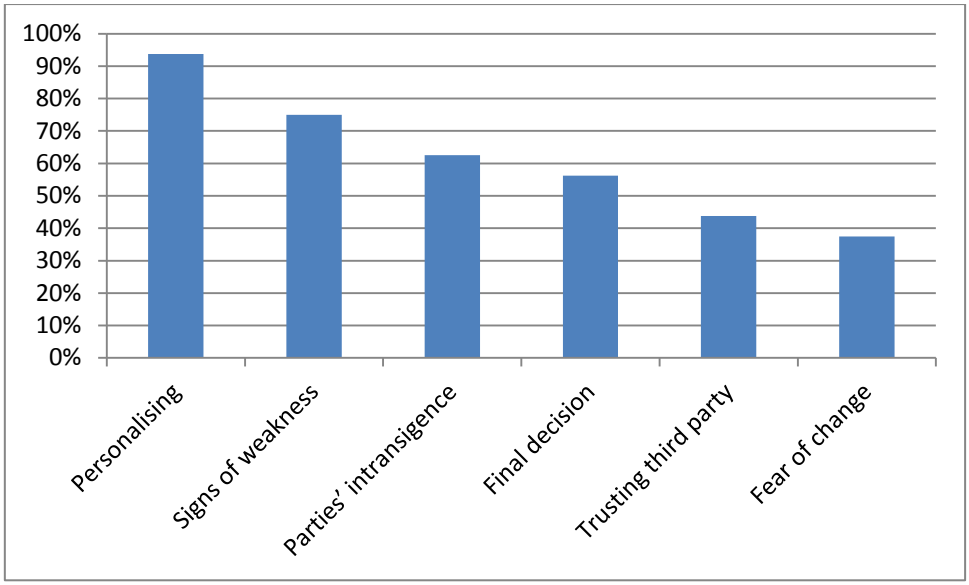

Figure 2: Cultural barriers to mediation

7.1 Personalising

One of the cultural aspects in construction disputes is taking projects' conflicts personally, in which this conflict turns into a personal conflict. Some interviewees found such an incident as normal human being phenomenon. Ninety three per cent of respondents thought that disputants always take their disputes as personal issues due to the prevailing adversarial methods of dispute resolution. A lawyer suggested that "people always think of revenge if they did not get hold of their desired rights". Disputants always seek justice in addition to the 'winner' feeling, so it is all about righteousness.

Mediation can provide the two above mentioned criteria 'justice and feeling'. Yes it might not be the feeling of 'winner' but it is the feeling of 'satisfied', an investor declared "why should I take it personally if we had a smooth resolution". However, mediation is not widespread actually most people never tried it or even heard about it, they never seen a result to be able to judge on the process abilities. An expert suggested 'Successful practice by influencing famous bodies to be revealed to public' by then people may accept to change their view towards taking disputes as personal issues.

7.2 Signs of weakness

The existing contracts do not contain clauses for ADR which shows proposing mediation, or any other form of ADR, as a sign of weakness. Proposing mediation gives, indirectly, feeling of defeat/victory for both parties. In this case, who offers mediation? This is an important question at the beginning of every dispute. In fact offering mediation in due course is a vital, however, none of the disputants have got the potential to offer resorting to mediation due to their prestige. Precisely, 75 per cent of interviewees agreed that offering mediation shows signs of weakness to their opponents, it is a common thought. The only found solution for this barrier is to articulate mediation in the contract at the beginning, so mediation will not be an optional choice any more it will become a compulsory in case of dispute.

7.3 Parties' intransigence

Intransigence is a cultural matter; parties in Kuwaiti construction industry sometimes do have the desire to break their opponent. Sixty two per cent admitted that they had this feeling during disputes and thought they could do it by litigation, however, professionals with their long experience have discovered the impossibility of such a desire, elderly and experts suggested this barrier can be eliminated by obligating parties to resort to mediation.

7.4 Concerns of the final decision's effectiveness

While the mediator's decision is not binding for parties, unless an agreement has been signed, parties have doubts of the reaction of their opponent. Fifty nine per cent of the interviewees noticed their concerns of the finality of the decision, a consultant stated "what if we agreed upon a settlement then the opponent felt uncomfortable and took their actions the next day". Clearly, this is can be addressed as miss-understanding (or low level of knowledge) of mediation. In fact the decision, of mediation, is binding after signing the settlement agreement; indeed nobody signs such an agreement timidly.

7.5 Concerns of trusting non-judicial bodies

Forty two per cent had doubt in ensuring the neutrality of the third party if s/he was not a judicial body. Three interviewees shared the same sentence "we do trust a judicial third party but not an ordinary third party". Hesitations towards the fairness of a third party came on surface because: low level of knowledge of the mediation process, lack of trained mediators and essential reason is *Kuwaiti judicial body's* Impartiality, as a lawyer in construction disputes insisted. Finding trusted, experienced and well trained mediators is definitely the perfect solution.

7.6 Fear of change

There are always fears of trying something new. Litigation and arbitration are readily available, even if these procedures are not convenient, smooth, slow and expensive. But they feel that they know these procedures very well, there is an old Arabic saying says *"what you know is always better than what you do not know"*. Even though the fear of change between workers in the construction industry is 40 per cent and this percentage is not as high as other barriers (see Figure 2) but it should be improved. It seems that the fear came on top almost due to the lack of awareness in mediation, some interviewees suggested helpful solution (i.e. edification and training courses). Although solutions to eliminate barriers are beyond the target of this study but some suggested solution will be discussed below.

8 How to eliminate the mentioned barriers to mediation

As a result, this study paved the way for further studies. Wherein some interviewees suggested new directions for supplementary studies; to eliminate the above mentioned barriers to mediation, and to improve the employment of the existing ADR in Kuwaiti construction industry's disputes:

8.1 Suggested instruments of cultural improvement and edification:

The interviewees suggested different ways to demolish the mentioned barriers. Some of these tools were revealed by other researchers:

- Education: (Schools or Illiteracy Centres);
- Training courses: (Academic or Coaching) trainings for (Long or Short) periods;
- Information: (Books, Booklets, Leaflets, Brochures, Electronics or Internet);
- Media: (TV, Radio, Newspapers or Internet);
- Practice: (by famous organisations and influential people); and
- Events: (Conferences, Workshops or Seminars).

These instruments have the ability to influence the culture and people's awareness.

8.2 Other suggestions to improve the employment of ADR in KCI's disputes

Thirty four per cent of the interviewees agreed that the government must obligate projects' parties to add clauses to the construction contracts in order to force disputants to go through ADR by law. Obligating parties towards ADR was discussed in the literature in different countries. Some researchers found that this approach might affect the voluntary nature of ADR in which does not achieve the goal of ADR (i.e. flexibility), and some other researchers found it as a must for construction contracts due to the massive cost of litigation and/or arbitration and the time overrun in adversarial types of construction dispute resolution.

9 Further discussions and Conclusions

9.1 Mediation in Kuwaiti construction industry and barriers

Although it is not specially designed for construction disputes, a role of mediation exists in Kuwait (see Table 4). Future role(s) of mediation in Kuwaiti construction industry can be considered in further studies. Particularly, while this study focused on the barriers to employing mediation, expectations of exploring future role(s) of mediation would be easier and available.

Table 4: ADR forms in Kuwait

Regulations of Mediation and Optional Arbitration in	Kuwait Mediation and International Arbitration Chamber - under	Kuwait Society of Engineers **KSE**	Should be mediation and optional arbitration	Under preparation expected late 2011	N/A

Engineering Projects	construction				

This is an in progress research which aims to substantiate the effectively of mediation to resolve construction disputes amicably, neutrally, cost effectively and within shorter duration than litigation. A settlement which keeps reputation of disputants, maintains their social and future business relationships. The above mentioned advantages of mediation were described, by the interviewees, as the deciding factors to mediation.

On the other hand, the interviewees highlighted the lack of awareness and the cultural barriers to use mediation in the construction disputes (i.e. personalising, signs of weaknesses, parties' intransigence, concerns of the final decision's effectiveness, concerns of trusting non-judicial bodies and the fear of change)

9.2 Barriers elimination vs. mediation implementation

Technically, in order to employ mediation as a trail to resolve construction disputes, parties should have agreed to resort to mediation in the case of dispute. The main reason of the pre-agreement is that disputants always feel weakness if they have offered mediation during dispute phase, which makes the agreement upon mediation as dispute resolution process is a must to be articulated as a clause in the contract. Other barriers can be eliminated partially; however, reducing the effect of the mentioned barriers could take long time especially the cultural aspects. Changing culture considered to be impracticable in short time periods. This ongoing research is intending to discover new ways of removing the barriers to mediation, in sequence to implement mediation in construction dispute.

10 Acknowledgements

This study faced two main limitations; low level of knowledge and lack of awareness on ADR; and the need for independent translation and editing. The authors of this article thank the interviewees for their time and efforts, and the 'society of engineers' and the 'society of lawyers' for facilitates finding respondents. The authors also are grateful for the anonymous translator and editor of both stages of interviews and the short sessions' notes, her efforts in both stages are appreciated. Finally, special regards to the proof reader, who finished his task quickly in a record time.

Reflections on the requirement for construction contracts in writing under HGCRA

Andrew Agapiou[1]

Strathclyde University, Glasgow, G4 ONG,
United Kingdom

Email: andrew.agapiou@strath.ac.uk

Abstract:
The deletion of section 107 of Part II of the Housing, Grants and Construction Act 1996 will have a profound effect on the requirements for contracts in writing under the adjudication provisions of the new Construction Act 2009. This paper presents a reflection on the legal provisions and case law concerning the requirement for contracts in writing under the provision of the 1996 Act, against the backdrop of new rules encompassing oral and partly-oral agreements between parties. While the new provisions are unlikely to have an impact in cases where there are formal contracts which incorporate adjudication clauses, the changes are more likely to have an impact where there letters of intent are involved and where contracts in writing are based on standard terms and conditions supplemented by oral agreements. While the legislative changes may not have an impact on the role of the Adjudicator, it may affect their modus operandi, requiring more efforts to ascertain the precise intentions of the parties under dispute.

Keywords:
Adjudication, Construction Act 2009, Written & Oral contracts

1 Introduction

Amidst a flurry of cases during the early years of adjudication, the courts appear to have achieved their aim of resolving questions thrown up by the 1996 Housing Grants Construction and Regeneration Act (HGCRA) and creating a reliable process for the pursuit of adjudication-related claims (Fenn et al, 2008). Increasingly, however, jurisdictional challenges have reduced the effectiveness of Adjudication and increased the cost of the process (The Scottish Executive, 2004). A 2010 study by the Glasgow Caledonian University found that upwards of 25% of challenges to the Adjudicators' jurisdiction were related to whether the contract was in writing (Kennedy et al, 2010). Against the backdrop of recent court decisions, it is clear that case law concerning the requirement for written agreements is still at an evolutionary stage. Given these developments it is timely to reflect upon the case law concerning written agreements against the backdrop of changes to adjudication legislation in the UK.

2 The nature of the Adjudicators' Decision

The creation of the Scheme for Construction Contracts and the Housing Grants Construction and Regeneration Act led to the development of the alternative methods of dispute resolution first proposed by in the Latham Report (Latham, 1994). Adjudication was introduced on a statutory basis under the Housing Grants Construction and Regeneration Act 1996.

Adjudication in the construction industry is a process that provides for the referral of a dispute arising under contract at any time, to a person (an adjudicator) who has to act impartially on the basis of such information as the parties to the dispute are able to provide them or they are able to ascertain for himself within a very limited timescale. He reaches conclusions as to the parties' rights and obligations under their contract on the basis of the information provided by the parties. The decision being set out is contractually binding on the parties until the original decision is finally determined in legal proceedings or by arbitration (if the contract so provides for between the parties) or by agreement between the parties. Adjudication is therefore not final and not binding. The dispute is not settled by adjudication, although it may be if the parties choose to accept the adjudicator's decision as final. Once the adjudicator has made his decision on the rights of the parties under contract, it is for the parties to decide whether they agree with those conclusions, or have the dispute heard again by a tribunal that will give them a decision that is final and binding. The parties are quite at liberty not to accept the adjudicator's decision, although they are bound by the decision, temporarily at least.

Adjudication by itself does not and cannot resolve the dispute. For the dispute to be resolved each party has to decide for itself that it will not take the matter further. An adjudicator states what his conclusions are as to the rights and obligations of the parties. This decision may be based upon very limited information. It certainly will have to be made in a limited time. Both these factors may well mean that the adjudicator's decision leaves a lot to be desired. The adjudicator may certainly not have sufficient time to make a full, forensic investigation. It may be that the adjudicator considers the dispute is of such a nature that it is totally impossible for him to reach any sort of conclusion. To refer a dispute to adjudication, a construction contract must exist (Royce, 2009). Examples abound where parties have argued that all or part of the contract is not 'in writing' to avoid any liability. The courts have considered this aspect on a number of occasions under the provisions of the 1996 Act and held that no contract exists where the agreement is too ambiguous to constitute a contract. What constitutes a contract in writing is an interesting question and fundamental to adjudication under HGCRA, but who decides if a contract is in writing? Does the adjudicator have the power to decide? If no contract exists, then it follows that the Adjudicator has no jurisdiction under the law. However, Adjudicators do not have power to decide on their own jurisdiction. Many adjudicators faced this challenge and either decided to resign or continue with proceedings.

Typically, the decision was an objective one, taking into account factors such the price and scope of works, as well as start and completion dates (Green, 2006).

3 Oral and Written Agreements: The provisions of the HGCRA

The HGCRA required construction contracts to be in writing. Whilst oral agreements were binding on the parties, the difficulty arose in determining the precise terms of that agreement in the absence of clear written evidence. It is for this reason that section 107 of the Act only applied to written contracts unlike the new state of affairs created under the provisions of the Construction 2009 Act. There was a complicated definition of what is meant by the term agreement 'in writing'. Section 107(1)-(6) of the HGCRA 1996 stated:

3.1 107 Provisions applicable only to agreements in writing

(1) The provisions of this Part apply only where the construction contract is in writing, and any other agreement between the parties as to any matter is effective for the purposes of this Part only if in writing.

The expressions "agreement", "agree" and "agreed" shall be construed accordingly.

(2) There is an agreement in writing—

(a) if the agreement is made in writing (whether or not it is signed by the parties),

(b) if the agreement is made by exchange of communications in writing, or

(c) if the agreement is evidenced in writing.

(3) Where parties agree otherwise than in writing by reference to terms which are in writing, they make an agreement in writing.

(4) An agreement is evidenced in writing if an agreement made otherwise than in writing is recorded by one of the parties, or by a third party, with the authority of the parties to the agreement.

(5) An exchange of written submissions in adjudication proceedings, or in arbitral or legal proceedings in which the existence of an agreement otherwise than in writing is alleged by one party against another party and not denied by the other party in his response constitutes as between those parties an agreement in writing to the effect alleged.

(6) References in this Part to anything being written or in writing include its being recorded by any mean'.

In circumstances where a contract was not be covered by section 107, Atkinson (2002) suggested that that courts had taken 'a robust approach to the interpretation of section 107, straining its meaning … so that parties without a contract can benefit from adjudication'.

In A&D Maintenance & Construction Ltd v Pagehurst Construction Service Ltd[1], the court confirmed that, although there was no written contract, both parties proceeded as if there was one and neither party denied a contract was in place, thus an agreement in writing existed. If either party had denied their intention to create a written contract, then an adjudicator would have had no jurisdiction under the provisions of the 1996 Act. In Grovedeck Ltd v Capital Demolition Ltd[2], Grovedeck sought to enforce the adjudicator's decision. In the enforcement proceedings, Grovedeck abandoned the post-dispute correspondence as evidence of the contract in writing and adopted the argument based on Section 107(5). HHJ Bowsher was unable to accept that:

'The contracts were not subject to any terms about adjudication when the Adjudicator was appointed and so, at the date of his appointment, he had no jurisdiction. Did something happen later to change the nature of the contracts between the parties and give jurisdiction to the adjudicator so as to bestow validity on what was proceeding as an invalid adjudication? The claimants say, Yes. The claimants' submissions involve this unstated proposition that even though in every communication after his unlawful appointment the defendants challenged and denied the jurisdiction of the adjudicator, those same communications themselves changed the nature of the parties' contracts and gave him jurisdiction. Freedom of contract has fallen, but I cannot believe that it has fallen that far'

The 'in writing' requirement was applied wholesale to the entire substantive agreement, as endorsed by the Court of Appeal decision in RJT Consulting Engineers v DM Engineering (Northern Ireland) Ltd [2002] All ER (D) 108 (Mar)[3]. *RJT Consulting Engineers Ltd* was the third decision of the Court of Appeal in respect of adjudication.

In RJT Consulting Engineers, the Technology and Construction Court (TCC) held that the documentary evidence and written material between the two parties was sufficient to bring their agreement within the adjudication proceedings. Accordingly the declaration sought by RJT that the agreement was not an agreement in writing for the Act was refused. The matter then came before the Court of Appeal, which overturned the decision of the TCC. RJT argued that there had been confusion regarding documents consistent with there being a contract and documents, which constituted a record of the entirety of the oral agreement. RJT maintained that the whole agreement had to be evidenced in writing in order to provide the certainty, which would enable the adjudicator to move swiftly to a decision within the short timetable provided by the 1996 Act. DM countered that all that was necessary was that there should be evidence in writing of the existence of a contract in writing, whether that would be the identities of the parties, the price and nature of the works to be undertaken. The Court of Appeal agreed with RJT. The invoices and other extensive evidence relied on by DM was simply evidence of the existence of contract. It was not evidence of the terms of the oral agreement between the parties.

Section 107 of the Act details what has to be evidenced in writing is literally the agreement, in its entirety. The only exception to that generally is where relevant parts

[1] A&D Maintenance and Construction Ltd v Pagehurst Construction Services Ltd [1999] (TCC) 64ConLR
[2] Grovedeck Ltd. v. Capital Demolition Ltd. [*2000] B.L.R. 181, 185*
[3] RJT Consulting case (RJT Consulting Engineers v DM Engineering (Northern Ireland) Ltd [2002] All ER (D) 108 (Mar)

of an oral agreement are alleged and not denied in written submissions in adjudication. The appeal was allowed; however, it was noted that what is more important is that the terms of the agreement are material to the issues giving rise to the adjudication and are clearly recorded in writing. The material terms of the agreement must be recorded in any one of the forms prescribed by section 107 of the Act for the requirements of that section to be met and for the agreement to constitute a 'construction contract'.

For a claimant to seek to say that a contract is evidenced in writing pursuant to section 107 (4) of the Act, they must show that the written documentation evidenced the whole of the agreement and not just part of the agreement, as was the case in Debeck Ductwork Installation Ltd v T&E Engineering Ltd[4]. However, in Cowlin Construction Limited v CFW Architects (2002)[5], only a little over a month later, HHJ Kirkham held that:

'It appears that the contract was made partially in writing and partly oral….It is clearly evidenced in writing. Pursuant to section 107(2) of HGCRA, this was a construction contract'.

Whereas, in Carillion Construction Limited v Devonport Royal Dockyard (2002)[6], HHJ Bowsher held that if a variation to the terms of a contract is agreed orally, this must be recorded or evidenced in writing, otherwise n adjudicator will not have jurisdiction to decide disputes arising under the oral agreement. While some suggest that the debate surrounding the requirement to satisfy section 107 has largely been resolved (Gould, 2003), some controversy remained. In RJT, the Court of Appeal decided that the whole of the terms of the agreement (not just the fact of an agreement) must be evidenced in writing, but the possibility to opt out of the 'RJT' principle does exist in particular circumstances. In Connex South Eastern Ltd v MJ Building Services Group Ltd (2004)[7], for example, the court held that there was no oral aspect to the underlying contract (i.e. the meeting minutes confirmed that Connex accepted MJ Building's tender in its entirety) and therefore the Act did apply, whereas in the RJT Court of Appeal case it was found that part of the underlying contract was oral, and the Act did not apply.

In light of the foregoing, it seems that the process of deciding what was considered 'evidenced in writing' and what was not was fraught with difficulty. The apparently restrictive interpretation of section 107 of the Act by the Court of Appeal in RJT remained of real concern within the industry, particularly among smaller firms who fell outside the provisions of the 1996 Act. Concern within the industry was expressed as early as 2004 in a report by the Construction Umbrella.

The report recommended that in respect of 'evidenced in writing', the law should be clarified particularly in light of the RJT case, to avoid undermining the adjudication process altogether if left unresolved. Gould (2003) and Akenhead (2003) both considered the decision in *RJT* unfortunate and suggested that it would create, or potentially create, major problems. Critics suggested that it would open the door to a 'flood of jurisdictional challenges'. There are many written agreements between the

parties to a construction contract that do not incorporate, necessarily or 'literally', every term which has been agreed. Indeed, some important matters are left to oral agreement, for example, the day on which the works are to commence (Tan, 2007). There may also be many minor immaterial matters, which have been agreed to and are not recorded in writing. If the majority view in RJT was taken 'literally', the construction contract would not be in writing or, at least, as fully in writing as the judgments had suggested were required. However, the House of Lords refused a petition to appeal.

Certainly, the RJT decision considerably limited the right to adjudicate where no written contract agreement exists, but the decision was reached not because the court wished to restrict the right to adjudicate, but as LJ Ward foresaw, the difficulty an adjudicator would have making a decision based on an alleged oral agreement within the tight timeframe provided by the process (Brawn, 2010).

Indeed, as LJ Ward stated:

*'*Certainty is all the more important when adjudication is envisaged to take place under a demanding timetable. The adjudicator has to start with some certainty as to what the terms of the contract are'

Nevertheless, there is still controversy about the effect of section 107 as construed by the decision in *RJT.* In the early 2000s, some within the construction industry called for the abolition of the requirement so that all construction contracts even those which are oral or partly in writing are covered by the Act (Bowes, 2007) (akin to legislation in New South Wales); others preferred the status quo (Kennedy et al, 2010).

4 Contracts in writing: recent developments

A closer examination of the precise terminology of the 1996 Act is fundamental to the understanding of the law concerning contracts in writing and the nature of what constitutes a contract under HGCRA. The 1996 Act used wording such as 'by reference to terms that are in writing'. There is no reference to a 'previous agreement that is in writing'. Indeed, there is no provision for adjudication in relation to an alleged construction contract made orally or otherwise not evidenced in writing –see Carillion Construction Limited. This would seem to be contrary to the provisions of section 107 (1) of the 1996 Act. What constitutes a construction contract? What is the basis of the agreement? There must obviously be agreement on scope, price and time. On the contrary, what if there was no agreement over time? Certainly, there would be an implied term within the contract that the works will be completed within a 'reasonable time', but does this provide us with certainty that a contract exists where the scope and price are more precise? What if the contract alluded to reasonable costs incurred? What if the identity of the parties was uncertain?

What if the scope of works was based on subsequent instruction or orders, which may or not be set down in writing? In such circumstances is there any guidance we can draw upon as to what constitutes a construction contract? Section 107 of the Act only applies where there is a contract in writing, meaning that all material terms must be in writing; see RJT as the leading authority in the area. Justice Jackson has also provided

additional guidance on the constitution of a construction contract more recently in the case of Mast Electrical v Kendall (2007)[8]. Justice Jackson noted that a thorough analysis of correspondence, meeting minutes and so on was warranted to establish whether a contract was ever concluded between parties. He also noted that where there had been performance '*the court would lean in favour of finding a contract if it could probably do so'.* What if there was no agreement on all the material terms between the parties? Under RJT principles there would be no contract, but the contractor may be entitled to a quantum meruit under contract law provisions.

In all circumstances, courts would be obliged to follow the principles established within RJT. In other words, as Brawn (2010, pg. 37) has noted, either:

- 'The contract must be in writing;
- Established by means of communication in writing;
- Evidenced in writing;
- Agreed by reference to terms in writing; or
- Exchange of submissions in proceedings in which the existence of contract is alleged by one party and not denied by the other party'

The decision of the court in Hart Investments Limited v Fidler (2006)[9] provides a further example of an authority in this area.

In terms of the role of the Adjudicator, they would need to adopt a rigorous approach in determining whether minor issues said to have been agreed orally between parties prevent an otherwise written contract pursuant to section 107 of the Act being considered as a contract in writing. The exercise itself must be objective and take into account the nature of the contract and the parties themselves. Nevertheless, what may be a minor issue in one contract may not be minor in another one**.** In for example, a 10 million pound project an oral agreement on different types of architectural hardware may be a minor issue but a major one on another development. The adjudicator would also need to consider the intention of the parties, and whether they intend to give affect to their oral agreement such that it becomes binding in written form at later stage. On the other hand, a later oral agreement may not be binding on parties because it lacks consideration or because it was not intended to be binding, as in the case of Allen Wilson Joinery Ltd v Privetgrange Construction Ltd [2008][10]. There remains a great deal of legal uncertainty about the effect of subsequent oral amendments to written contracts or oral variations to the scope of works, to the extent that differences of opinion have emerged among legal practitioners.

While some consider that the right to adjudicate was lost under the 1996 Act, others considered the right to adjudicate unaffected, particularly with respect to oral amendments to the works. The debate has provided a fertile ground for challenges to the Adjudicator's jurisdiction under the 1996 Act. Indeed, what if the written terms of

[8]

[9] Mast Electrical Services v Kendall Cross Holdings Ltd [2007] EWHC 1296 (TCC) (17 May 2007)
[10] Allen Wilson Joinery Ltd v Privetgrange Construction Ltd [2008] *EWHC 2802 (TCC)*

the contract were incomplete or further terms agreed orally, or significant changes to the scope of works agreed on an oral basis?

Is there any guidance we can draw upon in such circumstances? The answer to this question is yes. For instance, in Hatmet v Herbert (2005)[11], there was sufficient written evidence as to the scope of the work, price and timeframe, but little information on the basis of price revision. In these circumstances the provisions of section 15 of the Sale of Goods Act (1992) such that an implied term would apply that would require a reasonable price be paid for any price revision. In Carillion Construction Ltd v Devonport Royal Dockyard Ltd (2005)[12], a written contract was varied mid-way into the works by an oral agreement. This changed the basis of the payment to a cost-reimbursable one. The court held that the adjudicator had no jurisdiction to decide whether an oral agreement varied the written one. The adjudication was deemed invalid by the court under the prescriptions of the 1996 Act. Letters of intent are a common feature of the contract-forming process in the construction industry, but do they have any currency under the provisions of section 107 of the Act? The answer to this question is no.

Where the works are undertaken under a letter of intent it will be difficult, but not impossible, to demonstrate that an agreement in writing exists as prescribed under section 107. This is because by the time a dispute has arisen further agreements have usually been made that are either inferred from conduct, where they agreed orally, or not evidenced by the letter of intent. It is also common for parties to rely on particular documents as evidence that a contract exists during adjudication, but are there any legal implications under the provisions of the 1996 Act? The answer to this question is yes.

Where a party, relies upon a particular document as evidence of a contract when adjudicating, it will be bound by the terms within that document. Subsequently, if evidence emerged under the old rules that there are other terms not recorded in that document, even if they are recorded in other documents, then if the adjudicator takes those other documents into account in his decision, that decision is unlikely to be enforced by the courts. In for example, Redworth Construction v Brook dale Healthcare (2006)[13] the court concluded that while the 'contract' referred to adjudication, it did not meet the RJT test of an agreement in writing as prescribed under section 107. In terms of agreements as to the scope of works and subsequent oral variations, there are three noteworthy cases. In Deback v T&E Engineering (2002)[14], the contract between the parties was not adequately evidenced in writing because the fax relied upon by the plaintiff did not sufficiently establish the scope of works.

In Management Solutions Professional Consultants Limited v Bennett (Electrical) Services Limited [2006][15] and ALE Heavylift v MSD (Darlington) Limited [2006][16], the parties waived the need for instructions to vary the scope of works to be confirmed

[11] Hatmet Ltd v Herbert [2005] *EWHC 3259 TCC*
[12] Carillion Construction Ltd v Devonport Royal Dockyard Ltd [2005] EWCA Civ 1358
[13] Redworth Construction v Brookdale Healthcare (2006) 110 ConLR 77)
[14] Debeck Ductwork Installation Ltd v T&E Engineering Ltd, *Unreported October 14 [2002] TCC*
[15] Management Solutions Professional Consultants Limited v Bennett (Electrical) Services Limited [2006] EWHC 1720 (TCC)
[16] ALE Heavylift v MSD (Darlington) Limited [2006] EWHC 2080 (TCC)

in writing. The argument upheld by the courts was that the absence of confirmation in writing did not take the contract outside the scope of section 107 of the 1996 Act. The principle being that where a written contract provides that instructions allowing variations to the scope of works are permissible if confirmed in writing, a contract in writing still exists even if the instruction given under the authority of the contract is not confirmed in writing.

What about the inclusion of implied terms in a construction contract? Does this transform an otherwise written contract into one that is no longer written under the provisions of section 107 of the 1996 Act? The answer to this question is no. According to Royce (2009) '*it was manifestly not the intention of parliament to exclude from the jurisdiction of an adjudicator an agreement solely because it contains implied terms'*, as endorsed by the court in Connex South Eastern Ltd[17] *and more latterly* Allen Wilson v Privetgrange Construction [2008][18]. Rather, Parliament's intentions were to avoid a situation whereby one or other party would suggest that a contract, otherwise not complete under the provisions of section 107, could be completed after execution by virtue of implied terms representing the 'unexpressed intention' of either party, as noted in Galliford Try Construction Ltd v Michael Heal Associates Ltd [2003][19]. We know that implied terms operate by virtue of the law. Such terms are implied into contracts for different reasons. Whereas, some terms are implied into contracts to give effect [for example, business efficacy] to a contract, other terms are implied to provide context to an actual relationship between parties. Should we differentiate between different types of implied terms within the context of section 107? The answer to this question is no, according to Royce (2009).

Thus, there is no reason why any type of implied terms transform an otherwise written contract into one not covered by the provisions of the 1996 Act; see for example, Allen Wilson v Privetgrange Construction [2008][18], as an example of an authority in this area. The remaining provisions of Section 107 merit also closer scrutiny.

This is because they provide other means by which agreements can be made in writing under the provisions of the 1996 Act.

Section 107 (4) states

'An agreement is evidenced in writing if an agreement made otherwise than in writing is recorded by one of the parties, or by a third party, with the authority of the parties to the agreement'.

Section 107 (5) states:

'An exchange of written submissions in adjudication proceedings, or in arbitral or legal proceedings in which the existence of an agreement otherwise than in writing is alleged by one party against another party and not denied by the other party in his response constitutes as between those parties an agreement in writing to the effect alleged'.

[17] Group Connex South Eastern Ltd v MJ Building Services PLC *[2004] BLR 333*
[18] Allen Wilson Joinery Ltd v Privetgrange Construction Ltd [2008] *EWHC 2802 (TCC)*
[19] Galliford Try Construction Ltd v Michael Heal Associates Ltd *[2003] EWHC 2886 (TCC)*

The wording of Section 107 (5) is controversial and worthy of closer examination. The wording seems to suggest that if one party to adjudication alleges the existence of an oral agreement under their terms, and the other party does not deny the agreement on this basis, then there will be an agreement in writing. Thus, in spite of the ruling in *RJT* it does seem possible to create a written agreement from an oral agreement which is oral or partly oral if the agreement is asserted in written submissions in an adjudication, arbitration or legal proceedings where the other party does not deny that agreement. It is difficult to believe that Parliament's intention was to create something so manifestly unjust. Is there any guidance we can draw upon? The answer to this question is yes. In, for example, Grovedeck v Demolition [2000][20], the court held that section 107(5) had a narrow focus. In other words, it only applied where an oral agreement has been admitted in a previous adjudication, but most responding parties would raise an *RJT* jurisdictional challenge on the basis of section 107 in that first adjudication. Thus, a party who does not raise the challenge initially would lose the right to challenge on those grounds in subsequent adjudications. However, is it also worth examining the precise wording of section 107 (5) against the backdrop of parliamentary intentions and deliberations at this point. An examination of the proceedings of the House of Lords for 23rd July 1996 on the wording of section 107(5) reveals no mention of 'adjudication proceedings'. It seems that the upper chamber of Parliament incorporated an amendment proposed by the House of Commons, in which the words 'in adjudication proceedings or' would immediately follow the word 'submission'.

According to Royce (2009) Parliament's intention was to make reference to the '*other, prior'* adjudication proceedings, not to provide an adjudicator with jurisdiction over proceedings for which he did not have at appointment based upon submissions made by one party to otherwise unauthorised adjudication. We know that amendments to the Act will repeal Section 107 of the 1996 Act in its entirety.

This will mean that adjudication provisions will apply to all construction contracts whether written or oral, or even partly in writing and partly oral. However, the new Act will also amend section 108(2) whereby all the provisions setting out the required adjudication procedures will have to be in writing. If they are not in writing the Scheme for Construction Contracts will apply. There have been two recent cases that have caused some confusion among practitioners in relation to contracts in writing. In T & T Fabrications v Hubbard [2008][21], the decision of an adjudicator was not enforced on the basis that certain terms of the contract relating to the provision of drawings and the timing of the works were not in writing.

The terms concerned the scope, quality and essential of the works and there was a genuine dispute as to whether these terms had been agreed. Therefore, there was an arguable case that the terms of the contract were not in writing. However in the second case, Allen Wilson Joinery v Privetgrange Construction Limited [2008][22] it was held, firstly, that implied terms do not prevent a contract from being in writing and, secondly, that a budget price with a final price to be agreed does not prevent there being a contract in writing. In sum, the HGCRA required the contract to be in writing (or at least those

[20] Grovedeck Ltd. v. Capital Demolition Ltd. [*2000] B.L.R. 181, 185*
[21] T & T Fabrications v Hubbard [2008] EWHC B7 (TCC)
[22] Allen Wilson Joinery Ltd v Privetgrange Construction Ltd [2008] *EWHC 2802 (TCC)*

evidenced in writing), if the adjudicator's decision was not to be challenged on jurisdictional grounds. There have been large numbers of challenges where the contract was not in writing or not evidenced in writing under the UK regime, but much fewer incidences and disputes in other jurisdictions elsewhere. In New Zealand, for example, the Construction Contracts Bill (CCB) not only provides for written contracts, but also to oral or partly written and partly oral contracts (Tan, 2007). The BCISP Act in Singapore and NSW (Section 7(1)) too define a "contract in writing" in relatively wider terms, to the extent that it would extend to a loose collection of documents, exchanges and invoices (Chow, 2005). This suggests that the proposed amendments to HGCRA may not be as problematic as some commentators anticipate. The removal of section 107 of the 1996 Act, so the requirement for a construction contract to be in written form may render the RJT principles and subsequent legal judgements ineffectual. However, it is important to note that, until the amendments to the Act come into force, the case law remains effective.

5 The Construction Act 2009: implications of impeding change to the requirements for contracts in writing

The Local Democracy, Economic Development and Construction Act – *the Construction Act* 2009 -received Royal Assent in July 2009 (Brawn, 2010), and came into force on 1st October 2011 (in England and Wales). The new legislation amends Part II of the Housing Grants, Construction and Regeneration Act 1996.

The main benefits of the new Act, as conceived by the Government, was to improve cash flow in the construction supply chains and encourage parties to resolve disputes by adjudication rather than by arbitration or litigation (Gwilliam, 2010). The main changes effected by the new Act are:-

- Adjudicators will no longer be limited to contracts in writing;
- Adjudicators will be able to correct their decision if a clerical or typographical error is made; and
- Parties will not be able to agree a term which provides for who is to bear that costs of an adjudication until after the adjudicator has been appointed.

The most significant change is the abolition of the requirement for contracts to be in writing. The amendment will apply across the new Act and cover the payment provisions. This will mean that even purely oral agreements will now have to incorporate the payment provisions and the need for notices (Brawn, 2010). Nevertheless, some claim that the deletion of the requirement for contracts to be in writing will create greater uncertainty for the adjudication process, leading to a greater potential for injustice. Agreement on material terms, however trivial, is undeniable and for adjudication to be available these have to be in writing. This level of certainty provides the adjudicator with a greater sense of parties' intentions and further understanding as to the nature a contract. However, there is a perception that HGCRA mechanisms were open to abuse, particularly by those with the greater bargaining power within the industry (Gwilliam, 2010). The new legislation may not only provide smaller

contractors, often less adept at dealing with contractual matters with greater protection against abusive practices, but also greater access to the adjudication process itself. This is an important aspect of the change since many verbal contracts or written agreements involving oral variations typically involve smaller, more financially vulnerable sub-contracting firms.

6 Summary and Conclusions

This paper reflects on the legal provisions and case law concerning the requirement for written contracts under the provision of the HGCRA 1996, against the backdrop of new rules encompassing oral and partly-oral agreements. The HGCRA (s107) required contracts to be in writing (or at least evidenced in writing), to preclude challenges to adjudicator's decisions on jurisdictional grounds. Cases such as *Grovedeck Ltd v Capital Demolition Ltd* [2000]; *RJT Consulting Engineers Ltd v DM Engineering (NI) Ltd* [2002]; and *Carillion Construction Ltd v Devonport Royal Dockyard Ltd* [2003]; *Allen Wilson Joinery v Privetgrange Construction Limited [2008]* have demonstrated the position of courts pursuant to section 107 of the 1996 Act. It will be interesting to see how the amendments to Section 107 of the 1996 Act will operate in practice. We can only speculate on the likely impact on industry at this time.

While the new provisions are unlikely to have an impact in cases where there are formal contracts which incorporate adjudication clauses, the changes are more likely to have an impact where there letters of intent are involved and where written contracts are based on standard terms and conditions supplemented by verbal agreements. While the legislative changes may not have an impact on the role of the Adjudicator, it will affect their modus operandi. The adjudicator will need to find additional time to consider the formation of the verbal contract to ascertain the precise intentions of the parties. Inevitably, where oral agreements are concerned, adjudicators will also need to consult witnesses and where differing views exist there will be a need to probe witness statements through some form of cross-examination process. This is likely to be highly contentious, potentially giving rise to grievances, injustice and challenges to adjudicators' decisions.

Abstract:
In privity to an arbitration agreement of a state corporation whether commercial or public, the consent to the agreement is not always as straightforward as it is for a business corporation. This is because of substantial governmental influence over the structure, function and control of the state corporation which sometimes refers to state and state corporations as single economic unit. When an independent State entity enters into an investment agreement with a foreign investor substantial control and supervision of the owner state plays an important role in it. But in case of any liability of a state entity, in most cases, states raise the argument of separate legal personality of its entity. This is probably the main reason for the incorporation of independent state entity by the state. This paper examines the rationale behind the formation of a state entity and substantial structural and functional control of the government in the agreement of its entity, the reason why state should be a party to the agreement of its entity.

Keywords:
Agreement of State-entity, Investment Arbitration, Piercing Corporate Veil, State controlled over the entities.

1 Introduction

In most investment arbitrations where a state challenges the jurisdiction of a tribunal it argues that it is not a party to the arbitration agreement. Recent English Supreme Court decision has established the precedent that the state is not a party to the arbitration agreement of its independent state entity. [1] The initial stage of establishing attribution of conduct of a state entity to the state in investment arbitration is to determine whether the state is a party to the arbitration agreement entered into by its entity. The significant characteristics of most state entities are that they have separate legal personality incorporated under national law by the government to undertake commercial activities on behalf of the state. Besides operating commercial affairs they also have public policy objectives, which entail state entities to serve the purpose of the government in some form similar to government agencies established to pursue purely non-financial objectives.

[1]*Dallah Real Estate and Tourism Holding Company v The Ministry of Religious Affairs, Government of Pakistan* [2011] 1 A.C. 763.

If we look at the basic nature of formation of contract, an agreement of a competent independent business corporation is clear to prove consent or directive mind of whether or not it is an absolute consent or influenced unduly or it was not his consent at all. On the other hand, when we talk about privity to an arbitration agreement of a state corporation whether commercial or public, the consent to the agreement is not always as straightforward as it is for a natural person or ordinary business corporation. This is because of substantial governmental influence over the structure, function and control of the state corporation which sometimes refers to state and state corporations as single economic unit.[2] Moreover, when it comes to the question of attribution of state liability for the agreement of its entities, it would be unreasonable for the arbitral tribunal to predict whether they should separate the liabilities of state entities from the state.

When independent State Corporations enter into investment agreements with foreign investors under the substantial control and supervision of the state to realise a common economic transaction, advance planning for dispute resolution becomes an inherently complex mechanism.[3] One of such complexities involves lifting the corporate veil of state entities whether the state has to be a party to the agreement of its entity. The crucial impression such piercing leaves is that of uncertainty and unpredictability of the party hood of its parent state. Such uncertainties are detrimental to the legitimate expectations of the parties to a contractual relationship, and involve serious risks associated with the enforcement of arbitration awards. The aim of this brief paper is to examine the rationale behind the formation of a state entity and whether the home state is a party to the agreement of its entity. To this end an attempt will be made to analyse the negotiators and directing minds of state entity when they conclude investment agreement. This will also scrutinise and explain the specific relevance of piercing the corporate veil of state entities in investment agreement.

2 Rationale behind the Formation of a State Entity

In general state entities are separate legal personality and their conducts shall be treated as distinct from the activities of the government and shall not be attributed to the state. However, several exceptions may qualify these principles and hold the state liable for the agreements of its entities; the separate legal personality may not be respected if the corporate veil has been created as a means for fraud and evasion.[4] Besides, conduct of state entities will be attributed to the states in cases where the corporations exercise public power.[5] Another exception concerns a situation of ownership by the state where control is exercised in order to achieve a particular result.[6] To better understand the concept of piercing the corporate veil, it would be helpful to examine the need for having the corporate form of state-entities in the first place.

According to Janet Dine, the limited liability corporation is the greatest single discovery of modern business and trade practice in the world, because a greatest portion of the world's

business and trade is conducted by corporations.[7] However, corporations are most often used by the incorporator as a tool to avoid liability of any unforeseen debt incurred in the course of business conduct. In relation to state entity, the purpose is same to ordinary business corporations; they are created by government to undertake commercial activities on behalf of an owner government. Arguably, the main function of corporate law is defining the property rights over which the participants in a commercial firm can enter into contracts.[8] Henry Hansmann and Rainier Kraakman explained that "the essential role of organisational law is to provide for the creation of a pattern of creditors' rights a form of 'asset partitioning' that could not be practically established otherwise."[9] Therefore, it is obvious that rationale behind the incorporation of separate legal entity by a sovereign state is to put a veil between the entity and the state's assets against any foreign debt of its entity.

To separate incorporators and the participants from the liability of the corporation corporate scholars rely on two major theories concerning corporate personality which are the theory of legal entity, and the theory of legal fiction. The entity theory is based on the principle that the state created the corporation by granting it a charter, and, therefore, it has a separate "personhood."[10] On the other hand, according to the legal fiction theory, a corporation is an outcome of contracts, a more convenient way of structuring relationships with third parties, thereby limiting the participants' personal liability. The private corporation or firm is simply one form of legal fiction which serves as a nexus for contracting relationships and which is also characterised by existence of divisible residual claims on the assets and cash flows of the organisation which can generally be sold without permission of the other contracting individuals. [11]

The legal fiction supporters argue that the property might be given special qualities by the state or through contract, but remains property all the same.[12] Thus, the existence of a corporation independent of its owners is a fiction "the rights and duties of an incorporated association are in reality the rights and duties of the persons who incorporate it, and not of an imaginary being." [13] The entity theory school regards a corporation as an autonomous institutional actor separable from those with an interest in it.[14] In most cases in investment arbitration when it comes to the matter relating to state liability for its entities, the state argues on the basis of separate legal personality of the entities.[15] However, it has been noticed that states also argue to pierce the corporate personality to save its entity's asset from compensating foreign debt.[16]

The concept of legal fiction theory has probably started to emerge after the decision in *Salomon v Salomon* on the separate legal personality of a corporation.[17] This theory has not

just separated the incorporators and subscribers from company but also from its subsidiaries and holding companies. Frequently, reorganisation of corporate structure in corporate groups involves exclusion of especially risky activities in selected subsidiaries to shield the group as a whole from tort liabilities.[18] As Professor Blumberg put it, in such business planning, traditional entity law is being utilised to attempt to create a safe harbour for corporate groups seeking to externalise the costs of a subsidiary's negligence in conducting highly risky activities.[19] Similarly, very often purpose of incorporation of state-owned entities is to reduce the risk of reimbursements from the sovereign asset in case of entities' foreign debt. The principles of state sovereignty and political territoriality make separation of assets even more attractive.

The commercial world regards the principle of separation of legal identity and liability between different companies and entities as a universal legal assumption. All legal systems of major industrial countries recognise this principle.[20] The development of sophisticated multinational corporate structures was a response to various commercial factors, such as business expansion and diversification, the need for specialisation and efficient productive processes, raising capital finance, or reducing taxation liabilities. The invention of the concept of independent state-owned corporation is another development to that extent in support of advanced cross-border trade practice participated by the state. Almost every sovereign state has incorporated independent state-owned entity or sovereign wealth funds to serve sovereign commercial conducts. Almost 77 percent of the world's oil reserves are held by national oil companies with no private equity, and there are 13 SOCs with more reserves than ExxonMobil, the largest multinational oil company.[21]

3 Whether State can be a Party to the Arbitration Agreement of its entity

As discussed above the rationale behind the incorporation of a state-entity separate from the state itself is basically to limit the involvement and attribution of the state in case of any probable foreign debt incurred mostly out of investment agreement. Often it has been argued whether a state can be a party to the arbitration agreement with private corporations or a foreign investor in the first place. The following discussion of this paper will investigate the principle of state privity in the arbitration agreement of a state entity.

Most of the states have incorporated state entities for the purpose of serving governmental service or activates, often dealing with foreign investors in matter relating to the operation of national interest.[22] Consequently, policy issues and operational matters concerning foreign investments or investments in general are not handled by the relevant state departments or ministries but independent state corporations or sometimes they are known as sovereign wealth funds. However, these entities are most of the time substantially controlled by the relevant state departments or ministries. The position within the hierarchy of the government

and the degree of legal independence of these entities varies. The reasons for the establishment of these separate legal entities by the government are primarily specialisation and efficiency.[23] Thus, when a sovereign state needs to coordinating and giving a unified direction to any particular scheme, e.g. the development of schemes in Water and Power Sectors by the respective Electricity and Irrigation Department of the Provinces, states establish such para-statal entities. WAPDA, the Pakistan Water and Power Development Authority, was created in 1958 as a Semi-Autonomous Body for the purpose of coordinating and giving a unified direction to the development of schemes in Water and Power Sectors, which were previously being dealt with, by the respective Electricity and Irrigation Department of the Provinces. [24]

Incorporation of these state entities in relation to the foreign investment must be reconciled with the international principle of the unity of the state. This has raised the issue of attribution of acts of these entities to the state which are not restricted to the field of foreign investment. Domestic classification may not be decisive in this context. This question form part of general international law, and plays a significant role in matter relating to state responsibility. In relation to foreign investment, matters of attributions have most often come up on the side of the respondent state when a state argues that acts by state entities cannot be attributed to the state. However, the issue may also be relevant for a claimant when a respondent state considers a state entity single economic unit rather than a national of another state. [25] Therefore, conduct of a state entity to be attributed to the state needs further scrutiny about the negotiations and the directive mind of the state entity in its functional process.

4 Negotiation and Directive Mind of Contract for the State entity

The reasonable questions that need to be answered include who negotiate the investment agreement of state entities? Who has the *de facto* and *de jure* authority and directive mind to sign the agreement, in certain cases approval of financial securities? To illustrate, a businessman might actively negotiate a purchase agreement containing an arbitration clause, but at the last minute arrange for it to be signed by a company incorporated, owned and controlled by him. An application to extend the arbitration clause to the businessman could find support in the notion that buyer and seller intended the businessman to be a party to the agreement.[26] Similarly, investment agreements of most state entities are negotiated by the members of the government, often relevant ministers. Sometimes they are also signed by the members of government who is also the head of the state entity.[27]

In *Wintershall A.G., et al. v Government of Qatar*[28]the claimant and respondent entered into thirty years Exploration and Production Sharing Agreement (EPSA) in the offshore of Qatar on 1976. Under the agreement, government of Qatar granted exclusive right to explore, drill and produce petroleum in the defined offshore area. Due to the boundary dispute between

[28] *Wintershall A.G., et al. v Government of Qatar*, Partial Award on liability of 5ht February 1988, 28 ILM 795 (1989).

Qatar and Bahrain, the claimant was not permitted to drill in the area where petroleum rights were held under the authority of Qatar general petroleum corporation (QGPC). QGPC was a corporation incorporated and wholly owned by the respondent and the Minister of Finance and Petroleum is the Chairman of its Board of Directors.

The negotiations for the future dealing were unsuccessful. The claimants referred the dispute to arbitration, alleging the respondent breached the agreement in violation of law of Qatar and customary international law by denying claimants permission to explore in contractual area. The tribunal held that QGPC was acting as an agent of the Government of Qatar and, therefore, all actions attributed to the QGPC in this case shall be attributed to the Government. The tribunal did not in any respect deny that QGPC was created as a separate independent legal personality under national law of Qatar. However, in the event at issue in this arbitration, QGPC acted as an agent or an arm of the Government in all proceedings relevant to the tribunal's jurisdiction. The tribunal in this case had taken into consideration the functional control of the Government over its entity to be attributed to the state for the responsibility of its entity.

Perhaps the most striking facts supporting the identity of the QGPC and the Government in the event at issue in this arbitration, was that "The Board of Directors of QGPC were appointed by the Emir and consists of 7 to 11 members, the majority of whom are officials of the Department of Petroleum Affairs of the Government. They can be removed at any time by Emir at his will. The Minister of Finance and Petroleum is the Chairman of the Bard". Based on the submissions by claimants the arbitral tribunal is in agreement that as a matter of the domestic law of Qatar it is clear that QGPC is a separate legal entity but it operates as an arm or agent of the Government in respect of the concession areas held by it.[29]

A contrary decision can be seen in the case of In *Impregilo S.p.A. v. Islamic Republic of Pakistan*[30] in which the important issue before the ICSID tribunal was to determine the status of state entity WAPDA and its relation with the government. While examining the status of WAPDA, the involved independent State entity, the Tribunal, at the outset, noted that its examination would be conducted in accordance with the applicable internal law of Pakistan. The tribunal noted that status of state entity WAPDA as a party to the Contracts is a matter for the national legislation of Pakistan, being both the law by which WAPDA was established and exists, and also the law governing the Contracts.' To establish this contention the Tribunal then proceeded to perform some jurisprudential tests in accordance with the applicable domestic law of Pakistan in order to determine the status of the state entity WAPDA.

The ICSID tribunal adopted the criteria of whether the state practiced any structural control over the state entity WAPDA which means, did the government of Pakistan have the power to appoint any of its officials or not. The Tribunal found that the entity consists of a Chairman, and not more than three Members appointed by the Government required by Section 4 of the 1958 Act.[31] They "receive such salary and allowances" and are "subject to such conditions of service as may be prescribed by the Government" according to Section 5 of the said Act. Moreover, under Section 6 of the Act, the Government may remove the Chairman and any Member of the Board for various reasons, in particular if they become, in the opinion of the

[31] Section 4 of the 1958 Act of Pakistan.

Government, incapable of discharging their responsibilities under the Act or if they have been declared to be disqualified for employment in, or have been dismissed from, the service of Pakistan.'[32]

Further, the arbitral tribunal examined the status of the service personnel of the state entity WAPDA in order to determine whether working for the entity would constitute as working for the government of Pakistan or not. Based on the service structure of the entity the tribunal reached conclusion that 'Service under the Authority is considered to be service of the government of Pakistan, and every person holding a post under the Authority, not being a person who is on delegation to the authority from any Province, shall be deemed to be a civil servant for the purposes of the Service Tribunals Act, 1973[33] and within the meaning of Section 21 of the Pakistan Penal Code (Section 19(1)).' The Tribunal also adopted the criterion of functional control over the entity whether Pakistan practiced any functional control in WAPDA or not. The tribunal found that 'The power and duties of the Authority are defined in Sections 8 to 16 of the Act. Under Section 8, the Authority "shall prepare, for the approval of the Government a comprehensive plan for the development and utilization of the Water and Power resources of Pakistan". It also may frame schemes for a province or any part thereof, subject here again to approval by the Government.'[34]

Having examined the above two criteria the tribunal finally examined whether Pakistan practiced any financial control over the entity or not. The tribunal found that 'the accounts of the Authority are audited by the Auditor General of state of Pakistan annually. The Auditor Reports with the comments of the Authority are sent to the Government and the Authority "shall carry out any directive issued by the Government for rectification of an audit objection". Each year, the Authority submits to the Government for approval a statement of the estimated receipts and expenditures in respect of the next financial year according to Section 27 of the Act.' After performing all the aforementioned tests the tribunal concluded that 'Although the Government of Pakistan exercises a strict control on its entity WAPDA, in light of the terms of the 1958 Act that established it, WAPDA is properly characterised as an autonomous corporate body, legally and financially distinct from the state of Pakistan.'[35] According to the tribunal's view much of Impregilo's argument on this issue rested upon international law principles of state responsibility and attribution.

However, in the event at issue the tribunal has drawn a distinction between the responsibility of a State for the conduct of an entity that violates international law in this case breach of Treaty, and the responsibility of a State for the conduct of an entity that breaches a municipal law contract that is Impregilo's Contract Claims. To support its view the tribunal borrowed the principle from *Compañia de Aguas del Aconquija and Vivendi Universal v. Argentine Republic*, decided by *ad hoc* arbitration tribunal.[36] It seems the tribunal was reluctant to consider the matter of involvement of Government in the state-entity which consists of a chairman and three members appointed by the Government and may be removed by the government who are the civil servant of Pakistan. Moreover, the power and duties of the authority is subject to the approval of Government and the financial matter is strictly monitored by the Government of Pakistan. Therefore, in the event at issue in this arbitration it

might be concluded that WAPDA was working as an agent or arm of the government to extend the corporate veil to the point which the ICSID tribunal disregarded.

In relation to the above example of businessman, assume, however, that the businessman played no role in the contract negotiation and performance, but misappropriated corporate assets for personal use. If the corporation becomes insolvent for misappropriation of corporate assets by the incorporator, an arbitrator might feel justified in looking beyond the corporation to its owner, irrespective of what the parties had originally intended. For jurisdictional purposes, the corporation would simply cease to exist, leaving the businessman to inherit the arbitration clause.[37] To its further extent, the businessman actively negotiated the contract and the agreement was signed by the corporation wholly-owned and controlled by him. The utilised the assets of the corporation for distinct purposes or responsibility for any unusual circumstances which caused the corporation to go bankrupt. An arbitrator might also feel justified to extend the scope of arbitration agreement beyond the corporate veil. Likewise, state entities that are incorporated and wholly-owned and controlled by the state and utilise its dividends and assets to public sectors according to the will of the government or responsibility for any unforeseen circumstances for loss of its entity arbitrators will not be reluctant to lift the corporate veil.[38]

5 Piercing Corporate Veil in International Investment Arbitration

In breach of an agreement by a state entity to be attributed to the state, corporate veil must be pierced in between state and its entity. In that context, piercing the corporate veil does not involve bringing in the state in arbitral proceedings that has not signed an arbitration agreement, but its entity. This issue may arise among the parent companies, subsidiaries, private individuals, governmental and quasigovernmental entities, and states. To decide about the status of the state entity or a corporation in a particular dispute, arbitral tribunals usually rely upon the domestic law. It is to be noted that there is no uniformity regarding the principle of piercing the corporate veil across national legal systems. It is not unusual that the approaches of tribunals in investment arbitration also vary.

Piercing corporate veil may be invoked to rationalise either jurisdiction over a corporate affiliate or a company's liability for the substantive debts of another.[39] Even with respect to subsidiaries of foreign entities, American principles can apply to jurisdictional determinations. In *Taca International Airlines v. Rolls Royce of England*, a New York court took jurisdiction over a British company on the basis that its Delaware subsidiary was "a mere department" of its ultimate parent.[40] It can also be extended to sovereign state for the liability of its entity or to the state entity for the debts of its parent state. This does not mean, however, that arbitrators who join a non-signatory parent must or should find the shareholder liable for the subsidiary's obligations. On occasion, joinder might be justified on the basis of consent, as when a parent agrees to be bound in an arbitration based on contracts signed by its subsidiary.[41] Even though both entities have agreed to subject themselves to the same arbitral proceeding, the arbitrator might determine that neither company is liable for the other's

obligations. Conversely, one company might be liable for another's obligations, without necessarily subjecting itself to the same dispute resolution mechanism as contained in the primary obligation.

In the matter relating to piercing the corporate veil, usually, arbitral tribunal differentiate between "consenting non-signatories" to arbitration agreements that seek to arbitrate the dispute, and "non-consenting non-signatories" that challenge the jurisdiction of arbitral tribunal.[42] Arbitral tribunals that pierce the corporate veil of non-signatories resort either to implied consent or intention of the parties.[43] There is no clear line between these two justifications, however, as tribunals often pierce the corporate veil as a means to enforce the parties' original intention. The most popular case as regard to piercing the corporate veil is the *Dow Chemical Award* decided by International Chamber of Commerce in which consenting non-signatories were allowed to participate in the arbitration proceedings.[44] In this case, applying group of companies' doctrine, the tribunal allowed parent companies to bring claim on behalf of its subsidiary.

In *Dow Chemical,* the tribunal relied on the common intention of the parties which appears from the surrounding circumstances that leads to the conclusion of tribunals reasoning to pierce the corporate veil. The tribunal also followed trade usages conforming to the needs of international trade, particularly in relation to the group of companies' doctrine.[45] According to the single entity theory applied by the tribunal, a group of companies, despite the legal status of each of the companies, represents a single economic reality which the arbitral tribunal must take into account when ruling on its jurisdiction.[46] However, application of the "group of companies" doctrine remains uncommon. Some authorities suggest only one out of probably every four cases that purport to apply the "group of companies" doctrine did actually extend jurisdiction over non-signatories.[47] In a contract of state entity the doctrine can be extended to the non-signatory state to make it a party to the arbitration agreement of its entity if it can be circumstantiated that the entity was working as an agent or arm of the government.[48]

When it comes to the matter relating to arbitration between foreign investors and host state under bilateral investment treaties, the legal scholars stand in different opinion. It has been suggested that the rules relevant to shareholder claims under investment protection treaties need to be regarded as *lex specialis* as established by specific treaties.[49] This is despite the fact that under the national law of most jurisdictions, shareholders are not allowed to bring claims on behalf of the company in which they own shares.[50] Therefore, shareholders are deprived of their legal rights to bring claim under domestic law as they are not party to the arbitration agreement. As a result, the insertion of shareholdings into the definition of investment in a bilateral investment treaty would generally result in piercing the corporate veil for the benefit of the shareholder in investment arbitration. For instance, Article 1(6) of

the Energy Treaty Charter provides that "Investment" protected by the Charter includes "a company or business enterprise, or shares, stock, or other forms of equity participation in a company or business enterprise, and bonds and other debt of a company or business enterprise." [51]

A typical case of piercing corporate veil could be where an incorporator sets up an undercapitalised corporation to incur liabilities to a third party. In most cases this happens when the corporation does not have enough assets to repay its debt, and the controlling incorporator relies on the concept of limited liability to avoid personal liability. Consequently, third party ends up bearing the risk of the non-payment of the debt.[52] In such situations, the court or arbitration tribunal may intervene to prevent such injustice and pierce the corporate veil by holding the controlling incorporator, majority shareholder-incorporator or wholly-owned state liable for its entities.[53] Piercing the corporate veil in case of state entities as discussed earlier depend on the involvement of Government in the entities' structure and function and control. If it is found *prima facie* that the state-entity is working as an arm or agent of the Government to serve public and commercial activities the tribunal may find it justified to extend the corporate veil beyond the structure of the corporation.

In the United States a question relating to piercing corporate the veil was first raised in the case of *First National City Bank v. Banco Para El Comercio Exterior de Cuba*[54], whether a foreign state can be held responsible for the actions or obligations of its subsidiary, or vice versa. The issue arose in this case with respect to execution or attachment, where the plaintiff sought to enforce a judgment against a foreign state by executing against the assets of the state's subsidiary. The issue would also exist where a plaintiff seeks to impute the commercial activity of a state entity to the parent government for the purposes of establishing an exception to sovereign immunity. This case established a rebuttable presumption that "state entities or instrumentalities incorporated as juridical entities distinct and independent from their sovereign state should normally be treated as such." In explaining this general rule, the Court referred to the legislative history of the 1976 Act which states "Section 1610(b) will not permit execution against the property of one agency or instrumentality to satisfy a judgment against another, unrelated agency or instrumentality. There are compelling reasons for this. If U.S. law did not respect the separate juridical identities of different agencies or instrumentalities, it might encourage foreign jurisdictions to disregard the juridical divisions between different U.S. corporations or between a U.S. corporation and its independent subsidiary."[55]

The Court then stated that the presumption of separate legal personality can be rebutted upon showing either that the "corporate entity is so extensively controlled by its owner that a relationship of principal and agent is created" i.e., the parent is an alter ego of the corporation; or recognition of the separate corporate status "would work fraud or injustice" on the other party. It should be noted that, following amendments to the FSIA in January 2008, principle of Bancec case does not apply to execution or attachment in terrorism cases. Rather, in cases falling under Section 1605A of the FSIA, "the property of an agency or instrumentality of a foreign state that is a judgment debtor for a claim based upon acts of terrorism, including

[55] Sec. 1610 (b) Foreign Sovereign Immunities Act 1976 (quoting H.R. REP. NO. 94-1487, at 29-30 (1976), as reprinted in 1976 U.S.C.C.A.N. 6604, 6628-29).

property that is a separate juridical entity or is an interest held directly or indirectly in a separate juridical entity, is subject to attachment in aid of execution." [56]

Under the principal-agent exception, a court will typically pierce the corporate veil only where it is established that the parent exercises day-to-day operational control over the subsidiary.[57] Time has probably changed to disregard this kind of control that any sole shareholder would normally exercise over its subsidiary is insufficient to justify piercing the veil.[58] Under the fraud or injustice exception, courts apply a fact specific analysis to determine whether recognition of separate legal status would be unfair. Typically such cases involve the foreign state's manipulation of the corporate form for its own benefit, to the detriment of the plaintiff. In relation to the function of a state entity, if such situation arises, the arbitral tribunals or domestic court may extend the corporate veil for the attribution of state for the conduct of its entity.

7 Conclusion

In most of the investment arbitration where the state incurs liability for the agreement of its entities to foreign investors and the arbitral tribunal awards damages for the favour of foreign investors, states argue based on the separate legal personality of its entities that it is not a party to the arbitration agreement of its entities. Based on the above discussions in this paper it is pretty obvious that the negotiators and the directive mind of the state entities in their agreement with foreign investors are the government itself. State practice suggests that the government, specifically the relevant ministry, has structural and functional control over the state entities and the entities serve the governmental functions by the name of independent legal entity.

At the end of this incursion into a domain that requires further expansion of the corporate veil to cover the rationale behind the incorporation of a state entity and the purpose they serve towards establishing justice and equity ultimate goal behind the incorporation of a state entity by the state is to conduct commercial activities on behalf of the state under the banner of separate legal personality to limit the state liabilities for any foreign debt. This paper suggests that if it is to be found that the nature of the conduct of a state entity is as such that would have been otherwise performed by the state in the absence of the entity in question the corporate veil shall be disregarded and the incorporator state is to be considered party to the agreement.

Statutory Adjudication in Australia: Analysis of Adjudication Activity in New South Wales

Michael C. Brand[1] and Jinu Kim[1]

Email: MichaelB@fbe.unsw.edu.au; J.Kim@unsw.edu.au

Abstract:
The *Building and Construction Industry Security of Payment Act 1999* (NSW) (the NSW Act) is a unique form of statutory regulation for the building and construction industry, which gives virtually all industry participants a statutory right to, and a means of recovering, payments for work done under a construction contract. The research aim is to examine current trends in adjudication applications and determinations under the NSW Act. The data used for this study was the collected by the NSW Department of Finance & Services as part of a regular reporting régime for the period from 1 July 2011 to 31 March 2012. In general, adjudication under the NSW Act is being well utilised by stakeholders in the NSW construction industry as a means of payment recovery. Claimants are highly successful at adjudication in terms of the proportion of the claimed amount they are awarded by adjudicators, particularly in relation to small value claims (i.e., claims less than $40,000). There has been a significant decrease over time in the incidence of adjudication applications being reported as 'completed but not determined'. Currently, a much greater proportion of adjudication applications lodged with Authorised Nominating Authorities (ANA) are proceeding to determination than in previous years.

Keywords:
Adjudication, activity, New South Wales, security of payment.

1 Introduction

This paper reports on an on-going research project being undertaken by the authors' into the performance of the *Building and Construction Industry Security of Payment Act 1999* (NSW) (hereafter referred to as 'the NSW Act').[1]

The NSW Act commenced in March 2000 and was introduced as part of the New South Wales Government's policy to eradicate the practice of developers and contractors arbitrarily delaying payment to subcontractors and suppliers in the NSW building and construction industry (Iemma, 1999). The NSW Act was the first comprehensive legislative scheme to be introduced in Australia to provide, *inter alia*, contractors, subcontractors and building professionals with a statutory right to, and a procedure to recover, progress payments. While it embraces the philosophy of rapid 'statutory adjudication' of payment claim disputes introduced in the UK[2], the NSW Act is substantially different in its structure and operation from its UK counterpart. Similar legislative schemes to that operating in NSW and the UK

[1] New South Wales (abbreviated as 'NSW') is one of six states of the Commonwealth of Australia.
[2] *Housing Grants, Construction and Regeneration Act 1996* (UK) pt. 2.

have since been introduced in all Australian states and territories[3], New Zealand[4], Singapore[5] and the Isle of Man.[6] On March 8 2011, the Irish Construction Contracts Bill 2010 was passed by the upper house of the Irish Parliament. At the time of writing, the Malaysian Building and Construction Industry Payments and Adjudication Act remains pending.

'Statutory adjudication' is a process defined in the NSW Act of referring a payment claim dispute to an independent third party known as 'adjudicator'. Whenever a claimant[7] endorses a payment claim as a claim made under the NSW Act, the claimant may elect to have the payment claim adjudicated upon under the NSW Act if the respondent[8] withholds payment.

The NSW Act has undergone two significant amendments since its introduction – the first in 2002[9] and second in 2010.[10] Accordingly, 'the NSW Act' referred to here is the NSW Act as amended.

This paper will be concerned with the NSW Act only. The aim of the research was to examine adjudication activity under the NSW Act between 1 July 2011 and 31 March 2012. In particular, the trend in the number of adjudication applications and adjudication determinations as well as the success of claimants at adjudication made will be examined. Apart from improving security of payment, the NSW Act also intends to provide a fast and relatively inexpensive mechanism for deciding (on an interim basis) payment claims disputes. Consequently, the researchers attempt to ascertain any trends in the cost of adjudication.

The results of this research may be of interest in other jurisdictions where statutory adjudication for the construction industry has been introduced or is being contemplated.

2 Security of Payment

In the context of this paper, 'security of payment' is a generic term used to describe (NSW Government, 1996:41):

> [T]he entitlement of contractors, subcontractors, consultants or suppliers in the contractual chain to receive payment due under the terms of their contract from the party higher in the chain.

Thus, the security of payment problem refers to (Commonwealth of Australia 2002:7):

> [The] consistent failure in the building and construction industry to ensure that participants are paid in full and on time for the work they have done, even though they have a contractual right to be paid.

The security of payment problem has been an ongoing issue for those who carry out construction work, or supply related goods and services under a construction contract (Commonwealth of Australia, 2002).

[3] *Building and Construction Industry Security of Payment Act 2002* (Vic); *Building and Construction Industry Payments Act 2004* (QLD); *Construction Contracts Act 2004* (WA); *Construction Contracts (Security of Payments) Act 2004* (NT); *Building and Construction Industry Security of Payment Act 2009* (Tas); *Building and Construction Industry (Security of Payment) Act 2009* (ACT); *Building and Construction Industry Security of Payment Act 2009* (SA).

[4] *Construction Contracts Act 2002* (NZ).

[5] *Building and Construction Security of Payments Act 2004* (Singapore).

[6] *Construction Contracts Act 2004* (Isle of Man).

[7] The 'claimant' is the person *by whom* a payment claim is served – *see: Building and Construction Industry Security of Payment Act 1999* (NSW) ss. 4, 13.

[8] The 'respondent' is the person *on whom* a payment claim is served – *see: Building and Construction Industry Security of Payment Act 1999* (NSW) ss. 4, 13.

[9] *Building and Construction Industry Security of Payment Amendment Act 2002* (NSW).

[10] *Building and Construction Industry Security of Payment Amendment Act 2010* (NSW).

In sum, the security of payment problem is the result of the practice by principals and contractors in the construction industry of unduly delaying and devaluing progress payments owed to subcontractors for work done under construction contracts. The tactic of principals and contractors in delaying payments or unduly reducing the value of payments is largely designed to enhance their positive cash flow at the expense of subcontractors (Brand and Davenport, 2011).

The security of payment problem has long been a major source of commercial hardship for those operating in the construction industry, particularly for the many small and often undercapitalised firms, which operate at or near the bottom of the contractual chain (Iemma, 1999). It is suggested that, but for the systemically poor payment behaviour of principals and contractors, the problems of commercial hardship and failure amongst small firms in the construction industry would largely be avoided. Furthermore, one must not overlook the potential for the unnecessary generation of societal problems that often accompanies commercial hardship and failure (Commonwealth of Australia, 2002).

The next sections of the paper describe the research method adopted for this study, followed by a synthesis and analysis of the data. Conclusive remarks are then presented.

3 Research method

The operation of the security of payment legislation in NSW is facilitated by Authorised Nominating Authorities (ANAs). At the time of writhing, a total of nine such ANAs were operating in NSW. Their function is to accept adjudication applications, refer adjudication applications to adjudicators and issue, upon request, an adjudication certificate.[11] Furthermore, each ANA is required by the NSW Department of Finance & Services (hereafter referred to as the Department) to report regularly on a variety of matters relating to adjudication applications and determinations made in NSW. Reporting is required by the Department with a view of allowing it to "better monitor trends in adjudication" (NSW Department of Commerce, 2004:6).

Data used for this research was the adjudication activity data published by the Department as part of the aforementioned reporting régime. The adjudication activity data used for this research covers the period from 1 July 2011 to 31 March 2012 (NSW Department of Finance & Services, 2012).

It should be noted that, at the time of writing, no aggregated adjudication activity data have been published by the Department for the full period covering 3 March 2003 (i.e., the date of commencement of the 2002 Amendment Act) to 31 March 2012. Brand and Uher (2005) and Brand and Uher (2007) have previously reported on their analysis of the aggregated adjudication activity data published by the Department (then known as the NSW Department of Commerce) for the period covering 3 March 2003 to 30 June 2006. At the time of writing, the Department had not published any adjudication activity data for the period from 1 July 2006 to 30 June 2011.

The data published by the Department is not aggregated according to the participating ANAs. The format of the data used in this study has ruled out a statistical analysis. Instead, the authors' attempted to subjectively interpret trends emerging from the data and, where appropriate, relate them to the findings derived by the authors in their previous research into the performance of the adjudication process in NSW.

[11] 'Adjudication certificate' means a certificate provided by an Authorised Nominating Authority under the *Building and Construction Industry Security of Payment Act 1999* (NSW), s. 24.

4 Adjudication Applications

4.1 Number and statues of applications

For the period from 1 July 2011 to 31 March 2012, the total number of adjudication applications lodged with ANAs was 842 (see Table 1 below). The total value claimed for the period is in the order of 188 million AUD. The highest and lowest claimed amount for the period is 20.7 million AUD and 420 AUD respectively.

Table 1: Number and status of adjudication applications

Status	Number (% of Total)
Applications lodged	842 (100%)
Determination released	544 (64.6)
Determination pending release	200 (23.8)
Applications completed but not determined†	98 (11.6)

†'Applications completed but not determined' are application where no determination has been released by the adjudicator and no determination is pending release. In such cases, the adjudication process has come to a premature end between lodgement of the application with the ANA and a determination being made by the adjudicator.

From Table 1 above, it is can be seen that, of the total number of completed adjudication applications lodged with ANAs, 544 (or about 65 percent of the total number of application lodged) determinations had been released to the parties. At the time of writing, about 24 percent of the total number of completed adjudication applications were either pending determination by the adjudicator or pending release to the parties. About 12 % of the total completed adjudication applications were classified as 'completed but not determined'.

Whilst the Department does not indicate the reasons for an application being 'completed but not determined', Brand and Uher (2005) and Brand and Uher (2007) report that this is most likely to arise under two following conditions: (1) when the parties settle the dispute and withdraw the application before a determination is made by the adjudicator; and (2) when an adjudicator, after accepting the adjudication application, subsequently decides that the adjudicator lacks the jurisdiction to determine the application and subsequently withdraws their acceptance of the application before making a determination. Brand and Uher (2007) report that the first and second condition arises in about 37% and 45% of all cases, respectively. Similar results are reported by Brand and Uher (2005). Further study is needed to confirm if the two stated conditions still account for the majority of applications being classified as 'completed but not determined'. At the time of writing, there were no reported studies to indicate that there has been any shift in this regard.

Interestingly, Brand and Uher (2005) and Brand and Uher (2007) both report that about one-quarter of all adjudication applications lodged with ANA's were classified as 'completed but not determined'. As already stated, the Department's adjudication activity data for the period commencing 1 July 2011 to 31 March 2012 indicates that only about 12% of all applications lodged with ANAs were 'completed but not determined'. The results suggest that a much greater proportion of adjudication applications lodged with ANAs for the period 1 July 2011 to 31 March 2012 are being determined than for the periods between 3 March 2003 to 31 August 2004 and 3 March 2003 to 30 June 2006. The reasons for this apparent shift are unclear. Whilst further study is needed to confirm the extent of this apparent shift, it is suggest (based on the preceding paragraphs) that it may have two likely causes; firstly, that over time, the parties have been less inclined to settle payment disputes once the adjudication process has commenced; or secondly, that over time, adjudicators have been less frequently deciding that they lack jurisdiction to determine adjudication applications. Of course, the apparent shift may be the result of a combination of these factors.

4.2 Applications lodged

Section 14(1) of the Act provides that the respondent may reply to a payment claim by providing a 'payment schedule' to the claimant. A payment schedule is, in effect, a notice that must be served on a claimant if the respondent does not intend to pay the whole of the claimed amount by the due date for payment.[12] If the respondent fails to provide a payment schedule within the time allowed under the Act, the respondent becomes liable to pay the claimed amount to the claimant on the due date for payment.

A claimant may lodge an adjudication application under one of the following sections of the Act only: s.17(1)(a)(i); s.17(1)(a)(ii); or s.17(1)(b). Firstly, where respondent provides a payment schedule for less than the full amount claimed, and the claimant does not accept the lesser amount, the claimant is entitled to lodge an adjudication application with an ANA under section 17(1)(a)(i) of the Act. Secondly, where respondent provides a payment schedule for the full amount claimed but fails to pay the whole (or any part) of the scheduled amount by the due date for payment, the claimant is entitled to lodge an adjudication application with an ANA under section 17(1)(a)(ii) of the Act. Similarly, where respondent provides a payment schedule for less that the full amount claimed, and the claimant accepts the lesser amount, but the respondent fails to pay that amount by the due date for payment, the claimant is entitled to lodge an adjudication application with an ANA under section 17(1)(a)(ii) of the Act. Finally, where a respondent fails to provide an payment schedule and fails to pay the claimed amount by the due date for payment, the claimant is entitled to lodge an adjudication application with an ANA under section 17(1)(b) of the Act. It should be noted that if an adjudication application is intended to be lodged under section 17(1)(b) of the Act, and the respondent fails to provide a payment schedule in response to the payment claim, section 17(2) of the Act requires the claimant to give the respondent written notification of the claimant's intention to apply for adjudication under the Act. This notification, in effect, gives the respondent a second opportunity to provide a payment schedule to the claimant in response to the payment claim. The distribution of applications lodged (by section of the Act) for the period from 1 July 2011 to 31 March 2012 is shown in Table 2 below.

Table 2: Adjudication applications lodged (by section of the Act)

Section	Number (% of Total)
17(1)(a)(i)	482 (57.2%)
17(1)(a)(ii)	16 (1.9%)
17(1)(b)	344 (40.8%)
Total	842 (100%)

Table 2 shows that in the majority of cases (about 60 percent) respondents elect to provide a payment schedule in direct response to a payment claim. Whilst a significant minority of respondents (about 40 percent) elected not to provide a payment schedule in direct response to the payment claim, it is unclear what proportion of these respondents elected to provide a payment schedule in reply to the written notification made under section 17(2) of the Act. On that basis, no conclusions can be drawn as to whether there is, perhaps, an intention by these respondent to simply ignore payment claims in order to delay or escape payment, or whether these respondents are seeking to legitimately delay the provision of a payment schedule to the claimant and so make use of the additional time allowed under the NSW Act

[12] See: *Building and Construction Industry Security of Payment Act 1999* (NSW), s. 11(1).

 ISBN: 978-1-84219-840-7 .

to prepare the payment schedule.[13] Considering the time the Act has been in operation, and the consequences under the NSW Act for not providing a payment schedule, it is reasonable to conclude that the latter reason is the more likely.

5 Adjudication Determinations

For the period from 1 July 2011 to 31 March 2012, the Department reports that 544 determinations have been released to the parties in NSW. The highest and lowest adjudicated amount for the period is not reported by the Department. The number of adjudication applications (determination release) by payment claim value range is shown in Figure 1.

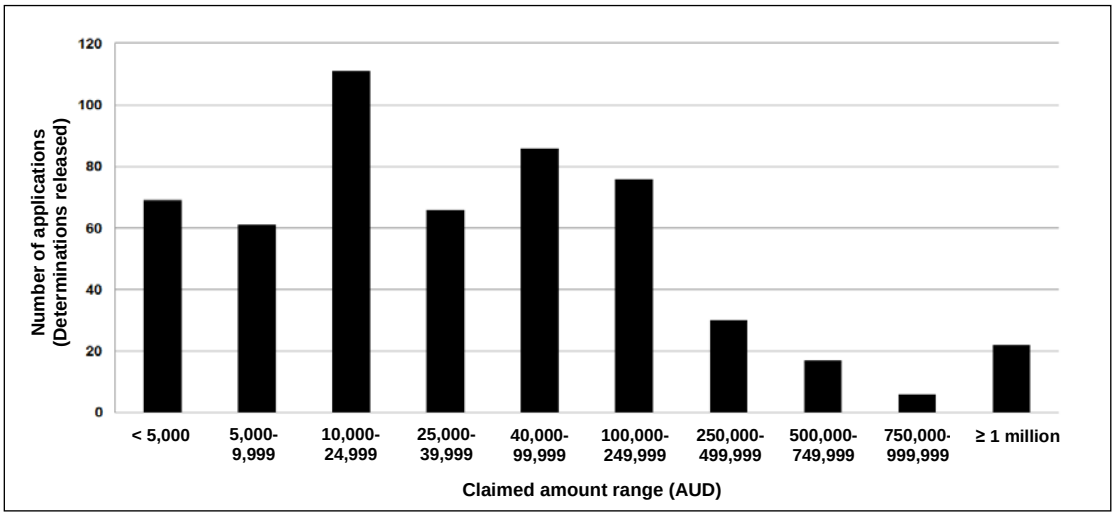

Figure 1: Frequency of claimed amount (by claim range).

Figure 1 shows that payment claims between < $5,000 to just under $250,000 tend to be the most frequent claimed amount values with a notable decline in the frequency of claimed amount values $250,000 and above. Claimed amount values of $250,000 and above represent about 14% of the total number applications lodged with ANAs. The most frequently determined payment claims were those of the amount between $10,000–$24,000 and $40,000–$99,000. This result is consistent with the results given in Brand and Uher (2005) and Brand and Uher (2007). Furthermore, a factor to be considered in determining the level of success of claimants at adjudication is the frequency of favourable outcomes experienced by claimants at adjudication. Figure 2 below shows the overall comparative values of the total claimed and adjudicated amounts for the period.

[13] Respondent is given an opportunity to provide a payment schedule within 5 business days after receiving the claimant's notice.

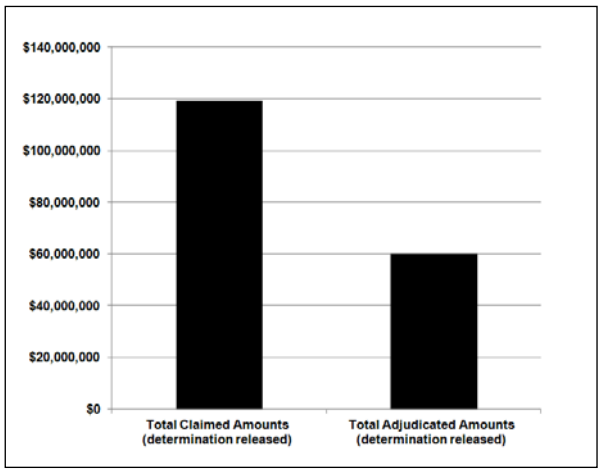

Figure 2: Total claimed and adjudicated amounts

Figure 2 shows that of the total number determinations released (i.e., 544), the total value of claimed amounts was 119.2 million AUD with a total value of adjudicated amounts being 60.1 million AUD. The results show that adjudicators, overall, award claimants about 50 percent of the clamed amount. This indicates that claimants' tend to have only modest success at adjudication in terms of the proportion of the claimed amount awarded by adjudicators. However, when examined across the spectrum of claim values, it is apparent that the level of success of claimants at adjudication varies considerably. This is shown in Table 3 below.

Table 3: Average claimed and determined amounts (by claim range)

Range of Claim Values ($)	No.	Average Claimed	Average Determined (% Av. Claimed)	No. awarded 100% (% of No.)
< 5,000	69	$2,618	$2,371 (91%)	49 (71%)
5,000 - 9,999	61	$7,357	$6,570 (89%)	42 (69%)
10,000 - 24,999	111	$15,919	$14,732 (93%)	70 (63%)
25,000 - 39,999	66	$32,415	$28,253 (87%)	37 (56%)
40,000 - 99,999	86	$66,804	$53,160 (80%)	37 (43%)
100,000 - 249,999	76	$159,470	$121,112 (76%)	28 (37%)
250,000 - 499,999	30	$358,365	$193,660 (54%)	6 (20%)
500,000 - 749,999	17	$584,337	$168,946 (29%)	0 (0%)
750,000 - 999,999	6	$924,850	$553,667 (60%)	0 (0%)
≥ 1,000,000	22	$3,207,742	$1,372,085 (43%)	0 (0%)
Total	544			

Table 3 shows that, in the case of small value claims (i.e., claims less than $40,000), adjudicators award, on average, about 89% of the claimed amount with claimants being awarded the whole of the claimed amount in about 65% of cases. In the case of medium value claims (i.e., claims from $40,000 to less than $250,000), adjudicators award, on average, about 77% of the claimed amount with claimants being awarded the whole of the claimed amount in about 40% of cases. Finally, in the case of large value claims (i.e., claims greater than $250,000), adjudicators award, on average, about 45% of the claimed amount with claimants being awarded the whole of the claimed amount in about 8% of cases. The results indicate that claimants making small to medium value claims (i.e., claims less than $250,000) are notably more successful at adjudication than those making large value claims, both in terms of the average proportion of the clamed amount awarded by adjudicators and the proportion of instances where the adjudicator awards the full amount claimed.

It is not clear to what extent (if any) the provision of a payment schedule impacts on the level of success of claimants at adjudication in terms of the average proportion of the clamed amount awarded by adjudicators and the proportion of instances where the adjudicator

awards the full amount claimed. However, Brand and Uher (2007) report that, generally, claimants' success at adjudication declines sharply when respondents' provide a payment schedule. To what extent this holds true across the spectrum of claim ranges is unknown. Further research is required in relation to these issues.

The reasons for claimants having less success at adjudication when adjudication involves large claims, rather than small to medium size claims, is also unclear. Brand and Uher (2007) contend that, generally, parties to large payment claim disputes are frequently assisted by lawyers or claim consultants at adjudication and that the relatively small return to claimants in the case of large payment claims appears to support the view that large payment claims tend to be overinflated. Through the author's direct involvement in the adjudication process in NSW, it is apparent that respondents, generally, do not defend small payment claims by employing lawyers or claim consultants in preparing payment schedules and adjudication responses. Similarly, claimants tend not to employ to lawyers or claim consultants in preparing payment claims and adjudication applications. One reason why respondent's may not engage lawyers or claim consultants in such cases is that respondents do not regard the overinflation of small payment claims as an issue of chief concern. Further research is required on this issue.

6 Cost of adjudication

One of the most important aims of the adjudication process is to provide claimants with a relatively inexpensive method of having disputes as to payment determined by a neutral adjudicator (Iemma, 1999). The distribution of the average total direct fees (i.e., the fees of the ANA and the fees and expenses of the adjudicator) for all adjudication determinations released in NSW for the period from 1 July 2011 to 31 March 2012 is given in Table 4 below.

Table 4: Adjudication fees (by claim range)

Claimed Amount	No.	Av. Fees ($)			Av. Fees (%)		
($)		Total	Respondent Share	Claimant Share	Total[1]	Respondent Share[2]	Claimant Share[3]
<5,000	69	570	545	25	21.8%	95.7%	4.3%
5,000-9,999	61	900	827	74	12.2%	91.8%	8.2%
10,000-24,999	111	1,249	1,193	56	7.8%	95.5%	4.5%
25,000-39,999	66	2,244	2,101	143	6.9%	93.6%	6.4%
40,000-99,999	86	2,937	2,575	362	4.4%	87.7%	12.3%
100,000-249,999	76	5,445	4,854	591	3.4%	89.1%	10.9%
250,000-499,999	30	8,353	6,181	2,172	2.3%	74.0%	26.0%
500,000-749,999	17	10,399	6,545	3,854	1.8%	62.9%	37.1%
750,000-999,999	6	15,553	12,960	2,592	1.7%	83.3%	16.7%
≥ 1,000,000	22	19,132	13,740	5,392	0.6%	71.8%	28.2%
Total number	544						

[1] Av. Total Adjudication Fee expressed as a percentage of the Av. Claimed Amount (Av. Claimed Amount is shown in Table 3 above). See Fig. 3 below.
[2] Av. Respondent share expressed as a percentage of the Av. Total Adjudication Fee.
[3] Av. Claimant share expressed as a percentage of the Av. Total Adjudication Fee.

The Department's data does not indicate under what circumstances claimants' are required to pay adjudication fees. Under the NSW Act, adjudicators have the discretion to determine the proportion of the adjudication fees each party is required to pay. Uher and Brand (2007) and Uher and Brand (2005) report that when adjudicators award a $nil to claimants, they are generally required to pay 100 percent of the adjudication fees. However, in the remainder of cases, the amount of the adjudication fee that claimants' are required to pay will vary.

Nevertheless, Table 4 above indicates that respondents are generally required to pay the greater proportion of the adjudication fees across the spectrum of claim values. Figure 3 below shows that there is an inverse relationship between the amount claimed and the total adjudication fee when expressed as a percentage of the amount claimed.

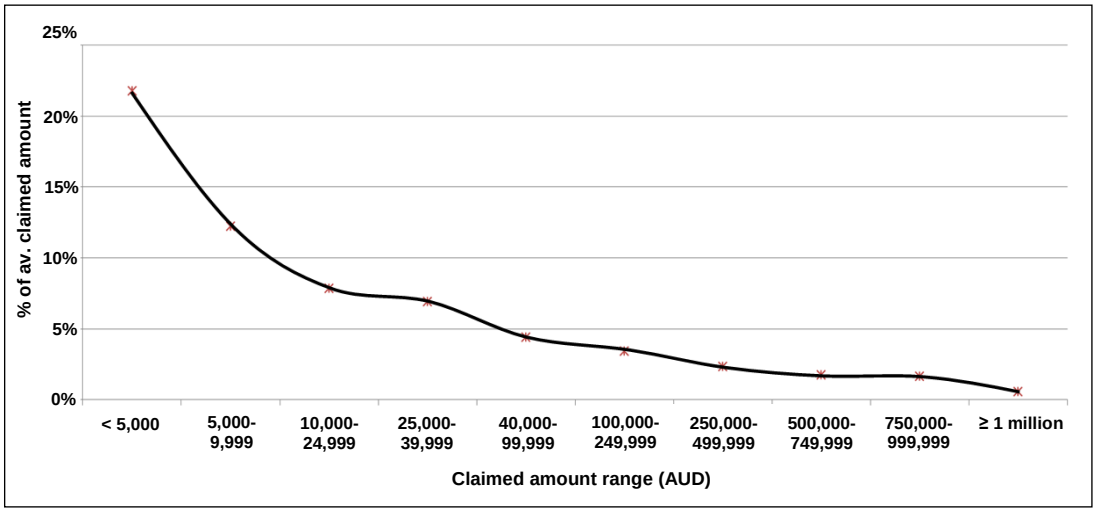

Figure 3: Av. total adjudication fee expressed as % of the av. claimed amount (by claim range).

It is interesting to note that, in relation to small payment claims (i.e., claims less than $40,000), the total adjudication fee equates, on average, to only about 12 percent of the total claimed amount. This increases to a maximum of about 22 percent for the claims of less than $5,000 down to a minimum of about 7% for claims between $25,000 to less than $40,000.

Compared to other forms of dispute resolution, such as arbitration and litigation, which are processes acknowledged as being costly (Carter *et. al.,* 2007), adjudication appears to have provided a financially viable option for those making small claims to have the dispute heard and determined by an independent third party. This conclusion is supported by the data in Table 4 above, which shows that just over half of the applications lodged with ANAs for the period were made in relation to small value claims.

7 Conclusion

The foregoing discussion of the data collected by the Department shows that, in general, adjudication is being highly utilised by stakeholders in the NSW construction industry as a means of payment recovery. The data reveals that claimants are highly successful at adjudication in terms of the proportion of the claimed amount they are awarded by adjudicators, particularly in relation to small value claims.

Adjudication fees appear to be modest enough to conclude that adjudication provides claimants with a relatively inexpensive means of determining disputes as to payment by an independent third party. The results indicate that adjudication is providing a financially viable option for those making small claims to have the dispute heard and determined by an independent third party. This result appears to justify the introduction of the NSW Act as a means of assisting smaller firms in the NSW construction industry to recover payment, and suggests that the aim of the NSW Act is being achieved.

The results suggest that there has been a significant decrease over time in the incidence of adjudication applications being reported by ANAs as ‘completed but not determined’. Whilst

further study is needed to confirm the extent of this apparent shift, the result suggest that the parties' have been less inclined to settle payment disputes once adjudication has commenced and/or adjudicators have been less inclined to find that they lack the requisite jurisdiction to determine adjudication applications.

Whatever the reasons for this apparent trend are, the consequence is that, currently, a much greater proportion of adjudication applications lodged with ANAs proceed to determination than in the periods between 3 March 2003 to 31 August 2004 and 3 March 2003 to 30 June 2006.

Participation by respondents in the adjudication process tends to be moderate, with only about 60 percent of respondents providing a payment schedule in direct response to a payment claim. However, the Department does not report on the number of respondents' that elect to provide a payment schedule in reply to the written notification under section 17(2) of the NSW Act. On that basis, the level of participation of respondents' in the adjudication process is arguably higher than the Department's data suggests.

Abstract:
This research is to identify the root cause for Chinese construction labour problems that might exist in subcontracting systems. It also explores potential economic incentives of tentative adjustments of subcontracting systems on subcontractors (SCs) for achieving sustainable employment improvement. The research examined the failure of recently promoted schemes in improving construction labour market in China. The causal analyses were done based on empirical observations of one representative construction general contractor (GC) in China. The failure of new schemes is due to ignorance of continuing development of SCs under existing subcontracting systems. With excessive competition by Cost-Based-Selection, and restrictions on subcontracting scope and layer, current systems fail to provide economic incentives for SCs' good performance. Japanese experience demonstrates the significance of facilitating SCs' development for efficient production and employment improvement. Furthermore, long term relationship (LTR) under Affiliated Companies by giant Japanese GCs is found to be indispensable for SCs' ongoing development. Under today's business environment with various uncertainties in China (e.g. workflow unreliability), enlarging subcontracting scope and layer, and promoting LTR amid construction supply chain are mathematically validated to have potential economic incentives for SCs' continuing development. It could ultimately lead to the realization of sustainable Chinese construction labour market.

Keywords:
Chinese construction, economic incentive, migrant labour, subcontracting, uncertainty.

1 Introduction

The functioning of construction industry consists of two aspects in most countries. Those are its contribution to the development of national economy and people's standard living, and its role in absorbing labour force. Experiences of many countries show that construction industry provides much needed employment for a large number of the poorer and less well educated labourers of the society. Regarding the labour market, there are basically three involved issues as the source of labour, the basis on which it is employed and the way it is treated (Wells, 2003). On the one hand, those issues have profound implications for project objectives, productivity, and skill development that are usually to be the immediate concern of construction industry

stakeholders. On the other hand, such issues as the number of jobs, the systems under which construction labourers are employed and managed, as well as their conditions can affect the achievement of social objectives such as the alleviation of poverty and the promotion of social stability and harmony. Therefore, studies of construction labour market should be of high priority from both economic and social views.

The Chinese construction has so far enjoyed a good opportunity for development, which has already been a leading contributor to the Chinese national economy. It has provided enormous employment for labour force as well, especially for those surplus rural labourers called 'migrant labourers' in China. However, the Chinese construction has recently been in a dilemma with an increasing labour outsourcing practice for construction production. It brings about widespread and increasing labour rights infringements, such as ignorance of occupational health and safety, payment default or wage squeeze, long working hours, instability of job or employment, lack of job training, few social securities, domestic problems due to separation from their families, etc. Those labour issues result in a negative image of the Chinese construction industry universally. It greatly hinders the recruitment and retention of construction labourers in recently China, especially among the growing new generation of migrant labourers. Construction industry employers in China seem too much lag behind other industries in how they conduct their people practices. This industrial gap must be closed; otherwise the recruitment and retention of construction employees will become chronic problems in the near future (Charles, 2007). Even worse, many grave social problems will be brought about. Those explanations argue that the future of Chinese construction calls for more labour-oriented strategies. To be more detailed, it is urgent for Chinese construction not only to pay close attention to improve current employment situation, but to raise the issue how to foster a sustainable construction labour market as a vital element to its future development. It is certainly a complicated and systematic task to be carefully tackled, since any frequently changeable or short-sighted interventions or regulations would not only make the existing problems unresolved but in turn bring new fatal problems and even aggravate the tension between construction enterprises and its labour force. The focus of this study is to explore labour-based strategies and adaptable measures for an economically effective and socially responsible Chinese construction.

2 Observations on Recent Chinese Construction Labour Market

China is a typical country in that most construction labourers are migrants from the rural areas, called 'migrant labourers'. They occupy more than 80% of construction workers on sites. The priority for them is to get work on a regular basis and improve income.

2.1 Corporatization among Informal '*Baogongtou*'

Recent studies in China described the central role of labour contractor, known locally as '*baogongtou*', who is head of the working team with labourers usually coming from the same rural area. *Baogongtou* exerts profound influences on the labour subcontracting business and the lives of construction workers. Through joining an informal team headed by a *baogongtou*, the labourers are provided with an opportunity to obtain work and acquire skills, which could bring them a higher income in a sense. However, this opportunity is mostly denied to those without family and social connections with

baogongtou. Thus, it is regarded as a barrier to training and innovation. Even worse, since labour subcontracting is prone to decreasing the level of upper contractor's control on labour force, it has a great potential of labour exploitation. It does take place in recent China. Those labour issues have been universally reported with an indiscriminate blame on *baogongtou*. As a result, *baogongtou* is generally considered to have negative connotations in China, which precipitated the government to prohibit informal *baogongtou* and promote formal labour subcontracting enterprise (LSE) as a substitute since 2005. However, the applicability and effectiveness of this enforcement may be reserved for further consideration in view of unsatisfactory progress in practice. During the investigation into one representative general contractor in China, those interviewed project managers admit that 'illegal' *baogongtou* remains to abound on sites in disguise since it is preferable to LSE in labour subcontracting business. The direct cause lies in the principle of Cost-Based-Selection under current competitive labour subcontracting market. It makes the informal *baogongtou* with lower labour cost by evading the overhead costs and on-costs of formal employment beat the competition. So LSEs are usually exposed to a vitally disadvantageous position in the business competition. That may explain the dumping of LSEs that depresses labour cost to an unreasonable degree just for getting jobs and survival. It is likely to bring about problems of quality, safety, labour issues, etc., and hinder the continuing development of LSEs themselves. The root cause may exist in subcontracting systems with excessive restriction on subcontracting layer and business scope (An, 2010). It ignores the potential of labour subcontractors to become a speciality one or even higher level amid the construction supply chain to a great extent. Regarding the limitation on business scope to labour-only for labour contractors, as most of them are small and medium-sized, it is harder for them to cope with various uncertainties inherent in today's business environment. In a word, under current excessively restricted and competitive subcontracting market, there is little economic incentive to promote corporatization among labour contractors. As a matter of course, LSEs have not matched the expectations in term of development. Furthermore, there becomes a huge imbalance in the numbers of general contractors, speciality subcontractors, and labour subcontractors. This is unlike normal construction industrial structure (Li et al, 2010). Up till now, general contractors complain that subcontracting market is too disordered and deficient in supplying qualified subcontractors with labour and specialist skills; meanwhile, *baogongtou* as well as LSE complain they could not see any promising future in today's insecure business environment. Thus, fundamental improvement of labourers' situation has not been achieved. Policies and regulations may need to be reassessed and adjusted. Instead of compulsive enforcement by administration, more efforts should be made to understand their economic behaviours.

2.2 Direct Control by General Contractor

Efforts have been made in many countries to overcome the disadvantages of labour subcontracting. Regarding the loss of control over the labour force and site work, one common practice is that general contractor adopts an arrangement whereby the labour is sourced through a labour contractor but paid and supervised on its own. It has also been promoted by the Ministry of Railways in China since 2005 in view of undying practice of multi-layer subcontracting. Through that, even when risk is passed down to the labour contractor with a fixed sum paid for a package of work, the site manager employed by the general contractor can still exercise a considerable degree of control.

Bresnan (1985) argues that it could be enhanced further through the use of known subcontractors with whom general contractor has a longstanding relationship, or through the employment of speciality subcontractors. It points out promising directions of system adjustment for current Chinese construction. As is acknowledged, direct control by general contractor is supposed to be a transitional mode seen from the development of construction industry in most developed countries. Along with the growth of general contractors who will gradually develop their capabilities for undertaking EPC or DB projects, concrete engineering works are usually subcontracted or sub-subcontracted to speciality subcontractors that are small-scaled but with highly specialized construction skills or technologies. Thus subcontractors should be cultivated and stimulated with more initiatives on developing their specialist skills and management capabilities to achieve more efficient construction production. Based on that, the conditions of construction labourers largely recruited and employed by subcontractors may achieve a fundamental and sustainable improvement. However, the significance of subcontractors has not been realized or truly understood in the competitive and risk transfer work culture amid construction supply chain in China.

2.3 Contractual Work Relations

Recent Chinese government thinks that one of the most important solutions of labour issues is labour contract, revealed by the promotion of LSE which is ought to sign a contract with labourers. It is believed that if there is labour contract, the conditions of labour force would be much improved. Of course, contract has legislated constraints by law enforcement in labour users regarding formal payment and welfare systems; however, it should be on the premise of sound law systems and legal compliance that are far from sufficient in current China. Many cases in other countries indicate that there is usually a large gap between regulations in principle and action in practice, suggesting that contract may not solve the problems fundamentally. Actually, schemes for improving the labourers' situation including welfare have also been devised in other countries like Egypt, India, and Korea, based on the acknowledging of labourers' temporary or casual status. Most of those schemes illustrate that the policy direction should be moved to accommodate the needs of construction labourers without requiring a fundamental change in the way labourers are recruited and employed. It again argues that the rigid prohibition of *baogongtou* in China may be one-sided with little consideration of their further development, and ignorance on their functioning of building a social bond to some extent. Although the latter argument should not be carried too far, it is important to recognize *baogongtou*'s close relationship with groups of labourers. The key should be to facilitate their development in specialist skills and management capabilities. A valuable approach is non-contractual cooperative relationships like Japanese long term work relations up and down the construction supply chain. It has facilitated the further development of downstream subcontractors, and consequently established a highly specialized subcontracting market.

3 Hypotheses for Developing Future Construction Labour Market

From above, current interventions by government to deal with some negative impacts of 'informal' labour subcontracting may not have to totally deny it. One of the root causes may exist in the excessively competitive and restricted subcontracting systems which

ignore subcontractors' further development by failing to provide economic incentives for them. Actually, informal employment and multi-layer subcontracting systems (MLSS) have their rationalities of existence, particularly in developing countries (Assaad, 1993; Aelim, 2010). Those schemes have positive meanings for both industrial structure adjustment and improvement of construction labour employment. To overcome some negative repercussions of the schemes, one crucial issue is to facilitate subcontractors' continuing development. It calls for a truly mutual understanding between general contractors (GCs) and subcontractors (SCs) regarding labour subcontracting business. GCs must recognize the functional change brought by outsourcing or subcontracting, and then understand the significant role of SCs' development in their business. Further, economic incentives for SCs to develop their competencies should be explored through understanding the barriers they encounter in subcontracting business. Based on that, the deregulation or adjustment of subcontracting systems could exert an effect in practice. It then argues that releasing restrictions on subcontracting layer and business scope, and meanwhile introducing cooperative work relations between GC and some certain SCs into existing competitive mechanism, would foster qualified speciality SCs. It will finally lead to the realization of efficient and effective construction production systems with just-in-time and efficient assembler (GC) and qualified suppliers (SCs). The hypotheses stated above are shown briefly in Figure 1 aiming at the development of sustainable construction labour market in China.

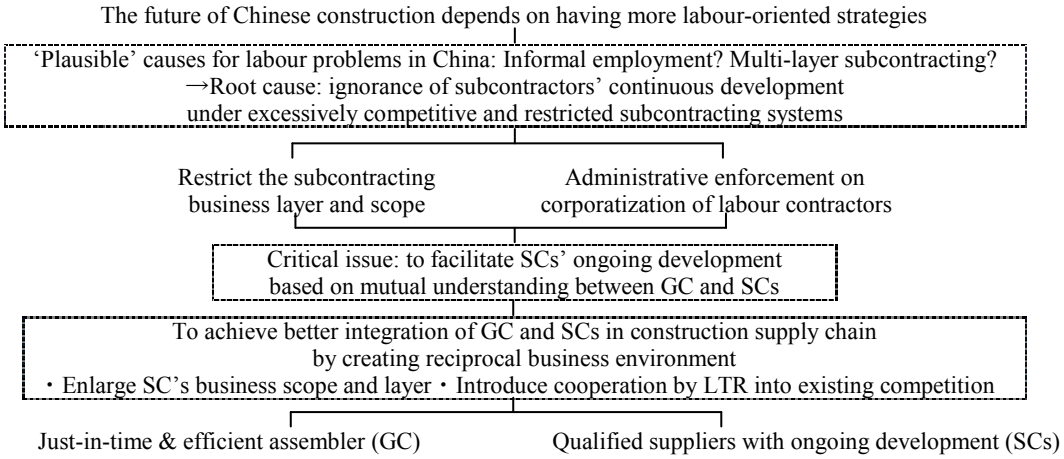

Figure 1. Hypotheses for developing sustainable construction labour market in China

4 Approaches for Exploring Economic Incentives

4.1 Japanese Experience on Fostering Subcontractors-Case of *Kajima*

Kajima is one of the Japan's big six construction general contractors, and the transition of relationships between *Kajima* and its subcontractors (see Figure 2), reveals a typical Japanese practice of facilitating the development of subcontracting market (Furukawa, 1963). In Japan, giant general contractors play a dominant role in fostering subcontractors' continuing development via establishing and developing its Affiliated Companies (ACs) among those subcontractors who enjoy long-term paternalistic but conclusive family work relations. This long term relationship (LTR) contributes to the achievement of efficiency and great success of the Japanese construction industry

(Bennett, et al. 1987). Generally speaking, within the construction industry, the value-added process is distributed across several organizations between GC and SCs. Without working together in a cooperative manner, supply chain efficiencies are difficult to realize. Through LTR under ACs mode, good integration between *Kajima* and its SCs in the construction supply chain is achieved. Regarding subcontractors' integrating process, foremen accumulated skills and technologies across the various projects that increase operational efficiency within the GC, which provided a high value to their business functioning. Their initial business with GC was to be an intra-company transaction, and then inter-companies transaction in the capacity of labour subcontractors with a construction corporative license. Afterwards, through becoming the Affiliated Companies of a certain GC, labour subcontractors got an opportunity to further develop their specialist skills as well as management capabilities in a secure business environment attributed to the long term working relationships. This opportunity facilitated them to be specialty subcontractors or even general contractors along with the business extension. Normally it at least takes a foreman at the bottom subcontracting layer 7-8 years to accumulate essential construction skills and management capabilities to become a specialty company in Japan. Thus it is inferred that gaining a regular work with the same contractor has a significant meaning in acquiring and accumulating skills or technologies that are essential for ongoing development of labour subcontractors, even though the whole process is generally informal and the time span of skill acquiring is varying. What's more, Japanese mode could decrease of uncertainty of transaction up and down the construction supply chain, and ensure labour subcontractors an economic incentive to further develop their specialist skills and management capabilities.

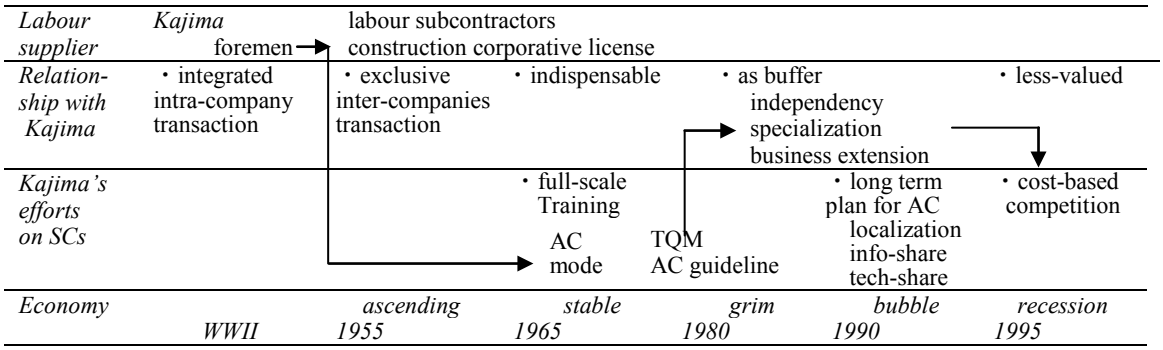

Figure 2. Transition of relationships between *Kajima* and its subcontractors within economy development

4.2 Mathematical Analyses on Potential Economic Incentives

As is known, LTR could reduce uncertainties to some extent. However, it is prone to adoption by SCs just as a short-term response to pressure from powerful clients or GCs, rather than a fundamental cultural change. Moreover, if it is not implemented properly, it could exert detrimental effects on SCs in turn (William, 2009). The real cultural change requires an understanding of factors that dictate the basic interests of the parties involved (Bresnen and Marshall, 2000). One great barrier for better integration of GC and SCs during construction process is workflow instability. SCs are generally fragile or vulnerable, since they are in the downstream of construction supply chain, and their further development is largely dependent on the fundamental accumulation on projects level as mentioned above. Furthermore, it is prone to arbitrary use and exploitation of

labourers by SCs as a buffer or leverage to cope with fluctuation of work. Thus striving for stable work flow is a basic interest for involved parties. Instead of conventional risk transfer that could not eliminate potential waste or loss brought by workflow instability, risk sharing under LTR and business scope enlarging might be better ways.

Given that the contract price between client and GC is reasonable enough so that GC does not have to worry about its payment by client, but is just concerned with how to complete project work efficiently with well coordination by SC. Stability of workflow is then mainly influenced by the degree of work plan reliability by GC, and reliability in providing necessary resources by SC. Derived from Sacks (2004), SC's net income could be expressed as $I = Total\ Income - Total\ Cost = min\{k, q\}W_D(U - C_M) - kW_DC_S$. Here, $k=R_A/R_D$, in which R_A denotes the actual resources provided by SC, and R_D is the quantity of resources demanded by GC to complete the planned work; $q=W_A/W_D$, where W_A denotes the quantity of actual work made available, and W_D is the quantity of work demanded. Figure 3 shows the relations between SC's net income (I), resource allocating strategy (k), and GC's plan reliability (q). In this scenario, SC could set the value of k to optimize its net income as its resource allocating strategy.

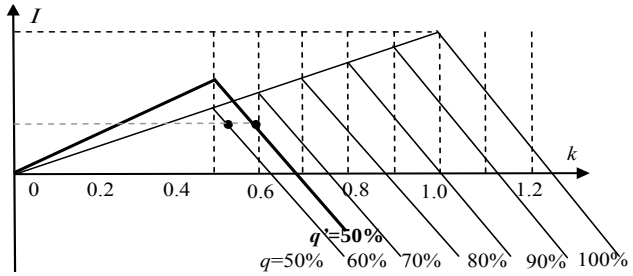

Figure 3. Relations between SC's net income, resource allocating strategy and GC's plan reliability

As can be seen, SC's net income is dependent on the reliability of work plan by GC (q), resulting in SC's different behaviours when providing resource (k). As q declines, not only SC's expected income will be reduced, but the loss is more easily incurred. It could explain that SC is liable to providing fewer resources than demanded if the work plan is less reliable. From SC's perspective, non-trust work relations will lead to its behaviour like not to be of honesty or integrity. It is consistent with the prior perception that SCs tend to provide fewer resources demanded by project managers, such as cheating on labour and materials (jerry building). For a rational SC, they must try to estimate the value of q, and then choose resource allocating strategy more appropriately (i.e. $k = q$) to maximize income. However, the actual value of q occurs with uncertainty $P_r(q)$ in practice. Since the value of q varies over the multiple planning periods, if a frequency distribution can be collected, then the expected value of q is possible to be estimated. It would be much valuable for SC, but it could only happen during a long term working period. In practice, even if SCs could not get access to the records of the value of q for each project, they usually have a mental impression of the plan reliability in each project. As can be inferred, under a stable working relation, this kind of estimation could be more accurate and beneficial for SCs to allocate resources appropriately.

Another interesting result is: the vulnerability of SC to the unreliability of work plan by GC could be influenced by subcontracting business scope. If SC supplies labour-only

(labour-only subcontractor), the slope (see the bold line in Figure 3) will become steeper. It means that SC becomes more vulnerable or sensitive to the degree of reliability of the work plan (q). On that occasion, with the same value of q, SC needs a bigger value of k to obtain the same profit. In other words, if the subcontractor supplies a significant proportion of the materials needed for the work, its vulnerability to work plan could be decreased. It is also consistent with prior knowledge that SC prefers subcontracting more services like materials and equipment, rather than labour-only. By doing that, SC could be less influenced by insecure business, and enjoy a higher potential to gain profit.

5 Conclusions

Regarding the underdeveloped Chinese construction labour market involving many labour issues, one of the root causes exists in the subcontracting systems. It ignores the continuing development of subcontractors with excessive competition by Cost-Based-Selection, and restrictions on subcontracting scope and layer.Japanese experience demonstrates the significance of facilitating SCs' development for efficient production and employment improvement in the long run.To facilitate SCs' ongoing development, enlarging subcontracting scope and layer, and promoting LTR amid construction supply chain are put forward. Those adjustments to current subcontracting systems have potential economic incentives for involved parties regarding the work plan and execution, which is a major concern in construction production. Hence, the proposals are believed to be able to motivate GC and SCs to become trustful partners amid construction supply chain, and realize sustainable employment improvement ultimately.

ABSTRACT

It is common knowledge that aged buildings are constantly growing in number with a concomitant growing pressure to maintain their utilitarian values in the face of changing technology, legislation and sustainability issues. Wholesale demolition of these buildings can be unhealthy from an environmental protection perspective as it causes heavy pollution as well as placing more demand upon depleting resources. The need for alternative to demolition and new-build is therefore, imperative and the current problems in the economy appear to have moved building owners from demolition and new build to refurbishment. Although refurbishment may involve numerous cost saving opportunities, it may also involve substantial risks and challenges which can jeopardise the achievement of desired outcomes. The objective of the paper is to evaluate the types of risks that are associated with building refurbishment schemes. The research question is: What constitutes a risk in refurbishment schemes? The paper is based on a comprehensive literature review as part of on-going PhD research programme on risk structure in building refurbishment schemes. The paper establishes a consensus that refurbishment projects contain high risk than an equivalent new construction and that the impact of individual risk or a collection of risks may jeopardise the attainment of desired goals, hence risk assessment is imperative to enable successful implementation of the scheme.

Keywords: existing buildings, refurbishment schemes, risks.

INTRODUCTION

While building refurbishment may be perceived as a well-established alternative to demolition and new-build for many years, it is now more widely recognised that it makes far greater sense to retain and refurbish buildings in preference to demolishing and new-build (Corus, 2010; Gorse and Highfield, 2009; Marsh, 1983). Indeed, from an environmental protection perspective, recycling of buildings through refurbishment and retrofitting is ideal whereas wholesale demolition of buildings can be quite unhealthy as it causes heavy pollution as well as placing more demand upon depleting

[1] i.babangida@bolton.ac.uk

resources (Zavadskas et al, 1998). Corroborating these views, Marsh (1983) argued that tearing down every building that became older than 30 years is a sheer waste of economic resources. Furthermore, through reuse of old and aged buildings, less construction waste is generated and less material resources are required (Edward and Turret, 2000), and therefore beneficial to the environment.

According to Corus (2010) refurbishment presents a means of improving the value and performance of existing buildings without the economic and environmental costs associated with new-build construction. This view is endorsed by different researchers across the globe that a refurbished building can be as functionally efficient and can attain the same environmental sustainability as new-build (Corus, 2010; GVAGrimley, 2010; Mansfield, 2009; Gorse and Highfield, 2009; Marsh, 1983). However, despite such significance and growing awareness, there is nevertheless a widespread view among researchers that refurbishment projects generally contain more risk than new build (CIRIA, 1994; Reyers and Mansfield, 2001; Mansfield, 2009; Lam et al, 2010; Rahmat and Ali, 2010). Indeed, the scope and extent of refurbishment is wide, its definitions also changes with financial size of the project while its decision-making process is hampered by the lack of clear and consistent definition from relevant authorities (Reyers and Mansfield, 2001). This view suggests that refurbishment projects are more complex to design, implement and manage.

Apart from the normal problems associated with refurbishment schemes, developers are currently faced with challenges to comply with current legislation to minimise carbon emissions in buildings. The emergence of modern concepts of sustainable development has gained international recognition in recent years. A typical example of such concerns were deliberated at the United Nations conference on Environment and Development, Rio de Janeiro (1992) and 10 years later at the World summit on sustainable development, Johannesburg (2002). This arises mainly from growing concerns for the depletion of natural resources, climate change as well as environmental pollution.

These growing concerns have forced Governments worldwide to enact and promulgate laws in order to minimise the effects of carbon emissions in buildings. However, in the UK there is divergence of opinions which suggests that although this can be achieved, it will require concerted efforts to meet the current targets. Indeed, the Task Force on Sustainable Development (2007) indicates that in order to achieve the anticipated improvements needed to address the environmental impact of the built environment; the construction and property sectors must engage more meaningfully and become more pro-active with the sustainable development agenda within the next 15-20 years. This is due in part to the mere fact that the UK has some of the oldest building stock in Europe (Office of the Deputy Prime Minister-ODPM, 2005; National Refurbishment Council-NRC, 2010). Indeed, these buildings pre-date the emergence of modern concepts of sustainable development. Notwithstanding, the UK Green Building Council-UKGBC (2008) articulated that existing buildings still have an important role to play as nearly eighty per cent of the buildings that will be inhabited in 2050 are those already standing. Nevertheless, the ability to refurbish these buildings to current regulations and standards is a huge step towards the sustainability agenda. Thus, this clearly emphasises the significance of refurbishing and retrofitting existing buildings up to standard not only to meet carbon emission targets, but also to improve the general living conditions fit for the occupants.

However, compelling as the modern concepts of sustainable development may be, it is no doubt a huge challenge to developers and building landlords. The main concern is: with the current economic climate, how viable are the current government targets? Such questions may emerge because the UK has some of the oldest building stock. Notwithstanding the efforts of the national government to address the negative impacts of sustainable development; the technical and physical constraints of existing buildings present particular challenges for those trying to align with the sustainable criteria (Mansfield, 2009). Therefore, given the nature of refurbishment projects, where a combination of risks and unforeseen discovery may impact on the achievement of desired outcomes, developers will have to weigh the returns against the risks, hence, the assessment of risk and uncertainty is a key component of the schemes.

REFURBISHMENT: GENERAL PERSPECTIVE

Building refurbishment has become one of the most important sectors of the national construction programme in the UK. The sector is claimed to have grown rapidly, and has become an important economic driver (CIRIA, 1994) and it has been expanding in comparison to new development, hence, Kherun et al (2002), CCCIS (2005) and Gorse and Highfield (2009) claimed that almost 50% of the constructions activities undertaken in the UK were mainly maintenance and refurbishment.

A review of international literature suggests that refurbishment can avoid the wholesale waste of resources that comes about when older buildings are cleared to make way for new. Being essential from both economic and environmental perspectives, refurbishment can offer a cost-effective way to extend the economic life of a building (Mansfield, 2009). Through refurbishment, the replacement of old and outdated facilities to one that meets the current standards is optimally achieved. Refurbishment is also considered to be a quicker and lower cost means of extending the lifespan of existing buildings as well as reintroducing a building back into the market (GVAGrimley, 2010; Gorse and Highfield, 2009) as it is substantially cheaper than demolition and new-build. Nevertheless, the extent of deterioration of existing buildings should be investigated before any informed decision can be made whether they are worth refurbishing (Zavadskas *et al.*, 1998). Arguably, to achieve the desired outcome, there is need for tripartite cooperation between designers, contractors and building users.

Furthermore, there is a wide spread view among researchers that all development projects be it refurbishment or new-works have an important role to play in achieving the current government targets for sustainable development concepts; since the construction industry is better placed to implement sustainable practices than other industries (Rees, 1999). The Organisation of Economic Co-operation and Development-OECD (2004) suggests that the existing stock can be considered as an unexploited asset with great potential to improve the environment; hence, Rees (1999) opined that new construction must be limited in developed countries while concerted efforts should be directed towards refurbishing existing building stock. Indeed, Resource for Urban Design Innovation-RUDI (2009) claimed that refurbishing the existing building stock must be a priority if only the set targets for sustainable

development are to be achieved, thus building refurbishment has become an important part of the entire building and construction process.

THE NEED FOR EFFECTIVE RISK MANAGEMENT TECHNIQUE

It is often claimed that contracting in the construction industry is very competitive and highly risky. Generally, the construction industry can be viewed as a complex environment and its activities are inevitably full of risks whereas a construction project is typically organised by hierarchically linked parties who possess differentiated skills and knowledge. As a consequence, complex relationships exist within project teams that, if not managed effectively, can adversely affect a project's performance (Walker, 1995). In many instances the perception of conflicting objectives among the parties involved in a construction project leads to adversarial relationships. Indeed, it is impossible to eliminate all project risks in construction (Franks, 1998). Mansfield (2009) suggests that risk and uncertainty exist in all projects, irrespective of type, size or location thus, the management of risks must be optimised rather than ignored (Cost Engineer, 1993) because risk has become a commercial product that is identified, priced and responsibility legally attributed (Centre for Public Services, 2004).

Risk can therefore, be considered to be the possibility of a forecast variable (for example, refurbishment cost) being different from that at completion (Mansfield, 2009). Furthermore, it is often argued that the delivery process of building refurbishment projects is assumed to be full of risk. Like new construction project operation, refurbishment projects are also guided by three primary objectives. These are cost, time and quality and it is worth taking note that, each of the project objectives are usually associated with risk and uncertainty. Indeed, Reyers and Mansfield (2000), Rawlinson and Wilkes (2008) and GVAGrimley (2010) claimed that dealing with an existing building introduces many sources of risks and uncertainties which can affect the scope of work, the total cost and the time or schedules. It therefore comes as little surprise that there has been significant interest in the management of refurbishment schemes. In addition, there is a plethora of literature advancing the importance of risk management in construction projects; this has led to the development of different versions of guidance notes relating to risk management. This includes risk management guidance (DCMS, 2000) and risk management in housing (Housing Corporation, 2001).

The review of literature suggests that through risk management (RM) strategy, it is possible to minimise risks and uncertainties associated with development projects. Hillson (2003) has argued that RM is recognised as an essential tool to tackle the inevitable uncertainty and risk associated with projects, leading to an acceptable and manageable level of risk. He further suggest that projects still fail to meet their objectives and expected benefits, despite the theoretical principle that RM should contribute to project success. Nevertheless, in refurbishment, effective risk management strategy will still be required to ameliorate potential risks and uncertainties associated with refurbishment schemes.

 ISBN: 978-1-84219-840-7 .

RISK ASSESSMENT IN BUILDING REFURBISHMENT SCHEMES

Risk assessment is considered to be the overall process of risk analysis and evaluation (Abd Karim et al, 2007). Indeed, managing refurbishment projects is faced with some unique problems in dealing with people, the environment and the project itself (Lam et al., 2010). In considering how complex and uncertain refurbishment can be, quite a number of remarkable studies on refurbishment highlighted that refurbishment projects generally contains high risk than new build (CIRIA, 1994; Reyers and Mansfield, 2001; Mansfield, 2009; Lam et al, 2010; Rahmat and Ali, 2010), due in part to the extent of deterioration which is hardly obvious at the outset of the project. They are also considered to be more difficult (CIRIA, 1994; Zavadskas et al. 1998; Rahmat and Ali, 2010), requires experience and capability (CIRIA, 1994; Zavadskas et al., 1998; Corus, 2010), more technical and economic uncertainties (Ali et al., 2010; Mansfield, 2008; Reyers and Mansfield, 2001; CIRIA, 1994), requires collaboration (CIRIA, 1994), fragmented and uncoordinated (Lam et al., 2010), thus, the complications experienced on new building projects doubles in refurbishment (Marsh, 1983; Abd Karim et al, 2007).

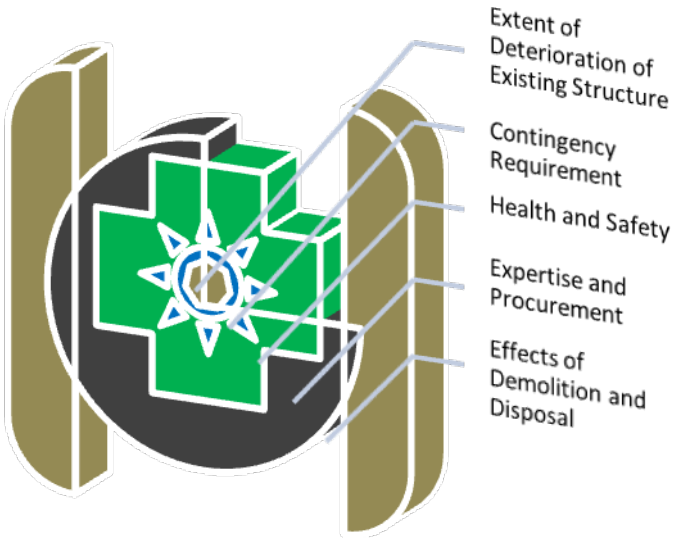

Fig. 1: Risks associated with Building Refurbishment Schemes

The aspect of risk and uncertainty associated with refurbishment may include the following:

- Lack of available information in relation to the building's original design and construction, including the existence of unrecorded alterations;
- The condition of the existing building such as the quality of original construction and the effects of wear and tear;
- The effects of demolition, alteration and temporary works on the progress of works and on the retained fabric and the removal and disposal of old materials;
- Higher level of contingency requirement for the increase risk of unforeseen costs associated with the schemes to deal with any unexpected difficulties;

- Health and Safety requirement for protection of workforce and surrounding buildings, the unexpected occurrence of hazardous materials such as asbestos and possibility of complex planning sequencing of construction programme, which may require expert risk assessment and management;
- The requirement for Expertise and Procurement to enable proper management and implementation of the schemes.

These areas of risks are summarised in figure 1 and presented as lack of information about original designs (CIRIA, 1994), issues on neighbouring buildings/party walls (Rawlinson and Wilkes, 2008; CIRIA, 1994), effects of demolition including disposal (Corus, 2010; Rawlinson and Wilkes, 2008), specialist expertise (CIRIA, 1994), the condition of existing structure (Rawlinson and Wilkes, 2008; GVAGrimley, 2010), building occupancy (CIRIA, 1994), health and safety issues (Corus, 2010; GVAGrimley, 2010; Highfield, 2000; Egbu, 1996; CIRIA, 1994), contingency requirement and procurement strategy (GVAGrimley, 2010), as well as the need to comply with statutory requirements (CIRIA, 1994; Highfield, 2000).

CONCLUSIONS

The review of international literature suggests that refurbishment projects contain more risk than new-build and indeed individual risk or a combination of the risks may jeopardise the achievement of desired outcomes. Literature also suggests that such risks in refurbishment can be managed and eliminated through the use of strategic risk management technique. The risk management technique allows the identification, assessment and proper management and implementation of the schemes successfully. However, to ameliorate such risks successfully, a tripartite cooperation is important between the designers, contractors and building users hence, risk assessment is an important part of the schemes.

Abstract:
Managing and controlling building processes to minimize waste has become a key concern for many contractors. To aid in the search for a more efficient and profitable business model, many contractors have embraced lean production philosophies. In doing so many contractors have adopted methods from the Lean Project Delivery System™ of Greg Howell and Glenn Ballard. This method has proven successful by lowering waste in construction processes, increasing profitability and improving workflow predictability. A key aspect of the Lean Project Delivery System™ is the Last Planner® System of production control – a method geared towards streamlining the workflow processes. Although the system has numerous reports of increasing project predictability and profitability, contractors are often frustrated when trying to implement the system. This study aims to identify key barriers encountered during the implementation process and evaluate common industry practices to overcome them. Although the lean transformation is becoming a mainstream goal for many organizations, a defined framework for Last Planner® implementation has not fully developed. This report will analyze a survey questionnaire sent to contractors implementing the Last Planner® System to develop an understanding of the barriers commonly faced and methods used to abate them. Conclusions and recommendations are provided in this report.

Keywords:
Barriers, Last Planner®, Lean, Production Control.

1 Introduction

Understanding the tools of lean construction, and how to evaluate a lean system is an important aspect of implementing lean in the construction process. With trying economic times across the globe, contractors have sought new ways to improve productivity and trim waste from construction processes. Seeking guidance from the manufacturing industry, principles from the Toyota Production System (TPS) have been studied extensively to understand how the system might be adopted for use in the construction industry. Lean manufacturing—the term synonymous with Toyota's manufacturing method is described as a way to design production systems to minimize waste of materials, time, and effort in order to generate the maximum possible value

(Koskela, 2002; Forbes & Ahmed, 2011). Put simply, the lean pursuit is one of maximizing value and minimizing waste for everyone involved. This report will try to evaluate these methods and the barriers that face contractors' adaption of the system.

The aim of this study is to glean an understanding of the current industry practices used to implement the Last Planner® System. To achieve this understanding this document will seek to:

- *Identify barriers commonly encountered by construction firms in their endeavour to improve workflow productivity and efficiency.*

Further, this study will critically analyze identified barriers in order to aid in the creation of an in depth implementation framework of the Last Planner® System.

1.1 Understanding Lean Construction

The pursuit of integrating Toyota's lean principles into the construction industry has proven quite difficult in an industry where variation is endless. Two men have made great strides in promoting the implementation of lean principles into construction management practices. Coining the term *"Lean Construction"*, Greg Howell and Glenn Ballard argue that implementing these policies is the next logical step in the evolution of the construction industry. Lean construction is the adoption of lean manufacturing principles and processes from the Toyota Production System (TPS) and making them applicable to the construction industry in hopes of removing waste from construction processes. Lean is a value seeking process that seeks to remove all activities that do not create value for which the customer is willing to pay (Howell & Ballard, 1998).

Understanding the key philosophy of lean construction is crucial to firms seeking to implement its principles in their organizations. The Construction Industry Institute (CII) identified five key lean construction principles in their Study PT 191 (Forbes & Ahmed, 2011):

- Customer Focus
- Culture and People
- Workplace organization and standardization
- Elimination of Waste
- Continuous improvement and built-in quality

These principles are identified as traits of a lean organization and should be the goal of firms seeking to become a lean organization.

Greg Howell and Glenn Ballard, co-founders of the Lean Construction Institute (LCI), assert that lean construction is an entirely new way to manage construction (Forbes & Ahmed, 2011). This new lean mindset led to the exploration of avenues in which to eliminate waste in the actual day-to-day management of construction.

Through the Lean Project Delivery System™ (LPDS), Howell expands the effort to eliminate waste in construction by outlining a process to conduct and manage construction projects. Treating construction as a kind of production, Howell and Ballard

seek to apply lean principles to the production processes. One key asset in this system is the Last Planner® System of Production Control in which lean principles are applied to the flow of work being put-in-place on construction projects.

The Last Planner® System (LPS) seeks to reorient the construction process from a push system, in which work is started based on the schedule—to a pull system where activities are started as prerequisite work is completed. The key aim in transforming the process is to eliminate wasteful variation and make construction a more predictable process (Elzarka, 2006). Studies show that there is less variance in cycles for a pull system than in an equivalent push system (Forbes & Ahmed, 2011). Eliminating variation allows the construction industry to move closer to the ideal manufacturing setting that companies like Toyota experience—where processes are repetitive and highly predictable.

1.2 Scope of the Study

The scope of this research is to evaluate current literature, publications and case studies in order to gain an in depth understanding of the barriers encountered by firms seeking to implement the LPS as a means for production control. Further, firms active with LCI will be surveyed, allowing for a more current understanding of what members in the industry are encountering and what methods are being used to overcome those conflicts.

1.3 Rationale for the Study

The Last Planner® System cannot be used as a stand-alone lean tool (Hamez & Bergstrom, 2010). Organizations should seek to deploy it as an extension of their lean initiative, specifically in the aim of eliminating waste and improving process efficiency. Research shows that when used in conjunction with other lean principles, the LPS can have a significant impact on operating profit (Howell & Ballard, 2003). Most of this increase is shown to come from decreased labor costs and savings on material waste. Therefore, the system is an attractive option for firms seeking new ways to increase profitability.

Even though there is a financial case for the system's implementation, many still lack the ability to utilize the system due to the unforeseen barriers and a lack of in-depth framework (Hamez, 2009). While many previous studies have focused on the positive outcomes of the LPS, an assessment of the current implementation of the LPS is needed to evaluate performance and suggest improvements.

2 Literature Review

2.1 Background

The lean principles found in the Last Planner® System can be traced back to Toyota's Engineer Taichi Ohno study of Henry Ford's business practices in the United States (Howell, 1999). Amazed by Ford's revolutionary production line, Ohno identified several ways in which the system could be improved with significant amounts of waste being eliminated. Ohno quickly returned to Japan and began the company's journey toward a movement that would revolutionize production around the world (Howell,

1999). As a result of this study, Toyota became a shining example of the benefits of lean production.

Research led by Greg Howell and Glenn Ballard pioneered new ways to apply Toyota's lean manufacturing principles to the construction industry with the goal of increasing stakeholder' value. Howell and Ballard created the Last Planner® System of Production Control as a means of controlling and planning the production processes on construction projects (Hamzeh & Bergstrom, 2010). However, despite a variety of success stories touted by the Lean Construction Institute (LCI) and the Construction Industry Institute (CII), widespread adoption of the system has still not occurred. One reason for slow adoption has been contractor's lack of awareness of the system and the overall lack of precedence within the industry. The necessary framework needed to implement such a system has yet to be fully established and tested (Hamez & Bergstrom, 2010), leaving contractors with high risk and limited historical data when facing barriers to implementation.

Therefore, as contractors strive to become lean organizations the LPS will continue to develop as a way to retool inefficient production processes. Developing a framework for successful implementation of the system will be predicated on encountering and overcoming obstacles to the system. An in-depth understanding of these potential conflicts is necessary for contractors seeking to capitalize on the benefits of the system.

2.2 Current Industry Knowledge

The Last Planner® System reinforces the controls of a project by working throughout the project to see that prerequisites to activities are met so work processes can be conducted as scheduled. Howell and Ballard (2003) state that the LPS create and improve predictability of workflow on projects. These outcomes are the result of direct communication and planning ahead to identify work needed.

Measuring the completion of tasks is crucial to productivity and is conducted through the Percent Plan Complete (PPC) method instead of 'after-the-fact' variance detection traditional to the industry (Ballard, 2000). The PPC method compares the number of activities that a subcontractor completes to the number of activities that should have been completed, giving a percentage of planned tasks that were completed. Managing workflow as problems arise is in line with a pull system instead of the push system that is inherent in 'after-the-fact' variance detection.

In the push system of production, the needs of consumers are anticipated with the hopes of users demanding the goods once they reach the market. The goal of the LPS is to restructure workflow processes to a pull system instead of the traditional push system (Figure 1) inherent in schedules created with the Critical Path Method (Howell & Ballard, 2003). The pull system (Figure 2) of manufacturing denotes a system in which the consumer of a resource sets the production into motion through demand.

The pull system outlined in the LPS reorients the traditional push system to ask the last planners what work 'will' be done (hopefully) matching closely with what the construction drawings say 'should' be done within the constraints of what 'can' be done (Ballard, 2000).

 ISBN: 978-1-84219-840-7 .

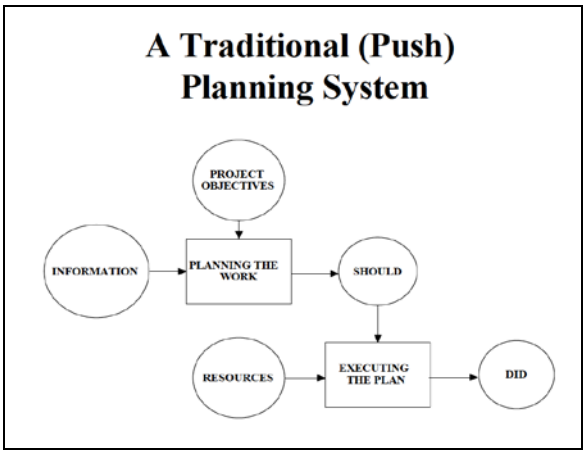

Figure 1: A traditional (Push) Planning System (Source: Ballard, 2000)

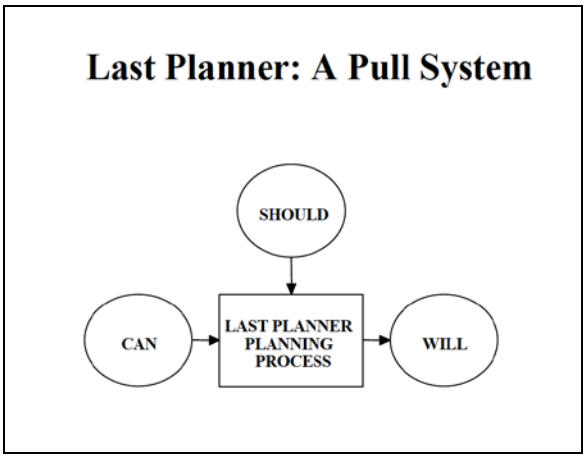

Figure 2: Last Planner®, A Pull System (Source: Ballard, 2000)

The adoption of the LPS has been slow in the last decade even though benefits of the system have been well documented. Many feel that the barriers come not from glitches in the framework but simply from failed management attempts to plan the implementation accordingly (Ballard, et. al, 2010). It is becoming more evident that successful implementation of the LPS framework comes not from the strict adherence to a practice or process, but rather from achieving buy-in from workers that understand the system.

Therefore, the current state of knowledge regarding the barriers and implementation of the Last Planner® System fall typically under the following areas:

1. Contractors seek to implement the LPS as a lean tool to increase project profitability through waste elimination and increased predictability of workflow processes.

2. Contractors commonly encounter barriers regarding the implementation and utilization of the LPS on projects, caused by a lack of understanding of the system.

3. Contractors currently lack established framework, backed by precedence, for the implementation and utilization of the LPS.

Understanding the current knowledge presented in literature allows for research to be conducted that will supplement current shortcomings. A need for understanding of the system and its drawbacks is clearly evident throughout the literature. Research that seeks to aid in the development and understanding of the system will be of great value to the construction industry moving forward.

2.3 Problems with Implementation

Based on the extensive review of literature from scholarly journals, technical articles, conference proceedings, and reports—barriers to the implementation and utilization of the Last Planner® System can be identified. The following issues are found to be prevalent throughout the literature:

Poor Planning*:* Many failures of LPS implementation can be tied directly to a failure to plan for its usage on the project. The core problem lies in the lack of implementation planning just like the poor planning on the projects that the LPS was created to help (Hamzeh & Bergstrom, 2010).

Lack of Leadership: Some failures of implementation resulted from a clear lack of leadership within the organization. In those failures there was a lack of commitment by upper management or top down mandates without active support (Ballard et. al., 2007). When no specific person is responsible for 'championing' the use of the system during implementation it is much more likely to fail.

Implementation Time Frame: Establishing usage of the LPS at phases throughout the project greatly hinders successful usage of the system. The LPS does have a learning curve that project team members must overcome. Implementing LPS at any time other than the beginning of a project greatly hinders successful utilization of the system (Hamzeh & Bergstrom, 2010).

Organizational Change: Commitment to a lean transformation is required for the successful implementation of the LPS. Fundamental change at the organizational level is very difficult to achieve in the short-term (Hamzeh & Bergstrom, 2010). Implementing the LPS is not simply applying a tool to a project—but changing the way the project team thinks, works, and executes tasks (Ballard, et. al, 2007).

Training: A lack of training and understanding of the system is seen as potentially the greatest barrier faced in LPS implementation. A lack of project team understanding is likely the root cause of other barriers such as the resistance to change that organizations face when implementing the LPS (Ballard, 2000).

These barriers are not meant to serve as an exhaustive list but instead denote barriers of failed implementations that organizations commonly encounter when utilizing the

system. Companies must make a concerted effort to be ahead of the curve on new technologies and training methods for implementing the system and make an organizational commitment to a lean transformation. When upfront planning and top-down commitment are made to the system through a lean transformation, these issues should not arise.

3 The Last Planner® System of Production Control

3.1 Overview

The Last Planner® System (LPS) is a fundamentally different method for controlling production workflow on construction projects. The system asks trade foremen, also known as "last planners", to plan work that can be made ready to perform efficiently, safely, and to a certain level of quality (Hamez, 2009). The LPS was first introduced in the United States by Greg Howell and Glenn Ballard in the early 1990s and has since been utilized on projects in the United Kingdom, Denmark, Finland, Indonesia, Australia, Venezuela, Brazil, Chile, Ecuador, and Peru (Ballard & Howell, 2003). The system is based on a new theoretical approach to scheduling that considers lean principles production flow. The system is of great benefit because of the following planning attributes: (1) planning in greater detail as work gets closer, (2) those performing the work are involved in planning, (3) identifying and removing work constraints increases reliability, (4) work is promised and execution is coordinated by trade partners and project team members, and (5) the continuous learning that results by finding root causes and taking preventative actions (Hamez, 2009). These attributes have contributed greatly to the popularity and adoption of this system around the globe.

In the LPS, production is thought of as flow, like a manufacturing assembly line, leading to an emphasis on reduction of uncertainty and on stemming the penalties of uncertainty (Koskenvesa & Koskela, 2005). Removing uncertainty means that workers will waste less time completing tasks that do not contribute value to the owner—while allowing contractors to better manage risk.

The success of the LPS has led many contractors to adopt the system in hopes of increasing profitability and decreasing waste. Proponents state the reason the system is successful is because it aims to ensure that all preconditions of a task exist when the task is scheduled to begin—allowing workers to complete assigned activities without disturbance (Koskenvesa & Koskela, 2005; Hamez, 2009) This goal is realized through the system's four major components that are aimed at better managing workflow: *Master Scheduling, Phase Scheduling, Look-ahead Planning, Weekly Work Planning, and in some instances daily plans.*

3.2 Lean Project Delivery System™

The Lean Project Delivery System™ (LPDS) is a project delivery method that incorporates lean principles into the various stages of a project. The LPS is an important subset of the LPDS and is critical to its effective deployment (Forbes & Ahmed, 2011). The LPDS is broken down into five phases that enhance the delivery of the entire project (Figure 3). Key to the phases is the concept of "built-in" efficiencies in a project (e.g. considering constructability issues during the design phase, etc.).

Undergirding these principles is the idea of work structuring and production control—culminating in continuous learning.

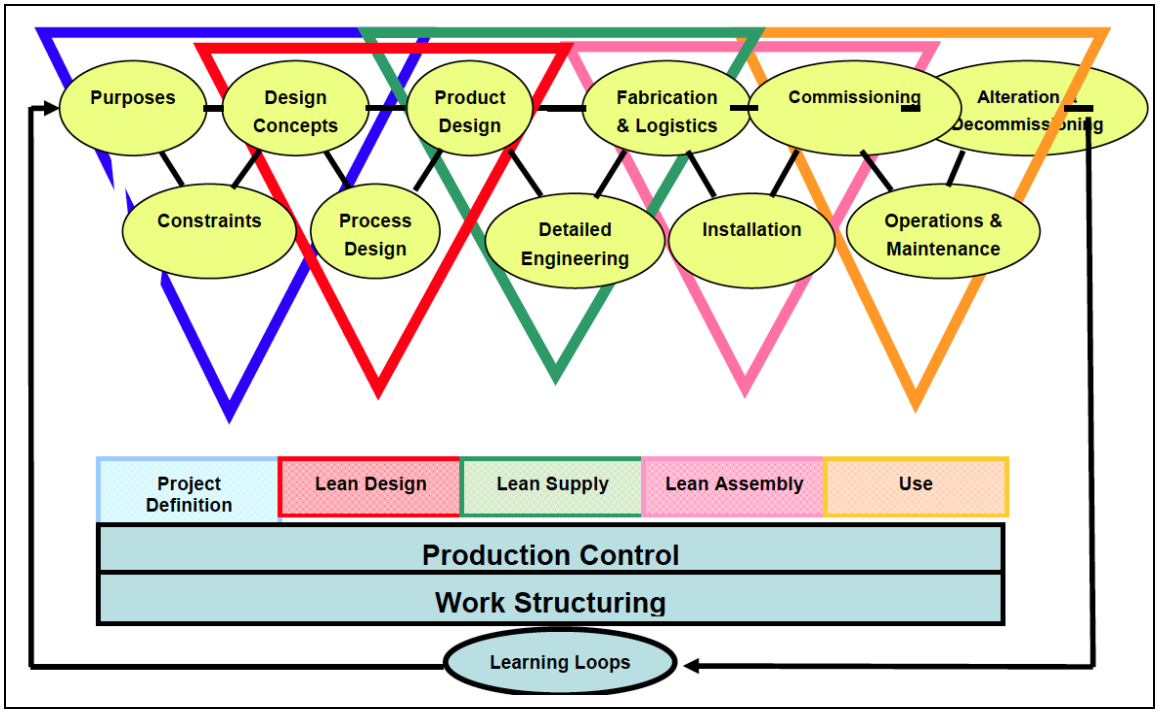

Fig. 3: Lean Project Delivery System™ (Source: Ballard, 2008)

Work structuring is a term developed by the Lean Construction Institute (LCI) to indicate process design (Ballard, 2008). The goal of structuring is to break work into defined production units that can be controlled—while simultaneously promoting flow. Dividing work into production units that can be controlled and monitored led Howell and Ballard to create the LPS.

According to Forbes and Ahmed, the LPDS improves project delivery by the following characteristics (Forbes & Ahmed, 2011):

1. Downstream stakeholders are involved in front-end planning and design through cross-functional teams.

2. Project control has the job of execution as opposed to reliance on after-the-fact variance detection.

3. Pull techniques are used to govern the flow of materials and information through networks of cooperating specialists.

4. Capacity and inventory buffers are used to absorb variability.

5. Feedback Loops are incorporated at every level, dedicated to rapid system adjustment (i.e., learning).

The LPS aides the LPDS in improving project predictability and is interwoven into the processes of the LPDS. The LPDS is Howell and Ballard's method for carrying out the ideas of lean construction; while LPS is a method for increasing predictability in the LPDS.

3.3 Components of the LPS

The LPS is comprised of four major components that address issues affecting the flow of production units throughout the duration of a construction project. The four tools, detailed below, include; *Master Scheduling, Phase Scheduling, Look-ahead Planning, and Weekly Work Planning*.

Master Schedule: The first step in front-end planning, translates owner's value proposition into a master schedule describing work to be carried out over the entire duration of the project (Hamez, 2009). It identifies major milestone dates and involves project-level activities mostly in relation to contract documents (Tommelein & Ballard, 1997).

Phase Schedule: Generates a detailed schedule covering all phases of the project and describes what tasks "Should" be done. It details a progressive detailing of the master schedule that is conducted by phase (Forbes & Ahmed, 2011).

Look-ahead Schedule: The first step in production planning uses screening and pulling to make tasks that "Should" be done into tasks that "Can" be done. Constraints are identified and responsibilities are assigned to members to remove them (Ballard & Howell, 1998).

Weekly Work Plan: Drives the production process, these could span a week but in some instances have moved to the daily operational level, called "daily huddles" (Hamez, 2009). The weekly work plan is also the level in which the percent plan complete (PPC) method is instituted—quantifying project success and profitability.

In the last planner process the master schedule is used to translate customer needs into value oriented milestones (Figure 4). *Phase scheduling* then utilizes "pull-planning" techniques to define activities and prerequisites for delivering those milestones. "Production planning starts with *look-ahead planning* which employs screening and pulling to make tasks ready for execution" (Forbes & Ahmed, 2011). These techniques ultimately culminate in producing a weekly plan to put work in place. The *Weekly Work Plan* drives the process from the backlog of "made-ready" tasks.

Finally, the LPDS system works best when all processes are developed in sync (i.e. schedules are compatible), involve project stakeholders, account for dynamic changes/updates, and utilize learning from planning failures for continuous improvement (Hamez, 2009). This understanding of a holistic delivery system—from conception through design and carrying into the construction process is what makes the LPDS a useful tool for lean construction.

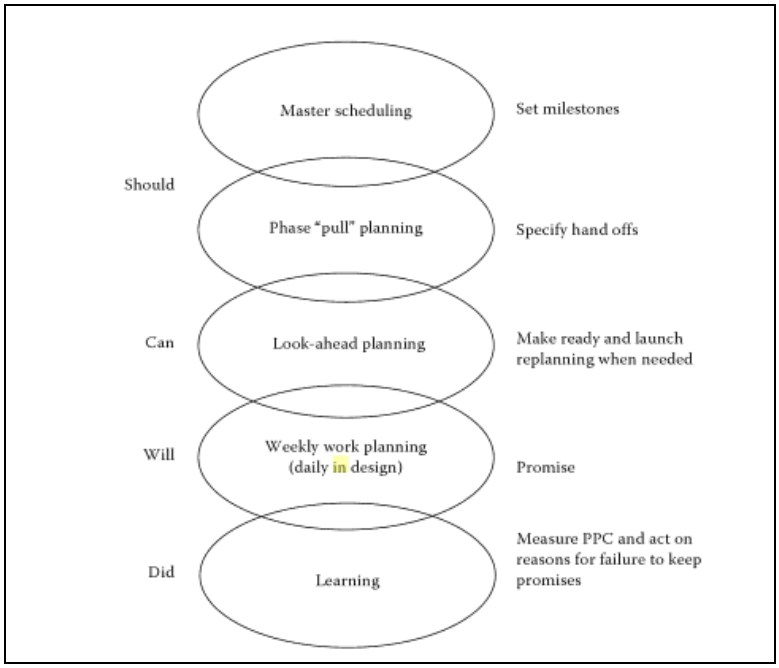

Figure 4: Interconnected Conversations (Source: Forbes & Ahmed, 2011)

4 Research Methodology

4.1 Overview

Essential to the design of the research method is the goal of obtaining data to support the aim of the research and help answer key questions raised in the initial stages of the study. In other words, the research design is an action plan for getting from 'here' to 'there', where 'here' is the initial set of questions to be answered, and 'there' is the answers to those key questions (Naoum, 2007). This action plan will culminate as a response to accomplish the goals set forth in the research objectives.

This research study is intended to provide contractors a reference for barriers that may be encountered during their attempts to implement the Last Planner® System on construction projects. The objectives of this study include:

- Providing practical solutions through applied research to the theoretical production management tools of the Last Planner® System.
- Understanding how contractor organizations implement and utilize the Last Planner® System of production control on construction projects.
- Identifying key barriers of the Last Planner® System on construction projects.
- Investigating possible solutions to barriers of implementing and utilizing the Last Planner® System of production control on construction projects.

Therefore, the research method chosen to gain those practical insights and data include the mixed methods research technique—in which both qualitative and quantitative

 ISBN: 978-1-84219-840-7 .

methods were utilized. The survey instrument will also be described in detail, as it was the method for primary data collection.

4.2 Reasoning for Methodology

In reviewing the background literature of the Last Planner® System it became obvious that both quantitative and qualitative methods would be needed to conduct a thorough investigation of the research objectives. Quantitative measurements would be useful to digest the survey responses and provide hard data to the conclusions drawn from the survey. Similarly, qualitative research would allow respondents to answer questions regarding their own experiences with the LPS and provide useful insight to the research process.

This study sought to bridge the gap between the Last Planner® System's theoretical nature with a means to allow for discovery of practical applications through an enhanced framework for barrier identification. The research methodology framework is outlined in Figure 5.

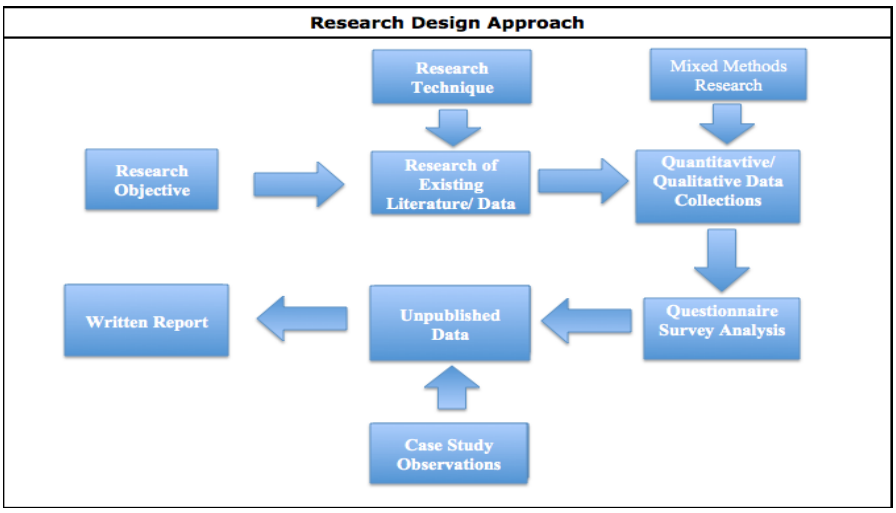

Figure 5: Research Methodology Framework

The purpose of the research methodology framework in (Figure 5) is to outline the crucial steps required in the process of this research study. Beginning with the research objective various steps are taken to formulate the written report that responds to the research objectives. Though many interpretations may be taken from the same data it is the researcher's responsibility to provide evidence for the assertions made within the report.

4.3 Primary and Secondary Data

There are two types of data used in the formulation of this report. First there is primary data described as, "data observed or collected directly from first-hand experience" (Naoum, 2007). Next there is secondary data, described as "published data and data collected in the past from other researchers" (Naoum, 2007). The secondary data in this report is the literature review that provided the existing knowledge of the subject. From this data the report gained a historical perspective on the topic of the LPS and the available knowledge of the system.

From the secondary data a survey questionnaire was formulated to gain first hand information of the LPS, which culminated in our primary data. These two data sources provide the necessary information needed to formulate responses to the research objectives.

An extensive literature search was needed in order to gain an understanding of the LPS and the existing knowledge of the system. From this research it was apparent that the system lacked a tangible framework for implementation. Many articles from the authors Glenn Ballard and Greg Howell of the *Lean Construction Institute* along with many others were consulted in the formulation of this report. Therefore, the barriers in the survey questionnaire stem from deficiencies and historical issues identified in those articles.

4.4 Survey Questionnaire

The method for collecting primary data in this research study was the survey questionnaire. This method of data collection aims to gather insight from industry participants' current in the means and methods of implementing and utilizing the LPS. From the respondents answers an analysis will be conducted to make inferences regarding the current use of the system and in what direction it may be heading.

The survey questionnaire allows for anonymous data collection of a certain population considered to be of adequate size. Questionnaires are composed of two types of questions: 'open' or restricted and 'closed' or unrestricted (Naoum, 2007). The survey used for this study consisted of both open and closed questions. The open questions allow survey respondents to input custom responses and the closed questions require respondents to select supplied answers. The closed question type allows for a better understanding of industry trends while the open questions allow for a broad understanding of a specific topic.

According to Naoum, there are three key issues imperative to the construction of the survey questionnaire: Question Design, Sampling Procedure and Data Collection (Naoum, 2007). For this survey the question design was developed from the key questions and research objectives mentioned earlier. The survey was sent to over 250 construction firms around the United States in order to gain a sufficient sample size.

5 Data Analysis and Evaluation

5.1 Overview

To analyze the results of the survey questionnaire it is important to evaluate the data as presented in order to reduce bias (Naoum, 2007). Limiting bias in results is difficult but necessary to ensure the validity of the study and potential findings. The results of the questionnaire survey used in this report are presented below with a clear description of what the data indicates. Extrapolating a more generalized significance regarding industry-wide trends should be done carefully as not to make inferences beyond the scope of realized data.

 ISBN: 978-1-84219-840-7 .

5.2 Survey Results

5.2.1 GOAL I: Population Identifiers

Before evaluating the survey it is important to understand which companies responded to the questionnaire survey. To accomplish this goal the initial questions of the survey sought to identify key characteristics of those entities.

The characteristics identified below will seek to identify typical traits among contractor organizations implementing the LPS. Many of the contractors participating in this survey operate in multiple market segments—with a majority of participants focusing on the commercial and institutional markets (Figure 6).

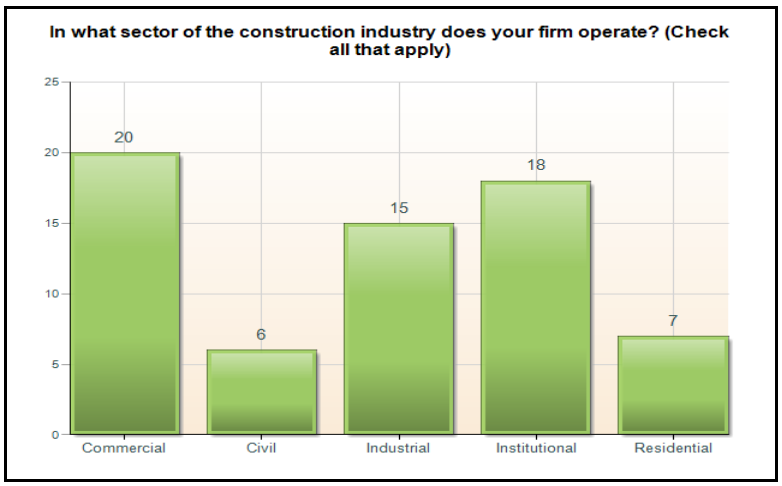

Figure 6: Contractor's Market Segments

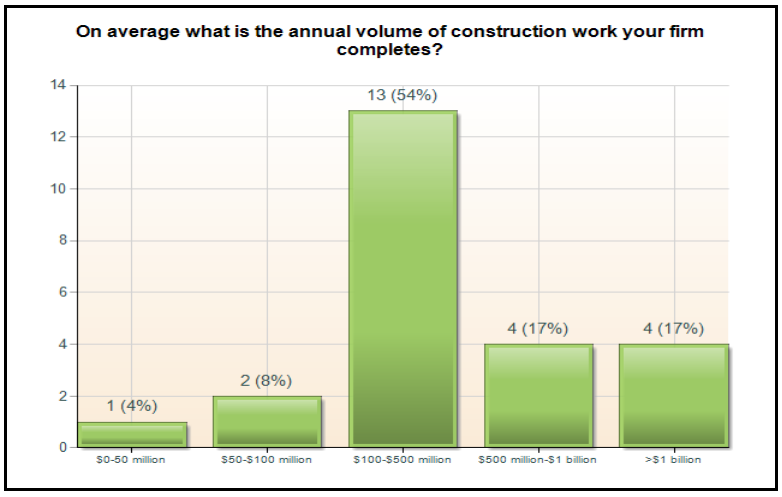

Figure 7: Contractor's Average Yearly Volume

Figure 7 depicts the contractor's typical contract volume completed within a year. The majority (54%) of respondents claim to complete on average between $100 - $500 million dollars worth of construction volume annually.

 ISBN: 978-1-84219-840-7 .

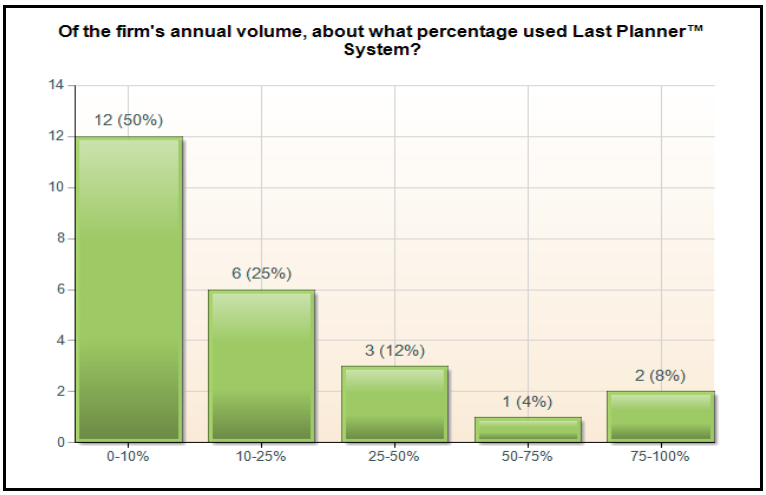

Figure 8: Yearly Volume Utilizing LPS

Figure 8 shows that most contractors surveyed only utilize the LPS for between 0 -10% of their construction volume. History shows that the construction industry is slow to adopt new practices without clear precedents for success and tangible implementation procedures (Graham & Reginato, 2011). The relatively small utilization of the LPS for projects could be linked to the learning curve associated with adopting and implementing the system.

In conclusion, industry participants utilizing the LPS seem to vary leading to the conclusion that firms across the spectrum are using the system to some extent. However, within that broad spectrum the survey data shows that firms in the commercial and institutional market segments are most heavily using the system. Further, firms with an annual volume between $100-500 million (54%) are mostly participating in LPS utilization. Those firms utilizing the LPS show reluctance for widespread adoption—with data showing that only (50%) of respondents utilizing the system on less than 10% of the firm's annual construction volume.

5.2.2 GOAL II: Projects Best-Suited for the Last Planner® System

The secondary focus of the survey was to identify a key type (if applicable) of project that is best suited for utilization of the LPS. In order to determine trends in project factors, respondents were asked to quantify variables related to project type and delivery method.

The goal for understanding what type of projects respondents typically utilize the LPS on is to gain a general understanding of the factors that influence a contractor's decision for choosing the system.

Figure 9 shows that (38%) of respondents identified *Integrated Project Delivery (IPD)* and another (38%) stating that *none are more important than the other* for the system's utilization. In IPD project teams are more reliant upon each other to successfully complete the requirements of the project, making the LPS attractive due to its collaborative workflow management. However, respondents do not identify one method over the other as superior for successful implementation.

 ISBN: 978-1-84219-840-7 .

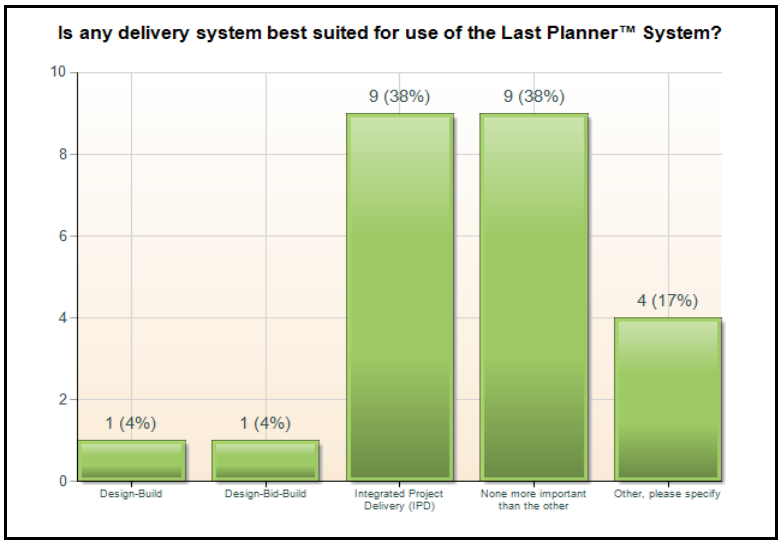

Figure 9: Key Delivery Methods for LPS

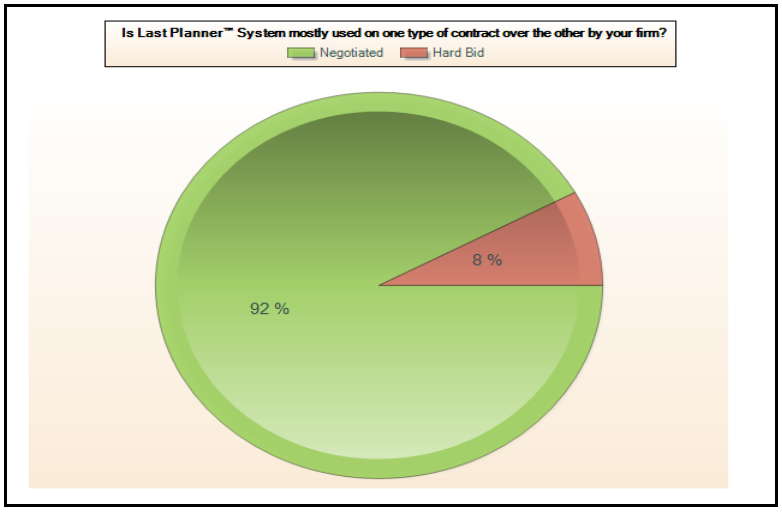

Figure 10: Negotiated v. Hard Bid

In determining an ideal contracting method for LPS utilization, Figure 10 shows that contractors, almost unanimously (92%), state that the system is most useful under situations in which the project has been negotiated. This again could be due to the learning curve associated with the system or the inherent adversarial nature of hard bid construction projects.

As demonstrated in Figure 11, contractors rank *healthcare* (42%) with *commercial* (38%) as the most susceptible project types for utilizing the LPS on projects. However, an even higher percentage of respondents rank *Other* (46%) as the best project type in which every respondent indicated that the project type was insignificant. This clearly demonstrates contractors' belief in the system as a workflow management tool—no matter the project market segment.

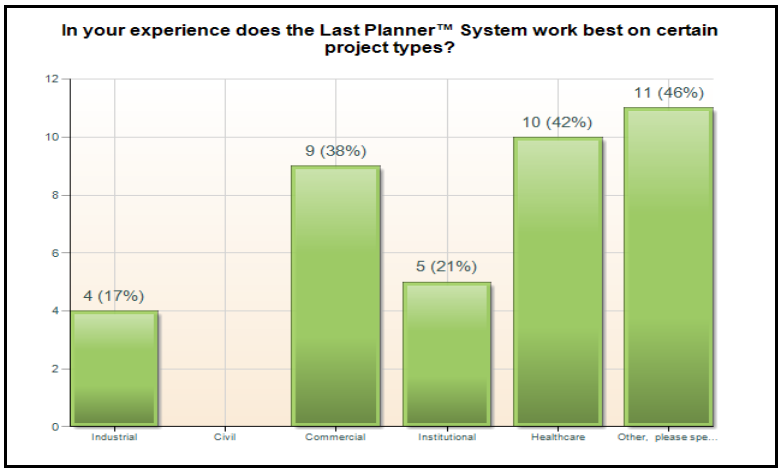

Figure 11: Business Segment of Project

Lastly, Figure 12 demonstrates the ideal contract amount that respondents believed the system was capable of successfully managing. The two main categories identified were the *$20-50 million* range (21%) and the *$50-100 million* range (17%). Both of these ranges were very low—with the major identifier (50%) being the *Other* category in which respondents again unanimously stated that the contract volume does not matter. This leads to the understanding that the system is not limited by the contract amount and can be used to successfully manage workflow of various project sizes.

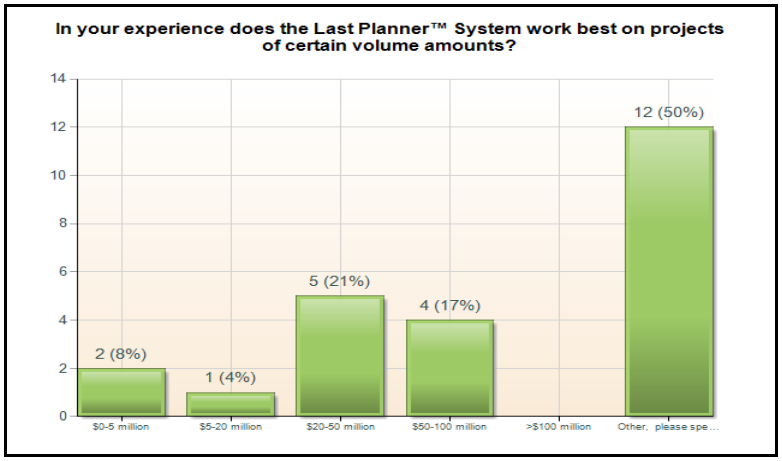

Figure 12: Contract Amount

In conclusion, survey respondents did not limit usage of the LPS to a best-suited project type. Instead a few key factors were heavily favored when implementing the system. Contractors favor the system's usage under a negotiated contract but did not limit LPS usage by market type, contract amount or delivery method leading to the conclusion that the system can be beneficial to contractors across the industry.

5.2.3 GOAL III: Key Factors Determining Utilization of the Last Planner® System

The third aim of the survey was to identify factors influencing the utilization of the Last Planner® System. In this phase of the survey respondents were asked to rank various

 ISBN: 978-1-84219-840-7 .

factors such as; barriers at the project and corporate level, motivational factors for LPS usage and procedures to overcome the obstacles encountered.

Determining the key reasons contractors implement the LPS has been evident in the development and evolution of the system since its early formation (Howell & Ballard, 2003). To aid in this discovery, respondents were asked the context in which they implemented the system in order to gain a clear understanding of the setting in which barriers were encountered.

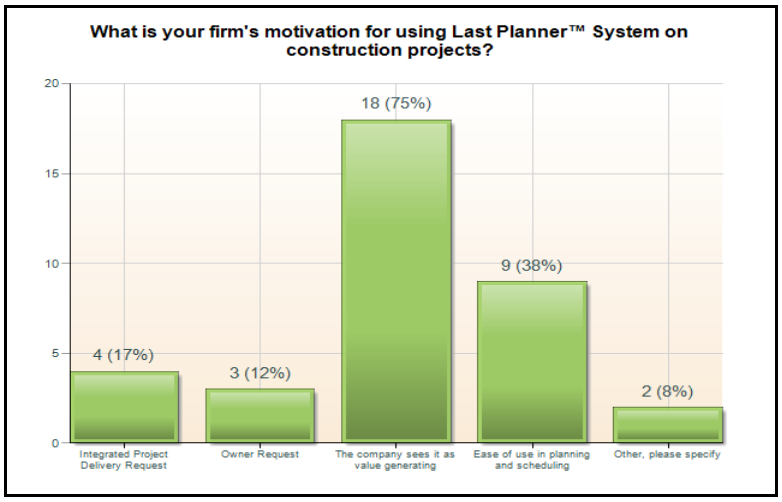

Figure 13: Motivation for Utilization

Figure 13 depicts the key factors that motivate contractors to implement the LPS. In order to gain a broad view of motivators there were five factors listed for respondent selection—with a majority (75%) of contractors identifying that the company believes the system is in line with the value-generating goal of lean construction. The next most respondents (38%) ranked *Ease of Use in Planning and Scheduling* as the reason they choose to implement the system.

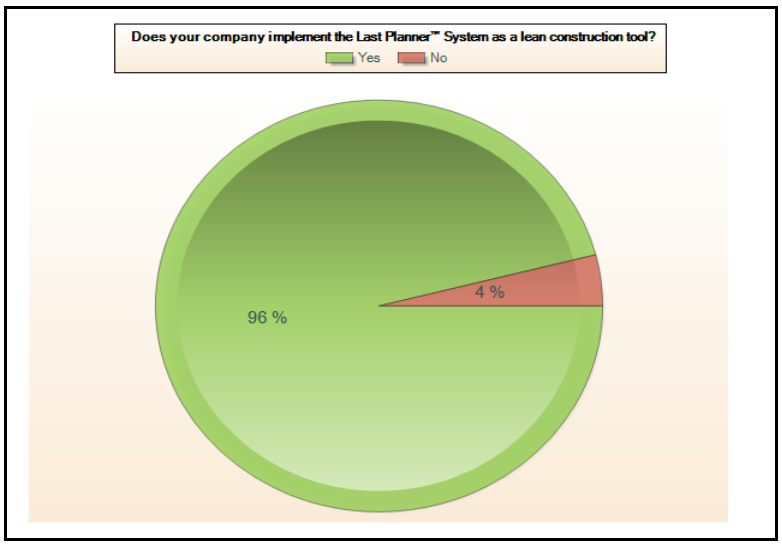

Figure 14: Lean Collaboration Tool

 ISBN: 978-1-84219-840-7 .

Respondents also stated (96%) that the system should be implemented as a tool in collaboration with the firm's lean transformation initiative (Figure 14). This view is in line with Howell and Ballard, where the authors state that the system cannot expect to be successfully utilized in a firm that has not committed to the lean framework (Howell and Ballard, 2003).

5.2.4 Characteristics of Firm Utilization

In order to understand the importance firms place on the LPS, respondents were polled about the system in comparison to other methods of scheduling and planning workflow. (Figure 15) displays that a majority of respondents believe that a *Combination of Methods* (38%) should be used when managing projects. Another (25%) of respondents identified the LPS as vital to their scheduling and management needs. Similarly another (25%) said that they were unsure of the importance of different systems demonstrating a slow growing reliance on the system as a vital tool to manage workflow.

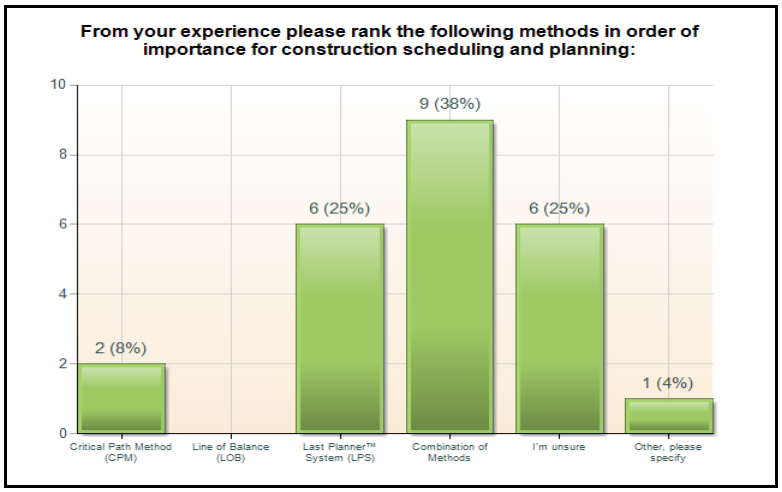

Figure 15: Importance of Systems

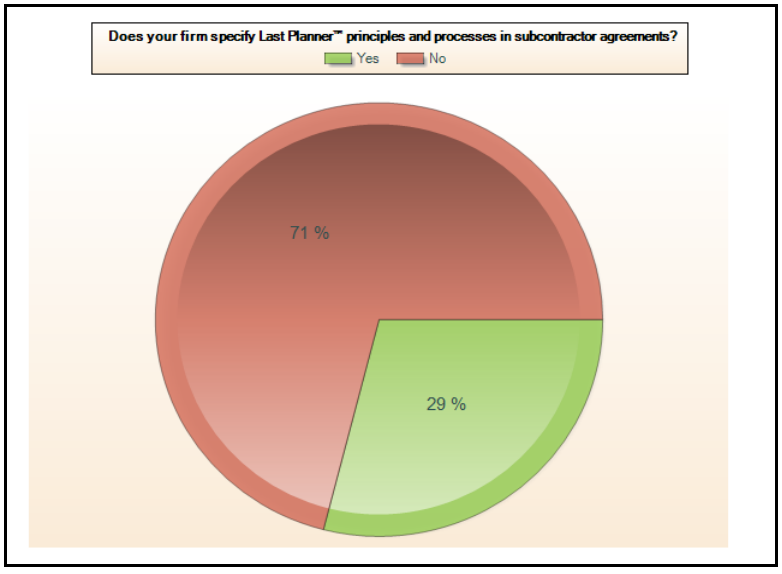

Figure 16: Subcontractor Agreements

When asked if respondents added contractual terms to subcontractor agreements requiring certain LPS principles to be observed, contractor's responded no (71%) of the time. However, (29%) of respondents did indicate that it was required demonstrating a possible growing trend of contractual integration of LPS principles in subcontractor agreements (Figure 16).

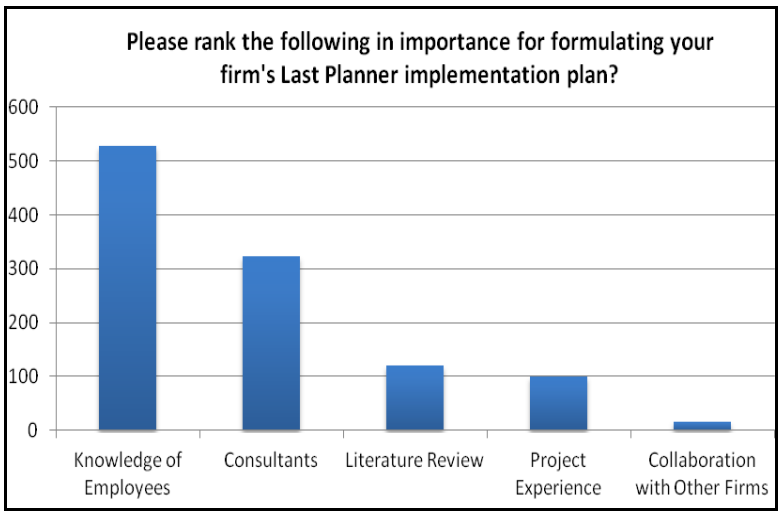

Figure 17: Implementation Plan Formulation

Lastly, respondents were asked about how they specifically implemented the LPS on a corporate basis for individual projects. To gain an understanding of how firms are preparing employees to utilize the system respondents were asked in Figure 5.12 to rank the methods they used to formulate implementation protocols. Data shows that respondents ranked the choices in order of importance as: *Knowledge of Employees, Project Experience, Collaboration with Other Firms, Literature Review and Consultants* (Figure 17). Surprisingly, contractors responded that only (50%) required project teams to attend training related to implementation.

5.2.5 Barriers to the System

In order to gain an understanding of the research aim of this study, respondents' were questioned about barriers they encountered when seeking to implement and utilize the LPS on construction projects. Barriers to be identified are located at the corporate level as well as the project level in which the system is actually utilized. The corporate level question seeks to display what barriers contractors believe to be a problematic when trying to achieve widespread usage.

In contrast, project level barriers seek to identify key issues faced when contractors implement the LPS on construction projects. Figure 18 shows that respondents ranked the corporate level barriers in order of importance as: *Resistance to Change, Lack of Buy-in From Top Management, Corporate Fragmentation, Technological Barriers, and Industry Climate.*

Ballard observed the implementation of LPS on various construction projects and documented similar barriers to implementation. Projects in the study experienced strong resistance to change on the part of project team members within the organization (Hamez & Bergstrom, 2010). In some cases, implementation challenges were the result

 ISBN: 978-1-84219-840-7 .

of a lack of leadership during the process. In other cases, there was a lack of commitment by upper management or top down mandates (Hamez & Bergstrom, 2010). Contractors still struggle with the same issues observed by Ballard while studying the actual implementation of LPS on projects—further displaying a lack of advancement in implementation framework throughout the years.

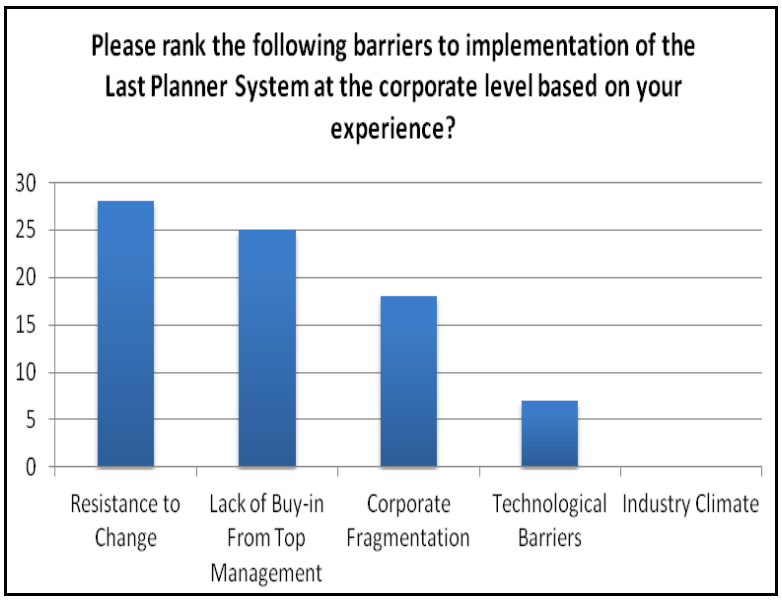

Figure 18: Corporate Level Barriers

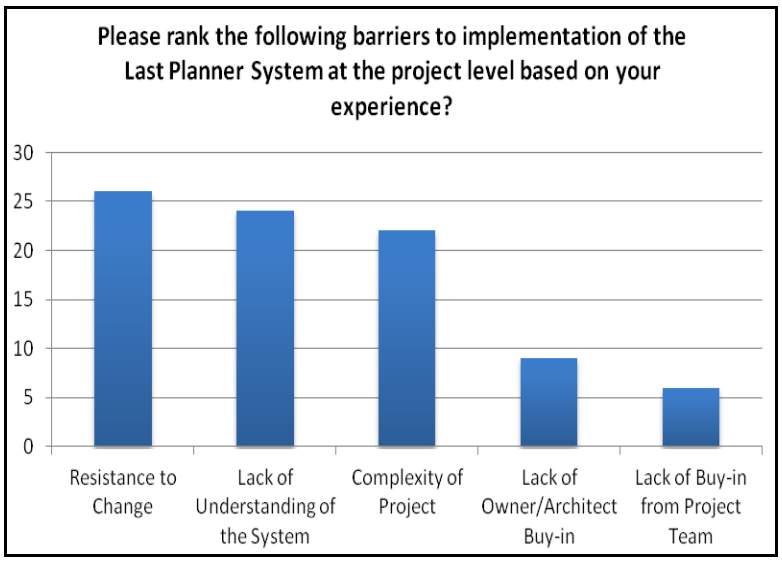

Figure 19: Project Level Barriers

Figure 19 ranks project level barriers in the following order of significance: Resistance to Change, Lack of Understanding of the LPS, Complexity of Project, Lack of Owner/Architect Buy-in and Lack of Buy-in From Project Team. This clearly relates to the corporate level barriers in that they are more tangible concerns that affect a working understanding of the system. If project team members do not understand the system or simply refuse to use it then the LPS is clearly unable to be of benefit to a project.

 ISBN: 978-1-84219-840-7 .

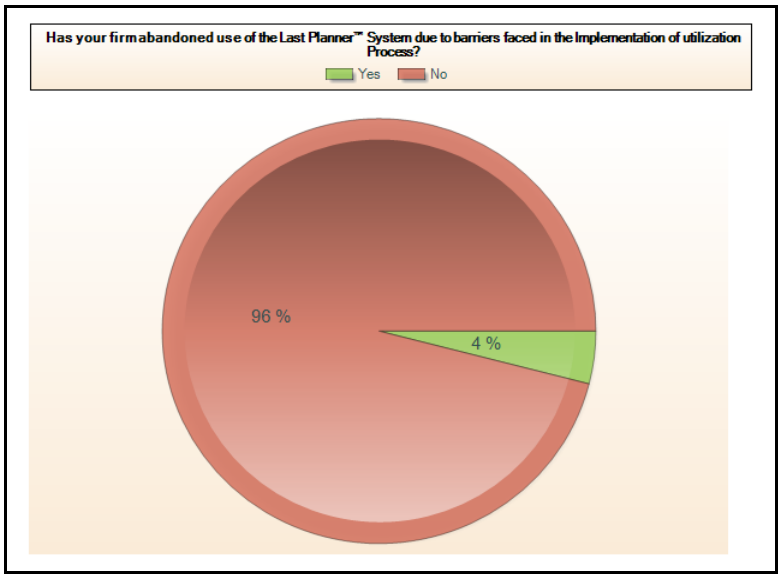

Figure 20: Abandonment of LPS

Finally, when contractors were questioned whether barriers resulted in the complete abandonment of the system only (4%) responded that they had indeed abandoned the system due to complications in the implementation process (Figure 20). This leads to the conclusion that the most significant barriers encountered in the implementation process are: *Resistance to Change, Lack of Buy-in From Top Management and Lack of Understanding.*

5.2.6 Overcoming Barriers to the Last Planner® System:

After obtaining a clear understanding of the obstacles faced by contractors it is important to understand the necessary steps contractors made to overcome those obstacles. Respondents listed LPS *Training* (*non-implementation based*) as the most important factor in overcoming barriers, followed by *Integrated Delivery with Knowledgeable Partners* as also being important (Figure 21).

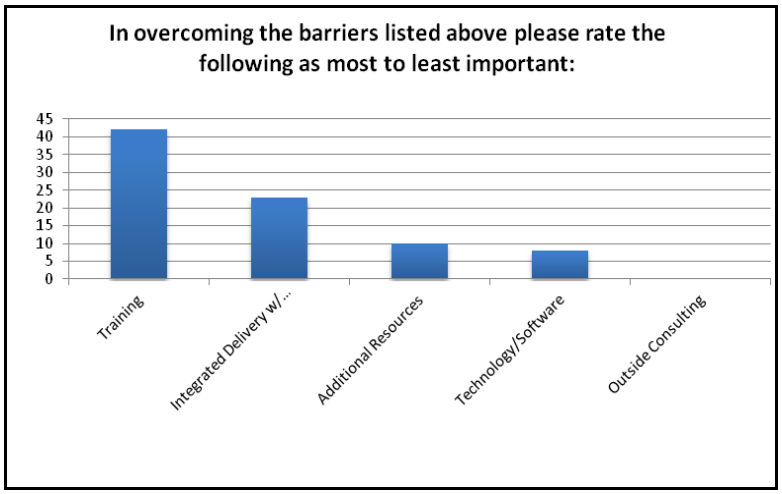

Figure 21: Mitigating Factors to Barriers

6 Conclusion and Recommendations

6.1 Conclusion of Results

This research study has observed barriers faced in the utilization and implementation of the Last Planner® System of the Lean Project Delivery System™. Respondents of the survey provided valuable insight to the issues contractors face when utilizing the LPS along with the methods used to overcome those barriers. With declining profitability and increasing competition the move towards lean construction practices will ultimately increase. Therefore, this research provides data to aid in the formulation of a necessary framework of the system.

The following factors were identified as key to the successful implementation of the system:

- Key Characteristics of Contractors Implementing the System
- Ideal Project Types for System Utilization
- Best Practices for Formulation of Implementation Plan for LPS
- Identified Corporate Level Barriers
- Identified Project Level Barriers
- Practices to Overcome Barriers

6.1.1 Scoring of Responses

Survey respondents were asked to rank factors pertaining to the LPS. The Likert Scale used was as follows and also had assigned intensity factors:

- Very Important (+2)
- Important (+1)
- Slightly Important/Neutral (0)
- No Effect (-1)
- Unimportant (-2)

To calculate the intensity of responses for each factor, the number of survey responses was multiplied by the assigned weight (e.g. 2, 1, 0, -1, -2) for that category.

Characteristics of those responding to this survey indicate that slightly over one-half of the respondents are contractors with an annual volume of $100 million to $500 million and are engaged in commercial, institutional and industrial construction. In addition half the respondents indicate that the LPS is used only rarely on their projects.

Also, about one-half of the respondents indicate that they are proponents of the LPS regardless of the type project or project size. However, the vast majority (92%) indicate that LPS utilization is best suited for negotiated contracts.

Tables 1, 2, 3 and 4 show the relative rankings that were observed through the course of this study.

6.2 Recommendations

The data shows that widespread usage of this system is capable of producing favorable results. The LPS is a valuable tool to firms committed to lean principles. This system should not be used independently of a committed lean approach. Survey data shows that contractors implementing lean principles and the LPS commonly encounter resistance to change by firm's employees—greatly limiting the success of the system.

Respondents identified training as a very important aspect of the successful use of LPS. Removing the project team's fear of the risks associated with implementing a new system will come through educating the team of the potential barriers and benefits of the system. Respondents identified that an integrated form of delivery with knowledgeable partners is a very important part of overcoming the project team's resistance to change.

Therefore, in order to successfully implement the system: the human capital on construction projects must be incentivized to utilize the system, and be given proper resources and autonomy to successfully implement the system.

Abstract:
The energy saving potential of the housing stock is considered to be large. Also this is considered to be the sector where energy efficiency measures can be pursued in the most cost effective way. In Europe the Energy Performance of Buildings Directive is a driving force for member states to develop and strengthen energy performance regulations for new buildings and set up a system of energy certificates for the existing stock and develop improvement policies based on these regulation tools. The goals are to build net zero energy buildings in 2020 and to reach a neutral energy situation in the whole stock by 2050. By now in the Netherlands a large share of the housing stock is labelled (Energy Performance Certificate). This paper is based on a research in which the indicated energy use according to the issued labels are compared to the actual energy use in the dwellings. The results point out that the influence of occupants on the actual energy use are large and potential savings might be (far) less in practice: in low labeled dwellings the energy use is less than expected, in the high labeled dwellings the energy use is somewhat higher than expected. What is the impact of these findings for the improvement policies of governments and housing associations?

Keywords:
Energy performance certification, energy use, housing, policy, building control

1 Introduction

Buildings are responsible for approximately 40% of EU's energy consumption. In order to achieve a significant reduction in energy consumption of the residential and utility sector through informing renters and buyers of the energy consumption of their dwelling, the European Performance of Buildings Directive was issued in 2002, setting an EU framework for energy performance certification (EPBD 2002/91/EC). The general requirements of the 2002 EPBD regarding residential buildings were to develop a system of energy certification for new and existing buildings, regular inspections of heating and air-conditioning systems and setting of minimum energy performance standards for new buildings and extensively renovated existing buildings with a useful floor area over 1000m2. Mandatory energy certification , which is the focus of this paper, is set for all properties constructed, sold or rented out.

All member states have implemented the directive by the end of 2009, some more efficiently than others (Andaloro, 2010). The two major deficiencies of the directive as was concluded in the EU project IMPLEMENT, are the looseness of the regulations in the directive, which leave extensive room for interpretation and the fact that no sanctions are given in the cases where the rules of the EPDB are ignored (for example no energy certificate when selling a house). Furthermore, the European Project IDEAL-EPBD was specifically aimed at investigating why energy performance certificates seem hardly to motivate dwelling owners to take measures to improve the energy performance of their dwelling, proposing several policy improvements to improve the impact. However, all these projects are dealing with EPBD implementation strategically, overlooking the accuracy and outcomes of the calculation methods implemented. This undoubtedly varies throughout the EU, since the methodology of the energy performance certificates (EPC) has not been defined by the directive and is in hands of individual member states. They have developed very different approaches and methodologies. However, in 2004 the EC appointed the CEN (mandate M/343) to develop a series of standards. These include the following: EN 15217 (energy performance of buildings—ways of expressing energy performance of buildings and for energy certification); EN15603 (energy efficiency of buildings—overall energy use and definition of energy rating); EN ISO 13790 (energy performance of buildings - calculating energy used for heating and cooling). Still, the methodologies are not fully following the standards in all member states (Andaloro, 2010), including the Netherlands.

Despite having developed all the standards and despite the flood of information regarding the implementation of the directive itself, there are only a few studies examining the calculation method, and comparing the calculated energy consumption, which represents the basis for the label, with what the dwellings actually consume. It is clear that the theoretical values are merely an estimation of the actual consumption, since they are based on standard values and do not take occupant behaviour into account. However, the labels also provide homeowners/tenants with information on possible energy saving measures, and the pay back times of the measures are directly related to the theoretical consumption. Most energy reduction policies are based on the theoretical energy reduction potential. Consequently, future energy reduction targets are formulated. If the label is to become an efficient advocate for reducing household energy consumption in line with the set targets, the theoretical decrease in energy consumption when improving a dwelling's energy label should be close to the actual decrease of energy consumption. This paper aims to quantify, how the certification of buildings relates to actual energy consumption and how this fits the imposed targets for household energy consumption reduction, on the example of the Netherlands.

2 Existing studies on actual energy consumption

According to Perez (2008), the lack of a complete database of energy performance certificates on a national and EU level, hinders the evaluation of the energy saving policies. Poor availability and accessibility of energy label databases for researchers is probably the main reason for this topic to remain largely under researched. The limited available literature that relates the label of the dwellings to their actual performance are mostly based on small samples, with the intention of quantifying the impact of

occupancy as an explanation for differences. The following studies have been identified: Guerra Santin (2012) compared the actual and expected energy consumptions for 313 Dutch dwellings, built after 1996. The dwellings were categorised according to their EPC value (the Dutch energy performance coefficient for new buildings existed already prior to implementation of EPBD directive and has been periodically strengthened from 1996 on). The EPC (NEN 5128) calculation method is roughly similar to the energy index calculation method, which is nowadays used as the basis for the energy label. In energy inefficient buildings with a high EPC, actual heating energy consumption was almost twice lower than expected, whereas in buildings with a low EPC (energy efficient) both heating energy consumptions coincided much better. Due to the relatively small sample size the differences between the actual heating energy of buildings with different EPC values were insignificant, although the average consumption was consistently lower in buildings with lower EPC.

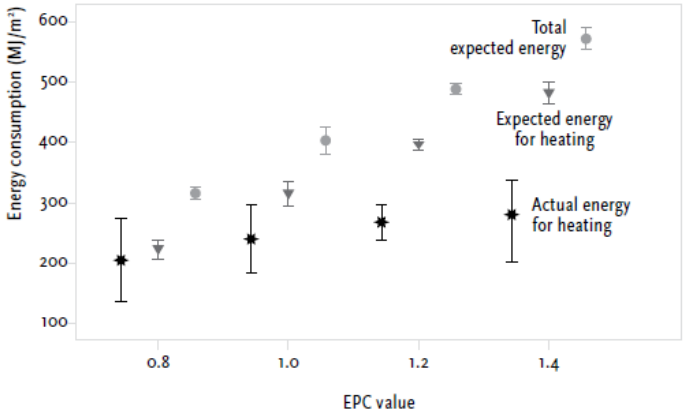

Figure 1: Mean and 95% confidence interval for the actual energy consumption (MJ/m2), total expected energy (MJ/m2) and expected energy for heating (MJ/m2) per EPC value (Source: Guerra Santin, 2012)

In another research conducted in The Netherlands by Tigchelaar (2011), a so-called heating factor was calculated (actual heat demand is divided by theoretical). The average heat factor in a sample of 4700 representative dwellings was found to be below one, meaning that the theoretical consumption is overestimated. Cayre et al. (2011) studied actual and theoretical energy consumption in 923 French dwellings and reached similar conclusions – the French EPC model overestimates the theoretical energy consumption in the sample, representative for the French dwelling stock. Similar was discovered by Hens (2010), observing actual consumption of two types of dwellings in Belgium (from 80s and 90s) – the consumption on average was only half of the calculated energy use. On the other hand, in 12 multi-family thermally retrofitted buildings in Austria, Haas (2000) has found evidence of actual energy consumption significantly exceeding the expected. Similar results were obtained by Branco (2004) in a multi-family complex in Switzerland and in a similar sample in France (Marchio, 1989). Based on these results, it seems that the theoretical energy consumption tends to be overestimated when looking at the average dwellings and less energy efficient dwellings and underestimated when observing new or retrofitted buildings. Usually this phenomenon can be partly explained by the so-called rebound effect (Berkhout, 2000). The idea is that more efficient technologies (such as a low energy dwelling) make

 ISBN: 978-1-84219-840-7 .

energy services cheaper and thereby encourage to an increased consumption within the same service. A typical example of rebound effect was found to be the type of temperature control (Guerra Santin, 2010) - dwellings with thermostats actually turned out to consume more energy than dwellings without thermostat.

Sorrell (2009), provides an overview of methods for calculating rebound effect and a summary of available studies. He concludes accordingly, in OECD countries, that the mean value of the long-run direct rebound effect is likely to be less than 30%. This means that up to 30% of the efficiency gained through technical improvements of building and appliances are turned into increased consumption (higher comfort) following from direct change in user behaviour.

However, the size of the samples in these studies is relatively small, which sometimes leads to problems when assessing statistical significance of the results. Moreover, the representativeness of the sample is not addressed in the studies where the main goal is to investigate the sample and not the national dwelling stock. Therefore, even though there are some studies comparing the national theoretical energy consumption, which is the basis for energy label, it is very hard to predict what the energy label means globally within a member state. Even in countries where energy label databases do exist, there are only a few analyses of energy performance certificates available. The EPC in The Netherlands is based on the 'Decree on Energy Performance of Buildings' (BEG) and the 'Regulation on Energy Performance of Buildings' (REG) from December 2006. Despite the fact that the EPC fully came into force in 2008, however, the household energy data in The Netherlands does not show any relevant decrease in gas or consumption over the past 3 years (De Nederlandse Energiebranche, year) on a household level (taking temperature correction into account). The electricity and gas consumptions for the whole Dutch dwelling stock have also not decreased in the mentioned period (De Nederlandse Energiebranche, year).

3 Household energy efficiency and energy label in The Netherlands

3.1 The state of household energy efficiency in The Netherlands

The energy efficiency of the Dutch housing stock has improved by 28% (Odyssee ECN, 2009) in the period 1990 – 2008. The main reason for this significant improvement is believed to be the introduction of high efficiency condensing boilers. Moreover, the energy performance regulations for new dwellings have been strengthened, which has significantly increased the efficiency of newly constructed dwellings, resulting in halving their energy consumption in 2008 with respect to 1990. However, Guerra Santin (2010) argues that the trend of decreasing energy consumption in new dwellings has failed to continue after the year 1998, despite strengthening the EPC. Nevertheless, the improvements in energy efficiency can be noticed through the average household gas consumption in the same period (Odyssee ECN, 2009). Despite these promising achievement, the Dutch dwelling stock has grown steadily in the same period, approximately 1% each year. This two phenomena's together cause the total household gas consumption to stagnate rather than to decrease, despite the improved efficiency (Error! Reference source not found.). Even though the measures implemented in that period in the Netherlands place it in the lead of the European residential sectors (Odyssee ECN, 2009), there is no consistent evidence for reduction in gas consumption

(the consumption in 2008 was only 5% lower than in 1990) and moreover electricity and oil consumption have in the same period grown for 32 and 39% respectively, which means that the total energy consumed by household has also grown for 5%.

Yucel (2011) claims that new construction can only achieve a limited reduction of energy consumption within the sector, since it contributes about 1% annually with a small fraction of demolishment of about 0,2%. According to Yucel, the new construction causes a very marginal energy consumption reduction by 2020, assuming the expected periodic strengthening and demolition and new construction rates. Renovation of the existing stock together with increased turnover is seen as the solution in for significant reduction of energy consumption. The Energy label strives to promote renovation and the turnover of more efficient buildings. Regarding renovation of labelled dwellings, a research conducted in Denmark (Kjærbye, 2008) showed that there was no significant energy reduction within 4 years after owners purchased the house (and received the label), with the exception of label A in first two years after purchase. Unfortunately, no similar study was found for the Dutch case at the time of writing this paper. On the other hand, the increased turnover of more energy efficient buildings has been observed in the Netherlands by Kok and Brounen (2010). The data acquired in this study enables an insight into real potentials for future energy savings, which the energy label scheme can lead to and thereby assess whether it will help in achieving the set objectives or energy and CO2 reductions.

3.2 Method of calculating the Dutch energy label for dwellings

The first goal of labels is to provide occupants and home owners with information on the thermal quality of their dwellings. The Dutch energy label calculation is described in ISSO 82.3. To increase to practical significance of the label, the expected (theoretical) energy usage of the dwelling is also mentioned on the Dutch labels issued from January 2010, expressed in kWh electricity, m3 gas and/or GJ heat.

An energy label ranges from A++ to G (Table 1). The categories are determined based on the Energy Index, which is calculated on basis of total primary energy consumption demand (Q_{total}). Q_{total} sums up the primary energy consumed for heating, hot water, pumps/ventilators and lighting, subtracting for the energy gains from PV cells and/or cogeneration (Equation 1).

$$Q_{total} = Q_{space\,heating} + Q_{water\,heating} + Q_{aux.energy} + Q_{lighting} - Q_{pv} - Q_{cogeneration}$$

Equation 1: Calculation of total energy consumption (Q_{total})

The energy index directly correlates with total energy consumption, but is corrected for the floor area of the dwelling and the corresponding heat transmission areas (Equation 2) in order to not disadvantage larger dwellings and dwellings with a greater proportions of envelope adjoining the unheated spaces (different dwelling types) at constant insulation properties and efficiencies of the heating/ventilation/lighting system. A shape correction is applied also when considering infiltration losses within space heating demand – the air permeability coefficient depends on building shape factor. Such correction for compactness is common also in other European countries, although it has

 ISBN: 978-1-84219-840-7 .

been previously argued that not correcting would better promote energy efficient architectural design (PREDAC WP4 report, 2003).

$$EI = \frac{Q_{total}}{155 \cdot A_{floor} + 106 \cdot A_{loss} + 9560}$$

Equation 2: Calculation of energy index (EI)

The total primary energy demand can also be expressed as described in equation 3. Since primary energy is an energy form found in nature, that has not been subjected to any conversion or transformation process, appropriate heating values need to be taken into account when calculating it. The assumed heating value for gas is 35,17MJ/m^3 and the energy content of 1kWh electricity is 3,6 MJ. The efficiency of the electricity network is considered to be 0,39.

$$Q_{total}[MJ] = Q_{gas}[m^3] \cdot 35,17 \left[\frac{MJ}{m^3}\right] + Q_{electricity}[kWh] \cdot 3,6 \left[\frac{MJ}{kWh}\right] : 0,39$$

Equation 3: Calculation of total primary energy

Carbon dioxide emissions depend on the fuel used. For 1MJ of energy coming from gas, 0,0506kg CO_2 is emitted into environment and for 1MJ of electricity, 0,0613kg CO_2 (this is taking into account the network efficiency).

ENERGY INDEX								
A++	**A+**	**A**	**B**	**C**	**D**	**E**	**F**	**G**
< 0,50	0,51- 0,70	0,71-1,05	1,06-1,30	1,31-1,60	1,61-2,00	2,01-2,40	2,41-2,90	> 2,9

Table 1: Dutch Energy labels and the corresponding energy index values

The Energy Index and consequently the energy label are based on average occupancy, average outdoor climate and does not depend on the variation in behaviour of the occupants. The energy index reflects the thermal quality of the building. The ventilation, internal heat production, energy use for lighting and heat losses during water circulation all depend directly on useful floor area, which are defined as areas that are a part of the heated zone, including the rarely heated areas such as halls, toilets, washing rooms and storages. The attic is also included if it is heated and the roof insulated. The cellar and garage or other big storage areas are not included, since they are normally outside of the thermal envelope. The ventilation is calculated using a ventilation coefficient, which depends on the ventilation type. The infiltration losses are relative to the type of dwelling, since for each type of dwelling, characteristic lengths of frames, joints etc. are assumed (ISSO 82.3). The efficiencies are set also for all kinds of heating and hot water installation systems. Heat gains from the sun are taken into account during the heating season at rate of 855MJ/m^2 on a south vertical surface, accounting for frames and dirt on the glass. Possible gains if energy through PV cells or micro co-generation plants are accounted for.

 ISBN: 978-1-84219-840-7 .

4 Research methods and data

4.1 Energy label database

This research used all Dutch energy labels issued from beginning of January until December of 2010, counting over 340.000 cases with 43 variables (regarding building location and technical characteristics, properties of label itself etc.). This data set was provided by AgentschapNL – a public organisation appointed by the Dutch Ministry of the Interior and Kingdom Relations.

This data file was, on the basis of the address of the households, coupled to actual energy use data, which was provided by the CBS (Statistics Netherlands). CBS collets this data form the energy companies. The files of the two data sets were linked by the CBS to ensure anonymity. A clean-up of the combined data file (deletion of doubled addresses based on the label registration date, deletion of missing addresses based on missing value) was executed, leaving 247.174 cases. Because the CBS reported doubts about the quality of the data obtained for the actual energy of collective installations, it was decided to leave households with collective installation systems out of the analysis. Dwellings which have multiple installation systems were eliminated as well, since these are very specific cases. Cases where electricity consumption was 0 were removed as well, and missing values for gas consumption were defined. At this point, the gas values which were defined as missing were investigated. It turned out that most of them belong to dwellings with installations systems, which in fact do use gas. Such cases were deleted, and only the ones which use electricity as power source were kept in the database. The gas use was then redefined to 0 for these cases. Upon checking the theoretical energy use and areas of the house, outliers have been detected. The cases with the floor area of more than 1000m^2 and primary energy use of more than 500.000 MJ were discarded. Finally, the actual gas consumption values for 2009 were corrected towards the number of degree days used in the theoretical calculation. Ultimately, the sample contained 198.228 cases.

In this study, the variables energy index transformed into energy label, theoretical electricity consumption, theoretical gas consumption and actual electricity and gas consumption were used. Other variables, such as household floor area, dwelling type, construction and renovation year were examined to get an impression of the representativeness of the sample, but were not used in analysis.

4.2 Theoretical vs. actual energy consumption

The theoretical calculation method takes into account only energy for certain end uses and attempts not to take into account the end uses which are depend largely on occupant behaviour. On the other hand, as the name indicates, the actual gas and electricity consumption are derived from the dwellings energy bill and reflect the consumption for all possible purposes. An overview of differences can be seen in table 2. An important difference in electricity consumption are the household appliances which are not taken into account in theoretical calculation, but do appear on the electricity bill (and therefore in the database used). Appliances do constitute for 32,4% of household electricity consumption. The difference in gas consumption in gas used for cooking, which is only reflected in the actual value.

 ISBN: 978-1-84219-840-7 .

	Theoretical	**Actual**	**% consumption of electricity/gas respectivelly**
Electricity	· Hot tap water	· Hot tap water&heating	14,7%
	· Heating/Cooling	· Heating/Cooling	17,6%
	· Auxiliary energy (pump/ electronics/ventilation in heating installation, ventilation system)	· Auxiliary energy (pump/ electronics/ventilation in heating installation, ventilation system)	unknown, very small
	· (Negative) PV/WKK production	· (Negative) PV/WKK production	unknown, very small
	· Lighting	· Lighting	14,7%
		· Household appliances	32,4%
Gas	· Heating	· Heating	72,7%
	· Hot tap water	· Hot tap water	23,3%
		· Cooking	3,9%

Table 2: Comparison of end uses of gas and electricity in actual and theoretical consumption together with their contribution within the Dutch dwelling stock (source milieucentraal.nl)

4.3 Representativeness of the sample

The total Dutch dwelling stock accounted for 7,104 million dwellings in 2009 (CBS Statline). The researched sample therefore represents slightly less than 0,3% of the total dwelling stock. Since there were only a few cases in categories A++ and A+ the A labels were all aggregated into one category. The distribution of labels was then more normal and the results statistically more significant. As one can observe from Figure 3, more than half of the dwellings in the energy label database belong to the categories C and D. As for the rest of the dwellings are concerned, only 1% belongs to either one of the three most efficient categories (A, A+ or A++) and around 4% to G, which is the label of the most energy intensive dwellings. In the total Dutch dwelling stock, there is a slightly lower percentage of dwellings labelled with B and C (Figure 3).

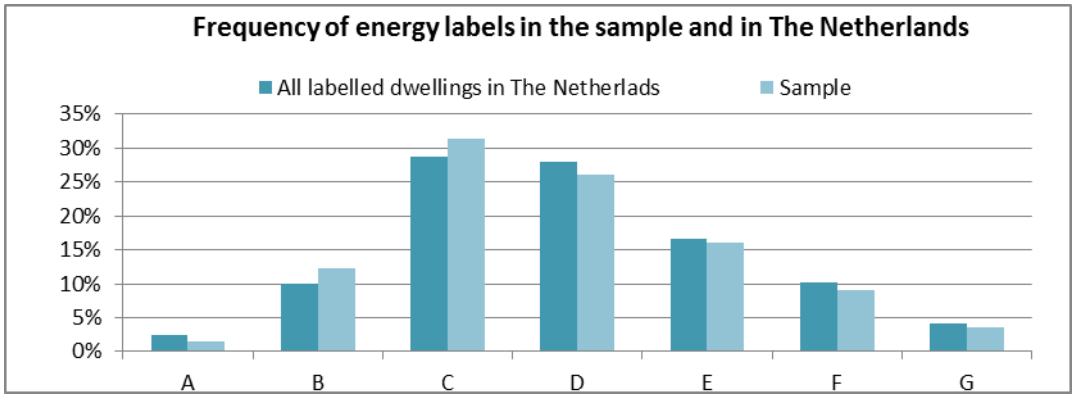

Figure 2: Shares of energy labels in the studied sample and in the Dutch dwelling stock (source Majcen and Itard, 2012)

Almost half of the dwellings were constructed in the 70s and 80s, until the year 1995. If this is compared to the whole Dutch dwelling stock, one can see that the distribution in the whole dwelling stock is slightly more even – more very new dwellings and more very old (Figure 3).

 ISBN: 978-1-84219-840-7 .

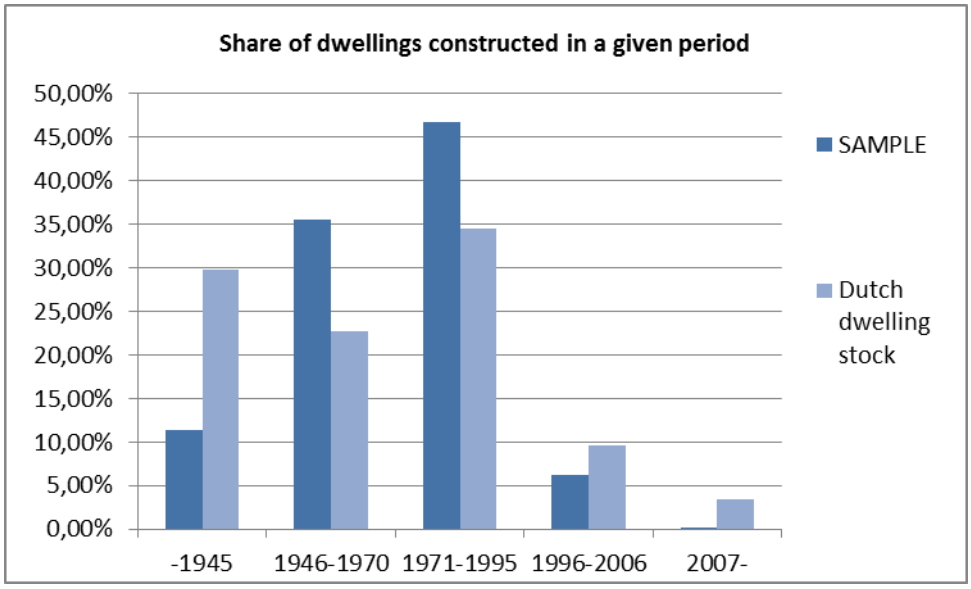

Figure 2: Number of dwellings per period of construction/renovation (source Majcen and Itard, 2012)

62% of Dutch dwellings are row houses. 11% of all dwellings are detached (single family) houses and the there is an equal share of apartments. This differs from the distribution in our sample of dwellings, which was aggregated to the same four categories in the Figure 5. The distribution of dwelling types according to the CBS in year 2009 is also plotted in Figure 5, and also differs slightly (the total stock is considered here to be 6,993 million dwellings). Discrepancy is the largest in the category of flats, which accounted for almost 36% of the sample, but represent only slightly more than 25% of the housing stock in 2008 according to the Energiecijfers database. There is less than average number of detached dwellings in the sample. On the other hand, there are more flats. This is also reflected in average size of a dwelling, which is more than 10m^2 smaller in the sample than is the Dutch average (Meijer & Itard, 2008).

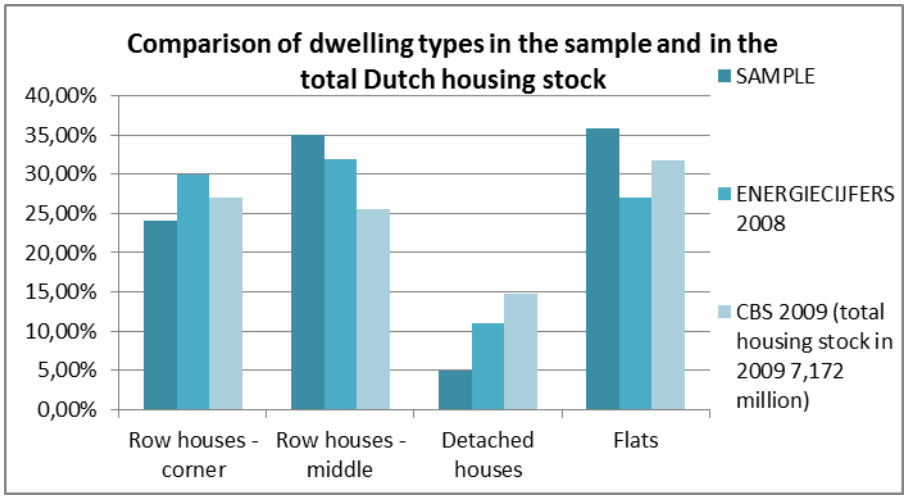

Figure 3: Representativeness of dwelling types in the sample and in the whole Dutch housing stock (source Majcen and Itard, 2012)

In terms of ownership structure, the sample differs significantly from the Dutch average (Energiecijfers database). Only slightly over 20% of the labelled dwellings are private owner occupant, while in the total dwelling stock the share is more than half (55%). Only 1% of dwellings in the sample is owner rental properties, whereas in the Netherlands, there are 12% of such dwellings. The third category is social housing, and is much better represented in the sample than in the total Dutch dwelling stock (79% vs. 33%), see Figure 6. This is caused for a large part by the lack of enforcement of this compulsory label for owner occupants.

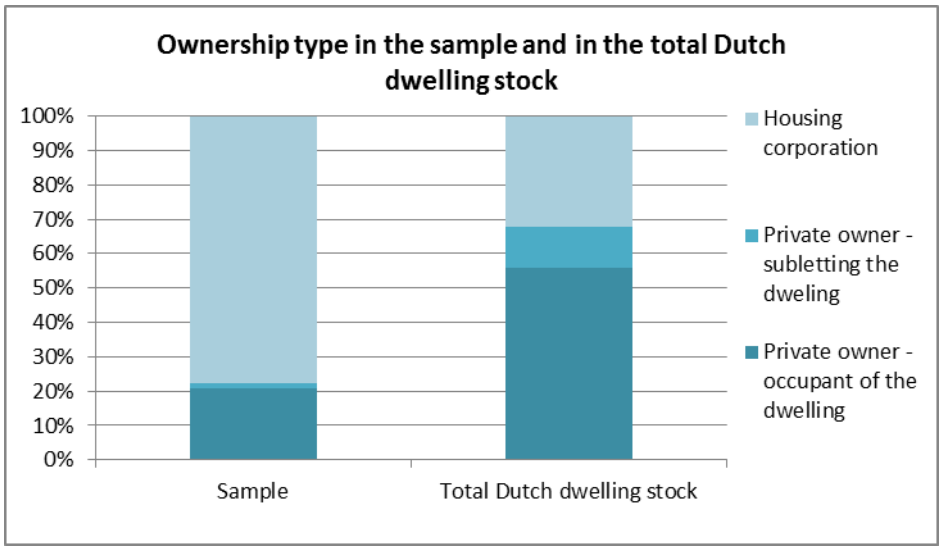

Figure 4: Ownership type distribution in the sample and in the total Dutch dwelling stock (source Majcen and Itard, 2012)

5 Results

5.1 Actual vs. theoretical energy consumption

First of all, a comparison was made between the actual and theoretical energy consumption per m^2 of dwelling in the abovementioned sample. The values appeared to be very well comparable, as can be seen from Figure 7. However, since it is known, that the theoretical consumption does not take into account end uses such as by household appliances (Table 2), which account for about 22% of total household energy consumption and gas for cooking, which contributes 1,3% it should intuitively be smaller. Because of gas and electricity as the two main energy sources in Dutch households are used for distinctive purposes, they are also examined separately in this study.

Within the analysed sample, the theoretical value for gas consumption is much higher than the actual, and the theoretical electricity consumption is significantly lower than the actual consumption of the same dwellings (Figure 7). In the case of electricity consumption, the fact that electricity from appliances is not taken into account, could to some extent cause the large underestimation of theoretical value, but judging from the values in Table 2 (appliances' contribution to electricity consumption is on average 32,4%, if the overestimation in our sample is due to appliances, they would contribute

64%) this is not the only cause. This might indicate that either the estimation for electricity consumption of household appliances is inaccurate, or the electricity consumption for hot tap water and heating are higher than predicted. As opposed to electricity, gas consumption is over predicted. Since the end uses of gas are the same with the exception of cooking, the differences in consumptions reflect either a deviation from assumed user behaviour or divergence from assumptions used to estimate space heating demand (air infiltration, U-values, floor area, transmission areas etc.) different than assumed in the theoretical calculation. This study does not aim to quantify where the discrepancies come from, but rather, the consequences of the inconsistencies for future household energy consumption.

In the total Dutch housing stock (Figure 7), 3480 kWh (32123 MJ) of electricity was consumed in a dwelling on average, according to Energie Nederland 2010. This is around 700 kWh (6224 MJ) more than the average in the studied sample. Similar goes for gas, around 1617 m^3 (56870 MJ) was the average consumption in 2010 according to Energie Nederland, whereas the consumption in our sample was app 1500 m^3 (52264 MJ). This discrepancy is likely to be caused by the larger average size of the dwellings in the whole Dutch dwelling stock.

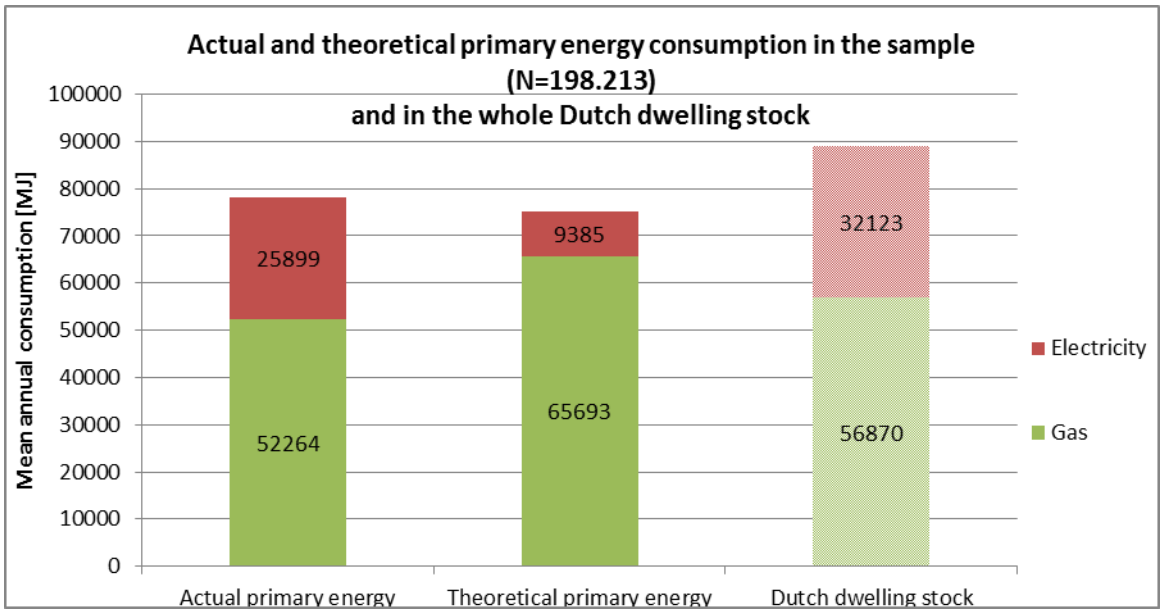

Figure 5: Actual and theoretical primary energy consumption in the sample and in the Dutch dwelling stock (source Majcen and Itard, 2012)

5.2 Energy consumption vs. energy label

5.2.1 Gas

To get an insight in how the energy label relates to the discrepancies described in the previous section, we examined gas and electricity consumption in the various label categories. The plots in this paper are presented with +/- 1 standard deviation. Because of the extremely large size of the sample it is not relevant to plot the 95% confidence

 ISBN: 978-1-84219-840-7 .

interval, which is always very small, meaning that the location of the mean value is known almost without any uncertainty and all the differences were statistically significant on a 95% interval.

Figure 8 represents the actual and theoretical gas use per dwelling and Figure 9 the consumption per square meter of floor area of dwelling. What changes in the latter is the consumption of dwellings with label A, since those were found to be considerably larger than all other dwellings (Figure 10). From these figures it is clear that, although the increase of actual gas consumption corresponds to the increase in label, there is a clear difference between the mean theoretical and mean actual gas consumption of each label. For the most energy efficient categories: A, A+ and A++ as well as for category B Figure 8 and Figure 9 show underestimated theoretical gas consumption as opposed to the rest of the categories where the theoretical gas consumption is largely overestimated. The theoretical and actual values are only for label C quit similar. It is worth noting that in label category G, the actual gas consumption is only half of the theoretical consumption. The theoretical gas use predicts a much higher span between an energy efficient dwelling (A) and an energy intensive dwelling (G) than we observe in the actual gas use. If the two consumptions are thought of as a linear function, they greatly differ in their slope.

When standardizing the consumption per dwelling to the consumption per m^2 of dwelling, a better match between actual and theoretical gas consumption was expected since the dwellings could have different mean sizes in different categories. However, Figure 9 shows that this is not the case. The difference therefore does not arise because of different sizes of dwellings. It is noticeable that the standard deviation of theoretical consumption decreases in the Figure 9, meaning that the spreading in square meters floor area is responsible for a large part of the spreading in theoretical gas consumption at dwelling level.

(source Majcen and Itard, 2012)

 ISBN: 978-1-84219-840-7 .

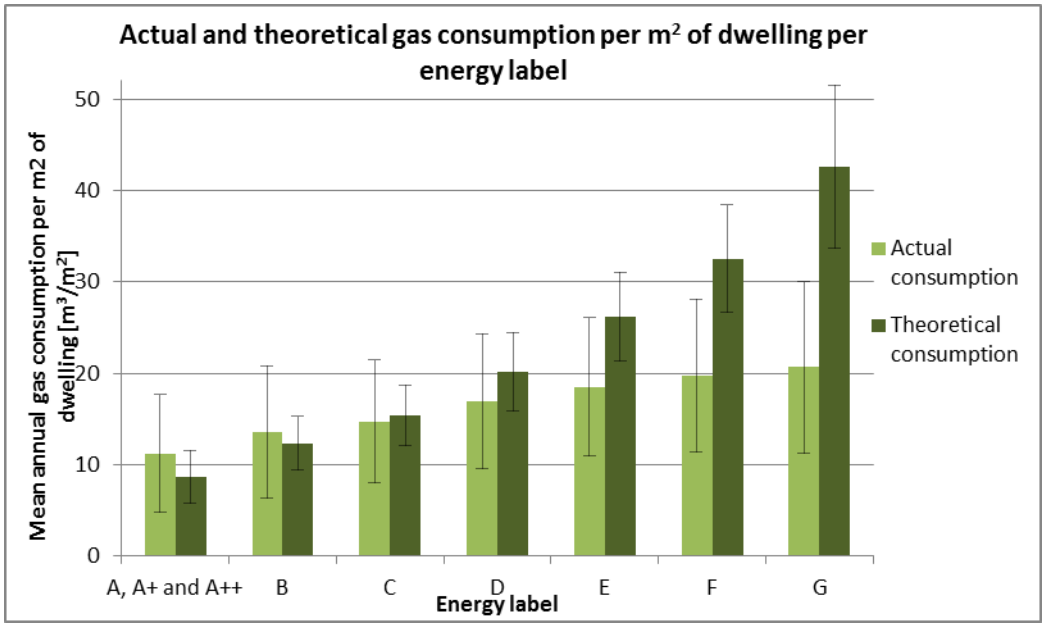

Figure 7: Actual and theoretical gas consumption per m2 of floor area per label (source Majcen and Itard, 2012)

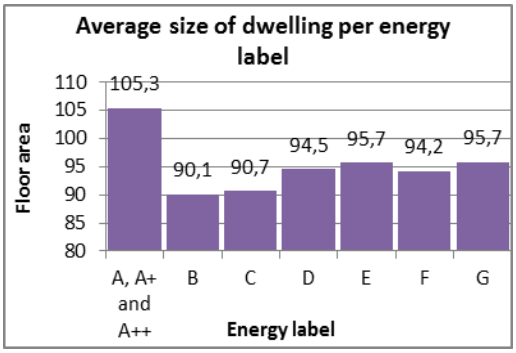

Figure 8: Average dwelling size (m2 floor area) in different label categories (source Majcen and Itard, 2012)

5.2.2 Electricity

As opposed to what we observed in the previous chapter on gas consumption, the theoretical electricity consumption is underestimated (Figure 7). In Figure 11 we can observe that both the actual and the theoretical electricity consumption does not depend much on the label. There is a very slight trend towards higher consumption in labels A, D and E which might be attributable to the electricity that is used for space and water heating in certain households or/and the larger floor areas.

Figure 12, where the electricity consumption is given per m^2 floor area, shows that the higher consumption in label A relates to larger floor areas, which seems not to be the case in labels D en E. The curve shows a slightly convex shape for the actual electricity consumption and a concave shape for the theoretical one, but finally the label will not appear to be very significant for the difference in electricity consumption. However, the

 ISBN: 978-1-84219-840-7 .

differences between labels are very small compared to what was observed in gas consumption.

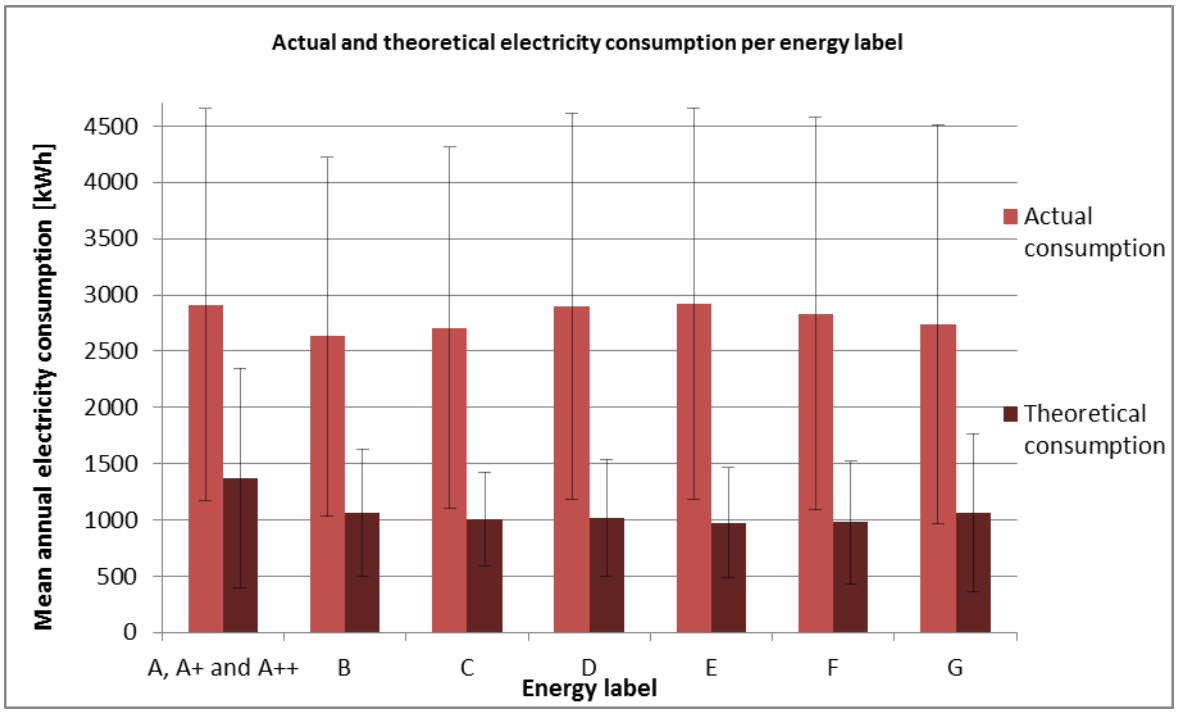

Figure 9: Electricity consumption in different label categories
(source Majcen and Itard, 2012)

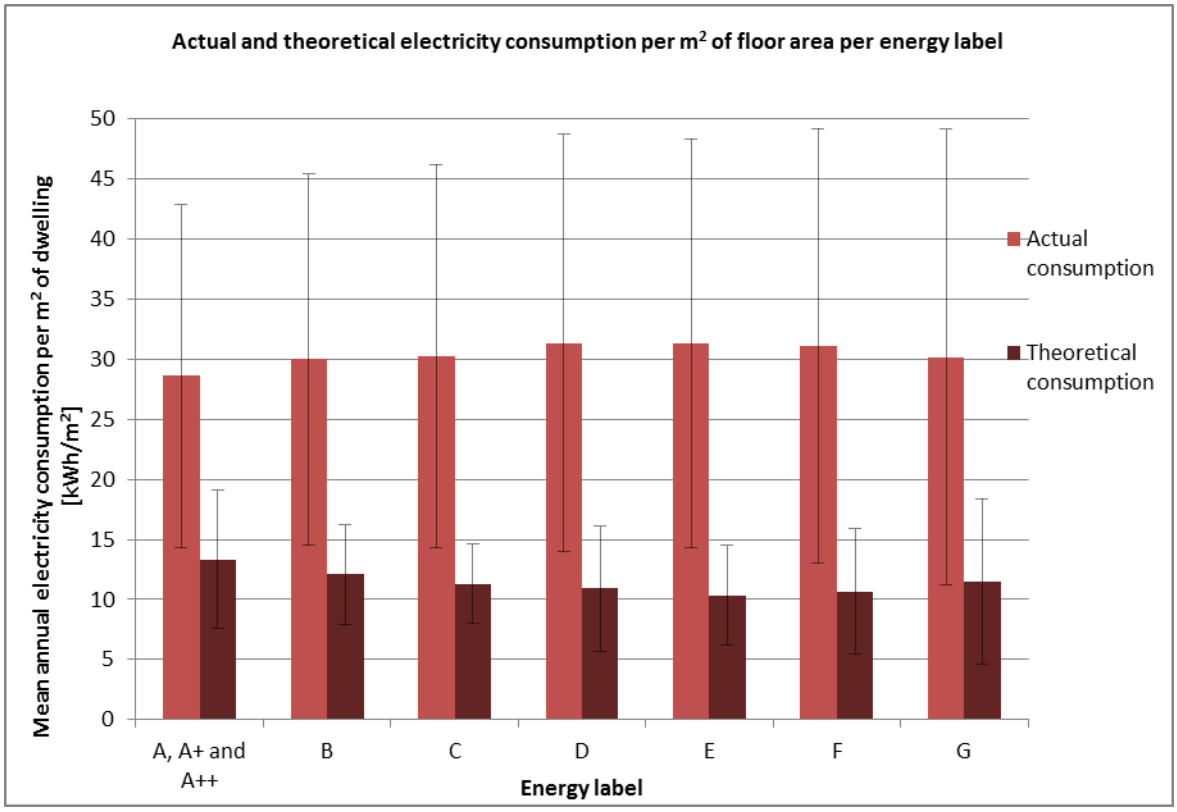

Figure 10: Electricity consumption per m2 dwelling in different label categories

(source Majcen and Itard, 2012)

5.3 Total primary energy and CO_2 emissions per label category

An interesting insight into the total primary energy consumption (Figure 13), can be gained if summing up the gas and electricity consumption according to equation 3. From this figure, the occupants in dwellings labelled with A – D label can expect to consume more than it is pointed out in the label. This will be partly a consequence of higher gas consumption and party due to the fact that the household appliances are not a part of the label.

However, what is worrying here is the fact that the span of theoretical consumption is much higher between label A and G than it is the case in reality (looking at actual values). This might have a very strong influence on the pay back times and on the achievable savings. The labels E to G seem to be consuming a very similar amount of actual primary energy, even though the technical characteristics are much better in E than in G. The label thus might reflect the technical characteristics of a dwelling, but if the actual primary energy consumption seems to be almost identical in each of the three categories, it might not be worth it to improve the technical specifications of houses labelled with G. From this figure it is clear that the savings which are expected to arise when improving the technical characteristics of a house, do not occur in practice. The theoretical primary energy consumption of label A is 70,2% lower than the consumption of label G, but the actual primary energy consumption of label A is only 27,8% lower than label G.

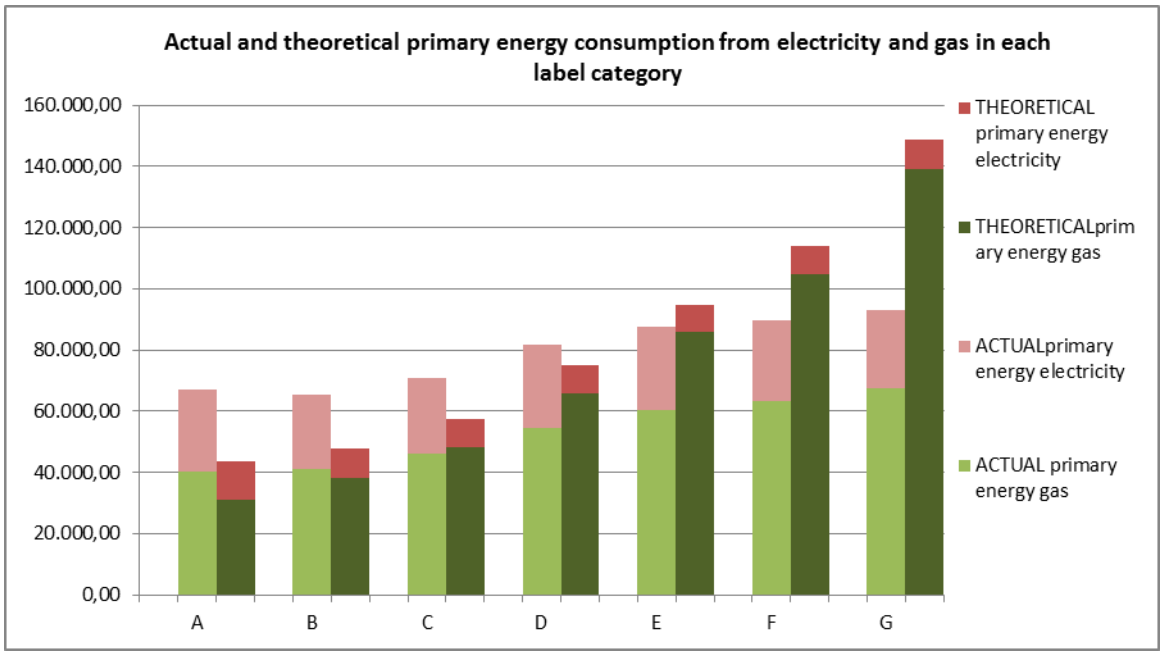

Figure 11: Primary energy consumption in different label categories

(source Majcen and Itard, 2012)

Moreover, since European targets are not solely aiming on reducing the energy consumption but also on reducing the CO_2 emissions, therefore it is illustrative to see what the energy label means in relation to CO_2 emissions. Since one megajoule of

 ISBN: 978-1-84219-840-7 .

electricity produced in The Netherlands causes a larger CO_2 emission than a megajoule of gas (0,613kg vs. 0,508kg of CO_2 per MJ energy at household), a chart was produced, examining the emissions related to each label category. Electricity is responsible for more CO2 emissions per unit energy than gas, therefore it plays a stronger role in this chart. Theoretical CO_2 emissions are lower than actual in all labels except label G, because the household appliances are not taken into account in theoretical emissions. Interestingly, there is no significant decrease in CO_2 emissions among labels G, F and E and the label A is responsible for more CO_2 than the label B. The CO_2 emissions when improving a label from G to A, decrease for 55,4%, whereas in reality, looking at actual consumption, this decrease is only 13,1%.

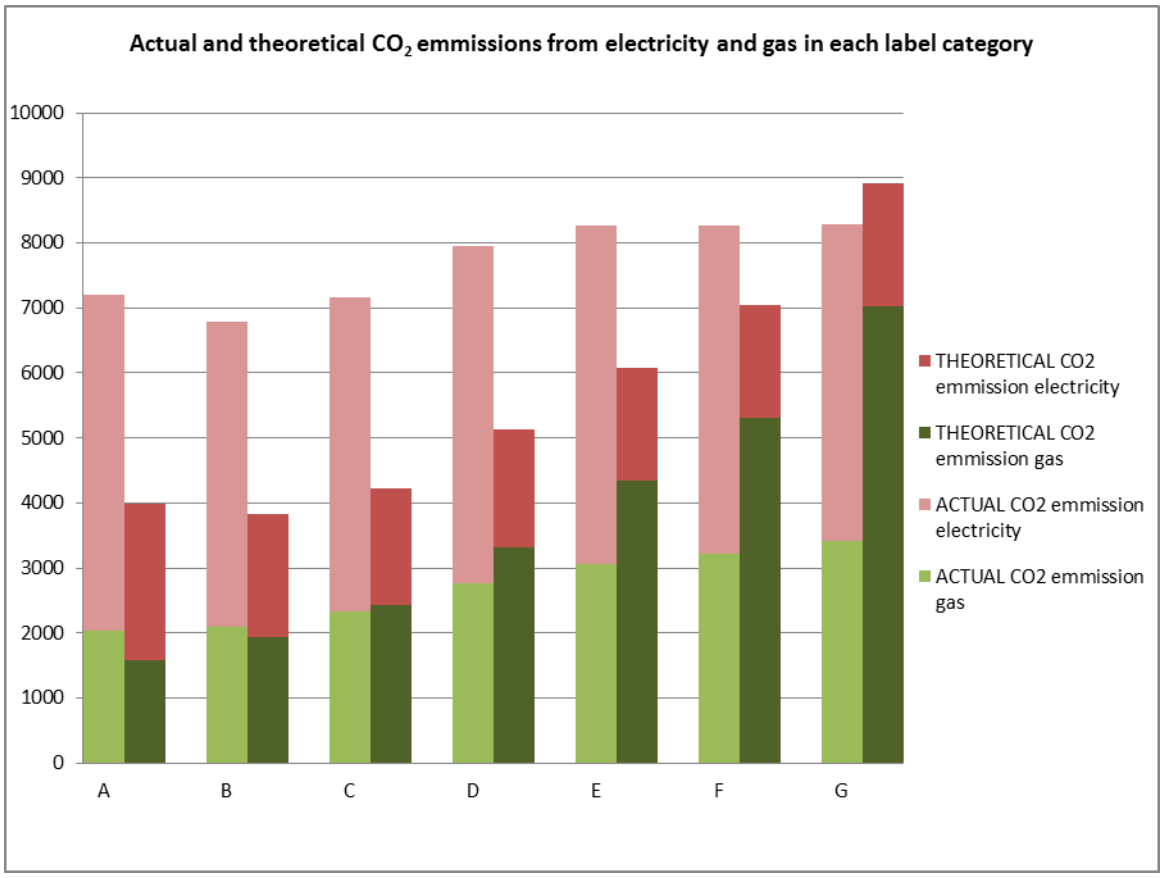

Figure 12: CO2 emmissions in different label categories (source Majcen and Itard, 2012)

6 Conclusion

This study was based on a large sample of households. Figure 3 showed the representativeness of the sample regarding the frequency of label categories, which was an important finding, since this study aimed to compare actual and theoretical energy consumption within a label and extrapolate the predictions which are made within the energy label calculation to the whole Dutch dwelling stock (section 4.4). Other aspects of the sample, such as type of dwellings or ownership type showed poorer representativeness, but this does not influence the results of this study, it might

however, be useful information for further research and helpful to explain why there is a large discrepancy between actual and theoretical energy consumption.

Considering the fact that most of the gas consumption in The Netherlands is used for space and water heating, it can be concluded also from this study that the actual heating energy consumption is on average lower than the theoretical for most dwellings (in our study for dwelling with labels C to G) as was observed previously by Guerra Santin (2012), Tigschelaar (2011), Cayre (2011) and Hens (2010). Guerra Santin already pointed out that at a lower EPC value (for new dwellings), the difference between expected and actual will be smaller. Our study has proved this, and showed that in very energy efficient dwellings actual gas consumption can even exceed the theoretical use (Figure 8). On the other hand, low efficient dwellings are characterised by over prediction of gas consumption, the theoretical gas consumption seems to be around twice the actual. On the contrary to gas consumption, the discrepancies between theoretical and actual in electricity consumptions in different label categories are relatively constant (Figure 11) and most of the difference is likely to arise from consumption of household appliances. The fact that labelled dwellings differ in gas consumption, but not much when it comes to electricity consumption proves, that the energy label can (on a large scale) only be efficient in reducing gas consumption, at least as long as this is the main source of heating energy. However, in in Figure 14 one can see the importance of electricity in the carbon footprint of households – it is responsible for approximately 2/3 of all CO_2 emissions, which is why efforts should be made in the future for reducing not just the household heating demand, but also the electricity demand.

An important finding of this study is, that the primary energy consumption reduction, which is assumed to happen when improving a building from label G towards label A, turns out to be much lower when looking at actual primary energy consumptions of dwellings. This could lead to a miscalculation of payback times of the measures for improving the energy efficiency of the dwelling and the targets that have been set for primary energy as well as CO_2 reduction might not be realistic looking at actual energy consumptions. It was found out that even by refurbishing the whole Dutch dwelling stock to a label A (which is an unrealistic assumption), the actual primary energy savings cannot yield most of the current targets. However, if the theoretical consumptions are considered, most of the targets are achievable. The targets for gas consumption and reduction in CO_2 emissions turned out to be similarly problematic.

7 Implication of the findings

The energy performance certification of existing dwellings is considered to be an essential element of the European energy efficiency policies. This research has shown that a policies that are only based on improving the energy efficiency of dwellings and the heating and cooling services most likely will not lead to the energy and CO2 reduction goals as formulated. This is mostly due to the fact that in very bad performing dwellings the energy use is not as high as expected due to a lower comfort level (behaviour) and in very high classified dwellings not as low as expected due to lacking performances of the buildings and services (building control) and the rebound effect (behaviour).

Before renovation of bad dwellings the actual energy consumption and use of the dwelling should be investigated before one can say something about the potential savings. Maybe not all the provided comfort in renovated dwellings is desired or actually consumed. Whit an adjusted heating behaviour more saving could be achieved. To reduce the CO2 emissions the use of PV panels for the provision of domestic electricity use seems very effective.

Evolving Legal Strategies for Sustainable Urban Construction in Nigeria.

Olusegun Michael Osinibi[1]

Department of Pivate Law

Olabisi Onabanjo University, Ago-Iwoye, Ogun State

Nigeria

E-mail: *osinibimike@yahoo.com*

Abstract:
In Nigeria, the discovery of oil and economic growth precipitated a mass exodus of citizens to urban areas as agriculture was abandoned in favor of city life. Unfortunately, massive corruption in government has occasioned a failure to observe urban planning laws culminating in indiscriminate, unregulated construction and unplanned cities. Overpopulation, flooding, spread of diseases and increased criminal activities characterize such unplanned cities. The neglect of government to supervise and enforce building regulations has resulted in a spate of collapsed buildings in Nigeria's built environment. Poor governance in Nigeria and the resultant economic downturn have fostered a situation where most citizens choose to save the cost of construction by employing unqualified builders to construct infrastructure instead of building experts. The unqualified builders, in a bid to cut costs, resort to substandard building materials thus leading to collapsed buildings, loss of life and properties. This paper argues that for construction in Nigeria to be sustainable, there is a need to draft new laws to reflect new developments and evolve ways of enforcing the laws consistently.The paper examines whether a paradigm shift in the socio-economic policies of government can improve the economy and reduce or eradicate the phenomenon of collapsed buildings.

Key Words:
Building regulations, Legal strategies, Nigeria, Sustainable construction, Urban planning

1 Introduction

Nigeria is afflicted by multifarious problems ranging from widespread corruption, lack of basic socio-economic infrastructure, insecurity, high rate of illiteracy and low life expectancy. The dearth of the basic necessities of life such as food, clothing and shelter is a most worrisome trend. A vast majority of Nigerians live below the poverty line and are therefore unable to meet the expense of providing adequate and enduring shelter for themselves (Adekoya ,C, 2009,37) while a lot of those who can afford to build their own houses resort to the use of substandard building materials in a bid to reduce the expenses associated with erecting a building.The failure of the Nigerian government to adequately enforce town or urban planning laws has led to the indiscriminate construction of houses in violation of extant laws and has engendered the growth of unplanned cities and towns thereby fostering urban chaos(Olujimi,J, 2009) as well as

avoidable deaths occurring from collapsed buildings. The prospects of achieving sustainable construction in a planned built-up environment appears bleak as an increasing number of Nigeria's surging population migrate from rural areas to the urban areas in search of better conditions of living as opposed to reliance on agriculture thereby putting a pressure on the hard-pressed space and resources available in the cities.
This paper examines from a legal perspective, how some semblance of order can be restored into Nigeria's urban environment such that sustainable construction will become a reality in Nigeria. This paper is divided into four parts excluding the introduction and the conclusion. The first part gives an insight into the legal framework regulating urban construction in Nigeria; the second part highlights the impediments to effective urban planning and sustainable construction in Nigeria; the third part discusses the essence of planning law while the fourth part identifies the legal strategies needed to attain sustainable construction in Nigeria.

2 Legal Regime Of Urban Construction In Nigeria

There is presently a plethora of statutes regulating building development; housing and regional planning matters in Nigeria and an overview of the statutes is apposite. The Nigerian Urban and Regional Planning Act [1]stipulate the types and levels of physical development plans to be executed in Nigeria. At the Federal level, the Act provides for a regional plan; a sub-regional plan; an urban plan and a subject plan with similar plans also existing at the State and Local levels.[2] Section 2 of the Nigerian Urban and Regional Planning Act defines the responsibilities of the Federal Government of Nigeria with regards to matters of urban planning and development and these include preparation and implementation of the National Physical Development Plan; the formulation of urban and regional planning standards for Nigeria as well as the promotion and fostering of the education and training of town planners and support staff amongst other duties. This Act establishes a National Urban and Regional Planning Commission which is responsible for supervising and monitoring the implementation of the National Physical Development Plan and development control[3] which responsibility is carried out through the Development Control Department of the Commission. This Control Department is vested with such powers that its approval shall be required for any land development in the federation.[4] It is pertinent to note that this Act is mindful of the impact of urban development on the environment and citizens as it provides that a developer's application for development may be rejected if in the opinion of the Control Department, the development is likely to have a major impact upon the environment, facilities, or inhabitants of the community or if the development contains such additional facilities which are not within the estimation of the Physical Development Plan for that community. The Act is however silent on how the discretion of the Control Department is to be exercised in approving or rejecting an application for development. The absence of such guidelines may be an avenue for arbitrariness. Of importance to this paper, is the power of the Control Department to demolish any building found to be defective with the cost of demolition to be borne by the erring Developer.[5]

[2] Section 1, Nigerian Urban and Regional Planning Act
[3] Section 5, Nigerian Urban and Regional Planning Act
[4] Section 28(1), Nigerian Urban and Regional Planning Act
[5] Section 62, Nigerian Urban and Regional Planning Act

Another relevant statute is the Federal Housing Authority Act.[6] This Statute establishes the Federal Housing Authority, an agency of government having the responsibility of preparing a National housing program for Nigerians of different income groups in major cities and in every state across the nation and executing the program as may be approved from time to time by the Federal Government. This agency also has the duty of making recommendations to the Government on such aspects of urban and regional planning, transportation, communications, electric power, sewerage, and water supply development as may be relevant to the successful execution of the housing program approved by the Government.[7] The vision of this agency as publicized is to be the leading provider of housing and facilitator of access to sustainable housing solution in Nigeria and to become a model government agency while the mission is to be the leader in the provision of sustainable housing in Nigeria and to facilitate home ownership for all Nigerians (Federal Housing Authority, 2010). According to the official statement by the agency, the functions of the agency have further been expanded in the National Housing Policy to include the provision of sites and services for all income groups with special emphasis on the low income group; the provision of low income and rural housing in all states of the Federation and the Federal Capital Territory from funds provided by the Federal Government and other sources; the development and management of real estate on commercial basis in all states of the Federation and the Federal Capital Territory(Federal Housing Authority, 2010). Even though the Federal Housing Authority was established in 1973 as part of the Federal Government's commitment to make affordable housing accessible to all Nigerians, thirty –nine years later, more Nigerians are homeless as affordable housing has become far less accessible.

The need to effectively regulate the profession of town planning is underscored by the enactment of the Town Planners Registration Act.[8]The Act establishes the Town Planners Registration Council which is the body responsible for the registration of town planners and is charged with the duty of determining what standards of knowledge and skill are to be attained by persons seeking to become members of the profession of town planning and reviewing those standards, from time to time, maintaining discipline and controlling the practice of the profession in all aspects and ramifications.[9]

In the area of providing finance to facilitate urban development in Nigeria, the Urban Development Bank of Nigeria, a limited liability company was established by Law to foster the rapid development of urban infrastructure throughout Nigeria through the provision of finance and banking services.[10]This Bank may raise funds from off-shore sources such as the International Bank for Reconstruction and Development, the African Development Bank and other such sources to facilitate urban and infrastructural development projects in Nigeria. Where such funds are obtained by other entities, the said funds whether by way of general loans, tied loans, bilateral loans, or grants on government to government basis must be channeled through the bank and accordingly managed by the bank. [11]

[6] CAPF 14 Laws of the Federation of Nigeria 2004
[7] Section 3, Federal Housing Authority Act
[8] CAP T7 Laws of the Federation of Nigeria 2004

[9] Section 2 Town Planners Registration Act
[10] Section 3 Urban Development Bank of Nigeria Act, CAP U16, Laws of the Federation of Nigeria,2004
[11] Section 5 Urban Development Bank of Nigeria Act

The Federal Mortgage Bank of Nigeria is important in the provision of affordable housing to Nigerians as it has the function of providing long-term credit facilities to mortgage institutions in Nigeria at such rates and such terms as to enable the mortgage institutions to grant comparable facilities to Nigerian individuals desiring to acquire houses of their own.[12]

In a similar vein, there is in place a National Housing Fund established by the National Housing Fund Act to facilitate the mobilization of funds for the provision of houses for Nigerians at affordable prices; ensure the constant supply of loans to Nigerians for the purpose of building, purchasing and improvement of residential houses and more importantly, encourage the development of specific programs that would ensure effective financing of housing development, in particular low cost housing for low income workers.[13]

In view of the elaborate legal regime on regional planning and housing existing in Nigeria, it is startling that Nigeria consists of unplanned or poorly planned cities where majority of the citizens have no access to affordable housing.

3 Impediments To Effective Urban Planning And Sustainable Housing Construction In Nigeria

Olujimi noted that one of the key features of urbanization in Nigeria and other developing countries is rapid growth without any corresponding significant industrial expansion thus placing a high demand on the available infrastructure available for basic services and housing on one hand while also accelerating poverty (Olujimi,J, 2009). Thus, there is a need to improve basic facilities and utilities to correspond with the demographic changes (Ogundele,F,et al, 2011). According to Olujimi, an urban center or a city can only serve as an engine of development if properly planned and efficiently managed in the absence of which an urban sprawl materializes, characterized by "haphazard housing development in the urban suburbs where majority of the structures are without planning permit in an uncoordinated layout".[14]From this scenario, it can be concluded that the fundamental factor impeding effective urban planning and building control in Nigeria is the lack of political will on the part of government to implement development control measures manifested in the form of insufficient planning staff and lack of equipment such as development control monitoring vehicles(Olujimi,J, 2009). This position is re-echoed by Ogundele who noted that government's inadequate funding of development control characterized by the lack of vehicles as well as the unavailability of modern land use maps to reflect the trend of development are impediments to development control.

The prevalent incidence of corruption in the Nigerian society is also a great impediment to effective urban planning and sustainable housing. Corruption within the urban planning regulatory authorities has been responsible for double standards in approving or rejecting development plans as an applicant who has furnished some gratification is more certain to have his development plan approved than another applicant who has failed to do same. Furthermore, paying gratification to regulatory authorities has encouraged citizens to illegally convert residential buildings into mixed-use buildings such as residential and commercial,(Ogundele,F,et

[12]Section 5 Federal Mortgage Bank of Nigeria Act, CAP F16, Laws of the Federation of Nigeria,2004
[13] Section 2 National Housing Fund Act CAP N45 Laws of the Federation of Nigeria 2004
[14] Building control in Nigeria falls under the purview of the town planning authorities.

al, 2011) thereby altering the designated urban master plan. With regards to housing construction, the impact of corruption is seen when importers of building materials are allowed to import substandard materials and sell same into the Nigerianconstruction market culminating in the rapid collapse of buildings.

It has also been noted that the dearth of reliable information on demographic factors such as the population is a major obstacle to planning (Oduwaye, L, 2009). One of the fallouts of the discovery of crude oil in Nigeria was the steady relegation and neglect of agriculture as the mainstay of the economy. This resulted in mass movement of citizens from rural areas to urban areasin what Agbola and Agunbiade (2007) termed as an invasion. They state that population increase due to mass exodus from rural to urban areas causes unusual land and demographic pressure triggering an unprecedented demand for land. Accordingly, the invasion leads to uncontrolled and unorganized developments lacking basic infrastructure and facilities (Agbola T and Agunbiade, 2007)

The problems bedeviling urban planning and sustainable construction in Nigeria are succinctly stated in the findings of Oloyede, et al (2010) that the causes of building collapse in Nigeria include 'improper design, faulty construction methodology, poor town planning approval/development monitoring process; non-compliance with specifications/standards by developers/contractors; use of substandard materials and equipment; inadequate supervision or inspection/monitoring'. There is no gainsaying that without the proper enforcement of town planning laws as well as the enactment of strict development or building control laws, Nigeria's built-up environment will continue to be an unplanned concrete jungle bedeviled by constantly collapsing buildings.

4 The Essence Of Planning Law

Planning law governs the processes involved in getting planning permission for the erection or change of use of buildings.[15] The learned writer, Utuama believes that the essence of planning law lies in its "use as a law for analyzing and resolving conflicts in diverse use of land arising from their interaction one with the other by drawing up plans to indicate where and when development should take place; by devising policies to cope with current and anticipated problems in the use of land; the movement of the people and goods, and the quality of the environment" (Utuama,A.2006). As such, where planning laws do not exist or are not properly enforced, the repercussions extend beyond hapless citizens and have a very negative effect on the environment. In this regard, Utuama states that an environment can only be as friendly as the degree of land use planning to which it is subjected. Thus, he suggested, and rightfully so that planning law is of utmost importance in the protection of the environment, especially in a country like Nigeria whose major cities are heavily characterized by environmental imperfections amongst other issues of concern such as provision of housing and conservation of natural resources. He concluded his argument by advocating for a constitutional review that will make urban and regionalplanning a concurrent legislative matter, in the interest of developing a national, comprehensive and all-embracing land use planning system that will bring Nigeria into purposeful planning in response to national goals (Utuama , A.2006)

[15]http://www.unbiased.co.uk/glossary/letter_p viewed 29/06/2012

In addition to establishing a model urban planning law, there is a need to ensure sustainable construction in Nigeria. It has been observed by Isover that while standard building practices are guided by short term economic considerations, sustainable construction is based on best practices which emphasize long term affordability, quality and efficiency (Isover,2012). The importance of ensuring sustainable construction is underscored by the fact that buildings and construction works have the largest single share in global resource use and pollution emission. Apart from individual buildings, Isover further disclosed that poor patterns of building development often lead to congestion and inefficient use of land, resulting in greater energy consumption and travel time, loss of productivity, polluted runoff to surface water and wastewater treatment systems, loss of agricultural lands, fragmented habitats, and fiscal stress to local communities. Due to the implications for the environment, sustainable construction has extended beyond national boundaries and is now a global issue. According to Edward Schwarz, 'achieving sustainable construction requires a multifaceted worldwide approach by all nations, sustainable building practices must occur in every place, address a variety of problems, happen on many levels, work in various contexts ,respond to many needs and restraints, be applied at every scale and employ many disciplines'(n.d). The international dimension of sustainable construction and its impact on the world's environment is demonstrated by the United Nations Environmental Project (UNEP)'s Sustainable Buildings and Climate Initiative which is a partnership of major public and private sector stakeholders in the building sector working to promote sustainable building policies and practices worldwide.(UNEP)

In Nigeria, unfortunately, the attention is on the spate of collapsed buildings. Recently, the Director-General of Nigerian Building and Road Research Institute was reported as stating that the collapse of buildings had become too frequent and a source of worry to all professionals in the industry and that the effect on the economy and the loss of human lives had become a great burden on the nation(Amaefule,E,2012). The Director-General further stated the causes of collapsed buildings in Nigeria as failure to obtain building approval from relevant authorities, the activities of quacks in the building industry, the use of deficient materials and the absence of supervision by government authorities.

5 Evolving Legal Strategies

It must be observed that in spite of the problems associated with housing and construction, the Constitution of Nigeria contains certain provisions which are relevant to the issue of housing. Section 15 of the Constitution provides that the state shall secure full residence rights for every citizen in all parts of the Federation, The environmental objectives of the Nigerian government as stated in the Constitution is to the effect that the government shall protect and improve the environment and safeguard the water, air and land, forest and wild life of Nigeria.[16]The Constitution further provides that suitable and adequate shelter, suitable and adequate food, reasonable national minimum living wage, old age care and pensions, unemployment and sick benefits and welfare of the disabled are provided for all citizens. The crucial shortcoming of these rights guaranteed by the Constitution is that the same Constitution renders the rights unenforceable thus rendering these vital rights as rights of mere paper value. There is thus an

[16]Section 20 Constitution of the Federal Republic of Nigeria.

urgent need to amend the Constitution to change the status of the right to shelter and other associated rights to enforceable rights.

Particularly, it is strongly suggested that there must be a paradigm shift in the socio-economic policies of the Nigerian government. At present, the fundamental obligations of the Nigerian government to the citizens as enshrined in Chapter II of the Nigerian Constitution titled 'Fundamental objectives and directive principles of state policy' have remained unfulfilled leading to a loss of confidence in the government and fostering a situation where citizens have to resort to self-help in the absence of government provision . The absence or irregular supply of basic facilities such as water, electricity and good roads in urban centers in Nigeria needlessly drives up the cost of construction as citizens are compelled to find the means of providing these amenities for themselves. This encourages unethical practices as certain individuals attempt to cut the cost of construction by using cheap, sub-standard construction materials and also cutting back on the standard measurements required to make solid concrete thereby creating a potential risk and negating the very essence of sustainable construction. The high rate of inflation in the economy and the loss of purchasing power of citizens have also brought about a situation where most citizens employ artisans to design and build houses as opposed to consulting professionals such as Architects, Quantity Surveyors and Civil Engineers. It is submitted that this situation does not bode well for sustainable construction and housing in Nigeria. If the government makes an effort to fulfill its economic objectives, poverty will be reduced and cutting corners by citizens to achieve their housing dreams will be greatly reduced. For instance, the Nigerian Constitution states that it shall be the duty of the government to control the national economy in such manner as to secure the maximum welfare, freedom and happiness of every citizen on the basis of social justice and equality of status and opportunity.[17]Similarly, the Constitution further provides that the government shall harness the resources of the nation and promote national prosperity and an efficient, dynamic and self-reliant economy. Unfortunately, this is presently not the case as Nigeria is nowhere near a self-reliant economy. Notwithstanding the fact of being the tenth largest producer of oil in the world, the Nigerian economy is solely dependent on imports as most local industries have shut down due to an unfriendly business climate. A situation where construction materials are mostly imported also drives up the cost of construction thereby making sustainable construction in Nigeria a distant dream.

There is a need to draft new laws on building practice which will strictly specify the use of authentic and environmentally friendly building materials in the construction industry. This will achieve the dual objective of ensuring sustainable construction and also protecting the environment. To make this possible, there must be stricter supervision not only by the relevant government agencies but also by professional institutions having a stake in construction in Nigeria.This position finds credence in the words of I.O.Smith, (2006) a renowned Land Law expert,

> Although planning control is not necessarily conterminous with environmental law, it is apt to say they are complementary. Land use has a critical impact on the environment and sustainable development. The issue of environmental protection is a mirror of the use to which land water and air have been subjected by man.While environmental

[17] Section 16(1)(b) Constitution of the Federal Republic of Nigeria 1999

> protection may be the end,planning is a veritable instrument for achieving a healthy environment and sustainable development.

One of the main causes of insufficient housing in Nigeria is the prohibitively high cost of building materials as Nigerian buildings are basically made up of concrete as opposed to developed countries where construction is mainly done with bricks and wood. The high demand for cement used in making concrete blocks and the corresponding astronomical increase in the price of cement has made housing unaffordable for Nigerians especially in a country where over half of the population lives below the poverty line. Inadequate housing leads to the establishment of slums in the urban centers thereby creating an urban planning nightmare. Likewise, the unrestrained continued use of cement in building is antithetical to sustainable construction as well as sustainable environment. Thus, there is need for new regulations in this regard. The use of mud bricks which was the predominant building component in Nigeria in the past needs to be revisited and adapted to modern construction techniques for the best results.

6 Conclusion

Nigeria's built up environment is in a state of untidiness as existing urban planning laws are flouted with impunity while regulatory authorities are unable to monitor development control let alone implement the laws effectively. The high rate of poverty in Nigeria and the needlessly high cost of purchasing construction materials have further contributed tothe problems associated with construction in Nigeria. As a result, Nigeria is contending with the phenomenon of collapsed buildings and unrestrained environmental pollution in an age where the world is focused on achieving sustainable construction and environmental sustainability.Unfortunately, the government has not manifested any intention to remedy the situation. There is a pressing need to address the problems of housing, urban development and sustainable construction in Nigeria before a major crisis results as the consequence of such crisis will unbalance the West African sub-region and have its effects felt all over the world as Nigeria is by far, Africa's most populous nation. To avert a housing crisis in Nigeria, the government's objectives must be totally focused on the welfare and best interest of the citizens of Nigeria as opposed to the present situation where citizens are unable to identify any government measures to address the myriad of problems afflicting Nigerians.

Owner-occupiers and the quality of their dwellings

Frits Meijer[1], Milly Tambach[1] and Henk Visscher[1]

Abstract:
Home-owners are in principal responsible for maintaining the physical quality of their dwellings. It is in their own interest to do this in an adequate manner, but all kinds of constraints can and do occur in practice. Lack of financial means and insufficient (technical or practical) knowledge are only two of the possible barriers. The quality of owner-occupied housing sector exceeds the individual interest, there are also general concerns to consider. Qualitative seriously substandard owner-occupied dwellings can have various negative effects on the neighbourhood. This paper is based on an on-going research project on the quality and maintenance situation of the owner-occupied sector in the Netherlands. Within this project almost 4.000 Dutch home–owners have recently been questioned about issues concerning the quality of their dwelling, the maintenance actions they undertake, the problems they encounter and the help or advise they would like to get. This paper presents the first results. The results especially will give insight in the way home-owners cope with maintaining the quality of their dwellings. Are they doing an adequate job or are interventions of the Dutch authorities (for parts of the sector) necessary?

Keywords:
home-owners, housing quality, housing stock, maintenance, policy instruments

1 Introduction

This paper deals with the physical quality of the owner-occupied sector in the Netherlands. During the last decades the owner-occupied sector has increased considerably. The principal view of the central government is that home-owners themselves are responsible for the quality and maintenance of their dwellings. Governmental support in general is not necessary. In a growing number of municipalities however the quality of the owner-occupied housing sector has become a matter of concern during the last years.

As this paper shows home-owners in general are perfectly able to maintain the quality of their dwellings. Nonetheless there are some 'problem segments', where the owners are not able (or willing) to invest in maintenance and repair. Especially local authorities observe that the physical quality of parts of the older owner-occupied stock is far from satisfying and partly seriously substandard. Various reasons to intervene can be named. In the first place local authorities have the statutory requirement (based on the Housing

Act) to supervise the housing quality. The building regulations establish an minimum level for existing dwellings. If a dwelling falls below that level the local authorities can summon owners to improve the situation. In general this only happens when the safety or health of the occupiers themselves and/or neighbours are endangered. Besides that the owner-occupied sector is of importance for the liveability of neighbourhoods. A row of dilapidated owner-occupied houses in a street could have serious negative effects on the neighbourhood. Municipalities can play a role to prevent that such problems occur. Furthermore national government and municipalities have established ambitious goals to reduce CO_2 emissions. In order to realise these ambitions the energy performance of the existing dwelling stock has to be improved on a large scale. To get the owner-occupiers on the move to invest in energy saving measures an important role is foreseen for local authorities. Because of these mix of reasons seven municipalities have decided to join in a research project that focusses on the question: "What is the quality of the owner-occupied sector and how can local municipalities act to improve the quality of the private owned housing stock"? This paper reports about the first findings of the research project. The paper starts in chapter 2 with a short overview of the owner-occupied housing stock. Chapter 3 elaborates on the 'problem segments' and the efforts local authorities undertake to intervene. Section 4 focuses on the overall perception on housing quality of the owner-occupier. In section 5 first conclusions are presented.

1.1 Research approach and methodology

The research project is being carried out by OTB Research Institute for the Built Environment (Delft University of Technology). Besides the seven municipalities the Dutch Stimulation Fund for Housing (SVn) and the Nicis Institute participate in the project. SVn administers funds that are provided by (local) authorities and invests (via low rented loans and revolving fund constructions) in the quality of the housing sector. The Nicis institute is the Knowledge Institute for Dutch Cities. The project focusses on the quality of the owner-occupied sector as a whole but also on the 'problem segments'.

Various research methods are used. In case studies in the seven municipalities the efficiency is explored of the policy instruments that are used to solve the quality backlogs in the 'problem segments'. Via desk research and in-depth interviews the extent of the problem and the (cost) effectiveness of the policies in each municipality are described and analysed. The interviews are being held with representatives from the municipal councils, service counters, financial organizations, Home-Owners' Associations, etc.
To get insight in the overall situation in the owner -occupied sector a general survey was recently carried in the seven municipalities. Via a multi staged sampling process owner-occupiers were in selected each municipality. A distinction was made between multi and single family dwellings and four construction periods (one pre-war and three post-war periods). Some 26.000 owner-occupiers were approached with the invitation to fill in an internet questionnaire. The questionnaire was divided in the following sections: characteristics of dwellings and occupants, perceptions of housing quality, operation of Home-owners' Associations, maintenance work and housing repairs in the recent past and near future and energy-use. Fifteen per cent of the owner-occupiers have completed the questionnaire.
With respect to contents the research project focusses solely on the situation in the Netherlands. In a later phase the results and insights will be placed in an international

 ISBN: 978-1-84219-840-7 .

perspective. Although emphasis lies on the results of the general survey, the paper touches also upon the 'problem segments' and the municipal instruments used to tackle the problems.

2 The owner-occupied sector

Table 1 gives an overview of the developments in the Dutch housing stock over the last forty years.

Table 1. Development of the housing stock by tenure (in %)

(Source: ABF Research B.V. Syswov 2011)

	1971	1980	1990	2000	2010
Owner-occupied	35,1	40,7	45,3	52,5	59,3
social rented	37,1	37,9	38,5	35,8	31,7
Private rented	27,8	21,4	16,2	11,7	9,0
Total	100,0	100,0	100,0	100,0	100,0

Until some decades ago the importance of the Dutch owner-occupied sector lagged behind those in neighbouring European countries. In the meantime this situation has changed. The last decades showed a remarkable growth of the owner-occupied housing stock. In the last forty years owner-occupation grew from some 35% up to almost 60% at present. The private rental sector declined from 28% to 9% at present. The last two decades the relative importance of the social rented sector decreased from 38% to almost 32%. The growth of the owner-occupied part was the combined result of a strong absolute as well as relative increase of new construction (the lion share of newly built housing construction has been owner–occupied) and of the selling out of rented dwellings. In the same time the production of rented dwellings dropped while demolition of social rented dwellings showed a steady increase.
There are huge local differences in ownership proportions. Especially in the larger municipalities the relative importance the owner-occupied sector is far lower than the Dutch average. In the municipalities that participate in this research project 40% to 50% of the housing stock is owned by the occupiers.

The owner-occupied sector in terms of age and dwelling type is diverse. Table 2 gives information on the age of the owner-occupied and rental housings sector in categories. The table shows that the owner-occupied stock is relatively young.
None the less - as is the case throughout Western Europe - the Dutch housing stock is ageing. After the mass construction following WW II the addition of new dwellings has now dropped to (far) less than 1% annually. Though the Dutch housing stock is still relatively young – over three-quarter of the stock was produced in the fifty years after WW II – the ageing process is continuing. In 1973 almost 60 per cent of the housing stock was less than 25 years old. In 2010 this percentage has changed to 30.

 ISBN: 978-1-84219-840-7 .

Table 2. Age of the owner-occupied stock compared with the rental housing stock (in %)

(Source: ABF Research, Syswov 2011)

	Owner-occupied stock		Rental housing stock	
	N	%	N	%
Pre war	931.906	21,9	542.347	18,6
1946-1970	902.041	21,2	1.000.519	34,3
1997-1990	1.320.973	31,0	977.691	33,5
After 1990	1.099.699	25,9	397.260	13,6
Total	4.254.619	100,0	2.917.817	100,0

The owner-occupied stock consists predominantly (85%) of single-family housing. In the rental housing stock singe-family houses and multifamily houses are represented proportionally.
Again there are important local differences. In some municipalities that participate in the research project (e.g. The Hague) a large part of the owner-occupied stock is pre-war and situated in multifamily houses. In the Netherlands owners of apartments in multifamily houses must co-operate in an Owner-Occupiers' Association. The joint owners are responsible for maintaining the physical quality of the common parts of the building (e.g. façade, roof, staircase and elevator). According to the Apartments Act and the Housing Act apartment owners in an Owner-Occupiers' Association should appoint an administrator, meet at least once a year to discuss maintenance and reserve funding for (future) maintenance and major repairs.

3 Problem segments and policy instruments

From 1901 on (the year the first Housing Act came into force) local authorities have been active guarding the quality of the owner-occupied housing stock. In the 1970's and 1980's the quality of private housing became a political issue on a national level. Especially the quality of the pre-war housing sector was a point of concern. Extensive maintenance backlogs in the owner-occupied sector were improved with government funding. Based on the Urban Renewal Act and financed by the Urban Renewal Fund large scale urban renewal projects were developed with subsidy schemes for owner-occupiers. Besides the subsidy track, some local authorities bought private dwellings and renewed them.
Since this approach proved to be successful, the (predominantly pre-war) Urban Renewal assignment was considered to be completed (MVROM, 1992), the Urban Renewal Act was withdrawn, and the Urban Renewal Fund came to an end.

Until the year 2000 the quality of the Dutch Housing stock was monitored with 5 yearly Qualitative Housing Surveys. The last survey (held in 2000) showed that the Dutch owner-occupied stock in general was in a relatively good state. This was the sign for the national government to end its active involvement in the owner-occupied housing sector. The problems were solved and the minister responsible for the housing sector explicitly pointed out that taking care of the quality is the responsibility of the owner

(MVROM, 2003 en 2006; Dekker, 2005). All the same in recent years some subsidy and VAT reduction programs have been installed to promote energetic saving measures in the owner-occupied sector. A goal often combined to support the struggling building sector in these times of economic crisis.

3.1 Problem segments

Housing quality of the owner-occupied stock also has not been on the agenda of most local authorities the last decade. In most cases this can be explained because they did or do not see the need. Others however have argued that municipalities have lost the sight on the quality of the housing stock (Goudriaan and Ten Napel, 2004). In 2005/2006 research was carried out for a broad consortium of organizations in the construction and real estate sector. They showed concern about the quality development of the privately owned housing stock and the fading governmental attention. That research has shown that - although in general the situation in the owner-occupied sector was relatively good - there were some 'problem segments' where attention is needed (Meijer and Thomsen, 2006). As this on-going project proves the need for attention has not diminished. A growing number local authorities see the need to pay attention to the quality situation in some parts of 'their' owner-occupied housing sector. Even though many local authorities miss actual and exact information about the physical housing quality, the following trouble spots can be identified.

The quality backlog is relatively great in pre-war (single-family) dwellings in smaller municipalities and in multifamily houses (built before 1945 and in the period 1945-1970) which predominantly are located in larger municipalities (Meijer and Thomsen. 2006).
The (pre-war) single family houses can be found in relative sparsely populated areas, where the economy is shrinking. In these areas the demand for owner-occupied houses is low or almost absent. Under these circumstances the current owners are not prepared - but more important often not financially able - to invest in the upkeep of their dwellings. The houses that already are in a bad state of repair deteriorate further.
The maintenance backlogs in pre-war and early post-war multifamily housing in the larger municipalities are caused by a combination of several factors. In the recent past many apartments haven been individually sold (by housing associations or private investors) to the renters. The starting quality of these dwellings was already low and most of the buyers belong to a lower-income group. To worsen things the Owner-Occupiers' Association in which the buyers should co-operate carrying out maintenance on the communal parts of the multifamily house was (and is) in most cases not functioning. This means: no co-operation, no proper communal management, no meetings to plan future maintenance and no reserve fund for common repairs and maintenance.
These two segments need attention in terms of improving the physical quality. The strong increase in the percentage of elder people could influence the maintenance quality of the Dutch owner-occupied stock in the near future on a more general level. In general the population is getting older and owner-occupiers stay far longer in their dwellings. These occupants are reluctant or find it more and more difficult to invest in the maintenance of their dwelling. The current economic crises could also have a negative effect. The value of owner-occupied housing is declining and average incomes

are falling off. This makes is it not attractive (or sometimes impossible) to invest in the dwelling.

As mentioned briefly before in section 1 the national government and municipalities have established ambitious goals to improve the energy performance of the Dutch housing sector. In the owner-occupied sector the potential for energy saving is huge (Meijer et al, 2009). More than 60% of the owner-occupiers believe that it is quite feasible to lower the energy use (either by taking measures or by changing behaviour). Around 25% up to 30% has the opinion that more energy saving is not possible and the remaining 10% has no idea.

Of an entirely different order are problems with rotten wooden pile foundations. An estimated 750,000 dwellings (especially in the western parts) in the Netherlands are built on a wooden pile foundation. The number of residential buildings with (hidden or acute) foundation problems has been estimated at about 200,000 up to 250,000. This could be doubled in in the coming decades if no adequate measures are taken. At least half of these will have to be provided with a new foundation. The repair costs vary from € 45,000 up to € 60,000. Many owner-occupiers face (and probably will face) this problem. These are expenses they can impossibly afford. Help and support (from authorities and or housing associations) is needed to tackle the problems.

3.2 Policy instruments

On a national level some regulatory steps have been taken special aimed at owner-occupied multifamily housing. In 2008 the Apartment Act has been changed and from that time on Owner-Occupiers' Associations are statutory obliged to have a maintenance fund. When an apartment is sold it is obligatory to provide information about outstanding balances (from the other owners) and current contents of the maintenance fund. No legal arrangements have been made about the height of the fund or planning of major repairs. In 2011 the Housing Act has been changed in order to give municipalities the power to act to activate non-functioning Owner-Occupiers' Association. In the case of imminent major maintenance backlogs it is possible for local authorities to intervene.

To stimulate energy saving measures in the built environment the covenant More with Less has been negotiated between the government and stakeholders in the construction industry and both the social as owner-occupied housing sector (2008/2009). One of the instruments is that owner-occupiers could get subsidy to determine the energetic performance of a dwelling and the measures that could be taken to better the situation. This subsidy program has stopped in 2011.

In the meantime more and more local authorities have developed specific instruments to tackle the problems as mentioned above. In some cases the instruments are specifically aimed at Owner-Occupiers' Association Act and in other cases on certain types of repair (e.g. the façade or energy saving measures). In many cases local authorities aim at combined results. For instance when foundations are being replaced or restored it is also logical to take measurements to improve the energy performance (e.g. insulating the ground floor). The case study research that is being carried out in this project analyses the effectiveness and efficiency of the instruments local authorities have brought into action. In general these instruments are aimed at stimulating the owners through

communication and financial incentives. The overall effectiveness and efficiency of these instruments seems to be rather low. Local authorities invest relatively large financial and personal efforts whereas the yields are low. In depth analyses of the results will in the near future be reported in separate papers and articles.
In the next chapter the 'problem segments' are left behind and attention will be paid to the situation in the owner-occupied sector in general.

4 Home-owners and the quality of their dwellings: overall view

This section presents the first results of the survey that has been carried out in this project. The survey was conducted (end of last/beginning this year) under owner-occupiers in the seven participating municipalities. In total almost 3.800 questionnaires were returned.

4.1 Considerations in advance

The results presented in this chapter are based on a work in progress. These general results so far have been presented only to the local authorities. The data is representative on a municipal level; no further breakdowns (building age and housing type) have been published yet. The data sketch a good overall picture of the situation in the seven municipalities as with respect to the way owner-occupiers are dealing with the (physical) quality of their dwellings. The results are comparable in the seven municipalities. The data presented were gathered in The Hague.

Another consideration to be made is the representativeness of the home-owners that have participated in the survey. Owners that participate in this kind of research are relatively more enthusiastic and satisfied by the importance of such kind of research. First analyses (on the available data on a national level) has shown that the average respondent is higher educated than the average Dutchman. The income level however seems not to deviate from the average income level of the Dutch home-owner. In order to be able to draw more conclusions about the representativeness of the owners that have participated, comparisons with municipal data should be made. In many cases however it is questionable if there is reliable data available about the personal characteristics of home-owners on a municipal level.

4.2 Perception of quality

The home-owners were asked to assess the quality of their dwellings and neighbourhood. This section deals with the quality assessments of the owners themselves. No physical inspections (by a professional) of the dwellings were held. This could produce a biased picture. The judgment of an owner results does not always corresponds with the actual state of repair.
Three quality aspects are taken into account:

- State of repair of the outside (exterior) and inside of the dwelling.
- Ease of use and comfort of the dwelling.
- Living conditions (residential area).

Each of these three aspects is divided in subcomponents. Figure 1 gives an illustration of the assessments of the outside of the dwelling.

 ISBN: 978-1-84219-840-7 .

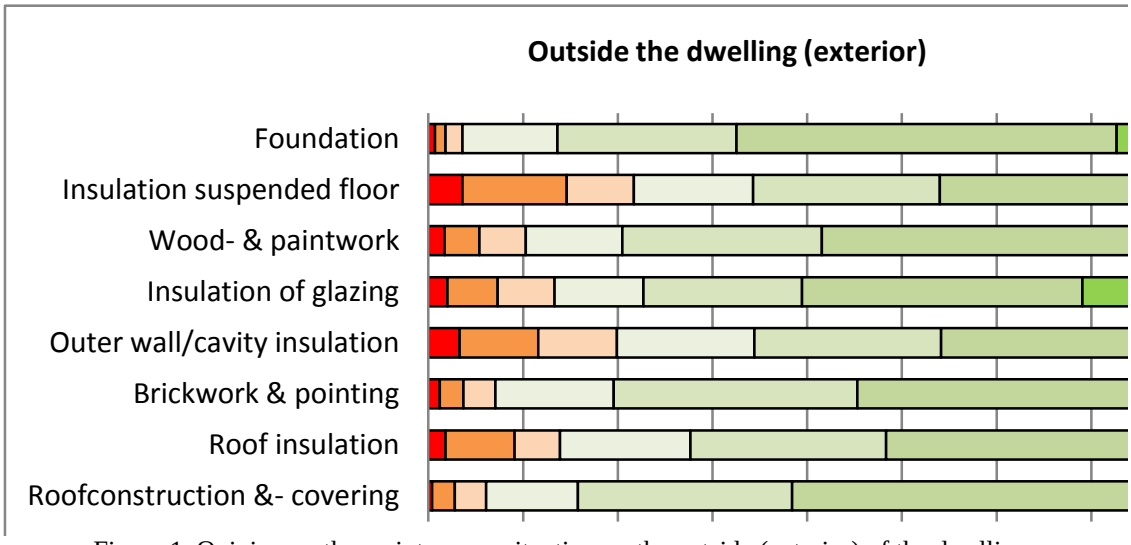

Figure 1. Opinion on the maintenance situation on the outside (exterior) of the dwelling
1-2 = bad 3 -4 unsatisfactory 5 = almost satisfactory
6 -7 satisfactory 8 -9 good 10 = excellent

Most owner-occupiers are satisfied with the exterior of their dwelling. More than half of them asses the state of repair as being good up to even excellent. Components that score relatively low are the insulation of the dwelling. Roughly 20% of the owners consider the insulation level - especially of the ground floor and outer wall – as unsatisfactory.
To a large extent these correspond with 'national' data: 83% of all Dutch households (fully) disagree with the proposition *"my dwelling is in a bad state of repair"* (AFB Research, 2010). These 83% include households that rent. This group could have influenced the results in a negative way. The fact that there are insulation backlogs (especially with respect to the ground floor and façade) is also backed by data gathered on a national level (Meijer, et al, 2009).

As figure 2 shows home-owners are even more satisfied with the inside of their dwelling than with the outside components.

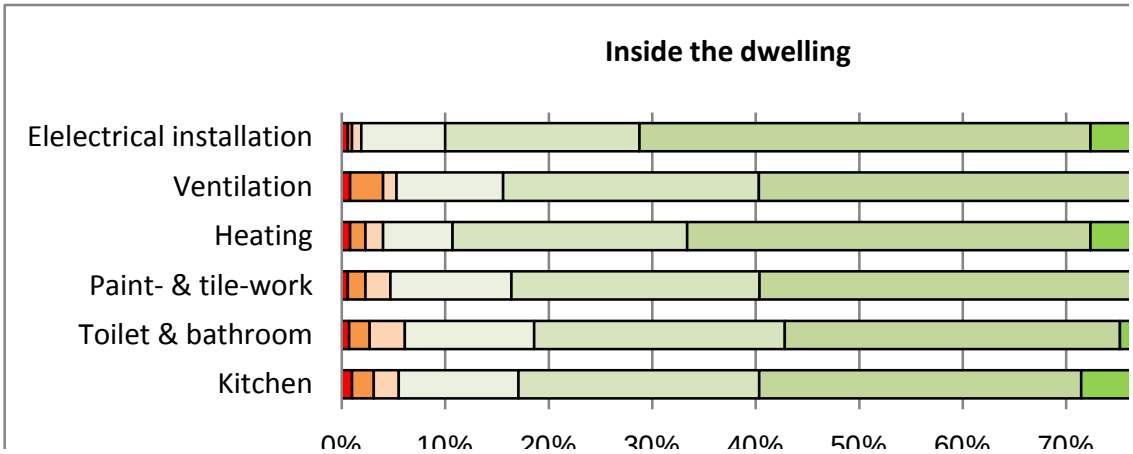

Figure 2. Opinion on the maintenance situation inside the dwelling
1-2 = bad 3 -4 unsatisfactory 5 = almost satisfactory
6 -7 satisfactory 8 -9 good 10 = excellent

 ISBN: 978-1-84219-840-7 .

The overall judgement of the owners is good up to excellent. Less than five per cent of the home-owners is dissatisfied with some components inside their dwelling. This is in accordance with other data that is gathered on a national level: 97% of the Dutch home-owners are (very) satisfied with their dwellings (AFB Research, 2010).
The ease of use and comfort is also being considered as 'good'. Especially size and lay out of the dwelling prove to be (quite) satisfactory. Only the insulation aspects (see also figure 1) have in general a relatively less good score.

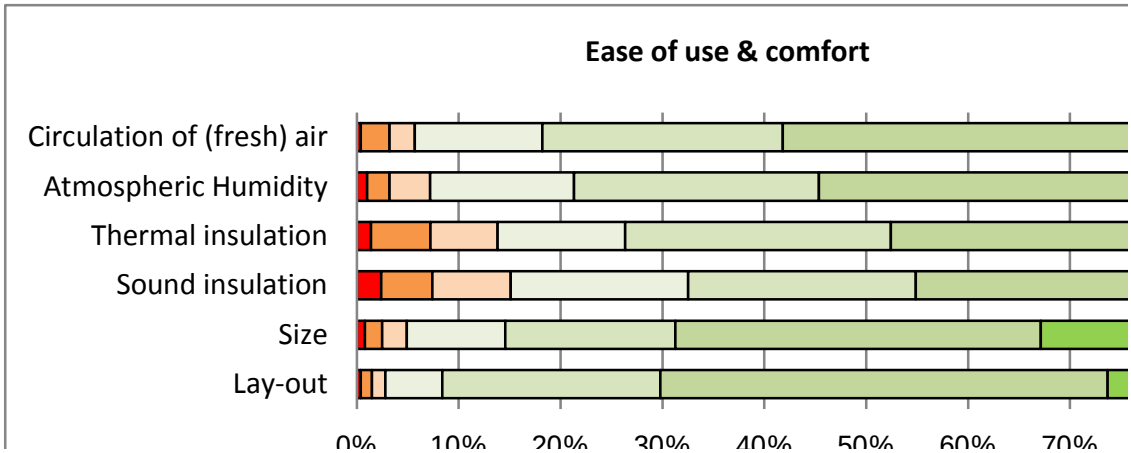

Figure 3. Opinion on ease of use and comfort of the dwelling

1-2 = bad 3 -4 unsatisfactory 5 = almost satisfactory
6 -7 satisfactory 8 -9 good 10 = excellent

The National Housing Survey (AFB Research, 2010) shows that 86% of all households (fully) agree with the proposition; *"the lay-out of my dwelling is OK"*. Other relevant outcomes are

- *"My dwelling is too small"*: eighty per cent of all households (totally) disagree.
- *"My dwelling is too large"*: almost three quarter of all households(totally) disagrees

Figure 4 shows how owner-occupiers consider the living conditions in their direct environment (street and neighbourhood).

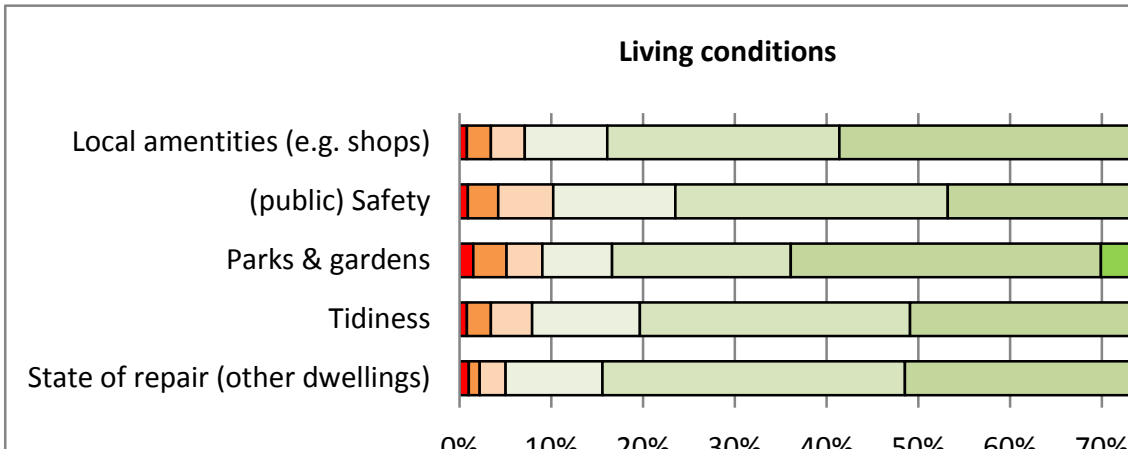

Figure 4. Opinion on living conditions

1-2 = bad 3 -4 unsatisfactory 5 = almost satisfactory
6 -7 satisfactory 8 -9 good 10 = excellent

 ISBN: 978-1-84219-840-7 .

The lion share of the home-owners is satisfied with their direct living environment. Nonetheless some 10% consider the (public) safety, green space and tidiness as being insufficient.
In the Netherlands as a whole around six per cent of all households is (very) unsatisfied with their direct environment (AFB Research, 2010).

The overall picture that emerges from the data presented in the figures 1 through 4 is that owner-occupiers in general are (very) satisfied with their dwelling.

4.3 Maintenance and repair activities

The average home-owner appears to be quite active maintaining their dwelling. Maintenance activities have been carried out in more than three quarters of the dwellings (over a period of 2 years). The most important reason for owners who have not done anything is because it was not necessary (see figure 5).

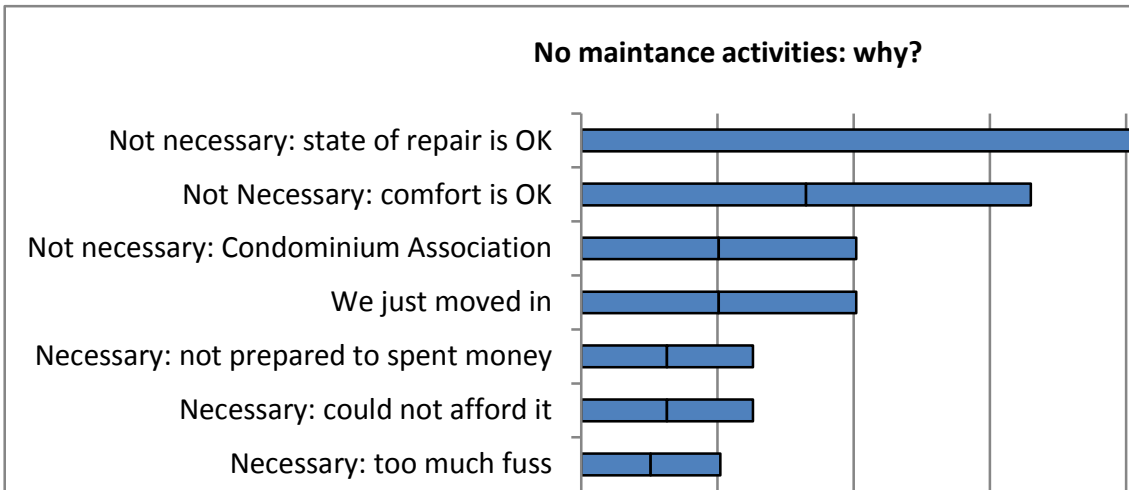

Figure 5. Reasons why no maintenance activities have been carried out the last 2 years

The reason most mentioned is that the state of repair of the dwelling is in order. In some 10% of the cases the Owner-Occupiers' Association deemed it not necessary to carry out maintenances jobs. In relatively few dwellings (5% to 7%) necessary maintenance has not been carried out because a lack of money or skills.

In the questionnaire a distinction was made between three groups of maintenance (or repair) activities:

- Work on the outside (or exterior) the dwelling (e.g. repair of roof or outer wall; wood- or repaint work).
- Work on the inside of the dwelling (e.g. repair or replacement of kitchen, toilet or bathroom, repaint- or retile-work).
- Installation/insulation work (e.g. replacement of the boiler. insulation of roof, glazing, floor or wall).

Figure 6 illustrates that work on the exterior of the dwelling has had priority during the last two years.

 ISBN: 978-1-84219-840-7 .

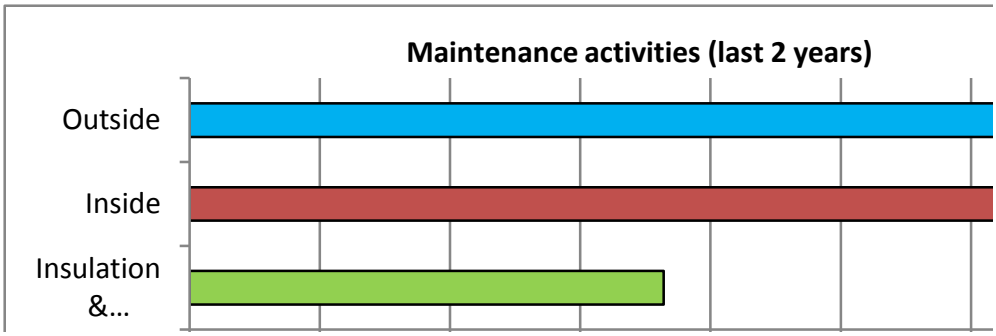

Figure 6. Maintenance activities (categorized) that have been carried out the last 2 years

Three-quarter of the owner-occupiers that have carried out maintenance work did some jobs on the exterior of the dwelling. Particularly the paint and woodwork on the outside has been repaired (done by 70%). Another thirty per cent of the owner-occupiers has repaired their roof-covering (construction) and/or gutters and drainpipes.
Although a lot of work has also been done inside the dwelling, the percentage of home-owners that paid attention to the inside is a bit lower than those who worked on the exterior of the dwelling. Of the owner-occupiers who made repairs inside the dwelling:

- Around seventy per cent did paint, (re)paper and or tile jobs.
- Some 35% repaired, improved or replaced their toilet and or bathroom.
- Followed by 25% who did some work on their kitchen.

Comparatively the least attention has gone to work on installations and/or insulation. Two thirds of the people who did some work inside the dwelling replaced their central heating boiler. About 20% of the owners made improvements on the insulation of their glazing and roof. The extent of these improvements is not known. Hardly any owner-occupier (less than 1%) has installed a renewable energy source in their dwelling during the last 2 years (e.g., solar panels or a heat pump).

The main reasons to carry out repair and maintenance jobs are sketched in figure 7. Logically, the reasons differ per category.

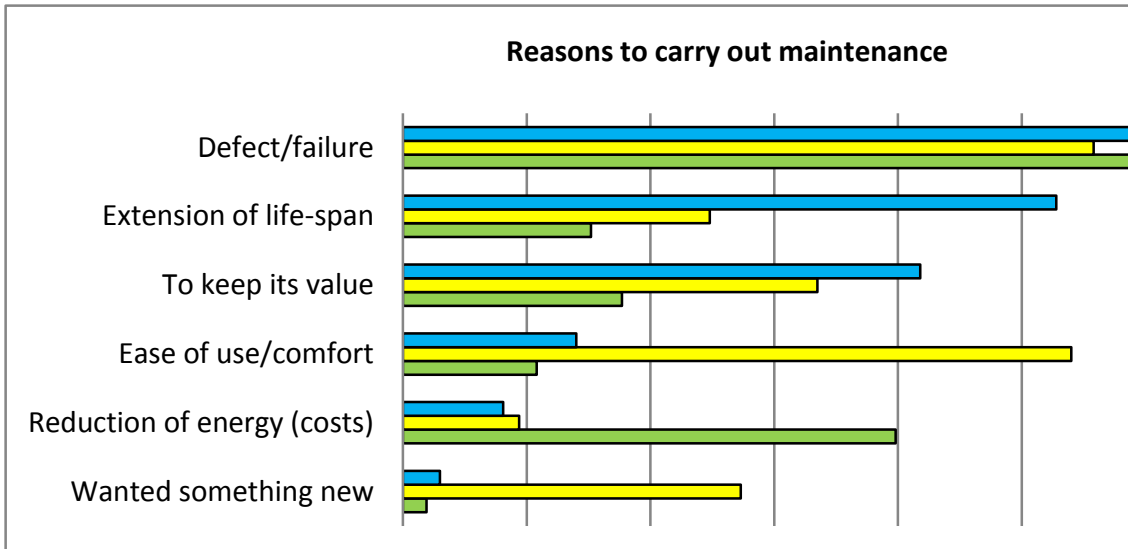

Figure 7. Reasons to carry out maintenance and repairs (in categories)

For all three categories of maintenance jobs the fact that the building component failed or was defect has been the most important reason to undertake action. Additional reasons to carry out maintenance on the exterior of the dwelling are to prolong the lifespan and to keep the value of the dwelling. 'Inside jobs' are carried out to enlarge the ease of use and the comfort of the dwelling. Insulation- or installation work is done in order to reduce the energy use of the household (and subsequently lower the energy bill).

4.4 Investments

The data about investments (per job and category) is still being analysed. Other recent research shows (see table 3) that an average home-owner invests € 4,760 in his/her dwelling on an annual basis (Vereniging Eigen Huis, 2011).

Table 3. Annual expenditure of an average homeowner on maintenance and improvements (in €)

(Source: Vereniging Eigen Huis, 2011)

	Average expenditure on an annual basis in €
Regular maintenance	2,022
Major repairs	1,740
Improvements	996
Total	**4,758 (= 397 a month)**

Regular maintenance: e.g. painting, garden maintenance, maintenance central heating boiler, small reparations on the roof, replacement of a faucet.
Major repairs: e.g. replacement of roof gutter, replacement of boiler, replacement of roof topping, replacement of electrical installation.
Improvements: e.g. placing of double glazing, floor- or roof insulation, dormer, construction of a carport.

On the basis of the Dutch Real Estate Appraisal Act it can be calculated that an average owner-occupied house has a value of € 263,000. Every year an average owner-occupier invests almost € 4,800 in his dwelling. This accounts for more than 1.8% of the average value. A little more than € 2,000 is invested in regular maintenance. These repairs (and their costs) are recurring on a frequent basis. In major repairs an amount of well over € 1,770 is yearly invested on average. Relatively the smallest amount (€ 1,000) is spent on improvements on the dwelling (Vereniging Eigen Huis, 2011).

The current research project shows that a small minority of the owners (less than 10%) lends money to pay for the expenses for repair and management of the dwelling. In these cases the mortgage on the dwelling is raised and/or surplus value is used.
The vast minority pays with their own money (savings). In the case of multifamily housing a relative important part of the maintenance and repair cost on the exterior of the building is paid from the maintenance fund of the Owner-occupiers' Association. Ideally the apartment owners add money to this fund on a monthly basis.

4.5 Need for advice and information

In the last two years a little more than half of the owner-occupiers have had some support or advice with the maintenance of their dwelling. From those who have had support or searched for advice and information roughly 40% to 50% needed more information on:

 ISBN: 978-1-84219-840-7 .

- How the repairs could be carried out.
- How a reliable builder/constructor could be found.
- How to determine the costs of the repairs.

Remarkably often (in around two thirds of the cases) a construction or maintenance firm has been asked for advice and information. It is possible that these owner-occupiers have called in these constructors to carry out the job. In most other cases (around 40%) the owner-occupiers have used family/friends and/or the internet as a source of information. In less than 5% the local authorities have been asked for information and advice.

Asked for the need of support and advice in the near future a little less than 50% of the owner-occupiers say they (probably) need information and advice. This is roughly the same percentage as in the last 2 years. The determination of costs and finding a building or construction firm are here also the highest scoring subjects (see figure 8).

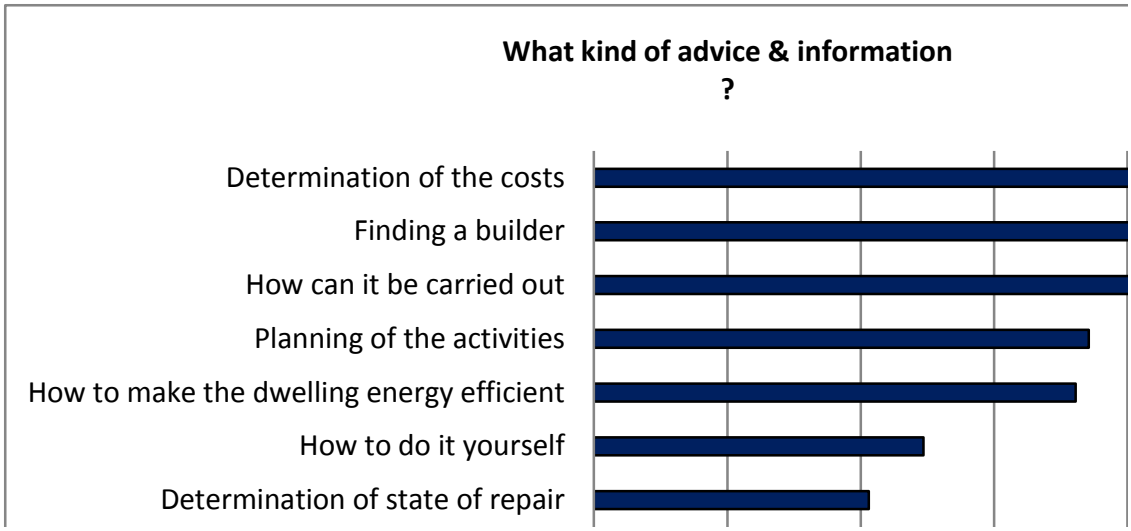

Figure 8. On what subjects advice and support is needed in the future?

The internet and construction firms are named by some two thirds of the owners as the source they would like to get their information from (figure 8). Around 50% of the home-owners will ask their family and friends for help. A quarter of the owners mention the local authority as the place they would like to go for information and support. Compared with what they actually have done in the recent past this percentage is remarkably high

 ISBN: 978-1-84219-840-7 .

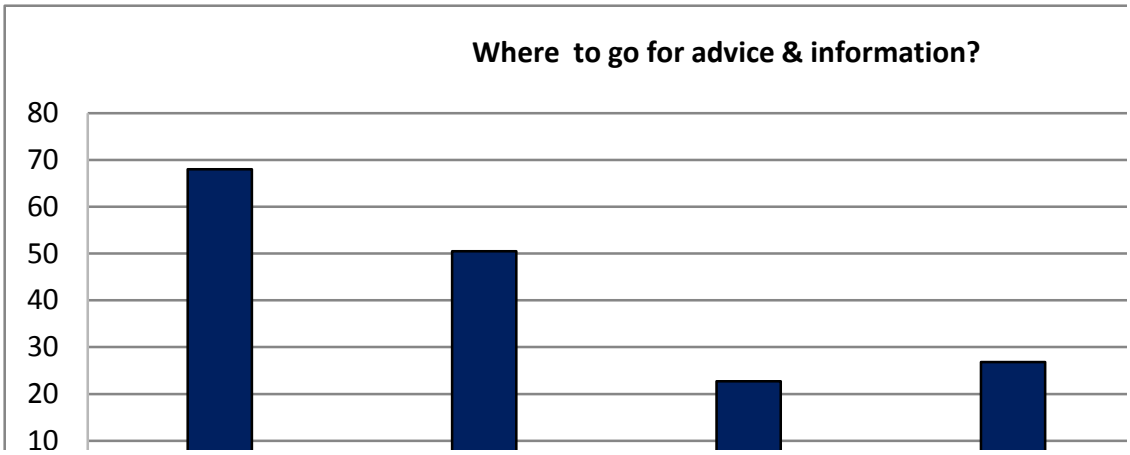

Figure 9: Where to get advice and information?

5 Conclusion

The last decades the owner-occupied stock has undergone a notable growth. From the 1980's on owner-occupation grew from some 40% up to 60% at present. The private rental sector declined from 21% to 9% at present. The growth of the owner-occupied sector can be explained by a substantial growth through new construction and by the selling out of private and social rented dwellings. The national government has made propositions to sell out large numbers of social rented dwellings in the near future. A further growth of the owner-occupied sector can be expected.
The local differences of the owner-occupied sector (in terms of size, age and housing type) are vast. In the larger municipal areas the relative importance the owner-occupied sector is far lower than the Dutch average. In these larger municipalities multifamily housing also has a larger relative significance.
Although the owner-occupied stock is still young, the ageing process is continuing rapidly. Relatively few owner-occupied dwellings have been built the last decade. When existing social rented dwellings are going to be sold out in vast numbers this ageing process will be accelerated. As a relative large part of social rented dwellings is located in multifamily housing, this will also influence the characteristics of the owner-occupied sector. At this moment more than 85% of owner occupiers live in single family houses.

The average Dutch home-owner is quite satisfied with his dwelling. The vast majority of owner-occupiers award their dwelling with satisfactory up to excellent marks. This applies as well to state of repair of the exterior and interior of the dwelling, the ease of use and comfort of the dwelling as the living conditions (residential area). This appraisal is based on the owners own opinion. The actual situation (especially with regard to the state of repair) could be different.
Owner-occupiers are quite active maintaining their dwellings. Only a small fraction of the owner-occupiers indicate that although (major) repairs or maintenance activities were necessary, nothing has been done. The lion share of owner-occupiers seems to maintain their dwellings in an adequate way. The most efforts are aimed at the exterior of the dwelling (especially exterior paint- and woodwork). A lot of work is also done inside the house (repainting, repapering and retiling and improvements of toilets,

bathrooms and kitchens). Installation and insulation jobs occur relatively the least. In most cases the central heating boiler is being replaced.
The most important reason to carry out maintenance work (and this applies to all three repair categories that have been distinguished) is because the building component was worn-out or had broken down. Other important reasons to repair the exterior of the dwelling is prolonging its lifespan and increasing its value. Work inside the dwelling is further predominantly done to increase ease of use and comfort. Reduction of energy use is an important additional reason for carrying out installation and insulation work.
On average a Dutch home-owner spends almost € 4,800 annually to maintain, repair and improve his dwelling. Compared with the average value of an owner-occupied dwelling (€ 263.000) this is quite a substantial expenditure.

In general owner-occupiers seem perfectly able to maintain their properties in an adequate manner without any help. Via communication instruments and partly (if available) subsidy and financial instruments some of these owners can be guided and stimulated.
The overall quality condition of the owner-occupied stock is as such not a convincing reason for the introduction of generic instruments and incentives. Nonetheless there are some 'problem' segments that may need attention from authorities. For these segments special dedicated instruments for quality improvement in the owner –occupied sector could be advocated and already have been developed.
With respect of maintenance backlogs a worrying situation can be identified in some parts of pre-war (single-family) dwellings in smaller municipalities and in multifamily houses (built before 1945 and between 1945-1970) which predominantly are located in some urban areas of larger municipalities. Current (communicative and financial) instruments are now being analysed in case study research. This could lead to a further sharpening and adaption of these instruments. It could also be wise to back these instruments up with some regulatory force. Local authorities have the possibility to intervene in non-functioning Owner-Occupiers' Associations with major repair backlogs. It is feasible that this is broadened to other parts of the owner-occupied stock. This should be done under the express conditions that this regulatory intervention is confined to a certain space (specific area) and time period. Besides that intervention should be based on a firm democratic foundation based on a univocal cost-benefit analysis.

Main goal for the future is – under the principle that prevention is better than cure - to take care that that current quality backlogs do not spread further. A final aspect to consider here is that social rented dwellings should not be sold out without conditions Demands should be made on minimum quality levels before sale, the selling process and (the organization of) maintenance after sale.

REVIEW AND ANALYSIS OF THE RESIDENTIAL BUILDING CERTIFICATION PROCESS IN SOUTH EAST QUEENSLAND

Ben Smith[1], Geoff Mitchell[2] and Jim Smith[3]

[1,2]*GMA Certification P/L, Gold Coast and Sunshine Coast, Queensland, Australia.*

[3]*Institute of Sustainable Development& Architecture, Bond University, Gold Coast, Queensland, Australia.*

ABSTRACT

In Australia, building certifiers ensure that building projects are constructed to required standards as specified in the building regulations. The certification process involves the assessment of the building and design documentation for compliance before the building work commences and then verifies that the work is carried out in accordance with the approved plans. In Queensland building certifiers are accredited and licensed by the Building Services Authority (BSA). Inspections for building work can also be carried out by a local council building certifier, but many councils now permit owners and builders to employ their own private certifiers. The building certifier inspects the project during progress of the work and can give directions, issue permits, notices and orders as required ensuring compliance. Owners and builders employ building certifiers, often as private certifiers to give their advice on their proposed projects. The four stages of approval stages of building certification are described. A sample of the inspection and certification records of 109 houses in South-East Queensland and analyses their progress through each of the stages. The incidence of minor faults and failures are examined together with requests for further information. Trends in these incidents are enumerated, described and analysed with a view to improving the process.

Keywords: building certification, faults, residential buildings

INTRODUCTION

The private building certification system was established in 1998 in Queensland following the lead of the state of Victoria, which established the system in the Building Act 1993 (State Government of Victoria, 1993). With nearly 15 years of experience of private building certification it is now well established as part of the building approvals environment in Queensland. The task previously carried out by local government building departments is now the responsibility of private certifiers.

Building certifiers ensure that building projects are constructed to required standards as specified in the building regulations. The certification process involves the assessment of the building and design documentation for compliance before the building work commences and then verifies that the work is carried out in accordance with the approved plans. The building certifier inspects the project during progress of the work and can give directions, issue permits, notices and orders as required ensuring compliance. Owners and builders employ building certifiers, often as private certifiers to give their advice on their proposed projects. If regulations are breached building certifiers may issue notices and orders through the local council and when required they may prepare reports and provide evidence as expert witnesses in court cases. The aim of this preliminary study was to quantify the number and extent of the referrals and failures in the building certification process and to ascertain whether the private certification was working satisfactorily.

THE BUILDING APPROVALS PROCESS

Discussions before the *approvals stage* are known as the consultation stage and are aimed towards compliance with relevant legislation, local authority requirements and any other extraneous issues that should be addressed by the applicant before formally lodging the works. During these discussions the building certifier will try to focus on the client's questions and endeavour to answer all the questions as accurately as possible. Accuracy of the information given to the client at this stage is of utmost importance and is essential as this will allow for better progress with future processes once a formal applicant is lodged with the office. The building approvals process is summarised in a flowchart in Figure 1.

After the final administration checks have been completed (Consultation and Review in Figure 1) the actual building approval can be finally issued. Once issued the document explains to the applicant all the specific and standard conditions the certifier has applied to the application to highlight what the construction will need to comply with – these conditions could be viewed as "guidelines" for the applicant to keep be aware of during the life of the building approval.

For instance a standard slab on ground, brick veneer, timber or steel framed dwelling has 5 inspections that are required by the Standard Building Regulation 1993 (Government of Queensland, 1993). These stages are:

1. Site – inspection of the applicable site to ascertain everything matches the approved plans and that no services may be located in a different position to the council plans. A land surveyor may have also positioned the dwelling's footprint to ascertain setback distances at this stage.

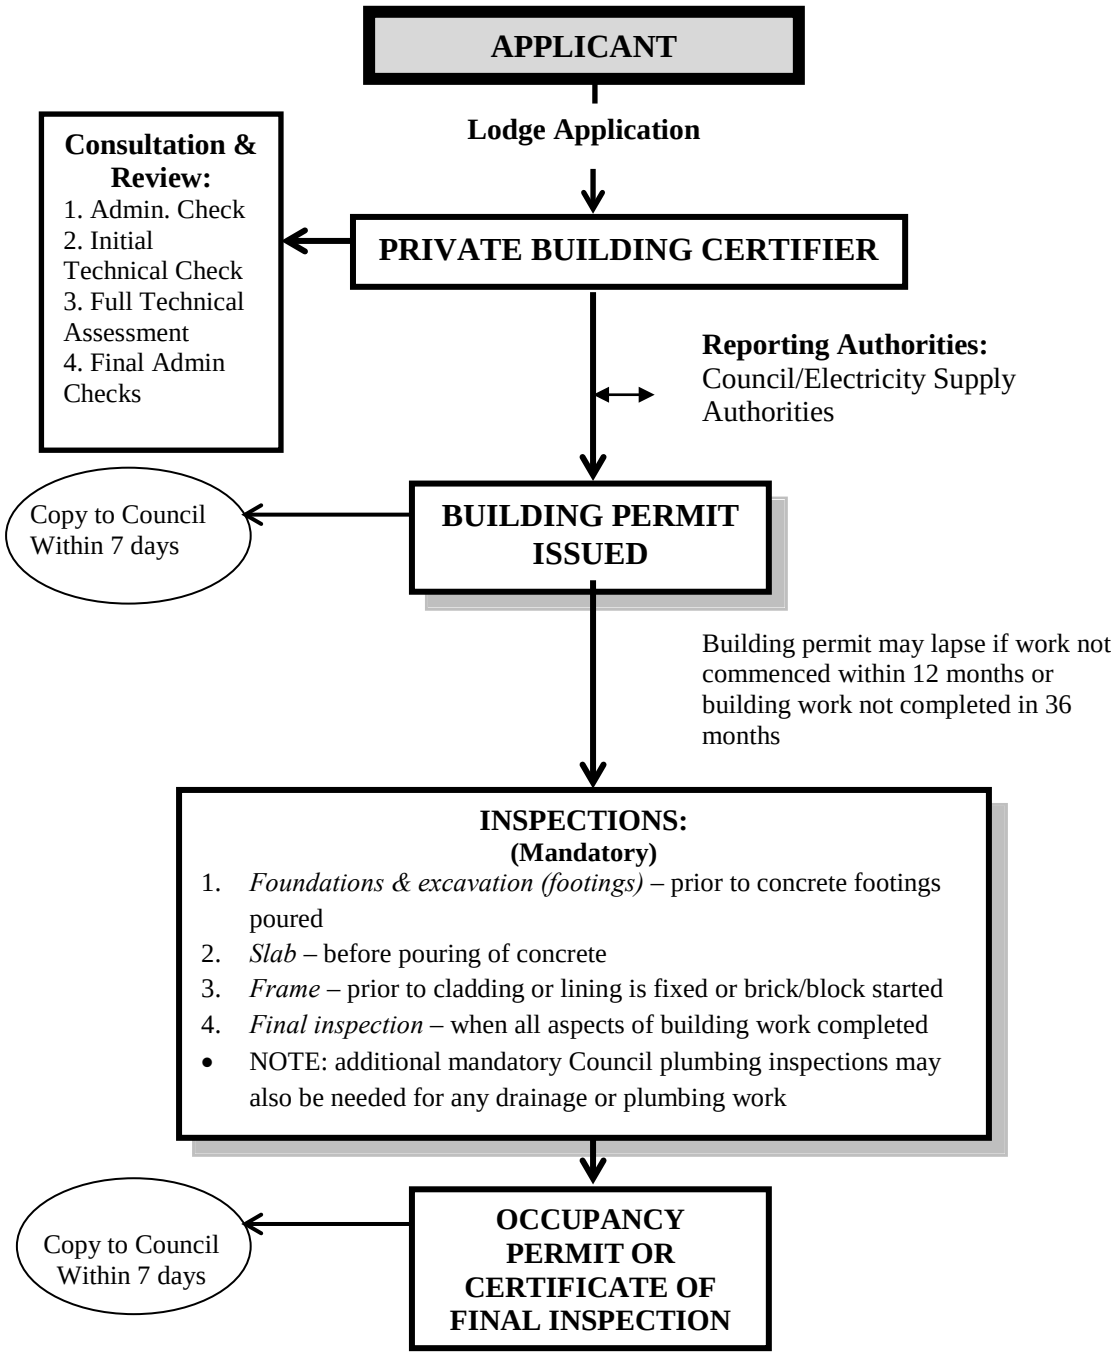
2. Footing – this is an inspection of the excavations, which will support the dwelling. Sometimes this inspection includes checking reinforcement. This inspection occurs before concrete is poured to confirm sizes/depths of footings and reinforcement spacing and size.

3. Slab – similar to the footing inspection stage, the slab stage is done after the footings have been poured. Aspects of this stage include checking the reinforcement, plastic membrane installation, compaction of soil/sand and also any lagging to horizontal plumbing penetrations.

 ISBN: 978-1-84219-840-7.

4. Frame – the framework will either be assessed against the Standards Australia (2010) *Australian Standard AS1684.2-2010 – Residential Timber Framed Construction* or an engineer's design for timber and or steel. General inspection items are tie-downs, bracing, structural member sizes and also truss installation.

Figure 1 Building Permit Process and Inspection Stages



5. Final – the last of the required inspection stages will have differing aspects to inspect depending on the design of the dwelling. Items that are usually inspected closely are termite protection, weather and vermin proofing, smoke alarms, stairs/balustrading, wet areas and even site drainage.

Lastly, the building approval decision notice contains advice for all the applicants on their appeal rights against the building certifier's conditions contained within the decision notice. The applicant has 20 business days to lodge an appeal with the Building and Development Dispute Resolution Committee, who notify the relevant certifier if this occurs. If the applicant fails to lodge an appeal with the Committee within 20 business days the conditions of the decision notice are deemed accepted.

METHODOLOGY

Access to a private certifier's inspection data base was given to the authors and 109 houses were randomly selected from the data base based on the year 2010. The first 109 new houses were selected from the list of all houses. All the houses were built in south-east Queensland from the Gold Coast and the Brisbane region. This was the area covered by the private certifier. The full range of inspections was conducted to completion. The records of each house inspection at each of the stages were examined with the detailed notes of each inspection reviewed and analysed. The inspector's notes were often extensive and detailed and the authors condensed these down into the main causes of problems in approval for that stage. The localities, builders (or owners), values of work were as random as well as the selection of houses.

Inspections reviewed were 4 in total; footings, slab, frame and final.

Incidents recorded and tagged in database were summarised and coded as follows:

a) RFI = *Requests for Information* from the builder before a final decision is made.

b) P = *Pass* (the inspection confirms the work is in accordance with code and other documents.

c) M = *Minor problem*. Approval not given for minor infringement to documents and/or code.

d) F = *Fail*. Inspection shows work cannot be approved unless rectification work carried out.

DATA ANALYSIS

Requests for Information (RFI)

Of the 109 buildings in total, 55 buildings (50.5%) required a RFI at some stage in the approvals process. RFIs are related to minor faults and fails where more information is needed, with most occurring at the final approvals stage.

Minor Faults

A summary of the total number of the minor faults at each stage is shown in Table 1. The final two stages, Frame (3) and Final Inspection generated the largest number of minor faults. Some houses had multiple incidents of minor faults.

Table 1 Minor Faults at Each Inspection Stage

STAGE	1. Footing	2. Slab	3. Frame	4. Final
No. Incidents	4	3	49	56
% Total Houses Affected	3.70	2.80	45.00	51.40

Footings

Only 4 recorded incidents on footings inspections were noted. These were in the minor (m) category and these only represent 3.7% of the total sample of 109.

Slab

A total of 3 minor incidents were recorded over the whole sample. This is 2.8% of the total sample.

Frame

49 minor incidents were recorded. This represents 45.0% of the total number of houses inspected. In addition, there were 3 instances (2.8%) of a failed inspections (f/re=p or m) with a resubmission (re). The results show that 2 of the 3 instances resulted in a pass (p) and the remaining one still had a minor fault (m). This one eventually passed.

Final

The results show that 89 of the sampled houses (51.4%) had minor faults when the inspection took place. Again, 3 houses (2.8%) had initial failed inspections (f/re=p or m) and required a resubmission. One of the resubmissions passed and the remaining two had minor faults needing rectification, but they eventually passed.

Overall

All 109 houses passed all their inspections.

REQUESTS FOR INFORMATION (RFI)

As noted earlier around half of the 109 buildings required a RFI at some stage in the approvals process. These RFIs consisted of the following types of information:

(a) Missing builders insurance and portable long service leave payment.

(b) Building's design does not comply with BCA or Australian Standards.

(c) Missing Engineering plans for all structural members including Engineer's Certification.

(d) Further Development Applications required – planning approvals, plumbing approvals, landscape approvals and operational works approvals.

(e) Various miscellaneous not catgeorised

CAUSES OF MINOR FAULTS

Analysis of the inspection records show that the major causes of problems at each stage can be summarised.

Footings

Of the 3 instances of minor faults the causes were as follows:

(a) The builder built within 1.5m of sewer line.

(b) Concretor had not installed second layer of mesh as per engineer design.

(c) Sediment barrier required to rear of property for stormwater control.

 ISBN: 978-1-84219-840-7 .

Slab

The 3 instances of minor faults are:

(a) Rain had filled footings; no termite barrier installed; missing formwork.

(b) Provide missing bar chairs for support & concrete cover as per approved engineers design (see photograph 1 below).

(c) Missing reinforcement at corners of slab & "Z bars" required as per engineers design

Frame

Of the 49 instances of minor faults the major causes can be categorised as follows:

Most of the framing issues all have a common theme for the minor issues and these are highlighted below. Some houses also have multiple items and these have been documented in the inspection reports for each house with minor faults:

a) Incorrect installation of bracing or missing bracing (90% of the houses with minor faults).

b) Tie down not adequate or incorrectly installed for the site (90%).

c) Trusses damaged or incorrectly installed (not as per truss layout(20%)

d) Incorrect timber sizes and incorrect stress grade for intended purpose(15%)

e) Miscellaneous items – smaller issues eg. No internal wall brackets or poor workmanship (<10%)

Final

Of the 89 instances of minor faults the major causes categories were as follows:

(a) Healthy and Safety issues - missing smoke alarms, missing balustrading (90%)

(b) Issues with installation or absence of the termite barrier installation (90%)

(c) Wet Areas were not complete (30%)

(d) Missing termite stickers – Queensland requires one in meter box and one under kitchen sink.(30%)

(e) Site drainage – incorrect fall away from the dwelling. This is often due to the landscaping being done at a later date(20%).

(f) Miscellaneous (<10%)

CAUSES OF FAILED INSPECTIONS

Analysis of the inspection records show that 6 properties failed inspections at the frame and final stages. These are now described for each stage.

Frame

Of the 3 instances of failed inspections the causes were as follows:

(a) Steel frame - missing screws at truss connections, missing screws at truss tie down points, roofing bracing to be correctly installed as per truss layout, tie down rods not tensioned and trusses to be installed as per engineer's detail.

(b) Diagonal bracing members not fixed as per approved plans to wall framing, rafters require tie down as per approved tie down plans and lintel fixing to wall frame not readily apparent, please identify method of fixing.

(c) Steel frame not installed as per manufacturer's design, "K" braces require bolts to corners of brace as per manufacturer's detail. The jack truss/truncated truss connection requires two screws as per truss layout, internal load bearing walls require tie down with brackets as detailed in manufacturer's manual.

Two of the instances involve missing screws and bolts, which points to a lack of attention to detail and possibly a lapse in supervision and quality control in these two areas. The third fault was lack of attention to the approved plans and not providing the required tie down requirements for the truss and fixing to the walls. Whilst none of these faults are serious they are sufficient for the inspector to not give approval.

Final

The 3 instances of failed inspections were:

(a) Seal all articulation joints. Ground levels are required to slope away from the dwelling, stormwater field gullies need to be connected to stormwater system. Patio not installed as per approved plans including stormwater system. Steps externally should not to exceed 190mm as per BCA volume 2. Stormwater must be connected to kerb discharge point and weep holes near gas cylinders should be unblocked.

(b) Dwelling located in a bushfire prone area – dwelling construction does not comply with AS3959-2009 Construction of Buildings in Bushfire Prone Areas for Bushfire Attack Level 12.5.

(c) No access to internal parts of dwelling and owner un-contactable.

CONCLUSION

Incidents and problems in certification come from two major sources. The number of Requests for Information (RFIs) and minor faults or problems are in most cases easily fixed and do not cause any major delay in the approvals system. The number of RFIs affected around 50% of the surveyed houses in the 109 sample. Their cause is mainly due to lack of information or missing paperwork. The incidence of minor faults is more pervasive. They rarely occur during the first 2 inspection stages (footings and slab) and they are more prevalent during the final 2 stages of inspection and approval (frame and final).

Explanations for this can be suggested from the experience of the authorS. The first two stages are crucial for the builder and for the engineering requirements and they must be correct. Failure to ensure full compliance with errors of detail, material or problems of construction can be expensive and time consuming. For instance, if the footings or slab does not comply with the drawings, specification or the Code it will probably entail removal of concrete, reinforcement and additional excavations. The

footings or slab may have to be removed and a new one complying would have to be laid.

The next stage, frame, consists of more materials, on site operations and activities providing the possibility of non-compliance. This is borne out by the statistics from the 109 houses. 49 Houses or 45% of the total sample have minor defects to be rectified before approval. These defects can often be rectified quite quickly and easily and their consequences are not as great as for the footings and slab.

The final stage has created the most minor defects requiring action. 56 of the 109 houses have defects at this stage and the reasons for the number is due to the same reasons as the previous frame stage. That is, there are more activities, work sections and trades involved in this final stage offering greater possibility of error. Again, the errors can quickly and at low cost and time be rectified.

The serious problem of failed inspections is not extensive. In fact, none occurred during the first two stages and three rejected approvals were identified at each of the framing and final stages. Three rejections represents 2.8% of the full sample of 109 houses and is not excessive or a cause for concern. It confirms the inspection process and the pre-inspection is working relatively well. If this rejection rate was 5% or above, then a review may be necessary and some criticism could be levelled at the inspection process. However, this is not the case, but the need for vigilance and striving for higher standards must continue and no short cuts with demands for self regulation should be accepted by the authorities. The building control and certification system is working well and the regulations, codes and trained personnel are maintaining high standards of construction and safety.

This limited analysis supports the view that private building certification appears to be working effectively. Analysis of the data shows inspections are carried out rigorously and that even minor infringements are being noted. An extended analysis of the inspection data covering more than 109 houses and involving more than one private certifier could evaluate and compare the results in this study with a more extensive analysis.

Roadmap of Regulating Zero-energy Buildings in Finland

Jaakko Kanerva[1], Ari Ekroos[1] and Saara Jämes[1]

[1]Real Estate research group (REG), Department of Real Estate, Planning and Geoinformatics
Aalto University, P.O. Box 15800, FI 00076,
Aalto, Finland

Email: jaakko.kanerva@aalto.fi; ari.ekroos@aalto.fi; saara.james@aalto.fi

Abstract:
Improving energy efficiency in buildings is of high level importance in EU. Measures that reduce energy consumption and thus also GHG-emissions are based on cost-optimacy. Directive on energy performance of buildings casts requirements for both new and existing buildings and therefore will have wide impact in the society as a whole. Implementation of the directive has been made in two stages. Regulation of new buildings involves the shift of treating the building as an entity when calculating the energy performance. Existing buildings – implementation currently under process - require a flexible but still accurate threshold for the purposes of applying energy requirements in renovations. Also the target of reaching nearly zero-energy buildings is soon at hand. Achieving of these improvements described in the directive require active measures in every member state. Finnish legislator has to face the climate conditions, heterogeneous group of building owners, administrative culture and Constitutional requirements of which the latter, more than others, seems to cause difficulties. However, ways to comply with the Constitution can be found. Overall, the Finnish legislation is obligated to take into consideration technical, functional and economic feasibility as the directive obligates.

Keywords:
Building regulation, energy efficiency, existing buildings, new buildings, zero-energy buildings.

1 Introduction

Finland as a member of EU shares the ambitious goal in climate and energy policy. New measures for increased energy efficiency are proposed by the European Commission which includes also obligations for energy performance of buildings.[1] Common target in EU, set out in the directive on energy performance of buildings, is to achieve nearly zero energy buildings in the year 2020. Improving the energy performance of buildings is a cost-effective way of fighting against climate change and improving energy security.[2]

[1] Energy Roadmap 2050, 2011, p. 9.
[2] McKinsey&Co 2012, p. 8.

The implementation of EU legislation poses huge challenges to Nordic countries like Finland since buildings constitute some 32% of GHG emissions and 38% of energy consumption in Finland[3]. These challenges affect not only new buildings but first and foremost existing buildings. Keeping in mind the fact that buildings constitute a huge share of national wealth, it is not indifferent how buildings are maintained. To achieve healthy and energy efficient buildings a high class engineering skills among rational legislation are required.

This work will introduce the Finnish way of implementation of the current energy efficiency legislation concerning buildings. The objective of this paper is to examine the current and forthcoming legislation and to point out some of the challenges in this area. Juridical focus highlights the constitutional requirements for the forthcoming legislation. The topic is highly current since the implementation is partly under process at the moment. There are recent studies and articles that deal with energy efficiency in building sector but there aren´t any with mainly legal perspective.

2 Conditions for action

Due to Finland´s somewhat Nordic geographical position and being the northernmost EU member, climate plays a crucial role in building sector. Finland´s climate (latitude 60-70°N) is characterized by great variation. Thermal winter is relatively long but in the summer it can get fairly warm. Climate change will significantly change the seasons but still cold winters will occur[4]. Recent studies implicate for example that rain and snowfall will rise.

In Finland 62% of energy related for housing is needed for heating rooms and domestic hot water.[5] Hence in Finland thermal insulation has played a crucial role in energy efficiency. Before the new directive on energy performance of buildings and the E-number, energy efficiency of a building were indicated with a U-symbol reflecting the heat loss of structural parts (e.g. wall, window, ceiling etc.). Concentrating to minimize the heat loss it was quite simple just to thicken the insulation layer. Now when calculating the E-number, other elements of energy efficiency of a building will be highlighted so it increases flexibility but at the same time sets much higher requirements. The latest tightening nationally in energy efficiency regulation for new buildings was only two years ago. Then the improvement was approximately 30 %, and now due to EU-based regulation 20 % tightening will be presented.

3 Energy Performance of Buildings

EU adopted on 19th of May 2010 a directive on the Energy Performance of Buildings (EPBD) (2010/31/EU). Under this directive member states must: 1) establish and apply minimum energy performance requirements for new and existing buildings; 2) ensure the certification of building energy performance; 3) require the regular inspection of boilers and air conditioning systems in buildings and 4) ensure that by 2021 all new buildings are so-called 'nearly zero-energy buildings'.

[3] Statistics Finland 2010.
[4] Towards a low carbon Finland 2009, p. 124.
[5] Energy visions 2050, 2009.

 ISBN: 978-1-84219-840-7 .

The EPBD is linked to several policies with high status in EU and has different objectives as well. Policies related to the EPBD are the following: fighting against climate change, improving energy security, creating job opportunities, promoting technological developments and also increasing the use of energy from renewable sources. One important objective of this directive is to reduce the large differences between member states´ results in this sector. Measures introduced in the EPBD are estimated to reduce final energy consumption with 5-6 % and to lead reduction of 4-5 % in carbon dioxide emissions by 2020[6].

3.1 Common requirements in the Energy Performance of Buildings Directive

The EPBD lays down frames in which the measures to improve energy efficiency has to be taken. These frames are common to new and existing buildings. In terms of practicality, when setting requirements, member states may differentiate between new and existing buildings and between different categories of buildings. Measures take into account climatic and local conditions as well as indoor climate environment and cost-effectiveness. A cost-optimal balance between the investments involved and the energy costs saved throughout the lifecycle of the building is a key factor when introducing these above mentioned measures. According to article 4 in the EPBD a member state shall not be required to set minimum energy performance requirements which are not cost-effective over the estimated economic lifecycle. The EPBD obligates member states to review the requirements at regular intervals of maximum five years.

A member state has a right not to apply the requirements to buildings with a little significance to energy efficiency i.e. member states may differentiate between different categories of buildings. This group includes: officially protected buildings and buildings with special architectural or historical merit; buildings used as places of worship and for religious activities; temporary buildings with a time of use of two years or less, industrial sites, workshops and certain types of non-residential agricultural buildings; residential buildings which are used or intended to be used for either less than four months of the year or, alternatively, for a limited annual time of use and with an expected energy consumption of less than 25 % of what would be the result of all-year use and stand-alone buildings with a total useful floor area of less than 50 m2. This easement leaves for example normal summer cottages out of the scope of the EPBD if a member state decides so.

Under the EPBD a member state has a right to set minimum requirements which are more energy efficient than cost-optimal energy efficiency levels. This means that the EPBD has a nature of minimum harmonization. However the Commission controls discrepancies between member states. The Commission lays down a comparative methodology framework for calculating cost-optimal levels of minimum energy performance requirements and then member states are obligated to use this framework to compare the results which they have adopted. If there is a gap between cost-optimal and the actual national standard, exceeding 15%, member states have to justify the difference or plan appropriate steps to reduce the discrepancy. Furthermore these measures mustn´t affect other requirements concerning buildings such as accessibility, safety and the intended use of the building.

[6] Ministry of the Environment in Finland ; European Commission, presentation, p. 5.

The method of calculating the energy performance of buildings is also harmonized in the directive. The methodology for calculating energy performance is based not only on the season in which heating is required, but has to cover the annual energy performance of a building. Moreover, several factors are included to the calculation method, such as thermal characteristics, heating and air-conditioning installations, application of energy from renewable sources, passive heating and cooling elements, shading, indoor air-quality, adequate natural light and design of the building.

3.2 New Buildings

Taking into account that new buildings constitute annually only a very small amount of the total building mass in EU, and also in Finland, and the fact that the life cycle of buildings is usually at least 50 years; the objectives in energy efficiency have to be future-orientated. In the year 2050 half of the buildings are constructed after 2012[7].

EPBD casts obligations for new buildings. According to article 6 in the EPBD all new buildings have to meet the minimum energy performance requirements set out more detailed in article 4. What´s important in article 6 is the requirement to consider and to take into account, if available, the technical, environmental and economic feasibility of high efficiency alternative systems before construction starts. These systems include for example decentralized energy supply systems based on energy from renewable sources, cogeneration, district or block heating or cooling and heat pumps. This requirement broadens the scope of the EPBD from buildings to surrounding built environment and energy systems.

Article 9 sets out that by 31 December 2020 all new buildings are nearly zero-energy buildings and after 31 December 2018 new buildings occupied and owned by public authorities are also nearly zero-energy buildings. This latter requirement points out the principle that public sector leads by an example, which is highlighted by the European Commission[8].

In Finland the EPBD concerning new buildings is implemented mainly through the National Building Code of Finland (NBCF). Even though the EPBD has some detailed regulations there is still a lot for national legislator to do. The NBCF contains regulations and guidelines that complement the legislation in the Land Use and Building Act (132/1999, LUBA), which is the main legislative instrument controlling land use, spatial planning and construction in Finland. In the NBCF there is division to regulations and guidelines; the building regulations must be followed, but building guidelines are not obligatory, and other solutions may be used in construction as long as all the compulsory regulations are observed[9]. Recently the connection between the LUBA and the NBCF has been questioned in relation to the constitution of Finland. Problems related to this will presented later in this paper.

The regulation required in the EPBD concerning new buildings will enter into force in Finland July 1st 2012. The Ministry of Environment gave the regulations March 31st 2011 in the National Building Code of Finland in sector D3. The new D3 reflects the Finnish way of implementing ambitious objectives set out by European Union and at the

[7] Ympäristöministeriön raportteja 4/2012, p. 74.
[8] see for example, EPBD page 4.
[9] Ekroos 2005, p. 58-59.

same time is a step forward in the road to almost zero-energy buildings in Finland. D3 has major changes to the previous regulation – it introduces the concept of "total energy consumption of a building" and the "primary energy factors" and also the concept of "standard use of a type of building".

D3 obligates to calculate the total energy consumption of a building according to specific information provided in the same regulation and in its´ annexes. The total energy consumption of a building is described as "E-number". The maximum E-number varies according to different categories of usage of the building. There are 9 different categories in which the buildings are divided (see table 1).

category 1	single-family houses (≥ 50 m²)	204-130 kWh/m² in a year
	log houses (≥ 50 m²)	229-155 kWh/m² in a year
	row houses and chain of houses	150 kWh/m² in a year
category 2	apartment buildings	130 kWh/m² in a year
category 3	office buildings	170 kWh/m² in a year
category 4	commercial buildings	240 kWh/m² in a year
category 5	accommodation buildings	240 kWh/m² in a year
category 6	educational buildings and kindergartens	170 kWh/m² in a year
category 7	sports halls (excluding ice- and swimming halls)	170 kWh/m² in a year
category 8	hospitals	450 kWh/m² in a year
category 9	other buildings and fixed-term buildings	no value, but calculated

table 1: The E-number mustn´t exceed certain values (kWh/m²/year).

For the category 9 there is no maximum E-number but the calculation needs to be done. Finland, as national feature, has its own value for log houses. Furthermore the value varies in case of single family houses and log houses according to the warmed net area (m²). The fundament with the calculation of the E-number is that it gives only the objective but the means achieving it are in the hands of architects and other designers. This will predictably increase also the possibilities to carry out more interesting architecture.

When calculating the E-number also the primary energy factors have to take into account. Factors reflect the use of natural resources in the production of energy. Primary energy types with different factors are following: electricity 1,7; district heating 0,7; district cooling 0,4; fossil fuels 1,0; renewable fuels 0,5. These factors encourage the builders to the use of renewable energy and generally environmentally friendlier types of energy. From the constitutional legal point of view these energy factors are at least questionable, because they have substantial significance, but they are not based on any Act, which is requirement of section 80 of the Constitution.

All new buildings require a building permit according to the LUBA section 125. The calculation of the E-number is presented in connection with building permit application. The building permit mustn't be granted if the E-number requirements aren´t met.

3.3 Existing Buildings

There is a great potential in existing buildings concerning energy efficiency. Firstly, existing buildings override new buildings in numbers; secondly, the current condition considering energy performance in the existing buildings is often quite poor in comparison with the new ones. In Finland 64% of the buildings (gross floor area) is built in the 1960-2000[10]. However the building stock in Finland is relatively young in contrast to most of Europe. On the other hand, improving the energy efficiency of existing buildings is more expensive and technically more difficult in comparison with new buildings.

Before the EPBD, energy efficiency regulation in Finland affected mainly only new buildings. According to the NBCF the regulations are applicable to renovations and alterations works only insofar as the type and extent of the measure and a possible change in use of the building require. After the Ministry of the Environment gets the implementation process through, the NBCF will affect the existing buildings accordingly to article 7 of the EPBD.

When buildings undergo major renovation, the energy performance of the building or the renovated part thereof is upgraded in order to meet minimum energy performance requirements set in accordance with article 4 of the EPBD. Also, when a building element, such as roof or wall, is retrofitted or replaced, the energy performance of the building element has to meet minimum energy performance requirements. Precondition for both cases – building or building element – is that the upgrade has to be technically, functionally and economically feasible. To fit in the scope of article 7, the building elements have to form part of the building envelope and have a significant impact on the energy performance of the building. Whether the conditions are met needs to be considered in connection with the building permit.

A "major renovation" is clarified in the article 2 of the EPBD; the total cost of the renovation relating to the building envelope or the technical building systems is higher than 25 % of the value of the building, excluding the value of the land upon which the building is situated, or, more than 25 % of the surface of the building envelope undergoes renovation. Member states may choose to apply either one of the definitions to act as a threshold for building permit application.

Also in the case of existing buildings, the alternative systems, as referred in article 6, are required to take into account before the renovation starts, if available.

Article 8 of the EPBD casts requirements for both existing and new buildings. It deals with technical building systems and obligates to cover at least heating and hot water systems, air-conditioning and large ventilation systems or a combination of such systems. According to article 8 for the purpose of optimizing the energy use of technical building systems, member states shall set system requirements in respect of the overall energy performance, the proper installation, and the appropriate dimensioning, adjustment and control of the technical building systems which are installed in existing

[10] Rakennusperintö 2011.

or new buildings. Here as well the technical, economical and functional feasibility has to be taken into consideration.

In Finland the legislative process concerning the implementation of the EPBD for the renovation of existing buildings is currently (May 28th 2012) under process. The Ministry of the Environment is in charge in the process. Timetable for the new acts, enactments and other regulations concerning the issue is quite strict. They need be published at latest of July 9th 2012 and entered into force January 1st 2013 concerning buildings occupied and owned by public authorities and for other buildings July 9th 2013. At the moment it is quite obvious that Finland can´t follow the schedule, since the proposal for the new regulation hasn´t been given out yet. After the proposal different parties interested shall give their opinion on the matter and then the Ministry will start drafting the final version. Changes to the LUBA are also required, so the governments' bill has to be drafted as well. Naturally the voting of the bill goes to the national parliament. According to official in charge of the implementation process, some of the details still lack of political consensus[11].

The EPBD leaves member states some margins to adjust the requirements to national conditions.[12] The Finnish tradition of flexibility in the energy efficiency requirements for renovations can still continue in some scale. The objective in the upcoming regulations is to apply the energy efficiency requirements if the need for renovation emerges. The new regulations, naturally, won´t launch renovations just by themselves; the decision whether a building is in a need of a renovation is in the hands of the owners of the buildings. After the decision to launch a renovation has been made, then the question of applying the requirements is relevant.

At this stage of the preparation some challenges, distinctively other than juridical ones, can be pointed out. Generally speaking the building industry is worried about the amount of highly enough skilled people in the designing and in the building sector. The most common worry is related to the question how to assure that new or renovated buildings will stand out technically and how the construction products will be developed and tested to meet the standards. Sufficient resources and level of professionalism in building control is also a question that has risen.

4 Juridical Challenges

Road of regulating energy performance of buildings faces also juridical challenges. One major question is related to the Constitution of Finland (11.6.1999/731). Section 80 in the Constitution deals with issuance of Decrees and delegation of legislative powers. According to the Constitution: "The President of the Republic, the Government and a Ministry may issue Decrees on the basis of authorization given to them in this Constitution or in another Act. However, the principles governing the rights and obligations of private individuals and the other matters that under this Constitution are of a legislative nature shall be governed by Acts." Furthermore the section 13 in the LUBA gives the competent ministry (the ministry of the environment) powers to issue technical and corresponding general regulations and instructions supplementing this Act, which are published in the Finnish Building Code. The question is: do the new

[11] Locus 2012, p. 36.
[12] Hollo 2011, p. 360.

requirements have a nature of technical regulations or do they affect the rights and obligations of private individuals? Chancellor of Justice in Finland has recently given his opinion on this matter. The message in his statement is quite clear, indicating the current situation to be in violation with the section 80 of the Constitution.[13] Thus, in order to rectify the legislative problem, the basis or principles of calculating the E-number needs to be given in the LUBA. Furthermore, the power of issuing decrees also needs to be described more definite in the LUBA and should be appointed apparently to the Government, instead of the Ministry of the Environment.[14]

Secondly, Chancellor of Justice also found problematic having the instructions with non-binding status situated in the NBCF at the same time with the regulations with binding status. Keeping this in mind, the implementation of the EPBD concerning existing buildings requires more profound legislative actions than just altering the NBCF.

Third challenge deals with taking the definition of "major renovation" into practice. The EPBD allows two kinds of interpretations; 25 % of the value or 25 % of the surface. The definition concerning the value is quite artificial and it could lead to different interpretations depending where the building is situated and what is the buildings value. On the other hand if the definition follows the 25 % surface condition, builders might have a temptation to make projects in smaller pieces and thus avoid the energy efficiency objectives. This is something that is needed to take into consideration when implementing the directive. The most appropriate way of evaluating the definition would be in connection with building permit or other permit.

5 Conclusions

Energy efficiency requirements in building sector concerns all member states. Finland has to adopt new legislation according to the objectives set out in the EPBD. From juridical point of view it is a challenge to create such legislation that would comply with constitutional requirement, constantly developing society, technology and with the Nordic climate. The constitutional question is highlighted in a situation like this when the current legislation is older than Constitutional requirements and new regulations have to be adopted.

Situation with new buildings is quite clear in the NBCF. Major challenges come along with the implementation of the EPBD concerning existing building. Defining the threshold of applying energy efficiency requirements for renovations is the most crucial factor in the forthcoming legislation. This will have huge impact on those who make decisions on how to maintain their real estate properties or to investors as well. The ideal legislation has to answer often contradictory virtues such as predictability, accuracy and flexibility.

Abstract:
Buildings play an important role in any society's urban development - socially, environmentally and economically. They affect the quality of life and productivity of their users. However, many designers overlook the social and environmental impact of their buildings and focus merely on minimizing capital costs while providing the minimal acceptable service. On the other hand, many global endeavors tend to encourage the adoption of sustainable/green concepts in buildings design. Thus, a research that provides framework for adopting green construction approaches in developing countries such as Egypt would be essential. An integrated framework to design building envelope systems (walls, windows and roof), focusing on importance of attaining thermal comfort and energy effeciency, without compromising costs, will be introduced. Following the framework principles, a model has been developed that functions through three main modules: (1) A Memory Module; (2) A Central Processing Unit (CPU) Module, and (3) A Control Unit Module. The model represents a comprehensive yet easy application tool for energy and costs trade-off analyses/optimization platforms. The developed model has been applied to a case study where many analyses were conducted. Finally, a simulation of possible building designs combinations was conducted to show the relationship between costs and sustainable indicators of different alternative designs.

Keywords:
Building thermal performance, Design optimization/simulation, Green buildings, Lifecycle cost, Sustainable design.

1 Introduction

In the context of global warming and its increased risks to the society, such as the rise in greenhouse gases emissions, resource depletion…..etc., it is extremely important to pay attention to the building's design in terms of sustainability. Using a sustainable design in buildings is a vital step towards energy and cost savings. However, Egypt is considered still limping in the field of energy savings or sustainable building designs. Till now, there is no established green rating system (Egyptian Green Building Council, 2012). Moreover, based on an Egyptian construction market survey, it has been assured that a worthy segment of professionals in the Egyptian private sector

neglects the use of sustainable building design approaches (Assad, 2011). This might have contributed to the huge growth of Egypt's residential electricity consumption to reach more than three times international and Arab-world averages for the period of 2002 to 2010 (Hussein, 2012). Meantime, many global efforts have been made to assist designers in applying green building designs. Simulation programs/tools such as: energy plus, DOE, ESP-r …etc., have been developed and used to assess the impact of design parameters on the building performance. However, they are perceived by most professionals as being complex and demanding since large amounts of information and detailed design, which is usually not available during first design stages, is required for their operation (McKay, 2007). Also, the iterative trial-and-error process of such tools is viewed by some professionals as being ineffective (Wang et al., 2005). On the other hand, since designers rarely consider only one criterion in the decision-making process, multi-objective optimization models have been proposed by many studies (Ginevieus et al., 2008; Kanagaraj and Mahalingam, 2011). Although multi criteria decision making provides a more integrating approach, it requires trade-offs between importance of different parameters by giving criteria weights that require great level of experience, accuracy and objectivity which might be difficult to find in some designers.

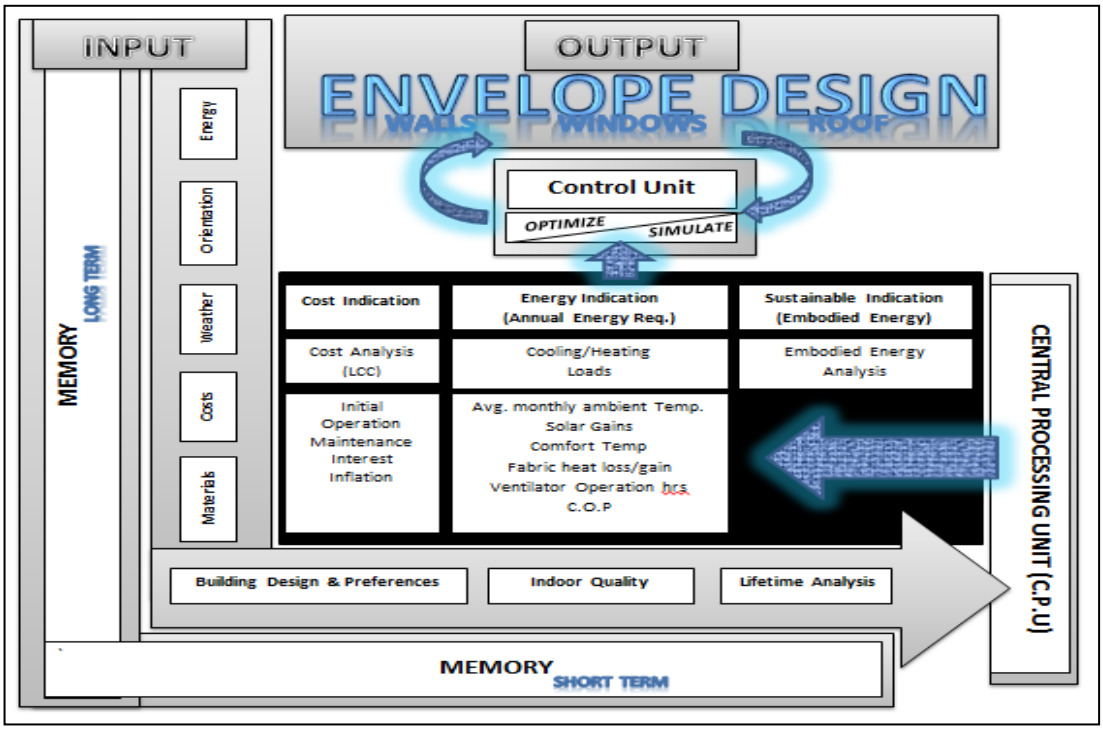
Due to the above, it is important to propose an integrated framework to promote the use of sustainable building design in Egypt. An easy comprehensive framework is recommended to be adopted for buildings envelope design. Moreover, a generic model is developed based on the framework to prove its applicability and comprehensiveness.

2 Proposed Framework for Optimum Sustainable Building Envelope Design

The proposed framework to reach an optimum sustainable building envelope design works through three main modules, as shown in Figure 1. These modules interact with each other dynamically to provide optimum green designs as will be illustrated.

1.1 The Memory Module

The first module is an organized memory that is subdivided to short term and long term. The long term memory stores information that could be used for different projects and designs. It can be categorized to five subsections. The first one includes basic construction materials and their associated technical properties such as: conductivity, U-value, shading coefficient and embodied energy. The second one stores cost related information which includes different materials costs and its lifetime (initial, maintenance, operation and replacement). It also includes general economic data as interest and inflation rates. The third and fourth subsections stores weather related data that depend on building location (city and country) and orientation. The information covers for each location the monthly average ambient temperature data, solar heat gain factors and the cooling load factors for each orientation. The last subsection in the long-term memory is related to energy data, such as energy costs associated to needed electricity loads. On the other hand, the short term memory includes three main categories which are: building design & preferences, indoor quality and lifetime analysis.



.

Figure 1: Proposed Framework

Short term memory mainly stores customized information related to specific building under analysis. Building design and preferences covers geometry information such as: area of building, height of floors, number of floors, area of windows, building location and orientation. Indoor quality covers preferred building interior temperatures in summer and winter. Finally lifetime analysis covers the analysis lifetime of studied building.

1.2 Central Processing Unit

The second module is responsible for doing different design assessments that help in selecting the optimum design. Three main assessments are used which are cost indication, Energy indication and sustainable indication. The first Indication is based upon life cycle cost analysis. It mainly covers initial, operation, maintenance and replacement costs of building envelope systems. Initial costs are mainly the cost of the materials and associated labour/equipment which can easily be retrieved from costs database available in the long-term memory. Operation costs in this research are mainly the electricity costs (LE). Electricity costs depends on number of operating hours of cooling/heating system, its coefficient of performance (C.O.P) and electricity price of 1kw.hr consumption. The central processing unit retrieves all cost values and assesses their repetition along the analysis period for all systems forming the building envelope. All costs are then discounted back resulting in an equivalent net present value (NPV) for the whole building. In this cost assessment, an effective interest rate for each repeated cost is calculated then used in the NPV calculation. The second assessment indication is related to energy demand. This indication assess the amount of heat/cooling load needed to reach satisfactory thermal comfort level. This assessment should be modelled / calculated to estimate the heating/cooling demands for residential buildings. The ASHRAE design book (ASHRAE, 1997) represents one of the easiest manuals to aid in such calculations. The final indication is associated to

sustainability. Sustainable indication is mainly related to the amount of embodied energy for each selected envelope design. Embodied energy includes the considerable amount of energy spent in the manufacturing, processes and transportation of various building materials. The energy content of different building materials/components such as: masonry walls, glass, insulation boards …..etc. can be integrated into a computation of the total embodied energy in a whole building envelope system. The control unit can use different tools for selecting the optimum envelope design. Both Optimization and Simulation can be used and significantly aid in making such decision.

1.3 Control Unit

The control unit is further responsible for selecting the final building envelope design that satisfies the needs of the user. Considerations as costs, adverse impact on environment and performances should all be accommodated. Both optimization and Simulation tools could represent significant aid for the decision making process.

3 Implementation & Analysis

To implement the proposed framework, a spread sheet model had been developed as shown in Figure 2. (a) A sheet is used as an interface which allows feeding the building information and preferences to be stored in the short term memory. (b) Various sheets are used as databases for material, costs, thermal properties, economic data and embodied energy which represent the long term memory of the model. Data used in the model and its source of retrieval are presented in Table 1. Based upon available materials, different design combinations for different systems as walls, windows and roof could be formed, and their technical data could be matched and retrieved.

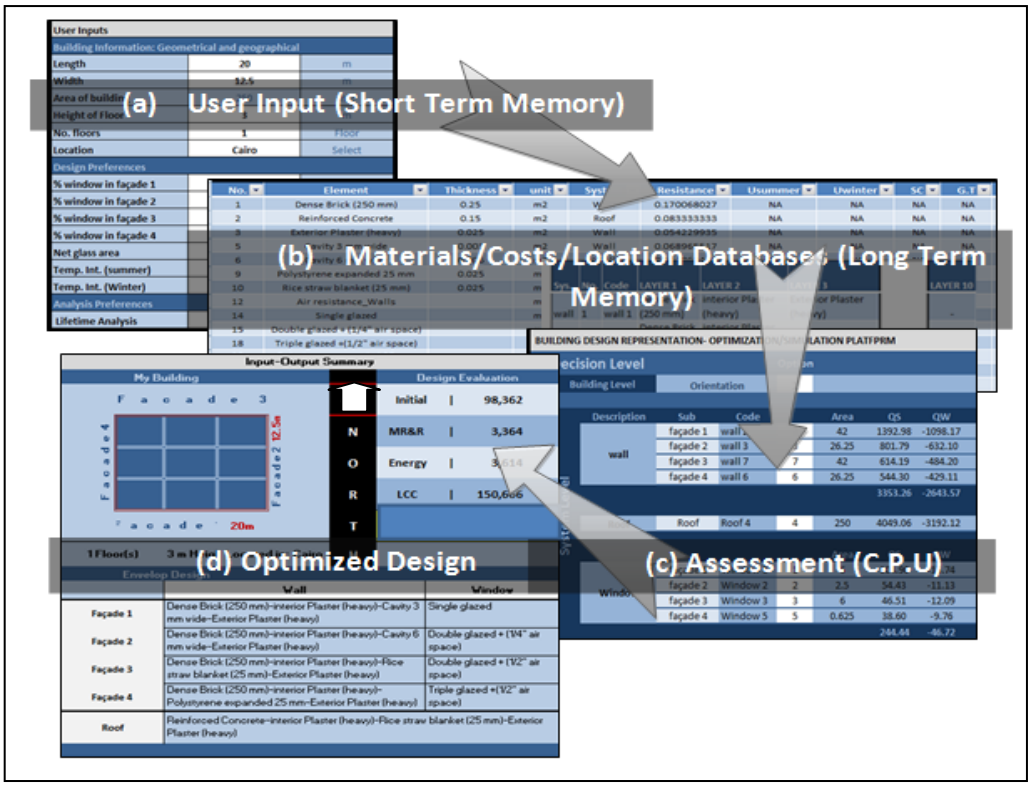


Figure 2: Model Spread Sheets

Sample of available design combinations for different systems for building envelopes are shown in Table 2. (c) A different sheet is used as the C.P.U module, where design assessments are carried. Three main indications are assessed which are costs, energy demand and sustainability. Costs are represented by lifecycle associated costs as initial, operation, maintenance, repair and replacement. Maintenance, repair, operation and replacement costs are all discounted at present value and added to the initial investment to represent the overall lifecycle costs of the building envelope. The ventilator operating cost is based on energy assessment. Energy assessment is based on proper decomposition for mathematical equations following the ASHARE design book (Mc Quiston and Spitler, 1997). The core of heating/cooling load calculation depends on three main calculations: (1) conduction through building walls/roof, (2) conduction through windows and (3) solar radiation through glass, and is shown in Table 3. (d) Finally, a conclusive sheet is presented to show the final optimum building design based upon optimization/analysis. This model uses both EVOLVER 5.5 and Crystal Ball (add-ins for Excel applications) for optimization/simulation purposes.

Table 1: Data type and its source of retrieval

Data Type	Source
Materials, Thermal & Costs data	Recent & available materials/technologies in the Egyptian market
Weather related data	The US department of energy weather data (Weather data, 2012)
Orientation related data	The ASHRAE design book (McQuiston and Spitler, 1997)
Electricity costs (price of 1kw.hr consumption of electricity)	Ministry of Electricity and Energy Cairo. (Egyptian Electricity Holding Annual Report, 2012)
Embodied Energy Information	Materials properties handbooks/publications. (Baird et al.,2007); (Venkatarama and Jagadish, 2003)
Economic data (EGYPT)	Egyptian central agency for public mobilization and statistics (Price Indices, 2011)

Table 2: Sample of Systems Alternatives in the Model Database

Systems	Composition Layers			
Wall 1	Dense Brick	Interior Plaster (heavy 25mm)	Exterior Plaster (heavy)

Table 3: Energy Assessment Based on Mathematical Equations Following the ASHARE Design

Energy Assessment (Demand & Costs) Equations	
Equation	**Identification**
Heat gain/loss through walls or roof ($Q_{Wall/Roof}$) $Q_{Wall/Roof} = U.A.\Delta T$	• A = area of element in (m^2), ΔT= temperature difference between inside and outside medium • U= overall heat transfer coefficient
Overall heat transfer coefficient (U) $U= 1/R_{Overall}$	• $R_{Overall}$ = total thermal resistance of the wall/roof depending on its composition
Total thermal resistance of the wall/roof ($R_{Overall}$) $R_{Overall} = R_{Int} + \Sigma R_E + R_{Ext}$	• R_{Int}; R_{Ext} = thermal resistance of the internal and external air film layer respectively. • R_E = thermal resistance of construction element in any multi-layer system.
Heat gain due to solar radiation in (Q_{Solar}) $Q_{Solar} = A_{glass.}$ SC. SHGF. CLF	• A_{glass} = net glass area • SC = shading coefficient of window glass • SHGF = solar heat gain factor for that orientation (watt/m2) • CLF = cooling load factor
Energy Demand (E_D) $E_D = Q_T$/ C.O.P	• Q_T =total amount of heat gain/loss in watts • C.O.P = coefficient of performance of cooling/heating system
Electricity Costs (E_C) $E_C = \Sigma (E_D. H. E_{Price})$	• E_C = Electricity costs per year (EGP /year) • h=number of operating hours of cooling/heating system • E_{price} = price of 1kw.hr consumption of electricity (EGP/kw.hr)

3.1 Optimization

A case study is considered and applied to the developed model. The case study input information is as follows: the building dimensions are 20 x 12.5 m with five floors of 3 meters height each. Windows are 30% of walls area, for the four façades. The user's preference interior temperature in summer is 16 ^oC and in winter is 23^oC. The building location is Al Minya governorate in Egypt, and the building is located that its main façade faces north. Finally, the analysis period covers 50 years. Optimization is set to reach the least lifecycle costs design. The variables are the available different design systems for the building envelope walls, windows and roof, considering their integration effect on each other. The constraint is a maximum allowed embodied energy of one million KJ. The optimum result was the following: for the walls, all walls facades required the wall type with the highest available insulation material and least costs and embodied energy in the database (rice straw blanket, 25 mm) along with double brick layer. For the windows, they are all found to be single glazed. This means that windows insulation does not contribute much to lifecycle costs savings although it does to energy savings. This implies that their relative initial costs outweigh their energy savings. Finally, the roof was optimized to be reinforced concrete with rice straw blanket which is the highest available thermal insulating material of least costs and embodied energy. By reviewing the optimization results, it

was found that the framework selected the green alternatives although the existing of less expensive alternatives in the formed database.

3.2 Simulation

On the other hand, simulation tools are also conducted to study the trade-off between life cycle costs (LE) and embodied energy (MJ), see Figure 3. The Figure shows the different design scenarios and their associated embodied energy and life cycle costs. The left half of the graph represents the least costs available scenarios, while the bottom half of the graph represents the least embodied energy scenarios. Designer can select designs on the left bottom on the drawn curve as they represent least relative costs as well as embodied energy. This trend shows that it is possible to save huge amounts in the life cycle costs with least available embodied energy designs. For example, point 1 represents an optimum building envelope design of least available embodied energy of 218,000 MJ and minimum available lifecycle costs of 177,000 Egyptian pounds.

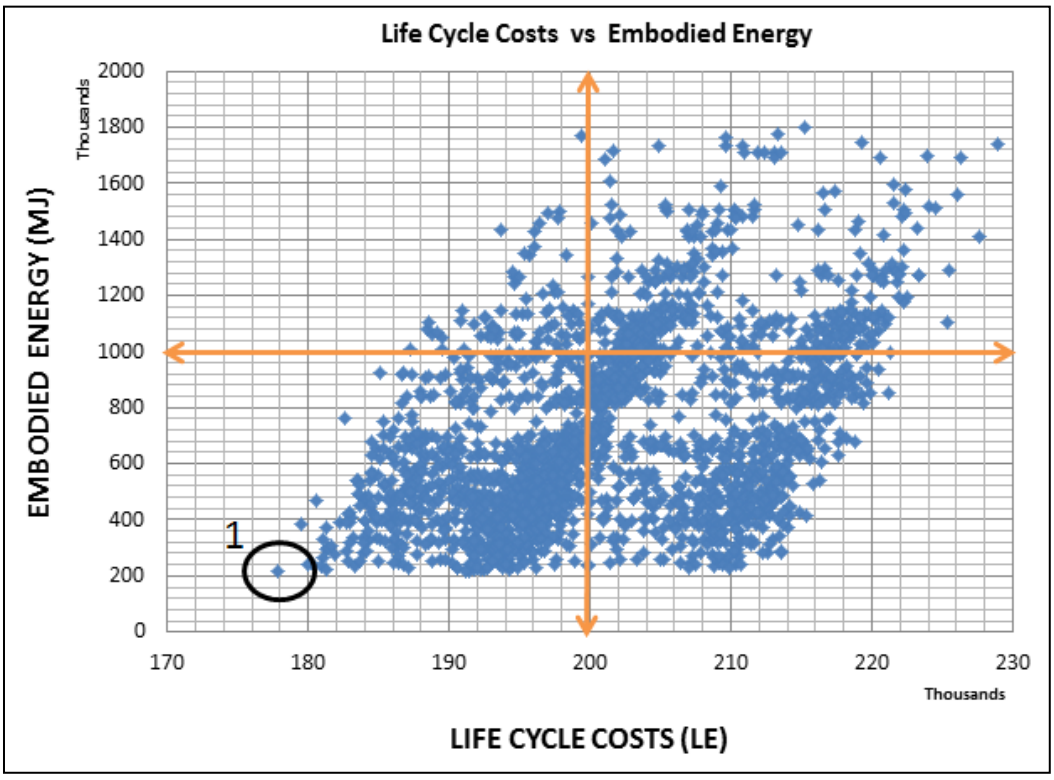

Figure 3: Life Cycle Costs Vs Embodied Energy

4 Conclusions

Different studies were done to optimize buildings design. However, most professionals in the Egyptian sector have neglected sustainable design approaches as they perceive it as being complex, time and money consuming and ineffective. Meanwhile, an integrated approach to reach sustainable building envelope design was presented considering thermal indoor quality, energy demand, embodied energy and lifecycle costs. The framework includes three main Modules: 1- A memory module, 2- A central processing unit module, and 3-A control unit module. Moreover, a new generic model was presented with case study as an application to the model and the

output of model was elaborated. Finally, simulation was conducted showing a trade-off relationship between embodied energy and lifecycle costs of available options. This model can be further accommodated and be used by investors or builder's owners at conceptual design to reach an optimum building envelope design with respect to costs, energy demand and sustainable indicators. The ease and simplicity of the model entries and use would encourage designers and investors to use it. Future work can be incorporated to include more analysis and indicators.

Abstract:
The Malaysian building sector approximately consumes 53% of national electricity generated, and emits 5,301 ktons of greenhouse gases (GHG) with an annual growth rate of 6.4%. While voluntary codes of practice for energy efficiency and use or renewable energy exist for non-residential buildings, Malaysia has yet to adopt mandatory energy efficiency legislation for its building sector. Mandatory building energy performance codes have been shown to be the most cost-efficient and effective policy instruments for reducing building energy-related greenhouse gas emissions. Therefore, without mandatory and comprehensive energy efficiency policy, Malaysia faces locking in substantial inefficiencies, and higher than necessary climate change impacts from its building sector. A comparison of energy efficiency policies from other South East Asian countries with similar climatic characteristics will be a valuable insight for Malaysia.

Keywords:
Building control, developing country, energy efficiency, policy development.

1 Introduction

Developing countries in Asia and Africa are rapidly urbanizing, which consequently caused a swift increase of GHG emissions as housing and energy demand escalates (Fujita et al., 2009). South East Asia (SEA) is one of the world's most dynamic regions with progressive economic developments in the past decades (ADB, 2009). The region mainly experiences tropical climate and has a large coastline (173,251 kilometres), which makes it one of the world's most vulnerable regions to the impacts of climate change (ADB, 2009). Already, the region is affected by climate change with rising temperature, rising sea level, and more frequent and extreme weather events that leads to massive flooding and landslides (ADB, 2009).

It is a pressing issue for SEA countries to take action in adapting to climate change, and reduce the environmental impact of energy consumption and GHG emissions that are already locked into the climate system (ADB, 2009). The building sector has been identified by the Intergovernmental Panel on Climate Change (IPCC) as the single largest sector for GHG mitigation potential in all countries (IPCC, 2007; UNEP-SBCI, 2010). A cost-effective global potential up to 80% reduction, of the projected baseline emissions by 2020, has been identified in the building sector (Levine et al., 2007; UNEP-SBCI, 2010; UNEP, 2009). Furthermore, the projected reduction are made available for new and existing buildings with proven and commercially available technologies (UNEP-SBCI, 2010; UNEP, 2009).

Buildings worldwide consume approximately 45% of primary energy sources, making it the single largest energy consumption sector (Iwaro & Mwasha, 2010; Yang et al., 2008). The building sector also globally generates approximately 40% wastes and consumes 16% of water (du Plessis, 2002; WBCSD, 2009). In Malaysia, electricity is the predominant form of energy consumed in buildings (90%), and approximately 53% of the total electricity generated is consumed in the building sector (Energy Commission, 2009). This is further broken down to 18% for residential buildings, and 28% for commercial or non-residential buildings (Shafii, 2008). Currently there is lack of published data for energy performance and actual energy consumption of buildings, especially for residential buildings in Malaysia (Shafii, 2008). Annually the Malaysian building sector emits approximately 5,301 ktons of GHG emissions, with an annual growth rate of 6.4% (UNDP, 2009).

Energy efficiency (EE) legislation exists in almost all developed countries while the developing countries are currently introducing such guidelines on a voluntary basis first to raise awareness among professionals (Iwaro & Mwasha, 2010; UNEP, 2007a, 2009). Energy efficiency legislation such as building energy codes and standards primarily set minimum requirements for energy efficient design and construction (Department for Communities and Local Government, 2007; Iwaro & Mwasha, 2010). Building energy codes are mandatory requirements, enforced to ensure building are constructed and perform according to the minimum energy requirements (Iwaro & Mwasha, 2010). These standards are used to "address energy use of an entire building or building systems such as heating, ventilation and air conditioning" (Birner & Martinot, 2002 p.44), which is also a popular instrument to expedite energy efficiency in the building sector (OECD, 2003; UNEP, 2007a). Conversely, energy standards are used as voluntary guidelines for building construction to promote energy efficiency and save energy cost-effectively (Iwaro & Mwasha, 2010).

2 Effectiveness of Energy Performance-Related Building Codes

It is argued that enforcing energy performance requirements in building codes is the most effective and cost-effective strategy in reducing GHG emissions from both existing and new buildings (UNEP-SBCI, 2009). Regulatory strategies are taken by governments to intervene in the market to achieve and assert changes within the sector (Lee & Yik, 2004). Enforcement of energy efficient building standards through regulatory control can potentially ensure a minimum level of performance is achieved across the building sector (Huovila et al., 2009; Lee & Yik, 2004; UNEP, 2007b). In Asia, energy efficiency initiatives is seen to be largely dependent on governmental

efforts (Hong et al., 2007). Countries in Scandinavia generally implement national building codes that regulates the physical, thermal and electrical requirements of building components, service systems and equipments to help promote energy efficiency (UNEP, 2007b). Building codes have also introduced energy performance standards to limit the amount of energy consumption according to building type (UNEP, 2007b).

Additionally, the effectiveness of these building codes and standards are dependent on level of enforcement and implementation (Birner & Martinot, 2002; Deringer et al., 2004; UNEP, 2007a). Moreover, in order to stay effective, building codes need to be regularly revised as technology advances and costs less (Birner & Martinot, 2002; UNEP, 2007a, 2009). This consequently leads to more efficiency, with the removal of least efficient products and encourage higher efficient product purchase in the market (Birner & Martinot, 2002).

Therefore, unless the criteria levels are easily achieved and does not impose heavy financial burden, the building sector would strongly oppose the legislation, or likely to encounter numerous violations rendering enforcement (Lee & Yik, 2004). Some suggest the voluntary-based environmental approach is more effective, whereby it offers greater flexibility for stakeholders to achieve its target (Lee & Yik, 2002, 2004). Voluntary initiatives are also aimed at influencing behavioural characteristics of individuals and companies, by providing examples of successful implementations (IEA, 2005; UNEP, 2007a). Voluntary agreements usually consist of negotiated energy use reduction targets, quantifying energy consumption and baselines, technical assistance services, sanctions for noncompliance, and incentives for compliance (IEA, 2005).

However, based on experience in public sector buildings with mandatory energy reduction programme have shown significant cost-effective energy savings. Federal agencies in the U.S. were obliged to reduce their energy consumption by 35% by 2010 compared to 1990 levels, which led to energy savings of 4.8 GWh annually (equivalent to 2.3 ktCO2e.) and cost savings of USD$ 5.2 billion (U.S. DOE, 2006 cited in UNEP, 2009). Mandatory energy efficiency building codes also provides an incentive for the private sector to invest in new technologies (UNEP, 2009).

3 Energy Efficiency Building Codes in South East Asia (SEA)

In many developing countries, energy efficiency building codes (EEBCs) exist only on paper and have failed to impact significant energy savings (Deringer et al., 2004; UNEP, 2007a). This is due to lack of enforcement, corruption, and different levels of rigor implementation (Birner & Martinot, 2002; Deringer et al., 2004; UNEP, 2007a). Additionally the United Nations 'Assessment report on energy efficiency institutional arrangements in Asia' (UNESCAP, 2010), countries in SEA share common barriers in promoting energy efficiency, i.e. lack of industrial awareness, lack of financial capacities, and lack of confidence in technology (UNESCAP, 2010).

For example, EEBCs are strictly enforced in Singapore, while EEBCs in the Philippines National Building Code only considers energy efficiency a voluntary requirement (OCEAN, 2009). Similarly, Thailand's Building Energy Code is mandatory for all commercial and government buildings, while Vietnam's mandatory Energy Efficiency Commercial Code hasn't been widely disseminated and not strictly enforced (OCEAN,

2009). Brunei, Cambodia, Lao PDR, Malaysia and Myanmar have yet to implement any mandatory EEBC, but some have introduced voluntary EE guidelines, conservation programmes, or codes for non-residential buildings (OCEAN, 2009; UNEP & BCA, 2011; UNESCAP, 2010). This reflects the lack of awareness, the different levels of implementation and enforcement of EEBCs across SEA. Brief comparison of existing EEBCs in SEA is presented in Table 1, thus presenting the current state of play.

Vietnam	EE Building Code, EE Standards and Labels, EE Commercial Building Code, Public Procurement of Works and Constructions–Law on Construction (No.16/2003/QH11), Law on Environmental Protection (No. 52/2005/QH11).	LOTUS VN Green Rating Tool, ASEAN Energy Management Scheme, Promotion on EE and Conservation (PROMEEC).

This energy efficiency policies comparative study for South East Asian building sector is mainly compiled from the Sustainable Building Policies on Energy Efficiency reports (UNEP & BCA, 2011) and the Compendium of Energy Efficiency Policies of APEC Economies (APERC, 2011). The comparison mainly focuses on policies related directly with the building sector, such as building codes, EE standards, and energy labelling schemes. It can be concluded that most countries in SEA has already implement mandatory EE policies related to the building sector. However, even if these policies were in place, the more pressing question now is to what extent is its effectiveness in

addressing environmental issues. Presented below are excerpts of each South East Asia's EEBC.

3.1 Brunei

Brunei is in the midst of introducing its own Energy Efficient Building Guidelines, that is expected to become a mandatory legislation and in supplementing the existing National Building Code (APEC, 2011a; UNEP & BCA, 2011). The guideline is set to cover building envelope, cooling and ventilation, lighting, heating, insulation, site orientation, and building design (UNEP & BCA, 2011). Albeit any mandatory guideline, there has been some voluntary initiative taken by the government and industry.

Voluntary energy audits were conducted to both government and industrial buildings to help determine the consumption pattern of Brunei's building stock (UNEP & BCA, 2011). This initiative was in collaboration with the Energy Division of the Prime Minister's Office, the Conservation Centre of Japan and the ASEAN Centre for Energy (UNEP & BCA, 2011). An Energy Efficiency and Conservation Initiative Awards Scheme was initiated in 2007, by the government and private organizations, in hopes to exemplify energy efficiency and conservation efforts (UNEP & BCA, 2011). The government also launched a voluntary Energy Efficiency Labelling Scheme targeting commercial, residential and government buildings, to raise awareness on more energy efficient product (at present only air-conditioners are being labelled as it represents the bulk of electricity consumption) (UNEP & BCA, 2011).

3.2 Cambodia

Cambodia has taken steps in promoting energy efficiency through voluntary programmes such as Promotion of Energy Efficiency and Conservation (PROMEEC) with the Energy Conservation Centre of Japan (ECCJ) (UNEP & BCA, 2011). PROMEEC aims to establish a standardized evaluation criteria for energy conservation, introduce energy conservation technologies, encourage and award best practices for buildings and other major industries (UNEP & BCA, 2011). Another example is through series of activities for capacity building and technical assistance, conducted by a French Agency for the Environment and Energy Management together with the Energy Conservation Research and Development Centre (ENERTEAM) (UNEP & BCA, 2011).

Cambodia also participates in the ASEAN Energy Awards, which promotes regional cooperation and partnerships between the private and public sectors (UNEP & BCA, 2011). Voluntary energy audits are also carried out on commercial buildings in efforts to promote more energy efficiency measures (UNEP & BCA, 2011). However, there is currently no mandatory regulation, no building rating scheme and is yet to develop any fiscal instruments to widely disseminate energy efficiency within the building sector (UNEP & BCA, 2011). Therefore, Cambodia needs to play catch up with its other SEA counterparts, in preventing potentially high inefficiency lock-in effect.

3.3 Indonesia

Indonesia applies mandatory energy conservation best practice measures for all its government office buildings, which is expected to submit monthly energy consumption

report every six months (APEC, 2011a; UNEP & BCA, 2011). Other mandatory frameworks are such as Law No.28/2002 regarding Buildings, which requires all buildings to comply with existing energy standards (SNI) that applies to building envelope, air-conditioning, lighting, and energy auditing (APEC, 2011a; UNEP & BCA, 2011). The Presidential Instruction No.10/2005 on Energy Efficiency requires government officials to implement EE measures such as lighting, air-conditioning, electrical appliances and office vehicles, within its institutions (UNEP & BCA, 2011). A Minimum Energy Performance Standards (MEPS) is also being developed to encourage energy efficiency through energy labelling for appliances (UNEP & BCA, 2011).

The Green Building Council of Indonesia introduced a voluntary green building rating tool, the GREENSHIP in 2008 (UNEP & BCA, 2011). GREENSHIP rates the environmental design and construction of buildings through six criteria; appropriate site development; energy efficiency & refrigerants; water conservation; materials & cycle resources; water, indoor health & comfort; and buildings & environment management (UNEP & BCA, 2011). A Public-Private Partnership Programme on Energy Conservation was introduced, by the government, to improve energy efficiency for industries and buildings with intense energy consumption (UNEP & BCA, 2011).

3.4 Lao People's Democratic Republic (PDR)

Currently, no legal framework for improvement of energy efficiency and conservation exists within the building sector in Lao PDR (ECCJ, 2011). The Ministry of Energy and Mines (MEM) is in the process of drafting a decree on Energy Efficiency and Conservation to encourage conservation measures in public buildings (ECCJ, 2011). Nevertheless, Lao PDR has taken steps to introduce energy efficiency by participating in the Promotion of Energy Efficiency and Conservation Project (PROMEEC) since 2001, similar to Cambodia and Vietnam (ECCJ, 2011). This project is aimed to provide capacity building on energy efficiency and conservation, in disseminating best practices and experiences from Japan to other ASEAN member countries (ECCJ, 2011).

3.5 Myanmar

Similar to Brunei, Cambodia and Lao PDR, Myanmar has yet to implement any mandatory energy efficiency legislation within its building sector (UNEP & BCA, 2011). Incidentally, available energy efficiency and conservation voluntary actions has so far only appear in the energy production industry (UNEP & BCA, 2011). However, energy conservation seminars have been conducted to raise awareness and promote for more energy efficient equipments in commercial buildings and electrical appliances in households (UNEP & BCA, 2011).

An Energy Policy and Strategy exits for the energy production sector, to encourage renewable sources and conservation of non-renewable energy sources (UNEP & BCA, 2011). The Ministry of Energy has also introduced the Energy Conservation Model Project, to conduct a feasibility study of energy demand and consumption of the industry sector, in efforts to develop energy efficiency and conservation policies that is unique to the current energy trends (UNEP & BCA, 2011). Myanmar also engages in a regional energy corporation between Bangladesh, India, Sri-Lanka and Thailand-Economic Corporation (BIMST-EC), for capacity building and technology transfer programmes and activities (UNEP & BCA, 2011). These initiatives are encouraging,

however more effort and focus must trickle down to the building sector in preventing a future lock-in of an inefficient building sector.

3.6 The Philippines

The Philippines introduced the Guidelines for Energy Conservation Design of Buildings and Utility Systems into its National Building Code (Republic Act No. 6541) (OCEAN, 2009; UNEP & BCA, 2011). However, the particular energy efficiency section of this building code is presently only as a voluntary basis, an only concerns building envelope, lighting, HVAC (heating, ventilation, and air conditioning), and water heating (OCEAN, 2009). A mandatory Energy Efficiency Labelling scheme was introduced to label energy efficient refrigerators, window-type air-conditioners, compact fluorescent lamps and linear fluorescent lamps; targeted at all types of building (UNEP & BCA, 2011).

Other regulatory instruments such as Malacanang Administrative Order (AO) No. 103, No. 183 and No. 228 has set requirements for public buildings facilities to achieve a 10% reduction in cost for consumption of fuel, water, office supplies, electricity (UNEP & BCA, 2011). The AO also requires public buildings to use energy efficient lighting systems, to turn off air-conditions at 4.30pm except those operate 24 hours daily, convert 20% of vehicles to liquefied petroleum gas, and to apply energy saving technologies (UNEP & BCA, 2011). Energy audits are also conducted for government buildings, under the Government Energy Management Programme (GEMP) (UNEP & BCA, 2011). Tax exemptions/reductions, grants and capital subsidies are also available via the government and other public institutions as fiscal instruments to promote energy efficiency (UNEP & BCA, 2011).

There are voluntary rating systems such as the Building for Ecologically Responsive Design Excellence (BERDE) and the Green Building Initiative (GBI), where one measures a building's environmental impact and performance throughout life cycle analysis (LCA), and the other focuses on green building design criteria (UNEP & BCA, 2011). Many building awards based on best practice of eco-friendliness, energy efficiency, and energy management are both voluntary instruments and market-lead to help promote a more energy efficient built environment (UNEP & BCA, 2011).

3.7 Thailand

Thailand's Energy Conservation Promotion Act (No. 2 B.E. 2550) enforces energy conservation practices for industrial, commercial and government building sectors (OCEAN, 2009). Additionally the Building Energy Code was introduced in 1994 and enforced in 1995, which covers building envelope, HVAC and lighting requirements (OCEAN, 2009). The mandatory code is applicable to all new and existing commercial and government buildings, in complying with the maximum standard of 55 watts per square meter (m^2) of gross floor area (g.f.a) (OCEAN, 2009).

Under the Building Energy Code, two specific decrees are imposed; Royal Decrees on Designated Buildings (B.E. 2538) and Royal Decree on Designated Factories (B.E. 2540). The B.E. 2538 prescribes "a) the standards, criteria, and procedures for energy conservation in designated buildings; b) the forms and schedule for submission of information on energy consumption and conservation; and c) the criteria, procedures and schedule for owners of designated buildings to establish and submit energy

conservation targets and plans" (APERC, 2011 p.208). Meanwhile the B.E. 2540 imposes "a) the forms and schedule for submission of information on energy production, consumption and conservation, including the criteria on and methods of recoding information on energy consumption and installation or modification of machinery or equipment that affects the level of energy consumption and conservation; and b) the criteria, procedures and schedule for owners of designated factories to establish and submit energy conservation targets and plans" (APERC, 2011 p.208).

Other regulatory instruments implemented as like the Minimum Energy Performance Standards (MEPS) and mandatory energy efficient refrigerator/air-conditioner programme (UNEP & BCA, 2011). The MEPS standard defines an energy efficiency performance threshold for six electrical appliances, such as refrigerators, air-conditioners, motors (three phase), fluorescent lighting ballast, fluorescent lighting tubes, and compact fluorescent lamps (UNEP & BCA, 2011). The Energy Efficient Air-Conditioner Programme (EEAP) and Energy Efficient Refrigerator Programme (EERP) are mandatory energy labelling for air-conditioners and residential-use refrigerators (UNEP & BCA, 2011).

Fiscal instruments aimed at providing tax exemption, corporate funds, and household energy credits are exemplary initiatives by the Thailand government and public sectors to highlight energy efficiency issues (UNEP & BCA, 2011). There are also a variety of voluntary initiatives done by both the public sector and the industry to push for energy efficiency, such as the Green Leaf Programme, the Thai Green Label Scheme, High Energy Performance Standards (HEPS), Government and Private Buildings Audit and Retrofit Programmes, and the Building Energy Awards of Thailand (BEAT) (UNEP & BCA, 2011).

3.8 Vietnam

Vietnam introduced its Energy Efficiency Building Code (No.40/2005/QD-BXD) and consequently the Energy Commercial Building Code (No.40/2005/QB-BXD) in 2005 (OCEAN, 2009; Pham, 2011). These mandatory codes cover building envelope, lighting, air-conditioning and ventilation, and are applicable to public, residential and non-residential buildings (APEC, 2011a; UNEP & BCA, 2011). Additionally, the Public Procurement of Works and Constructions, via Law on Construction (No.16/2003/QH11) and Law on Environmental Protection (No.52/2005/QH11), requires construction projects in Vietnam to submit an Environmental Impact Assessment (IEA) documentation (UNEP & BCA, 2011).

A Pilot Commercial Energy Efficiency Programme (CEEP) was introduced from receiving the Global Environment Facility (GEF) grant from the World Bank (UNEP & BCA, 2011). The CEEP (2004 to 2009) was aimed to increase capacity building in energy efficiency and conservation for organizations, and provided financial support for the private sector (UNEP & BCA, 2011). Other voluntary instruments are such as the LOTUS Green Rating Tool, ASEAN Energy Management Scheme and the Promotion on Energy Efficiency and Conservation (PROMEEC) programme (UNEP & BCA, 2011). The LOTUS Green Rating Tool was developed in 2010 by Vietnam's Green Building Council (VGBC) (UNEP & BCA, 2011). Currently, LOTUS is available in three categories, i.e. residential, non-residential and existing buildings (VGBC, 2011). LOTUS rates a building through nine criteria, i.e. energy, water, material, ecology,

waste and pollution, health and comfort, adaptation and mitigation, community, and management (VGBC, 2011).

3.9 Singapore

In comparison, Singapore's extensive sustainable building and energy efficiency commitment is reflected in its various initiatives that range from regulatory legislation, fiscal instruments, market-driven initiatives and voluntary schemes. Singapore introduced its Building Control (Environmental Sustainability) Regulations in 2008 (BCA, 2008; UNESCAP, 2010). This legislation requires all new buildings (residential and non-residential) and additions/extensions to existing buildings, with gross floor area of 2,000 square metres or more, to comply with a minimum Green Mark Score of 50 points (BCA, 2008; UNESCAP, 2010). The Green Mark assesses buildings by its energy efficiency (minimum 30 points), and other green requirements (minimum 20 points) such as water efficiency; environmental protection; indoor environmental quality; and other green features (BCA, 2012).

Aside from that, other relevant building codes implemented in Singapore are Code on Envelope Thermal Performance for Buildings, Code of Practice for Energy Efficiency Standard for Building Services and Equipment, Code of Practice for Air-Conditioning and Mechanical Ventilation in Buildings, Code of Practice for Artificial Lighting in Buildings, and Code of Practice for Lighting of Work Places-Indoor (UNEP & BCA, 2011; UNESCAP, 2010). The Code on Envelope Thermal Performance for buildings focuses on thermal transfer value of building envelope and roofs for air-conditioned non-residential buildings, envelope transmittance value for residential buildings, and roof insulation for air-conditioned buildings (APEC, 2011a; UNEP & BCA, 2011).

Additionally, under the Mandatory Energy Labelling Scheme (MELS), selected household appliances such as air-conditioners, refrigerators and clothes dryer sold in Singapore must include energy labelling (APEC, 2011a; UNEP & BCA, 2011). This is tied together with the Minimum Energy Performance Standards (MEPS), which requires air-conditioners and refrigerators sold to comply with a minimum level of energy efficiency (APEC, 2011a; UNEP & BCA, 2011). Singapore has also introduced the Energy Efficiency Building Benchmarking Programme to "promote energy efficiency in the building sector by recognizing energy efficient buildings (UNESCAP, 2010 p.85). The programme uses an online benchmarking system, the Energy Smart Tool, to evaluate energy performance based on air quality, thermal comfort, ventilation and lighting (National Environment Agency, 2011).

Fiscal instruments were also introduced by the government, in terms of tax exemptions/reduction, and various energy efficiency financial schemes and grants provided by the public sector (UNEP & BCA, 2011). A One-Year Accelerated Tax Depreciation Allowance for Energy Efficiency Equipment and Technology (One-Year ADAS) is an initiative by the government to encourage companies to invest in energy-saving equipment by providing tax allowance when replacing old and less efficient equipments (UNEP & BCA, 2011). Other fiscal support are such as Energy Efficiency Improvement Assistance Scheme (EASe), Grant for Energy Efficiency Technologies (GREET), Design for Efficiency (DfE) Scheme, and Green Mark Incentive Schemes (GMIS) (APEC, 2011a; UNEP & BCA, 2011).

4 The Need for Energy Efficiency Legislation in Malaysia

Using an energy index (total energy used in a building divided by gross floor area), estimation of the average energy consumption for a standard non-residential Malaysian building is between 250-300 kWh/m^2/year (Shafii, 2008; Zain-Ahmed, 2008b). In comparison, Singapore's average non-residential building energy consumption is at 220 kWh/m^2/year, while South East Asia's region average is at 230 kWh/m^2/year (Shafii, 2008; Zain-Ahmed, 2008b). The Malaysian building stock in approximately at 38 million m^2 floor area, and of which 11% of the buildings can be considered as energy efficient (consumes less than 136 kWh/m^2/year) (UNDP, 2009).

This clearly indicates that the Malaysian building sector is an energy intensive sector of the economy, and energy efficient strategies and guidelines is needed in order to reduce its overal energy consumption. The sustainable construction approach is still at its infancy phase for the Malaysian industry (Hezri, 2004). Additionally, Malaysia still lacks a consistent GHG emissions database (Fong et al., 2008) to further monitor its progress in the presented strategies. This is a key issue that needs to be addressed if Malaysia aims to achieve its voluntary 40% GHG reduction from the 1990 baseline, by year 2020 (Department of Environment, 2010).

Nevertheless, efforts by professional bodies like Architect Association Malaysia (PAM) and Association of Consulting Engineers Malaysia (ACEM) in Malaysia have served as a catalyst in addressing environmental issues in the building sector. The Green Building Index (GBI) Malaysia, created in collaboration by PAM and ACEM, rates building based on energy efficiency, indoor environmental quality, sustainable site planning and management, materials and resources, water efficiency and innovation (Greenbuildingindex, 2009). The GBI currently only applies for non-residential (existing and new), residential (new only) and townships (Greenbuildingindex, 2009). However, there is currently no reference for measuring GHG emission during building operational phase in the GBI assessment criteria, which reflects the lack of research and development into operational emission of buildings in Malaysia.

Also recently introduced in 2009 were tax exemptions and financial incentives by Ministry of Energy Green Technology and Water in attempts to generate interest for more green construction (Ministry of Energy Green Technology and Water, 2009). Such financial incentives are designated for energy efficiency, production and consumption of renewable resources, and green buildings (Ministry of Energy Green Technology and Water, 2009).

4.1 Lack of Energy Efficiency Building Codes in Malaysia

The Malaysian Standard Code of Practice on Energy Efficiency and Use of Renewable Energy for Non-residential Buildings (MS 1525:2007) was introduced in 2001, and revised in 2007, to guide the effective use of energy (including renewable energy) in new and existing non-residential buildings (SIRIM, 2004; Zain-Ahmed, 2008a). Also according to the MS 1525, the recommended amount of energy consumption for non-residential buildings is 135 kWh/m^2/year (Shafii, 2008; SIRIM, 2007; Zain-Ahmed, 2008b). As the average non-residential building in Malaysia consumes between 250-300

kWh/m^2/year, it noticeably implies that more drastic strategies are needed to comply with the energy efficiency guideline.

The Malaysian building sector is regulated by the Uniform Building By-Law (UBBL) that governs the minimum specifications that includes ventilation, structural and constructional requirements, fire safety (APEC, 2011b; Ministry of Finance, 2006). The by-law however does not include energy performance or energy efficiency guidelines, and the voluntary MS 1525:2007 is being used by the government as efforts to promote energy efficiency for the commercial sector (APEC, 2011b). However, the MS 1525:2007 is planned to be incorporated in the UBBL by 2015, under the National Energy Efficiency Master Plan (NEEMP), an initiative by the Ministry of Energy, Green Technology and Water (MEGTW) (APEC, 2011b).

The MEGTW has also been promoting energy efficiency to government-owned buildings. The Ministry's headquarters implemented a Low Energy Office (LEO) strategy, in efforts to reduce its energy consumption (MEGTW, 2009; Shafii, 2007). In 2006, an energy audit conducted to the LEO building and calculated its energy consumption was 104 kWh/m^2/year, which subsequently won ASEAN Building Energy Award (MEGTW, 2009; Shafii, 2007). Other non-residential buildings that have adapted energy efficiency strategies are like the Malaysian Energy Centre's Zero Energy Building in Bangi (ZERO building), the Energy Commission's Diamond Building in Putrajaya, and the Securities Commission Building in Kuala Lumpur (Shafii, 2007; Zain-Ahmed, 2008b). The ZERO and Diamond buildings were designed to reduce energy consumption to 50 kWh/m^2/year and 85 kWh/m^2/year, respectively (Zain-Ahmed, 2008b).

Albeit these incentives, and more significantly, a similar energy efficiency standard for the residential sector does not exist (SIRIM, 2004; Zain-Ahmed, 2008a). Residential buildings are not regulated nor promoted for energy efficiency, which is likely to have a significant implication on its energy end-use performance (APEC, 2011b). Without such legislation, the residential sector in Malaysia is locking itself for a predicted growth of GHG emission through building operation as purchasing power increases.

5 Conclusion

Malaysia falls behind in terms of implementing energy efficiency building codes compared to its other SEA counterparts. From the listed SEA energy efficiency policy and initiatives, Malaysia has a wide variety of examples to help design its own energy efficiency building code. These examples are furthermore applicable to the Malaysian context, as most of the countries share the same climatic conditions. Energy efficiency standard and guideline in the building sector has proven to reduce energy consumption and consequently help reduce total GHG emissions. The apparent gap for the residential sector in energy-efficiency research and legislation, coupled with rising trend of GHG emission, is set to put Malaysia at high risk of locking in high consumption and low-efficiency building. Therefore, to negate this lock-in effect, both residential and commercial sectors need to develop baselines for monitoring and mitigating GHG emissions from building operations. It is also crucial for stakeholders in the building industry to promote existing guidelines to reduce its overall environmental impact.

Abstract:
Society has an understandable desire to protect the environment, and this protection is reasonably extended to include the impact of building operations through various regulatory controls. However experience has shown that application of the same regulations in different contexts has resulted in very different levels of environmental protection and preservation. These outcomes are situated at the confluence of drafting and implementation of regulations, the monitoring and enforcement of those regulations and the intentions and actions of various stakeholders in the built environment. Although these are typically described in terms of a series of linear processes and interactions the reality is that the levels of ambiguity, informality, and interconnectedness inherent in their interactions are highly complex, and unique to each development. This paper proposes that a systems theory perspective would be beneficial in uncovering processes at work in the Environmental Preservation System, and presents a theoretical construct to that end.

Keywords:
Construction, environment, management, regulation, systems

1 Introduction

At the United Nations Conference on Environment and Development in 1992, the principles of Ecologically Sustainable Development (ESD) were formally adopted through Agenda 21. Signatory countries to Agenda 21, including Australia, acknowledged the adverse impact that human activities were having on the environment (ESDSC, 1992). Within Australia the Commonwealth government signified its commitment to Agenda 21 through the introduction of a plethora of regulatory policies aimed at achieving the principles of ESD and mitigating environmental degradation (Maund & London, 2009). On a State level, the New South Wales (NSW) government enacted the directives issued by the Commonwealth and introduced additional policy; whereby, they have produced what some consider to be an overly legalistic, complex and perplexing legislative system that may not fulfil objectives associated with environmental preservation.

Many of these regulatory controls impact directly upon the development and construction industry which has remained the most rapidly expanding sector, with an annual economic contribution of approximately $45 billion (Australian Bureau of Statistics [ABS], 2012).With such input the consequence has been the gradual exhausting of natural resources and irreversible environmental degradation (Hendrickson and Horvath, 2000; Li, Zhu & Zhang, 2010; Shen & Tam, 2002; Tam, Tam, Zeng & Chan, 2006).

It is not well understood whether current NSW State environmental planning regulation exerts sufficient control over on-site construction practice, particularly in relation to implementation of regulations, associated monitoring and enforcement operations. Interaction of these variables is considered highly complex and subject to ambiguity, informality and interconnectedness. The dilemma is compounded with these variables governed by industry stakeholders: the subjective human element. In effect, the actual ability of the current legislative system to cultivate environmental preservation remains undetermined. The problem appears to be one of a systemic nature and it is proposed that adoption of a systems theory approach would be beneficial.

Stewart and Ayres (2002) explained that 'for policy problems characterised by complexity (such as those concerned with environmental management and regulation, and urban re-development) using systems concepts offers a way of rationalising aspects of existing practice and of suggesting directions for improvement' (p. 79). Therefore, systems theory offers the opportunity to investigate interactions between regulation, enforcement and information flow with on-site construction operations to identify where critical interactions reduce effectiveness and thereby reduce environmental preservation.

Ideas proposed throughout this paper form part of a PhD thesis which is currently in the conceptual stage with an objective to develop a theoretical framework demonstrating how government regulations related to environmental planning influence environmental outcomes of on-site construction operations. It is suggested that systems theory would provide an investigative tool to rigorously interrogate interactions and critically analyse policy with regard to environmental management operations and outcomes. Although primary data collection will be confined to New South Wales, findings may inform wider national and international practices.

2 The Research Context

Within the literature it has been acknowledged that construction operations generate negative effects upon the environment (Shen and Tam, 2002; Tam, Tam, Zeng & Chan, 2006). Accordingly, Shen and Tam (2002) state that 'construction is not by nature an environmentally friendly activity' (p.535). The copious negative environmental impacts that result from industry practice may lead to environmental degradation and the exhaustion of natural resources (Shen and Tam, 2002; Tam, Tam, Zeng & Chan, 2006).

Impacts such as resource extraction related to fossil fuels and resource consumption affecting water, energy and materials significantly contribute to detrimental consequences. Environmental impacts fluctuate from toxic air emissions that include hydrochloric acid, chlorine, ammonia and methanol in addition to sulfur dioxide, nitric

oxide and volatile organic compounds. Tangible impacts affect both water and soil including solid, liquid and hazardous waste production and the contamination of land via chemical emissions (Hendrickson and Horvath, 2000; Shen and Tam, 2002). Although the actual impacts depend on the nature and method of construction, it is undeniable that all construction operations result in environmental degradation.

Theoretically, negative environmental consequences of construction operations may be a result of limitations within the regulatory domain. However, deficiencies in State regulation and enforcement mechanisms although responsible for achieving ESD, do not operate in isolation. Inadequate information flows within the subsystems of the environmental preservation system (see figure 1) and stakeholder interactions may also contribute to produce a significant disconnect with the consequence of potential ineffective environmental management practices. The research proposes to investigate regulatory policy, enforcement and information processes: a systems approach, to unveil the processes at work in the environmental preservation system and how they impact on-site construction environmental management.

3 Regulatory Policy

Policy may be considered a mechanism employed by organisations to regulate specific activities to achieve a set objective. Lee and Yik (2004) state: '…policies are institutional arrangements that influence the decision making of individuals and firms as they attempt to maximise their benefits under the constraints imposed by the policies' (p. 494). In this respect, a policy may be established by any organisation to manage set operations to ensure compliance with a set regime.

This research will explore regulatory policy, legislation, through a systems approach rather than individual organisational policy. Regulatory policy poses a slightly different definition in that it entails '…a set of authoritative rules accompanied by a mechanism, usually administered by a public agency, for monitoring and promoting compliance with those rules' (Johnstone and Starr, 2004, p. 4). It is this form of policy that is encompassed within the environmental preservation system presented in figure 1. The inauguration of regulatory policy within the environmental and planning domain involved formation of law where strict compliance was mandated. Enforcement was the mechanism employed to ensure conformity where violations may promote prosecution. This regulatory approach has been entitled the command and control approach (Lee and Yik, 2004). However, with the current proactive trend to encourage environmentally sound practices, regulation has evolved to incorporate flexible mechanisms that engage stakeholders into compliance. Typically, subsidies, taxes and voluntary agreements are employed to encourage compliance (Johnstone and Starr, 2004).

Although contemporary regulation has adopted a certain degree of flexibility, enforcement continues to play a major role in the environmental preservation system. Enforcement becomes the instrument by which compliance with regulatory policy is attained: a control mechanism. The objective of enforcement is to introduce accountability for violations against regulatory policy (United State Environmental Protection Authority [US EPA], 2012; Johnstone and Starr, 2004). The US EPA (2012) explains that ''…civil and criminal enforcement is an important part of ensuring

governments, companies and individuals meet their environmental obligations'. Even with the current combination of regulation, flexible arrangements and enforcement it remains questionable as to whether any real improvements in construction environmental management have occurred.

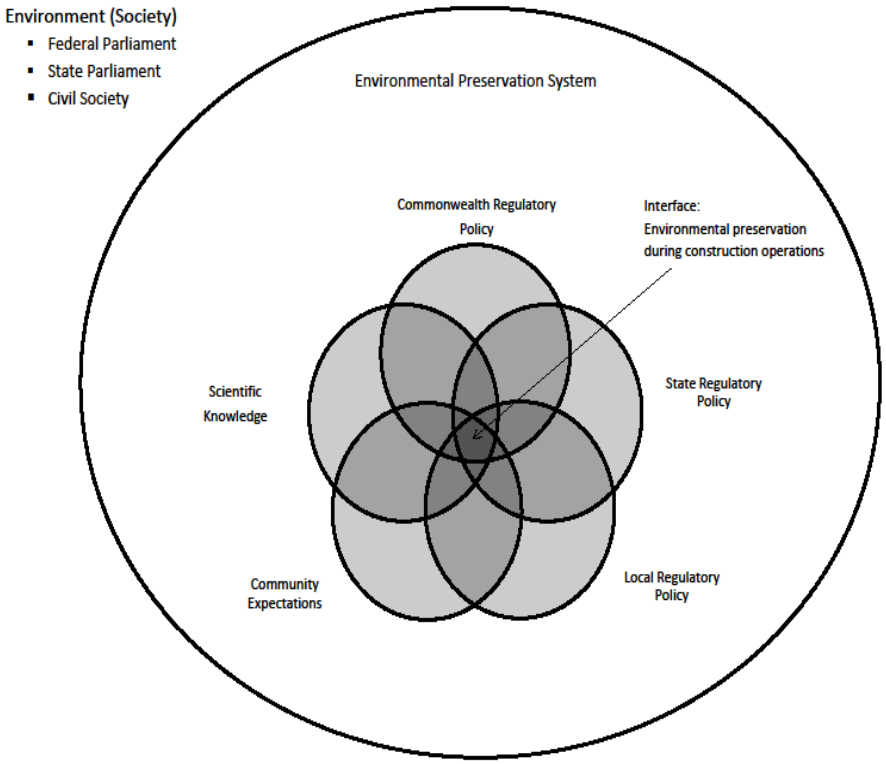

Figure 1, The environmental preservation system

3.1 The Regulatory Dilemma

The effectiveness of regulatory policy in environmental preservation has continued to be the centre of much debate. Kneese (1976) in his review of United States natural resource policy explained that 'It is inconsistent, often outdated, and grossly over dependent on direct regulation…' (p. 253) in addition '…policy also fails to recognize the tight interdependences among all resource problems, including those of environmental resources' (p. 253).

This view continues to be supported as Gunningham and Sinclair (1998) explained '…most existing approaches to regulation, are seriously sub-optimal…they are not effective in delivering their purported policy goals, or efficient, in doing so at least cost, nor do they perform well in terms of other criteria such as equity or political acceptability' (p. 1).

The efficacy of the environmental planning regulatory system within New South Wales has continued to evoke discussion as to whether it is able to achieve ESD. The existing

regulatory system is deemed so multifaceted and complex that the State Government identified a need to '…eliminate unnecessary and complicated red tape', and stated that the system is '…a confusing web of conflicting plans and instruments' (NSW Government, Department of Planning [DoP], 2005a; 2005b). Even after much review and amendment the State Government acknowledged the system '…remains lengthy, complex and confusing…', (DoP, 2007, p.3) and '…that the community generally feels disconnected with the planning process, deeply cynical about whether it is worthwhile to engage, and extremely frustrated about the current system' (NSW Environmental Defender's Office and Total Environment Centre, 2010, p. 3).

During 2011, the State opposition Government was elected into office where one of their first priorities was to undertake a New South Wales Planning System Review around the *Environmental Planning and Assessment Act* (EP&A Act), 1979, the primary document that governs development processes within NSW. An initial Issues Paper released in 2011 identified that considerable components of the Act remain outdated. The Act used '…overly legalistic language…' and '…overly complicated processes…' (DPI, 2011, p. 17) and contained complex provisions that interpretation and assessment practices were abstruse (DPI, 2011).

Regulatory policy appears to have a chequered history in its effectiveness and ability to achieve environmental preservation. It is proposed that this research will use a systems theory approach to investigate construction environmental management controls. What appears to be a main flaw of existing legislation is the inability to review the system as a whole. Any change to the system must be reviewed in a wholistic manner. All the interrelationships and subsequent implications must be given due consideration. This includes the stakeholder element: importantly the often neglected regulators. It is necessary to develop a theoretical framework to demonstrate how government regulations influence on-site operations in the context of examining the entire system. It is proposed that the existing regulatory system will be reviewed using systems theory to identify critical points of departure from achieving ESD.

3.2 The Regulatory System

To enable an examination of the policy system that regulates on-site construction environmental management practices it becomes necessary to first review the hierarchy of influences affecting that system. Within NSW the environmental and planning regulations that govern the construction sector may be conceptualised into a hierarchy of four tiers (see figure 2). Tier 1 and Tier 2 concern the intent conventions. Within Tier 1 these are represented as environmental constructs: principles and standards associated with environmental preservation. Tier 2 progresses upon these expectations though the introduction of mechanisms that propose to achieve standards: environment planning regulations. Tier 3 and Tier 4 are actual conventions associated with operational outcomes: the interpretation and implementation of the regulations. Tier 3 may be considered to have significant influence within the system. The human element is associated not only with the formulation of rules and project design but also with the interpretation and enforcement of those rules and on-site operations. The subjective interpretation and implementation processes associated with regulatory policy may fundamentally alter project outcomes. Systems theory in this research context will

review law interpretation and implementation and its potential to impact upon on-site construction practices.

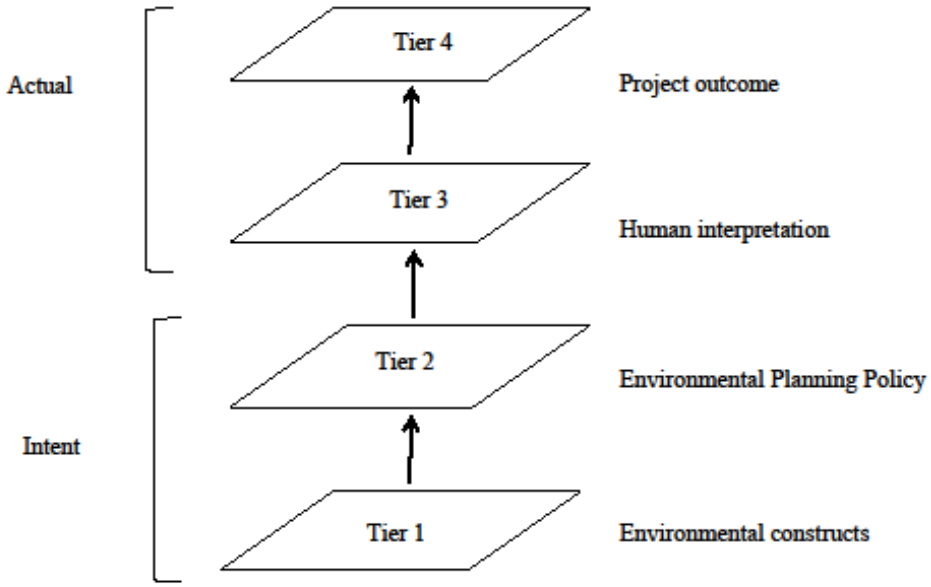

Figure 2, Conceptualisation of legislative-construction hierarchy

From the legislative-construction hierarchy it is possible to conceptualise the environmental preservation system further into elements and relationships. As can be seen in figure 3 the Environmental Preservation System consists of a range of inputs that considers all tiers of regulatory policy, scientific knowledge to stakeholder and community requirements: all elements within the system. Each of these inputs creates the need or desire for regulation and through subjective interpretation would consider regulatory control in different ways. The systems approach will be used to determine interaction of regulatory mechanisms, government agencies and construction stakeholders.

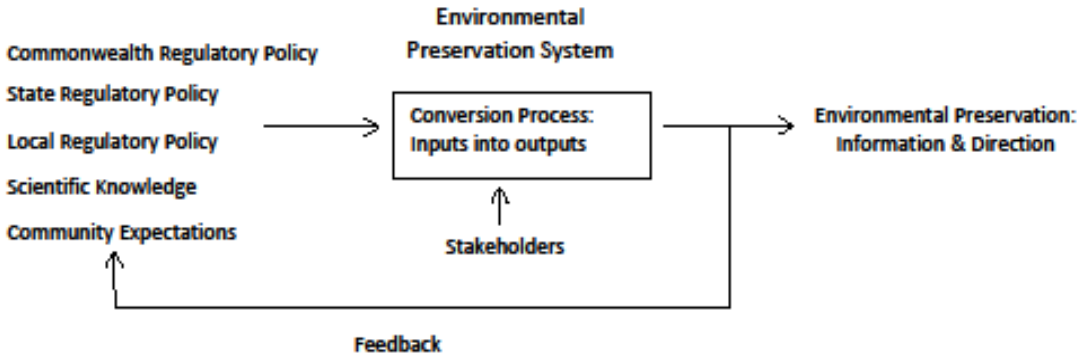

Figure 3, Interactions within the environmental preservation system

At the Federal level directives for many State regulations are established. In the same way many State regulations create the foundation for local level policy formulation. Therefore, all three tiers of regulatory control require consideration as part of the environmental preservation system. Scientific knowledge is a dimension that may demonstrate significant influence. New knowledge initiates innovative technologies and may also alter work place practices where policy must be amended or updated. Advances in knowledge often instigate changes to community perception. Communities have expectations about what environmental preservation should be and how operations should be conducted. Regulatory policy is also directed by the political view: community pressure for change or amendment. Topics of importance or a notable problem to the community are raised at a political level from which existing regulatory policy may be reviewed and possibly amended. This is a typical illustration of system connectivity and why elements, their interrelationships and subsequent consequences must all be given due consideration to enable a complete understanding of the environmental preservation system.

The impact of stakeholders cannot be underestimated. In many respects these include the developers, builders, subcontractors and other technical professionals related to construction processes. The community also forms part of the stakeholder group as their opinions, expectations and desires about proposed development may have a significant influence over the focus and outcome of a project. Within the assemblage of stakeholders, one group is often not given due consideration as an element within the system themselves: the regulators being the policy-makers, implementers and enforcers. These stakeholders are often not given due consideration in the formulation of policy; yet, they have the potential to significantly impact upon a development project.

All the variables discussed contribute to the assemblage of system inputs where the conversion process occurs: inputs are transformed into outputs. The outputs proposed relate to environmental preservation through information and direction on how to address issues raised. As the expected level of environmental preservation is not achieved one element or more are reviewed and the cycle continues to evolve.

Figure 3 illustrates a multi-complex system with numerous elements and interrelationships. An effective investigation of any element within the system requires consideration of all variable and relationships in operation. In order to understand the complexity at the interface of society and statute control, need to take a systemic view of the problem to assist deconstruct all the inputs and outputs. For this research, it is proposed that the systems theory approach: applied through the environmental preservation system will enable the foundation of a framework that will enable an effective investigation into on-site construction management operations.

4 Systems: Theory and Policy

The environmental preservation system is flexible and dynamic, consisting of many dimensions where change occurs according to energy inputs into the system. In general in its current application it may be considered a reactionary system, as an issue is raised there is an attempt to address the dilemma. This process is generally unsuccessful as it neglects consideration of the entire system and importantly interrelationships and

subsequent consequences. There remains a feedback process whereby there is an attempt to address previous issues or a new issue that has evolved. Systems theory provides a mechanism to investigate output of policy change in a holistic manner compared to what appears to be the current ad hoc method of assessing and making change to a single system element in isolation of its counterparts. Research will use systems theory to investigate the regulatory framework and the subsequent impact of stakeholders on that structure in achieving ESD.

Systems theory has potential to result in improved understanding of on-site environmental preservation as Stewart and Ayres have identified that 'Problems such as ecological deterioration, pollution…have been cited as examples of problems which citizens expect governments to act upon, but which are difficult to tackle within normal policy modes' (Stewart and Ayres, 2001, p82.).

Systems theory applies to the research as it would provide a way of reviewing regulatory policy interactions within on-site construction management and potentially highlighting areas where current policy achieves desired outcomes or remains inadequate. The theory encapsulates interdependencies, in this case regulatory policy and enforcement processes and their relationship with construction operations within the environmental preservation system. Importantly, it acknowledges that the system comprises various stakeholders both regulatory and non-regulatory. Although the research focus is with legislation, it will examine the impact of this regulatory policy on private organisations to determine how it impacts upon their ability to achieve ESD. Ultimately the environmental outcome for a given project will reside at the interface of all interactions of the system. It can be seen that the environmental outcome is ultimately the product of complex system interactions.

4.1 Defining Systems

A preliminary step in systems theory is defining the system of concern. Once the system is identified a framework can be developed to enable review of the elements and analysis of their interactions. According to Alexander (1956) a system is '…a group of elements, either physical or non-physical in nature, that exhibit a set of interrelations among themselves and interact together toward one or more goals, objectives or ends'. The definition is in tandem with that of Burch, Strater and Grudnitski (1983) who define as system as '…any set of objects and ideas, and their interrelationships which are ordered to a common goal or purpose'. A system is therefore, a set of interactions amongst entities or elements that have a direct result of achieving a set objective (FitzGerald, FitzGerald and Stallings, 1981, Smith, 1992).

The elements of any system may be defined as physical items or those that are intangible (Alexander, 1956). The framework of a system moves beyond the interactions of tangible entities or elements to what may be considered a subsystem of interrelated structures, concepts and strategies (Smith, 1982). These may present as organisational or managing structures (Alexander, 1956). Remington, Zolin and Turner (2009) define complex systems as demonstrating characteristics that make it difficult to predict outcomes. In essence, any system, regardless of its complexity, may constitute both material elements in conjunction with an array of intangible elements that work concurrently.

In the application of regulatory policy-making, a system 'is often used to describe the assembly of organisations to be found in a given policy field, and to suggest the interconnections between them…' (Stewart and Ayres, 2001, p. 82). To develop an understanding of a regulatory system that maintains a governing role over an area of operation, identification of each element is necessitated to enable determination of the interactions and critical points that affect ability of that regulation to achieve the desired outcomes. According to Mbiti, Blismas, Wakefield and Lombardo (2011) systems thinking considers the dynamics of a system through feedback control of the system itself. In this way a review of regulation related to on-site construction management would consider how the regulation and other system components affect policy effectiveness. Understanding systems provides the theoretical framework by which the effectiveness of any regulatory system can be explored. In this research the elements of the environmental preservation system must be identified. Elements are both tangible concerning regulatory policy and scientific knowledge through to those that are intangible relating to the subjective nature of policy interpretation and the more personal based interactions. Once the system is defined, systems theory can progress to understanding interactions to highlight efficiencies and potential areas for improvement.

4.2 Systems Theory

Smith (1982) and Stewart and Ayres (2001) state that to examine system operations and instigate change it is paramount that an examination of the whole system and all relationships be undertaken, rather than an ad hoc review of components in isolation. Systems theory has been defined as '…a unifying theory that seeks to identify relations and interdependencies among the elements of a system' (Alexander, 1956, p.14). This theory asserts that to understand the effectiveness of a system, its interactions and interdependencies and their impacts upon the desired outcome, an examination of the whole system is warranted. According to Mbiti et al. (2011) sub-entities exist in the construction industry to provide constructed space.

There are many benefits to a systems approach as it allows consideration of broader issues rather than investigating one or a couple of elements of a system. Only where the entire system is examined as one entity, including internal and external impacts, will a complete understanding be forthcoming (Smith, 1982). In effect, an attempt to improve a system by examining all elements and their interactions is likely to be more effective when compared to change of various components in isolation.

Smith (1982) explains that systems approaches may be considered 'divergent and flexible' (p.4) in his view of system analysis and mechanisms for approaching problem resolution. Importantly, within the systems approach the human element is identified and considered within the system. There is a need to not only recognise existence of this system 'element' but understand the significant influence humans have upon anticipated outcomes. In addition, it enables regulatory bodies: policy-makers and enforcers to become part of the system and their impacts upon operations measured.

Sub-entities in the construction industry form a system (the construction industry itself) and as such systems theory can be used to analyse interactions and critical points in regulation of the industry (Mbiti et al., 2011). Systems theory provides opportunity to describe and research the environmental preservation system in a wholistic way.

Tangible and intangible elements, the objective and subjective system influences, in conjunction with the human dimension, may be given due consideration to enable examination of system improvements through the proposed research.

4.3 Systems Theory and Policy Research

Within the literature it has been highlighted that a common result of public policy is its inability to achieve set goals and the creation of sometimes unforeseen negative consequences. There may be many reasons why policy fails to achieve its set goals; however, a main pretext concerns an inability to consider the whole system, all the related components or elements and their relationships (Stewart and Ayres, 2001).

Within the environmental preservation system there are multiple factors that may not be given due consideration in the formulation, implementation and analysis of regulatory policy. Stewart and Ayres (2001) identify a number of variables that contribute to policy failure including structure and processes, political imperatives, communication linkages for implementation, causes and consequences in addition to policy-makers not considering themselves part of the system. These variables are of relevance to this research and the intended outcome from investigating regulation, enforcement and information flow via the systems theory approach:

- Structures and operations
  The structures that govern policy are often the factors that inhibit policy success. In effect, it is the bureaucratic processes that limit policy and silo situations may evolve. Various government departments each focus upon their own component of the system or regulatory policy in isolation and within due consideration of the relationships or consequences.
- The political environment
  Regulatory policy is in effect a policy that has been adopted by Parliament. Parliament introduces political sway into the regulatory scheme. Regardless of the intent such as achieving environmental preservation, there is potential for political motivation to drive policy content and adoption. This may not always be the most suitable for achieving the intended outcome.
- Communication and information flow
  The silo approach automatically induces negative information flow within a system meaning policy has little chance of being successful. Communication channels are needed between those responsible for policy formulation, its implementation and enforcement. It is necessary to ensure that policy is feasible on a practical and economic level so that it may be implemented and regulated. Appropriate information flow may assist to reduce ambiguity and misinterpretation in application of regulatory policy.
- Consequences
  In development of policy it has been identified that insufficient consideration is often given to consequences. Implementation of new policy and amendment of existing policy have interactions within the system and affect outcomes. Typically, this relates to the silo effect where organisations working to an individual agenda have little success of achieving their desired outcome due to limited consideration of associated system variables such as affiliated organisations.

- Stakeholder inclusion
  The role of the policy maker, regulator and enforcer within the system is often overlooked. As stated by Stewart and Ayres (2001) 'they are themselves within and subject to the very system they seek to understand and influence' (p. 80). Consideration of these external non-contractual influences when examining a system is essential to ensure policy success.

Typically, where policy is formulated on the pretence that behavioural change will achieve a policy goal the ability for success is limited. As discussed, compliance is commonly used in policy to achieve outcomes. Stewart and Ayres (2001) describe this process as 'public policies aim to change behaviour target groups by changing key aspects of their environment…' (p. 84). For example, taxes should have an end result of reduced usage of a particular resource or material. There are various concerns with this view as the ability to drive change through this mechanism relates to a variety of factors, primarily project economics. Such factors may not always influence behavioural change as the costs of changing operations associated with the tax are not necessarily feasible for an organisation. Systems theory would enable a review of compliance coupled with system interactions and other policy options to highlight barriers and enablers to an effective environmental preservation system.

Stewart and Ayres (2001) explain that 'systems approaches can also be usefully employed as a way of generating distinctive analytical and implementation strategies from which policy-makers can fashion policy recommendations. More broadly, the systems approach offers policy-makers a fresh set of perspectives on the fundamentals of policy analysis. It suggests that policy design is as much a matter of choosing structures and relationships, as choosing instruments' (p. 91). Systems theory applied to the research would provide opportunity for innovation in looking at the system wholistically to find an efficient combination of elements. Remington, Zolin and Turner (2009) found severity of complexity of a system correspond with context and clarity. It is proposed that a systems theory approach would enable identification of areas in which the regulatory system is not achieving effective on-site environmental management.

Given an understanding of issues that have an impact upon the success of policy we can look at systems theory to provide a framework to better analyse the complex and dynamic environmental preservation system. Alexander (1956) states '…one of the benefits of the application of systems theory to management thought may be to resolve some of the conflicts that presently beset it by stressing the harmonious, integrative aspects of the management function' (p. 14). Although the comment relates to management processes, it remains applicable to the policy domain. As shown there are many reasons behind policy failure, many of which relate to fragmentation of the existing system from structures and process, poor information flow through to inappropriate consideration of causes and consequences. Systems theory offers the opportunity to establish a framework to consider all variables within the system and examine the disconnect between policy intent and actuality. It presents a means by which policy and its desired outcomes can be effectively analysed and assessed. The systems theory approach would assist in identifying key elements, interdependencies and opportunity for improved policy.

Traditional policy formulation involves identification of an issue for which regulation is necessitated, adopting a standard instrument or amending an existing one as applicable to that problem. This appears to be a linear process involving the identification of an issue and resolution mechanism in isolation of any other component of the system in which it operates. Systems theory mandates consideration of the whole system to understand the complexity of any problem. Consideration must be given to the entire system, *inter alia*, regulatory policy, stakeholders and information flow if policy is to succeed. For a policy area in crisis it is neither practical nor feasible to modify one component of the system and expect complete resolution (Stewart and Ayres, 2001). For example, within the environmental preservation system consideration must be given to all stakeholders: developers, builders, community but also the often neglected regulators who have the potential to significantly impact upon project outcomes. In this way a systems theory approach to analysing regulatory policy would consider inputs and outputs of policy.

Systems theory enables the policy maker to look at the system as a whole. This means consideration of all components of the system, considering variables that have the ability to influence change, consider cross boundary communication pathways, consideration of all stakeholders with a contractual or non-contractual influence and consequences of decisions, particularly to other areas within the system.

Application of systems theory to the research would allow for investigation of key aspects of policies and interactions with stakeholders. Systems theory would highlight areas where policy is effective or ineffective and allow for policy shift to target those areas in a way that would enhance systems functioning and thereby result in improved environmental preservation.

5 Conclusion

Construction activities cause environmental degradation. There is a lack of research linking on-site environmental construction practices and environmental management to the effectiveness of regulatory policy, enforcement and information flow. Ultimately there is a disconnect between intent and actuality associated with environmental protection. This research provides context for development of a theoretical framework within which examination of the on-site construction domain can be gauged against existing regulatory controls. In particular it allows development of knowledge about external non-contractual influences on project information flows and their environmental consequences.

With potential disconnect between regulatory policy, enforcement and information flow the research proposes to investigate these variables within the NSW context, to ascertain whether they achieve environmental preservation. Disconnect within interdependencies would be investigated using systems theory to highlight effective and ineffective dependencies and critical points where objectives may be met or skewed.

Application of systems theory in the research would present opportunity to understand all elements of the system and seek areas for system-wide transformation to improve environmental preservation. The large number of existing policies, stakeholders and

interrelationships in the highly complicated system of development and construction management requires a systematic approach of investigation. A systems approach would allow an examination that would improve understanding of the regulatory system and allow for change in the development system with key interrelations identified and areas for potential change highlighted.

ABSTRACT

Substantial research over the past several years has been performed on the data standards and exchange in the AEC/FM industry. The growing popularity of BIM is based heavily upon a perception that the technology can facilitate the sharing and reuse of information during a life-cycle. Therefore, we propose the conceptual BIM acceptance model for understanding why people accept or reject BIM. The objective is to understand the key factors affecting the acceptance of BIM in construction organizations. The external and internal variables identified through a literature review with respect to understanding the acceptance of new information technologies, and then to select external variables to increase BIM acceptance. The proposed model combines the TAM (Davis, 1989), the TTF (Goodhue and Thompson, 1995) and the motivation model (Deci and Ryan, 2000). The model consists of twenty-three factors that are hypothesized to have direct or indirect effects on BIM acceptance. The primary contribution of this paper is to propose the foundation of research on the BIM challenge in the construction as a guide for future research.

Keywords: Building Information Modelling (BIM), Construction Organization, Motivation Model, Task-Technology Fit (TTF), Technology Acceptance Model (TAM),

INTRODUCTION

In 2004, according to a NIST report, the capital facilities construction industry wastes $15.8 billion annually due to interoperability inefficiencies. These inefficiencies include the re-entry and re-creation of information and data, and a duplication of business functions (Newton 2004). Using Building Information Modelling (BIM), these inefficiencies can be solved (Mendez 2006). BIM is “a new approach to design, construction, and facilities management, in which a digital representation of the building process [is used] to facilitate the exchange and interoperability of

[1] selkizz@kw.ac.kr
[2] myazure@kw.ac.kr
[3] David.jeong@okstate.edu

information in digital format (Eastman, et al. 2008)". In the construction industry, there is a growing interest in the use of BIM for coordinated, consistent, and computable building information/knowledge management from design to construction to maintenance and the operation stages of a building's lifecycle.

Although many researcher and practitioner are in agreement about BIM's potential applicability and benefits in construction, it is still unclear how BIM could be used, and what the benefits are to implementing BIM. Thus, BIM adoption and use remains a central concern of BIM research and practice. One of the key measures of implementation success is achieving the intended level of usage of the Information Technology (IT). The IT usage is a reflection of the acceptance of the technology by users (Venkatesh 1999). There is a growing body of academic research examining the determinants of information technology acceptance and utilization among users (Patrick and Paul 2002; Taylor and Todd 1995). In particular, the Technology Acceptance Model (TAM) (Davis 1989; Davis, et al. 1989) has served as a basis for previous research in dealing with behavioural intentions and usage of IT. The previous research argued in favour of investigating antecedent variables that can explain the core TAM variables and extend TAM in a way that enhances our ability to better understand the acceptance and usage of existing and new IT. Factors contributing to the acceptance of an IT are likely to vary with the technology, target users, and context (Moon and Kim 2001). Most of the prior studies have been carried out in traditional and relatively simple but important environments, such as personal computing, e-mail systems, word processing and spread sheet software (Hong and Thong 2001). The technology assessment theories provide a sound theoretical base for examining the factors influencing the use of BIM for construction organizations. Constructs for use in this study are based on those discussed in these theories. Theses constructs were selectively used based on their relevance in the BIM context as evidenced by previous surveys and case studies on the use of BIM.

Therefore, we review acceptance behaviour related theories to propose the conceptual BIM acceptance model within a real business environment by considering it in the implementation of BIM. Namely, the goal of the present research is to identify the additional key determinants of TAM's perceived usefulness and usage intention constructs for a more systemic and integrative perspective of BIM. The primary contribution of this paper is to propose the foundation of research on the BIM challenge as a guide for future research

ACCEPTANCE BEHAVIOR RELATED THEORIES

Technology Acceptance Model (TAM)

The goal of TAM is to provide an explanation of the determinants of computer acceptance that is capable of explaining user behaviour across a broad range of end-user computing technologies and user populations, while at the same time being both parsimonious and theoretically justified. In this model, perceived usefulness and perceived ease of use are of primary relevance for IS acceptance behaviour. TAM proposes that external variables indirectly affect attitude toward use, which finally leads to actual system use by influencing perceived usefulness and perceived ease of use. TAM assumes that the effects of external variables (e.g., system characteristics, development process, training) on intention to use are mediated by perceived usefulness and perceived ease of use. Paul, et al.(2003) note that there is no clear pattern with respect to the choice of the external variables considered. Actually, external variables provide a better understanding of what influences perceived

usefulness and perceived ease of use, and the presence of external variables guides the actions required to influence a greater use.

Task-Technology Fit (TTF)

TTF matches the capabilities of a technology to the demands of the task. The availability of IT to support a task is expressed by the formal construct known as TTF, which implies matching of the capabilities of the technology to the demands of the task (Goodhue and Thompson 1995). TTF posits that IT will be used if, and only if, the functions available to the user support (fit) the activities of the user. Rational, experienced users will choose those tools and methods that enable them to complete the task with the greatest net benefit. Information technology that does not offer sufficient advantage will not be used. TTF models have four key constructs: the first two are task characteristics, technology characteristics, which together affect the third construct task-technology fit, which in turn affects the final construct outcome variable, either performance or utilization.

Motivation Model

Motivation is a key factor determining human behaviour and action (Lin 2007). An unmotivated person feels no impetus or inspiration to act, whereas when he/she is engaged in some activities toward an end, he/she is considered motivated. Some researchers suggest that individuals may have different amounts, as well as different types of orientations of motivation (Deci 1975). Two broad classes of motivation - extrinsic and intrinsic - have been defined and examined across various contexts and studies. Extrinsic motivation focuses on the goal-driven reasons, e.g. rewards or benefits earned when performing an activity (Deci 1985), while intrinsic motivation indicates the pleasure and inherent satisfaction derived from a specific activity (Deci 1975). Together, extrinsic and intrinsic motivation influence individual intentions regarding an activity as well as a person's actual behaviours (Moon and Kim 2001; Davis, et al. 1992).

THE PROPOSED BIM ACCEPTANCE MODEL

BIM acceptance of construction organizations

The construction industry has several unique characteristics that distinguish it from other industries. Also, the construction industry consists of various organizations (design, contractor, engineer, and facility manager). Therefore, it is necessary to describe the nature of the organizations in order to understand the problems that may influence the acceptance of BIM use by the construction organizations. BIM is being developed with a broad range of users in mind. As such, its uses are extremely varied and in many cases can differ significantly among build team members. A list of the potential uses is as follows:

- 3D visualization (architecture/structure/MEP)
- Clash detection
- Feasibility studies
- Model based quantity take off and estimating
- Visualized scheduling (4D) management
- Environmental analysis or LEED certification
- Creation of shop drawings and schedule management for installation
- Visualized constructability review
- Visual and geospatial coordination for construction of atypical shape
- Creation of as-built model for facility management

The acceptance of BIM means that construction organizations use BIM application for their task. As a highly collaborative and data-rich environment, BIM has the inherent capability to reduce costs and promote efficiencies. To successfully accept BIM in construction, effective collaboration and clear role sharing for modelling among users are necessary. Then, all users should comply with the standardized policies and procedures for modelling.

Overview of proposed model

The proposed conceptual model is constructed by integrating three empirically tested and proven research models such as TAM, TTF, and motivation model. The model provides the rationale for the variables based on theoretical backgrounds on TAM, TTF and motivation model, and incorporates additional variables based on literature on BIM use. Based on the above concepts, a research model for BIM acceptance is proposed (see Figure 1).

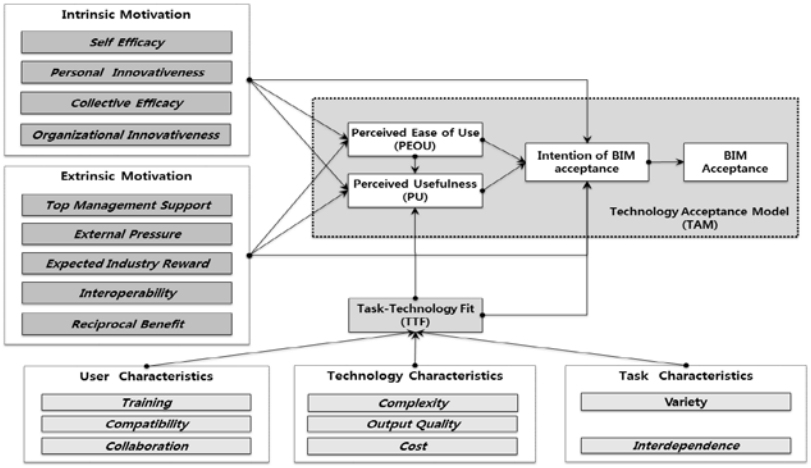

Figure 1 The conceptual model

External Variable for BIM Acceptance

In general, the result of user acceptance of information systems in the mandatory environment differs depending on external variables. Studying the external variables for BIM not only contributes to theory development, but also leads to improved BIM acceptance. As shown in figure 1, the components used to accept BIM in construction organization are 1) user related factors-individual and organization, and 2) technology related factors.

1) User related factors

First, although BIM acceptance is in the mandatory environment, the confidence that user can successfully utilize BIM is necessary to accept BIM, and the suitability of the potential adopter's work environment should be considered. Also, because effective collaboration and clear role sharing for modelling among construction organizations are necessary, unlike most system acceptance, organization factors should be considered for successful acceptance of BIM in construction organizations.

Self-Efficacy: The concept of self-efficacy originates from social cognitive theory (Bandura 1977). It refers to the conviction that one can successfully execute the behavior required to produce the outcome. Self-efficacy is used as perceived behavioral control, which means the perception of the ease or difficulty of the particular behavior. It is linked to control beliefs, which refer to beliefs about the presence of factors that may facilitate or impede performance of the behavior. ***Personal Innovativeness:*** Personal innovativeness is defined as "the willingness of an

individual to try out any new information technology". According to Agarwal and Prasad (1988), personal innovativeness helps identify individuals who are likely to adopt information technology innovations earlier than others. Learning a person's individual innovativeness would help us to further understand both how perceptions are formed and the subsequent role they play in the formation of individual behavior. ***Compatibility:*** Compatibility, defined as the degree to which the technology fits the potential adopter's previous experience, work practice, and needs, has been identified as an essential factor for innovation adoption (Moore and Benbasat 1991). Considerable prior research has reported a significant effect of compatibility on the user technology acceptance decision. ***Training:*** Training is a primary factor affecting the adaptation of a new technology within an organization because it helps users to understand how to best use and adopt BIM applications (Peansupap and Walker 2005). Without appropriate training, most technology users take time to learn and utilize only some capabilities of the technology. The level and type of training should ideally be based on the tasks to be performed by different departments or persons within an organization. Training was therefore used as a factor in this study. ***Variety:*** Task variety is the degree to which one has to conduct exceptions or a wide range of operations (Morgeson and Humphrey 2006; Sims, et al. 1976), and therefore different methods or procedures are needed for conducting the work (Van de Ven and Delbecq 1974). It is also referred to as the stability, rigidity, or repetitiveness. ***Interdependence:*** Task interdependence is the degree to which completing tasks requires interaction with other people (Liden, et al. 1997). Task interdependence consists of two types (Kiggundu 1991): initiated and received interdependence. When someone is dependent on the work of others, it is referred to as received task interdependence. In cases where someone affects the workflow of others, it is referred to as initiated task interdependence. It is all together the degree of 'interconnectedness' between jobs(Morgeson and Humphrey 2006), in which the success of one depends on the performance of others (Kiggundu 1981;1983).

Collective Efficacy: This concept refers to the organizational dimension to inquire about efficacy beliefs in organizations. Inquiry into collective efficacy beliefs emphasizes that teachers have not only self-referent efficacy perceptions but also beliefs about the conjoint capability of users. Such group referent perceptions reflect an emergent organizational property known as perceived collective efficacy (Goddard, et al. 2000; Hoy, et al. 2002). ***Organizational Innovativeness:*** We defined that organizational innovativeness as "the willingness of an organization to try out any new information technology". To successfully accept BIM, effective collaboration and clear role sharing for modelling among construction organizations are necessary. Then, all construction organizations should comply with the standardized policies and procedures for modelling. Therefore, personal innovativeness as well as organizational innovativeness should be considered. ***Top Management Support:*** Top management support has extensively been recognized as an important variable in technology implementation studies (Gilligan and Kunz 2007). The decision by an organization to adopt BIM may by a risky decision for the organization unless there is a firm commitment from top management. Gillgan and Kunz (2007) found that top management commitment was one of the major success factors for adopting BIM technologies. It is anticipated that firms that have significant top management support for adoption for BIM are more likely to it. ***External Pressure:*** External pressure involves the influences arising from several sources within the competitive environment surrounding the organization. Enacted user power measures the strength

of the influence strategy (e.g., rewards and threats) used to exercise that potential power.

Expected Industry Reward: Industry rewards can range from monetary incentives such as increased benefit and market share. Thus, this study expects that if organizations believe they can receive industry rewards by using BIM, they will develop more positive attitudes toward and intentions regarding the use of BIM.

2) Technology related factors

Second, unlike other technology acceptance, BIM can only be utilized in a data-rich environment. Thus, the quality of information which is included in BIM is a key factor affecting the acceptance of BIM. Also, to improve the information quality of BIM, the barriers of BIM acceptance should be solved, and an environment of collaboration among users in design and construction should be created.

Cost: Rogers(1983) noted that the less expensive an innovation is, the more likely it is to be adopted. The cost of an innovation includes the initial investment cost as well as the operations and training costs that facilitate effective use of the technology (Premkumar 1995). In previous technology assessment research, cost has been suggested as a major barrier to widespread adoption of innovative technologies (Premkumar 1995). Related research on BIM adoption has also shown that cost of BIM technology is a major factor (Gilligan and Kunz 2007; Timo and Martin 2008; Kunz and Fisher 2007). It is anticipated that firms that perceive BIM technology to be relatively less costly are more likely to adopt it. ***Complexity:*** Rogers(1983) defines the complexity of an innovation as "the degree to which the innovation is perceived as relatively difficult to understand and use" observed that although an innovation may appear to be useful, the organization may find it complex to use. They concluded that since complexity of an innovation functions as an inhibitor to adoption, it is usually negatively related to adaptation. Other researchers have also shown empirically that technology complexity is an important factor that influences technology adoption.

Output Quality: In the construction industry there is a growing interest in the use of BIM in construction for coordinated, consistent, and computable building information/knowledge management. The information collected through a BIM process and stored in a BIM compliant database could be beneficial for a variety of construction practices. Therefore, output quality of BIM is measured by capability of search, accessibility and trust of information. ***Collaboration:*** In construction industry, good communication between various organizations such as design, contractor, engineer, and facility manager is key factor to archive project success. However, East and Brodt(2007) presented several problems with communication between construction organizations. To solve these problems, the role, responsibility and workflow for loading data into the model should be clearly defined and also a legal framework for integrating owners' view in design and construction should be sufficient. ***Interoperability:*** Interoperability can be defined as software compatibility. If refers to the ability to seamlessly exchange data between different BIM applications (Eastman, et al. 2008). Several case studies have pointed out the importance of interoperability between different BIM applications that are used by project participants in order to drive the adoption and use of BIM technology (Fox and Hietanen 2007; Timo and Martin 2008; Kandanala 2005; Kymmell 2008; McFarland 2007; Staub and Khanzode 2007). It is anticipated that issues relating to interoperability influence the level of BIM in construction. ***Reciprocal Benefit:*** The social exchange theory assumes that people try to maintain a balanced relationship in

terms of resource exchange, which is known as the norm of reciprocity(Gouldner 1964). According to the social exchange theory, participants in a virtual community expects mutual reciprocity that can justify time or efforts spent to raise their knowledge (Thibaut and Kelly 1959). Davenport and Prusak(1998) pointed out that reciprocity is one of factors leading sharing of knowledge, and Kankanhalli, et al.(2005) found that under conditions of weakly shared norms, there is a positive impact on the use of electronic knowledge storage by knowledge sharers. These provide a sufficient possibility in forecasting that reciprocity will influence the use of the BIM.

DISSCUSION AND LIMITATION

Substantial research over the past several years has been performed on the data standards and exchange in the AEC/FM industry. The growing popularity of BIM is based heavily upon a perception that the technology can facilitate the sharing and reuse of information during a life-cycle.

The objective of this research is to understand the key factors affecting the acceptance of BIM in construction organizations. The proposed model combines TAM (Davis 1992), TTF (Goodhue and Thompson 1995) and the motivation model (Deci and Ryan 1987). The model consists of twenty-three factors that are hypothesized to have direct or indirect effects on BIM acceptance. The twenty-three factors consisted of two broad classes: (a) user related factors (*Individual*: self-efficacy, personal innovativeness, compatibility, training, and variety, *Organization*: collective efficacy, organizational innovativeness, top management support, and external pressure, and expected industry reward) (b) technology related factors (cost, complexity, output quality, collaboration, interoperability, and reciprocal benefit).

In future research, the measurement items for the BIM acceptance model in construction should be examined to ensure reliability and validity within the BIM in the construction context. Also, hypothesis testing for the relationships between the key factors that may lead to the high acceptance of BIM in construction needs to be conducted.

STRATEGIC AGILITY AND PROGRAMME ORGANISATIONAL STRUCTURE FOR ENERGY EFFICIENCY DELIVERY IN BUILDINGS

Kennedy Aduda[1] and Alfred Talukhaba[2]

[1, 2]*School of Construction Economics and Management, University of the Witwatersrand, Johannesburg, P. O. Private Bag X3, Wits. 2050, South Africa*

ABSTRACT

Various explanations have been adduced for underachievement in energy efficiency programmes for buildings. Certain quarters in energy efficiency programme management generally agree that energy efficiency governance and hence coordination mechanisms and programme organisational structure are key determinants of outputs. This is not far from the truth taken that organisational studies confirm that strategy and structure greatly influence performance. However, this remains to be investigated in programme management and energy efficiency context. A literature survey and pragmatic approach is taken in analysing the strategy and organisational structure for energy efficiency programmes for buildings run by South Africa's electricity utility giant, Eskom. Applying complex adaptive systems theory, diffusion of innovation theory and behavioral theory of the firm, suggestions are made on adoption of strategically agile programme organisational structures oriented to improve effectiveness of energy efficiency programmes in buildings. The value of the study is hinged on the fact that energy intensive nature of South Africa's economy, current electricity supply stress and significantly high greenhouse gas emissions per capita necessitates greater effectiveness and improved performance for demand side energy efficiency programmes.

Keywords: buildings, energy efficiency, programme organisational structure, strategic agility.

INTRODUCTION

Eskom, South Africa's public electricity utility corporation enjoys monopoly status as the main electricity producer and accounts for 96 % of total production (NERSA, 2001 Republic of South Africa, 2001). Eskom also directly distributes 40% of electricity (Khumalo *et. al.* 2000). South Africa's Electricity supply industry is regulated by the National Electricity Regulation Board of South Africa (NERSA) (Republic of South Africa, 2006). Two main drivers for electricity energy efficiency exist in South Africa; these are the near supply deficit and the high carbon intensity level of electricity industry. Dominant within the policy framework for energy efficiency is Eskom's integrated demand side (IDM) energy efficiency programme. The IDM programme divides initiatives into specific industry focus areas such as

[1] Kennedy.Aduda@wits.ac.za
[2] Alfred.Talukhaba@wits.ac.za

buildings, agriculture, mining, commercial and industrial sectors. IDM's perspective in buildings include activities in CFL and LED lighting retrofitting, energy efficient water geysers, energy smart farming, energy efficient use of pumps, support for energy service companies (ESCOs) amongst others (Eskom, 2007). Generally, energy efficiency programmes often present a challenge due to the fact that they are temporal yet they function within and lead to consequential long term complex realities. The complex realities within which they function include the fact that programmes are diversified; have high number of stakeholders' involvement, operate within rapidly changing market dynamics and are sometimes affected by rapidly changing legislative framework and monopolised industry structure. Consequential long term realities is inclusive of the fact that regulatory framework introduced to encourage the adoption of energy efficiency practices end up being a permanent fixture. In addition, the programmes may often lead to permanent market transformation. The IDM programmes are no exception and all modes of complexities are interplayed. These complex realities present great challenges and opportunities in organisational research. Given that buildings account for 30-40% of all primary energy use in the world (UNEP, 2007) and that 27% of South Africa's electricity use occurs are building related, makes the focus of this paper of great relevance (Department of Minerals and Energy et al, 2002). Subsequently, South Africa's buildings present a great opportunity to realise electricity demand reduction target set by the national energy accord and an opportunity for reduction in operational costs of facilities.

Electricity energy efficiency demand side management (DSM) programmes have great potential in realisation of energy savings and effecting market transformation (Hansen, 2009). However, debate exists on the performance and cost effectiveness of DSM programmes. Hansen (2009) attributes this to diverse foci and minimalistic scope. Other studies on the under-performance of DSM programmes argue that this is probably due to a combination of high transactional costs, agency related issues, inappropriate management strategies, non-supportive financial infrastructure, ineffective coordination framework among other issues (Sarkar and Singh, 2010; International Energy Agency, 2010; Zhou et. al., 2011). In a roundtable discussion on the issue, Tanaka (2010) singled out energy governance as instrumental in the delivery of DSM programmes. Tanaka (2010) and IEA (2010) conceptualise key components of energy efficiency programme governance as enabling framework, institutional arrangements and coordination mechanisms. The explanations given by Hansen (2009), Sarkar and Singh (2010), IEA (2010) and Tanaka (2010) and Zhou *et. al*., (2011) among others on energy efficiency programme performance may be summarised as related to strategy and organisational structure issues. This leads to the postulation that the 'marginal performance of the DSM programmes may be related to inappropriate or ineffectiveness of applied strategy due and organisational structure'. It is noted that the reported primary energy savings from IDM of 354.1 MW financial year 2011 (Eskom, 2012) is at best marginal and betrays an inability to ensure the targeted 14% electricity demand reduction via energy efficiency by 2014 (DME, 2005). This paper advances the argument that appropriate choice of strategy and programme organisational structure could significantly lead to greater outputs for IDM programme in South Africa.

METHODOLOGY

The paper interrogates the motivations and theoretical underpinning of strategy and programme organisational structure for the delivery of energy efficiency in buildings

by Eskom, in South Africa. The programmes run by Eskom were selected as the focus of this discourse due to the fact that they are the only countrywide programmes in South Africa. In addition, it is the only energy efficiency programme framework funded by NERSA (Eskom, 2011). The current investment by NERSA on energy efficiency under the IDM's framework totals R 5.44 billion for the years 2011-2013 (*ibid*). As such the programmes form the biggest demand side management cluster in South Africa. In addition, the institutional base of IDM makes it ideal for analysis. To achieve its aim the paper largely relies on literature review and information from Eskom's website on IDM framework. The strategy and organisational structure applied in the implementation of IDM programmes in buildings are analysed with intention to suggest possible improvements.

STRATEGY FOR ENERGY EFFEICIENCY PROGRAMMES

Three generations of DSM programmes are distinctly identified by (Faraqui and Fox-Penner, 2011). The first generation emerged in the 1980s as a reaction to the 1970s oil crisis and emphasized cash rebates and low interest rates to manage demand, energy costs and achieve short term gains in primary energy savings (*ibid*). The second generation identified by Faraqui and Fox-Penner (2011) are those which emerged in the 2000s and tend to focus on management of electricity prices through real-time pricing, peak demand management for systems with low reliability and wholesale consumers. Lastly, the third generation DSM programmes are those which centre on increasing customer awareness, interest and engagement; technological innovation; enactment of energy efficiency codes and standards and energy price innovation (Faraqui and Fox-Penner, 2011). Thus, two distinct categories of strategies are observed; these are the ***resource acquisition*** strategies often aimed at short term achievements or low hanging fruits (Rosenberg and Hoefgen, 2009) and the ***market transformation*** strategies which are often geared at permanent change in market behavior (McLean-Conner, 2009). Comments can thus be made to the effect that first and second generation DSM programmes pursued resource acquisition strategies whereas the third generation ones are designed to achieve market transformation. A close observation of the IDM programme portfolio highlights the fact that the activities constituting it are geared towards both resource acquisition and market transformation. Modern concept of strategy revolves around 'strategy fast' and hence strategic agility (Doz and Kosonen, 2008). This entails the use of strategically agile systems organised around the three meta-capabilities of strategic sensitivity, leadership unit and resource fluidity and is associated with (Doz and Kosonen, 2010). Pellissier (2011: 152-22) further explains that strategic agility would lead to the use of iterative strategies; emergence focused planning systems, decision making spirals, continuous interactive learning and innovative solutions. Using these observations, four main comments may be made with regards to Eskom's IDM programmes. First, that the programme designs must be continually anticipatory to constantly changing policy and legal environment. This is based on the fact that South Africa's energy efficiency policies are still at infancy stage and are continually changing. Energy efficiency programmes must therefore be able to not only anticipate changes in policy and regulatory framework, but also be adequately prepared to take advantage of the changes. Second, programmes must be reviewed continually to ensure real-time response to the market dynamics. Thus strategies employed could be fine-tuned in line with the energy efficiency programme life cycle to improve outputs and ensure rapid maturity. The fine-tuning of the strategies must take into account the lessons learnt by the organisation in its implementation process. Third, programmes should

ensure experimentation with innovative ideas and technologies that could provide home-grown solutions to the South African energy efficiency agenda. Last, there is need to run lean programmes that ensure operational and transactional costs that are kept at a minimum. In addition, the clientele should not find the adoption of energy efficiency practices in buildings prohibitive. This could be achieved via service integration and partnerships.

A demonstration of strategic agility in the form of 'fast fashion' is ably employed is in fashion industry (Sull and Turconi, 2008). Sull and Turconi (2008) explain that foundations of 'fast fashion' strategy revolves on the satisfaction of ensuring mass sales in the short term and integration of production and distribution in the long term. This can be successfully achieved by ensuring heightened situational awareness in a continually changing environment, ensuring high capital fluidity and outsourcing of non-core and non-sensitive business activities (*ibid*). Energy efficiency programmes in buildings is very much alike to the fashion industry in that in order to be cost effective, programmes must be structured such that adoption of energy efficient practices undergo the full cycle to maturity as fast as possible. Not to be ignored is the idea of outsourcing, as demonstrated in 'fast fashion', capital-intensive and complicated activities may be retained in-house while labour intensive operations get outsourced to proven networks (Sull and Turconi, 2008). This may ensure a nimble programme with improved ability for market based feedback (Doz and Kosonen, 2008). The ability to respond to market dynamics is thus a key determinant in strategy formulation and implementation for faster turnaround. However, this is only possible with sound market intelligence. Energy efficiency programmes must therefore have the ability to detect and effectively respond to market dynamics. This not only calls for an appropriate strategy but also a complementary programme organisational structure.

PROGRAMME ORGANISATIONAL STRUCTURE

Organisational structure can be described as the framework within which labour is divided to improve coordination towards realisation of strategy (Mintzberg, 1979). The programme organisational structure used in IDM implementation oscillates between 'functional structure with horizontal linkages (FSHL) and divisional structure (DS) in nature (Eskom, 2011). The IDM is run as an autonomous department in Eskom. Though anecdotal, it is noted that the current structure may be pervaded by slow response to market dynamics, hierarchical overload, dampened innovation and poor coordination as is symptomatic of FSHL and DS (Daft, 2007). It should be pointed out that programme organisational structure is uniquely guided by clear operational goals and objectives, and are largely temporal in nature. In the case of energy efficiency programmes the key goal is to achieve energy resource acquisition or market transformation (Rosenberg and Hoefgen, 2009; McLean-Conner, 2009). In addition it is observed that in energy programmes strategies are linearly set and only reviewed in cycles of 3-5 years (Rosenberg and Hoefgen, 2009). This is obviously informed by the school of thought advanced by Chandler (1962) and Mintzberg (1979) amongst others. This perspective is however defective in that it fails to effectively deal with complexities and associated emergences in the programmes. The DSM programmes in buildings may therefore be conceived as exhibiting *allopoietic* tendencies. This implies that due to influences in environment and strategy and programme organisational structure design, the programmes are forced to dynamically adapt for realisation of desired performance (Weis, 2008). Complex Adaptive System

tendencies manifest itself in the proposed research mainly as a result of the continually changing regulatory framework and market dynamics for DSM energy efficiency programmes. This implies the necessity of an equally constant changing environment and organisational governance structures. These demand increased activity levels in terms of feedbacks and management of emergences (Newell et. al., 2011).

Key determinants of an organisational structure are communications, coordination, integration and decision making (Daft, 2007; Mintzberg, 1979 and Galbraith, 2002). In particular, Cyert and March (1963) identify decision making process as a key function in the organisational structure and hence a major determinant in strategy-structure-performance construct. This is firmly rooted in behavioural theory of the firm which among other issues postulates that prevailing decisions in an organisation are estimates of decisions from other levels of its operations and the flow of information is determined by organisational structure (Cyert and March, 1963; Sah and Stiglitz, 1988). Thus, level of centralisation or decentralisation of structures determines decision making processes, coordination and communications (Csaszar, 2011). The choice between decentralised or centralised system is determined by the strategic delineation of the organisation, that is whether it is seeking exploitative or explorative agenda (Hill and Birkinshaw, 2008). Exploitative based strategies are often associated with refinement, increase of competency level and predictability or stability whereas explorative based strategies implicate experimentation with alternatives and need for adaptability (March, 1991). It can be conclusively stated that behavioural theory of the firm best explains strategy-structure interrelationship. This is evident from the fact that decision making defines organisational structure, interrelationship with strategy and is significant in coordination (Csaszar, 2010; De Canio, 2000 and Cyert and March, 1963). In addition, Eskom pursues multiple objectives and as such must adopt a structure and strategy that best ensures performance in all the areas of operations as observed by DeCanio (2000). This may include partnerships, outsourcing of services in energy efficiency programmes amongst others. For a temporal programme whose structure is dependent on market growth such as energy efficiency programmes, this may imply reconfigurable structures as advised by Galbraith (2002).

MARKET DYNAMICS

Considering the fact that this interrogation adopts a complexity approach, the influence of market and industry on strategy-structure interrelationship and performance DSM programmes must be considered. It is postulated that marginal performance of DSM energy efficiency programmes run by Eskom for building is related to the prevailing market transactional costs of the energy efficient innovations as a result of use of inappropriate strategy and programme organisational structure. Government intervention may thus be advised to reduce energy efficiency gap (Bhattacharya, 2010) and in terms of creating enabling regulatory framework, increasing disbursement of subsidies and reforming the industry structure to reduce costs associated with adoption of energy efficient technologies for buildings (Eto and Golove, 1996).With regards to the industry structure, the prevailing vertical integration and monopolistic characteristics in South Africa (Eberhard, 2000) could encourage non specialisation and reduced flexibility demanded for successful implementation of the programmes (Newell *et. al*., 2011). This may explain the marginal successes in terms of resultant programme outcomes. It should be further

noted that all energy efficiency programmes follow a generic market life cycle development no matter the category of strategy used in its design. McLean-Conner (2009) identify these stages as introductory, growth and maturity stage, associated unique characteristics and market related barriers and suggest possible application to monitor programme performance . For example during the introductory stage, the market is characterised by limited adoption rate, few channels and non-existent codes with great barriers being related to affordability, accessibility and awareness (*ibid*). On the other hand, the maturity stage betrays support from codes and no market barriers (*ibid*). This school of thought possibly emanates from the diffusion of innovation (Rogers, 2003). Such an indicator would be instrumental in ensuring dynamic market feedback necessary for an equally dynamic organisational restructuring alluded to earlier as the second challenge in applying strategy fast in energy efficiency programme.

CONCLUSION

Faster turnarounds are needed for Eskom's IDM programmes. This could be achieved by adopting strategic agility as the core of energy efficiency programme governance as it would ensure greater dynamism and responsiveness to changes in market situation, programme goals, technology, and clientele response. The study notes that that the full growth of programmes through the life cycle is hampered by poor governance and management that have resulted as a result of ill constructed structures.

RECOMMENDATIONS

For energy efficiency programmes in buildings, a five point agenda is suggested. This include: 1) actualising an open and inclusive strategy process for all stakeholders including building occupants, who are the product end users for technologies such as CFL and LED lighting fittings, 2) improvement in market intelligence to enhance feedback and self-correction capacities in programmes, 3) retrospective and anticipatory approach to programme design for South Africa' s buildings. This may include the ability to anticipate changing policy and legal environment such as recent introduction of SANS204X, SANS104000X, review of energy act among other issues and elimination of the 3-5 years review timeline (Rosenberg and Hoefgen, 2009) firmly rooted in classical linearly approach to management, 4) Lean programmes are needed to ensure greater cost effectiveness and reduce transactional costs of adoption. This could be achieved via service integration and partnerships; thus the local authorities, residents associations, property owners groups may be roped in as partners in programmes, 5) The adoption of a complex adaptive systems approach motivates for the need of self-correcting feedback mechanism. As part of this, the development of a market indicator based diagnostic instruments may help improve on organisational capacity for dynamic response. It is further proposed that field study investigating strategy and programme organisational structure for the case of IDM's programmes' framework be undertaken using documentary review and interviews with stakeholders. This approach is supported by Amitabh and Gupta (2010) who advocate for non-linear investigation of strategy-structure and performance construct for innovative organisational set-ups. The suggested methodological approach is therefore largely leaning towards interpretative and qualitative nature.

ACKNOWLEDGEMENTS

THE USE OF 3D BIM VISUALIZATION TO AID CHILDREN PARTICIPATION

Dr Emmajane Mantle[1]

[1]*University of Glamorgan, Faculty of Advanced Technology, South Wales*

ABSTRACT:

It is not uncommon in the planning process, for the opinions of community members to go unanswered, in the past ten years the Government has made much progress in ensuring that Community involvement is central to any Regeneration project. However when the opinion of Children are needed this level of involvement may not be efficient and more care will be needed in order to ensure that a child is given adequate support to help encourage a realistic response. This article will discuss the issues relating to the development of a childs play area. Furthermore this paper will identify how the use of a 3D BIM Model was used as a tool to aid the children's understanding, and encourage realistic responses when asked to generate ideas for a new Play Area within their village. This article shows that without the use of 3D visualisations and walkthroughs being presented to the children, they had very little understanding of the scale of an area, and an unrealistic perceptions of what the Park should include. The use of the Visual imagery generated from the 3D BIM Model not only resulted in more achievable suggestions being made by the children, but also resulted in reducing Development costs/quotes as a clearer understanding of what could fit into the area was achieved.

Keywords: 3D BIM, Animation, Visualisation

INTRODUCTION

'As the world gets more crowded, especially in Urban areas, more people are concerned about what happens with their neighbours' property' (Delaney, 2000). The professionals believe that they know best, however in order for a development to be successful and meet the end users requirements there is a need for the public to have a more active role.

There are several key reasons to why the public may want to be involved in developments, these includes; An interest of what is happening in their community, to support or oppose a development, or as a hope to see their area developed in a positive way. Whatever the reason for participation it is nonetheless an important factor to successful developments as it improves decision making, enhances cooperation and ensures that key requirements of those living in, around or using the areas are met.

[1] Ejmantl1@glam.ac.uk

However this should not only apply to Adults but also a process that should apply to children as they are the key to future use, and therefore "have a right to a voice in matters that concern them; they are experts on their own environments, well placed to identify the problems that concern them and the solutions that best address these concerns" (ANON, 2002).

According to Flynn (1983) "Children develope their awareness of distance and depth very slowly. Judgment of distance becomes clearer as the child has more experience with actually traversing the distance themselves" (Flynn, 1983)

"From a developmental psychology perspective; the 'middle childhood' stage of 10-12 years is widely considered to be an optimum time for children to develop environmental skills, because this is when children begin to explore their environments independently of adults (Wridt, 2010; de Vries et al., 2007). However, there have been examples where children as young as four successfully participated in spatial planning exercises (Horelli, 1997), whilst Roe's (2006) studied children aged 6–10 years old, illuminating how they understood their environment and boundaries, and how it contributed to their well being. A potential drawback of working with much younger children, however, is that they can sometimes lack a suitable level of knowledge and experience of planning systems to identify options for change" (Day et al., 2011). Therefore the way in which children participate needs to be discussed.

Research carried out by Ecorys (ECOTEC) and Loughborough University showed that "there is evidence from research and practice that children and young people can play a significant role within planning and regeneration processes" (Day et al., 2011), however "children's participation in local planning and development processes has experienced limited development in mainstream decision-making within the UK" (Day et al, 2011).

"The first National Play Strategy (DCSF, 2008) set out a long term vision to realise children's play rights. The Strategy followed the 'Fair Play' consultation, which received a response from 9,400 children and young people, and showed a clear demand for children's participation in the design and planning of local play spaces (Day et al, 2011).

Millar stated that "Outline research shows that children's perception of space is, in certain ways, different to the spatial perception of adults. By determining why these differences are there and how, throughout development, they change, it should be possible to inform design to be more responsive to children" (Miller, 2007).

Millers research into Children's' perception of space concluded that:

• The spatial perceptions of adults and children have differences, not least because the means by which they perceive space are different.

And

• The spatial organisation of buildings appears to have an effect on the spatial comprehension of children. Their ability to understand a building with strong visual links between spaces is much greater than a building based on a logical sequence, of cellular arrangement.

In order to encourage participation within children, Bryson (2009) suggested that 'A Multi-Method' approach should be used as "there is no set way of doing things. Using a range of techniques and approaches will ensure there is something that works for everyone" (Bryson, 2009). Day et al., (2011) suggested that "there have been few

 ISBN: 978-1-84219-840-7 .

previous attempts to categorise the range of approaches for supporting children and young people's participation in planning and design". This following section will discuss a study conducted by the author which focused on selecting the best methods to aid children and encourage participation.

SURVEY

In 2007, the author completed her research which investigated the different methods available to display proposed developments at Planning Events in order to enhance public understanding, and increase Participation.

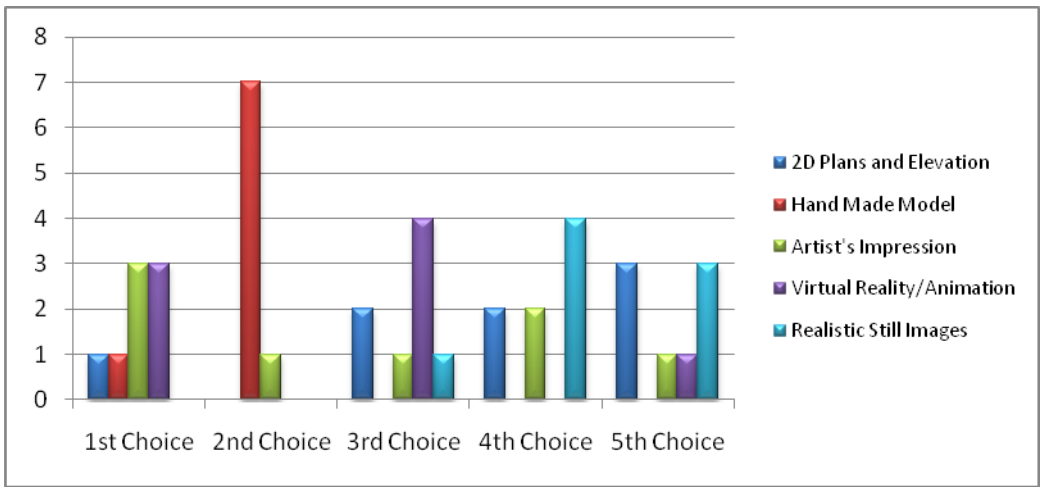
During the Survey Study several techniques for presenting design proposals were displayed for viewing. These Techniques included; 2D Plans and Elevations, A Hand-Made Model, Artist Impressions, Still Images and a Virtual Walkthrough displayed on a Laptop. Each participant were asked to rate which technique they found easiest to understand, and if they would feel more equipped to participate in future planning events if the favoured technique was adopted. The results of the study showed that in order to help members of the public to understand developments they would need to be shown 3D Visualisations, whether as Still Images (Photomontages), or 3D Walkthrough/Animations created from the 3D BIM Model.

This study targeted adults and adult opinion, therefore in order to get a view of how children perceived these techniques, a further study was conducted where only children under the age of 16 were asked to participate

The results of the survey were analysed within two separate age groups (7-11) which represented the Primary School Level, and (12-16) representing Secondary school level.

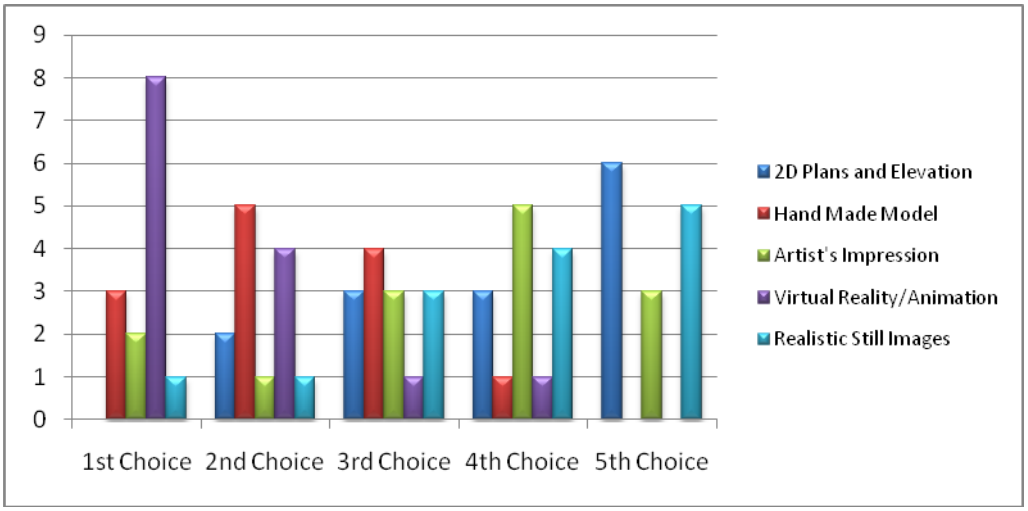
The Primary Group represented 37% (8) of the respondents, while the remaining 63% (14), were of secondary school age.

The children were asked to walk around the exhibition room and look at the different Presentational Techniques displayed. Once the children had finished they were asked to rank the techniques in order of preference. Graph 1.1 and Graph 1.2 below illustrates these results.



Graph 1.1: Primary School level Results

 ISBN: 978-1-84219-840-7 .



Graph 1. 2: Secondary School level Results

Graph 1.1 illustrated the Primary Groups choices in regards to what they rank as their 1st, 2nd, 3rd, 4th and 5th favourite presentational technique. The graph shows that their favourite choice with 38% (3) was the BIM Animation and the Artists Impressions, this could be due to a child's familiarity with drawing, and playing computer games.

In regards to the Secondary group, they also selected the BIM Animation as their favourite option with 57% (8), their second choice was the Hand Made Model 37% (5) with a further 29% (4) selecting the BIM Animation. The primary group also selected the Hand Made Model as their second most favoured technique with 88% (7)

Both groups listed their least favourite technique as 2D Plans and Elevations (38% (3) Primary and 43% (6) Secondary), and Photo realistic images (38% (3) and 36% (5)) Secondary.

Rybczynski, (2009) stated that "Building bricks were called 'rational' toys, and they were intended to ground children with an early understanding of engineering, gravity and physics" (Cited in Burgess, 2010), this could therefore explain why a Hand Made Model was considered as a second choice.

Analysing the responses from the children shows that once again, the most dominant technique displayed proved to be the BIM Animation. The fifth choice was the 2D Plans and Elevations. This was also reflected in the adult responses in 2007 with 41% of adult responses selecting the BIM Animation as their favourite and only 12% selecting 2D Plans and Elevations.

Today with the ever growing trend of Television Programmes which showcase the use of 3D modelling and Animations, 3D Televisions, Films and Computer Games, it is inevitable that 3D technology will continue to grow, and public demand will also increase. The demand for such software is now being recognised by the Building Design Industry with more and more seminars discussing its use, being organised throughout the UK. In 2010, a 3D Building Information Modelling (BIM) Seminar, which incorporates 3D visual designs along with 4D-Time Estimation, and 5D-Cost Estimation, was organised by 'Construction Excellence' but was cancelled due to lack of interest, in 2011 more Seminars have been held by a number of Organisations and are proving to be very popular.

 ISBN: 978-1-84219-840-7 .

However these Seminars focus only on the Construction Team and how 3D Models, created by BIM Software, can be shared throughout the Construction Process. No emphasis has been put on the need to use these modelling techniques to help promote public participation.

It is encouraging that the author has currently been approached by her local authority to create a model and animation to display at a local development Planning Event as they are aware that a 3D model will help the viewer understand more clearly what is being developed.

To further investigate the use of BIM for enhancing a Childs ability to participate within Planning Events a project was selected which focused on the regeneration of a local Play Area. The remainder of this Article will discuss how a BIM Model was created and demonstrate how its use not only allowed for Child Participation but also helped to reduce the financial aspect of the project.

PARK DEVELOPMENT

In May 2011 the Treforest community Group contacted the University of Glamorgan, situated in the same town, and asked for support with a development of the village Play Area, which currently is in need of regeneration.

From the outset of the Treforest Park development children from the local schools were asked to give examples of what they would prefer the development to include. Although the Children had been consulted, it was obvious from discussions with the committee that opinions gathered had been dismissed, this was due to the fact that regardless of how small the site, the children made some very large scale suggestions such as a Rollercoaster and ‘Death Slide’ a piece of equipment usually associated with Theme Parks.

Image 1.1: Existing Play Area

As the site, shown in Image 1.1 above, was only a small plot, measuring less than 150m2. It was obvious that these requests were unachievable, and these suggestions may be due to the child’s inability to visualise space and scale as discussed in research conducted by Day et al in 2011.

 ISBN: 978-1-84219-840-7 .

There are many Play Areas in South Wales which makes use of trees and landscape and the Committee was hoping to achieve a similar result, however before contacting the author several quotations from specialist Park development companies were received but were in the region of £70,000, a sum which was not acceptable to them. As a result they contacted the University for help.

Image 1.2: Play Area

As the author had several years experience modelling urban areas via 3D CAD/BIM software packages and creating Animations, she suggested creating a 3D BIM model of the site and designed several pieces of play equipment. This design can be seen in Image 1.2 above.

The Software selected was ArchiCAD by Graphisoft, the data was acquired from OS Plans and Digital Imagery and the proposed park was designed around the Committees requirements rather than the child's own requirements due to the inadequate responses provided. However with the aid of the completed BIM Model the children would be revisited in a hope that a better understanding would be achieved with the aid of 3D Visualisations.

Before presenting the final images to the Committee the author gathered several quotations from specialist companies, including one which had previously supplied the community with the £70,000 quotation.

Sending the 3D images gathered from the BIM Model to the different Park supply companies allowed them to price similar pieces of equipment from their catalogues, and as a result a quotation of £21,000 was received.

When meeting with the committee in July 2011 the author presented them with a large Poster, 3D Imagery and a CD with an Animation, when they expressed positive feedback to this design they were presented with the quotation and were extremely happy to have received a more achievable result.

 ISBN: 978-1-84219-840-7 .

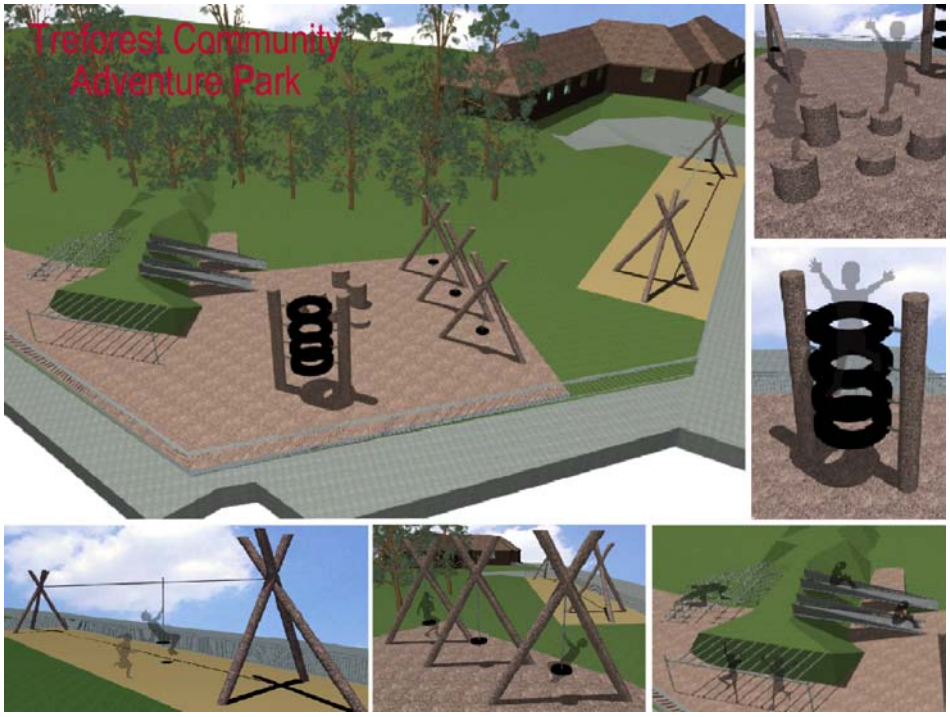


Image 1.3: Play Area Poster

Following the meeting, the secretary of the Treforest Residents Association stated in a letter to the Vice Chancellor of the university that: "We were shown a project that challenges young minds, and is far more fulfilling from all aspects of children's` play. The cost of the scheme is around £21,000, and given the increased benefits, the university`s expertise and support, and the much lower costs, there is a far greater chance that funding and a successful conclusion can be achieved. We are currently in the process of consulting with the children through schools play groups etc, but the early signs are that the children will fully endorse the plan".

With the aid of the provided Imagery, the committee revisited the Schools. The results of the school visits showed that the children could relate to the 3D imagery and therefore had a better understanding of the scale of the area thus, when the children were now asked to give comments regarding the model and what they would like to change or add, the responses were more realistic and merely included a baby swing.

CONCLUSION

This paper has discussed the issues relating to a Childs perspective when asked to participate in the development of a new play area and discussed how these issues were overcome by the use of a 3D Model. It is not uncommon for the opinions of children to be overlooked due to their lack of understanding when faced with such planning issues, and that a range of techniques and approaches should be considered for use in order to ensure that all levels of understanding are reached, and Children are given appropriate opportunity to participate in events which affect them. Furthermore this paper discussed the results from a survey which showed that in order for a child to fully participate and understand a development, there is a need for the provision of 3D views, whether from a 3D Walkthrough or Printed Imagery. With the ever growing 3D trend such as the development of 3D Television Screens and Cinematics, it is

inevitable that 3D technology will continue to grow, and public demand will also increase regardless of age.

In May 2011 the Treforest community Group needed advice in regards to encouraging a group of local school children to participate with the development of plans for a new Park in the area. This paper has shown that without the use of 3D modelling this task was more problematic. When meeting with the committee in July 2011 the author presented them with Imagery and Animations which could be taken into the School and used as a means to help children identify what is available and what is needed. As a result of these imagery it was proven that greater understanding could be achieved and a more realistic discussion with the children could be held. The gathering of data provided by the children during this second discussion proved to be a much more useable result.

FURTHER RESEARCH

In order to try and enhance the participation of Children within the Planning process, other techniques such as user controlled Animations, Augmented Reality within the Design Process, and a study of the requirements of levels of detail within 3D BIM environments in order to increase understanding of a development, will also be investigated.

A CONCEPTUAL DECISION SUPPORT MODEL FOR SUSTAINABLE HOSPITAL REFURBISHMENT

Grant Wilson[1] Mohammed Kishk[2] and Richard Laing[3]

[1,2 &3]*Scott Sutherland School of Architecture & the Built Environment. Robert Gordon University. Aberdeen. Scotland. AB10 7QB*

ABSTRACT

The refurbishment of the existing healthcare estate in the UK has become far more prevalent in recent times than the new-build approach of the last decade. This coincides with ever more challenging institutional and statutory requirements in regards to sustainability. A challenging economic landscape coupled with the unique challenges and restrictions imposed by works to an existing structure presents the Client and the Design Team with the requirement to make specification and financial decisions based on a 'best fit' and 'best compromise' scenario. The sheer scale of the healthcare estate, and the unique complexity of the hospital as a facility dictate that a Multi-Criteria Decision Modelling (MCDM) approach is essential to allow for the generation of alternatives which may provide the best compromise solution to a given project. This paper discusses this challenge with specific focus on the hospital. The main aim of this paper is to present a conceptual model of the entire decision making process for the activity of sustainable hospital refurbishment. The required phases will be discussed as the core processes required as the basis for a software based interactive model.

Keywords: conceptual model, hospital, refurbishment, sustainability

INTRODUCTION

The time period between the 1990s and the latter half of the first decade of the 21st century witnessed a significant focus on investment for new build National Health Service (NHS) projects. This may be attributed in large part to the UK Governments appetite and subsequent growth of the Private Finance Initiative (PFI). Correspondingly, across the same time frame, there has been a steadily increasing awareness and acceptance on issues of sustainability, environmental protection, and conservation, and perhaps more controversially, the phenomenon of anthropogenic climate change. National and institutional environmental and sustainability requirements have become arguably more onerous as a result of this. Although much focus has been given to the conjoined issues of energy efficiency and green house gas (GHG) emissions reduction through legislation such as the European Energy Performance of Buildings Directive (EPBD) and the respective UK Climate Change Acts, the environmental and sustainability agenda is far more encompassing. It may be argued that addressing the range of issues which will be discussed within this paper is less complex within a new build facility than a refurbishment, as the client, design team and contractor are starting with essentially a blank canvas. A refurbishment project however presents an existing structure with the inflexibility of orientation, materials, services etc, which nevertheless must still meet the legal and institutional requirements. In England there is the added mandatory requirement for all NHS

[1]g.wilson2@rgu.ac.uk
[2]m.kishk@rgu.ac.uk
[3]r.laing@rgu.ac.uk

Trusts, Primary Care Trusts, and Strategic Health Authorities to report annually to government on sustainability performance (SDU. NHS). To this end, the SHINE Final Report (2010) identifies that the majority of healthcare buildings which will be used throughout the 21st century have already been built, and that the reduction in public spending in the current economy shows no signs of this situation changing anytime soon. Therefore Wilson and Kishks (2011) observation that it is from the existing estate where the functional and statutory requirements in respect of sustainability must be met, seems valid.

THE SUSTAINABLE REFURBISHMENT CHALLENGE

Refurbishment is a challenging activity within its own right. Aside from the constraints placed upon the design team in regards to the requirement to work within and interface with existing structural elements and components; one of the most often cited concerns at the planning stage is the inherent uncertainty of the actual works (Egbu and Lee. 2006) (Quah. 1998). This is a no more prevalent challenge than in the hospital or healthcare setting where there may be the requirement to deliver clinical care on a 24 hour basis, and the potential for a continual and transient traffic of staff, patients, and members of the public.

The Requirement for a Decision Support Model

Given the size of the NHS estate, a complete conceptual (and ultimately operational) model must begin with a high level asset inventory of the entire portfolio. There is of course, no necessity that this be undertaken in every case, but is a decision which may be taken at health authority or regional level as appropriate. This may be further categorised between acute facilities, primary care facilities, or health centres etc, again, at the discretion of the estates management. Regardless of the number of assets to be considered, the holistic decision making process suggested by Zavadskas et al (2008) provides the four phase integrated framework for the complete process (fig.1)

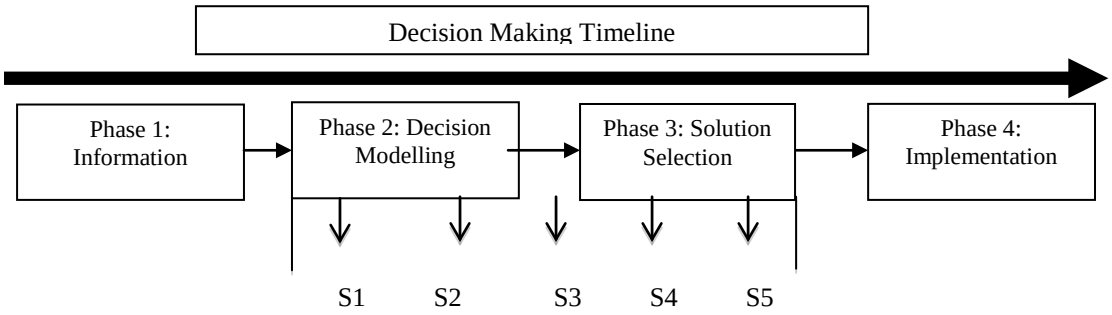

Figure 1: 4 phase decision making process showing the integration of the 5 Step (S) MCDM technique (adapted from Zavadskas et al 2008 and Zarghami & Szidarovszky 2011)

Each of the first 3 phases shown in figure 1 demand decision making processes within their own right, and this will be demonstrated in the ensuing sections of the paper. Phases 2 and 3 are viewed as the heart of the actual decision making process, and multi-criteria decision modelling (MCDM) techniques are applied using the 5 step MCDM process (Table 1) discussed by Zarghami & Szidarovszky (2011). This in turn is the key filtering and calculation process which identifies and measures the subjective information input, and assigns weightings (Step 4) that allow a quantitative and measured solution (or output) which is specific to the facility undertaking the refurbishment process. Given the vast range of hospital types, functions, ages,

locations, and funding parameters; the model provides the opportunity of optimising the planning, design, and construction decisions in a systematic yet flexible manner. To this end, identifying the most opportune moment in the *Business Case* process will be a key factor for the on-going research.

Step	Activity
1	Identify Goal (and Objectives)
2	Identify Criteria
3	Identify Alternatives
4	Alternatives/Criteria Evaluation
5	Make Decision

Table 1. 5 step MCDM process (adapted from Zarghami & Szidarovszky 2011)

It would be remiss not to briefly discuss the context of the decision making process, and how this interacts with the different 'classifications' of multi criteria decision analysis (MCDA). The process shown in Table 1 addresses the *discrete case.* The discrete case is employed in a scenario where there are a finite set of criteria, alternatives, or even evaluations of the alternatives. There is of course, still the potential for a large number of each of the aforementioned as will be discussed below, but the key attribute of the discrete case is that feasibility of each alternative may be filtered down to allow for comparisons and evaluation that satisfies and addresses all (or most) parameters and/or restrictions. The alternate classification of MCDA problem is the *continuous case*. The continuous case possesses a less limiting characteristic and may be applicable to a scenario where the variables are themselves continuous (or infinite). There is a clear advantage for the continuous case in its computational ability, although the argument for a discrete approach is that the model discussed within this research avoids unnecessary mathematical complexity and balances this against the goal of still presenting a multi criteria decision making process which is 'fit for purpose'.

Characteristics of the Research Model

The aforementioned scale of the NHS estate, coupled with the challenges of a sustainable refurbishment process presents a potentially vast choice of decision criteria and ensuing alternatives possibilities. Triantaphllou (2000) recognises the impracticality of considering every possible criterion and alternative with the key observation that MCDM is concerned with seeking the 'best fit' or 'trade off' when faced with such a potentially vast range of possibilities. This is a significant point to understand, in that the decision making process and associated MCDM techniques are by no means a 'black box' or 'quick fix' resource. On the contrary, a measure of professional subjectivity is encouraged in considering the hospital on an individual, case by case basis, as opposed to a 'one size fits all' methodology which is a common industry criticism of current assessment methodologies. The application of the discrete case in creating the model seems clear in this context.

THE MODEL PHASES

Although it is recognised that the 'whole' decision support model is an integrated system, the 4 phase approach described above has distinct interface points. The simplest means of identification is to understand that the final activity within each phase, provides the required level of information to generate the first activity of the following phase. This is most clearly seen in the transition from phases 1 through 4,

although there is scope for considering a feedback loop from *phase 4: Implementation* to each preceding phase of the process on similar or following projects.

Phase 1: Information

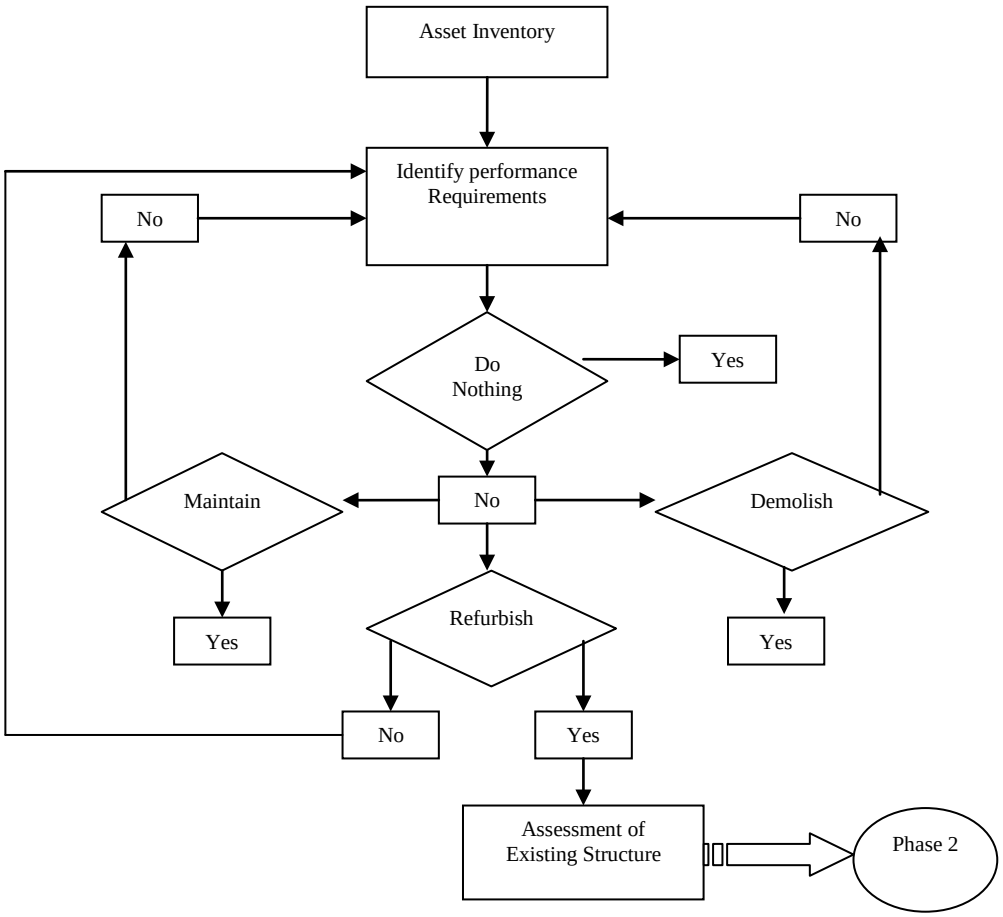

Figure 2. Phase 1: High level decision making process

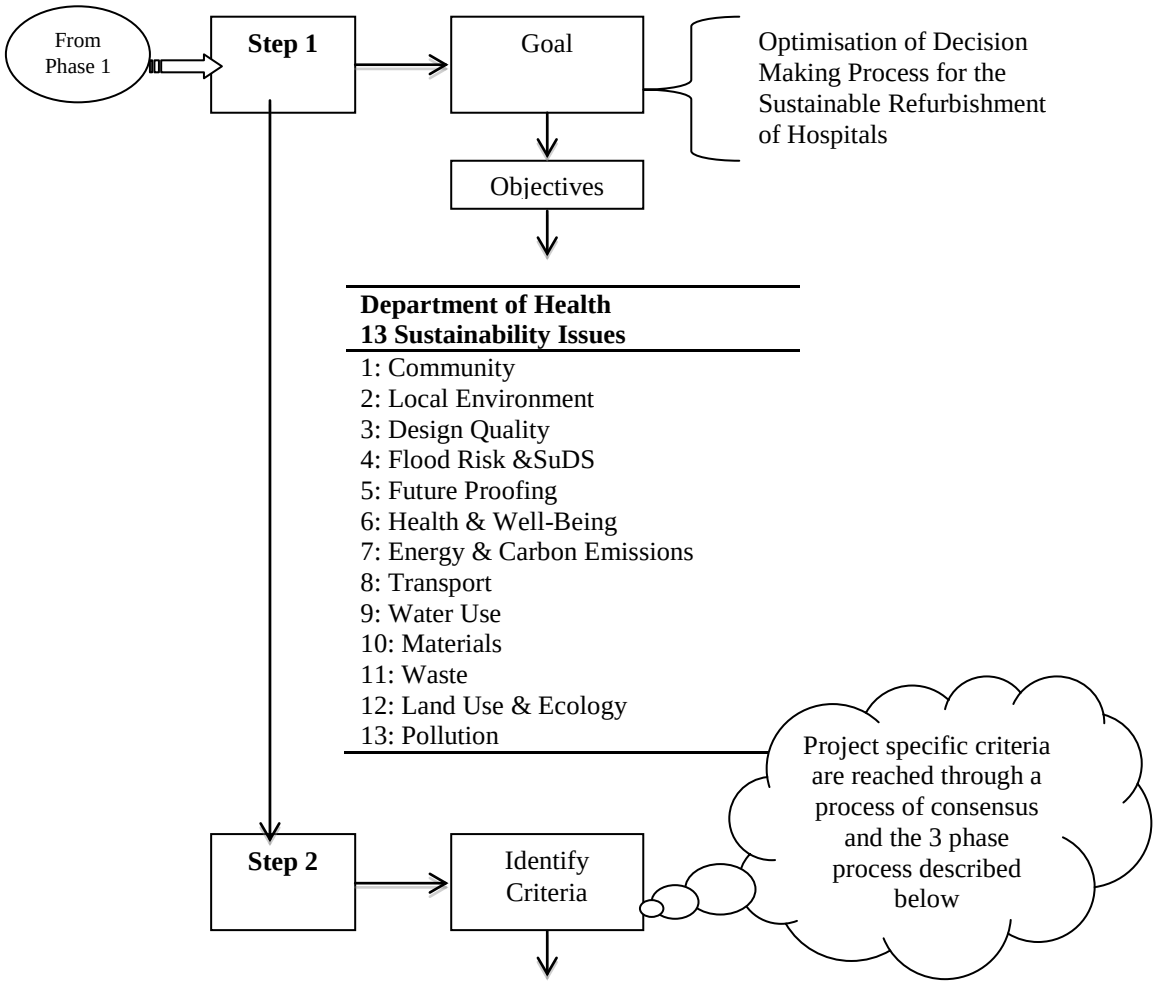
The discussion has thus far focused primarily on the MCDM aspect of phases 2 and 3 respectively. Although these stages are key to the quantification and assessment of the subjective into the objective, the 'full' decision making process must be understood prior to these activities. Figure 2 demonstrates this process. What figure 2 does not show is the specific variables and trade-off factors assigned to each decision node. A condition survey is vital from the outset, and is shown on an estates level within figure 2 as an 'asset inventory' followed by an appreciation of the required 'performance requirements'. It is completely reasonable to accept that the demolition and subsequent new-build of a facility may be a more viable alternative. Financially this may be driven by the access to funds through PFI (or similar), but a complete Environmental Impact Assessment (EIA) may also encourage the demolition of an ageing or dilapidated building stock which has limited upgrade possibilities. This issue has especial significance with relation to the Business Case process in preparing the *Outline Business Case* if bound by the guidance of the *English version* or *Scottish Capital Investment Manual* with clear impacts affecting the decision of 'preferred way forward'. Assessing where the MCDM aspect of the proposed model most effectively integrates within these processes is a key aim of the ongoing research. As

with most planning, design, and decision making processes, it is envisaged that an iterative approach will be necessary.

Phase 2: Decision Modelling



Generation: Initial set of Criteria	Relevance: Potential set of Criteria	Applicability: Final set of Criteria
Legislation	Relevance to Project	Availability of Data
Codes of Practice	Measurement Duplication	Measurability of Data
Health Technical Memorandum	Goal Conflicts	Ambiguities
Health Building Notes	Importance to Project	Evaluate Applicability
Clinical Output Specification		
BREEAM/AEDET		
Standard Checklists		

Figure 3: Steps 1 & 2 of the Decision Making process (adapted from HTM 07-07. 2009 and Braunschweig et al 2000)

The combination of Steps 1 and 2 are logically placed within the overall Decision Modelling phase (Phase 2) Although the Steps themselves are generic, Figure 3 clearly demonstrates the higher goal and the objectives required in attaining it. The objectives, which in this case are the Department of Health's (HTM 07-07. 2009) own 13 sustainability issues, are also the first layer of 'main criteria'. Each issue is independently considered by means of the process shown in Step 2. It may even be accepted that Step 2 is the generation of 'sub-criteria', and the filtering and selection

process applied to suit. The key aim at this point, is to identify circa 8 applicable criteria to be considered within the MCDM process.

Phase 3: Solution Selection

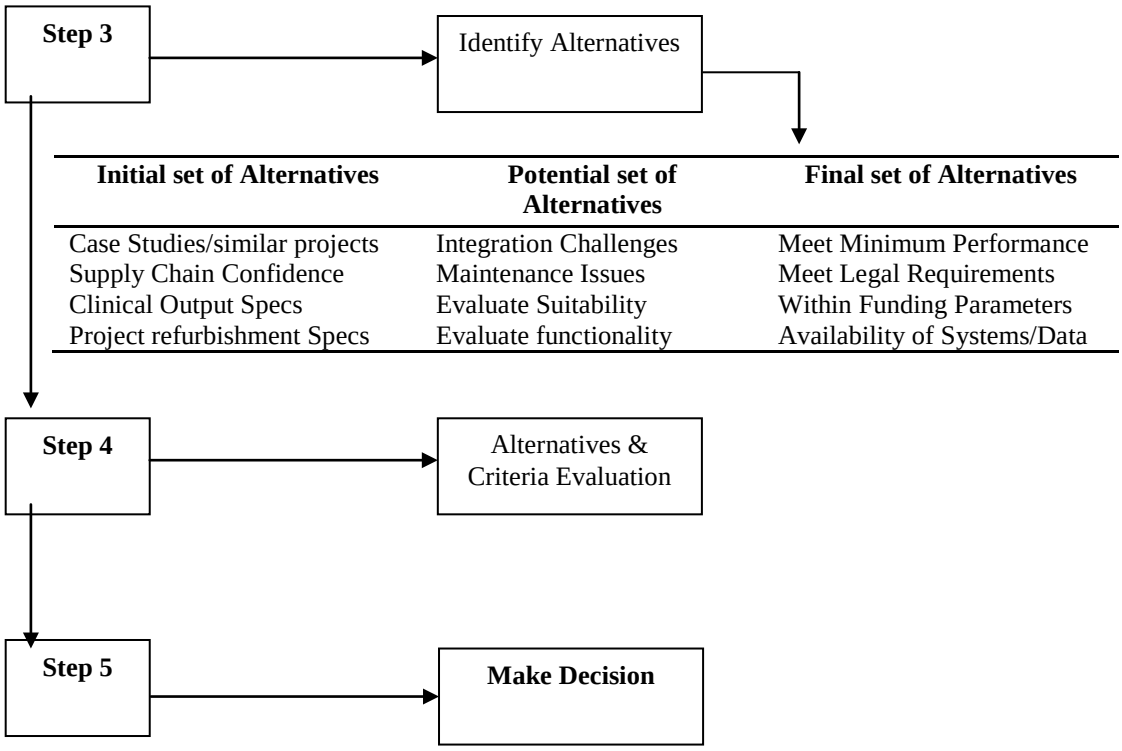


Figure 4: Steps 3, 4 & 5 of the Decision Making process. (Alternatives generation adapted from Kishk et al. 2004)

Steps 3, 4 and 5 of the MCDM process are encompassed within phase 3 of the decision making process, and it is proposed that all 3 Steps comprise the 'Solution Selection' and must be viewed as very much an integrated process. Braunschweig et als (2000) 3 phase generation process is again employed, following Kishk et als (2004) adaptation of the same in filtering and selecting the feasible alternatives. These steps of the model undertake a process of *pairwise comparisons* to compare 'each' criteria against 'all other' criteria. This *weighted evaluation* assigns the final weight of importance. The alternatives are then considered and rated to score how the decision maker assesses the level which each alternative meets the criteria's weighted values (Step 4) This will allow for objectivity to be introduced into the decision making process by means of a simple matrix. Sensitivity Analysis may then be undertaken to prioritise and address any financial constraints not already considered within the generation of alternatives.

Phase 4: Implementation

Arguably the most simple phase in *decision making* terms, the implementation phase takes the decision maker to the point where he/she may begin to specify elements, components or materials. In the *physical reality* however, the implementation phases is far from simplistic. It should be noted at this point, that when an alternative has

been selected using the system described within the paper, the exact same process may be undertaken to derive the best specification choice within the given alternative. A random example to describe this might be that the alternative selected in Step 5 (phase 3) may suggest the most beneficial (and trade-off considered) action would be to insulate an exterior wall. The range of insulation types would then need to be considered as would the insulation thickness which (again) meets the 'best fit' scenario when considering variables such as energy efficiency, emissions reduction, price of materials, cost of works etc.

The Implementation phase must also be considered within the overall Business case. This highlights the criticality of identifying the correct intervention points to introduce the model to the capital investment route and/or subsequent Public Private Partnership (PPP) route selected. Once the decision making requirements reach the contractual and procurement phases, there are obvious benefits and necessity to ensure that the correct parties are involved in the criteria and alternatives selection and evaluation. This in turn demonstrates the iterative nature of the 'utilisation' of the decision making model itself throughout the planning and delivery, and the potential to reconsider the final alternatives by revisiting and altering the criteria and variables.

CONCLUSIONS AND THE WAY AHEAD

It was identified that the refurbishment process is a complex and uncertain activity, and that the NHS as an institution are especially challenged given the vast differentiation in its built estate, and the functional complexities found uniquely in the healthcare environment. The paper has described a decision making process which incorporates the techniques of Multi Criteria Decision Modelling. The objective of the research is to simplify the often mathematically complex field of decision modelling, and a discrete conceptual methodology which centres on the processes of Pairwise Comparison and Weighted Evaluation has been described. It has been shown that given the capital investment frameworks associated with potential healthcare projects, it is critical to identify the intervention point(s) whereby the decision making process is most beneficial, and that the correct relevant Stakeholders are engaged. The discussion has highlighted that a realistic decision making process will always be a 'best fit' scenario based on the subjective approach by the decision maker in regards to criteria and alternative 'trade offs'

The conceptual model in this paper supports a wider PhD research project to develop an integrated decision support model for the sustainable refurbishment of hospitals. Future papers will demonstrate in greater detail the 5 Step MCDM process and associated weighting and alternative selection techniques. The final output of the wider research will be the development of a software based interactive model which will provide the decision makers and stakeholders with a 'user friendly' decision support system.

DESIGN AND PRODUCTION OF SUSTAINABLE STRUCTURAL CONCRETE

Adil K. Al-Tamimi[1] and Nadeem Iqbal[2]

[1,2] *Department of Civil Engineering, College of Engineering, American University of Sharjah, Sharjah, U.A.E, PO Box, 26666, Professor of Civil Engineering,*

ABSTRACT

Design and production of sustainable structures have become recently in big demand due to limited resources of materials and strict criteria on sustainability and environmental impact. There are many types of green materials that have come into the forefront in the past related to various areas of construction. Microsilica material is one of them that is used in this research to produce high strength and durable concrete. Relatively new concrete mixture design procedures according to the modified ACI-211 has been attempted to design and produce sustainable structural concrete. Several quality control measures have been applied to measure the concrete high performance such as flow test, temperature, air content, compressive and tensile strengths, Schmidt hammer test, and ultrasonic test. The study showed concrete with high strength of 80 Mpa is produced using carefully selected materials and design procedures. It also showed high workability, low void content, high surface hardness and low internal cracks.

Keywords: Sustainable concrete, ACI-211 code, high compressive strength, microsilica, workability.

INTRODUCTION

The concept of sustainability is brought up for the betterment of human species and not for the earth. The Earth can survive without humans. Sustainability is for human being to survive on earth. Everyone is aware of the fact that the life on earth is degrading day by day. The quality of life on earth has gone from best to worst in the past 150 years. We should all work towards making our environment green and sustainable because we are the ones who are responsible for getting it into such a ruined state. With a drastic growth in the world's population, there also is a dramatic increase in the demand for buildings and homes.

The industrial revolution may have been partly responsible for the change in the way that homes and buildings were constructed. The industrial revolution brought about the invention of the steam engine, discovery of low-cost petroleum, improvements in coal mining, and the invention of rail transportation that helped provide an environment which altered the way people designed and constructed buildings and other products because of the benefits of concentrated energy. No matter how cold or inhospitable the climate may seem, buildings and houses could be built since they could be heated with wood, coal, and oil. A limitless amount of energy supply led to little thought being dedicated to the impact that the extractive and refining processes of fossil fuels would have on the environment. As a result, the price of energy today has increased because of the lack of its availability and finally the realization has dawned upon mankind that consuming large quantities of fossil fuels actually prove costly and damaging to the environment.

Construction primarily is the building of structures to provide shelter and storage, transportation, and utilities that service the day-to-day activities of people. As time has progressed we have come to see a much broader description of construction with terms such as sustainable construction, green building, climate change, and environmentally friendly building being used when defining and describing construction projects.

A deeper study of these terms depicts building processes and practices that prove to make use of resources efficiently and at the same time are environmentally responsible in the planning, design, and construction of structures as well as their demolition towards the end of their life cycle. It is to be noted that all of the above mentioned benefits are in perfect coordination with the traditional perception of construction that highlights durability, economy, utility, and comfort. "Green building is ultimately about the relationship of a house and its occupants to the world around them. It's a process of design and construction that fosters the conservation of energy and other natural resources and promotes a healthy environment.

Green construction

A green building is one which uses less water, optimizes energy efficiency, conserves natural resources, generates less waste and provides healthier spaces for occupants, as compared to a conventional building. A significant shift towards the development of green construction projects is highly noticeable nowadays. Building green does not necessarily mean major sacrifices in comfort, convenience, or even safety in the design and construction of homes or buildings. Minor changes in site planning and layout can

result in the alteration of water runoff to great significance and at the same time eliminate subsequent pollution issues as well. The orientation of a home or building in a way that allows a passive solar gain in the wintertime can reduce heating costs. Roof overhangs can provide shading in the summertime and can offer budget savings on energy costs and the eventual net impact reduces heating and cooling costs for the occupants.

The subsystems of a home or building include the site, foundation, framing, roof, electrical, ventilation--heating and cooling, door and window systems, insulation, plumbing, and even the landscaping details. Each of these systems contributes to the overall building design, form, function, and as such efficiencies, economies, and impacts on the environment can be readily realized through careful planning.

The addition of efficient heat pumps or geothermal heating and cooling systems can provide comfortable interiors at lower energy costs and impact on the environment while solar panels and photovoltaic arrays can provide heat and electricity. Door and window construction, along with building insulation, can provide significant savings and comfort. It is important to note that green construction is not only limited to new buildings but also involves renovation of existing structures to achieve the green outcome, and this is taking place around the world currently and at the same time is also a topic for numerous case studies. At present in Dubai if there is one shopping mall that has done justice to the green building concept then it will be none other than Dubai Festival City where the ceiling of the entire structure is made up of glass facades. This enhancement in the structure allows for sunlight to filter through the glass in the mornings where the sun is always there to greet us in a country such as the United Arab Emirates where you have an average temperature of about 40 degrees almost all year round. By allowing the sun's rays to come through, the entire mall is illuminated all the way till the afternoon which allows for a significant saving in light electricity till evening arrives. Another mall which follows the same concept of having glass facades as the ceiling is Marina Mall in Abu Dhabi. Along with the saving of electrical energy, the mild rays of the sun filtering through the glass give a very relaxed feeling to the visitors of the respective malls.

In New Delhi, India, a structure that happens to be considered as one of the greatest architectural delights in the world when it comes to culture and religion is the Baha'i Temple or more often referred to as the Lotus Temple due to its flowerlike shape. Inspired by the lotus flower, the design for the House of Worship in New Delhi is composed of 27 free-standing marble clad "petals" arranged in clusters of three to form nine sides. The number "9" is considered a very sacred number in the Baha'i religion and as a result everything from the number of petals to the door entrances as well as the pools is nine in number. The main attraction for this structure when it comes to green building is the fact that there are no air conditioners installed in it. All of the cooling that is achieved in this magnificent structure is done through careful designing of the petals and placement of the nine gigantic pools around it that allow for the coolness of the water to be trapped within the giant petals that eventually drive the winds in and provide the perfect temperature all over the temple.

Cementitious Materials

 ISBN: 978-1-84219-840-7 .

One of the largest construction materials that are produced and consumed nowadays is cementitious materials. They were used as floor lime mortar more than 9000 years ago in the Middle East. In addition, gypsum based mortar was also used in ancient Egypt around 3000 BC in the construction of the pyramid of Cheops. There was a dire need for a cementitious material that could harden under water in order to support piers and sea walls and this in turn motivated engineers and scholars to search for the right materials. The breakthrough came in around 27 BC when the Romans mixed lime mortar with fine volcanic ash or used a material named pozzolana. This allowed the Romans to create a cementitious material that could harden under water. The major leap forward in the development of the cementitious materials was in the 18th century when scholars such as John Smeaton, James Parker, and Louis Joseph Vicat contributed in greatly improving cementitious materials.

It was in the 19th century finally when Henry Le Chatelier invented Portland cement in his research by stating that tricalcium silicate is the main cementing phase of cement. He was able to explain the chemistry behind Portland cement and the many phases it runs through. Along with this the work of numerous other scholars in the 20th century led to the development of chemical admixtures. Furthermore, continuous research and development led to better understanding of the materials and creation of concrete with high performance and strength. All of this has facilitated the construction of many large structures never seen in the history of the world such as the Petronas towers in Malaysia, Burj Khalifa in the United Arab Emirates and the Empire State Building in the United States.

Sustainable Concrete

Sustainable concrete is a type of high performance concrete since it utilizes the materials to produce a concrete with high compressive strength. The materials used in the concrete mix include coarse aggregate, fine aggregate, cement, superplasticizers, micro silica and water. It is critical to use materials of high quality and strength or otherwise the failure could come from the aggregate. Moreover, quality control in casting the concrete is also very important it should be casted at control temperature and well cured or the failure could come from a weakness in the cement paste. Moreover, to produce concrete of high strength it is important to control the temperature, the materials quality and it must be well cured after hardening. However, unlike conventional concrete where the weakness is usually in the cement paste and the bond in high strength concrete the bond and cement paste is strong but the weakness mainly comes from the aggregate. That’s why one of the most important things in producing high strength concrete is to use high quality aggregate with high compressive strength. In addition, it is critical to know the compatibility of cement and superplasticizers. The more compatible the more effective it will be in improving workability and reducing water cement ration thus increasing the strength and durability of the concrete. One of the main draw backs of high strength concrete is that it is not very workable which makes it labor intensive and time consuming. However, if done well and with care its benefits are great such as high strength, durability and long service life. From the general principles behind the design of high-strength concrete mixtures, it is apparent that high strengths are made possible by reducing porosity, inhomogeneity, and micro cracks in the hydrated cement paste and the transition zone. In high-strength concrete, the aggregate plays an important role on the strength of concrete.

The low-water to cement ratio used in high strength concrete causes densification in both the matrix and interfacial transition zone, and the aggregate may become the weak link in the development of the mechanical strength. Extreme care is necessary, therefore, in the selection of aggregate to be used in very high strength concrete.

DESIGN CRITERIA

The objective of this research was to produce high strength, low carbon and sustainable concrete with a compressive strength of 80Mpa. The project included the following:

ACI-211 design procedures:

Step 1: Selecting the Water/ Binder Ratio
Selection of the W/B ratio depends on the target concrete strength and the compatibility of the super-plasticizer with the cement.

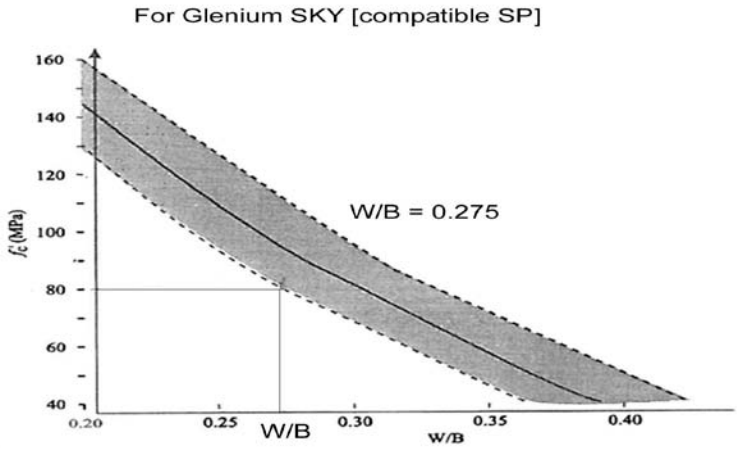

Figure 3: W/B ratio selection

Step 2: Selecting Water Content
One of the most important parameters when it comes to strength is water content. Water is required to guarantee a workable concrete however, it reduces concrete strength drastically. Subsequently, the lesser the water in the mix the stronger and more durable the concrete is. The selection of the water content depends on the dosage of super-plasticizer. The higher the super-plasticizer dosage the higher is the water content. Below is the graph used for the selection of the water content.

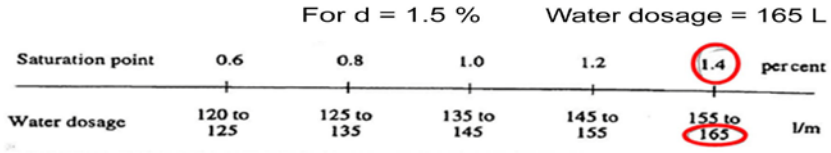

Figure 4: Water Content Selection

Step 3: Selecting Coarse Aggregate Content
Coarse aggregates make up the bulk of a high strength concrete. The selection of the coarse aggregate content depends on the shape of the available coarse aggregate. The given coarse aggregate is average to cubic.

 ISBN: 978-1-84219-840-7 .

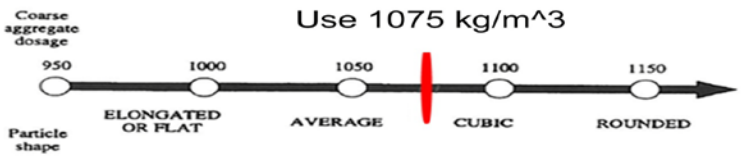

Figure 5. Coarse Aggregate Selection

Step 4: Cement Content
The binder content is another important factor controlling concrete strength. It's made up of 90% type I OPC and 10% of micro-silica. The binder content is determined by the water content and the water-binder ratio previously obtained.

Step 5: Mix Design Calculations
Once the above parameters are fixed, the rest of the mix design calculations could be performed based on the mix design sheet. The required calculations to determine the mix proportions are shown in the following table. The mix properties are outlined along with the super-plasticizer calculations in part one while the mix design calculation results are presented in part two.
The trial batch mix can be calculated in column 6. Each number appearing in column 5 has to be multiplied by a factor *f,* equal to the desired mass of the trial batch in kg, divided by the mass in box 16.

Required Samples		Weight (kg)	Total Weight (kg)
Type	Quantity		
Cube	6	2.5	15
Cylinder	2	13	26
Beam	1	10	10
Air test		15	15
		Sub-total	66
		10% wastage	6.6
		Total	72.6

f = 72.6 / 2373 = 0.030594

RESULTS

Fresh Concrete Results:

A- Flow Test: Flow test resulted in the following:

d_{max} = 650 mm, d_{perp} = 630 mm, S = (d_{max} + d_{perp}) / 2 = 640 mm

B- Temperature:

The temperature measuring device was used to measure the temperature of the fresh concrete and it turned out to be 23.4^{o} C.

C- Air content:

The concrete pocket (cylinder) was used to measure the air content which turned out to be 1.7%.

General Features of Concrete Mix:

Temperature (^{o}C)	23.4 ^{o}C
Air Content	1.6%
Flow Test (mm)	650, 630mm

Compressive Strength of Cube of concrete specimens, Sample age at test: 3 days Curing Condition: Water tank

	Compacted					
Sample	1	2	3	4	5	6
Compressive Strength at 3 days (Mpa)	47	48	47	45	47	48
Projected Compressive Strength at 28 days (MPa)	80	82	80	78	80	82

Splitting Tensile Strength Cylinder Concrete Specimen: Sample age at test: 3 days Curing Condition: Water Tank

Sample	Average diameter (mm)	Average length(mm)	Maximum Load (MPa)	Projected Load at 28 days (MPa)
1	100	200	3.72	5.58
2	100	200	3.09	4.64

DISCUSSIONS

The fresh concrete mix resulted in a flow test of 650 mm and 630 mm which represented high workability. The temperature of the mix was found to be around 23.4 °C and had an air content of 1.6%. The cube with the highest projected strength was 82 Mpa and it failed under the load of the compressing machine which indicated that it was of strong bond and had little voids that resulted in it exploding.

The cylinders had projected tensile strengths of 5.58 Mpa and 4.64 Mpa respectively in the tensile splitting test. The projected modulus of rupture of the beam was found out to be 10.84 Mpa. The failure could have resulted from the aggregate and because it took a long time to settle in the first place meant that the concrete would take a longer time in curing to harden to the design strength. Moreover, the harsh mix and hard workability owing to the weakness of the mixing machine could have also contributed to the failure.

The crushed cubes had a couple of cracked aggregates and major failure on multiple planes. The Schmidt hammer test gave a lower compressive strength than was found by the crushing machine. However, this could result from the Schmitt hammer being uncalibrated and because it is a non-destructive test which means that the numbers are approximate of the real strength. The ultrasonic test is a non-destructive test that tests the concrete quality and cohesion by finding the velocity of the wave travel in the concrete. The ultrasonic test detects if there are flows inside the concrete.

CONCLUSIONS

High strength concrete mix design was carried out according to ACI-211 procedures. Fresh concrete showed high workability measured as slump flow of 635 mm. The concrete resulted in very low air content of 1.6% Microsilica was used to produce sustainable concrete with average high compressive strength of 80 Mpa.

The hardened concrete showed high surface hardness. Failure showed explosive mode and occurred mostly through the aggregate particles. The resulted concrete is regarded sustainable because waste materials were used and produced high strength, workability and durability.

FOOD IN SUSTAINABLE DEVELOPMENT

Della Madgwick[1]

[1]*University of Brighton, Division of the e Built Environment and Civil Engineering Cockcroft Building Lewes Road Brighton BN2 4GJ*

ABSTRACT

The concept of sustainable communities in the UK has lead professionals in the built environment to embrace ideas about energy efficiency, waste recycling and water use with direction on these being included in policy documents such as UK Building Regulations. These regulations have begun to impact on designs for new developments within sustainable communities. As yet food, although being identified as a scarce resource in a period of rising population and climate change and despite being a significant contributor to carbon emissions rarely features in government policies or is even considered by built environment professionals in their designs; it still being the assumption that people will buy their food. Drawing on a three year evaluation of Harvest Brighton and Hove a lottery funded project to improve access to local food and embed sustainable food policies within an urban community and following on from a paper presented at Cobra 2010 this paper identifies how the urban food movement is beginning to influence policy makers in Brighton describing the new Planning Advisory Note and other key project outcomes. It provides planners, designers and developers with some innovative ideas about how food can successfully be included within the design processes for buildings and landscaping in the urban realm.

Keywords: built environment, food, innovation, sustainability, urban communities.

INTRODUCTION

The climate change debate combined with rising urban population has hi-lighted the significance and contribution of food miles to the carbon foot-print of cities and urban environments due to dependence on global, rather than local networks for food supply (Deelstra and Girardet, 2008). In addition the contribution that urban agriculture makes to community cohesion and health and well-being is increasingly recognised and bio-diversity of urban form is increased when significant areas of vegetation are added (Jean-Pierre,L 1998). So what are the obstacles facing those who try to embed urban agriculture into our cities? What do Built Environment researchers need to consider to preserve food supplies and biodiversity within the increasing urban sprawl?

[1] d.madgwick@brighton.ac.uk

 ISBN: 978-1-84219-840-7 .

The report from the 3rd (SCAR) European Commission Standing Committee on Agricultural Research Foresight Exercise Feb 2011 concludes with the following relevant main messages:

1. The increasing scarcity of natural resources and destabilisation of environmental systems represents a real threat not only to future food supplies, but to global stability and prosperity.
2. Many of today's food production systems compromise the capacity of the earth to provide food for the future
3. Drastic change is needed in regard to both food demand and supply
4. The average Western diet with high intakes of meat, fat and sugar is a risk for individual health , social systems and the environmental life support systems
5. Coherence between food, energy, environmental and health policies and across all levels of governance are pre-requisites for a timely transition to sustainable and equitable food systems
6. Sufficiently –orientated research, innovation and communication must become the new priority
7. A radical change in food consumption in Europe is unavoidable to meet the challenges of scarcities.

Between now and 2050 a growth in global population and changing diets in emerging countries are expected to bring about a 70% increase in food demand, as an average of all different possible scenarios (Freibauer et al 2011). At the same time depletion of fossil fuels will increase the demand for bio-fuels, natural resources are being depleted and climate change is affecting the global productivity of crops how then can more resilient and sustainable systems feed a global population rising to nine billion people?

To the Built Environment Professional it is interesting to note that against this back-drop of European concern for resource depletion, the new requirements, driven by policy makers for example UK Building Regulations or the Code for sustainable homes (UK department of communities and local government 2006) or BREEAM ratings (BRE) provide a set of sustainable design principles 'rating the whole home' under design categories which fail to recognise food as a scarce natural resource instead they focus on items such as:-

- Energy and CO2 emissions
- Water
- Materials
- Surface water run off
- Waste
- Pollution
- Health and well-being
- Management
- Ecology

Whilst there is consideration of provision for low energy transportation (bicycles) and the opportunity to use private out-door space, and water butts they fail to give consideration to food, accepting the age old belief that people will 'buy' their food but it is time to consider where from and the impact of the importing of food into urban spaces against each of the above criteria.

Within Built Environment research it is clear that with increasing urban populations there is a need to engage in a coherent and innovative debate about food, energy, the environment and health.

This paper looks at the on-going evaluation of a project which has been running in Brighton and Hove to increase the amount of food grown within the city and considers how some of this learning can be translated into more resilient food systems for urban city dwellers.
Incorporated within the project are the following aims:-

- *'Increasing the amount of food produced locally by increasing the space available to produce food, enabling communities to manage land sustainably and increasing the productivity of the land.*
- *Improving access to local food by increasing opportunities across the city to grow, taste and buy local produce*
- *Increasing Skills and confidence of local people in growing food and*
- *Improving awareness of the benefits of growing, buying and eating local produce across all sections of the community.'*
- *'Ensuring strategies and guidance that support land use and infrastructure for urban agriculture are developed and implemented within the city and elsewhere'.*

HARVEST BRIGHTON AND HOVE

Harvest Brighton and Hove is a 4 year £0.5M Beacon lottery funded project funded to increase the amount of food produced within the city as a result of global concerns over increasing urbanisation, expanding population and climate change. (Madgwick 2010)

It considers the need to refocus on the use of photosynthetic processes in cities which can provide a host of benefits to urban residents (Deelstra and Girardet 2008) most notably environmental benefits e.g. preserving biodiversity, tackling waste and reducing transport, social benefits e.g. environmental awareness, education and community engagement and financial benefits e.g. supporting local economies in line with localism agenda where food has become a common entry point for consumers to think about the impact of their choices on the local economy.

The evaluation of the first year of an urban growing project (Madgwick 2010) aimed to consider how the project developed in the first year against a set of outcomes identified in the Business plan as above, this current paper considers further the out-comes.

Methodology

GIS is used to record information on a map to indicate the changing position regarding Open Space and its use within the City boundary. Further evaluation of the project which is extensive and broad comprises both quantitative and qualitative tools for project partners and stakeholders in the form of questionnaires, some specifically adapted to capture information which is relevant to the five distinct goals listed above.

Project Outcomes

New growing spaces

There are currently nearly 60 projects identified within the city boundary where food is now being recorded as produced by community groups. These range from small vegetable plots in public parks, to community allotments often being run as community support schemes for individuals who are marginalised, schools and gardens of care homes etc.

Out of the 60 projects identified, the vast majority take place in allotment sites or in gardens of existing properties where service users, vulnerable people, or people with learning difficulties are encouraged to grow to develop social skills and learning, in addition there is a plot where students are carrying out growing, a small orchard which has been planted through local fruit futures and a vegetable garden at a children's centre.

Grow your neighbour's Own

The project has resulted in 27 gardeners gardening 17 gardens in other people's homes. The learning around this project appears to indicate the difficulties in seeking successful matching pairs which is more complex than originally envisaged, this is sometimes due to location, since those home owners with the biggest gardens tend to be outside of the city.

There has been much made of the scheme in the local and national press, yet it appears that it is difficult for people to give up their own garden to complete strangers. This could benefit from further research.

Scrumping project

The on-going picking of fruit trees in public spaces, dilapidated orchards and in private gardens by trained volunteers, who then use the food for education, for re-sale or for turning into chutneys continues. Fruit collected included apples and pears, cherries, cherry plums and walnuts. All of this is undeniably 'local' produce which contributes to healthy eating programmes through-out the city.

The weight of fruit in total collected in the second year was 3000 k; and this continues to grow; lack of volunteers being the limitation in expansion as more trees are already identified for the on-going continuity of the project.

A new direction for the project; given that financial sustainability is part of its core driver may be to consider picking from those trees with the greatest yield.

This project serves to illustrate the part which trees can play in feeding urban populations since trees are often part of new developments in towns. It is well established that municipal authorities in the UK provide staff to take care of the their parks and gardens, maybe taking care of the fruit and nut trees within our city boundaries is a future requirement. The project has been able to secure some premises within a local park with direct access onto the South Downs, when fresh juice has been sold at these premises, for example on summer weekends this has proved popular with cyclists and walkers this leads to more sales and less pasteurisation required. This builds on other research (Madgwick, Ravenscroft 2011) which determines that local food becomes more attractive when located in a position which is conducive to its consumption.

Allotments

Allotments are generally better used around the city and when new ones have become available a number of them have been given to community groups which have

essentially increased their production. Brighton and Hove now has 36 sites with 2,800 tenants.

In addition learner plots have been created, which are small plots to enable people to learn to grow on. With on-going support from the Local Authority another 100 new allotment plots have been created in the city and most redundant plots have been brought back into use.

The plots are being inspected regularly to increase food production and the local authority is working on provision of adequate water supplies to new and existing plots.

Breaking new ground

Much time has so far been invested in supporting local projects to set up new growing spaces. As identified in 3.1 a number of derelict plots of land have been resurrected as growing plots.

New projects are springing up over the City where the motivation is individuals and groups wanting to produce food. One example is a group of residents living near a station which approached Southern Rail about growing food in some of the neglected spaces around the station and along the railway line.

In addition, support is being given to a group of tenants who wish to set up a 'patchwork garden' around the base of their tower blocks. Ecological impact and social impact will be interesting to note.

Training programmes and communications

The Team at Harvest excel in promoting training events. Some are held in-house and others take place in the established community gardens around the city There are up to 20 events taking place within the city every month, though it is hard to evaluate the impact of these courses, particularly in any long term way.

In excess of 100 further people have attended courses. Everybody who attended the courses stated that they were more confident growing food. One stated that they had 'renewed enthusiasm for growing vegetables' another stated that they would put their name on the allotment list and start growing on their balcony.

In addition training courses have been held on bee keeping and bio-diversity. The web site hits continue to increase and media interest in Harvest continues from both local and national press and television.

The small grants scheme

Applications were received from 50 groups. Harvest have been able to fund 34 projects in schools and communities 20 of them encouraging participants to eat more local food and grow more of their own. The other 14 projects focus on improving cookery skills and increasing healthy eating

Local food events

There have been a number of local food events held around the city. The local food week in September has become a success with around 20 businesses taking part and demonstrating creative ways of growing vegetables in urban spaces and a local food picnic being held in a park. In addition events continue at a rate of around 10 per month such as:

- Seedy Sunday where seeds are brought and sold
- Cook ability

 ISBN: 978-1-84219-840-7 .

- Container gardening
- Seed-bomb workshops

Brighton, with the only green MP in the House of Common makes much of its local food culture and restaurants and fairs advertise their connections to the local food agenda.

Demonstration garden

The demonstration garden has doubled in size after discussions with the Local Authority. New volunteers have offered support and the garden provides invaluable advice to members of the public around growing in small urban spaces.

A regular blog keeps people informed of developments in the garden suggesting what to sow and when and it is assumed that this is copied in various gardens around the city.

The demonstration garden produces a wonderful marketing opportunity for harvest and has provided inspiration for work in other parks around the city which have set up similar schemes, pumpkin patches and herb beds etc.
In addition, it is hoped that it has influenced people to start growing within their own back.

Community composting

Through a community association there has been established two locations where around 45 house-holds compost their un-cooked vegetable, fruit waste, tea bags and coffee grounds. It has been estimated that this saves 3 tonnes of organic waste from landfill per year.

INFLUENCING POLICY

Since one of the aims of the project were to ensure strategies and guidance that support land use and infrastructure for urban agriculture are implemented within the city and elsewhere, there was a discussion held with city planners around how the project could best be used to influence policy. As result of this there was a suggestion that a Planning Advisory note (PAN) could be drawn up, this would provide some basic technical considerations as well as offer inspiration on how food may be incorporated into new proposals. Consultation was sought from groups representing the following: Allotments, Ecology, Arbiculture, Environmental Health, Healthy Urban Environment Group, Housing Development and Economic Development. As a result of this and out-comes of the project to date a draft was drawn up which was adopted by the local authority in September 2011. The PAN is the first of its kind nationally and is designed to be an innovative model that other Local Planning Authorities might adopt.

Planning Advice Note

The Planning Advice Note applies to new build commercial, residential and mixed use developments and it is intended to be used as a guide to what is achievable depending on the context of the development.

Technical and Practical Considerations

It was agreed that the initial considerations should be of the following:

- Land:

 ISBN: 978-1-84219-840-7 .

- Use of building
- Aspect and light:.
- Water:
- Wind:
- Soil/growing medium:
- Compost:
- Contaminated Land:.
- Access:
- Storage:
- Management:

Planning and Design Regulations
Depending on these practical and technical considerations there are several design options which are referred to:-

- **Rooftops**
  Intensive accessible green roofs can be used for edible plants subject to adequate design for loading capacity.
- **Balconies**
  Design of balconies can provide small spaces for individuals to grow a limited selection of plants and are particularly suited to high density residential developments. It is critical to consider aspect.
- **Walls**
  Vertical growing on external and internal walls, the latter usually in atriums or courtyards, can be adapted for food production. Maintenance of productive green walls is high, as they will require harvesting and seasonal replanting, and therefore will need to be accessible.
- **Internal atriums/courtyards**
  Designing buildings with atriums or courtyards with adequate exposure to sunlight can create deliberate opportunities for food growing allowing high value tender plants such as tomatoes and citrus fruits to be cultivated. Ground level beds or planters can be used, as well as living walls. Care must be given in internal spaces to providing irrigation systems and allowing for water run-off.
- **External landscaping and integrating ornamental with edible planting**
  Depending on the land available around the building or on the site various options are available. Cropping can be integrated within areas of soft landscaping with a minimum cost outlay.

It is still early to comment on how the plan has been received by local developers and whether it is likely to be implemented by other authorities. Results may be small scale: the provision of allotment space within residential developments; landscaping with edible plants; planting fruit trees in place of non productive varieties.

CONCLUSION

There is still much to do learn regarding embedding sustainable food consumption within the city in its wider context but there are certain things which are beginning to happen :-

An urban growing programme such as harvest can start to make better use of some of the land in urban areas if food is seen as a priority. In Brighton, much of this land to

date has been local authority land and existing gardens but with increased research and innovation and using the Planning Advisory Note there is the as yet unexplored potential to develop this to private or commercial land and buildings. In addition the community composting scheme provides invaluable resources from existing city dwellers to ensure nutrients are fed back into the land and thereby continue to make it rich and fertile and Seedy Sundays encourage the swapping of seeds
The development of resilient new food systems in the city may add to its productivity. In reducing transport and packaging costs the growing of food within the city may help to conserve the fossil fuels.

With its wide remit for education, harvest has not only tried to teach people to be better at growing but additionally encourage people to eat more healthily and respect biodiversity, it aims to add to, not replace an existing agricultural supply of food currently delivered to the city and can therefore assist in the increased demand which comes from the rising population.

The Harvest project works with schools providing education on growing and on healthy foods, individual projects such as the scrumping project, regularly presses fruit at schools to demonstrate to children the pleasures of drinking fresh juice without additives. The wide extent of new community allotments encourage people to become more active and lead healthier life styles, the more people engaging in growing the more opportunities to cook from fresh and to understand fully the implications of eating high levels of meat, fat and sugar.
Coherence between food, energy, environmental and health policies sits at the very heart of the project and policy influencing is a key out-put being achieved by academic evaluation critical appraisal and understanding of the key drivers behind the project.

Certain plants which can be grown in cities may well become established as local products whilst it is still accepted that vast amounts of food will still be brought in to the city. Harvest produces via its web site a central place to co-ordinate activities regarding local food. In addition, increasing green roofs, balconies and green walls and creating green pathways through cities can increase bio-diversity.
This paper aims to encourage researchers in the Built Environment to critically evaluate existing literature and ideas on ‘sustainable communities’ so that this research can be extended to contribute to the developing urban form.

A radical change in food consumption in Europe is unavoidable to meet the challenges of scarcities Consumption and production is at the heart of Harvest Brighton and Hove in both the production of new food systems and the education of the wider community.
To add to this; one of the challenges facing the Built Environment professional is to try to engage others in the notion that food as a scarce recourse needs to be considered along with water and energy in design codes for new developments if we are to be able to feed the growing urban population over the next 30 years.

ABSTRACT

Over the past decades, many parts of the world have been subject to various natural disasters, including the 1995 Kobe (Japan) and 2011 Christchurch (New Zealand) earthquakes; tropical cyclones Larry (2006) and Yasi (2011), Queensland (2010–11) floods, the Ash Wednesday (1983) and Black Sunday (2009) fires in Australia; hurricane Katrina (2005) in USA; and, the tsunamis in South and Southeast Asia (2004) and Japan (2011). Natural disasters such as these appear to be a feature of the global climate and landscape, and they continue to pose economic, social and environmental challenges to many nations. Disaster responses have often focussed on the built environment, health and social factors. However, as identified in a number of key reports, cultural values, such as cultural built heritage (CBH), are also likely to be affected by natural catastrophes. Considering the historical, national and communal implications of CBH, there has been surprisingly little debate and research on the question of how to protect CBH from risks posed by changing climate and increased natural hazards. Building upon a review of existing scholarship on CBH, resilience, and disaster recovery, this paper proposes an alternative strategy for preparing, recovering and conserving CBH. Resilience is explored as a means of developing strategies for recovering and preparing the CBH.

Keywords: Cultural built heritage, disaster recovery, natural disasters, Resilience.

INTRODUCTION

Over the past decades, Australia has been subject to a number of natural disasters, including the tropical cyclones Tracy (1974), Larry (2006) and Yasi (2011); the Sydney Hail Storm (1999) and the Pasha Bulker Storm (2007); the Nyngan (1990), Charleville (1990) and Queensland (2010–11) floods; the Ash Wednesday (1983) and Black Sunday (2009) fires; the Great Easter Drought (2002–06); and, the Newcastle (1989) and Ellalong (1994) earthquakes. Natural disasters such as these 'are a feature of the Australian climate and landscape' (DPC 2009: iii) and continue to pose

[1] Jamie.Mackee@newcastle.edu.au, Hedda.Askland@newcastle.edu.au
[2] Louise.Askew@coakesconsulting.com

economic, social and environmental challenges to the nation. Two factors that are believed to enhance the risk of natural disasters are climate change and urbanisation (The World Bank 2010). Due to climate change, hazards (i.e. natural phenomenon with adverse effects, such as floods, storms, droughts and earthquakes) are increasing in intensity, frequency and distribution. Coupled with the increased size and density of Australian cities, this exposes a growing number of people and properties to the risk of natural disasters. Responses to the potential threat posed by climate change and severe weather events have focussed on their impact on the natural environment. However, as identified in the Garnaut Climate Change Review (Heath 2008), '[c]ultural values, such as built heritage, are also likely to be affected by climate change'. The threat that these events pose to the Cultural Built Heritage (CBH) of affected zones is generally limited to individual sites and landscapes. The localised nature of CBH suggests that risk may be mitigated through early identification of impact and targeted strategies for adaptation and conservation, subsequently reducing the risk of damage to, or loss of, non-renewable CBH resources (Sabbioni, Brimblecombe & Cassar 2010).

This paper explores issues related to natural disasters and CBH and presents the idea of disaster preparedness as being integral to CBH protection and conservation. The paper briefly considers some of the elements that form part of the debate surrounding CBH and natural disasters and explores key elements of current scholarship on conservation, before it investigates how the concept of resilience can be integrated into the conservation debate through the notion of adaptive cycles and panarchy. Ultimately, through this paper we aim to reconceptualise CBH and disaster management through the concept of resilience with the aim of building a disaster preparedness and risk assessment framework that can support communities when dealing with the vulnerabilities of their built environment.

BACKGROUND

CBH holds both cultural and national significance, and recovering CBH from natural disasters has individual, social, cultural and national implications. This argument is based upon the perception of CBH as sites of cultural significance that 'enrich people's lives, often providing a deep and inspirational sense of connection to community and landscape, to the past and to lived experience' (Australia ICOMOS 1999: 10); CBH carries a historic, aesthetic, social, scientific or spiritual value for past, present and future generations. Such places of cultural significance represent historical records 'that are important as tangible expressions of […] identity and experience' (Australia ICOMOS 1999: 1), which provide communities with narratives about who they are, as well as about the landscapes that have formed them as collectives (Australia ICOMOS 1999). Restoration of damaged heritage is, however, often neglected in post-disaster reconstruction plans and in the development of disaster mitigation strategies (MacKee 2011, Taboroff 2003, Look & Spennemann 2000, 2001). Disaster management agencies do often not distinguish CBH from the general built environment, and there is great divergence in countries' official interest in incorporating CBH into the activities of the disaster management community (Taboroff 2003). This scenario is commonly worse in developing countries where CBH protection is often way down the list of developmental priorities in normal circumstances.

If CBH is to be successfully integrated into disaster management approaches it must, however, be explored not only in relation to response to and recovery from disasters. It also requires consideration of pre-disaster circumstances, mitigation practices and preparedness as the impact of a disaster will be a reflection of preceding decisions that have been made over an extended period of time. Indeed, understanding risk and vulnerabilities is a key issue when dealing with the impact of disasters on CBH (Look & Spennemann 2001, Taboroff 2003, Spennemann 1999). CBH, which is a vulnerable resource under normal circumstances, is particularly exposed due to the fragile nature of aging structures and the subsequent risk of collapse or legal intervention. At the time of a natural catastrophe, the evolving risks and vulnerabilities of CBH are dramatically increased as issues related to structure and legality are brought together in one devastating event of significant change. This notion of change resulting from natural disasters is at the heart of the argument presented in this paper, which rests upon an integrated and holistic approach to preparedness of CBH for natural disasters.

RESILIENCE

Systems that integrate variables of two co-evolving systems, such as for example socio-ecological systems, convey particularly high levels of complexity (Brekes, Colding & Folke 2003; Berkes & Folke 1998; Walker & Salt 2006). Efforts to understand such complex systems have transpired into the theoretical field of resilience thinking. Holling first developed the concept of resilience in 1973 (Holling 2001) in the field of ecological science. His concept of ecological resilience deals with the structure and function of ecological systems, and he defines resilience as 'the capacity of a system to absorb, utilize or even benefit from disturbances and changes, and so to persist without a qualitative change in the system's structure' (dos Santos & Paridáro 2005: 29). Since then, the concept has evolved and it has been adopted by a number of disciplines, including archaeology, disaster management, urban planning and studies of climate change. Although the concept of resilience has not yet been used in the context of CBH, it can provide a useful lens through which issues related to protection of CBH can be explored. From a resilience perspective, CBH can be understood as a complex system that, in a world of growing turbulence and uncertainty, must be able to absorb disturbances without collapsing.

Understanding the complexity of co-evolving systems—such as the social-ecological system of CBH—and recognising their interrelationships, change dynamics and transformation have provided a rich foundation for looking them from a resilience perspective (Berkes & Folke 1998; Berkes, Colding & Folke 2003; Walker & Salt 2006). At the heart of resilience thinking is the very simple notion of coherence despite change and the idea that to ignore change is to increase vulnerability and forego emerging opportunities (Walker & Salt 2006: 9–10). In resilience thinking, humans and nature are considered as interdependent elements of the one system, which both must be considered when seeking an understanding of the system (Walker & Salt 2006).

Adjunct to this argument is the concept of the adaptive cycle, which has been derived from comparative studies of ecosystem dynamics. The adaptive cycle consists of four key phases: growth or exploration (r); conservation (K); collapse or release (Ω); and, reorganisation (α) (Figure 1). The concept of adaptive cycles can inform studies of cultural heritage conservation, with conservation (K) representing one of the four

distinct phases of socio-ecological system dynamics (Resilience Alliance 2007). Holling (2001: 393–4) explain that there are three key properties that shape the adaptive cycle and the future of a system: the system's inherent potential for change (wealth); the internal controllability of a system; and the system's adaptive capacity.

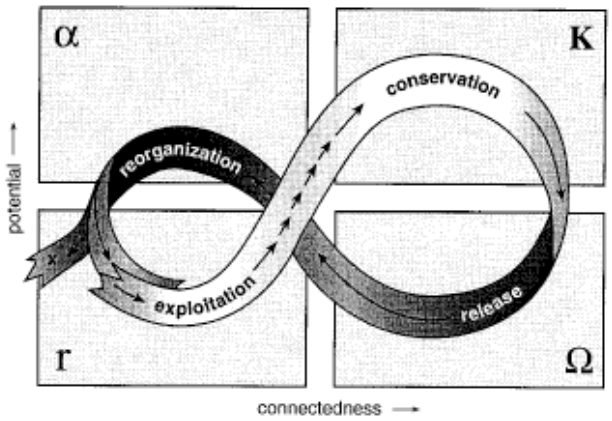

Figure 1: The model of the adaptive cycle (adapted from Holling 2001: 394).

Represented in this cycle are two major phases, often referred to as 'transitions'. The first transition, *foreloop*, runs from r to K. It is characterised by slow incremental growth and movement. The second phase, *backloop*, runs from Ω to α. This is the rapid phase of the cycle, which leads to reorganisation and growth (Holling 2001).

The third dimension of the adaptive cycle is resilience. As Holing (2001: 395) explains, the resilience of a system will shrink 'as the cycle moves towards K, where the system becomes more brittle. It expands as the cycle shifts rapidly into a back look to reorganize accumulated resources for a new initiation of the cycle'. This process is illustrated in Figure 2, which shows the relationship between resilience and adaptive cycles.

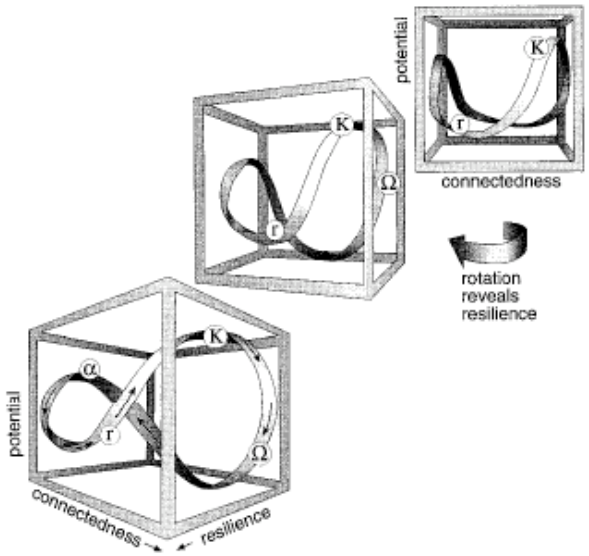

Figure 2: The connection between resilience and the adaptive cycle, with resilience being the third dimension of the adaptive cycle (adapted from Holling 2001: 395)

Understanding and dealing with change is key to Holling's concepts of adaptive cycles and resilience. As such, this theory provides a valuable link to issues related to CBH and natural disasters and it may help address issues related to risk and vulnerability. The ideas of change, transformations and adaptive cycles are notions that are related to how CBH can be perceived through time and explored in terms of general conservation and more specific preparation for potential future disasters. The application of resilience thinking to the conservation of CBH provides an opportunity to explore the persistence and survival of heritage against the ongoing forces of disasters that result in physical, social and natural change. That is, resilience thinking engages in a trans-disciplinary way the dynamic interconnections and interdependencies amongst the key systems. Moreover, it provides a holistic perspective through which issues related to CBH can be explored and a comprehensive approach to the protection of CBH in the wake of disasters can be developed.

LINKING RESILIENCE WITH THE PROTECTION AND PREPAREDNESS OF CBH IN THE WAKE OF DISASTERS

In a discussion of how to build resilience and adaptive capacity in social-ecological systems, Folke *etal*. (2002) identify four critical factors that must exist for the success of a resilient system. These factors, which are summarised in Table 1, include: learning to live with change and uncertainty; nurturing diversity for resilience; combining types of knowledge for learning; and, creating opportunity for self-organisation towards social-ecological sustainability (see also: Folke et al. 2002). They argue that these for factors, which interact across spatial and temporal scales, are required to successfully deal with natural resource dynamics during periods of reorganisation and change.

Table 1: Four critical factors for a resilient system (adapted from Folke *etal*. 2002:)

	Critical Factor	**Description**
1	Learning to live with change and uncertainty	Creating a knowledge base for how to relate to and respond to environmental feedback
2	Nurturing diversity for resilience	Functional diversity and redundancy as per nature
3	Combining different types of knowledge for learning	Integration of knowledge and their sources for a holistic approach
4	Creating opportunity for self organisation towards socio-ecological sustainability	Adaptive co-management by which institutional arrangements and ecological knowledge are tested and revised in a dynamic, ongoing, self-organised process of trial and error

These four factors (Folke *etal,* 2002) provide guidance for developing a framework that can be used when applying the concept of resilience to the conservation of CBH. The first factor would relate to the fact that CBH, as a historical record, has over time endured and responded to environmental feedback that may influence the system in

uncertain and unpredictable ways and place it at the mercy of change. As previously discussed, disasters represent a major moment of change and uncertainty, and for CBH to respond to such change there is a requirement of creating a sound understanding of how CBH as systems can prevent harm from and respond to natural disasters.

Whilst the specific knowledge base that is required to deal with uncertainty surrounding a piece of heritage can incorporate the heritage's unique characteristics with lessons drawn from various sources, the second factor illustrates the unique and complex demands underpinning resilient systems. The factor of nurturing diversity for resilience requires understanding of the specifics of the particular piece of heritage and the diversity of the built environment within which it exists. A requirement for this factor in heritage is an understanding of the conditions of redundancy and obsolescence.

Although understanding of particularities is important, this should not be at the expense of a holistic approach and, as suggested by Folke *etal*. (2002), a resilient system requires the integration of multiple types of knowledge for learning. In the context of CBH this refers to the need for a multidisciplinary approach that incorporates the knowledge and expertise held by the many stakeholders. This is imperative for a holistic approach, which is often lacking in heritage conservation (MacKee 2009). For a system to be resilient it has to hold the opportunity for self organisation towards social-ecological sustainability. In relation to CBH, this factor relies on an understanding of conservation as a sustainable process that builds on the implementation of the appropriate institutional processes, which acknowledge the dynamic nature of cultural heritage and the importance of a suitable management organisation.

Finally this initial proposal for an adaptive cycle that may be used to describe the planning for or conservation of CBH offers an initial framework for the integration of resilience to the preparedness and conservation of CBH in the aftermath of disasters. From these very first steps work needs to focus on the further integration of the four critical factors identified by Folke et al. (2002) (see Table 1). These are important to the success of the integration of resilience and conservation of cultural built heritage. Whilst this theoretical framework might seem quite removed from the initial discussion of conservation theories the notion of adaptive cycles and the theoretical concept of resilience can be applied in both European and Asian contexts through the emphasis on a holistic understanding of the system (CBH) as it sits within its particular geographical, climatic, cultural, social and ecological context.

CONCLUSIONS

This paper has posited an argument for resilience and the concept of the adaptive cycle to support a more holistic and integrated approach for the protection and preparedness of CBH in the aftermath of disasters. The concept of resilience and adaptive cycles provides a theoretical framework that allows, we argue, for an approach that can potentially lead to a functional, culturally relevant, framework for developing mitigation, preservation and preparedness strategies for safeguarding CBH in the wake of natural disasters. Further work is required to fully understand CBH as resilient systems, and also to see how this theoretical framework can adopt various

perceptions of CBH and, subsequently, expand the governing discourse through incorporation of more holistic-systems conceptions.

ABSTRACT

In recent years, sustainable regeneration has been recognised as major socio-economic concerns in the world. In the UK, the government has initiated a number of evaluation methods in dealing with some of the problems associated with regeneration programmes. However, attempts aimed at implementing sustainability have primarily been limited to the evaluation of environmental impacts, with the socio-economic impacts often neglected. While there have been numerous studies on evaluation of regeneration projects in the UK, there has not been any well-defined research that has been able to deal holistically with the broader issues of sustainability impacts to the communities concerned. The study presents the findings of an exploratory study that interviewed six directors of leading construction and consultant organizations involved in regeneration projects in the UK. The findings reveal a lack of early stage evaluation frameworks for socio-economic impact evaluation of sustainable regeneration projects. The results also suggest that the environmental factors of sustainability continue to be the most dominant as compared to the socio-economic factors. This research is drawn from an on-going study for which the general area of investigation is the development of a framework for the socio-economic benefits evaluation of sustainable built environment regeneration projects.

Keywords: Social and economic impacts evaluation, sustainable regeneration.

INTRODUCTION

The concept of sustainable development and regeneration has been an essential focal point of government policy for sometime in the UK and it has contributed to the enhancement of many communities' physical structures (Haran *et al*, 2011). Many of the earlier initiatives that were meant to tackle socio-economic disparities have focused on improving the physical and environmental aspects of regeneration. In more recent times, there have been a number of researches which sought to study and analyze how the UK built environment is responding to the challenges of integrating sustainability into regeneration projects (Dixon, 2006). The Sustainable Development Commission, (SDC, 2003), suggested that the development of regeneration has

proved to be a testing and on-going challenge for government agencies, construction industry practitioners and communities within the UK. The appreciation of such challenges has led to the development of various management strategies and systems to guide and direct industry practitioners to achieve higher and improved sustainability standards. According to Brandon and Lombardi (2011), previous works undertaken on sustainable regeneration have shown that they lack a conceptual clarity related to sustainability assessment. Brandon and Lombardi (2011) identified sustainable regeneration/development as an evolving field and suggested the need for further study as they asserted that there had not been a well-defined evaluation framework developed that was able to deal with the issues of social and economic benefits/impacts and their evaluation in a comprehensive and a decisive manner. Consequently, the quest for sustainable development and the need for better sustainable regeneration outcomes calls for an exploration of new ways of evaluating, at an early stage, sustainable regeneration projects that are under-pinned by strong socio-economic considerations; and which better address sustainability concerns in a holistic manner to maximise the sustainability benefits of these projects.

LITERATURE REVIEW

Sustainable Regeneration a driving force for sustainable development

The post war era has seen a significant number of transformations in the form of regeneration schemes, designed to improve the conditions of areas that have experienced a dramatic decline in their socio-economic fortune (CLG, 2010). A seminal work by Roberts (2000, pg 17) defines regeneration as a *"comprehensive and integrated vision and action which leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental condition of an area that has been subject to change".* Roberts' work established the baseline for urban regeneration initiatives and the need to view regeneration activities as an integrated and comprehensive approach which requires a greater balance between the creation of the physical environment and socio-economic development of the communities. Fundamentally, regeneration is about closing gaps (Community and Local Government (CLG), 2010) and tackling the spatial disparities that exist within the communities (HM Treasury, 2007). Yet, the traditional project management approach adopted to deliver such regeneration objectives has accounted for their failure (Sorrell and Holti, (2007). It has also been suggested that many of such regeneration initiatives have been planned without the fundamental components of sustainability as a parallel strand, resulting in the inability of regeneration projects to deliver on such shared objectives underlying sustainable development. The UK government Audit Commission report (2007) has revealed that many regeneration activities are yet to have a consistent and positive impact on most deprived localities. The report suggested that the level of long-term unemployment in the communities where regeneration initiatives have taken place has remained static and targeted work to develop skills and access to employment for these communities still remains under developed. However, to deliver such sustainable regeneration goals as advocated by Roberts (2000) and the UK government report (CLG, 2010) will require a strong and strategic approach to sustainable regeneration development to meet local needs. Since socio-economic disparities are seen to be directly rooted in our community set up, focusing on sustainable regeneration has enormous potential to drive the local communities towards becoming sustainable communities (Smith, 2006). It is believed

that if future regeneration is to make greater sustainable impact on the communities concerned then the current regeneration projects' priorities will have to be altered to reflect the priorities needed to achieve the sustainable development objectives of the affected communities (Raco and Henderson, (2009). It has been suggested that the sustainable regeneration processes which are based on the strategic evaluation plans that are holistic in nature are more likely to drive the sustainable regeneration agenda to achieve the desired sustainable development outcomes for the affected communities (Hemphill *et al,* 2004).

Limitations of the current projects evaluation systems

A plethora of evaluation systems and tools have been developed for the purposes of appraising the environmental and sustainability performance of building projects, in areas such as the use of energy in buildings, indoor environment and building materials containing hazardous substances, etc (Forsberg and Von Malmborg, 2004). While some of these evaluation systems and tools have focused mainly on evaluating the environmental and sustainability performance of the proposed developments, others have placed emphasis on the assessment of their environmental and sustainability impacts (Ding, 2008). The development of these various forms of evaluation methods has largely been informed by the desire to provide building projects with a better profile of environmental performance and the achievement of the best practice in sustainable building design, construction and operation. Yet neither of these evaluation systems has been able to offer such sustainability solutions capable of focusing simultaneously on all the social, economic and environmental aspects of sustainability. Recent work by Brandon and Lombardi, (2011) pointed out that the current lists of available sustainability evaluation methods do not reflect the complexities of issues they were designed to address. A study conducted by CLG (2010) indicated that several attempts to evaluate the impact of regeneration projects to date have been seen to be only partial in their nature. The report went on to encourage practitioners to undertake a vigorous evaluation of regeneration projects and challenged practitioners to be prepared to act on any evidence pointing to a lack of sustainability success. However, a greater demand for sustainable regeneration coupled with the requirement to develop such systematic and multi-dimensional sustainability evaluation models (Ding, 2008), calls for a paradigm shift toward the systems that constitute a satisfactory integrated approach to the evaluation of sustainability impact (Lee, 2006). Such evaluation systems should be clearly set out and define their boundaries and parameters.

RESEARCH APPROACH

In order to meet the objectives of the study, an initial exploration was undertaken through a literature review as a starting point to ascertain the background information relating to the current sustainability practices. A qualitative research design was then adopted with semi-structured interviews used to collect rich data. This approach reflected an interpretivist philosophical position that made use of inductive research strategy and qualitative methodology. A qualitative research approach is considered as an effective method that occurs in a natural setting which enables the researcher to develop a level of detail from involvement in the practice (Creswell, 2009). Initially, 20 leading construction and consultant organisations in the UK were selected, based

on their experience and knowledge in sustainable regeneration projects, through a purposive snow balling sample technique. Formal letters were then sent out to these organisations as an invitation to participate in the study. Follow up telephone calls were also made to these organizations to further explain the purpose and the context of the study. In all, a total number of six (6) organisations agreed to take part in the study. The profiles of these agreed organisations/interviewees are shown in the table 1 below. Face-to-face in-depth semi-structured interviews were then undertaken (between August 2011 and March 2012) with the senior sustainable/regeneration managers of these respective organisations. Each interview lasted for between 40-45minutes. The interviews were formatted around a range of open-ended questions to explore the sustainability issues under investigation. The responses to the exploratory nature of the questions were analysed to identify the emerging themes and issues in the current practices related to early stage evaluation of sustainable regeneration projects.

Table 1: Profiles of interviewees and their leading organizations.

Interviewee	Position	Type of organization
1	Sustainability/regeneration director	Contractor organization
2	Sustainability/regeneration director	Consultant organization
3	Sustainability/regeneration director	Contractor organization
4	Sustainability/regeneration director	Contractor organization
5	Sustainability/regeneration director	Consultant organization
6	Sustainability/regeneration director	Consultant organization

DISCUSSION OF RESULTS

It is widely acknowledged that various contributors in different fields have classified the impacts of sustainability indicators in different ways. However, from a built environment regeneration perspective, the socio-economic aspect of sustainability can be seen as a potential measure of success when implementing sustainability within regeneration projects. The main themes that emerged from the data analysis included sustainability factors, sustainable regeneration objectives/benefits, the evaluation framework and socio-economic impact/benefit. The gap between theory and practice has also been summarized in figure 1 below.

Sustainability Factors

The first interview question put to the interviewees explored their organizations' understanding of sustainability and the importance the practitioners and their organizations attached to such sustainability factors when evaluating project viability. A significant theme that emerged from their responses was the lack of conceptual clarity of what are 'sustainability factors' by the interviewees. All the interviewees provided relatively simplistic definitions and understanding of sustainability in relation to their business operations. Typical of the comments made were as follows:

"Sustainability is something ingrained and inherent in our business processes something that the business has to pay attention to in order to stay competitive…It is about protecting our business from the risks of today and ensuring that we respond to the challenges and opportunities that tomorrow brings…" (Interviewee 5).

"I think sustainability is being one of the key driving forces behind our operations. It has a short to long term benefit to our business. First and foremost it fits with the vision and values of our business. Adopting sustainability makes us competitive in the environment in which we operate…" (Interviewee 2).

The responses highlighted the limitation in the practitioners' perception and understanding of sustainability. The ambiguity of what constitutes sustainability was also identified as a major problem in work done by Brandon and Lombardi (2011)

Sustainable regeneration objectives and benefits

When the practitioners were further asked about their understanding of the main objectives of sustainable regeneration projects, the respondents provided mixed responses. Some interviewees commented:

"…To ensure comfort and safety. To be aware of the social and physical environment and to endeavour to improve the quality of life to residents…" (Interviewee 3).

"All regeneration needs to be profitable otherwise, there's no point doing it, if there won't be any kind of benefit. So without the benefit element, no regeneration happens unless you get a philanthropic developer who just wants to spend millions of pounds to make people happy for things to happen." (Interviewee 1).

Discussing the issues further about the benefits to their organisations and the end-users, most of the respondents indicated that company reputation and profit making was the main benefit for adopting the sustainability principles by their organisations. However, the majority of respondents were of the opinion that issues related to energy usage and in particular cost savings on fuel bills was the main benefit to the end-user.

Evaluation and evaluation framework/mechanisms

In exploring the evaluation mechanisms currently in practice, many of the interviewees indicated BREEAM as being the main evaluation mechanism used for their projects. As some interviewees noted:

"BREEAM is the main assessment method used for our projects as it focuses on low or zero carbon technologies and designs. It is a vital part of our culture and a scheme to promote the adoption of cohesive sustainable solutions across all our specialism as a best practice guide to meet our sustainability objectives" (Interviewee 3).

"…BREEAM is easy to use as it provides a guideline and specifies the environmental impact of the final products. BREEAM ultimate benefits are recognisability of sustainability in the sense that it tends to capture the main environmental aspects of projects…" (Interviewee 4).

Evidence from the interviewees showed that sustainable regeneration practitioners still consider environmental factors to be the most dominant feature of sustainability and they tend to neglect the consideration of any socio-economic factors. Most of the respondents emphasized on the environmental credentials of BREEAM and also

regarded its application as representing the industry's best practice in relation to sustainability. It is worth noting that BREEAM parameters are prescriptive in nature and largely based on quantitative assessment which tends to ignore the processes and issues relating to socio-economic factors of sustainability of the projects. When asked further about just when the evaluation frameworks were being applied during the project life cycle, there were mixed responses. Some of the interviewees noted:

"Ultimately it depends on the nature and duration of the project…We adopt a flexible and innovative approach based on the requirements of the project we are involved in by demonstrating compliance with the specific targets and key performance indicators agreed by all parties on sustainability relating to the construction and operation of the facility…" (Interviewee 4).

In addition, another interviewee who alluded to the use of an evaluation model commented: *"We do not have a structured evaluation framework per se, what we do have is some models for planning and benchmarking…Yes we tend to apply our models throughout our project duration to identify and address actions as soon as possible where the greatest sustainability impact may be available…"* (Interviewee 6).

These responses however revealed the lack of a structured evaluation framework and a lack of an appreciation of early stage evaluation mechanisms for appraising the direct and indirect socio-economic impacts of their sustainable housing projects.

Socio-economic impact/benefit

Finally, when interviewees were asked for their views about the socio-economic impacts of their regeneration projects on the communities, a significant misconception emerged between sustainable regeneration projects, community redevelopment and renewal projects. Although all the respondents interviewed were involved in sustainable regeneration projects, their responses indicated a limited knowledge of socio-economic aspects of sustainable regeneration projects. This was demonstrated by the comments given by some of the interviewees as:

"Remediation of an existing hazardous environment in a sustainable way. Creation of public amenity, the improvement of public access on site and improved existing wildlife habitats that will encourage greater biodiversity on site…Redevelopment of site for use of both commercial/residential and public open spaces" (Interviewee 5).

"It is the social and economic impacts that we find most problematic. Our main goal across all our disciplines is to take a responsible attitude toward renewal of our communities. We are keen on providing modern community facilities, improving the physical environment of our communities as well as safeguarding the environment as a whole for the benefit of our communities" (Interviewee 2).

Many of the interviewees expressed their views in line with the potential environmental benefits of a project and also gave emphasis to sustainability factors that fitted within their own understanding and agenda.

THE GAP AND BARRIERS BETWEEN THEORY AND PRACTICE

Much of the sustainable regeneration literature has shown that the concept of sustainability has not been well understood by many stakeholders within the built environment. The summary of the gap and barriers identified within the exploratory study with the practitioners are presented in figure 1 below. The current gap and barriers existing between theoretical concepts and the 'reality' in practice was amply revealed from the findings as all the six practitioners have consistently emphasized on the environmental credentials to the neglect of the social and economic sustainability aspects of projects. This was evident in the trend of responses in all the main areas explored. Following the exploration of the issues with the practitioners, it is seen that the challenges associated with the current delivery of regeneration projects are direct products of the key players' knowledge, perception and understanding of sustainability. Consequently, this is reflected in the way sustainability has been articulated and applied in practice (see figure 1).

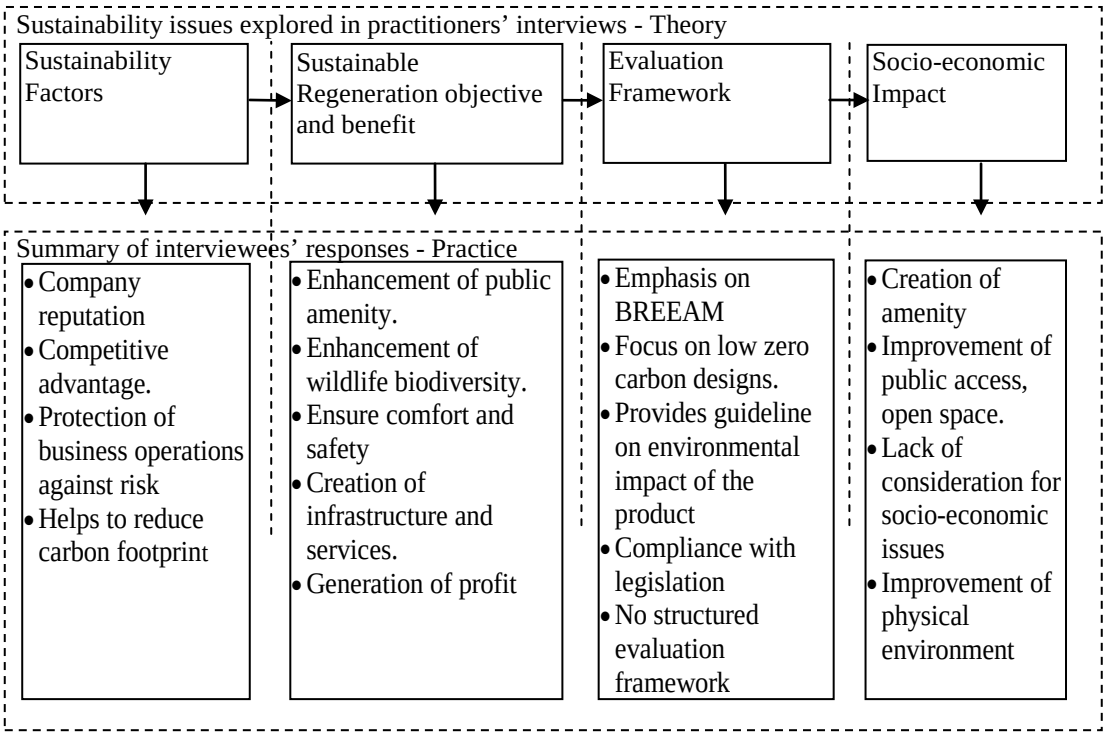

Figure 1. Summary of the sustainability issues and findings

CONCLUSION

The evaluation of socio-economic impacts of sustainable regeneration projects in the UK has been explored through an initial study that used a semi-structured interview approach to collect rich data from practitioners in the field. The study identified a disparity between the theoretical concept and the reality in practice of sustainability factors on a personal and organisational level (see figure 1). The main findings from the study established that the consideration of sustainability was still viewed as being concerned with environmental issues by built environment practitioners to the neglect of the social and economic factors in sustainable regeneration projects. Another major limitation that was identified in the interviews was the lack of any structured

evaluation frameworks or mechanisms for evaluating the direct and indirect impacts/benefits of social and economic outcomes of sustainable regeneration projects. The findings also identified that while all the interviewees seemed to have accepted the sustainability concept in principle; their responses indicated a lack of appreciation of the broader meaning and understanding of the elements of sustainability. The results of this initial study support the need to collect more data from other built environment regeneration projects to enhance the reliability of the findings.

SUSTAINABLE INTERVENTION PLANS FOR THE IGBO CULTURAL REGION OF NIGERIA

Bartho C. Ekweruo[1] and Nnezi Olugu Uduma[2]

Department of Horticulture and Landscape Technology, Imo State Polytechnic, Umuagwo, Nigeria.

Departmewnt of Architecture, Ahmadu Bello University, Zaria, Nigeria.

Department of Architecture, University of Lagos, Lagos, Nigeria.

ABSTRACT

The Igbo cultural landscape region comprises of rural autonomous communities made up of clusters of kindreds and villages until the colonial period when townships were established at about 64 kilometers intervals by the colonial masters for ease of administration. In spite of the existence of townships serving as trade, political and administrative centres for more than one century, the rate of urbanization is very slow. Communities have developed physically, economically and socially at astonishing rates consuming farmlands and traditional community boundaries and causing ecological hazards. The purpose of this paper is to unveil those natural and cultural values and principles of traditional heritage that sustained continuous regional growth solely through community efforts and the consequences of lack of formal regional control in recent times. Wholesome integrated strategies for sustenance of growth in the unique region is proffered. In conclusion, an "adaptive planning" concept which considers the natural and cultural peculiarities, improves on the existing control structure and specifies the performance requirements that ensure effective growth management is recommended for adoption in Igbo cultural region in particular and developing countries in general.

Keywords: adaptive planning, community development, control mechanism, igbo cultural landscape, suburbanization.

INTRODUCTION

Emergence of a new phenomenon in regional growth

The igbo cultural region was traditionally founded on rural autonomous communities made up of clusters of compounds, kindreds and villages untill the colonial period when townships were established. One would think that the townships, after more than one century of existence, would drain the population in the rural areas leaving the rural communities with scanty population of improvised illiterates, farmers, traders, the weak and elderly. But instead the communities have developed dramatically beyond traditional community boundries, destroying rural character and creating ecological hazards since

[1] ekladcom@yahoo.com; ladcomek@yahoo.com

[2] nnezi@designedscapesafrica.com; designedscapes_limited@yahoo.com

the last four and half decades. Today the population has continued to grow on very limited developable land area of about 28, 078km^2. There is a strong rural economy sustained by the steady flow of fund in the region and very strong market system. Hence the new phenomenon- A simultaneous regional growth pattern in which the rural areas aggressively compete with the urban areas and the resultant effect is that the rural areas are wearing urban characters with multiple environmental impacts.

Goals and objectives

The aim of this paper therefore, is to unveil the traditional values and principles of natural and cultural heritage, that sustained aggressive growth while maintaining balanced relationship with nature in igbo cultural landscape region. It will also unveil the interventions that altered the traditional pattern and causes of the ecological hazard within the inherited land constraint and suggest appropriate planning for the region.

Objectives

1. Definition of the igbo cultural landscape region in terms of physical characteristics, gross and net coverage.
2. Determine the inherent regional ecological order including the pattern and distribution of the watersheds, characteristics, resources and settings for traditional order of settlement.
3. Determine the traditional living system in the region and associated social and spiritual needs, order of existence or land use pattern, their interaction with the ecological order, the resultant symbols, nodes, links and landmarks.
4. Determine the traditional agricultural practices and the products including, their natural uses; values in social, nutritional, health and spiritual terms to determine their existence and importance in the traditional economy, the traditional methods of farming on limited and fragmented land since existence and the role of the different products in the economic growth of the region.
5. Determine the traditional regional market system, the market hierarchy, distribution in space, the relative position in the living (spatial) system, economic and social functions, symbolic importance, regional flow of money, the local farm produce, content and sustenance.
6. Determine the traditional principles or measures of conservative importance adoptable with or without modification.
7. Description of the phenominal wholesome growth pattern and the resultant continous suburbanization that defiles the traditional push and pull principle of urbanization.
8. Determine the traditional control and management mechanism and network for conservation, and community development.
9. Determine points of interference with the traditional order and the consequence.

METHODOLOGY

Field studies

The authors carried out levels of studies since 1980 at different parts of the region and at different periods including very busy festivity periods of Easter (March –April), Abroad

meeting and New Yam Festivals (August – September), Christians and New Year (December-January)

- Soil Erosion problems in Ohafia region 1979/80. Subsequent studies on gully erosion in the region were conducted by the authors and other researchers and documented.

- 1984 Igbo Traditional architecture and the living system (pattern of settlement)
- 1985 study on Natural and Cultural adaptations in Igboland
- In 2004, studies were carried out on Traditional Agricultural practices and the Regional market system in Igboland
- 2003 – A. Study of traditional conservation methods as a way of life in Igbo communities.

A. Direct Participation in Community Activities.
The Authors direct participation in community activities as president Generals of their respective communities for four years at the Eastern and central parts of the region.

B. Literature review
Elaborate consultations of books and other relevant publications on the physical Landscape of South Eastern Nigeria were made in addition to field experiences at the different parts of the region using google earth map and physical map of the region.

FINDINGS

1. The Igbo territory covers about 41,538 square kilometers in gross terms and lies at about latitude 7^0 North of the equator. By this location in the humid tropical rainforest region, it has longer period of rainfall (about eight months) and shorter dry season, daily average rainfall of 250mm and an annual average of 3200mm, high humidity of between 80 and 100%, average daily temperature of 80^0F. It occupies the South East central portion of the lower Niger Basin characterized by mosaic Landscape comprising portion of the Niger Delta, Palm belt, Western edge of the cross River basin and the scarplands with such Land forms as hills, plateaus, Valleys, escarpments and ridges at about 330 meters above sea level at the highest points. The hills, valleys, numerous rivers, streams and lakes reduce the developable land area by 20% which is about 28,078km^2 only. Hence the acute shortage of land.

2. The region is drained by Rivers Niger, Imo, Cross River and Njaba as well as numerous tributary streams and all running Southwards to form part of the Niger Delta. The plateaus, terraces and flat plains within the multiple watersheds provided settings for the well drained traditional settlements that metamorphosed into multiple communities enclosed by dense network of vegetation of multi –storey levels. The vegetation is characterized by dark and moist forest floors, dense network of climbers, herbs, thick and tall trunks of hard soft and semi hardwood timber for furniture, bridges, building and railroads and supported wide varieties of wildlife typical of tropical rainforest. The wide range of forest resources provided opportunities for agriculture, traditional medicine, trading, shelter, science, technology and inspiration for arts and crafts.

3. The traditional regional entity can be physically described as covered with multiple units of settlements distributed randomly in the region in conformity with the ecological

order of the respective watersheds. Each settlement or village was founded on well-drained soil and organized in response to the gross scarcity of land and in cluster pattern focusing on hierarchies of open spaces at close proximity providing for the social and spiritual needs of people. The public places constituting landmarks contain symbolic cultural elements/facilities such as halls, shrines, drums, shade trees and markets beyond the scale of the basic compound units. The landmarks which serve as nodes are linked with community routes. The landmarks/open spaces are enclosed with close-to home farms with sustainable vegetable and fruit trees that give the rural character. Each village or kindred over the period matures into autonomous community through spontaneous organic growth process occasioned by competitive community projects. Today there are about 2,500 o fself sufficient autonomous communities in the limited land area. Each community is sustained by, at least, 2 primary schools, secondary schools, commercial schools, skills acquisition workshops, orthodox church parishes (Catholic, Protestant and Methodist), many Pentecostal churches, hospitals or health centres, maternity homes, and community banks, market places and trading activities. The communities are connected through intra and inter community routes. Hence, the complete network of roads connecting the communities, village centers and markets serving as nodes to ensure continuous flow of movement for trading activities and exchange of information in the region.

4. Traditional agricultural practices in Igboland is characterized by

i. Organic Farming through the use of farmyard manure and Livestock droppings particularly in close –to-home farms. Pesticides and herbicides are not applied as the indigenous crops are adapted to the environment. Hence, the products of rural agriculture in Igboland are health foods.

ii. Owner operated holdings: Family members carry out farming on owner operated basis

iii. Small but bountiful: Though the farmlands are small and fragmented, the collective affect at community scale is more than 1000Ha. of cultivated land for wide range of crops at any particular season. The sum total of the varieties of livestock including pigs, goats, sheep and poultry birds at community scale is startling and sustained through maintenance of good local breeds.

iv. Effective intercropping of wide range of relatively adaptable crops is generally practiced

v. Effective integrated farm activities including varieties of livestock, vegetables, cash crops, fruit and vegetable trees, bananas, plantain, snailry, mushrooms etc particularly in close-to home farmlands.

vi. Effective management: Small farm holdings have the principle advantage of effective management in terms of weed, pests and soil conservation.

vii. Regular supplies through regular harvest of crops, vegetables, maize, fruits, nuts, etc. taking advantage of numerous streams, long period of rainfall and moist environment.

viii. Processing of products including drying of fish and meat, multilevel processing of cassava, yams, palmnuts etc. provide jobs and trading opportunities

ix. Food self-reliance: The region produces many varieties of vegetables, processed food and herbs, beverages, vegetable oil and other forest products that sustain the vibrant markets and local demand for delicacies for the regular festivities.

 ISBN: 978-1-84219-840-7 .

5. Trading is the traditional occupation of the Ibos who established numerous small scale processing and fabricating technologies with elaborate marketing network. The local economy in the religion is sustained through traditional market system comprising hierarchy of daily, four-day and eight, markets. The eight-day markets are inter-community markets serving multiple communities within their sphere of influence and are the pivots for development and potential regional growth centers (Ekweruo, 2003). As market days vary alternatively traders are always on the move to patronize big markets within their reach. Hence, the highly mobile nature of the Ibos with the markets acting as magnetic forces recycling goods, information and money. Farming has been the traditional complimentary occupation of the Ibos on which trading heavily depends. The rural economy is reinforced by the fact that most of the agricultural products reach the markets in multiple forms. Hence, the multi-level labour and trading opportunities for children, women and men (Ekweruo, 2004).

6. In adaptation to the physical, ecological and climatic peculiarities of the region traditional conservative principles were observed

i. The cluster settlement pattern to conserve land in response to gross scarcity of land resource.

ii. On- site run-off management through effective harvesting of rainwater with detention and retention measures, use of cisterns to collect street run-off and sustainable vegetation cover with the timber, fruit and vegetable trees of evergreen nature in close-to-home farms. The cisterns and the enclosing vegetation help to drain the environment through permeable soils to recharge the underground aquifer. Selective harvesting of forest products and planting of trees help to conserve the green environment

iii. Regular clean up of public places by children and women in turns.

iv. Formation of intercommunity watershed association to sustain regular flow and quality of the streams in the respective watersheds

v. Recycling of organic waste in close-to-home farms to sustain soil fertility and production of health food.

vi. Domestication of trees, shrubs and vines of medicinal and nutritional value

vii. Establishment of bans in close-to-home and distant farms to preserve tuber crops such as yam and cocoyam for subsequent planting seasons:

viii. Creation of educative and recreational environment through designation of common spaces for people in direct relationship with the respective homes, compounds, kindred, villages and communities for spiritual and social needs and for sustenance of cultural heritage of physical, spiritual, educational, economic and recreational importance

7. Young males and females moved to urban areas to learn trading, venture in skill acquisition in areas like tailoring, carpentry, building, machines and automobile repairs, paint production, food processing, block moulding, machines and tool fabrication etc through apprenticeship. With inherited work attitudes, sense of aspiration and entrepreneurship many successfully graduated and established their businesses in their respective communities back home. Trainees and apprentices who graduated within the specified period were established by their masters to become trainers and traders. Hence, the will of progress was established across the region. The strong rural economy is therefore sustained by the steady flow of fund in the region through mandatory and voluntary contributions, rural cottage industries, strong market system, many rural workers and student, churches, service trades, banks, high volume of transportation business, local government headquarters and the enterprising traders, artisans and technocrats who compete traditionally in fund raising, building country homes, factories,

 ISBN: 978-1-84219-840-7 .

schools, civic centers hospitals and other life support facilities. **All these, therefore, explain the comparatively slow rate of development in cities and relatively high rate of rural development in the region.**Simple agricultural processing machines were installed for palm produce, cassava processing, maize and beans/cowpea processing in markets, compound spaces or mounted in locally made two-wheel trucks for mobile services. The intercommunity routes connecting the eight-day markets serving as regional nodes produced opportunities for transportation business and employment for drivers and mates. The establishment of local government system with headquarters in selected communities brought employment to rural dwellers and enhanced rural growth.

According to 1963 census the population of the region was about 6,223,831 people and urban population was only 752,884 making up only 12% with 13 townships classified as urban (Ola C.S. 1977). That is to say that the Igbo region is traditionally not urbanized. Today the population has grown to about 20 million on net developable land of 28,078sqkm making the population density about 700 per square kilometer. Urban areas have risen to about 50 suggesting that 37 communities have grown up organically to be classified as township or urban. At the same time villages have metamorphosed into autonomous communities transformed into suburban areas. Many communities coalesced spontaneously to form megacoms (mega communities). It is on the limited land area that the Igbo region have 5 states, 5 capitals, three large commercial cities (Onitsha, Aba, Nnewi), 5 other urban areas or townships, 10 megacoms, numerous suburban areas, about 2,250 autonomous communities and 125 local government headquarters all connected with federal highways, regional roads, rural roads and community roads.

8. The control mechanism in Igbo rural communities comprises the traditional rulers with the cabinet members made up of Chiefs from respective villages and the Town Unions. The traditional rulers are the custodians of culture and tradition and vested with the power of ensuring security. The Town Unions are structured on three levels of male and female wings comprising the central body, the home base union and the village union. Town Unions are responsible for organizing political, social, market and physical development activities, festivities and control of resources, and constitute the fourth-tier government. Branches of the Town Unions are established in cities and foreign countries and they maintain regular links with the Central Bodies to enhance social, health and educational development. Unfortunately, the Town Unions cannot effectively controle the overwhelming rate of development within the last four decades because of lack of professional competence and fund to train physical planners. However, it is noteworthy that the viability of people in Igbo communities is rooted on the decentralization of production, integration of living spaces with cultural and working spaces and community control of resources.

9. The harmonous relationship of people with nature and the sustainable living system established in the traditional landscape was dramatically disrupted during the colonial period. Urbanism took different pattern with alien forms and systems introduced in colonial townships. Deforrestation was massive for timber. Housing took the antisocial grid pattern with extensive linear streets. Gutters lined- up the streets for storm run-off that emptied in lakes, streams, depressions etc. The colonial influence changed the mind-set of people who lost values for traditional conservation of resources and order of social spaces that ensured convivial environment. Hence, the antisocial settings and disruption of ecological balance enhanced scarcity of land, flooding, erosion and loss of serenity established through living with nature.

Results

The issues and consequencies of uncontrolled or unmanaged growth in igbo rural landscape are obvious.

1. The traditional cluster method of housing in compounds which ensured economy in land management, common use of space and conservation of resources was replaced with the anti-social western style houses hence, acute shortage of land and destruction of farm lands.
2. Buildings erected without regards for existing natural order affect flood plains, drainage courses are blocked, air ways blocked and aquifer recharge areas are blocked with ecological consequences.
3. Close-to-home farms with lots of vegetables and fruit trees, vines and herbs that give rural character have given way for massive structures with upto 100% coverage of hard surfaces thereby generating 100% run-off and heat, creates food shortage while traditional herbs go to extinction.
4. Uncontrolled massive building activities have moved beyond close-to-home farms to distant farms to claim farm-land and vegetation at different locations in respective watershed hence, generating run-off and causing deforestation and food shortage.
5. Factories and hauling activities; large volume of cars at weekends and festive periods pollute the environment with noise, fumes and droppings.
6. Over-clearing of sites and establishment of numerous access roads serving unplanned development open the land for erosion, and flooding which affect aquatic life through deposition in water bodies.
7. The continuous high rate of population growth puts a lot of pressure on the scarce land leading to more fragmentation of land and causes social vices.
8. Excessive farming causes soil bleaching while wrong technique of hillside farming causes land- slide.
9. Underground water level is reduced drastically as more water is drawn through the borehole while little recharging goes on because pavements cover recharge areas.

10. Gross ignorance and insensitivity resulting from lack of knowledge of ecological consequencies of unplanned building activities aggravated the issues.
11. Ibo rural landscape which represents one “unique native resources” endowed with wealth of knowledge and comprising tropical vegetation, wildlife, aquatic life, human living system and cultural landmarks is being replaced aggressively with suburbanization and massive erosion to the detriment of future indigenes (Ekweruo, 2003).
12. Absence of efective regional development control created the vacuum in which aggressive indiscriminate development strived.

SUSTAINABLE INTERVENTION THROUGH ADAPTIVE PLANNING STRATEGY

A civilization with its wealth of knowledge established over a period of about 2500 years is experiencing degradation accelerated in the last 30 years since the oil and trade boom. If the present pattern of development continues in the next 50 years a regional conurbaton will emerge with complete destruction of convival rural resources and consequently increased multiple impacts. Hence, the call for appropriate regional landscape intervention plans which must be tackled through“adaptive planning”- a multi-dimensional approach with great sense of purpose. Adaptive planning is a planning strategy that incoporates all thoughts, aspirations, attitudes and values of a particular

society expressed in physical and non-physical forms in the landscape to enhance the socio economic life of the community in the context of the prevailing ecology (Ekweruo 1985). It helps to achieve the planning objective of inducing everybody to participate in the growth process and promoting community involvement in the prevention and control of natural disaster.

SUSTAINABLE INTERVENTION PLANS

A broad issue based 50-year regional cultural landscape master plan must be embarked upon with immediate, short and medium term intervention plans to be reviewed every 5years. Public participation must be wholesome and involves the local residence and indegenes, physical planners, journalists, church organizations, town unions, traditional rrulers, local government authorities, academic insttitutions, women organizations and non governmental organization (NGOs) etc.The elements of the sustainable regional master plan include but not limited to:

A. Education plan

1. Massive public enlightenment/education plan to sensitize the indigenes and other stake holders on the issues and the consequencies. Journalist and churches must be part of the resource agents.

Introduce from next year basic environmental studies in secondary education with emphases on environmental degradation so that the young ones will grow with the knowledge.

2. The general studies programme in tertiary institutions must carry atleast one semester course on environmental degradation and conservation and must be compulsory for all disciplines.
3. Introduce environmental engineering programme to cover erosion,flooding, pollution, and waste management.
4. There must be short training programmes on environmental degradation and conservation for builders, engineers, farmers, civil servants etc.
5. Studies in rural landscape to be included in curricular for centre for environmental studies to be established in different institutions.

B. Physical development plans

1. Inter-state regional rural development plans to harmonize state plans particularly the areas in some watershed

a. Specify standards for coverage of pavements in aquifer and non aquifer recharge areas.
b. Generate plans for rainwater harvesting and specify standards for run-off control for mandatory implementation.
c. Generate standards and regulations for construction of rural roads.
d. Produce forest regulation and regeneration plans to re-establish tropical plants and wildlife threatened to extinction (Longman and Jenik,1978).
e. Develop soil restoration and conservation plans.
f. Encourage and regenerate cloes-to-home farms with vegetable and fruit trees, herbs, spices, vines etc.
g. Develop effective techniques for intensive farming adaptable in the fragmented farm land to boost agricultural production in rural areas (Ekweruo, 2004).
h. Produce rural population growth reduction plans for effective contrrol of population.
i. Develop inter-state water resources development and protection plans.

j. Set the standard for regional based erosion control master plan to be adopted by each state.
k. Concept of extension planners. Each state government in the region to invest on training of landscape architects and town and regional planners with emphasis on environmental engineering to cover erosion and flood control, pollution and waste management, on-site and off-site run-off control etc. The professionals will be employed and posted to local government headquaters from where they will be sent to communities as extension planners.

Summary/conclussion

There is relatively rapid development of special nature in Igbo ccultural region traditionally founded on limited land space and sustainable societal values. The increase in population, volume of unplanned development and unmanaged physical construction in highly fragmented land ownership puts unprecedented pressure on the terrestrial environment hence, deforestation, massive erosion gullies and degradation of aquatic resources. It is also obvious that there is no documentation of similar regional growth pattern in the same context to establish knowledge base.

This study has provided the background or framework on which broad based study can be conducted. The research will continue as knowledge base for wholesome rebranding of regional planning, prevention of further erosion and related ecological harzards, provide strategies for protection of aquifer recharge areas and effective conservation measures for rehabilitation of devastated terrestial and aquatic resouces. While creating opportunity for determining the performance requirements to reinforce the suggested intervention plans efforts will be geared towards mass education to change the negative mindsets and re-establish sustainable value system required for growth management.

THE INCREASING IMPORTANCE OF ENVIRONMENTAL ATTRIBUTES IN COMMERCIAL BUILDING RETROFITS

Sara Wilkinson[1]

[1]*Faculty of Design Architecture and Building, School of Built Environment, University of Technology Sydney, PO Box 123, Broadway, Ultimo, NSW, 2007, Australia.*

ABSTRACT

Compelling reasons to undertake building retrofit are largely economic and environmental but also social. Retrofit can be less expensive than new build and typically delivers faster projects. Sustainable development is a force for retrofit as the built environment contributes approximately half of total greenhouse gas emissions. Governments search for effective and efficient methods of mitigating the contribution of cities to climate change and building retrofit presents a realistic means of lessening building associated emissions. In Melbourne, the 1200 Building Program is a strategy which aims to escalate commercial retrofits; targeting 1200 Central Business District (CBD) office retrofits by 2020. This research examined all CBD retrofits from 2009 to 2011 to distinguish the nature and extent of retrofits and to ascertain the inter-relationship between retrofits and property attributes. 1422 retrofits were analysed between January 2009 and July 2011. Following an earlier study of retrofits from 1998 to 2008, this research determines whether environmental attributes have become more important over time. The findings support building retrofit in identifiable circumstances and are clearly relevant for increasing built environment sustainability. The research used existing buildings in an international city to ensure relevance to urban settlements where existing buildings can lessen the impact of climate change.

Keywords: Australia, commercial property, refurbishment, retrofit, sustainability.

INTRODUCTION

There is a view that dense cities are an essential component in man-kinds attempts to mitigate the effects of global warming. Furthermore most urban building stock was constructed without consideration of sustainability. In Australia environmental sustainability for commercial buildings became part of the Building Code of Australia in 2006, with minimum standards for energy efficiency applied to new build and some retrofit projects. Acknowledging the importance of retrofits, the City of Melbourne launched the 1200 Buildings Program in 2008 to deliver carbon neutrality by 2020 after Arup (2008) concluded 1200 retrofits would deliver a 38% reduction in greenhouse gas emissions. This research examines whether there has been a shift by assessing the importance of environmental attributes.

Building Retrofit

Multiple attributes are important in retrofit and are categorised as economic, location and land use, physical, legal, social and environmental. Although costs can be traded against social and environmental gains, retrofit has to be economically sustainable (Kincaid 2002). Based on whether the intention is to occupy or lease, different features are more or less important. Owner occupied stock had higher levels of adaptability criteria compared to speculative designs (Arge 2005) and a greater return on investment over the whole lifecycle, whereas positive user demand and active marketing by stakeholders were important in the reuse of vacant stock (Ball 2002).

Pre and post retrofit value is a success indicator and one Hong Kong study found a positive relationship between retrofit and value (Chau et al. 2003). Another economic indicator is vacancy rates (Ball 2002). Depending on condition, quality can be increased (Kersting, 2006) where quality is measured by amenity features, services, fixtures and fittings. Whilst it is possible to increase quality, rental and capital value; the capacity to upgrade depends on condition and location (Snyder 2005). Total costs are important in retrofit (Davis Langdon 2008), typically at around 66% of new build costs. However where buildings are complex, heritage listed, and or have deleterious materials retrofit costs can surpass new build.

The physical building determines whether retrofit is possible and desirable and all studies identified age as important (Ball 2002). Some buildings feature construction forms and materials making retrofit more expensive or challenging because of compliance issues. Height, construction type, and frame condition was important (Gann & Barlow 1996) with steel frames being more adaptable because of the ease of cutting into beams (Kincaid 2002). Floor size was significant in London retrofits where buildings with unusual floor plates or sizes were more difficult to adapt and suited a limited range of users (Kincaid 2002). The location of the services core was significant in Snyder (2005) affecting the sub-division of space. A central location gives greater scope for sub-division whilst minimising corridor and circulation space. Whether a building is detached or attached affects the ease or desirability for retrofit. With less attachment contractors work faster and cause less disruption to users (*Isaacs* in Baird et al. 1996). Access or, the number of entry and exit points affects retrofit potential across a range of property types (Ball 2002). Studies established optimal benchmarks for building width in retrofits between 15 to 17 metres (Arge 2005) and showed these buildings could accommodate a range of space configurations and user needs more frequently. Similarly the distance between the structural columns affected the ease of retrofit for new and other uses (Arge 2005). Floor strength is vital (Kincaid 2002) and has to be assessed to determine the land uses which are possible and suited physically; it is not possible to accommodate office use in a building with floor strength of 3kN/m², unless strengthening or replacement is undertaken. The technical grid and services equipment is significant and whether the building can accommodate extra capacity (Arge 2005) for example, raised floors allowed for IT cabling to be upgraded easily. Modularity refers to modules which can be rearranged or interchanged and 'plug and play' allows for a fast change of layout, change of services and wall systems (Arge 2005). Buildings which offer scope for extension are more adaptable (Arge 2005). Other attributes were form and organisational space and ease of compartmentalisation.

Location is considered in terms of proximity to public transport which is environmentally positive. The amount of on-site parking is significant where little or no public transport is available (Douglas, 2006). Land use attributes are important (Arge, 2005) where existing use affects the potential for a new use. The existing planning zone determines legally permissible development, though it is possible to have sites rezoned. Swallow (1997) concluded that retrofit is affected by tenure because it affects the funds the party is willing to invest. An owner has an interest in perpetuity whereas a lessee's interest lasts for the lease term. Institutional owners invest to maximise the return on investment and probably use professional consultants to advise on retrofit. Private owners may or may not use professional consultants and may reside overseas. They may hold property for many reasons, such as future development or for rental income or capital growth and may engage in less retrofit; though this is unknown.

Retrofit is affected by building occupation. With single tenants when the lease expires there is opportunity to adapt, however, with multiple tenants, it is unlikely all leases expire simultaneously and the building may be partly empty (and not income earning) before the building can be retrofitted. Historic listing protects architecturally or socially significant buildings for society (Ball 2002). Heritage retrofit can be more expensive because of costs in using traditional materials, techniques and craftspeople. There is benefit in proactive policies and legislation in building retrofit (Snyder 2005) and research on London and Bristol docklands found proactive policy and legislation enhanced the retention of existing stock (Bromley et al. 2005). Hostile factors such as noise are less desirable and can adversely affect retrofit. Deleterious materials, such as asbestos, are hostile factors. Hostile factors present social and economic barriers driving up costs. Some buildings have a social stigma making retrofit problematic, for example mental asylums had negative emotions associated with the prior use (Binder 2003).

The scope and extent of environmental aspects of retrofit has increased (Kincaid 2002). There is an overlap with social, economic and location aspects, i.e. proximity to public transport provides environmental, location, economic and social benefits; where attributes can be interpreted on multiple levels. The most significant environmental impact of buildings is the greenhouse gas emissions associated with energy use (Douglas 2006). Buildings, assessed under recognised environmental assessment methods have met specified standards in a range of environmental criteria including energy use. Retrofit offers a chance to reduce energy and water use and to recycle, harvest and re-use water. The transport occupiers use affect sustainability (Davis Langdon 2008). Public transport has less environmental impact and emissions than private cars, and proximity to public transport is positive (Davis Langdon 2008). However car-parking is desirable in the Property Council of Australia building quality grading matrix and represents a paradox in market perceptions of quality and the perception of environmental features. Sustainability was mandated in the Building Code of Australia in 2006 and the research covers the period from 2008 to 2011, where the influence of environmental attributes remains to be seen.

Research methodology and design

Analysing decision making with regards to building retrofit is multifaceted (Wilkinson & Reed, 2011) and many found the precise classification of the attributes influencing retrofit difficult to identify and subjective. This study adopted an

approach previously used where a database of retrofits and attributes determined important attributes (Wilkinson & Reed, 2011). Advantages are that a large number of retrofits can be studied and that it does not rely on subjective views. Much research uses a case study approach with small samples of buildings (Kucik 2004, Arge 2005). Using the criteria identified as important in these studies, the researcher designed and populated a database. The approach is different due to the detailed volume of data and method used. Identified retrofit criteria formed the fields for the database. The sources used included the Building Commission of Victoria Building Permit database and 'Cityscope' database. Commercial data from the Property Council of Australia (PCA 2007, PCA 2008a) and visual inspections completed the database. As every retrofit was recorded in the Building Permit database a census approach was adopted; 1,422 retrofit events. The variables were coded physical, social, legal, economic and environmental. The research aimed to examine retrofits in a mature commercial market and the Melbourne CBD in the form of the original street grid set out by Hoddle is a distinct geographical location, occupied since 1834.

Principal component analysis (PCA)

PCA is a reliable technique of weighting dimensions in cross sectional data (Horvath 1994) having the ability to reveal, untangle and sum up configurations of connection within a dataset. From a number of original variables PCA reduces data into a smaller set of new merged factors with the least loss of information (Hair et al. 1995). The aim was to ascertain the highest level of variance explained by an interpretable group of factors and all attributes were appraised. All variables were input into the PCA to generate a lesser number of components where factors with Eigenvalues exceeding 1.0 were retained. The factors were rotated using an oblique 'Oblim' rotation method; the result being a table of specific factors which includes the loadings of single building attributes. Works were classified as minor works, alterations, change of use, alteration and extensions, new build and demolition. 'Alterations' accounted for 1275 retrofits, 89% of all events. To determine meaning the researcher interprets the pattern of the factor loadings; a subjective process (Hair et al. 1995). Following an analysis of the loadings across the factors the minimum threshold was 0.5 recommended by Tabachnick & Fidell (2001). With the list of each factor containing high loading building attribute variables, the researcher assigned factor names. This analysis examined all events classed as 'alterations' the second most extensive degree of retrofit in the study and coded as level 2. For the retained property attributes the Kaiser-Meyer-Olkin (KMO) score and Bartlett test are shown in Table 1.

Table 1 KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.606
Bartlett's Test of Sphericity	Approx. Chi-Square	1621.785
	df	45
	Sig.	.000

The KMO of 0.606 exceeded 0.50 and with the significance less than 0.05, the PCA was continued. A total of ten property attributes were analysed and produced a ten factor table (table 2).

Table 2. Total variance explained PCA 'alterations' retrofit events

	Initial Eigenvalues			Extraction Sums of Squared Loadings		Extraction Sums of Squared Loadings	Rotation Sums of Squared Loadings[a]
Component	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total
1	3.162	31.622	31.622	3.162	31.622	31.622	2.859
2	1.479	14.788	46.411	1.479	14.788	46.411	1.414
3	1.358	13.577	59.988	1.358	13.577	59.988	2.072

10	0.148	1.479	100.000				

Extraction Method: Principal Component Analysis.
a When components are correlated, sums of squared loadings cannot be added to obtain a total variance.

Four factors of attributes had the highest effect on building retrofits between January 2009 and July 2011. After the initial extraction using 42 variables, the reduced variables retained for 'alterations' retrofits were: vertical services location, number of storeys, PCA grade, NABERS rating, type of construction, Green Star rating, parking, historic listing, street frontage and aesthetics. The first heading shows the variance explained by each of the ten variables. Four components explain 69.99% of the original variance. The third section shows the Eigenvalue of each of the four rotated components, as the components are correlated with each other there is some overlap in the variance explained by each factor. For the rotated solution the factor loadings and correlations are given in the table 2. Table 3 shows the four components for this PCA.

Table 3. Pattern Matrix[a] for Level 2 retrofit events.

Property Attributes	Environmental / physical (Factor 1)	Social / physical (Factor 2)	Physical (Factor 3)	Environmental (Factor 4)
PCA grade	**0.89**	-0.06	-0.02	-0.20
NABERS	**0.82**	0.33	0.18	0.16
Aesthetics	**0.78**	-0.28	0.03	0.01
Number of Storeys	**-0.63**	0.10	0.46	0.07
Historic listing	0.20	**-0.76**	-0.24	-0.12
Construction type	0.00	**0.52**	-0.13	-0.22
Parking	-0.31	**-0.51**	0.37	-0.25
Street frontage (metres)	0.10	0.20	**0.96**	-0.04

Green Star rating	-0.06	-0.07	-0.05	**0.95**

Extraction Method: Principal Component Analysis.
Rotation Method: Oblimin with Kaiser Normalization.
a. Rotation converged in 9 iterations.

Results

In component one the attributes Property Council of Australia building quality grade, NABERS rating, aesthetics and number of stories are all highly or very highly loaded on component 1 (table 4). The variables explain 32% of the original variance where component one has four attributes, the first three relate to sustainability (environmental and social) and the fourth relates to property height (physical). It is possible to refer to these attributes as 'environmental and physical'. Aesthetics is loaded on component one and relates to appearance indicating that buildings of poor appearance are less likely to be adapted. The final variable 'number of stories' is strongly and negatively loaded and relates to physical dimensions of the building.

Three attributes loaded high on component two; historic listing, construction type and parking (table 3) and explained 15% of the variance. In component two attributes were influenced by social and physical factors. Historic listing applies to the social values or characteristics. Construction type and the provision of parking relates to physical attributes. Historic listing limits to some degree the level of work which any owner or user can undertake. Parking is negatively loaded.

In component three, attributes street frontage (building width) and vertical services location are very strongly and moderately loaded, explaining 14% of the variance (table 3). The attributes can be described as physical and relate to the size and dimensions of the building and flexibility in terms of space configuration. One attribute green star rating is very strongly loaded on component four and explained 10% of the variance (table 4). The attribute measures the provision of an environmental rating for a floor or a building. The variable is described as environmental. Table 4 summarises the main PCA component categories and the component names ascribed by the interpretation.

Table 4 Summary of Level 2 alterations PCA Component Categories.

Component number	Component name	Component attributes
1	Environmental and physical (32%)	Property Council of Australia building quality grade (29%) NABERS rating (26%) Aesthetics (25%) Height (number of storeys) (20%)
2	Social and physical (15%)	Historic listing (42%) Construction type (29%) Parking (28%)
3	Physical (14%)	Street frontage (60%) Vertical services location (40%)
4	Environmental (10%)	Green Star rating (100%)

CONCLUSIONS

'Alterations' retrofits, the second level of works, had the highest number of events, showing that Melbourne office building owners were more likely to engage in this type of retrofit from January 2009 to July 2011. Although it covered the period immediately following the Global Financial Crisis of 2008, 1422 events occurred, around 46 events per month. 'Alterations' retrofits are undertaken when leases expire and new tenants move in or to refresh spaces to attract new tenants to maintain the low vacancy rates. When all building permits were analysed, commercial buildings accounted for 55% of all work in the CBD, followed by retail at 29% therefore the City of Melbourne are targeting the sector which currently is the most active and has

the potential to deliver the highest level of emissions reductions. The 1275 alterations retrofit events were analysed in the PCA because at least 100 cases or five times the number of attributes are required to undertake a reliable PCA (Jackson, 2003). As there were 42 attributes to analyse the minimum sample size would be 210 and only the 'alterations' satisfied this criteria. The results show that ten attributes group into a four components and account for 69% of variance in retrofit. This is a reasonable degree of importance for a small number of attributes and the 32 attributes which were removed account for the 31% of importance in retrofit.

The results of the alterations PCA shows that two environmental attributes, the rating tools NABERS and Green Star are important in building retrofit at a minor level and this is a major change from the earlier study (Wilkinson & James, 2011). The property attributes do not group together in a neat pattern, i.e; physical attributes pair with environmental and social attributes in one component. Previous studies had simplified the groupings of attributes based on logic rather than a quantitative process. The PCA overcomes this, using a quantitative objective method and a large sample . Physical attributes featured in three of the four components and show that the physical attributes remain important; however other attributes such as social and environmental are included. Whilst economic attributes did not feature greatly it is possible to interpret the Property Council of Australia building quality grade as an economic attribute as well as an environmental one. Similarly the provision of parking and an historic listing could enhance a building's capital and rental values. The research questions were; (a) *are environmental attributes are important in office retrofit?* and; (b) *where is the sustainable office retrofit market trending?* This analysis shows, environmental attributes were important in alterations retrofits in the Melbourne CBD between January 2009 and July 2011. The NABERS rating tool accounted for 26% of the importance within component one. In the fourth component the environment attribute Green Star accounted for 100% of importance within the component. The second research question asked where the sustainable office retrofit is trending and on the basis of this analysis it would appear the Mandatory Disclosure legislation of 2010 requiring owners to disclose energy rating at the point of lease or sale is having an effect where more buildings are rated. It is likely that this will continue as more leases expire over the coming 4 year period and the opportunities for sustainable retrofits present themselves to building owners.

AN ASSESSEMENT OF THE IMPLEMENTATION OF QUALITY CULTURE IN CONSTRUCTION

Wasiu Adeniran Bello[1], Aliu Adebayo Soyingbe[2] and Modupe Akinwamide[3]

[1, 2&3]*Department of Building, University of Lagos, Akoka, Yaba, Nigeria*

ABSTRACT

The abstract text should not exceed over 200 words. The font set at Times New Roman 10 point for the abstract body and keywords only. A strong quality culture has been recognised as an important prerequisite to the achievement of sustained competitive advantage to deliver products and services that can meet customer needs and satisfaction. The study attempts to assess the implementation of quality culture in the Nigerian construction industry. A total of 200 structured questionnaires were administered with 45% response rate. Mean statistics and analysis of variance techniques were used for data analysis. Respondents were asked to assess the factors of quality culture implemented in their respective organisations. The findings of this survey revealed that leadership and top management commitment is the highest ranked factor implemented while customer management/focus and suppliers' partnership and communication followed. The least factors implemented are training and education, reward and recognition and quality planning. ANOVA test conducted among the three groups of respondents (client, contracting and consulting organisations) revealed that out of the fifty factors of quality culture tested; thirteen factors differ significantly in their mean scores. It is recommended that cultural audits, extensive awareness and training programs should be initiated and or reemphasized to improve understanding and increase willingness and commitment in implementing quality culture.

Keywords: construction industry, factors, implementation, Nigeria, quality culture.

INTRODUCTION

Construction impacts the quality of life for building facilities and plays a major role in a nation's economy and development. According to Farooqui, Masood and Aziz (2008) construction sector is globally considered to be a basic industry on which the development of a country depends. To a great extent, the growth of a country and its development status is generally determined by the quality of its infrastructure and construction projects. According to Jackson (2004), quality is contained in the tripod of construction management; it does not only impact appearance and durability but also the performance of a project. Performance evaluation in construction project generally focuses on a limited number of performance elements which is the act of

[1] wasbel2001@yahoo.co.uk
[2] dodoaliu123@yahoo.com

fulfilling the project goals related to the product, which are completing the project on time, within budget and with the required quality and to client satisfaction (Blismas, Sher and Thorpe, 1999; Egemen and Mohamed, 2006). Nowadays, both from public and private sectors place more emphasis on the quality of products rather than the cost and time which was the major concern in the past (Abdul-Rahman, Wang and Yap, 2010). Therefore, in order for construction clients and end users of completed facilities to realize best value, the concept of quality culture must be stressed in the industry to improve the quality of product and services (Idrus and Sodangi, 2010). The willingness to change the quality culture and the commitment of top management towards quality will determine the success of total quality management in the industry (Zeynep, Arditi, Dikmen and Birgonul, 2008). Quality and efficiency have been identified as the major imperatives lacking in Nigeria's construction industry. From a general knowledge, a number of construction firms in Nigeria under-pay their workers, with this poor salary package "quality might never be ingrained in culture". Construction labours tend to focus more on the number of hours worked and quantity of work done rather than the quality of work executed. In regard to this, all stakeholders involved in construction projects have a role to play in order to deliver a quality product. On this note, this study sets out to assess the implementation of quality culture in the Nigerian construction industry.

LITERATURE REVIEW

According to Hoonakker (2011) clients demand improved service quality, faster buildings and innovations in technology. Improving quality of construction is the easiest way to improve the industry. Culture is a complex issue that essentially includes all of a group's shared values, attitudes, beliefs, assumptions, artifacts, and behaviors, to the extent that members are not even aware they are influenced by it (Tharp, 2009). The concept of culture is difficult to be expressed explicitly; instead, it can be sensed, felt and perceived (House et al, 2002). According to Harvey and Stensaker (2008) being shared means that it is a social phenomenon that is learned and involves arbitrarily assigned, symbolic meanings. In this regard, culture is ingrained in believes and values. Typically, the construction industry has a culture, that is, shared understandings about what is expected, by all participants, in the way relationships are conducted between participants in the construction process (Rowlinson and Root, 1996). It is not only the final product that is subject to criticisms but the processes, the parties, the materials etc., are under tremendous pressure for better quality in construction (Mahmood et al 2006 ; Sodangi, Idrus and Khamidi, 2010). Failure of any of the parties will seriously affect the quality of the final project (Sodangi et al., 2010). The construction industry tends to define quality as the ability of products and processes to conform to the established requirements and specifications (Arditi and Gunaydin, 1997; Mahmood et al. 2006). Quality is a persuasive concern throughout the entire construction project process, as the performance of each phase in the process will affect the performance of next phase (Sodangi et al., 2010). Quality may perhaps serve as a measure of client satisfaction, project and contractor's performance. Contractors often perceive total quality management as an extra cost, but they do not realize that it is not the quality that costs but rather the non conformance to quality that is expensive (Pheng and Teo, 2004). Sodangi, et al. (2009) posited that a strong quality culture continuously delivers high quality products and services are an important prerequisite to sustained competitive advantage. Hence, rather than understanding culture and quality as independent entities, it is important to understand that quality actually stems from a broader

cultural perspective (Harvey and Stensaker, 2008). However, the quality culture of an organisation is a subset of an organisation's overall culture (Cameron and Sine, 1999).

Elements of quality culture

The goal of organisations is to create a culture of quality across the entire project site, get the job done right, the first time and every time (PHCC, 1996). From the stand point of Stark (2011) total quality is a description of the culture, attitude and organisation of a company that aims to provide, and continue to provide, its customers with products and services that satisfy their needs.

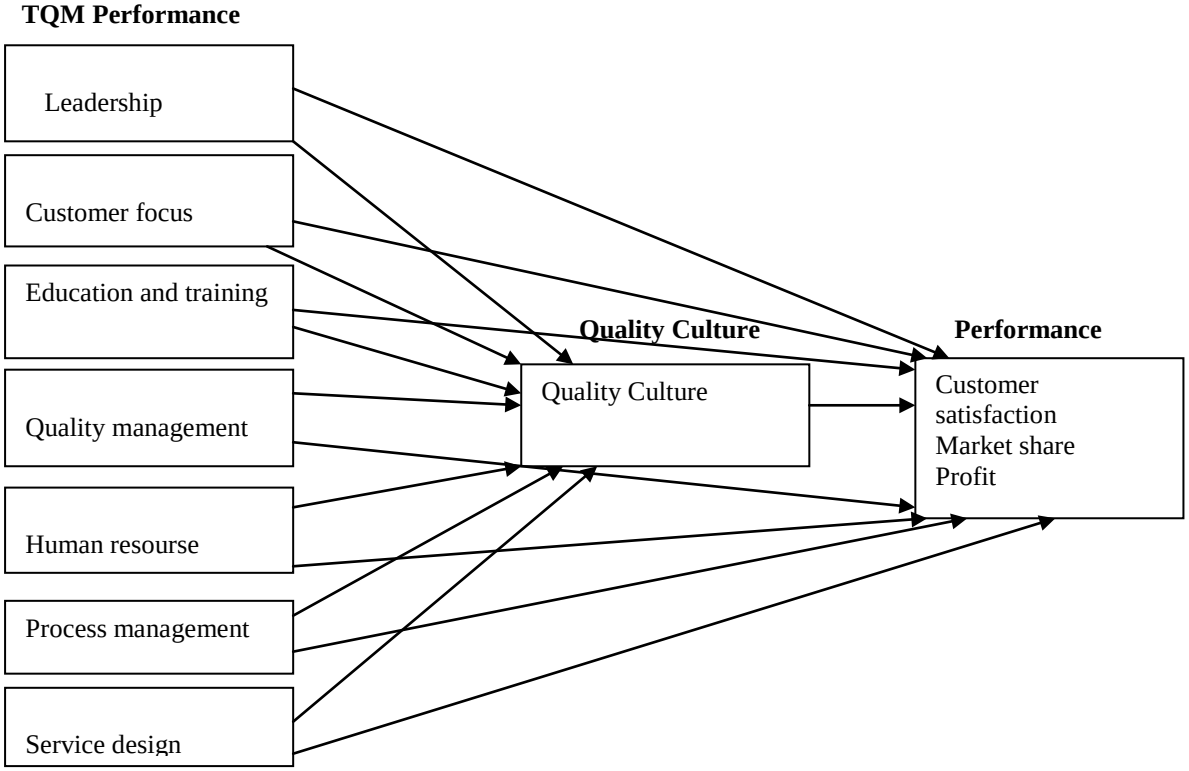

Figure 1: Theoretical model (Source: Mojtahedzadeh and Arumugam, 2011)

There is a consensus among professionals and researchers that the solution to quality problem lies in total quality management at all levels of design, procurement and construction (Sodangi, Idrus, and Khamidi, 2010). However, quality culture does not change in a short time because for changing this factor, the company needs a long-term process (Mojtahedzadeh and Arumugam, 2011). Figure 1 demonstrates the relationship that exists between the elements of total quality management (TQM), quality culture, and performance. The elements of quality culture in the report of Mahmood et al., (2006) are the success factors of total quality management in most total quality management literatures. From this review it can be postulated that:

$$\textbf{Quality culture} = f\ \textbf{(TQM factors implemented)}$$

Bason (2011) asserts that total quality management (TQM) is reached when a culture of quality is established and becomes entrenched at all levels of an organisation. A number of researchers have identified several factors for the successful implementation of total quality management in both developed and developing nations. Some of these factors are discussed in the works of Baidoun (2003, 2004), Al-Jalahma and Gallear (2010), Haupt and Whiteman (2003); Lam, Wang and Lam (2008); Pheng and Teo (2004); Sebastianelli and Tamimi (2003). There are ten (10) important elements of quality culture which TQM practitioners generally agree should

be present in organisations whose culture complements TQM implementation and these according to Mahmood et al. (2006) include leadership and top management commitment, customer's management, training and education, teamwork, people management, and empowerment, supplier partnership, quality planning and strategy, process management, rewards and recognition and effective communication.

RESEARCH METHOD

A sample of 200 was chosen from contracting, consulting and client organizations in Lagos State. Lagos was chosen because of its commercial nature and being a state with array of construction sites and concentration of construction companies. The target population consisted of various construction practitioners. A survey questionnaire was designed to elicit information on a list of 50 factors - classified into ten categories - obtained through literature review. The respondents were required to choose from a scale of 1 to 5 representing 'not implemented' to 'very highly implemented' respectively. Data analysis process was carried out using statistical tools such as frequency tables, mean and analysis of variance (ANOVA). A total of 89 questionnaires were received from the respondents which represents 45% response rate. The demographic data revealed that senior staff constituted the highest proportion (39%), site engineer 15% and project manager (15%) Quality control officer (10%), while the least percentage included Managing Director (5%), construction manager (4%) followed by partners (5%) and assistants (7%). The respondents are professionally qualified. Corporate members accounts for 66% of the respondents while 2% of the respondents are fellows of their professional institutes. Organisational distribution includes 42% consulting firms, 40% contracting firms and 18% of client organizations. Ownership structure of respondents indicates that 82% of the organisations surveyed are predominantly large and medium sized companies.

PRESENTATION AND ANALYSIS OF DATA

Factors determining implementation of quality culture in construction work

The analysis of factors used in assessing quality culture is presented in Table 1; top managers' act as role model for quality culture is the factor with the highest mean score (3.88); this is followed by quality is not compromised for productivity with a mean score of 3.71, closely followed by communicating, motivating, supporting people and encouraging effective participation having a mean score of 3.69. The least factor implemented was authority is equal to responsibility (3.44). At present, it is safe to infer that these factors are presently being significantly implemented in the Nigerian construction industry. **Customer management (Focus);** high technical competences of workforce and quick response to owner / customer's request (3.67) stand to be the highest ranked, while the least sub factors implemented are good appearance of jobsite and good appearance and conduct of workforce (3.39). This result shows that the industry is achieving quality on the technical competence of workforce. **Training and Education;** from Table 1 on the job training (3.55) and in-house sessions for quality (3.37) were the top factors implemented for training and education. However, training of subcontractors and suppliers (2.35) and International training (2.44) were the least ranked revealing less implementation. This indicates that on the job training and in-house sessions for quality is the major training available to majority of construction work force. **Team work;** result indicates that key players in construction are involved at the inception of construction works (3.51) and they are

enthusiastic about change (3.28). Rewards and recognitions to reinforce teamwork was the least with a mean score of 2.92; this is a relative quality implementation.

Table 1: Assessment of the implementation of quality culture in construction

Factors	Sub factor code	R	Mean	Overall Mean
Leadership and top management commitment	Top manager act as role model for quality culture	1	3.88	3.55
	Quality is not compromised for productivity	2	3.71	
	Elimination of zero defect (do it right the first time) slogan by leaders and top managers	4	3.53	
	Eradication of training by top managers	7	3.18	
	Provision of training, working tools, machinery and materials	5	3.46	
	Authority is equal to responsibility	6	3.44	
	Communicating, motivating, supporting people and encouraging effective participation	3	3.69	
Customer management (Focus)	High technical competence of workforce	1	3.67	3.50
	Good appearance of job site	6	3.38	
	Good appearance and conduct of workforce	5	3.39	
	Quick response to owner / customers request	2	3.56	
	Safe operating procedure	4	3.46	
	Minimal occurrence of accident on job site	3	3.55	
Training and Education	On the job training	1	3.55	2.91
	In-house sessions for quality	2	3.37	
	Training of supervisors and hourly paid workers	7	2.80	
	International training	9	2.44	
	Seminars / workshops on quality	6	2.84	
	Training on statistical process control tools (SPC tool is a prescribed recipe for quality improvement)	8	2.56	
	Technical education in construction	5	2.91	
	Training of subcontractors and suppliers	10	2.35	
	Management training	3	3.24	
	Team training	4	3.02	
Team work	Key players enthusiasm for change	2	3.28	3.22
	Involvement of key players at the inception of construction work	1	3.51	
	Rewards and recognitions to reinforce teamwork	4	2.92	
	Team approach (such as quality circles ,cross functional teams) in problem solving and continuous improvement	3	3.17	
Suppliers partnership	The choice of suppliers is based on quality rather than price	2	3.21	3.30
	Promotion of the concept of customer/supplier relationship	3	3.16	
	Long-term relationship and working partnership with key suppliers	1	3.52	

Table 1: Assessment of the implementation of quality culture in construction (cont'd)

Factors	*Sub factor code*	*R*	*Mean*	*Overall Mean*
Process management	*Documentation of the quality process*	1	*3.47*	*3.16*
	Assign a process member to be responsible for the execution of each construction process	3	3.20	
	Use of statistical analysis tools in managing quality process (e.g. measurement of rework cost ,waste ,materials etc)	4	3.02	
	Establish measures and target to be used as evidence of the success of attaining customer values attached to the process team	2	3.21	
	Recognize and reward individual contribution to the process team	5	2.89	
Quality planning	Set up a quality committee/council to provide strategic direction to quality plan	2	2.87	2.88
	Integrating total quality management (TQM) into all planning	1	2.91	
	Development plans for handling non –conformance to quality	2	2.87	
Reward and recognition	Reward for result (quality of work done)	1	3.08	2.91
	Compensation is equitable	3	2.88	
	Job security of employee	2	2.93	
	Set up recognition and reward programmes (monetary and non-monetary) to maximize employees support and involvement in the attainment of quality	4	2.75	
Communication	Effective top down, down top management communication	2	3.35	3.30
	Communicating mission and vision statement to employee	1	3.44	
	Communicating success and progress of project /activities between management and employee	3	3.41	
	Elimination of communication barrier among employees and top management (which could be as a result of cultural values, mindsets of the top management or employee)	4	3.00	
People management and empowerment	Employee fulfillment(employee being proud of their work)	1	3.36	3.12
	Employee are recognised for superior quality performance	2	3.31	
	High level of participation in quality decisions by non-supervisory employees	3	3.03	
	Top management pushes decision making to the lowest practical level	4	2.78	

Suppliers partnership; According to the result presented in Table 1 long-term relationship and working partnership with key suppliers ranked first (3.52). This is followed by choice of suppliers is based on quality rather than price (3.21) while promotion of the concept of customer/supplier relationship (3.16**)** was the least. The mean ratings of these sub factors show that suppliers' partnership has been implemented but not highly implemented. **Process management;** The result revealed

that documentation of quality process (3.47) and establish measures and target to be used as evidence of the success of attaining customer values attached to the process team (3.21) were ranked first and second while recognise and reward individual contribution to the process team dropped from being averagely implemented with a mean score of 2.89. **Quality planning;** the factors under quality planning in Table 1 dropped from being averagely implemented on a five point scale. In the order of ranking, integrating total quality management (TQM) into all planning (2.91), set up a quality committee/council to provide strategic direction to quality plan (2.87) and development plans for handling non –conformance to quality 2.87. This is an indication of lack of planning for quality in the Nigeria construction works. **Reward and recognition;** reward for result on quality of work done (3.08), and Job security of employee (2.93) were ranked first and second for reward and recognition in the table. On the other hand, set up recognition and reward programmes (monetary and non-monetary) to maximize employees support and involvement in the attainment of quality was least ranked with a mean score of 2.75. Apparently, these factors are approximately 3.00 on the likert scale, thus, it can be concluded that their level of implementation in the industry is not sufficient enough to achieve the benefit of total quality management. **Communication;** communicating mission and vision statement to employee (3.44) was ranked first followed by effective top down, down top management communication (3.35), communicating success and progress of project /activities between management and employee (3.41) was ranked third while elimination of communication barrier among employees and top management (which could be as a result of cultural values, mindsets of the top management or employee) was ranked fourth with a mean score of 3.00. Presently, these factors are treading on the path way of quality culture implementation. **People management and empowerment;** based on the experience of the respondents, employee fulfilment (employee being proud of their work is being implemented in the industry with a mean score of 3.36 this is followed closely by employee fulfilment (employee being proud of their work) with a mean score of 3.31, top management pushes decision making to the lowest practical level was the least with a mean score of 2.78. Generally, these factors are being averagely implemented in the construction industry.

Table 2: Summary implementation of quality culture in construction work

Factors	Mean	Rank
Leadership and top management commitment	3.55	1
Customer management(Focus)	3.50	2
Supplier partnership	3.30	3
Communication	3.30	3
Team work	3.22	5
Process management	3.16	6
People management and empowerment	3.12	7
Training and Education	2.91	8
Reward and recognition	2.91	8
Quality planning	2.88	9

Summary of factors determining the implementation of quality culture.

Table 2 reveals that leadership and top management commitment is the highest ranked factor implemented with a mean score of (3.55) while customer management/Focus

(3.5) was ranked second by the respondents with a mean score of (3.30), suppliers' partnership and communication were ranked third. Furthermore, the table indicates that training and education, reward and recognition and quality planning are the least factors implemented with a mean score of 2.92, 2.91 and 2.88 respectively. The result presented reveals that the mean scores were less than 4.0 but greater than 3.0 on a five point likert scale. This signifies that construction industry in Nigeria does not have a full blown culture of quality.

Table 3: factors of quality culture with statistical significance difference (p<0.05)

S/N	Factors of Quality culture	Contracting	Client	Consultant		ANOVA
		Mean	Mean	Mean	F-value	P-value
	Leadership and top management commitment					
1	Quality is not compromised for productivity	4.00	3.06	3.69	6.163	**.003***
	Training and education					
2	International training	2.13	2.93	2.52	3.828	**.026***
3	Training of subcontractors and suppliers	2.18	1.87	2.72	5.094	**.008***
	Team work					
4	Rewards and recognitions to reinforce teamwork	2.89	2.37	3.20	6.538	**.002***

	Reward and recognition					
12	Compensation is equitable	2.73	2.50	3.19	3.476	**.035***
	Communication					
13	Communicating success and progress of project between management and employee	3.31	2.80	3.72	4.449	**.015***

***Significant at (p<0.05)**

Test of hypothesis

The study tests the following hypothesis:

$H_0 : \mu_1 = \mu_2$ There is no significant difference in the assessment of quality culture implemented by contracting, consulting and client organisations.

Analysis of variance (ANOVA) at statistically significant ($p<0.05$) was used to determine whether any significant difference exists between contracting, client and consulting firms on the implementation of quality culture. From the results of the ANOVA test, thirteen of the fifty two sub-factors analysed differ significantly in their mean values at $p < 0.05$. This is an indication of significant difference in the level of quality culture implemented between the groups of firms. The null hypothesis of no significant difference between the level of quality culture implemented in contracting, consulting and client organisation was rejected for these factors.

Discussion of findings

Leadership and top management commitment and customer focus have been implemented in the Nigerian construction industry with an approximated mean score of 4.00 on a 5 point likert -scale. In a survey research carried out in Malaysia, top management commitment was ranked first with a mean score of 3.65 (Eng and yusof, 2003). Also, leadership and top management commitment were found to be the highly implemented and practiced strategy in the findings of Dilber, Bayyurt, Zaim and Tarim (2005) and Eng and Yusof (2003). However, these results are apparently lower than the result of a survey in Thailand (Hoang, Igel and Laosirihongthong, 2010) where top management commitment was ranked second with a mean score of 4.02 and customer focus took the lead with a mean score of 4.08. The least factors of quality culture implemented in Nigeria are not different from that cited in the findings of Hoanga, et al., (2010) and Eng et al., (2003).

CONCLUSIONS

The results of this survey shows that there is need for construction industry in Nigeria to focus on improving the practices and implementation of quality culture, especially reward and recognition, training and education and quality planning, in order for quality culture to be wholly embraced and implemented. To assure quality of construction projects, companies should impose a quality plan to be followed by all key players involved in construction projects, subcontractors and testing laboratories. To a limited extent, some factors of quality culture are prevailing in construction works in Nigeria while others are still in their formative and or maturing stage. Leadership and top management commitment and customer focus were seen to be treading on the path of total quality management. However, other factors like training and education, teamwork, suppliers' partnership, quality planning, process management, communication, reward and recognition people management and empowerment are still in their maturing stage in the industry. Training should be considered as primarily a vehicle for implementing and reinforcing quality practices. Moreover, clients should advance from the accustomed practice of awarding tenders to the lowest price and promote rewarding the best team and suppliers who could provide the best service. With proper training and quality awards, the quality awareness can spread widely throughout the construction industry in Nigeria and the achievement of quality culture can be maintained. In addition to the aforesaid, great effort is required from the management to develop the whole company quality culture. The paper recommends that companies should embark on cultural audits before

implementing quality culture so that shared values, objectives and behaviours can be aligned to the goals of the quality plan. Also, an extensive awareness and training programs be initiated to improve the clients' understanding and approach toward quality and hence increase their achievement of quality culture, which would in turn improve coordination, teamwork, productivity, and construction industry performance.

ABSTRACT

The current contracting environment in the construction and services sectors in Italy is heavily impacted by poor economic conditions, making new methods and innovations in procurement and supply chain management attractive. Prior to the implementation of any new restructuring methods or innovations, a proper understanding of the overall state of the Italian economy, including legal implications, current contracting trends, and goals is requisite. Government reports, published statistics, and a recent industry survey are examined and compared. The main challenges in the Italian construction market are identified as: a primarily price-based selection criterion, difficulty for vendors to differentiate themselves, administrative challenges, and decreasing investment. A survey is developed and distributed to Italian construction professionals in order to gain insight into these current industry challenges. Targeted areas and strategies for potential improvement such as financing, procurement, selection, pre-planning, management, and supply chain innovations are suggested. Proposed solutions to the challenges identified are analysed and a future direction for potential Italian construction industry innovations is formed.

Keywords: contracting, Italian trends, management, survey.

INTRODUCTION

As one of the consequences of the financial crisis, the European Union (EU) is experiencing a major downsizing of construction sectors and associated potential output (European Commission 2011). Construction activities within the EU-27 in 2006 generated almost 1,200 Billion Euros, more than 10% of the EU's Gross Domestic Product (FIEC 2007). More than 2.7 million companies, mostly small and medium enterprises, compose the sector and five countries contribute more than three quarters of the total production: Germany, the UK, France, Italy and Spain (Pellicer et al. 2009). With a focus on Italy, the construction and real estate sector is essential to the national economy and accounts for 15% of Italy's GDP. The sector has entered its

[1] kristen.barlish@asu.edu
[2] alberto.demarco@polito.it
[3] giulio.mangano@polito.it

fourth year of decline and is struggling to achieve post-crisis minimums. Beginning in 2008, total investments in construction have decreased by over 20% and are now at approximately the same level as they were in the late 1990s. For public works, the reduction of investments in the same period is 37.2% and, if taken into account the already negative place since 2005, the decline in production loss reaches 44.5%. Overall, 250,000 sector jobs have been lost since the onset of the crisis and company bankruptcies have increased by 102%. The decline is expected to continue in 2012 and 2013 (ANCE 2011 and Bevini 2011).

Italy is seeking solutions and making reforms to ameliorate these economic challenges via a series of governmental actions aimed at reducing the budget deficit and promoting internal growth (ANCE 2011, The Economist 2011). However, Italian construction market research and surveys tend to focus on problems instead of potential solutions (PPN 2011, Inarcassa 2011). Interestingly, the problems of the Italian construction market of the past are quite similar to the present (Pietroforte and Tangerini 1999). Therefore, the objective of this paper is to assist the Italian construction industry and field of research in: identifying innovations to assist with the industry's problems, selecting the appropriate target areas for developing practical solutions, and aid in realizing plans for improvement in the future. Through government reports, published statistics, and surveys, it is discovered that the key areas needing further analysis in order to propose restructuring ideas for the supply chain are in: selection, value-enhancement innovations, administration, and funding.

METHODOLOGY

The Italian construction industry's challenges and current trends are discussed and potential solutions are proposed in response to these problems via an industry survey. The Italian National Welfare and assistance fund for engineers and architects released a survey to its members in order to analyze current challenges and problems (Inarcassa 2011). Based on the trends, a series of questions are further drawn to gain insight into how potential innovations in these areas can be properly implemented. A survey is composed regarding these extracted areas of innovation and solutions. The survey was released to the same group of professionals in the Italian construction and services industry that was originally surveyed regarding the industry's problems in order to gain feedback regarding solutions and matching them with innovations for the overall supply chain improvements. The results of the survey are analysed and recommendations are developed regarding industry solutions.

MARKET ANALYSIS

The European construction market saw deterioration of economic activity in the latter part of 2005, which was manifested also in 2009. The effect of this descent brought about an increase in the need for companies to obtain short-term financing. With an increasing number of banks reluctant to provide liquidity, the access to finance became more problematic for construction companies (Mocanu 2009). Moreover, the EU construction industry has been constantly facing challenges to improve, meet market demand, and overcome skills shortages (Nadim and Goulding 2011).

As far as Italy is concerned, investments in construction projects are declining ((Table 1)). Due to government incentives for renovation works such as tax deductions for green building renovations, the market for residential renovation activities has been the only growing segment of the Italian construction sector in recent times (ANCE 2011; European Commission 2011). Some potential reasons for this decline suggested are: delay in public works payments to contractors by the central and local

governments averaging 6 months and often exceeding that threshold; and red tape as it's estimated that only 45% of the lifespan of an infrastructure project consists of the actual site work, while the rest is consumed by bureaucratic procedures (Bevini 2011). Overall foreign investment in Italy is cited to be declining, leading to less employment opportunities and being hindered by similar factors such as lack of flexibility, high taxes, and bureaucratic procedures (USCS 2011).

Table 1 – Italian Public Investments in Construction (Values in USD Millions) (Bevini 2011)

Segment	2009	2010	2011	2012

ITALIAN INDUSTRY PERCEPTIONS

Professionals in the construction and services industry in Italy are witnessing the impacts of these difficult economic conditions and are struggling with the potential resolutions. In December 2011, the Italian National Welfare and assistance fund for engineers and architects released a survey to its 2,000 members in order to analyze current challenges and market trends (Inarcassa 2011). With 353 responses (18% response rate), the survey uncovered some of the main challenges as: a primarily price-based selection criterion, difficulty for vendors to differentiate themselves, administrative challenges, and decreasing investment. Upon further analysis, the challenges survey identified key areas unmet needing further analysis in order to suggest industry solutions in the areas of: selection, value-enhancement innovations, administration, and funding and investment.

Selection

In Italy, a contracting authority has the ability to choose the selection method for their projects in compliance with the legislation (Pacciani and La Rosa 2010). Prior to the onset of the crisis, 50% of infrastructure projects were awarded via discretionary awards and negotiations (Pietroforte and Tangerini 1999). The situation has not changed much, as an analysis of the vendor selection process reveals that the negotiated procedure without publication of notice is the selection method most used in Italian public works projects (Table 2) and has increased overall in usage from 2009 to 2010 (AVCP 2011a).

Table 2 – Italian Public Contracts – Selection Methods vs. Type of Project (AVCP 2011a)

Method	Works	Goods	Services
Negotiation without publication	42.1%	23.2%	23.1%
Open	41.0%	60.3%	50.3%
Negotiation	7.7%	7.2%	10.8%
Restricted	6.1%	7.1%	8.0%
Other procedure	0.4%	0.2%	2.2%
Not identified	2.7%	1.9%	5.6%

Value-Enhancement Innovations

The two selection criteria available for Italian Public Procurements are lowest price and the Most Economically Advantageous Tender (M.E.A.T.). As the M.E.A.T. criterion represents a vendor's opportunity to differentiate themself based upon factors other than price, vendors can provide an indication of their added value via sub-criteria such as: quality, technical merit, aesthetics, environmental, etc. (AVCP 2011b). Prior to the crisis, a lack of consideration regarding past experience and qualifications made price the primary selection criterion in awarding contracts (Pietroforte and Tangerini 1999). The situation has not changed much, with 86.6% of works contracts that used the criterion of the lowest bidder (AVCP 2011a).

By dividing the sectors (Table 3), it can be seen that a majority of the public works projects (10,051 projects) utilize lowest price (AVCP 2011a). While it is commonly held that performance factors should be taken into consideration in the selection criteria, few real project examples have been provided by the literature (Watt et al., 2010). Moreover, M.E.A.T. is used less frequently than its competitor, lowest price, and appears to be difficult to apply in Italy as it is referenced in over thirty individual decrees and laws, is the subject of confusion and fear of legal implications in numerous publications (AVCP 2011b), and is cited to be more time-consuming (AVCP 2011a). The current selection criterion that accounts for performance and overall vendor innovation is not easy to apply and has severe legal consequences, resulting in lowest price being primarily used and vendors not having the opportunity to differentiate themselves and prove their overall value.

Table 3 – Italian Public Works Contracts Awarded vs. Each Criteria (AVCP 2011a)

Selection Criteria	Number of Projects	%	Total Cost	Cost %
Lowest Price	10,051	86.6	7,726,591,293	61
M.E.A.T.	1,527	13.2	4,880,519,841	38.5
n.c.	31	0.3	54,390,430	0.4
Total:	11,609	100	12,661,501,564	100

Funding and Investment

As evidenced by the initial economic market analysis, funding and investment are decreasing in the Italian construction market, causing fewer projects and works awarded. The current funding and investment mechanisms are not adequately providing project opportunities, which seems to result in late payments and decrease in projects under the current framework. According to a survey by ANCE (2011), 48% of construction firms reported that the contract terms for financing already in place had changed throughout the course of their projects. Additionally, the demand for loans by construction companies is increasing due to the following: need to cope with payment delays of public administration (42%), changes in production requirements (30.5%), and inability to self-finance (23%) (ANCE 2011).

Administration

The Italian administration can be seen from its performance as an EU Member State and made up of agencies at the state, regional, and local levels. The Italian administration has a Public Procurement Code that encompasses the European Commission Directives and the Government Procurement Agreement (GPA). The current Italian administration and management are not easy to work under due to reported lack of flexibility, high taxes, and bureaucratic procedures (USCS, 2011 and World Bank 2010). The World Bank (2010) currently ranks Italy 80th (76th last year) on a list of 183 countries for business friendliness, below all other OECD countries,

and 92nd in building permit issuance (bottom 5 of EU countries). The effects of these challenges are in project changes, such as increases in price and schedule. Overall, 68% of projects identified experienced time impacts and 14% experienced cost impacts (AVCP 2011a).

SURVEY FOR SOLUTIONS AND INNOVATIONS

After reviews of the literature, public procurement records, reports, and surveys, it became apparent that the industry could potentially benefit from solutions in:

- Selection - what if there was a system that utilized other factors of selection?
- Value-adding innovations - how can vendors be promoted to add value?
- Administration - how can the burden of administration be lessened?
- Funding and investment - how can funding be increased or stimulated?

A survey was distributed to see if certain innovative solutions to these challenges could benefit the industry as perceived by Italian professionals. In order to receive a more complete portrayal of solutions matching challenges, the solutions survey was distributed to the same Italian National Welfare and assistance fund that took the challenges survey. The survey received 377 responses (19% response rate) and was made available from March 2012 until May 2012. Participants rated the degree to which they agreed that specific solutions could potentially solve specific problems.

Background

Survey respondents were primarily designated as professional architect/engineer/technical services/designer and consultants. Respondents had an average of 237 projects per year. The average overall reported satisfaction with the Italian construction and services industries was 4 (on a scale with "1" being dissatisfied and "10" being highly satisfied).

DISCUSSION OF RESULTS

The suggested innovations were agreed to by a majority of respondents. An analysis was carried out that divided the results based on their scores as "1-3" as disagreed; "4-7" as unsure, and "8-10" as agreed. Overall, participants agreed that the solutions of performance/value-based selection (64%), a holistic business model (54%), aggregation/integration (46%), PFI (62%), PPP (44%), and continuing education (46%) would ameliorate the industry's challenges.

Table 4 – Survey for Solutions and Innovations 2012

No.	Challenges	Solutions	Agree	Unsure	Disagree
1	It has been observed that vendors are primarily selected based upon their price.	Consideration of other selection factors, such as performance, overall capability, and opportunities for vendors to provide innovations could solve this problem.	64%	28%	9%
2	…projects struggle to meet schedule, cost, and achieve client satisfaction and objectives.	A business model and methodology that focuses on vendor risk management, pre-planning, and performance measurements…	54%	37%	10%
3	…organizations are struggling with providing their same level of service and are not financially capable in the current economic conditions.	Strategies such as aggregation and integration (providing more cross-disciplinary services to clients)…	46%	43%	11%
4	…owners do not have the	Strategies such as Private Financing	62%	31%	7%

	financial capacity to initiate new projects in the current economic conditions.	Initiative (PFI)...			
5	…vendors face problems associated with organizational and administrative barriers of owners.	Partnering or Public Private Partnerships (PPP) arrangements…	44%	49%	7%
6	…there is a lack of proactivity and communication between vendors and owners.	General/Project Management training and continuing education to technical employees…	46%	44%	10%

Selection and Value

For the challenges involving selection and value-adding innovations by vendors, a holistic system is proposed in which the entire life-cycle of projects and organizational methodology are addressed in a complete business model. The suggested model of Best Value (BV) applies to organizations via the mechanisms of performance measurement, transparency, accountability, and leadership (Kashiwagi 2011). The term "Best Value for Money" is also widely used in the Italian market and signifies the removal of unfair barriers to competition (Pacciani and La Rosa 2010), which is part of the purpose of the BV Business Model. By focusing on performance, price is no longer the main criterion; instead, clients are given the tools to properly select vendors that provide measurements of their overall value. As an owner-driven program, BV focuses on improving quality through the removal of waste via: reducing client decision making by aligning the most appropriate vendor to the client through performance information; and minimizing the need for redundant client management and direction by successfully transferring risk to the party best fit to address the risk and holding them accountable for the results (Kashiwagi 2011 and Sullivan 2011). Therefore, the problems of the construction industry are addressed via providing performance considerations and complete efficient operations by utilizing the BV Business Model.

Funding and Investment

As a solution to reducing the funding problem, Project Finance Initiative (PFI) is proposed to develop public infrastructure and social facilities in Italy. Under this mechanism a private sponsor finances, designs and builds the project and then operates it for a specified concession period. During this concession period, the sponsor collects revenues from operating the project to recover its investment and earn a profit. Due to the shortage of public funds and increasing demand for construction of public social facilities, privately financed projects have been considered a desirable solution to provide services for the public (Zayed and Chang 2002). Governments increasingly see PF initiatives as a way to relieve the financial burden of the state and attract international investment and technology or to develop domestic technology (Wolfs and Woodroffe 2001). The use of PFI has grown dramatically over the years. Financing almost 4000 projects in 113 countries, the total amount of project finance raised between 1991- 2005 amounts to $1077 bn. While the US, with $186.4 bn accounts for most project finance (followed by Australia and the UK), this form of financing has also been used in emerging economies: such as Taiwan ($64.2 bn), China ($58.9 bn) and Malaysia ($46.5 bn) (Kleimeir and Versteeg 2010).

Administration

For the problems associated with administrative barriers, and bureaucratic procedures of owners, a more extensive usage of owner-contractor shared special purpose vehicle companies and PPP forms of arrangements are suggested. For enhancing pro-activity and communication between vendors and owners, it is recommended that staff be trained with Project Management continuing education in order to let technical employees integrate both soft and hard management skills into their background technical expertise. This is expected to enhance planning, monitoring and communications skills for better proactive project delivery.

CONCLUSION

Based on the survey responses regarding potential solutions and supply chain innovations, it is recommended that the Italian industry should investigate all of the identified innovative strategies. Special attention and analysis should be given surrounding the highest rated strategy of performance/value-based selection of vendors. Overall, participants agreed that the solutions would ameliorate the industry's challenges. Returning back to the original questions, new industry and research directions can be drawn:

- Selection - explore systems that utilize factors of selection besides price.
- Value-adding innovations – find ways to educate or encourage vendors to be promoted to add value to their projects in pre-planning.
- Administration – work towards lessening the burden of administration.
- Funding and investment – encourage increase and simulation funding via proper planning.

The Italian construction industry is facing difficult times and future downturn could be ameliorated with these solutions and innovations. It is recommended that feasibility studies be carried out with respect to these methods to determine their potential impacts. Additionally, surveys from differing perspectives (i.e. vendors, owners, etc.) and different countries (other European countries, the Americas, Asia, and a comparison with other countries) would provide benefit to future research.

DRIVERS AND OBSTACLES FOR EMPLOYEE-DRIVEN INNOVATION IN LARGE CLIENT PROJECT ORGANISATIONS

Henrik Sørensen[1] and Søren Wandahl[2]

[1] *Department of Mechanical and Manufacturing Engineering, Aalborg University, Aalborg, Denmark*

[2] *Department of Engineering, Aarhus University, School of Engineering, Aarhus, Denmark*

ABSTRACT

In recent years implementation of various types of development and innovation approaches has been adapted in the construction industry, without any of them fully matching the expected success. Through a focus on, how to generate most value in the daily work and problem-solving processes, and in sequence increased revenue, this study suggests that the key source for innovation is the employees. Employee-driven innovation (EDI) is a methodology to take advantage of employees' spoken and tacit knowledge in the development of new tools and structures. To utilise this approach in optimising the construction project management processes is a relatively new approach to engage innovation. In this broad perspective the aim is to map the boundary conditions for an EDI approach in a client project organisation and compare these with the theoretical methodology for conduction EDI. Trough semi-structured interviews this study will discover the conditions such as drivers and obstacles for EDI within major client project organisations. The field around EDI will be studied to discover the most potential management philosophies and methods. Based on this study, the theoretical approach to engage EDI in client project organisations is compared to the boundary conditions of the organisation.

Keywords: construction innovation, change management, employee-driven innovation, knowledge sharing, project organisations.

INTRODUCTION

The construction industry is, in many countries, considered to be a slow adopter of new technology and new processes. In general, it is not regarded as an innovative industry (Wandahl et al. 2011a). Instead focus is on short-term gains, instead of long term planning of development and innovation. When the industry booms, the industry gear up, man and machinery wise, and engage in as many projects as possible, disregarded the cost, more or less (Wandahl et al. 2011b). There is a lack of competition, and construction companies feel no need to use resources on innovation. In times of recession competition is substantial, and the companies gear down, and cut

[1] hensor@mil.dk
[2] swa@iha.dk

off all possible costs including R&D. Thus, the focus on long-term development and innovation has rough conditions to subsist in the industry.

In large project organisations that are based on new bonds and relations in drifting systems (Christensen and Kreiner 1991), the employees are an important and effective source of innovation that are often ignored or unseen in innovative approaches. In terms of their experience-based and up-to date knowledge about the projects, employees possess the newest and most valuable knowledge about materials, markets, customers, processes and customers/users. Hence, it is an obvious source of information and knowledge within the organisation, who can share their practical experiences and know-how in informal networks or forums (Høyrup 2010).

State-of-the-art

Involvement of employees has been a research topic for some years, but it has never been formalised in terms of a theoretical or practical framework (Bakker and Demerouti 2008) Hence, a methodology to take advantage of employees' spoken and tacit knowledge in the development of new tools, structures, and processes to optimise the construction project processes, is an emerging approach to engage innovation.

There are many traditional ways to use the employee's experiences in evaluation of the working processes in the organisation, e.g. team meetings, walk and talk session, evaluation schemes. A more recent theory, in using employees in the development of organisations, is Employee-driven innovation (EDI). This approach adapts a systematic involvement of employees in the innovation process, centred on idea-generation from employees, and a framework that can transform these ideas into new tools or working processes.

In general the EDI approach is a bottom-up process that focuses on innovation driven by the employees' ideas, creativity, competences and problem-solving abilities. The process needs to be supported and organised by management. Furthermore, it concerns all types of innovation activities; process, product, organisation, market, and so forth, both incremental and radical (Høyrup 2010). EDI is not a well-documented field of research in the general innovation literature. EDI is often seen in a greater innovation context, in which it often is de-emphasised contrary to product and process innovation (Høyrup 2010). Dobni (2006) presents "The innovation blueprint", a general innovation model where the employee's figures in the organisational mindset that should drive the organisation towards innovation. Hence, a company that succeeds in innovation cannot only be defined in the company's external behaviour and actions, it is to a great extend also determined by the culture and the mindset of employees in all levels of the organisation. In The Innovation Blueprint model the employees' competences and development is an important factor in an organisation's desire to invest in innovation and development. This model differs from the basic perception of EDI in the way that the employees are not considered a source for innovation, but merely as a support function that is aligned with the R&D or market innovation. Hamel (2006) also focuses on this paradox. He emphasises that more competitive advantages are developed from the non-technological innovation compared to the innovation developed from technologies and laboratories. Hamel denotes examples on how to link management and innovation in large project organisations by focusing on employees and management, and on how to create innovation through organising, leading, coordinating and motivating the employees. In project based organisations within the construction industry, knowledge and experience in terms of products and processes are often closely related to individual

employees and often irregularly driven by these employees. This knowledge is often very difficult to identify, collect, share, and utilise. Therefore the approach requires a systematic structure or methodology such as EDI, which features tools for managing structure, culture, and methods in project organisations (Teglborg-Lefévre 2010; Høyrup 2010).

Development of methodologies to coach or train employees in identifying problems in the working processes, generate ideas, and transform them into solutions, is also considered to hold a higher level of novelty. Furthermore, it is essential that this development is seen in an interdisciplinary perspective, thus it can be deeply rooted in all units and at all levels in the organisation, and in the end be beneficial and value adding.

Objectives
This research takes its departure in the following objectives

- Deriving a map of the boundary conditions and point of reference for conducting EDI in a client project organisation
- Discussion of possible drivers and obstacles for conducting EDI in large client project organisations.

METHODOLOGY

This study takes its departure in a desire to challenge the capabilities for innovation and willingness to change in the construction industry, based on the challenges in a client project organisation. The focus on the employees is based on, how to capture and utilize their tacit and spoken experience and knowledge in the development and innovation of the organisation and its products and services.

Semi-structured Interviews
To map the boundary conditions and identify the point of reference for approaching EDI in a large client project organisation, various employees have been interviewed.

The interview approach was conducted through a semi-structured interview to ensure an open and focused two-way communication with the employee. Using this method should ensure a confirmation of what is already known, and the possibility to investigate new point of views. Selection of respondents is based on these criteria: they should be affiliated with a geographically spread office location; they should occupy different job-functions; they should have various experience and length of employment; and they should be of various ages. Table 1 illustrates the selection of respondents in relation to these criteria.

Respondent	Job function	Experience	Location	Age (app.)
1	Architect - PM	8 years	East office 1	50 years
2	Engineer - CM	3 years	Vest office	38 years
3	Chartered Surveyor - CMM	2 years	North office	30 years
4	Engineer - CMM	4 years	South office	32 years
5	Engineer - CM	25 years	East office 2	60 years

Table 1 – Selection criteria for semi-structured interviews. PM = Project Manager, CM = Construction Manager, CMM = Construction Maintenance Manager

To ensure that the interviewee was open-minded and spoke without stinting, they all figure anonymously in the documentation. All questions were formulated as openly and objectively as possible, to both ensure that the interviewee did not sense any bias from the questions, and to compel them to reflect why they answer in the given way. All interviews were audio recorded to enhance documentation and following analysis.

The collected qualitative data was processed in two ways. Some of the answers were, as far as possible, quantified to see how many of the interviewees that answer in the same way. Furthermore, the semi-structured interviews are transcribed in full length and the answers are analysed for recurrences, keywords or statements that could indicate an attitude or feeling to a specific subject that are not clearly spoken in the answer.

Employee-Driven Innovation

The empirical data must be compared to the theoretical approach to discover the drivers and obstacles for conduction EDI in the case organisation. The theoretical approach to EDI embraces elements of a variety of management philosophies, such as *entrepreneurship*, *lean construction*, *managing innovation*, *workplace learning*, *change management*, *the learning organisation* and *value-based management*, inspired from Ramboll (2006) and (Høyrup 2010). These philosophies should explore a framework for EDI that in one end captures or contains ideas from employees and in the other end ensures that the ideas are developed into new tools to optimise the processes and problem-solving.

Hence the review of these management philosophies shall explore the most beneficial and high impact segments of these methodologies in developing a framework for an EDI approach to innovation in a large client project organisation.

THE CASE ORGANISATION

In this research, the case organisation is the governmental client organisation Danish Defence Estates & Infrastructure Organisation (DDEIO), who is an integrated part of the Danish Defence. DDEIO's main focus is to develop, operate, and deliver the physical conditions that are necessary for the operational forces, but also to the other authorities within the Danish Defence organisation.

The Construction Division (CD) within DDEIO is organised in three departments; the Project Department that primarily conduct new build, the Maintenance Department that conduct all maintenance of Defence properties, and the R&D department that support all R&D, legal, technical, and administration issues. The organisation around CD is still affected on older military traditions, which are realised in a bureaucratic and hieratical organisation, in which you communicate along the chain of command. This also results in a culture, wherein many officers and managers are involved in projects and thus want their influence forced through. Most of the employees are relatively highly educated in terms of architects, engineers, Chartered Surveyors, lawyers, controllers, and so forth. Hence, the potential to involve employees in development and innovation tasks is evident in this organisation.

RESULTS

The most relevant questions from the semi-structured interviews and the respective answers for mapping the boundary conditions for EDI are shown in Table 2.

 ISBN: 978-1-84219-840-7 .

	1	2	3	4	5
Q1	Do you feel that the employees are motivated to get involved in development, if they feel that they have ideas to optimise the working-processes?				
Yes/no	No	No	Partly	Partly	No
Keyword	Generational change	Innovation from new employees	Mostly know-ledge sharing between employees	Younger and new employees are more active	Time is prioritised for production
Q2	Does your department have systematic activities to ensure that experiences and new ideas are captured and utilized in the development work?				
Yes/no	No	No	No	No	No
Keyword	Based on individuals	It is running autonomous, autodidact	Only informal and related to individuals	Experienced employees feel it is a waste of time	Only briefly, if any, on weekly department meeting
Q3	Are the employees broadly and systematically involved in the development, or is the participation in development activities randomly?				
Yes/no	No	No	No	No	No
Keyword	Spontaneous or randomly	Emanates randomly from the same employees	Only through random meetings in experience sharing groups	Based on passionate individuals, primarily younger	Time and resources are prioritised to production processes
Q4	What do you see as the most significant obstacle for the development to be driven by the employees on the floor?				
Keyword	Culture for curiosity and wondering	The R&D-function, it is invisible	Culture, framework for working processes	Time, resources, no prioritising of development	Time, support from upper management, organisation

Table 2 – Output from semi-structured interviews.

Q1: 3/5 of the respondent's answers indicate that in general the employees are not motivated for involvement in the development processes. 40% indicates that there could be some motivation in participating in development. 60% also indicates that the motivation to engage in development is mainly visible amongst the younger employees and that the development merely is based on informal knowledge-sharing between employees.

Q2: 5/5 of the respondents answer that their department has activities that systematic neither gathers experiences and ideas nor utilises them in the development of the organisational processes. According to a keyword analysis, the knowledge-sharing and idea generation are based on individual employees and the process is informally and irregularly driven. The effort is mostly seen with employees with less experience, since they are more open minded and have less faith in the bureaucratically paradigms defining the problem-solving processes. Whereas the more experienced employees have been in the system for a longer period and have adjusted to the organisational culture and processes, thus they do not have the same need for change.

Q3: 5/5 of the respondents answer that there is no broad and systematic involvement of employees. The keyword related to the answers suggests that the process is randomly and based on the same individuals, who are passionate in seeing new solutions and innovative approaches to the problem-solving processes. Hence the potential is related to a more systematic approach in involving the employees.

Q4: Two of the most significant obstacles for the development to be driven by the employees are the time and resource issue and the management support in prioritising the development approach in daily working processes.

DISCUSSION

In the following writing the key issues from the theoretical approach to EDI are presented, contemporary with a discussion of the results from the semi-structured interviews against the current perception of EDI. This should discover some of the drivers and obstacles for conduction EDI in a larger client project organisation.

A fundamental dilemma in EDI is the fact that the decision authority lies with a small number of specific functions and managers. The vast majority of the employees in the organisation are not involved (Kesting and Ulhøi 2010). Hence the thoughts behind *The learning organisation* on daily and continuous learning in all levels of the organisation are the essential parts in preparation for securing the innovation capabilities of an organisation (Wang and Ahmed 2003), could be sensible to integrate in a framework. An obstacle in the CD organisation in DDEIO could be derived from Q2, where the involvement in development and innovation is not present. And from Q4, where management support and prioritising of development are absent. Hence the lack of management support and organisational culture to secure innovative capabilities are absent. Another dilemma in adopting an EDI approach is managing the employee's incentives between on one hand the curiosity in exploration and in the other exploitation in the daily production processes (Hellmann 2007). From Q3 it comes clear that the focus in CD is on the production related tasks and the incentives to and curiosity in idea generation are more or less non-existing. This could be approached by integrating some of the elements in the philosophies *Change Management* and *Managing Innovation*, where it's important to have a structural approach to the innovation. Hence a systemized procedure, that organises how the innovation opportunities are discovered, to select the right ideas, develop and implement the idea and capture the benefits (Tidd and Bessant 2009).

The existing theory within the field of EDI focuses on the basic premise that the employees' possess hidden abilities for innovation, and further how these abilities can be integrated in the development routines of the organisation. Research on EDI has to take the underlying management and decisions-making processes into consideration (Kesting and Ulhøi 2010). Hence development of a structure or systematic approach to capture and store the experiences and ideas from the employees is of the essence, when it comes to further idea generation, development and implementation of the input. The answers from Q2 strongly indicates, that this could be a strong obstacle, when 5/5 of the respondents from various geographically located departments cannot recognise these activities in their working processes.

One of the key notes in Kesting and Ulhøi (2010) stresses that the employees, delivering innovation inputs, should participate in decision-making procedures from which the innovation is triggered and determined. This directs attention to both *Lean* thinking (Howell and Ballard 1998), and to the *Entrepreneurship* philosophy (Praag and Versloot 2007). In which the employees are respectively focusing on reducing waste and making radical innovation. Thus it will be obvious to integrate the most relevant from those philosophies.

Contrary to R&D based development, EDI focuses on a bottom up development and innovation approach from all employees in the organisation. This bottom up approach relies on the managers to plan for and facilitate the employees' involvement in these decision-making procedures. And simultaneously, the process will be valuable for the organisation. This perspective could be an inspiration from both *Value-Based Management* (Tissen et al. 1998) and *Workplace Learning* (Billet 2001), also focusing on, how the employees engage these learning and development procedures, which Q1 suggest could be obstacle for the EDI approach. One of the drivers could be the younger employees desire to optimise the organisational routines and processes.

The upper management's information is often limited to strategic levels, thus the awareness and the knowledge of the operational routines in the problem-solving processes are often inadequate in terms of the development and innovation potential (Kesting and Ulhøi 2010). Q4 suggests that this is a key obstacle in both organisational culture and management support and prioritising of the development processes. This can entail inadequate communication up- and downwards including the fact that information about employee ideas and needs will only to a less extent reach the R&D-function, whereas the potential for a successful innovation process is reduced.

CONCLUSION

The drivers and obstacles for conduction EDI in a client project organisation are through this research discovered as:

Obstacles: No incentives or motivation to engage development and innovative activities; Management focus is on production tasks, hence no management support; No systematic approach to facilitate idea generation or knowledge-sharing; Organisational culture, development and innovation are based on individuals.

Drivers: The curiosity emanating especially from the new employees; Motivation could emerge from management support in prioritising time to development and idea generation.

Some of the obstacles discovered through the interviews are convergent with those emphasised by (Kesting and Ulhøi 2010), indicating that they are of a more general character and could be point of departure for a broader framework for conduction EDI.

This research is a part of a PhD study, thus conduction of an extensive literature review is one of the obvious research areas in the near future. Furthermore, this will form the base for developing a framework of tool and methods for engaging EDI in client project organisations. It could also be advisable to analyse the relations between the obstacles, as they could originate from the same sources. Another future research area is making the framework transferrable to other types of organisations within the construction industry.

IDENTIFYING COMMON DEFECTS IN NEW RESIDENTIAL BUILDINGS: A NEW ZEALAND STUDY

Funmilayo Ebun Rotimi[1] and John Tookey[2]

[1,2]*Construction Management Programme, School of Engineering, Auckland University of Technology, Private Bag 92006, Auckland 1142.*

ABSTRACT

Improved quality performance within the residential sector has been an issue of concern for both government and building approval authorities in New Zealand. As a result, the quality of new residential buildings has come under scrutiny, particularly the nature of the defects occurring in new homes at handover. Therefore the objective of this study is to compile common defects identified by new homeowners in new residential buildings in New Zealand with a view to improving quality achievement levels. A questionnaire survey approach was employed to administer mail questionnaires to new homeowners in five major regions in New Zealand. A list of common defects was included in the questionnaire with research participants required to indicate the defects that they observed at the time they took possession of their properties. The analysis of data from 216 respondents is presented as part of a larger study being undertaken in New Zealand that seeks means of improving quality achievement levels in new residential buildings in the housing sector. It is hoped that the result of this research will help the residential construction industry to establish more aggressive and proactive measures of monitoring its final product to the satisfaction of new homeowners.

Keywords: defects, homeowners, New Zealand, quality, Residential buildings,

INTRODUCTION

The residential building sector forms an essential part of the New Zealand economy. The sector alone has a total market value of between NZ$450 and NZ$500 billion making it the largest asset class in New Zealand (DTZ New Zealand, 2004)). More recently (in March 2012) there is indication that the value of residential buildings has picked up since the recession, with the value of residential building consents rising by 30% compared with March 2011. This current spike is the highest value of residential building consents recorded since September 2008 (Bascand, 2012). This increase in the number of residential buildings will mean that more proactive measures are required to monitor the quality of the final product in a way that it meets project owners' needs. Recognising also that home ownership means so much to New Zealanders and settlers, good quality homes will mean high satisfaction levels with

[1] frotim@aut.ac.nz
[2] jtookey@aut.ac.nz

the performance of home builders. New Zealand has a high rate of home ownership (67% or 1.5 Million owner occupied dwellings in 2006 (Fortes and McCarthy, 2010).

The fact that most of the country's wealth is tied up in buildings means that any unnecessary quality non-achievement will impact the general economy. Therefore an understanding of the nature of defects will create awareness that could help to enhance building performance levels. More so the Building Research Levy in New Zealand identifies the residential building sector as one of the key areas requiring performance improvement.

Sufficient evidence suggests that there are significant number of defects in new residential buildings (Craig, 2008, Love and Sohal, 2003, Mills et al., 2009, Page, 2011, Rhodes and Smallwood, 2002, Sommerville, 2007). For example Craig (2008) estimates an overall industry average of 53 defects per new homes in the UK from a period of 2002-2006. Mills et al. (2009) on the other hand reveal that one out of eight buildings have defects and the estimated cost to rectify these defects is 4% of construction contract values. Craig's study was a first step towards providing a benchmark figure for the house building sector in the UK (Craig, 2008). This serves as an example for other countries to emulate.

In New Zealand, Page (2011) identified some defects during a pilot study of new house owners. Page's study was aimed at monitoring call backs, as an indicator of construction quality. The result of the study found that a significant number of new homes (60%) require defects rectification, suggesting that improvements were needed to work performance by home builders. The current study extends Page's pilot work with a view to providing more detailed data on the nature of these defects.

Therefore the current study extends previous study findings on defects in New Zealand. It presents the results of an investigation into the nature of defects common to new residential building in New Zealand, at the point when new homeowners take possession of their properties. The authors believe that through an understanding of the common defects in new residential buildings, home builders can better focus their attention to these salient problem areas. This should also benefit whole-of-industry by helping to keep pace with the ever-continuing rise in quality expectations.

BRIEF LITERATURE REVIEW

Defects in Residential Buildings

According to (Georgiou et al., 1999) a defect is a situation where one or more elements of a building do not perform its intended function. Similarly defect refers to failure or shortcoming in the function, performance, statutory or user requirements of a building that manifest itself within the structure, fabric services and other facilities of the building (Ilozor et al., 2004). So long as the expected final product fails to meet the required quality, then a building is said to be defective (Kim et al., 2007). Georgiou, (2000) identifies three different forms which defects in residential buildings could take: technical, functional and aesthetics. Technical defects are contraventions to building regulations and this aspect relates to workmanships, materials or designs that fall short of statutory requirements. The functional aspect relates to omitted parts or features that do not meet functional requirements, while the aesthetic aspects relate to the physical appearance and features of completed buildings. Alternatively Kim et al. (2007) identifies two categories of defects from a functional perspective: a final product that does not function appropriately, and a final product that functions but does not provide satisfiable results. Kim et al's (2007) two categories were perspectives not only from building inspectors or project managers

but also from homeowners. A more detailed categorisation of defects that could occur in a house building project is given by Sommerville and McCosh (2006). The categorisation includes seven complex combinations of: aesthetics, aesthetics and technical, technical, technical and omission, omission, omission and aesthetics, and aesthetics, technical and omission respectively. These distinctions are important because they provide an understanding of customers' needs and focus that are required to be met by home builders. It is made clear from these seven aspects and combinations that defects occur either during the building process or after buildings have been completed. Identifying and rectifying these defects would allow home builders to track improvements that could provide better quality products and services to the end user.

Homeowners represent both the 'paying' customer and the 'buying' customer (Torbica and Stroh, 1999). Therefore their needs and expectations are vital as these define the quality attributes of any building project (Dikmen et al., 2005). However, Craig (2008) explains that new homeowners are more likely to have a strong emotional attachment with the quality of the product itself and the softer issues of quality such as aesthetics. Auchterlounie (2009) study also confirm that aesthetics and the finishing aspects of buildings are of greater importance to homeowners, because homeowners view the technical aspects has a 'given' as they are covered under the various regulations and building standards. Craig (2008) study on 3696 new homes in the UK found a total of 199,095 defects of which about 90% of the defects were classified as aesthetic defects. While these are not likely to create health or safety problems, they are annoying to owners and suggest a lack of concern for quality achievement in new buildings (Page, 2011). These findings seem to suggest that aesthetics and the finishing aspects of buildings are of greater importance to homeowners. It is common for new house buyers to carry out visual inspection before the purchase of their new homes, although this visual inspection may not identify all defective works due to homeowners' lack of knowledge.

Record keeping of minor or major defects have become imperative components of the house building sector in New Zealand (Beattie, 2011). However the sector still lacks large database of historical defects that could help monitor the nature of defects in its final product. Though monitoring is often suggested, it is rarely carried out, especially with new builds (Rotimi et al., 2011). A comprehensive and effective monitoring system could enable defects to be traced and categorised so that their root cause(s) could be determined. When carried out, homeowners could have better recourse to address the issue of defects, particularly with respect to how the defects can be managed, who should be responsible and what not to be accepted (Isa et al., 2011). One major benefit of identifying common defects in new residential buildings, as an upstream quality improvement practice, is the positive effect it can have on new homeowner satisfaction. It is therefore reasonable that experts (building inspector) are engaged to undertake in depth investigation on building quality. This benefits the home buyer as they become rest assured of the quality of their purchase and equally benefits the home builder since historical record of quality achievement or non-achievement will improve their future performance.

METHODOLOGY

The aim of the research is to investigate the nature and extent of defects occurring at hand over of new residential buildings to homeowners in New Zealand. It is an aspect of an on-going study, which has one of its objectives as identifying common defects in new residential buildings. The study uses more detailed data than available in

previous studies. In order to satisfy the aim of the research a mixed method approach was adopted involving questionnaire survey to new homeowners and interviews with well-established home builders. The result of the interviews is not presented in this paper. Johnson et al. (2007) describe mixed method research as a situation where a single investigator collects and analyses data, integrates the findings and draws inferences using a combination of qualitative and quantitative approaches.

The data used for this study was collected from new residential homeowners within five regions in New Zealand. New homeowners were selected by random sampling in order to provide an unbiased subset of the population (Collis and Hussey, 2009). Out of 1290 questionnaires administered to new residential homeowners, 228 were returned of which 96% were usable and the remaining 4% unusable. The total number of usable questionnaires after data clean-up was 216, representing an overall response rate of 16.7%. Though the percentage of response appears small, the total number of response as a whole is statistically significant. A total number of 127 questionnaires were returned because the delivery points could not be located by the postal agency.

A simple interpretive and descriptive method of presentation is adopted for the study findings so that these could be communicative and understandable to readers. McQueen and Knussen (2002) explain that descriptive statistics are used to describe, illustrate and summarise information using three ways: forming numbers into tables, generating charts and diagrams from the numbers, and then calculating general statistics.

RESULT AND DISCUSSION

The opening section of the questionnaire was designed to capture demographic information of the research participants. Some of the questions asked covered: type and period of ownership of their homes, house type, number of bedrooms and information on who built their homes. The objective of these questions in this section is to determine the nature and demography of the respondents and to be able to use the information to explain responses to other parts of the questionnaire.

The majority of the research participants indicated that they own their homes (98.6%) with only (1.4%) under a rental agreement. This is in line with the focus of the research which aims to target new residential homeowners only.

In response to the question on how long homeowners have owned their homes, the result shows that the largest percentage (58.6%) of the participants has owned their homes for between six months and two years, followed by the participant who indicated that they have owned their homes for over two years (27%). The desire of the study was to target recent homeowners so that their opinions on defects they observed after they purchased their new homes could be determined, as opposed to maintenance related defects.

The third question required participants to indicate the types of houses they own. This is to enable the research to understand the different categories of houses surveyed. The results shows that majority of the participants (94%) fell into the house category which means the buildings are single family dwellings. 5% of the participants owned a town house, while only 0.5% of participants owned a unit and retirement village respectively. None of the respondent owns apartment buildings.

The fourth question required participants to indicate the number of bedrooms in their homes. The purpose of this question is to match the number of defects indicated by the participants to number of bedrooms. The result shows that majority (53%) of the participants occupy four bedroom houses, while 33.5% three bedrooms, 7.4% had five

or more bedrooms and 5.6% of the participants with two bedrooms. One bedroom occupants account for the lowest responses (0.5%). Participants were further asked to indicate the number of occupants in their homes. The result shows that 41.9% of participants had two occupants. Another 24.7% had four people living in their homes. 13% of participants had three and five or more people occupying their homes, while few participants (7.4%) indicated that they were the only occupants in their homes. Comparing these two questions, one could conclude that the buildings were moderately occupied (moderate density). Considering that the highest percentage of the new buildings had more than four bedrooms yet the highest percentage of building occupants was two.

The last question in the section covers the type of builders that built the homes. 62.8% of the participant's indicated that their houses were built by registered Master builders and 14.4% by certified builders. 8% of the respondents were owner-built, while 11% of respondent had their houses built by private developers. Only 4% of the respondent indicated that they do not know who and how their houses were built.

Defects Observed by Respondents

This section of the questionnaire required the research participants to indicate the types of defects that they observed when they took possession of their new homes. The objective of this question is to allow participants to identify from their own perspective which items were defective in their homes when they took possession. 43 common defects in residential homes were provided by the researcher in line with standard terms extracted from previous literature. The participants could also add more to the list if they had observed defects different from the ones provided in the questionnaire. A total of 81% of participants responded to this question. Meaning a significant percentage (81%) of participants had identified a defective item when they purchased their home. The remaining 19% could be said to be defect-free at the time they took possession of their homes.

On the whole the research participants confirmed observing 42 of the defects provided and also identified 13 additional defects. The 10 most occurring defects in the order of their frequencies are: uneven painting, nail pops, poor finish, flooring, door/window handles, kitchen units, cracks, toilet/WC, locks, and concreting. What may not be obvious from this result is the number of defects experienced by individual homeowners. For example a worst case situation was a total of 43 defects experienced by one of the homeowners. The homeowner attached the list of the defects with the questionnaire to support their opinion that their home builder under-performed. This particular homeowner had indicated that another builder was called in to rectify the defects, after three court cases with the original builder.

The nature of defects identified by the participants are in line with Auchterlounie's (2009) study that found that aesthetics and the finishing aspects of buildings are of greater importance to homeowners, because homeowners view the technical aspects as a 'given' as they are covered under the various regulations and building standards

Distribution of Defects by House Size

Table 1 shows the distribution of defects identified by the participants across 216 buildings. The purpose of this section is to determine the total number of defects in each property type. The defects were grouped into 4 categories: 0 - 5, 6 - 10, 11 - 15, and 16 - 20. A total number of 752 defects were identified across all 216 buildings surveyed from 2008 to 2011. The result show that four bedroom houses had the highest number of defects of between 0 - 5 defects, followed by three bedroom

houses. Four bedroom houses also recorded the highest in defects between 6 - 10 defects. From the analysis of the data by house size, it is clear that as the number of bedrooms in homes increase, so did the number of defects.

Table 1: Distribution of defects across 216 buildings

No. of Defects	Total no. of houses	1 Bdrm	2 Bdrm	3Bdrm	4 Bdrm	5 Bdrm & over
0 - 5	165	1	10	59	85	11
6 - 10	41	0	2	9	25	4
11 - 15	6	0	0	1	4	1
16 - 20	3	0	0	3	0	0
Totals	215	1	12	72	114	16

Extent of Defects

The research participants were asked to indicate on a five point Likert scale (with 1 being Very High and 5 being Very Low) the extent of defects they observed when they took possession of their new homes. The purpose of this question was to provide an alternative approach to defects observed by new homeowners. 82.8% of the participants responded to this question.

The result shows that all the 82.8% of the participants that responded to this question had identified some defects or quality failures which needed to be rectified at some point during occupation of their buildings. However, a significant number (54%) of the participants indicated that the defect they noticed when they took possession of their homes was very low. 14.4% indicated average defects, 7.9% low, 4.7% high and 1.9% very high defects respectively.

Though a significant number of the participants indicated very low defects, it is possible that the results may be different if suitably trained building inspectors had undertaken the inspection of the buildings after possession. Most of the participants experienced minor construction defects, but not all of these defects were dealt with efficiently. Many of the participants commented negatively about the quality of workmanship of their new homes which they had not identified during possession, but were finding it annoying as they lived in it.

CONCLUSION

The study has shown that the occurrence of defects at handover is evident in new residential buildings. The study collected information from homeowners and they have indicated very low defects. But in spite of this low number of defects, they were considered annoying and homeowners would prefer defect-free homes. 10 common defects were identified in the study. These include: uneven painting surfaces, nail pops, poor finishes, poor flooring, poorly fixed door and window handles, poorly installed kitchen units, building cracks, poorly fixed toilet/WC, locks and concreting. Overall a total of 55 common defects were identified from the 216 residential buildings studied.

Residential building construction requires creative and sustainable solutions that could transform current poor quality performance. One important measure that could help in accomplishing this goal is to establish an efficient and effective monitoring of defects during building production processes. Home builders need to keep records of their call backs in a manner that could permit positive contribution to the improvement of current and future performance. This will make it possible to establish a set of quality criteria that could be delivered consistently to homeowners.

These criteria would have as a basis an understanding of homeowner needs and expectations. The common defects identified relate largely to aesthetics and the finishing aspects of buildings.

ACKNOWLEDGEMENT

MEASUREMENT CONSTRUCTS TO EXPLORE INNOVATION DIFFUSION IN CONSTRUCTION

Timothy M. Rose[1] and Karen Manley

[1]*School of Civil Engineering and the Built Environment, Science and Engineering Faculty, Queensland University of Technology, Brisbane, Queensland, Australia.*

ABSTRACT

Although the drivers of innovation have been studied extensively in construction, greater attention is required on how innovation diffusion can be effectively assessed within this complex and interdependent project-based industry. The authors draw on a highly cited innovation diffusion model by Rogers (2006) and develop a tailored conceptual framework to guide future empirical work aimed at assessing innovation diffusion in construction. The conceptual framework developed and discussed in this paper supports a five-stage process model of innovation diffusion namely: 1) knowledge and idea generation, 2) persuasion and evaluation; 3) decision to adopt, 4) integration and implementation, and 5) confirmation. As its theoretical contribution, this paper proposes three critical measurements constructs which can be used to assess the effectiveness of the diffusion process. These measurement constructs comprise: 1) nature and introduction of an innovative idea, 2) organizational capacity to acquire, assimilate, transform and exploit an innovation, and 3) rates of innovation facilitation and adoption. The constructs are interpreted in the project-based context of the construction industry, extending the contribution of general management theorists. Research planned by the authors will test the validity and reliability of the constructs developed in this paper.

Keywords: construction projects, diffusion process, innovation.

INTRODUCTION

The study of construction innovation remains an important topic for researchers as innovation is recognized as an essential survival trait for construction organizations (Gambatese and Hallowell 2011). With input from research on how innovation can be maximized, construction organizations are placing greater strategic emphasis on purposefully managing innovation (Gann 2000). Despite increasing emphasis on how innovation can be maximized within and across construction organizations, challenges remain over the complexity of innovation diffusion in construction. This involves understanding how contextual variables influence the accumulation of innovation knowledge across project teams to evaluate the potential benefits of an innovative idea put forward. Indeed, guidance is scarce on the process of how construction organizations assess the potential of an innovation (Hartmann 2006a). These challenges partly stem from the unique nature of the construction innovation system, where there are high levels of interdependency concerning the innovation diffusion, requiring intensive interaction and collaboration between a wide range of functions for success (Bessant 2006; van der Panne et al. 2003).

[1] tm.rose@qut.edu.au

Thus, a construction organizations' ability to encourage the uptake of an innovative idea depends heavily on the nature of their external environment, in light of their internal capabilities. For example, the cultural attitudes of interrelated project organizations can have a significant impact if a proposed innovative idea is implemented in a construction project (Hartmann 2006b). Similarly, the temporary nature of construction teams makes it difficult to build the strong relationships often needed for the diffusion of innovative ideas. There is a large body of construction management literature advocating the need for improved supply chain integration for the benefit of project outcomes, including innovation supply-chain integration (London 2001; Gann and Salter 2000; Hinze 1994). Not only does the nature of the project production method lead to discontinuities across project relationships, it also introduces risk adversity when considering new ideas due to the limited previous dealings between project stakeholders. Established long-term relationships can have a major impact on the willingness to adopt an innovation (Bossink 2004). Despite this, there remain diffusion difficulties relating to a lack of ongoing accumulation of innovation knowledge across project organizations and from project to project, that can lead to unwillingness to consider innovative ideas for adoption.

For these reasons, in terms of theory, it is not advisable to use generalized innovation diffusion concepts for use in the project-based construction industry. As innovation is context specific, research and policy needs to be fit-for-purpose to suit the unique nature of project based firms (Blindenbach-Driessen and van den Ende 2006). Clear differences between project-based industries, such as construction and say, the manufacturing industry requires innovation models to be carefully contextualized and applied to suit different perspectives (Blindenbach-Driessen and Van den Ende 2010; Widén 2006). This paper responds to this need by developing a conceptual framework that proposes three critical measurements constructs to be used to inform the nature of the diffusion process in the context of a construction project.

Firstly, the research is contextualized, to define the process model for innovation diffusion and highlighting the stakeholder characteristics required for effective transfer of innovation knowledge on a construction project. This work draws from management literature on innovation diffusion with particular emphasis on the diffusion model originally developed by Everett Rogers in 1962. Although there has been many variations to Roger's diffusion process model (e.g. Wolfe 1994; Cooper and Zmud 1990) with greater or lesser graduations between stages, Roger's model is the most influential and frequently cited (Nutley et al. 2002). According to Larsen (2005), Rogers' innovation diffusion theory provides 'the most comprehensive and cogent presentation of the theory' (p.788). To date, according to Google scholar search engine, Rogers book "Diffusion of Innovations" has been cited over 39,000 times and is the seventh most widely read book concerning innovation in the world (Folkestad and Gonzalez 2010).

Secondly, measurement constructs to assess the effectiveness of the innovation diffusion process are proposed. The framework is presented in light of the prior conditions required for effective innovation idea generation and diffusion. The framework enables exploration of the characteristics of key construction industry stakeholder in the diffusion process. It is intended that this framework will be employed to improve understanding innovation diffusion on construction projects. The following section provides background information on innovation diffusion and

the associated process model, followed by a discussion of our conceptual framework incorporating our three-fold measurement constructs across the diffusion process.

INNOVATION DIFFUSION

The seminal author of innovation diffusion research, Everett Rogers, defines diffusion as 'the process by which an innovation is communicated through certain channels over time among the members of a social system' (Rogers 2003, p.5). A key element to this definition is the importance placed on understanding innovation diffusion as an action within a complex social system of key diffusion actors. This definition emphasizes the role played by communication, relationships and the decision making process involving acceptance or rejection across a social system.
Innovation diffusion research has a rich history, spanning more the 50 years of intense activity. The vast amount of innovation literature has led to many typologies of diffusion research focusing on the innovation process within a social system. Early research focused on the innovation adoption behavior of individuals that was criticized for being overly simplistic for interpreting organizational adoption behavior, resulting in a shift of focus towards the organization as the main unit of adoption (Nutley et al. 2002).

According to Wolfe (1994), innovation diffusion research can be split into three key typologies. These comprise: 1) Patterns of diffusion; where researchers have explored the patterns of uptake across potential adoptions and the unit of analysis of the innovation itself; 2) Organizational innovativeness: where researchers explore the determinants of innovativeness with organizations, where organizations are the level for analysis; and 3) Process theory; where researchers explore the processes organizations (and individuals) go through in adopting innovations; where the unit of analysis is the innovation process.

The type of diffusion model examined here fits the last category – process theory. There are a wide variety of staged process models proposed in the diffusion literature. However, it is argued there are significant overlaps between them (Wolfe 1994). There have also been more recent arguments over the simplistic nature of diffusion process models, with claims that innovation diffusion is a complex, unpredictable and 'messy' journey (e.g. Van de Ven et al. 1999). However, classic diffusion model supporters, including Rogers, responded to this criticism claiming a linear approach is an appropriate approximation of typical processes.

CONCEPTUAL FRAMEWORK

With this in mind, Rogers (2003) five-stage representation model of the innovation-decision process is adapted in the development of the conceptual framework proposed in this paper. Although Roger's innovation-decision process is a ubiquitous diffusion model in the general management literature, it appears to have only guided one previous study in the construction industry context (Larsen 2005). Figure 1 presents our conceptual framework.

Rogers (2003) argues the process of adoption occurs in the following stages:

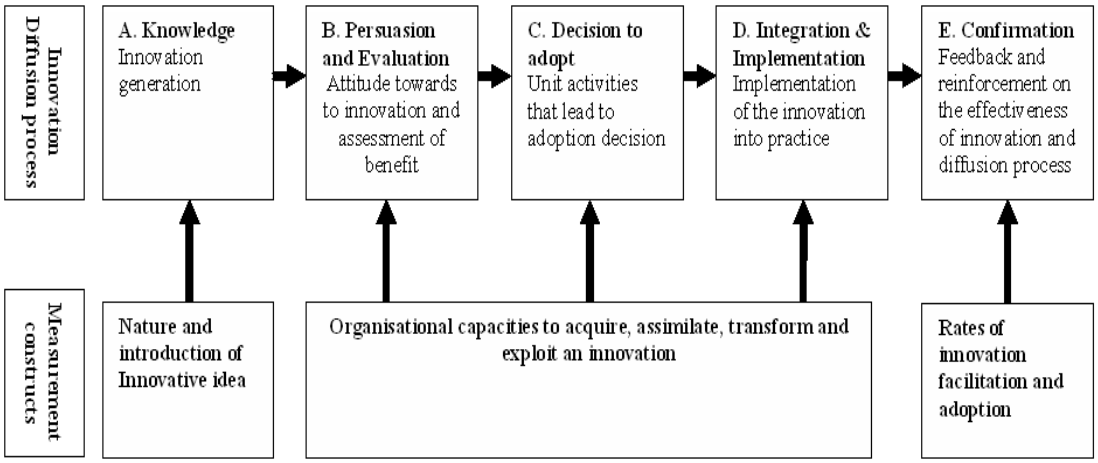
(A) Knowledge and innovation generation; where a potential adopter learns about the existence of an innovation and gains some understanding of it.
(B) Persuasion and Evaluation; where a favorable or unfavorable attitude towards an innovation is formed based on the organizational context.

(C) Decision; where activities are undertaken which lead to the adoption or rejection of an innovation.

(D) Integration and Implementation; where an innovation is implemented and/or integrated into a wider system on a larger scale.

(E) Confirmation; where information on the value of an adopted innovation and the innovation diffusion process is gathered potentially reinforcing effectiveness on a wider scale. From the innovation level, if an innovation is perceived to poorly perform or there are mixed messages of its performance, may result in the decision to reverse ongoing adoption, depending on the context.

Figure 1 Conceptual Framework



Adapted from Rogers (2003)

Rogers (2003) also argues the steps through each stage are influenced by the nature of the decision-making unit (e.g. the project team), prior conditions (such as previously standard practice and experience) and the communication channels across stakeholders. In the context of our framework, these influencing factors can be simply split into 1) the internal capability of a stakeholder organization to indentify, integrate and apply innovation in light of previous experience and practice; and 2) the inter-organizational relationships the influence the effectiveness of innovation knowledge sharing across organizational boundaries. Thus, these two elements shape our conceptual framework; influencing the effectiveness of the diffusion process.

Although Rogers's innovation-decision process theory provides a practical and generic process theory focusing on innovation communication channels as a central and critical element, it does not consider the specific context in which an innovation is diffused (Larsen 2005). Therefore, to adapt the model to the context of construction, we propose three measurements constructs namely: 1) nature and introduction of an innovative idea, 2) organizational capacity to acquire, assimilate, transform and exploit an innovation, and 3) rates of innovation facilitation and adoption.

Firstly, according to our framework 'the nature and introduction of an innovative idea' in the context of construction influences the ability of a potential adopter to learn about the existence of an innovation and gain an understanding of it. Drawing from the construction innovation literature, Winch (1998) argues new ideas stem from a 'top down' and 'bottom up' approach in construction projects: top down focuses on

a new idea adopted by organizational managers (proactive innovation), while bottom up ideas are as a result of problem-solving during a construction project in response to changing conditions that are learned later in the procurement process (reactive innovation). Also, the type of stakeholder influences the effectiveness of the knowledge and idea generation stage. Broadly, Rogers (2003) identifies the typologies of stakeholders to propose new ideas and adopt innovation can be split into five groups in order of their willingness to introduce and support the introduction of a new idea: 1) innovators, 2) early adopters, 3) early majority, 4) late majority, and 5) laggards. In assessing who are key introducers of new ideas on projects, emphasis is on 'innovator'-types, who are more willing to take on the risk of proposing a new idea for consideration, which will inform the subsequent decisions of potential adopters.
Once the new idea has been proposed, it's assessment during the persuasion and evaluation stage can be considered by the following measures (Rogers 2003): *Relative advantage*: the degree to which the innovation is perceived as better than the idea it supersedes; *Compatibility*: the degree to which the innovation is perceived as being consistent with existing values, past experiences, and needs of potential adopters; *Complexity*: the degree to which the innovation is perceived as difficult to understand and use; *Trialability*: the degree to which the innovation may be experimented with on a limited basis; and *Observability:* the degree to which the results of the innovation are visible to others. Additionally, *legitimacy* is also argued to be a driver in the persuasion and evaluation of an innovation. Thus, organizations' choice to adopt an innovation can be partly driven by institutional pressures associated with 'fads' rather than hard evidence to support their uptake (Abrahamson 1991).

In light of these theoretical concepts, knowledge and ideas generation across construction organizations is to be explored by identifying who introduces and supports the introduction of new ideas to projects, and how innovative ideas are put forward for consideration. A key feature of Rogers (2003) diffusion model is that, for most members of a social system, innovation adoption decisions depend heavily on the decisions of the other members of that system. Thus, stakeholder characteristics involved in the innovation process (and interactions between them in the organizational context) will determine early diffusion effectiveness (Nutley et al. 2002). Additionally, it is proposed this measurement construct should also identify at what stage innovative ideas are introduced (e.g. earlier during design and tender stages or informally throughout the delivery of a project).

It is useful for policy makers to understand the construction innovation diffusion process in light of its dynamic and interactive nature and the need for construction organizations to effectively communicate throughout the process for successful diffusion. In doing so, it is important to identify where new ideas originate from and how the development of such ideas can be encouraged.

Secondly, our framework proposes the persuasion and evaluation of an innovative idea for consideration, the decision to adopt, and innovation implementation is driven by internal organizational capacity across the construction network. Drawing from the construction innovation literature, knowledge flows in a construction project environment tend to be discrete and disordered causing difficulty for the organization to capture knowledge and learn from feedback (Gann 2000). Within this environment, innovation is driven by the learning capacity of organizations to identify, assimilate and exploit innovation knowledge for project specific tasks across a project network

(Gann 2001). Thus, the diffusion of an innovation (once an idea has been developed) is dependent on both the learning ability of the individual organization and the learning ability of all organizations within the project network.

This internal capacity of the organization (or decision-making unit) to evaluate, decide to adopt and then externally implement an innovation is argued to be assessed through absorptive capacity. Absorptive capacity forms a key construct in our framework as a measurement construct. This capacity refers to the learning process and ability of an organization (or inter-organizational form) to identify assimilate and exploit knowledge from its external environment (Cohen and Levinthal 1990). Zahra and George (2002) define four phases constituting absorptive capacity: acquisition, assimilation, transformation and exploitation. Acquisition refers to an organization's ability to locate, identify, evaluate and acquire external relevant knowledge to aid in the internal development. Assimilation refers to an organization's ability to understand external knowledge i.e. ability to classify and process external knowledge for internal use. Transformation refers to an organization's ability to combine newly acquired or assimilated knowledge with existing knowledge and adapt existing knowledge for new purposes. Finally, exploitation refers to an organization's capacity to take the knowledge that has been acquired and assimilated, and transform and apply it externally for indentified benefit. In the construction context, these four phases need to be understood in a project-based production environment.

Finally, once innovation is implemented, it is proposed feedback and reinforcement of the effectiveness of innovation diffusion is measured through innovation adoption activity. Innovation adoption activity can be measured by the number of construction organizations that had implemented or facilitated the implementation of innovation on construction projects. Additionally, innovation activity data will also indentify what sectors are the most active in implementing or facilitating the implementation of innovations - to provide feedback on innovation diffusion effectiveness. Although innovation activity is generally measured by innovation implementation according to the innovation implementer (e.g. ABS 2011), we propose the measure for construction innovation activity should include organizations that have facilitated the implementation of innovations. This is due to the team-based nature of construction project production (Dubois and Gadde 2002), where 'brokers' of innovation play a key role in implementation (Bessant and Rush 1995). By combining these constructs, this framework establishes a theoretical foundation for testing in fieldwork planned by the authors.

THE PLANNED EMPIRICAL STUDY

The authors, supported by both public and private sector industry partners, have been tasked to undertake a large-scale study of innovation diffusion in the Australian road construction industry, to be completed in 2013. The aim of this study will be to identify key inputs and outcome variables relating to innovative product diffusion, namely the nature of innovative idea generation, innovation activity difficulty and obstacles that restrain new product adoption. The study also aims to gather data relating to the organizational capacity to diffuse innovations on projects (including absorptive capacity) and examine the relationship between these variables towards innovation adoption. The study will contribute to the innovation literature and improve the understanding of the construction innovation diffusion process, guided by the conceptual framework developed in this paper.

CONCLUSION

The study of construction innovation is increasingly seen to require an understanding of the closely interconnected nature of the diffusion process. Thus, innovation process constructs need to be examined in a holistic manner and not in isolation to gain a more complete understanding of diffusion. This is partly due to emphasis placed on the interactive view of construction innovation that relies on the result of a team effort between a collective group of industry organizations. Thus, the focus of the process model developed here is to explore the effective integration of external knowledge sources – driven by the internal capacity of construction organizations to capture, integrate and use innovation knowledge for project benefit.

This paper contributes to understanding of innovation diffusion knowledge on construction projects, by developing a conceptual framework founded on existing diffusion process constructs from the general management literature. As guidance remains scarce on how to effectively assess innovation diffusion in specific construction contexts, the framework and proposed empirical study presented in this paper respond to this need. It is expected the framework presented here will help to reveal gaps in the knowledge flow process – from ideas generation through to implementation and confirmation - that impede the diffusion of innovation.

As a theoretical contribution, this paper proposes three critical measurements construct which can be used to inform the nature of a five-stage diffusion process. These measurement constructs comprise: 1) nature and introduction of an innovative idea, 2) organizational capacity to acquire, assimilate, transform and exploit an innovation, and 3) rates of innovation facilitation and adoption. Data obtained about these constructs in future empirical work will enable informed policy advice to effectively harness the power of knowledge networks, increasing innovation diffusion and improving project performance. The authors are planning to confirm and build upon the proposed framework and further define the critical relationships and actions required to promote innovation diffusion on projects. This empirical work is expected to assist in maximizing the potential for adoption of construction innovations in response to a growing need to deliver construction projects of increasing size and complexity.

REFLECTIVE PRACTICE: SCOPING ITS APPLICABILITY FOR SUCCESSFUL CONSTRUCTION PROJECT DELIVERY

Chamila Ramanayaka[1] and James Olabode Bamidele Rotimi[1]

[1]*Construction Management Programme, School of Engineering, Auckland University of Technology, Auckland 1142, New Zealand*

ABSTRACT

This paper reports on an on-going initiative to determine the applicability of reflective practice for successful construction project delivery. There are evidences to suggest that technical rationality approaches in construction projects sometimes fail to yield desired objectives. Selective inattention, reductionism, context independency and practitioner independency are identified as major aspects of ineffectiveness in technical rationality techniques. The aim of this initiative is to introduce reflective practice as an alternative to technical rationality approaches in construction project planning. The approach is based on the belief that the complexities of construction project planning and execution sometimes require strategies that are both creative and generative. Reflective practice offers a bridge between theory and practice through practitioner engagement in a learning process that allows reflection from three different dimensions: reflection in-action, on-action and for-action. The formalization of reflective practice for project planning is based on a systematic approach which enhances the ability to interpret the interconnection of different entities connected with project planning. The study discusses how a document analysis is used to find the applicability of reflective practice and strategies on past successful projects.

Keywords: reflective practice, strategies, technical rationality.

INTRODUCTION

There is the need for philosophical changes to fill gaps between academic solutions and practical issues. According to Schon (2001, p. 186) "professionally designed solutions to public problems have had unanticipated consequences, sometimes worse than the problem they were intended to solve". Further, Dias and Blockley (1995) explain that many engineering curricular describe most physical phenomena in terms of engineering science and mathematics which leads to scepticism and that those technical rationality (TR) approaches are inadequate to handle complex situations. Thus an alternative paradigm, 'reflective practice' (RP) was introduced by Schon (1992) for practitioners. Winch (2010) suggests that construction practitioners should be reflective practitioners that could apply disciplines holistically from the inception to the completion of construction projects. The current study aims at seeking the applicability of the RP

[1] cramanay@aut.ac.nz
[2] jrotimi@aut.ac.nz

paradigm as a complement to TR approaches in construction project delivery. It uses a preliminary analysis of information on Construction Manager of the Year Award (CMYA) winners in the UK to show the pertinence of RP in construction project planning. The latter part of the paper describes the future study that is designed to cope with the limitations of this preliminary analysis so that a comprehensive investigation into the appropriate paradigm for project execution can be undertaken.

TECHNICAL RATIONALITY AND REFLECTIVE PRACTICE

The following treatise describes the TR and RP paradigms using their characteristics, basis, models and techniques. The information is summarised in Table 1 in line with Dias and Blockley (1995).

TR seems characterised by 'selective inattention' providing solutions for problems which can be described through theoretical phenomena only. However, most social, political and culturally soft issues, which may be the ones that mostly influence construction project success, are very difficult to describe in terms of science or mathematics (Dias & Blockley, 1995). RP on the other hand is characterised by reflective interaction as opposed to selective inattention. Thus, by reflecting in-action and on-action, practitioners become encouraged to deal with problems through a learning process that comprise a high level of thoughtfulness (Schon, 1992).

Table 1-Comparison between TR and RP

Paradigm	**Technical rationality**	**Reflective practice**
Characteristics	Selective inattention	Reflective interaction
Basis	Science (Analytical, Reductionist, Context independent and Practitioner independent)	Systems (Synthetic, Holistic, Context independent and Practitioner dependent)
Models		
Grounding	Truth	Dependability
Specification	Precision	Appropriateness
Improved by	Calibration against world	Comparison with world
Techniques	Mathematics	Artificial intelligence

(Source: Dias & Blockley, 1995)

On the basis of these paradigms, Dias and Blockley (1995) explain that TR provides a reductionist approach to issues. Thus, TR inspires practitioners to provide answers by dividing the whole into parts. However, one may ask: can those separate parts replace or even explain the whole? For example human beings are able to talk and walk due to cooperation amongst the sub-holons that make up the body, but these sub-holons themselves do not have those abilities (Dias & Blockley, 1995). In construction, project success could be explained by the sub-holons of time, cost, quality etc. However, if one considers one dimension separately, projects may fail in other dimensions. Conversely holism, which is the basis for RP, emboldens practitioners to think about entities both as a whole and in parts (Dias & Blockley, 1995). This encourages project managers to have a global understanding of the effects of an action or decision on, not only one part of the project, but other parts as well. According to Rand (2000), this includes considerations for all project objectives in terms of cost, time and quality towards the achievement of successful project outcomes. Further, Rand (2000) opines that it is necessary to understand the basic behaviours of any project management environment before decision making. This limits the TR paradigm in its application because it is

both context and practitioner independent (Dias & Blockley, 1995). No doubt that construction project achievement (success or failure) is highly influenced by project managers and the team involved in its execution (Bourne, 2007). RP therefore finds relevance as it requires practitioners' artistry to tackle with real world problems (Dias & Blockley, 1995).

An examination of the nature of current planning techniques gives further credence to the limitations of TR approaches. Considering the trend for management tool development, we posit that some of these tools are sub-optimal and a complementary approach in the form of RP may provide significant benefits to construction practitioners. Table 2 provides information on the nature of TR in planning tools such as: Critical Path Method (CPM), Program Evaluation and Review Techniques (PERT), Critical Chain Planning Method (CCPM) and Earn Value Management (EVM). Specifically their nature is explained under TR deficiencies: Reductionism (R), Selective Inattention (SI), Context Independency (CI) and Practitioner Independency (PI).

Table 2: TR natures in current planning tools

	CPM/PERT
R	Managing time, quality and cost as separate sub-problems and violating other requirements when one sub-problem is addressed. Considering non-critical activities separately may cause them to happen in critical path later.
SI	People's attitudes such as 'student syndrome' cannot be formalized.
PI	Activity durations are based on probabilistic mathematical procedure. Practitioners are not encouraged to use their judgment and experience.
CI	Nature of the activity, construction pace and site conditions are not considered.
	CCPM
R	Quality considerations must be considered separately.
SI	Though constraint removal is stepped down, identifying constraints and taking decisions demand practical skills in-addition to engineering knowledge.
PI	Buffer calculations are dominated by probability based mathematics.
CI	50% duration from the sum of critical activities is added as the project buffer without considering actual risk levels.
	EVM
R	No way to count the whole effect of Cost and schedule variances.
SI	Difficult to find the optimum time for performance calculations based on theories.
PI	Variances are predicted from monitoring records, practitioners work as calculators.
CI	Predictions do not consider wavering progress in projects.

R - Reductionism **SI** - Selective Inattention **PI** - Practitioner Independency **CI** - Context Independency

Further, there are efforts to achieve success by facilitating decision making through models and generic algorithms. Those decision support models seem to address only selected issues (again a reductionist approach), hence sub-optimal. Underhill (1994) concludes that the reliability of computer programs to implement heuristic procedures is low, some occasionally provide correct solutions but with grossly sub-optimal results.

Based on the above treatise, the current study intends to proffer solutions in line with the philosophical change encouraged by Dias and Blockley (1995) and similar studies.

It is one aspect of a doctoral programme that seeks appropriate strategies for construction project planning.

RESEARCH METHODOLOGY

The study comprises a document search and analysis of archival information provided by the Chartered Institute of Building (CIOB), UK on Construction Manager of the Year Award (CMYA) winners. Archival analysis research strategy is a way of arranging and analysing archives and is suitable for the current inquiry due to three reasons: the researchers did not need to control actual events, the questioning type was based on 'what', and the study investigated past events (Yin, 2003).

The CIOB represents a whole range of construction professionals including but not limited to project managers, designers, developers, client organisations (CIOB, 2010). Qualitative information on winners of the Construction Manager of the Year Award (CMYA) was filtered through to determine common themes relating to two issues: 1/ what makes construction project implementation challenging (identification of problems) and 2/ what are the approaches that could help to overcome these challenges and achieve ultimate success (providing solutions). Awardees profiles were collected for the period from 2009 to 2011 and resulted in a total of 66 Construction Managers and 66 projects for the study.

NVIVO 9 software, a qualitative research tool for data sorting and analysis, was used for data sorting while analyses of the relevant information were done manually. The NVivo software required the creation of parent, child and sub nodes respectively to facilitate collation of similar themes within the archival information provided. Figure 1 gives a screen shot of the different nodes created and their arrangements for the study. The representation of the various nodes is explained later.

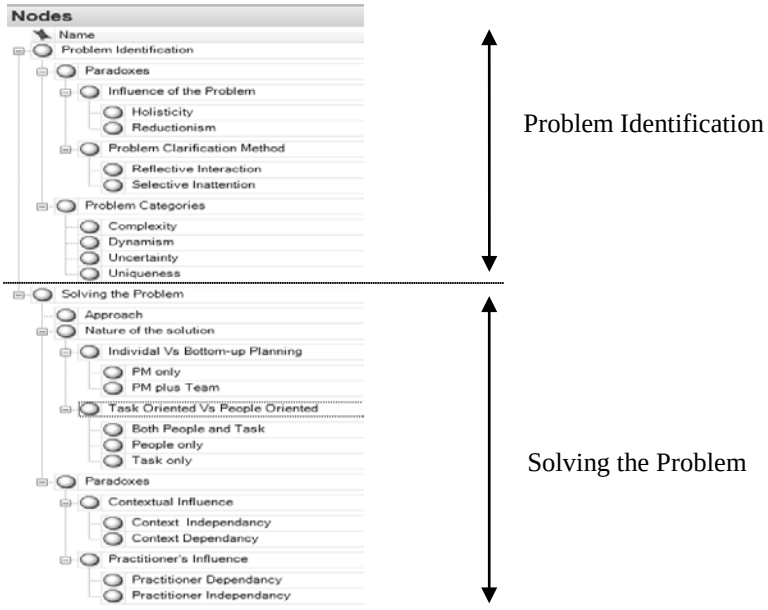

Figure 1: Arrangement of nodes in NVivo 9

RESEARCH FINDINGS

What make construction project implementation challenging?

The first aspect of the analysis was aimed at determining what made construction project implementation challenging. Archival information provided on the award winners (CMYA) was sorted using NVivo nodes. The parent node created was

'problem identification' and consisted of two child nodes, 'problem categories' and 'paradoxes'. The 'problem categories' child node was further divided into four sub-nodes: complexity (difficulty in grasping due to complication), dynamism (sudden changes to project activities), uncertainty (unpredictable/unexpected project events) and uniqueness (novel approaches to project performance). Similarly, the 'paradoxes' child node was divided into two sub-nodes named 'influence of the problem' (reductionism (R) versus holisticity (H)) and 'problem clarification method' (selective inattention (SI) versus reflective interaction (RI)). The following definitions explain the paradoxes.

SI - Problem could be explained by using engineering theory and historical data

RI - Problem could not be explained as a theoretical formation

R - Problem could not be considered separately (as a part only) without considering its interrelationship with other activities (as a whole)

H - Problem could be dealt with separately

Following the creation of nodes and sub-nodes, it was possible to determine the frequency of occurrence of each nodal theme within the archival information provided (CMYA award statements). The scope of NVivo software was limited to data sorting, thence manual interpretation was required to categorise issues under the different nodes and sub-nodes.

First, the project challenges/problems were categorised under complexity, dynamism, uncertainty and uniqueness. The frequency counts and percentage occurrences for each year are summarised in Table 3. From the table 3, it is observed that out of the 66 projects studied, only 5 projects (8%) had no project information that could be placed under the four sub-nodes and therefore unrelated. Of the remaining 92% of projects, both complexity and uncertainty generated the highest frequencies (67 and 61% respectively). Dynamism and uniqueness also provided challenges to project realisation within 36% and 17% respectively of the total projects studied.

Table 3: Characteristics of CMYA award winners' projects

Characteristics	2009	2010	2011	Total (%)
Complexity	15	15	14	44 (67%)
Dynamism	14	6	4	24 (36%)
Uncertainty	18	15	7	40 (61%)
Uniqueness	5	3	3	11 (17%)
Unrelated	2	2	1	5 (8%)

Considering the identified paradoxes of the study, the first paradox (reductionism versus holisticity) helps practitioners to identify if it is important to see issues both as a part and a whole. While the second paradox (selective inattention versus reflective interaction), would indicate the importance of problem clarification by using either theoretical concepts or reflection in and on action. In 66 projects, it was possible to identify 136 issues and solutions provided by the CMYA awardees. The summary is presented in Table 4.

From the 2nd to the 5th columns, the frequency counts of the two paradoxes depict the actual nature of problems in the industry. It seemed that major issues encountered as barriers for the CMYA project implementation could not be described through engineering theoretical formulations. Out of 136 issues, 132 issues (97%) seemed to be understood through reflective interaction. Only 3% of issues appeared to be clarified purely through engineering science. Regarding reductionism versus holisticity, 28% issues looked likely to be solved as separate problems without considering its

consequences on other activities. However, the majority of problems (72%) appeared to interrelate with succeeding and parallel activities.

Table 4: Project evaluation by paradoxes

Year	Problem				Solution			
	SI	RI	R	H	CI	CD	PI	PD
2011 (n=33)	0	33	6	27	0	33	0	33
2010 (n=56)	3	53	17	39	3	53	1	55
2009 (n=47)	1	46	15	32	1	46	1	46
Total (n=136)	4	132	38	98	4	132	2	134
As a % (n=136)	3	97	28	72	3	97	1.5	98.5

What are the approaches that can help to overcome challenges?

For the identified 136 issues, solutions provided were reviewed and sorted under the 'approach' node. To overcome challenges and hence to achieve success, the award statements mentioned project strategies as the construction managers' approach. Considering that strategies aim at coping with messy situations, the term 'strategy' could be defined as 'that which assists the construction manager in decision making and problem solving within the complexities, uncertainties, dynamisms and uniqueness of the construction process'.Then, strategies were sorted under two paradoxes: Context Independency (CI) versus Context Dependency (CD) and Practitioner Independency (PI) versus Practitioner Dependency (PD). The following definitions clarify the paradoxes.

CD - Solution created is specific to the project context
CI - Solution created can be applied generally to any project context
PD- Solution created had an influence from practitioner's creativity and experience
PI - Solution was straightforward and based on theoretical knowledge.

The resulting frequency count is shown in the last four columns of table 4. On observation of the result, one could see that context dependency and practitioner independency (97% and 98.5% respectively) dominated in strategic solutions over context independency and practitioner independency (3% and 1.5% respectively). The result shows that it is important to include contextual and practitioners' effects in a reliable planning approach.

After that, the CMYA award statements were reviewed for the natures of strategies. First, strategies were categorized under the controversy of 'individual decision making' (project manager only) versus 'bottom-up planning' (project manager with the team). Individual decision making is a characteristic of the TR paradigm as opposed to bottom-up planning in the RP paradigm (Dias, 2002). Here, the 'team' means every stakeholder except the project manager, including client, design team, sub-contractors and specialists. 'Bottom-up planning' is not to be confused with stakeholders' positions, but it describes the nature of problem solving: getting strategic direction from the team and developing them by the project manager. According to provided information on 136 strategies, in 71 strategic solutions (52%), project managers seemed to craft strategies by themselves and in 65 incidents (48%), they demanded suggestions from their teams.

The second controversy is relevant to strategy focus. The RP focus is on people and the TR focuses on tasks (Dias, 2002). Out of 66 CMYA projects, 55 projects (83%) were implemented by using the combined strategies of people and task oriented. From the

rest, 9 projects (14%) mentioned about task oriented strategies only and 2 projects (3%) used people oriented strategies only.

DISCUSSION

Investigation on the paradoxes shows that it is necessary to develop approaches having feasibility to consider contextual backgrounds specific to project environments. The result further encourages practitioners to identify problems based on reflective interaction in addition to theoretical knowledge. The CMYA descriptions showed that holistic view can be applied to construction projects in different ways. The holism of the ultimate end result means that projects should achieve considerable outputs in all dimensions. However, that does not mean that achieving all objectives in each and every activity is a must. It can be seen as a reductionist attempt since an activity is considered separately from other activities. For example, changes to the construction method of an activity may cause program gain but less profit margin or losses. However, the overall effect may still be worthy when consequences are counted on interconnected activities. Further, project managers may recover any profit deficit by using value adding techniques for other activities. Not only in tasks, but also even in stakeholder responsibilities, holistic thinking seems to be important. For example, the award statements mentioned considerable cost and time variations in projects. According to contractual obligations, contractors could claim those variations from clients. However, in those situations, CMYA awardees used value adding strategies to cut the total cost and give resulting benefits to clients to ensure that projects could be run within the same budget. That kind of thinking can result in indirect advantages such as ensuring smooth cash flow, winning clients' commitments and getting future business opportunities to work with the same client.

Table 5: Relationship between TR and RP in construction project activities

Activity	RP		TR		Relationship
	Reflective interaction	RP technique	Focus of attention	Scientific/ Mathematical technique	
Selecting construction materials	Ease of construction, availability, suppliers' certainty, discounts, credit facilities	Experience, technical skills, information handling skills, etc.	Quality level of materials	Referring standards of the materials, testing, etc.	TR becomes the context of RP Calculation of activity duration	Working space, material supply, plant capacity, uncertainties, etc.	Experience, technical skills, conceptual skills, etc.	Measuring quantities of work, relationship between number of hours, quantity and hourly output	Basic mathematics such as addition, multification and division	RP is a precondition for TR 
Choice of a construction method	Noise, vibration, interruption, space requirements, etc.	Experience, technical skills, communication skills, etc.	Cost optimization	Cost-benefit analysis	RP is a constraint for TR Rescheduling	Finding causes of overruns, getting corrective actions, etc.	Experience, conceptual skills, information handling skills	Referring to progress records such as grant charts.	MS Project	TR is a precondition for RP 
Further, the result shows that strategic solutions have natures from both paradigms. Dias and Blockley (1995) say that the two paradigms are not independent, but are related in three ways: TR becomes the context of RP, RP is a pre-condition for TR and RP is a constraint to TR. Table 5 shows these three relationships plus an additional relationship showing that TR becomes a precondition for RP. One should note that the relationships depend on practitioner's behavioural sequences. For example, if a practitioner pre-uses CPM data and equations to find out issues in the programme to

create solutions, TR can be considered as a pre-condition for RP. However, if that practitioner predicts possible consequences prior to the occurrence and thence use CPM to make revised program RP becomes a precondition for TR.

Although strategies and both the TR and RP paradigms were mentioned as the causes of successful project implementations, it was difficult to quantify their effect on project implementation. The limitation suggests further studies, which is planned to be progressed under the larger doctoral study that this paper is based on. Influences from strategies and the paradigms are to be investigated through hypotheses verification by using a questionnaire as the research strategy. If correlations are considerable then the study will further focus on creating strategy models for construction project planning. For the proposed study, the participants will be the construction excellence award winners selected by the New Zealand Institute of Building (NZIOB) from 2001 to 2011.

CONCLUSION

Construction projects report cost and time overruns, quality failures and owner dissatisfactions regularly. This study shows that current planning tools are characterised by TR dominated natures such as reductionism, selective inattention, context independency and practitioner independency. The analysis of information on Construction Manager of the Year awards shows that a combination of both RP and TR paradigms could ensure project success. Strategies appear to be the approach to practice this emergent paradigm. Further, the study recognizes that it is important to make decisions both in individual and group basis. Planning tools like CPM and PERT consider only tasks, but the study shows that both tasks and people must be the basis of a reliable planning approach. The current study investigation could not quantify the effects (as high or low) of strategies and the two paradigms. Therefore further studies will focus on this limitation as well as strategy modelling to help the industry to achieve project deliverables in a more reliable manner.

SHOULD COST MODELLING – A NEW DESIGN DEVELOPMENT MANIFESTO

Barbara Chomicka[1]

EC Harris LLP, Arcadis Company, 34 York Way, London N1 9AB

ABSTRACT

The traditional approach to cost modelling in the UK construction industry consists of a bottom-up cost estimate based on the proposed design, followed by a value engineering exercise to bring that cost estimate closer to a pre-set development budget. As a result of this approach, the design team is unaware of the pre-set development budget constraints, which frequently results in a costly re-design process. This traditional, reactive approach to cost modelling and design development is progressively being replaced by a proactive, top-down form of cost analysis that influences the entire development process. The "Should Cost Model" precedes the design, allowing the overall cost plan to progress in parallel with the design development and ensuring that resources are allocated where they generate greatest value. By establishing key commercial success criteria and efficiency ratios for all asset components, this new tailor-made cost model informs the budget for each asset component. Should Cost Modelling has the potential to revolutionise construction design methodologies by establishing a basis for design and future design variances to be monitored against.

Keywords: Design Development, Should Cost Modelling.

INTRODUCTION

The principles of contemporary cost management systems in the UK construction industry are deemed by researchers to be very similar to the ones that have been used since the mid-1920s (Johnson and Kaplan 1987). These principles centre on cost consultants pricing architects' design, i.e., establishing how much the project 'will cost'. This approach yields a bottom-up cost estimate based on design; an outcome of design approach (Ballard 2006). Such cost estimates are usually greater than the client is able to, or should, pay, and clients who reject them typically then instigate a value engineering exercise to bring that cost estimate in line with their pre-set development budget. Thus begins an iterative process of re-design and costing, ending when there is an acceptable fit. This cycle of design and estimation -- or re-design and subsequent cost estimate revision -- is nowadays considered to be inefficient, reducing the value that can be profitably delivered to construction clients (Theodorakopoulos 2009). Moreover, this traditional, backward-looking, 'will cost' methodology has become inappropriate for managerial purposes, in the post-crash commercial

[1] bchomicka@gmail.com

landscape, because 'will cost' information tends to be too late, too aggregated and too distorted to be relevant for project planning and control (Johnson and Kaplan 1987).

Some recent Finnish academic literature has proposed that designing to cost targets – Target Costing - maximises value for construction industry clients. Target costing is in widespread use in Finland (Pennanen, et al. 2011).

Similar to the Finnish Target Costing method, EC Harris LLP, a leading global Built Asset Consultancy, has developed an alternative to 'will cost' management methodology both in the UK and internationally. This alternative maximises clients' Return on Investment (ROI) on built assets. It is a specialised form of cost analysis which is essentially a Should Cost Model, tailored to the distinct circumstances involved in construction design and delivery processes, and focused on ensuring that cost decisions are linked to income and value. Should Cost Modelling is a design steering tool that enables monitoring of, and challenges to, the design development process, ultimately maximising value to the client.

RESEARCH METHODOLOGY

The starting points in this research were cost modelling issues faced by the wider construction industry in the UK, and her professional experience with an innovative solution. The primary purpose of this research was the documentation and interpretation of the Should Cost Modelling methodology for the advancement of knowledge, and included a review of three confidential case studies. The results of this research describe a unique EC Harris LLP design-steering method, which allows management of the design process toward a set value target for the project.

The following research methods have been carefully selected for this study: literature review and case studies analysis. This study has two phases: 1) an investigation of existing research into design steering; and 2) exploration and interpretation of three case studies. In phase one, the literature review focused on research in the field of cost and design management, with particular emphasis on literature concerned with design steering, lean costing and target costing. The literature review was chosen as the starting point of this research and the intention was to establish subject background, learn from other research, formulate research problems, synthesise the work of others, and compare with other research strategies (Ridley 2008). In phase two, the findings of the literature review were compared with and used to analyse three confidential case studies and the Should Cost Modelling methodology practised by EC Harris LLP.

SHOULD COST MODELLING BACKGROUND

One of the first known references to the Should Cost method is found in the US Army Materiel Command (US Army Procurement Research Office) Should Cost Analysis Guide (1972). This Guide believes that Should Cost began as a civilian application, with a large, nationwide consumer goods chain applying the method to the suppliers of its appliances, hard goods, and other items. The method has been successful in obtaining consistently low prices from the suppliers (USAMC 1972). Based on this observation, in 1967 the US Department of Defence, following runaway cost overruns on many military programs that generated severe criticism in the public press and continual debate in the Congress, implemented a programme to aggressively apply and expand the Should Cost methodology on major procurement programmes. The

results proved that the Should Cost approach brings significant cost savings and long-term management improvements (USAMC 1972).

At present, Should Cost is used to describe a variety of approaches to pricing. The National Society of Cost Estimating (1986) defines it thus: 'Should Cost is a concept of contract pricing (…) to identify uneconomical or inefficient practices in the contractor's management and operations, to quantify the findings in terms of their impact on cost, and to develop a realistic price objective for negotiations (…)'. According to Sourcing Innovation (2010), '[Should Cost] knowledge is critical for identifying mis-priced parts, parts with high mark-ups, parts improperly sourced from vendors who are not suited to produce the part, and overly complex parts in need of simplification and re-engineering' . In line with these various definitions and applications, there are various recognised approaches to Should Cost modelling, including Should Cost Modelling based on industry averages, sequential, bottom-up strategies, top-down strategies, cooperation models, negotiation models and combined negotiation and cooperation models (iprocurement 2011).

The EC Harris LLP proposal for the construction industry is a top-down form of cost analysis based on benchmark data. The aim of the proposed Should Cost Modelling is to provide an initial indication of the current out-turn costs of the development that has been derived from benchmarked data from final accounts and priced cost plans (ECH 2011). Should Cost Modelling is used by EC Harris LLP as a design management tool for reducing the cost of the product and identification and protection of value. This approach is based on Tanaka's (1993) proposition that the cost of the product is considered to be an important strategic factor that should be decided by management, not designers. Should Cost Modelling is based on a desired functionality and performance instead of on proposed design.

SHOULD COST MODELLING METHODOLOGY

The Should Cost Modelling methodology provides a robust platform and commercial strategy to deliver predictability of outcomes at all stages of the design and construction. It revolves around the establishment of a robust commercial platform (baseline) and commercial success criteria for delivery of projects and programmes of work, at the earliest opportunity. The Should Cost Modelling approach allows the overall cost plan to progress in parallel with design, as well as to ensure that resources are allocated where they generate the most value.

Should Cost modelling permits:

- creation of a cost model to reflect the minimum achievable cost-to-deliver products that meet the brief(s),
- identification of extra costs for specific site conditions and constraints
- all enhanced design over the base to be approved on a business case basis
- establishment of key efficiency ratios for all asset components
- establishment of the basis against which future design variances can be monitored
- identification of value management opportunities to meet or better the should cost basis
- identification of risks and opportunities
- review and sign off of spend / design decisions with the client

- development of an informed budget for each asset component

EC Harris LLP's Should Cost Modelling methodology has three distinct steps shown in the Table 1 below.

Step	Question	Solution
1	How much would the optimum product cost, given perfect conditions?	The creation of a Zero Cost Model – a theoretical cost model with no external influences or abnormalities
2	How much should this product cost given all known conditions?	The creation of a Should Cost Model – a theoretical cost model overlaid with all known external influences
3	Testing of the Cost Estimate against the Should Cost, thus challenging and maximising value.	The creation of a Cost Estimate – a cost estimate which includes value and income driven decisions

Table 1 – Should Cost Modelling methodology

The Should Cost Modelling adds value to the client by making transparent the differences between stages: e.g., why the delivery of Zero Cost optimum product is not possible or desirable, why the Cost Estimate differs from the Should Cost, and what value and income decisions were made to arrive at the Cost Estimate.

For example, in line with the initial Zero Cost Model, there might be an allowance of £500 per m^2 for the cladding, but the Should Cost Model would take into consideration a planning requirement for an enhanced façade, and increase the cladding allowance to £600 per m^2. The resulting final Cost Estimate could also contain a further allowance of £100 per m^2 for special cladding to appeal to a certain type of tenant. The Should Cost Methodology transparently identifies – and more importantly, *explains* – these differences, arming the client with the right information at the right time to facilitate decision-making. It also informs the basis of the design (client's brief) and the design team's development of detailed design proposals.

From a cost management perspective, the main difference between Should Cost Modelling and traditional cost-estimating is that Zero Cost and Should Cost allow the client and his teams to understand the basis of the Cost Estimate. It also allows for project-specific circumstances (project abnormalities) to be incorporated into the ideal (Zero) position resulting in realistic (Should) position. This in turn allows the client to judge emerging design proposals and associated cost estimates on their objective merits to see if they would add value to the project.

THE CREATION OF A ZERO COST MODEL

The Efficiency Database of EC Harris LLP, one of the largest cost consultancies in the world, provides valuable benchmarking data (such as value, function, time, and design and cost efficiency) from every project. This data creates the starting point for project cost estimation - an ideal Zero Cost Model. The creation of a Zero Cost Model follows a three step process, shown in Table 2 below.

Step 1	Data stored in the efficiency databases informs the benchmark cost model.
Step 2	This data is updated for each cost model, taking into consideration the optimum parameters for its particular function (typically consisting of commercial metrics, energy performance, project performance, variance to statutory benchmarks).
Step 3	This data is tweaked to create the optimum product available. Taking the example of a commercial office building, the likely functional efficiencies that would be transformed to optimum would be the nett to gross ratio, façade cost/m^2, programme/m^2 built, MEP cost vs. occupancy density, reception costs vs. reception area, riser/plant areas, preliminaries/area, wall-to-floor ratio, glass-to-solid ratio, preliminaries/week, WC costs vs. occupied area, cost of façade vs. wall to floor ratio, BREEAM/LEED ratings, cost/per m^2 floor plate and many other aspects of the development.

Table 2 – Zero Cost Modelling sequence.

The key cost influencing factors, such as architectural intent, procurement and buildability are not included in the Zero Cost Model; only the most efficient design for its particular function is allowed for.

Once the above three steps have been completed the end result is a Zero Cost Model for a hypothetical building, based on must-have, extreme functional efficiencies and no external influences (such as shape, size, planning, rights of light, site constraints or existing conditions). The Zero Cost Model is therefore not an estimate per se, but the optimum outcome for a project if all influencing conditions were perfect.

THE CREATION OF A SHOULD COST MODEL

To create a 'live' cost model, the Zero Cost Model has to be overlaid with project-specific details and circumstances. This exercise usually involves updating cost information with inefficiencies driven by the site constraints, client brief, commercial business case, budget, design criteria, functional efficiencies, pricing levels, construction, statutory implications and any other known influences on the end product. Architectural intent, buildability issues and selected procurement strategy are taken into account at this stage. The end result of this exercise is a Should Cost Model detailing how much a particular building *should* cost, based on all external circumstances.

THE CREATION OF A COST MODEL

The beginning of the design development process also marks the start of the evolution of the Should Cost Model towards a Cost Estimate. At this stage the value of the Should Cost Model becomes apparent, as the subsequent estimates are constantly evaluated against the model's development baseline. As the design progresses, this comparison exposes inefficiencies or deviations from the Should Cost Model, and allows assessment of their impact on and value-add to the project.

In parallel with the evolution of the design, the original Should Cost Model is updated to reflect other essential project activities, such as market testing or the quantification of risks. All these activities feed into the cost estimate as part of the estimate testing cycle against the Should Cost Model until the actual Cost Model (project cost estimate) is completed.

 ISBN: 978-1-84219-840-7 .

THE VALUE OF SHOULD COST METHODOLOGY - REVIEW OF CASE STUDIES

Three case studies were used in this research – two confidential large, complex mixed-use schemes located in the UK (£4bn and £411m) and one confidential project located in Middle East (£undisclosed). In each case the Concept Design Order of Cost Estimate (Cost Model prepared at RIBA Stage C) was prepared using Should Cost Modelling methodology. The estimate was prepared on the basis of the building areas assumed by the architect within their Concept Design submissions. Composite rates per m^2 of built area were generated from EC Harris LLP's in-house database system, which provides final costs on all projects that EC Harris LLP has delivered in a particular region. All rates were amended to reflect current market conditions (e.g., commodity prices and labour markets) which are tracked by the EC Harris LLP research team on an ongoing basis. Where information was not available, lump sum allowances were made and subsequently refined. The focus of the Concept Design Order of Cost Estimate was to provide an initial indication of out-turn cost on the development that has been benchmarked against the final accounts of previous and similar projects.

In all three case studies, the Should Cost Model identifies targets that have to be achieved to maximise return on investment. This resulted in, for example, additional extra over-costs associated with the residential specification uplift and the façade uplifts called for within the clients' brief. The Should Cost Model also identified key components that require review in structured workshops to ensure that the approach of 'design-to-budget' is maintained (e.g., basement and car parking, lighting options, ratio of gross to nett lettable floor areas, external landscaping, façade specifications, LEED and environmental strategy review, MEP strategy review, interior options or traffic study review). The project teams were provided with a clear understanding of the cost to develop the scheme and the model informed the setting of the client's brief.

The design 'steering' provided by the Should Cost Model allows the design team to ensure that the project costs either equal or better the budget (all three case studies are now at RIBA Stages C+ to E). The design teams involved in the case studies recognise that there are many possible design solutions for each project definition, resulting in a variety of building costs.

CONCLUSIONS

The Should Cost Modelling concept is already in use by EC Harris in the construction industry in the UK and internationally, with encouraging results. In the three case studies reviewed, this methodology provided design steering and helped mutual understanding among designers, cost consultants and clients, enabling achievement of target costs and purposed value for the clients. The main limitation to the wider adoption of top-down cost management methodology in the UK construction industry such as Should Cost Modelling seems to be the cultural change required to replace the entrenched 'will cost' approach. As observed in Finland, where a form of top-down costing methodology (Target Costing) has been used since the 1980s, architects initially resisted the new approach, thinking that the design is "right" in and of itself and that any challenge and/or change to a proposed solution due to set cost targets was "wrong". But in 2011, Finish researchers reported that most Finnish architects

now require well-analysed target cost information before commencing design work, proving that the top-down approach also benefits the design process (Pennanen, et al. 2011).

Broadening the use of this methodology in the UK would probably require incorporation of the Should Cost Methodology into the RIBA's Plan of Work, with the Zero Cost Model and Should Cost Model written into the detailed description of project stages as exemplified in Table 3 below.

RIBA Stage	Description and activities
Stage B	• Development of initial statement of requirements into the Design Brief, by or on behalf of the client, confirming key requirements and constraints. • Identification of procurement method, procedures, organisational structure and range of consultants to be engaged for the project. • **Output: The creation of a Zero Cost Model**
Stage C	• Implementation of Design Brief and preparation of additional data. • Preparation of Concept Design including outline proposals for structural and building services systems, outline specifications. • **Output: The creation of a Should Cost Model**
Stage D	• Development of concept design to include structural and building services systems, updated outline specifications. • Completion of Project Brief. • **Output: Cost Estimate**

Table 3 – Should Cost Methodology incorporated into RIBA Plan of Work. Based on RIBA Plan of Work (2008)

The findings of the case studies reviewed suggest that greater transparency on goals, processes and information models of clients is needed to support the commitment of design teams to Should Cost driven design processes. A valuable area for future research is therefore cost model design steering and design-to-cost targets.

ACKNOWLEDGEMENTS

UNDERSTANDING INNOVATION MANAGEMENT IN THE CONSTRUCTION INDUSTRY

Ayda Abadi[1] and Peter Fenn[2]

[1,2]*Mechanical, Aerospace and Civil Engineering School, University of Manchester, Manchester M13 9PL, UK*

ABSTRACT

There has been a long history of criticising the construction industry for its lack of innovation as a source of competitive advantage. However, some recent literature argues that the problem is not that there has been no innovation indeed the industry is a source of new ideas. Through a literature review it was found that the problem with managing innovation in construction has its roots in misconception of innovation. Despite many attempts to develop a model to understand the innovation process in the construction industry, no one model adequately addresses all the need of the process of innovation at an organisational and particularly project level context. In this critical review, the literature on innovation management in the construction industry is reviewed with a view to inject a fresh perspective of the problem. A case is made for the need for deep attention to strategic management as the foundation for innovation in pursuit of competitive advantage and how innovation as a part of strategic thinking of an organisation could motivate participants involved in construction projects to innovate.

Keywords: construction industry, innovation management, strategy.

INTRODUCTION

The low level of innovation within the construction industry has been a source of discussion between scholars. Many researchers considered the construction industry as an old and backward industry (Woudhuysen and Abley 2004) and criticised it for lack of innovation. However, few authors argued that the image of the industry as lacking innovation seems unfair (Ozorhon et al. 2010) and the industry is "a source of lively new ideas" (Winch 1998). On the other hand, the problem is the rate of innovation which lags behind. Innovation has been long recognised as a source of competitive advantage (Ozorhon et al. 2010, Stewart and Fenn 2006, Thomson 2006, Porter 1998). It is generally regarded as a way to increase productivity and quality in the construction industry (Barrett and Sexton 2006). Therefore the wisdom of low rate of innovation could justify the need for improvement of construction project performance in terms of quality and product functionality. Through this review, it was found that there is lack of research on strategic approach to innovation in the construction industry.

[1] ayda.abadi@postgrad.manchester.ac.uk

This paper reviews the construction innovation literature, and examines implementation of innovation theories in construction. This paper discussion is organised in three sections. Firstly, trend in research on construction innovation are traced from three most highlighted view of construction innovation. Secondly, the importance of competitive advantage approach is highlighted. Finally, this review calls for limitation on strategic thinking as a motivation for innovation and the importance of client's role in stimulating the players involved in the construction industry to innovate.

TRENDS IN RESEARCH ON CONSTRUCTION INNOVATION

A review of innovation concept within the construction industry

"Ideas are intangible assets locked in human minds taken to mean the starting point for innovation" (Kim 1999, Barrett and Sexton 2006). Intangible activities are not simple to manage even in an ideal organisation. The process of bringing ideas into practice called 'innovation' (Robinson Fayek et al. 2008). Innovation in general term is defined as a process of adapting/adopting new knowledge into new products, processes or services (Johnson et al. 2008, Ozorhon et al. 2010). In addition, it is regarded as a complex and multidimensional process and totally people-centred process. It is mainly because of complexity in behavioural and cultural change within an organisation which is much difficult aspect of innovation than hardware amendment (Rothwell 1992). There is still no precise prescription or recipe for successful innovation and no one model can adequately address all the needs of the process of innovation whatever the context (organisational, project-based industries) (Thomson 2006, Tatum 1984).

Taking these explanations into account, there is no generally-accepted definition on innovation in the Construction Industry. Scholars have different views on this concept. The context of construction innovation has been discussed in different categories depending on the level of focus from where the research stems for example material or method. The similarity and often confusion in practice of the terms *invention*, *change* and *problem solving* have been also discussed by many authors and distinguishes made from innovation i.e. (Tatum 1987, Slaughter 1998, Johnson et al. 2008). Barrett and Sexton (2006) by studying seven small construction firms concluded that practitioners define successful innovation as: "the effective generation and implementation of a new idea, which enhances the overall organisational performance". Although, the generalizability of this concept has not been confirmed.
Scanning the literature, innovation in the construction industry mainly arises from three domains: Product, process and organisation. Moreover, many discussions have been made based on three main categories: 1) Its typology 2) An institutional viewpoint i.e. (Latham 1994, Fairclough 2002, Egan 1998) 3) An organisational viewpoint (i.e. top-down innovation and bottom-up innovation)

Typology viewpoint

The example of innovation typologies is Slaughter (1998) who has provided a set of models of construction innovation to what she believes reflect the nature of the construction industry and activities of specific construction companies. The proposed models are incremental and radical innovations, modular and architectural innovations, and system innovation. She argues that much of the research concerning innovation within construction is based on examples of the manufacturing of products for the industry. Consequently, it remains a failure to assess innovation within the

context of construction as a mode of production. Even although the products produced are for construction, the process of innovation tied to the principles and production methods of manufacturing. It could be argued that the interaction of innovation within the context of the construction environment is neglected.

Institutional viewpoint

Another perspective of innovation within the construction industry is observed at institutional level. In the UK, the improvement of construction innovation has been set as a government agenda for example the Egan report titled 'Rethinking Construction' published in 1998 to address the wider competitive problems followed by the Fairclough report in 2002. As opposed to the Egan report, Winch (2006) states that the approach tends to be process oriented and ignores the product, particularly the way in which it generates value for client. However, the Fairclough report with its different approach focuses on university sector and the construction industry reveals the poor level of R&D and gives evidence that construction industry and university sector have been poorly coupled. It could be argued that the attempts in institutional viewpoint of construction innovation highlights the typical characteristics of the industry such as its immobility, complexity, durability , costliness and high risk of failure as a barrier to innovation. Although the institutional view point of innovation is essential, it is necessary that to increase the focus on more practical level of construction innovation.

Organisational viewpoint

The organisational viewpoint of construction innovation exists to examine the practical role of organisation and firms within innovation process. A few authors raised the point in hierarchical approach (top-down and bottom-up) to examine the challenges and opportunities to stimulate implementation of construction innovation (Winch 1998, Slaughter 2000). In addition, other related research area were also discussed including identification of effect of organisation environment with firm size on innovation management (Sexton and Barrett 2003); study of organisational culture and structure in decision-making and implementing of innovation (Nam and Tatum 1997) and finally investigation of barriers and factors to innovation by comparison to manufacturing (Van de Ven et al. 2000).

CONSTRUCTION INNOVATION IN PRACTICE

Understanding the realities of innovation within construction projects requires understanding both nature and variation of innovation (Thomson 2006). It has been stated that within the context of the construction *organisation,* it is possible to discuss innovation as existing similar terms whereas using *product* and *process* term within construction *project* context is not easy. Thomson (2006) mentions that the traditional understanding of *product* innovation is that it is product led. This is apparent in manufacturing firms and is evident within context of construction *organisations*. However, it becomes inappropriate with regard to the construction project. This is because of the typical characteristics of construction projects. The Construction industry is mainly a site operation and does not have the advantage of production process and mass-production system. The high level of product complexity and failure risk creates the need for various specialised professionals, which results in a fragmented environment. The product in the construction industry is novel with separated product design function and production. Moreover, the nature of construction products is costly with high level of responsibility involved, which leads

to discouraging the implementation of trial-and-error as a main driver of innovation. A construction project is by comparison client led, in that its demand stems from specific need identified to the project team by the client (Salter and Gann 2003) whereas a construction organisation can peruse a product innovation through its presentation to market in a speculative manner (i.e. a type of housing package), the construction project due to its nature remains reactive to the needs of the client (Thomson 2006).This changes the dynamics of our understanding behind the concept of product and makes it a difficult term to use when referring to the *end product* of the construction project. In addition to this difficulty, the uniqueness of each project must be considered. Although they are unique they do not necessarily represent an innovation either during production or in its end state.

Barrett and Sexton (2006) discuss the context of innovation in two schools of thought on what drives innovation: the 'market-based' view of innovation and the 'resource-based' view of innovation. They argue that construction innovation actively is stimulated by changing in clients need and unpredictable project-specific conditions. Depending on the mode of external environment whether it is enabling or constraining the client relationship become either value-oriented or cost-oriented.

The Process of innovation could be broadly categorised as rational school and behavioural school. The rational school of innovation considers innovation as a linear process, which has been widely criticized for not considering the dynamic environment and uncertainties within the project environment (Barrett and Sexton 2006). The behavioural school of thought couples the innovation process with the ambiguities and uncertainties of organisational reality. The process of innovation in project-based firms is described as mainly behavioural. This illustrates the gap between current performance and the desired performance of a construction firm as a dynamic process with peaks and troughs over the time which represents the innovation as 'action' and resistance to innovation 'reaction' (Barrett and Sexton 2006). A successful innovation happens when action forces the reactions. Taking into account these arguments, the scholars have mostly focused on the operational format approach and failed to employ any strategic management approach.

COMPETITIVE ADVANTAGE APPROACHES

As mentioned, despite the fact that innovation has been recognised as a source of competitive advantage (Ozorhon et al. 2010), historically the construction industry has been recognised for low innovation levels. Furthermore construction has been criticised for its inability to adjust itself to the ever-changing of modern business environment through its identification as a negative influence on wider problems such as productivity and quality (Nam and Tatum 1997, Thomson 2006, Rose and Manley 2011, Egan 1998, Fairclough 2002). In the past few decades competitive advantage has been in the centre of strategic thinking. In the other word, companies need some advantage over the competition in order to sustain itself in marketplace. Competitive advantage motivates the organisation to explore new philosophies to over their competitors (Dulaimi 2008). Porter (1998) describes competitive advantage as the added-value that a firm is able to create for a buyer which exceeds the cost of creating it. He also explains the route to competitive advantage is 'strategy' formed from unique insides of organisation into industry relationships. Dulaimi (2008) describes examples of business development agenda of some organisation including quality assurance, total quality management and lean thinking and argues that such new ideas in most cases has allowed companies to achieve only incremental improvement to the

existing practice. However, in a very 'crowded market' the organisation success cannot longer sustainable unless with a sustainable innovation strategy which continuously creates and exploits new markets rather than competing in existing markets (Dulaimi 2008). The innovation strategy provides a gap for the competitors and increases the value for customers. To remain successful such firms need to rapidly exploit newly discovered markets before competitors catch up (Dulaimi 2008).

STRATEGIC MANAGEMENT APPROACH AND MOTIVATION FOR INNOVATION

The term strategy has its root in the military and has existed for centuries. The realisation of strategy as an academic discipline and distinct business sense which first arose in America is far younger. Johnson et al. (2008) define strategy "as the direction and scope of an organisation over the long term, which achieves advantage in a changing environment through its configuration of resources and competences with the aim of fulfilling stakeholder expectations". Porter (1996) states that "If there were only one ideal position there would be no need for strategy". Individual imagination and creativity plays a main role in strategy activities as well as highly motivating especially when connected to practical outcomes and reward structures (Stewart and Fenn 2006). However, low presence of strategy as the foundation of innovation in the construction industry is noticed. It can be argued that this is due to the attitude of the industry (Cheah and Chew 2005). Innovation without strategy-oriented either is blind or will never happen and no goal to exploit the ideas in pursuit of. In general, without strategy there is no motivation for innovation. Stewart and Fenn (2006) state that "A strategic perspective on innovation and strategic thinking will motivate the organisation to look beyond the product and the process to the entire system for delivering value to the customer". Strategy activity requires strategic thinking which is 'a process of identifying, diagnosing, convincing and realising solutions to problems regarding the organisation using a balance of rational analysis and generative creativity' (Whittington et al. 2003). Stewart and Fenn (2006) highlight that seeing how things 'might be' different is the inception of strategic thinking. At the meantime, construction managers need to recognise the feasibility with the pragmatism and the products of strategy discourse.

Despite many efforts on strategies driven by competition the firms fail to innovate and choose imitation over innovation or achieve no more than incremental innovation. In contrast, 'value innovation' pushes manager to go beyond the incremental improvement to totally 'new way of doing things' and highlights equal on value and innovation.

According to Brochner (2008), there is a general belief that clients are the only participants in construction who have the ability to take an overview across the inception and process of innovation and encourage all the actors in the process. However, Tzortzopoulos et al. (2008) argue that most of clients in construction have a desire to avoid innovation because of the associated risk with it. If clients do not see the benefits from innovation they would have no reason to support them. Sir John Egan states that clients in the construction industry are not educated and have the habit of interest in low-cost rather than value. Their procurement approach provides less opportunity for contractors to add value through innovation; and to enable this down the supply chain. Winch (2008) argues that the effective creation of value in construction is the alignment of incentives to all the players involved in construction

process not only one group of players. He also mentions that the understanding of constructed product as an asset is important. Seeing construction products as an assets rather than artefact should be developed. In addition, clients need a strategic overview on their goals to understand the benefits of innovations made by contractors. They could provide incentives to other players to innovate by choosing appropriate procurement methods (Widen et al. 2008).

CONCLUSIONS

The problem with innovation management in the construction industry is a longstanding one. The main focus of this paper has been to broaden the understanding of innovation with the construction industry in both project and organisational context. The literature reviewed highlighted that the management of innovation in construction project is very complicated and the characteristics of the construction industry create problems for the speed of integration of new ideas. In order to understand innovation management in the construction industry, distinguishing project innovation and organisational innovation is essential. This far, scholars have mainly focused on the theoretical level of construction innovation and failed to assess the practical view of innovation within construction environment. It could be concluded that most of the literature focused on R&D and product innovation obtained from manufacturing production and failed to observe the innovation context within construction environment. Through this critical review, it is noted that there is very little appreciation on strategic management approach on construction innovation and no incentives provided for players to innovate. Clients as a main potential driver of innovation in the construction industry play a crucial role to motivate other players. This can be achieved by providing appropriate procurement methods. Clients need to provide incentives for innovation by strategic overview of goals of a project.

A Taxonomy For The Impact And Management Of Variation Orders In Construction Projects

Jawad Alsuliman[1] and Graeme Bowles[1]

[1]School of the Built Environment,
Heriot Watt University, Edinburgh, EH14 4AS,
United Kingdom

Email: ja1689@hw.ac.uk ; g.bowles@hw.ac.uk

Abstract:
Variation orders usually negatively affect the progress of construction projects, to the detriment of their objectives. They typically involve dealing with additional work that was not anticipated at the time the contract for a project was signed, which generally leads to delays, cost overruns, quality defects and even disputes and conflicts among the different parties involved in the construction project. A review of the literature is conducted to develop a taxonomy on the impact and management of variation orders in construction projects. The paper therefore attempts to introduce the taxonomy as a theoretical framework. This framework will support the theory of this research, with the purpose of more effectively managing variation orders in the construction industry.

Keywords:
Construction project; management of variations; taxonomy of variation orders; variation orders.

1 Introduction

The construction industry has been described as complicated and uncertain in nature, as each construction project has its own unique circumstances and conditions. The complexity of construction projects means that it is almost impossible to deliver a project without any change in its lifecycle; that is, every construction project is unique in many respects, but liability to change is an attribute that generally characterises almost all projects. This has led Revay (2002) to claim that change is *a fact of life* for a construction project. Baxendale and Schofield (1986) define variation orders as any change that can occur to the basis of the project that differs from the agreed and signed contract. Following the same line of thought, Ssegawa, et al. (2002) explain that sources that might trigger change in a construction project can be as simple as a change of mind on the part of the clients, or their consultant, or unforeseen problems raised by the main contractor or sub-contractors.

This paper intends to highlight the impact and management of variation orders in construction projects by reviewing the existing literature in relation to this. The first section of the paper addresses the types and causes of variation orders. Following this, the paper attempts to review the developed methods and models to manage variation

orders. Then, an approach will be made to analyse and categorise the literature to develop a taxonomy of variation orders with regards to impact and management.

2 Research Problem

Variation orders affect the progress of any construction project and will have an influence on the achievement of its objectives. Variation orders typically involve dealing with additional work not anticipated when the original contract was signed, leading to delays, cost overruns, quality defects and even disputes and conflicts among the different parties involved in a construction project (Baxendale and Schofield, 1986). Therefore, a better understanding of the literature review needs to be introduced into the construction industry in order to clarify the negative impact of variation orders. Furthermore, this study attempts to achieve more effective management of variation orders by developing a taxonomy of the variation order literature review.

3 Research Aim

The proposed paper will draw a map and develop a taxonomy for variation order literature worldwide in terms of the impact of variation orders and managing them to introduce a theoretical framework. This framework will support the theory of the proposed research and assist the researcher to produce a solid base for managing variation orders in construction projects. Moreover, the developed taxonomy will assist in gaining a better understanding and increase the efficiency of dealing effectively with variation orders in construction projects. Additionally, project teams can use this taxonomy to ensure all the key factors related to variation orders are covered, in order to manage them more easily.

4 Literature Review

4.1 Possible Impact of Variation Orders

The possible impact of variation orders is well-documented in the literature (CII, 1986; CII, 1990; Clough and Sears, 1994; CII, 1994; Thomas and Napolitan, 1995; Fisk, 1997; Ibbs *et al.,* 1998; Arain and Pheng, 2005). However, according to Arain and Pheng (2005a), the most commonly acknowledged impact is often referred to in terms of 16 aspects. These are:

4.1.1 Impact on progress

One of the most cited impacts of variation orders is that affecting the overall progress of the project (for example, CII, 1994; Assaf and Al-Hejji, 2006). Put another way, variation orders often result in delay and, in business, time is always the equivalent of money. However, the effect discussed here may vary depending on the time delay the variation order might cause and, subsequently, the amount of money needed to complete the project.

4.1.2 Cost

Another commonly addressed element that might demonstrate the potential impact of a variation order on a project is that of cost. A change in one of the project elements, for example, design, might result in a change in cost. This is why a contingency sum is often maintained, in order to allow for any possible variations in the project. This was supported by Clough and Sears (1994) and Assaf and Al-Hejji (2006).

4.1.3 Employment of new professionals

Although the frequency of variation orders differs from project to project, they are often described as "frequent" in complex technological projects (CII, 1995) where there is a need for experts and professionals, whose expertise is considered a fundamental requirement for such complex projects (Fisk, 1997). Hence, hiring new experts or replacing existing teams might arise as essential requirements for a project and this would involve a variety of impacts on the progression of the project.

4.1.4 Increase in overhead expenses

Implementation of any variation orders requires, as O'Brien (1998) describes, processing procedures, paperwork and reviews before they can even begin to be implemented, which would generally result in an increase in overhead expenses for the stakeholders. This where the contingency fund mentioned earlier comes to the fore.

4.1.5 Delay in payment

Another related element is delay in payment which, if such a delay occurs frequently enough (CII, 1990), often results in preventing progress in the project, leading to impediments in achieving the targeted milestones during construction (CII, 1995) and timely payment to contractors. Additionally, there is also the possibility of serious problems where subcontractors are not paid due to the delay in the contractors' payment.

4.1.6 Quality degradation

High frequency of variation orders might have an impact on the quality of work (Fisk, 1997). To CII (1995), the quality of work was generally poor due when there were frequent variations as contractors tended to compensate for the losses by cutting corners.

4.1.7 Productivity degradation

Variation orders have a direct relationship with individual and group productivity, especially in cases of lack of materials and information, as well as the work being out of sequence. Frequent interruptions, delays and redirection of work are often associated with psychological aspects that could easily de-motivate personnel at all levels. Accordingly, productivity is questioned, as Ibbs (1997a) describes, as a negative association between variation orders and productivity can be translated into labour cost or dollar value. In this respect, Thomas and Napolitan (1995) concluded that variations normally led to disruptions and these disruptions were responsible for labour productivity degradation. Hester *et al*. (1991) suggest that productivity is often influenced because individuals have to endure longer working hours, work overload and

prolonged periods of compensating for schedule delays. Management of variation therefore requires management of disruptions, though disruptive effects might be inevitable.

4.1.8 Procurement delay

Hester *et al*. (1991) observed that procurement delays were common effects of variations in relation to new resources for construction projects. O'Brien (1998) explains that variation orders that occur when construction is on-going may require revised procurement requests. Procurement delays can be frequent due to variations that require new materials and specialised equipment.

4.1.9 Rework and demolition

While variations required while construction is in progress, or even completed, can lead to delays in project completion (CII, 1990), it is not uncommon to encounter rework and demolition as a result of variations in construction projects (Clough and Sears, 1994). The knocking down and rework of certain areas might be predictable due to variations during the construction phase but they can also happen even after project completion.

4.1.10 Logistics delays

Fisk (1997) explains that, when variations are made on the basis of the need for new materials, tools and equipment, it is not uncommon to expect logistics delays. Similarly, Hester *et al*. (1991) observed that logistics delays were a significant outcome arising from variations in construction projects.

4.1.11 Damage to firms' reputations

While variations can be described as a major starting point for construction claims and disputes (Fisk, 1997; Kumaraswamy *et al*., 1998), it can be anticipated that such claims and disputes would affect firms' reputations, which might, in turn, result in insolvency in severe cases. In fact, variations can result in endless and serious disputes between the different groups of stakeholders.

4.1.12 Poor safety conditions

Safety conditions within any given project can be affected by variations (O'Brien, 1998; Arain *et al*., 2004) as changes in construction method(s), materials and equipment might necessitate additional safety measures during the construction process.

4.1.13 Poor professional relationships

As mentioned previously, disputes are often triggered by variations (Fisk, 1997), which can create a tense atmosphere between different groups of stakeholders. This is why the procedures presented in the contract and the fair allotment of risks can be helpful in putting an end to disputes through finding the middle ground, rather than initiating a court case (CII, 1986; Arain *et al*., 2004).

4.1.14 Additional payments for contractor(s)

Unsurprisingly, any additional payments for a contractor(s) involved in a project could increase the potential impact of variations in construction projects. This is why the

contractor often anticipates variations as they frequently entail extra payments. Variations are therefore seen to be a customary source of extra work for the contractor (O'Brien, 1998).

4.1.15 Disputes among professionals

Similar to poor professional relationships, the potential for disputes between the different groups of stakeholders formulates possible effects of frequent variations in construction projects. Though such disputes over variation orders and claims are often expected, and might even become inevitable (CII, 1986), procedures presented in the contract and the fair allotment of risks can be beneficial in relation to putting an end to disputes through finding the middle ground, rather than initiating a court case (CII, 1986; Arain *et al*., 2004).

4.1.16 Completion schedule delay

Completion schedule delays can also be considered to be a direct result of variations in construction projects (Ibbs, 1997b). Zeitoun and Oberlender (1993) reported that 9% of the original schedule for the 71 fixed price projects studied were due to variation orders. Likewise, Kumaraswamy *et al*. (1998) examined claims for time extensions due to excusable delays in Hong Kong's civil engineering projects and their findings claimed 50% of the delayed projects resulted from variations.

4.2 Types of Variation Orders

The concept of variation orders has become well established in the literature and a number of typologies have been developed. Cox (1997) put forward a trichotomy that describes types of change. According to Cox (1997), this includes:

a) a formal change order: this is an actual document called a *change order*, which might be issued by a client and might result in modifying the contract terms, plans or specifications;

b) a productive change order: this is extra contract work performed pursuant either to oral or implied owner directives, or as a result of problems for which the owner is responsible; and

c) a principal change order: this may occur whenever there is a considerable amount of work required outside the scope of the original contract.

Similarly, Ndihokubwayo (2008) cites Arain and Pheng (2005b), who categorise these variation orders as *beneficial* and *detrimental*. According to Arain and Pheng (2005b), a beneficial variation order is one delivered to better the quality standard or trim down the cost, timetable or degree of difficulty in a project.

On the other hand, detrimental variation orders, explains Ndihokubwayo (2008), represent the negative side. Here, Ndihokubwayo (2008) cites Arain and Pheng's (2005b) description of a detrimental variation order as "one that negatively impacts the client's value or project performance". Put another way, a client who is experiencing financial problems may require the substitution of quality, standard, expensive materials to substandard cheap materials.

In a similar manner, Motawa et al., (2007) classify the types of variation orders as a "*gradual change*" or a "*radical change*", based on the level of severity, or an "*anticipated change*" or an "*emergent change*", based on whether it is intended or not.

4.3 Causes of Variation Orders

While reviewing the literature indicates that different stakeholders (for example, the client, architect, contractor etc.) might be direct causes of variations, it also implies that variations can be initiated for different reasons, be they design-based, financial, aesthetic, changes in drawings, weather, geological or geotechnical reasons (Ssegawa, et al., 2002 and Turner, 1984). However, Arain (2005) classifies the causes of variations into five categories. These are:

1. *owner-related variations (ORV),*
2. *consultant-related variations (CRV),*
3. *contractor-related variations (CTRV),*
4. *other variations (OV), and*
5. *combinations of causes (CC)*

Following a similar line of thought, Enshassi, et al. (2010) provide a list of the top ten most common initiators of variation within the construction industry. These are: "*lack of materials and equipment, change in design by consultant, lack of consultant's knowledge of available materials, errors and omission in design, conflicts between contract documents, owner's financial problems, lack of coordination among project parties, using inadequate specification for local markets by international consultant, internal politics, and change in specification by owners"*

Correspondingly, Alnuaimi, et al. (2010) and Oladapo (2007) state that client requested additional works and modifications to the design are the main causes of changes in construction projects. Furthermore, Motawa (2005) noted that *"design errors, change in the functional requirements of the project and unforeseen conditions"* are the most important factors in the occurrence of variation orders.

4.4 Management of Variation Orders

Due to the inevitability of variation orders, as well as their potential impact on the planning, design, progress and completion of any given construction project, it is not uncommon for the literature (for example, Arain and Pheng, 2005; Krone, 1991) to devote considerable effort and time to the experimentation and theorisation of how such orders can best be managed. In this respect, Arain and Pheng (2005) assert, "*The issue of managing variations has received much attention in the literature. Despite many articles and much discussion in practice and in the academic literature, the issue of learning from past projects in making timely and more informed decisions for the effective management of variation orders has not been explored much in the literature*".

In fact, several strategies have been acknowledged as useful in managing variation orders. According to Charoenngam, et al. (2003), among the various strategies used to manage variations is that of involving the creation of good communication and

cooperation between project team members. Charoenngam, et al. (2003) further explain that, in making information accessible to all stakeholders, it is important to establish such communication and cooperation and that is why the authors advise making good use of Internet technology as the communication media, where accessibility to timely and accurate information is not bound to a time and place. While Jacob (1978, p.64-65) noted that *"lax attitudes and unfamiliarity with proper change order procedures have led to serious financial loss and insolvency",* Chan and Yeong (1995) assert that good contract documentation and good communication and cooperation between building team members are major elements that can make the task of managing change orders easier. As for good documentation, explain Chan and Yeong (1995), it is generally facilitated by designing an efficient change order system, geared towards understanding the change order process or "*workflow"*, which can be collected from the standard forms of contract. With regards to good communication, however, it might be facilitated by providing information using a well-timed procedure.

In a similar manner, Krone (1991) suggests *a variation order process,* in which efficient administrative processing is promoted. Krone's (1991) attempt claims to address the day-by-day demands of changes in the construction process. Here, the contractual analysis technique (CAT) suggests that the initial announcement and submission of proposals helps to maintain management control and avoid impact claims. Although CAT paved the way for future contract variation clauses in construction management, such a proposed process was bound to administrative processing and addressing the day-to-day demands of variations in the construction process. On the other hand, functional analysis concept design (FACD) was another methodology offered to reduce the number of variation orders in construction projects (Stocks and Singh, 1999). To these authors, FACD was a practical method that could reduce construction costs overall. Following a similar line of thought, Harrington, et al. (2000) introduced the management of change in the organisational context (MOC). This is a theoretical model, which includes a structured process consisting of seven phases. These phases are:

(1) clarify the project;

(2) announce the project;

(3) conduct the diagnosis;

(4) develop an implementation plan;

(5) execute the plan;

(6) monitor progress and problems; and

(7) evaluate the final results.

According to Harrington, et al. (2000), MOC or, rather, its structure can be applied outside the organisation to any project change management. Gray and Hughes (2001) proposed another strand of controlling and managing variations, where their theoretical model had the central idea of *"recognize, evaluate, resolve and implement variations in a structured and effective way".*

Similarly, the Construction Industry Institute (1994b) and Ibbs, et al. (2001) introduced the change management system (CMS), which is a two-level process model, with principles as its foundation and management processes to implement those principles. The model was based on five main principles, which can be summarised as:

(1) Promote a balanced change culture;

(2) Recognise change;

(3) Evaluate change;

(4) Implement change; and

(5) Improve from lessons learned.

However, CMS was subject to much criticism on the basis that it lacked the basic principles and processes for implementing controls for future variations in construction projects. However, most of these models have their pros and cons and while one of them might be suitable for one project, it might not be practical enough for another. Nevertheless, it can be claimed here, as well as elsewhere (Charoenngam, et al*.,* 2003), that success in managing change orders results in uninterrupted construction operations and an agreed final project cost, as well as duration.

5 Taxonomy of Variation Orders

Generally speaking, a taxonomy is identified as a *"process or a system of organizing things into different groups that show natural relationships"* (Longman Dictionary, 2007). Theoretically, the development of a taxonomy takes into consideration the importance of separating components within groups. Here Sun and Meng (2008) carried out a study into the taxonomy for change causes and effects in the construction industry, to fill a knowledge gap, by: (1) reviewing the existing literature on project change causes and effects; (2) developing two taxonomies for change causes and effects and (3) showing how taxonomies can be used.

At that time of the abovementioned study, 101 papers were found on variation orders in the construction industry. These publications covered most of the research areas worldwide. Sun and Meng (2008) categorised variation order papers in terms of paper source, published year, country of the study and research method. Subsequently, these papers were categorised into three groups, as follows: (1) papers addressing change causes, (2) papers addressing the impact of the changes (3) and papers addressing both causes and impacts of changes.

Moving to this study, which follows a different perspective and criteria from the aforementioned study, the proposed research focuses on variation orders in the construction industry from a higher perspective with regards to impact and management levels, rather than causes and impact levels. To achieve that, a preliminary review found numerous papers on the proposed research area. The majority of these papers fall into two main groups, which are group (A), which deals with the causes and impact of variation orders and group (B), about managing variation orders. Both groups have been divided into three categories in terms of the research purpose, the methodology and the results of these studies.

Firstly, in group (A), the most common purpose of these papers, which deal with the influences of variation orders in the construction industry, is to determine the types and

causes of variation orders. The majority of these studies deal with particular construction projects and countries, such as the research by Alnuaimi, et al. (2010), Oladapo (2007), Ndihokubwayo (2008), Moselhi, et al. (2005), Ssegawa, et al. (2002) and Arain and Pheng (2005a).
The methodologies used in most of the aforementioned papers in group (A) were questionnaires, interviews and case studies, where the researchers wished to determine the impact, types and causes of variation orders, in particular, across a small number of construction projects. The results of these studies proved that variation orders have a negative significant impact on the project progress and performance in terms of time, cost and quality. Moreover, in some cases, variations led to disputes and conflicts between the project parties.

Secondly, in group (B), researchers, such as Motawa, et al. (2007), Arain and Pheng (2005; 2007), Hassanein and El Nemr (2007), Hao, et al. (2008), Senaratne and Sexton (2009), Arain (2005), Motawa (2005) and Charoenngam, et al. (2003), aim to manage variation orders in order to minimise the frequency of change orders and to avoid the problems associated with them. In addition, they sought to speed up the processes of obtaining a change order to save time and money.

In order to achieve these objectives researchers attempted to create a database, develop a model or implement a change order management system (COMS) to deal with a large number of construction projects and to manage variation orders effectively. However, these methods require the comprehensiveness and quality of the project records (Sun and Meng, 2008). The results of the research indicate that good communication, co-operation among the project teams, good contract documentation and learning from similar past construction projects will assist in reducing the frequency of detrimental change orders. Table 1 shows a summary of the taxonomy of variation orders in terms of impact and management.

Table 1. A summary of the taxonomy of variation orders

Type of study	Purpose	Methodology	Results
Group (A): Impact of variation orders	1-Types of variations e.g. (Arain and Pheng, 2005a) 2- Causes of variations e.g. (Oladapo, 2007)	1-Questionnaire (Alnuaimi, et al., 2010) 2- Interview (Hassanein and El Nemr, 2010) 3- Case study (Oladapo, 2007)	Variation orders have a negative significant impact on the project progress (Alnuaimi, et al., 2010; Oladapo, 2007)
Group (B): Managing variation orders	1-Speed up the process (Arain and Pheng, 2007) 2- Minimise variations (Arain and Pheng, 2005) 3- Avoid problems (Hassanein and El Nemr, 2010)	1- Creating a database (Charoenngam, et al., 2003) 2- Developing a model (Motawa, 2005) 3- Implementing COMS (Motawa, et al., 2007)	1- Good communication (Arain and Pheng, 2007) 2- Cooperation (Charoenngam, et al., 2003) 3- Good contract (Hao, et al., 2008) 4- Learning from past projects (Arain and Pheng, 2005)

The proposed taxonomy can be implemented in different construction projects and used as a framework by project teams to ensure all key factors related to variation orders are covered. In addition, this taxonomy can assist the project team in dealing with managing variation orders efficiently by having good communication skills, good co-operation among the project parties and well-written contract documentation. Additionally, reviewing and evaluating the most common causes and types of variation orders from past similar construction projects will help the project members to deal with variations.

6 Conclusion

Variation orders are an important component of the construction industry, which can simply be described here as a change, whether radical or reasonable, in the quantity or quality of the work agreed to in a contract, as shown in the drawings or described in the specification, listed on a schedule. It can also be a change in the time allowed for completion and this why the consequences of such changes often entail various impacts on the budget. Due to their importance and inevitability, variation orders, as integral components of the industry, are therefore considered as one of the main influential factors in the failure to deliver a construction project successfully. In fact, in some cases, variation orders can be beneficial, providing better quality standards, saving time and reducing costs as well. However, since most variation orders have a negative significant impact on construction projects, leading to time delays and cost overruns, various researchers have shown interest in examining the most effective way(s) to manage variation orders. As this research is based on the existing literature review it has led to establishing a taxonomy for the impact and management of variation orders in construction projects to be implemented in the construction industry in the future. The proposed taxonomy provides an analysis of variation order impact and management literature to help project teams to minimise the occurrence of variation orders and, moreover, to assist to deal with managing them effectively by reviewing and evaluating the most common negative impacts of variation orders.

7 Acknowledgements

I would like to take this opportunity to express my thanks and appreciation to my sponsor, the Ministry of Higher Education in Saudi Arabia. Furthermore, this research could not have been conducted without Dr. Graeme Bowles, who helped me to write this paper. Big thanks also go to my parents and my wife.

Abstract:
Despite the promise of Building Information Modelling (BIM) providing increased scope for inter-project participant collaboration the reality has thus far been disappointing. Whilst issues of interoperability (technological compatibility) are partially responsible for this it is also frequently observed that existing conventional building contracts act as barriers to ICT-mediated collaboration: BIM is particularly sensitive to the legal environment within it is being deployed for the success or otherwise of attempts at collaboration. Yet it remains likely that the various permutations of procurement and standard forms of contract will be likely to be continued to be used into the foreseeable future. It is therefore desirable to identify and understand the ways in which conventional contract conditions have the potential to prove inappropriate or counterproductive in a BIM-enabled project environment. This paper presents a taxonomy of the legal and contractual issues related to BIM integration, which provides a suitable basis for future application to the analysis of specific standard forms of construction contract.

Keywords:
BIM, business barriers, contracts, legal barriers

1 Introduction

The Architectural Engineering Construction and Facilities Management (AECFM) industry is commonly characterised as being fragmented, frequently stricken by crisis and conflict, with high levels of client disappointment and dissatisfaction (Sexton and Barrett, 2003). Numerous Royal Commissions, investigations and industry round tables have concurred with this negative assessment and have gone on to produce an array of recommendations. Two suggestions emanating from Egan's (1998) report into the industry recommended the encouragement of collaborative project teams using emerging Information and Communication Technologies; specifically computer

modelling of the end product to minimise problems during construction and checking for conformance to customer expectations.

Building Information Modelling (BIM) has emerged as the computer-based assessment that Egan flagged. This has been defined as an:

> *"IT enabled approach that involves applying and maintaining an integrated digital representation of building information for different phases of the project lifecycle in the form of a data repository"(Gu and London, 2010 p. 988)*

BIM goes beyond the simple parameters set by Egan of conformance checking and minimisation of construction problems, to include visualisation of design code checking, quantity take-off and cost planning, facilities maintenance and services clash detection (Eastman, Teicholz, Sacks and Liston, 2011). Ultimately the benefits of BIM adoption san be summarised as the overall reduction of project risks and the encouragement of collaboration between project team members (Kymmell, 2008).

In spite of the wide ranging benefits of BIM adoption and use technology uptake remains chiefly among design team members, with limited adoption by those downstream of the design phase (Sebastian, 2011). Research into laggard behaviour has focused on the barriers to BIM adoption including: justifying its uptake from a business perspective (Aranda-Mena, Crawford, Chevez and Froese, 2009); building a business case for its implementation (Gu and London, 2010); the interactions between the technology, users and other existing business systems and processes (Owen, Amor, Palmer, Dickinson, Tatum, Kazi, Prins, Kiviniemi and East, 2010).

Succar (2009) mapped the changes required for BIM implementation and developed three main categories: Technology , Policy and Process. Within the Policy step he identified two key areas requiring change: Contractual and Regulatory. McAdam (2010) built on these areas and identified several key themes of legal issues. This paper synthesises the items identified in Succar's (2009) "Policy" step and expands on the detailed Regulatory and Contractual issues identified by McAdam. This is achieved through a systematic meta-synthesis of literature associated with BIM Implementation.

2 BIM: Legal, Regulatory, Technical and Contractual Issues

A systematic literature review was undertaken, directed by the tenets of Succar's (2009) "Policy" process step and McAdam's (2010) detailed expansion of "Regulatory" and "Contractual" issues. Thereafter an inductive meta-synthesis (Walsh and Downe, 2005) was undertaken of these sources to reveal nine thematic areas: Intellectual Property and Security; Professional Liability; Standard Conditions of Contract / Contract Documents; Risk Allocation; Public Sector Capacity and Capability; Protocols and Processes; Procurement Policy and Processes; Legislation and Judicial Precedence, and; Compensation and Consideration. These are now explained in detail.

Generally, the legal and associated technical issues arise variously from the technology itself, how the technology is used within the project, or the procurement method

adopted (Ashcraft, 2008). To expand on the last of these, the polar extremes would be to use BIM in a traditional/construct-only procurement method, or in a collaborative environment using an integrated procurement method. Using BIM in either of these instances presents significant challenges for the legal, regulatory and procedural workflows associated with construction procurement.

2.1 Intellectual Property and Security

Determining Intellectual Property (IP) combined with maintaining data security is one of the most commonly identified legal issues associated with the use of BIM in a project setting. Adding to the complexity of IP and data security is the increasing use of BIM in a collaborative procurement environment such as an Integrated Project Delivery method. Haynes (2009 p3) frames the issue:

"What is more difficult in the BIM context is the fact that there may be numerous 'designers' creating models and various data bases and exchanging such models and information among various project participants, and even engaging in modification or alterations of such models through the creation of derivative models."

The issues associated with BIM IP and data security can be grouped under three subheadings: Ownership/Copyright of the Design; Ownership and Copyright of the Digital Model, and; Model and Information/Data Security. These are overarched by the twin matters of ease of data transfer, and increased formal and informal design collaboration between all project participants.

Determining how BIM affects the ownership and copyright of the facility design (including designs completed by contractors and subcontractors) has emerged as one of the major concerns of designers and legal commentators. Some of the specific issues encountered are how contracts address the issue of IP. This includes the mechanisms for tracking design changes, the jurisdiction of IP and finally ensuring all team members are conversant with the rules and regulations associated with the project The actual legislative requirements can be quite complex and can include international agreements as produced by the World Trade Organisation, Federal, State and local government acts and regulations.

Closely associated with the IP of the design is the ownership and copyright of the actual digital model. The model contains a wealth of information which can be valuable to the client, designer, contractor and subcontractors. Consequently, dependent upon contractual conditions, specific parties may not be allowed to use the information encapsulated in the model for future projects. Thus a selection of issues need to be considered, including the ownership of the model incorporating all derivative models, the final use of the model, if it will be used for facilities maintenance, tracking future modifications to the original, and the status of objects created by others that are incorporated in the model.

Ensuring the security of the model and confidentiality of the data contained within is the final sub-area. As project documents shift to file sharing websites or general access to project servers is provided, there are a number of concerns emerging related to data protection and security. This can include ensuring that the data is secure from outside

 ISBN: 978-1-84219-840-7 .

access, manipulation and damage or unauthorised access by stakeholders within the project team itself. For example confidential information, trade secrets, patents and proprietary data requires protection. Further, if the project is commissioned by the Public Sector consideration of what information will become publically accessible after completion due to archiving and reporting requirements (Ashcraft, 2008).

2.2 Professional Liability

Professional Liability is another key area that has emerged from the implementation of BIM within procurement practices. There is a clear subdivision of liabilities relating to the creation and management of the design. For example, in the USA there is a clear divide between the liabilities associated design and that of construction, commonly referred to as the Spearin Doctrine. Other liability issues which have materialised are: the use of the model after construction; how much detail is inserted into the model by the designer and the standard of care with which it is introduced into the system; automated design by BIM authoring tools; establishing the entity responsible for managing the BIM; the contractual status of the model, and; changes required to insurance cover. Finally, the effects of collaborative methods in relation to liability is a key issue in BIM integration (Hurtado and O'connor, 2008; Larson and Golden, 2007).

2.3 Standard Conditions of Contract / Contract Documents

Currently there is a limited range of Standard Conditions of Contract which specifically reference or address the issues associated with BIM. Compounding the issue existing legislation and practices tend to favour printed two dimensional drawings and specifications. If a model is used as a contract document then its status as such needs to be clearly articulated with the actual contract. Lastly confirmation of any design changes need to be confirmed with all project stakeholders (Ashcraft, 2008; Olsen and Taylor, 2010).

2.4 Risk Allocation

Reflecting more generally on the ICT protocols required to manage a construction project, the items related to this category focus on the management of the technology such as hardware limitations, security concerns and change management issues (Wong and Lam, 2011).

2.5 Public Sector Agency Capacity and Capability

From the perspective of the public sector approving agencies there are two main legal issues which directly affect the ability assess and process digital models. The first is the requirement for the designer or other head consultant to lodge the design for approval and/or conformance checking (Allen, Becerik, Pollalis and Schwegler, 2005; Ashcraft, 2008). Secondly, there is usually a statutory requirement to submit the project design and specifications in a hardcopy format. These issues highlight extent to which legislators and the building approval regulations themselves have failed to accommodate the use of a digital model to convey design intent. More practically the approving and reviewing agencies do not have the knowledge or the capability to either process or assess digital models, nor have they developed specific standards for submitting models for assessment.

Stability of the design is the other key factor associated with Public Sector Agency (Ashcraft, 2008). One of the key benefits of BIM is the ability to accurately reproduce the proposed facility in a digital format. This accuracy goes against the current convention of the design professional in only producing enough information to convey design intent (Olsen and Taylor, 2010). It is this design intent which is submitted for authority approval. Further, the coordination of the various design disciplines and the detailed design development usually occur late in the project documentation process usually triggering a revision of the design. Any changes to the documentation tend not to form part of the approval process or submitted for revision of the design approval unless there is a significant departure from the original intent. Conflict and legal repercussions could occur if there is any discrepancy between the approved design, the construction model[s] and the actual construction onsite. Therefore Ashcraft (2008) notes the importance of defining what is needed for approvals and inspections, in addition to the acknowledgement within the legislative framework and agency ability to process a digital model for approval.

2.6 Protocols and Processes

The allocation of risk and consequent levels of reward to the most appropriate party to bear it is a major legal consideration. This consists of: the risk/reward for the initial designer/BIM modeller (Olsen and Taylor, 2010); risks associated with the software used to model; the effects of using a collaborative environment, and; types of insurance and responsibility for its acquisition.

2.7 Procurement Policy and Process

Allen et al (2005) note that public sector procurement law requires following a stringent set of policies and procedures that paradoxically reinforces the fragmented nature of the AECFM industry. Typically, the process uses a Traditional Design-Bid-Build procurement method, with little scope for collaboration. This reduces the advantages of using BIM, which is best suited to a collaborative environment. Moreover different procurement methods have different stakeholder risk profiles.

2.8 Legislation and Judicial Precedence

Legislation, or judicial precedence in the form of previous case law which is associated with the implementation and formation administration of e-business or e-construction is another major category. For example, a judicial precedent in America - the Spearin Doctrine - delineates the responsibility for errors in the design to the Architect and errors relating to means and methods of construction to the Contractor (Ashcraft, 2008) or the legislative requirements for forming a formal e-contract (Cooperative Research Centre for Construction Innovation, 2007).

2.9 Compensation and Consideration

The legal issues surrounding the topic of compensation and payments/consideration can be differentiated into two subcategories; the cost of implementing the technology and compensation/reward relating to its use by the project participants. Determining who pays for the implementation of the technology at both a project and business level is one of the most commonly issues associated with the legal barriers to BIM implementation.

For example the costs of training staff, purchasing of BIM software, upgrading of hardware, changes to workflows and the initial reduction in productivity whilst staff adapt to the new circumstances all have cost implications to a business and therefore require either a loss provision or some form of compensation. Thompson and Miner (2006) highlight the process for applying a standard practice risk assessment approach to implementing BIM in a business setting (Figure 1).

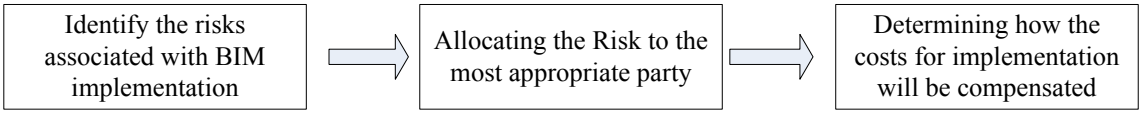

Figure 1. Determining Risk & Compensation

The second critical point relating to compensation and reward is how remuneration will be aligned with the changing risk profile of BIM use within a project procurement method. As noted previously the three traditional risk perspectives are associated with the client, designer and contractor. In a BIM enabled environment the designer is seen as taking much of the risk for little reward. This is related to the increased level of detailing BIM authoring tools are capable of which have previously been unachievable using conventional documentation methods. In essence the designer can now digitally document and coordinate a project to a high level of accuracy which goes beyond the traditional role of conveying design intent. Previously the builder was responsible for coordination and constructability, but clients are now expecting this task to be completed by the designer, prior to the commencement of construction. The effects of this are that the designer may not be paid for the extra effort or the additional risk it is assuming because of the increased level of design detail and coordination responsibilities. Further, there is also a lack of benefits to the designer for increasing the level of detail in a project, as they are realised later in the project. In the event a design & build or relational procurement method is used the underlying risk/reward conundrum still remains between the builder and the designer if a design consultant is engaged by the builder.

Another issue relating to remuneration is the change to traditional payment structures and sequencing when BIM is used in an integrated procurement delivery approach, and the additional costs such as insurance for data loss, new roles, and responsibilities associated with the project specifics. For example, due to the capacity and capability of BIM authoring tools the detailed design phase occurs earlier in the project design lifecycle. Both the designer and client need to be aware of the changing cash flow requirements. In addition, payment structures could be revised to incorporate key performance indicators linked to specific efficiency and productivity gains or value added by the model. Wheatly and Brown (2007) highlight the need for consideration of new roles and responsibilities within the project team (e.g. the model manager), requiring the control and management of project information that is unique to BIM-enabled projects. Other costs that require some form of compensation include the expenditure for data protection insurance and the costs incurred by subcontractors.

In summary: from a comprehensive review of the literature nine key areas associated with the legal and regulatory use and implementation of BIM, broadly corresponding to the tenets of Succar's (2009) "Policy" process step and McAdam's (2010) detailed expansion of "Regulatory" and "Contractual" issues were identified. These were subsequently given detail through a process of meta-synthesis, the specifics of which were explained in the previous sections.

3 Discussion

Research into the legal and business barriers associated with BIM is an emerging field within the AECFM industry. Industry based research associations and think tanks such as buildingSMART and the CIB have convened working parties to investigate and report on the issues, problems and enablers. The industry itself has published several new technical/process related BIM contract documents, management and implementation manuals such as the ConsensusDOCS and American Institute of Architects' BIM addendum and NATSPEC's Preliminary clauses. However these documents simply attach to the main contract with little or no attempt to address the changing risk allocation.

One of the emerging challenges facing the implementation of BIM is the lack of standard form contracts which specifically address the legal issues associated with the use of BIM (Lowe and Muncey, 2009). The reworking of contractual frameworks such as risk allocation and reward mechanisms, which allow for the inclusion of BIM processes, is an extremely complex process. The construction industry's reluctance to change and the current limited investigation into the relationships between legal implications and BIM use is making it even harder to achieve a consensus.

From a procurement systems perspective, discussion has focused on using a relational, or design and build system to achieve the full benefits of BIM, thereby overcoming many of the legal obstacles. As McAdam (2010) points out, there has been little empirical research into the law and procurement focusing on BIM in a contractual sense. This lack of empirical data, and the state of uncertainty in which the legal issues are understated or not fully understood, could be the next major impediment for BIM implementation with a collaborative procurement method. For example, Ashcraft (2008) notes there are little if any common law judgements clarifying the roles, responsibilities or legal standing relating to BIM.

Two developments within the industry that relate to BIM are the move towards relational procurement, and the increasing use of digital information as a contract document. One of the key functions of a contract is the allocation of risk to the different parties (Hughes and Greenwood, 1996). Ashcraft (2008) does not believe any new risks are created when using BIM in either a traditional or relational procurement system. The critical point is allocating the risk to the party most capable of managing/controlling the risk if it cannot be engineered out of the project. Moreover, when using a Design and Build system, making risk the responsibility of the contractor does not make the issue disappear: it is simply transferring the risk to another party. If the risk is not completely understood, an adverse outcome may be generated. Figure 2 highlights the four main standard procurement systems: Traditional, Design & Build

and Management approaches all have default risk allocations which have been developed over many years of trial and error, whereby relational approaches aim to manage risk as a collective or in a collaborative approach.

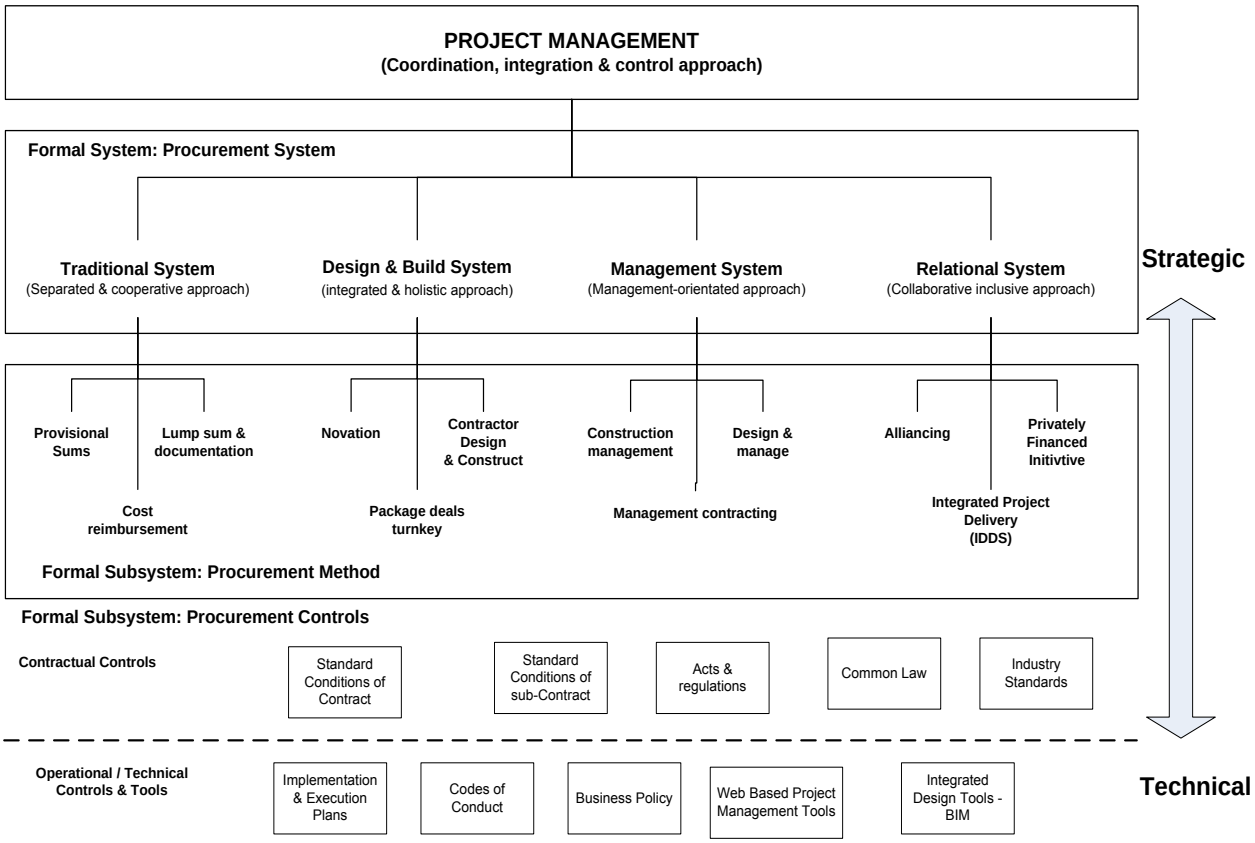

Figure 2 Categorisation of Procurement Systems (adapted from (Love, Skitmore and Earl, 1998)).

McAdam (2010) also discusses the chief legal risk when designers, contractors, subcontractors and suppliers collaborate as being the redirection of design responsibility to unsuspecting project participants and therefore the potential for them to acquire potentially crippling liability. This risk goes beyond Professional Liability and affects many of the other key legal areas. For example, using the taxonomy outlined in section 2 of this paper, Figure 3 maps an example of contractor design involvement and some of the potential outcomes (one of which is the addition of a tenth, interoperability domain). Early contractor design involvement or collaboration can affect the contractor's liability and risk profile. To ensure the changing liability is acknowledged and addressed appropriately, the risk allocation needs to be reflected in the conditions of contract. Further, the contractor will require contractor professional services insurance if it wishes to protect itself against any claims against design related errors. Moreover the client may well include the requirement for adequate professional indemnity insurance in the conditions of contract. An understanding of how prior judicial ruling protections are affected is also desirable. Finally, it is necessary to determine the extent that the contractor is entitled to additional compensation for early design involvement.

 ISBN: 978-1-84219-840-7 .

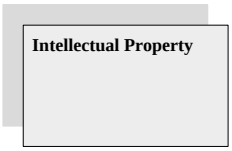

Figure 3 Cognitive model of the potential effects of contractor design input into BIM

From the perspective of the use of the BIM as a contract document, three main approaches have emerged (Ashcraft, 2008):

1. The BIM is a co-contract document but it is not submitted to any approval or permitting agencies,
2. The BIM is an inferential document that is used as a mechanism for visualisation of the design intent, and
3. The BIM is used as an accommodation document which can be used by the project participants but not wholly relied upon.

Whilst design liability in a collaborative environment, and the status of the BIM are considered to be crucial contemporary legal issues, others will continue emerge as the use and integration of BIM continues to evolve. Many of the low level technical and procedural legal issues have been addressed in contractual addenda and procedures manuals; however many other significant legal concerns still require further empirical investigation. In addition, as disputes over BIM reach litigation a whole new body of judicial precedence will provide a framework for BIM status and operation.

4 Conclusion

As the use of Building Information Modelling becomes more widespread within the AEC industry, the legal and associated technical issues identified will continue to pose problems and could hinder its integration into the procurement process. To summarise, the two main legal challenges are the shift from paper based drawings and specifications

forming the contract being superseded by digital models; in conjunction with a drive to embrace relationship/collaborative based procurement systems and methods. Specific contractual remedies are starting to emerge which address some of the technical issues, however the challenge is to remodel the procurement and business landscape which both supports the quantum legal shift in project and provides clarity and order to an otherwise chaotic design and construction process.

Abstract:
Adaptation in Spain to recent European Union directives in the building sector enables the assessment of energy performance of buildings in order to improve their sustainability. Royal Decree 47/2007, of 19 January, specifically approves the basic procedure to certify energy performance in new buildings. Consequently, a scale is generated to ensure better energy rating and lower CO_2 emissions. This paper analyzes a pioneer study on a terraced family house in Spain. Construction features, especially the thermal envelope and the facilities of the building, which comply with new building regulations, and the climate zone where the building is located, are considered with a view to obtaining different energy performances. The private costs of these performances, including depreciation cost, facility management cost and energy consumption cost during the service life of the house, are analyzed. From this analysis, it can be concluded that the better energy performance is, the higher the private cost. A carbon tax equivalent to the social cost is, therefore, suggested as a means to promote better energy performance to, in turn, improve housing sustainability.

Keywords:
Carbon tax, construction law, energy performance in buildings, private cost, social cost

1 Introduction

Greenhouse gases (GHG) emissions caused by human activity contribute significantly to climate change. The third report of the International Panel on Climate Change indicates that global GHG emissions have increased significantly since the preindustrial era due to rising energy needs. In the construction sector, only buildings consume between 20% and 40% of energy in developed countries (Pérez-Lombard, et al. 2008),

and bearing in mind that much of the industry is related to building, this percentage could come close to the upper limit of 40% (Diakaki, et al. 2008). In the United States, figures reach up to 50% of buildings emissions (La Roche 2010). However, buildings are one of the elements that can reduce CO2 emissions more cost-effectively if compared with other emission-producing sectors.

Improving energy efficiency in buildings is considered a useful measure to decrease carbon emissions. In the European Union (EU), the Energy Performance of Building Directives[1] (EPBD) constitutes the regulatory framework to regulate the energy needs of buildings. According to these regulations, EU Member States must apply minimum requirements to rate the energy performance of buildings. European directives establish principles and basic requirements, and these regulations must be transposed by EU Member States to adapt them to their own particular conditions (Concerted Action, EPBD, 2008).

In Spain, the EPBD was partially transposed by means of three royal decrees:

- Royal Decree approving the Technical Building Code (Código Técnico de la Edificación, or CTE, in Spanish), approved by the Council of Ministers on 17th March 2006 and published in the Official Gazette on 28th March 2006. One of the 'basic documents' of the CTE, entitled CTE-HE, deals with energy saving. The requirements regarding energy performance in buildings in this document are in line with those set out in the EPBD in terms of energy saving and renewable energy systems. As of 17th September 2006, these requirements became mandatory for new buildings and buildings undergoing major renovations.

- Royal Decree on the Basic Procedure for Energy Performance Certification of new buildings, approved by the Council of Ministers on 17th January 2007, and published in the Official Gazette on 31st January 2007. Certification became compulsory for new buildings when applications for building permits were made after 31st October 2007.

- Royal Decree approving the review of the current 'Regulations for Thermal Installations in Buildings (RITE)', approved by the Council of Ministers on 20th July 2007 and published in the Official Gazette on 29th August 2007. RITE came into force on 1st March 2008.

The EPBD was partially transposed in Spain because the energy performance certification of existing buildings is not covered by the new decrees. Certification of existing buildings is still awaiting administrative approval.

This is a valuable tool to promote more energetically efficient buildings and, therefore, more sustainable ones.

[1] Directive 2002/91/EC of 16 December 2002 on the Energy Performance of Buildings.
Directive 2010/31/EU of 19 May 2010 on the Energy Performance of Buildings.

However besides these regulations, it is necessary to analyze the economic repercussion of such legislation in order to study the degree of implementation that can be reached by the most energetically efficient housing.

The main objective of this paper is to describe the existing legal procedure in Spain to certify the energy performance of new residential buildings and to study the economic viability of more efficient ratings.

2 Energy performance certification in residential buildings in Spain

Energy performance certification depends on three factors:

a. The building type. The energy certification methodology followed in Spain and Europe is based on the EPBD which distinguishes between residential houses and apartment buildings. Although apartment buildings are more common in Spain than houses (30% of residential dwellings are houses according to the Spanish 2001 national census) the study was made using houses because they are simpler to model for cost data and CO_2 emissions, and more importantly, because individual houses are less energy efficient and therefore incur greater social costs than apartment buildings. A recent study in the United Kingdom shows that the effects of the dwelling type on energy expenditure are significant, being flats more efficient than houses (Thanos and Dunse 2012).

b. The climatic zone of the building location and the 12 Spanish climatic zones, according to the CTE, have been included in this study. The CTE divides Spain into 12 climatic zones which are defined as the energy demand of buildings. Each provincial capital is assigned to a zone and the classification of the corresponding area reflects that of the provincial capital. However, within the same province different climatic zones may exist when altitudes vary by more than 200 meters from that of the provincial capital (Appendix D.1, CTE-HE1).

c. The thermal envelope of the building which is composed by all the enclosures that limited living spaces with the external environment (air or ground or another building) and all internal partitions that limit the habitable spaces with no habitable spaces which in turn are in contact with the external environment. The constructive section of the envelope is a key factor to consider, together with the design criteria, in order to reach high energy efficiency.

2.1 The case study building

The analyzed building is a terraced family house with a garage and utility installations in the basement and a ground and first floor for residential use. The surface area is 68.10 m^2 on the ground floor and is 58.88 m^2 on the first floor. It is located on the end of a terraced row and points 25 °N, and is considered to be the worst of the 13 houses forming the development from an energy efficiency point of view. This is due to the fact

that longer façade is exposed and it also presents a less favourable orientation. Figure 1 shows a section of the case study.

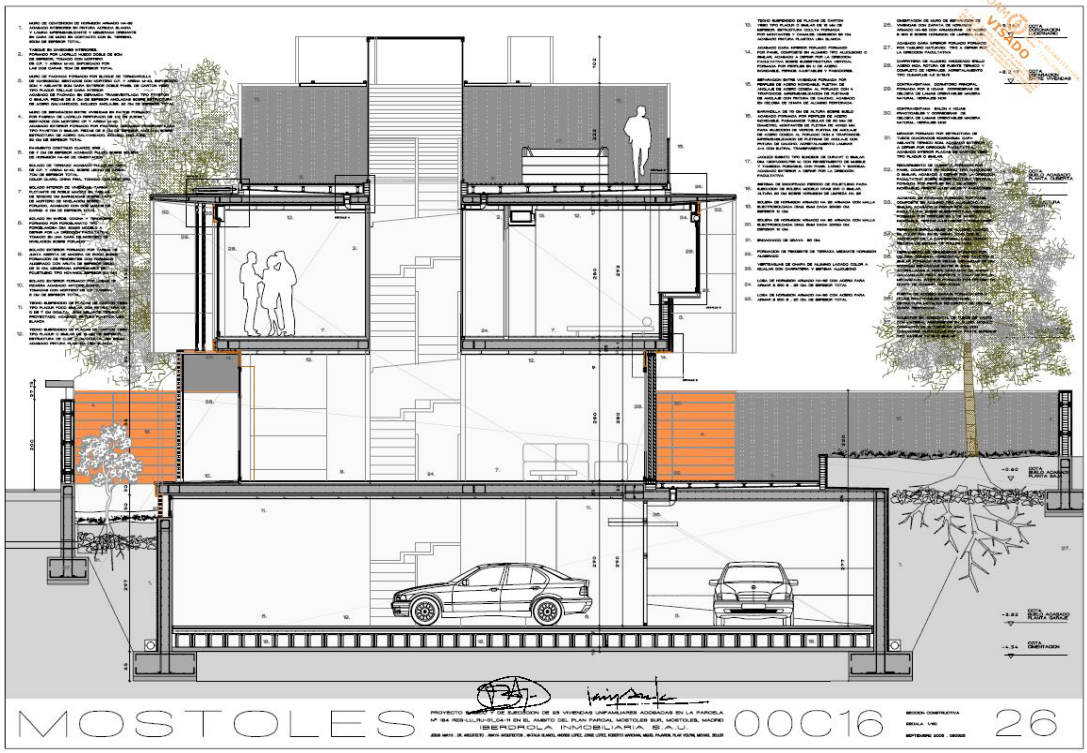

Figure 1. Section of the case study house

2.2 The climatic zones

According to the CTE, there are 12 climatic zones in Spain, which are defined according to the energy demand of the buildings. The system used to name the climatic zone is composed of a letter and a number indicating the severity of winters and summers, respectively. On the one hand, a letter A indicates mild winters and a letter E denotes the coldest winters. On the other hand, a number 1 indicates cool summers and a number 4 suggests the hottest summers. Consequently, the progression from climatic zone A to E indicates an increased need for heating, while the progression from climatic zone 1 to 4 suggests an increased need for cooling. A representative city has been selected for each climatic zone. The empty cells in Table 1 represent non existent combinations.

Table 1. Climatic zones and cities chosen to represent areas

COOLING	**HEATING**					
	Min					**Max**
		A	B	C	D	E
Min	1			C1 Santander	D1 Pamplona	E1 Burgos

	2			C2 Barcelona	D2 Logroño	
	3	A3 Málaga	B3 Castellón	C3 Granada	D3 Madrid	
Max	4	A4 Almería	B4 Seville	C4 Badajoz		

2.3 Regulations for the energy performance certification procedure

Procedures for rating the energy performance of residential buildings in Spain is detailed in the document *Energy rating scale. New buildings* (AICIA 2009). New buildings are assigned an energy rate on a scale of five values indicated by letters A to E, with A being the best rating. According to Royal Decree 47/2007, new buildings are assigned a label indicating their energy rate corresponding to this scale. These ratings are based on annual emission values in kg of CO_2 and on the annual primary energy consumption in kWh depending on: the type of building; the thermal envelope, the climatic zone; the municipality in which the building is located, and the minimum solar contribution to the domestic hot water (DHW) required in the municipality. Lower grades of F and G can be used in existing buildings, but new buildings that meet the technical building code must have an E grade or above.

According to the CTE, there are two options for certifying new buildings: simplified and general. The general option is required when certain physical characteristics of a building exceed given thresholds (over 60% of the façade contains openings and over 10% of the roof has skylights). The simplified option is used to check that the thermal envelope of the building (walls, roof, windows, etc.) does not exceed certain thermal transmittance limits (W/m^2K). This ensures a rating which will be E or D. There are several officially Ministry-approved methodologies to apply the simplified option (CE2, CES, CERMA, etc.).

However, higher energy performances (C, B, A) can be reached only with the general option. This consists in using two complementary programmes which are, to date, the only official option. The Lider program measures the adaptation of a project to the energy-saving part of CTE-HE-1. A building modeled in Lider can then be exported to the Calener-VYP program and energy rating is done after entering demands for heating, cooling, DHW and air-conditioning. Calener provides a label which indicates the energy performance of the simulated building, as shown in Figure 2.

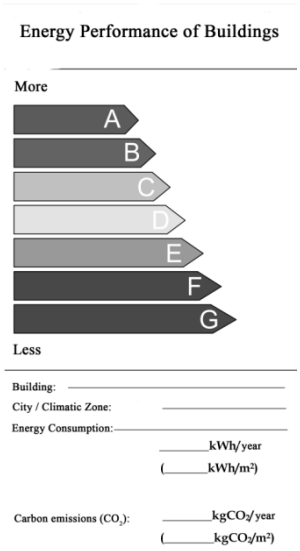

Figure 2. Energy efficiency label according to Royal Decree 47/07

3 Energy performance and building costs in a terraced-family house

3.1 Energy performance rating with Calener VYP

Initially, the constructive solutions of a building are the minimum requirements for the fulfilment of energy demands that the CTE specifies for the general option. Afterward, some solutions needed to reduce emissions are applied. These solutions have to do with the thermal envelope of the house and with its facilities. On the one hand, constructive solutions such as increasing the thickness of the insulation layers in the envelope, changing the materials of window profiles (aluminium, wood), the thickness of window panes, and so on, are used to improve energy performance. On the other hand, facilities also contribute to this improvement, which include heating, air-conditioning and DHW. Electricity is always used for cooling facilities, whereas heating and DHW facilities are simulated with different kinds of boilers and energy sources, such as electricity, natural gas or biomass, by taking into account the minimum input of solar energy for DHW according to the CTE. The combination of materials, constructive solutions and facilities allows various configurations to be obtained for each energy performance and climatic zone. There are 60 possible combinations resulting from the five energy performance grades (A-E) and the 12 climatic zones. Only 50 combinations are obtained because performance E was not reached at times after implementing the commercial format of constructive solutions, and because performance B could not be achieved on occasion with the materials and facilities used in this study.

3. 2 Private costs calculation

Once the configurations have been obtained, costs are obtained. These include the costs from the building site until the end of the service life of the house. They are considered private costs since they have to be paid by users. Private costs are the sum of three costs, these being:

- Depreciation cost: firstly, the investment cost is calculated by drawing up an estimation or budget with the chosen constructive solutions. Several solutions are used:

different insulation thicknesses, types of glass and window profiles, various heating or air-conditioning systems, etc. Moreover, prices are adapted to the Spanish province and to the total built-up area being considered. Prices have been adapted to the Spanish province by means of the Cype S.A. database for construction prices. To obtain the depreciation cost, it is necessary to estimate the service life of the different elements making up the building, which allows the cost per year to be estimated. The service life for the whole building is considered to be 100 years, as confirmed in various sources (Johnstone 2001a, 2001b; Rudbeck 2002; Davies and Wyatt 2004) and in valuation regulations[2]. This matches the observed ages of buildings from the Spanish building stock according to Spanish National Statistics Institute (INE) data. The service life for facilities and materials, which is shorter than that of the building considered as a whole, ranges from 10 to 25 years. Fifteen years is the time adopted for facilities, while 25 years is used for constructive elements such as tiles, kitchen utilities, and so forth. A linear depreciation is to be considered with a null residual value.

- Maintenance cost: this is calculated in accordance with different authors (Piper 1995; Brown 1996; Liska 2000; Kaiser 2001; Brathal and Langemo 2004) and prestigious institutions in the building sector, such as the Catalonian Technological Institute. The *Libro del Edificio* (Building Log Book) is also reviewed. This is a document drafted when a building is constructed and it contains, among other things, several aspects of the building management during its operational phase. There are certain regulations, which vary slightly from one province to another, that also deal with this aspect[3]. Measurements and prices for each task have also been considered, as has the periodicity with which they will occur during the service life of the building. Finally, 45 tasks were considered in terms of their periodicity in the total service life of the building.

- Energy consumption cost: three types of energy are considered for heating and hot water: electricity, natural gas, and biomass. Only electricity is used for cooling. The rates for electricity and gas are obtained from the Spanish official state gazette (BOE 31.12.09) and VAT was excluded. In the absence of official rates, biomass prices including delivery were obtained as market price averages from various suppliers.

Table 2. Private costs in €/m^2/year

Zone/Rating	A	B	C	D	E

Regional Decree 322/2000 of 2 October: Building Book regulations in Navarre.
Decree 14/02/02: it approves the Building Book in the Murcia Region.

C3	24.80	--	--	26.52	--
C4	24.12	--	--	23.55	--
D1	31.82	29.31	29.31	27.47	26.68
D2	30.54	28.57	28.57	28.47	26.94
D3	30.75	--	--	27.06	--
E1	29.62	27.61	27.61	26.63	--

From Table 2 it can be concluded that the better energy performance is, the higher the private costs. Therefore, by taking into account the three aforementioned costs and given the current conditions, better energy performance is not profitable. This means that it is unlikely that more sustainable dwellings are to be promoted if considering their energy efficiency.

On the other hand, better energy performances imply less CO_2 emissions. This could be used as an argument to promote better energy efficiency. The carbon emission cost can be considered an externality and it is difficult to value because there is no market for carbon emissions of residential buildings. This constitutes a social cost which can be internalized by means of an environmental tax so that users would be willing to improve the energy performance of their houses. Some north European countries have already used an environmental tax for CO_2 emissions. Finland, Norway, Denmark and Sweden set carbon taxes in 1990, 1991, 1992 and 1996, respectively. This solution seems to be successful according to different studies which confirm a drop in carbon emissions of 3% and 7% in Norway and Sweden, respectively, and a 10% fall in energy consumption in Denmark (Dresner and Ekins 2006).

From the values obtained for the 50 configurations, some mathematical models have been developed in accordance with the energy performance and climatic zone explanatory variables. Moreover, a model for CO_2 emissions, which considers the two aforementioned variables, was also carried out to obtain this social cost.

3.3 Private costs and CO_2 emissions models

CO_2 emissions and private costs components can be modeled by a multiple regression analysis by ordinary least squares in which the dependent variable (V) is expressed as follows:

$$V = a + b_1 X_1 + b_2 X_2 + \ldots\ldots + bn\, Xn + \varepsilon \qquad (1)$$

where:

a : constant term

bi : coefficients of the explanatory variables

Xi : explanatory variables

ε : random disturbance term

The variables used in the analysis are:

1. Dependent variables:

- C_{DEP}: Annual depreciation cost per square meter (€/m^2/year)
- C_{MAN}: Annual maintenance cost per square meter (€/m^2/year)
- C_{EN}: Annual energy consumption cost per square meter (€/m^2/year)
- KCO_2: Annual CO_2 emissions per square meter (kg CO_2/m^2/year)

2. Explanatory variables:
   - Energy performance defined by five dummy variables (A, B, C, D and E), one per energy rating
   - Climatic zone, quantified by the average annual temperature (T).

Table 3 shows the costs and CO_2 emissions models:

Table 3. Costs and carbon emissions models (significance:**0.01;* 0.05)

	Model 1	**Model 2**	**Model 3**	**Model 4**
	Dependent variables			
Explanatory variables	**C_{DEP}**	**C_{MAN}**	**C_{EN}**	**KCO_2**
T	0.082 (0.041)*	-0.381 (0.054)**	-0.246 (0.023)**	-1.862 (0.275)**
A	3.260 (0.270)**	--	-0.869 (0.154)**	-28.802 (1.826)**
B	2.402 (0.295)**	--	-1.350 (0.168)**	-20.191 (1.997)**
C	1.337 (0.270)**	--	-0.748 (0.154)**	-11.961 (1.826)**
D	--	--	--	--
a	9,389 (0,633)**	16.925 (0.829)**	7.731 (0.361)**	61.55 (4.279)**
N	50	50	50	50
Adjusted R^2	0,769	0.495	0.793	0.866

The models in Table 3 show that the average temperature significantly explains depreciation, maintenance, energy consumption and CO_2 emissions. Energy performance D is not significant, meaning that there are no differences between E and D. It is logical to assume this by considering that an E energy rate is reached only in five climatic zones (B4, C1, C2, D1 and D2) and, moreover, that the kilograms of CO_2 obtained almost reaches the upper limit for energy rating D.

Model 1 indicates that the depreciation cost will increase by 1.34, 2.40 and 3.26 euros/m^2 for energy performances C, B and A, respectively.

Model 2 shows maintenance costs and reveals that there are no differences for the various energy ratings. The initial cost of €16.93/m^2 decreases by €0.381/m^2 for each degree of increased temperature in the climatic zone. Temperature explains up to 49% of the variability of maintenance cost. Maintenance work differs little between the ratings as many operations are the same, for example, painting, fire prevention, audiovisual, or ventilation facilities, etc. Such changes are quite insubstantial in the

 ISBN: 978-1-84219-840-7 .

global computation of the maintenance costs with just a few operations becoming cheaper from among the 45 routines considered.

Model 3 shows the cost of energy and indicates that temperature and energy ratings C, B and A explained 79% of the value obtained. In this case, the temperature variable has a negative coefficient, indicating as expected that the cost of energy consumption decreases in warmer areas.

Finally, Model 4 shows emissions of kg de CO_2 as a function of temperature and variables of the C, B and A energy rating. All the variables together explain 86.6% of the variability of emissions and have negative coefficients. This means that the warmer areas have lower emissions and these emissions decrease as the energy rating improves. The way the coefficients diminish between the ratings C, B, and A follows a logical and expected pattern as kg of emitted CO_2 is the indicator that the VYP Calener v.01 program uses to qualify buildings. The maximum emission is 61.55 kg per year for ratings D and E, and this decreases at a rate of 1.862 kg for each degree increase in temperature; and 11.96, 20.19 and 28.80 kg for the ratings C, B and A, respectively.

Standardised residuals were analysed in comparison with the established prognostic values to test the linearity and homoscedasticity of the models.

4 Conclusions

The Spanish building industry is presented with an opportunity to achieve a reduction in CO_2 emissions and build with greater energy efficiency. Recent European and Spanish regulations aim to encourage sustainable development of new housing in Spain. The first steps have been taken in this direction with the establishment of climatic zones and issuance of energy ratings. This makes it possible to assign a rating to each housing construction and relate it to investment costs and annual maintenance costs over its lifetime. In addition to the initial investment costs and annual energy costs, we have modelled the annual maintenance costs that would be incurred during the use of the dwelling for all the Spanish climatic zones and for each of the five possible energy ratings. In each zone, improving the energy ratings meant greater initial investments – but maintenance costs remained the same. In contrast, energy costs and CO_2 emissions decrease as energy ratings improve.

According to this study, more energetically efficient dwellings imply higher costs for users, which means that energy efficiency promotion is unlikely to happen. The perspective could change if considering social costs such as those related to CO_2 emissions. According to the model developed for CO_2 emissions, there is a clear decline in emissions as energy performance improves. If this could be monetized and introduced into the global sum of considered costs, there would be more arguments for energy performance improvement. This could be done by establishing an environmental tax for CO_2 emissions.

Evaluation of The Assessment Criteria to Determine Practical Completion as Provided for in The CIDB Endorsed South African Construction Contracts

Moyo L[1], Maritz MJ[1]

[1]Department of Construction Economics, University of Pretoria, South Africa

Email: lovemoremoyo@gmail.com; tinus.maritz@up.ac.za

Abstract:
Practical Completion (PC) is a term that is used in the construction industry to signify the completion of the works in part or whole depending on the form of contract in use, and is indicative of a fundamental achievement in the project life cycle. Literature, however, indicates that definitions of PC and its assessment criteria contained in standard contract documents are ambiguous, which have resulted in the interpretation of PC being a major basis for construction disputes (Always Associates, 2011). The problem is compounded in the case of projects that require varying degrees of completion to attain overall PC. Standard South African construction contracts such as the JBCC PBA (2007) and GCC (2004, 2010) and international construction contracts such as the NEC 3 (2005) and FIDIC (1999) do not define the determination of PC as such, but rather leave the assessment of PC to the discretion of the principal agent, project manager or engineer as the case may be; a subjective undertaking that is one of the major causes of disputes referred to above. This paper therefore seeks to establish an unambiguous and standardised definition of PC that would prevent disputes attributable to the definition of PC. The identification of clear assessment criteria to determine PC forms part of this process. Using South Africa as the geographic limitation of the study, the opinions of construction consultants were obtained by using a structured questionnaire survey, which was based on the literature reviewed. The survey was conducted among senior registered architectural, project management and engineering built environment professionals identified through their respective council registers.

Keywords:
Assessment criteria, completion, construction contracts, practical completion.

Abbreviations used

CIDB	Construction Industry Development Board (SA)
ECSA	Engineering Council of South Africa
FIDIC	International Federation of Consulting Engineers (the acronym stands for the French version of the name)
GCC	General Conditions of Contract
JBCC	Joint Building Contracts Committee

NEC	New Engineering Contract
PA	Principal Agent
PC	Practical Completion
PM	Project Manager
SACAP	South African Council of the Architectural Profession
SACPCMP	South African Council of Project and Construction Management Professionals

1 Introduction

The term "Completion" as used in the construction industry is both perplexing and compound (Egglestone, 2006). As a result Practical Completion (PC), a synonym for "Completion" has been at the centre of many construction disputes (Always Associates, 2011). The precise meaning of PC has caused a great deal of difficulty in the industry because the term is not uniformly defined in contracts (Wallace, 1986).

Wallace (1986) states that it is amazing that PC continues to cause disputes in the industry despite the fact that it has always been a common feature in construction contracts. The cases of *Westminster Corporation v J Jarvis and Sons*[1]*; H W Nevill (Sunblest) Ltd v William Press & Sons*[2], and *Emerson Eastern Ltd v EME Developments Ltd*[3]*, to name but a few* among the multitude of cases, serve as a reminder of the complexity surrounding PC (Egglestone, 2006). As a result of similar occurrences Wallace (1986) suggests that the meaning of PC in construction contracts should be addressed via the law. In addressing the matter the law also has to consider the following PC related sub-problems:

- There is no standard construction industry definition or term for PC;
- The definition of PC in standard construction contracts such as the JBCC PBA (2007), GCC (2004), NEC 3 (2005) and FIDIC (1999) is ambiguous;
- The interpretation of PC in standard construction contracts such as the JBCC PBA (2007), GCC (2004), NEC 3 (2005) and FIDIC (1999) is subjective, and therefore open to debate; and
- The occurrence of PC carries a number of significant commercial and legal consequences for the parties involved in a construction project (McLeod & Thompson, 2010).

[2] *H W Nevill (Sunblest) Ltd v William Press & Sons* (1981) 20 BLR 78
[3] *Emson Eastern Ltd v EME Developments Ltd* (1991) 55 BLR 114

2 Hypothesis

PC needs to be clearly defined by, inter alia, stating the deliverables which are expected as a minimum, making the certification of PC, or first delivery, non-subjective and more procedural, and thus ensuring consistency. The inclusion of a clear definition will contribute towards significantly reducing the number of conflicts related to PC.

The main hypothesis can be divided into the following sub-hypotheses:

- There is a need for a clear definition of PC.
- Measurable assessment criteria such as aesthetics (architect), functionality (mechanical, electrical, structural and civil), cost–value (quantity surveyor), health and safety (health and safety agent) have to be used to determine PC.
- The determination of PC should be executed by means of a team approach using a criterion based score card.

3 Literature Review

3.1 Construction project overview

As with any other process a construction project has a beginning and an end. The end or completion of a construction project in standard contracts is of great significance because it triggers a number of obligations and consequences such as listed by Pickles (2005):

- *The transfer of the responsibility for the care of the works from the contractor to the employer;*
- *The commencement of the patent defects liability period;*
- *The date when the contract works insurance cover comes to an end;*
- *The contractor's entitlement to have his performance guarantee/surety returned to him, or to have the amount of the construction guarantee reduced;*
- *The contractor's entitlement to the payment of the first moiety or part of retention monies (where retention is provided for);*
- *The beginning of the period of time allowed for the preparation and finalisation of the final account; and*
- *The end of any period of delay for which the contractor may be paying penalties*.

The industry has, however, been beset by a number of disputes relating to the completion of a construction project. As mentioned earlier, these disputes are usually related to the definition and assessment of completion (PC).

3.2 Construction contracts

In general, a standard form of contract for construction projects must entail the following:

- The execution of construction work i.e. alterations, new construction, rehabilitation or renovation;
- Mobilisation of resources to execute the works by providing in house or outsourced labour;
- A set of obligations for both parties; and
- A set date for completion referred to as the date for PC.

3.3 Defining PC

The lack of a standard industry definition or term for PC is largely due to the fact that various forms of construction contracts exist in the construction market. The CIDB (2011) endorses the following forms of contract in South Africa:

- JBCC PBA (2007);
- GCC (2010);
- NEC 3(2005); and
- FIDIC (1999).

Each of these contracts has a unique definition of or term for PC. The research will indicate that this phenomenon has led to different interpretations of PC. A brief narration of these definitions and terms as per the contracts is provided in Table 1.

Table 1: Narrative definition of PC

CONTRACT	TERM	DEFINITION	ASSESSMENT CRITERIA	DECISION MAKER
FIDIC	Taking Over	State where works are complete as per the contract	None	Engineer
GCC	Practical Completion	State when the works have reached a stage which allows their use for their intended purpose without danger or undue inconvenience.	None	Engineer
JBCC	Practical Completion	The stage of completion where the works or a section thereof is substantially complete and can effectively be used for the purposes intended	None	Principal Agent
NEC	Taking Over	State where the contractor has done all the work that the work information states is to be done by the completion date	None	Project Manager/ Engineer

It is evident from Table 1 that there is no standard definition or meaning for PC. PC also does not have a pre-established meaning as a matter of law (Ang, 2006). The matter is further complicated by the reality that a contractor never completes construction work in the true sense of the word, as he remains liable for latent defects which may manifest at any time in the future. As a result of this, many forms of contract indirectly define PC as a state of “less than complete completion”, an inference that PC is that stage of the works where there are no patent defects while acknowledging that there are or could be latent defects. The arguments presented thus far indicate that there is neither a standard definition nor a unified process for assessing PC.

This is surprising, given the fact that PC represents that stage of the works where a substantial portion of the mandatory obligations in the contract have been satisfied. As such, PC is a significant achievement in the life cycle of a construction project (Silver, 2006), which warrants a standardised definition and assessment criteria. Grewal (2009) states that this issue has become even more significant given the volatility of the industry as employers

may be less keen to take possession of completed works due to lack of money to pay the contractor for the work done, whilst contractors wish to leave the site as soon as possible to avoid carrying unnecessary risk for work done. The determination of PC is therefore a complex matter resulting in many disputes as stated hereinbefore.

3.4 PC procedures and protocols

Each standard form of contract has a set of procedures and protocols that the parties to the contract have to complete in order for the works to be certified as complete.

These broadly entail the following:

- PC inspection(s) undertaken by the principal agent (PA) / project manager (PM) / engineer who may be assisted by other members of the design team,
- Identification of defects and compiling a PC defects list, and
- Attainment of PC if the defects are considered to be trivial or rescheduling of a PC inspection if the defects are critical.

Standard forms of contract advocate that the works would be carried out in accordance with the requirements detailed in the contract documents, i.e. the contract drawings and project specifications which specify the minimum standards of acceptable workmanship. A PC inspection therefore determines whether the works have been completed in accordance with these drawings and specifications.

Any deviation from the contract documents is regarded as a defect. The test for PC is subject to a limited test of reasonableness known as the *de minimis* principle meaning that certification of completion of the works should not be refused if there are only trivial defects in the works (Mills, 2011).

3.5 Disputes

A dispute is a disagreement between contracting parties (JBCC, 2007; FIDIC, 1999). The construction industry has quite an unsavoury reputation with regards to disputes. Disputes between contractors and clients are widespread and ever increasing across all types of construction projects (Sally & Fitch, 2011). These disputes may emanate from a number of areas such as:

- Poor workmanship by the contractor;
- Failure to make timely payment;
- Failure to deliver the project on time; and
- Disagreement regarding the achievement of PC.

Disputes are frowned upon in industry because they are time consuming and costly (Sally & Fitch, 2011). It is thus surprising that the industry tolerates an increasing number of PC related disputes, given the fact that the matter seems controllable.

3.6 Establishing a standardised definition for PC

The following observations and/or recommendations can be made from the lessons deducted from the literature review and the related case studies examined:

- PC is easier to observe than to define, as a result the assessment of PC should include a visual survey;

- The definition of PC has to be carefully drafted at the start of a project;
- Qualifying criteria have to be added to the definition of PC at the start of a project;
- The definition of PC has to be accepted by the parties to the contract and communicated to the project team;
- The project team has to establish a list of possible patent and latent defects for the acceptance of or rejection of PC;
- Should there be no definition for PC, PC will mean a state of affairs in which the works have been completed free from patent defects other than those ignored as minor (these minor defects have to be identified);
- If the contractor achieves PC, it implies that the outstanding work has to be completed in an already occupied building, a task which can prove to be difficult. It is advisable that a contract indicates work restrictions, timescales and damages payable in respect of such work (Mills, 2011); and
- The *de minimis* principle applies in the determination of PC.

The regular occurrence of disputes as previously highlighted indicates that it is imperative for the parties to a contract to agree on the basis upon which PC will be determined. Such an approach leads to greater assurance in the agreement between the parties and a higher degree of trust which in turn encourages and facilitates a more successful outcome for all of those involved (Mills, 2011).

4 RESEARCH METHODOLOGY

4.1 Research method

Ndihokubwayo (2008) suggests that the research method affects the analysis of the data, which in turn affects the research findings. In order to preserve the integrity of the findings a descriptive research approach was adopted. This type of research involves identifying a situation as it is through a survey without manipulating it (Leedy & Omrod, 2005). Furthermore, Zikmund (2003, p.55) states that descriptive research seeks to clarify answers to the "who, what, when, where and how" questions. As such, a questionnaire was developed and used as the main approach to suitably address the main objectives of this paper, which sought to clarify the following:

- Who is better suited to determine PC, an individual or should a team based approach be adopted?
- What are the causes of PC related disputes?
- What additional documentation is required for certifying PC?
- When and how can PC related disputes be mitigated?

4.2 Population and sampling

The population (or research sample group) for the research consisted of built environment professionals who are registered with the following bodies:

- SACPCMP professionals;
- SACAP; and
- ECSA.

The built environment is infamous for its low survey response rate and against this background a purposeful targeting process was preferred to increase the response rate and the

confidence level of the responses. In the design of the structure of the questionnaire, the research problem and sub-problems were taken into consideration and it was endeavoured to address them by testing the proposed hypotheses.

The research questionnaire consisted of seven sections that can be summarised as follows:

- Section 1: Background
- Section 2: Level of use and understanding of construction contracts
- Section 3: Definition of PC
- Section 4: Assessment of PC
- Section 5: Documentation of PC
- Section 6: Skills and technical expertise
- Section 7: Research results

5 RESULTS

The number of respondents to whom the survey questionnaire was sent numbered one thousand. Two hundred and thirty five completed questionnaires were submitted from a combination of registered SACPCMP, SACAP and ECSA members, which resulted in a response rate of 24.2%. Response rates in the built environment are usually below 30% according to Crafford (2008). Consequently, the level of responses received can be deemed satisfactory and renders it possible for adequate inferences to be made regarding PC.

Survey Monkey was used to generate data tables and data frequencies for analysis and interpretation of the findings. The researcher's comments and analyses are thus based on these tables. The responses represented an almost equal distribution from the Engineering Construction sector (one hundred and ten responses) and from the Building Construction sector (one hundred and twenty five responses).

This fairly balanced distribution of responses received between the two sectors provides a realistic view of PC from an Engineering and Building Construction point of view. Figure 1 captures the survey findings in respect of the sector of the construction industry to which the respondents belong to.

 ISBN: 978-1-84219-840-7 .

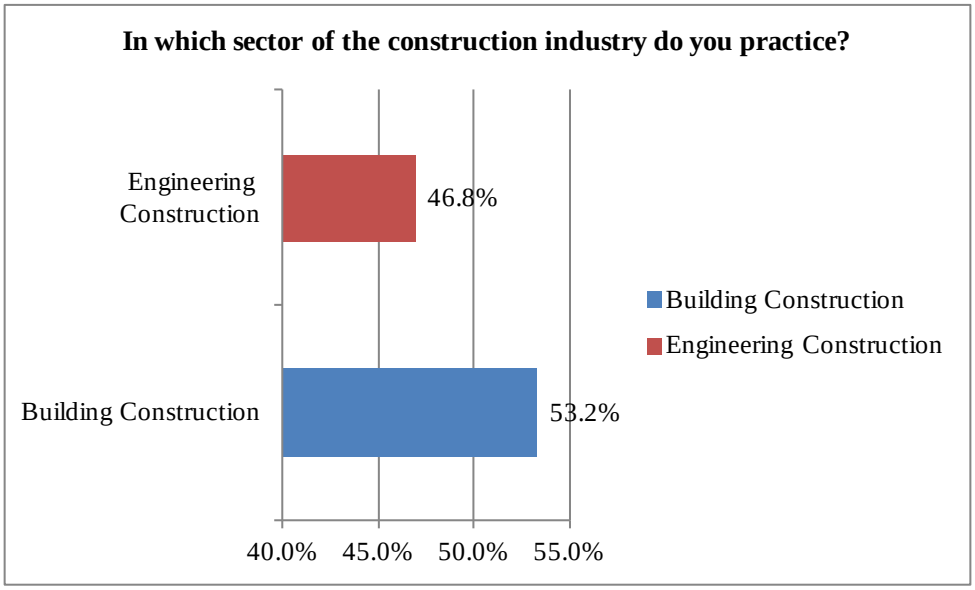

Figure 1: Sector of the construction industry

5.1 Response rates

A researcher should endeavour to use as many techniques as possible to increase the response rate (Zikmund, 2003), and the following additional steps were undertaken by the researcher to boost the response rate:

- The questionnaire was administered in three forms, mainly as a drop-off questionnaire and subsequently via email (with an attached Word version of the questionnaire) and on-line (Survey monkey);
- A reward of R1,000 was offered to one lucky respondent for successfully completing the questionnaire;
- The respondents were assured of anonymity;
- A reminder letter was sent after three weeks, including an additional questionnaire, email and Internet survey prompt request; and
- A reminder email was sent two weeks after sending the reminder letter.

5.2 Profile of participants

The profile for respondents indicates that the majority of respondents in the survey questionnaire where PMs (63.2%) followed by engineers (30.3%) and architects 6.4%). Figure 2 below captures the survey findings regarding which profession the respondents are qualified in.

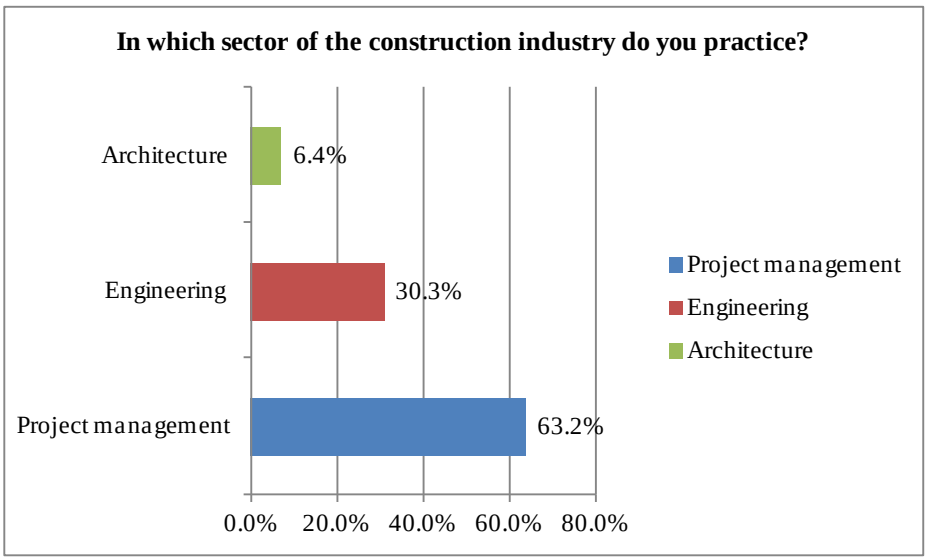

Figure 2: Professional qualification

PMs are often nowadays the key project drivers in the construction industry and they are responsible for making determinations regarding PC in contemporary building projects. Traditionally the architect and engineers were responsible for making determinations regarding PC. As a result the profile of participants is indicative of a fair mix of modern and traditional thinking regarding the questions posed in the survey questionnaire.

5.3 Participants' understanding of construction contracts

Respondents were requested to rate their understanding of construction contracts in use in the South African construction industry namely the JBCC PBA (2007), GCC (2004), NEC 3 (2005) and FIDIC (1999) suite of contracts. Of the total number of respondents 46.4% indicated that they had a high understanding of construction contracts while 41.4% of the respondents indicated an average understanding of construction contracts. The combined total of understanding of construction contracts is 87.5%. An assumption can therefore be made that the responses received can be relied on as being fairly accurate.

5.4 Training profile of participants

Respondents were asked whether they had received any formal training in the use and application of construction contracts namely the JBCC PBA (2007), GCC (2004), NEC 3 (2005) and FIDIC (1999) suite of contracts. Of the total number of respondents 75.4% indicated that they had received some formal training in the use of basic construction contracts, which further consolidated the reliability of the results.

5.5 Most familiar construction contract

Respondents were then requested to indicate which contract suite they are most familiar with. The majority of respondents (47.1%) indicated that they are most familiar with the JBCC suite of contracts. This is in line with the response rate that indicates that the majority of respondents are from the building construction sector. The building construction sector favours the JBCC suite of contracts over other forms of contract. The GCC and NEC follow next in terms of popularity with 26.5% and 17.2% respectively.

5.6 Significance in execution of projects

Respondents were also requested to indicate which items are significant in the execution of a project. The majority of respondents indicated that handing the project over to the client is the

most significant event in the execution of a project. This question was raised so as to appraise the respondents' understanding of what happens at PC. Figure 3 captures the survey results on the significance of items triggered at PC.

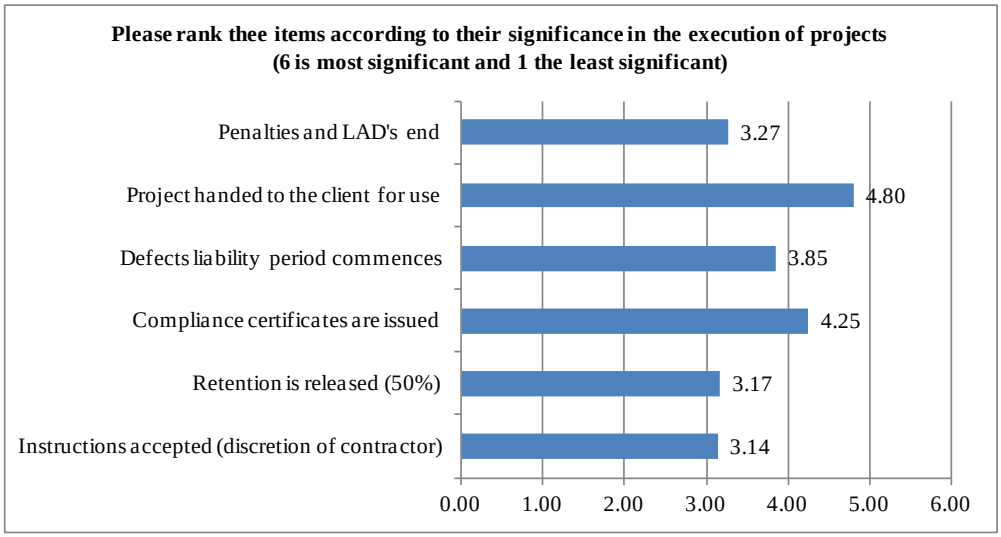

Figure 3: Significance in the execution of projects

6 FINDINGS

6.1 Sub-hypothesis 1

The first sub-hypothesis states that "… there is a need for a clear definition of PC". In view of this, respondents were requested to select the statement that best defines the respondents' understanding of the term PC. It was envisaged that if there is a clear definition of PC respondents would select one common response. The results as captured in figure 4 below however indicate the contrary.

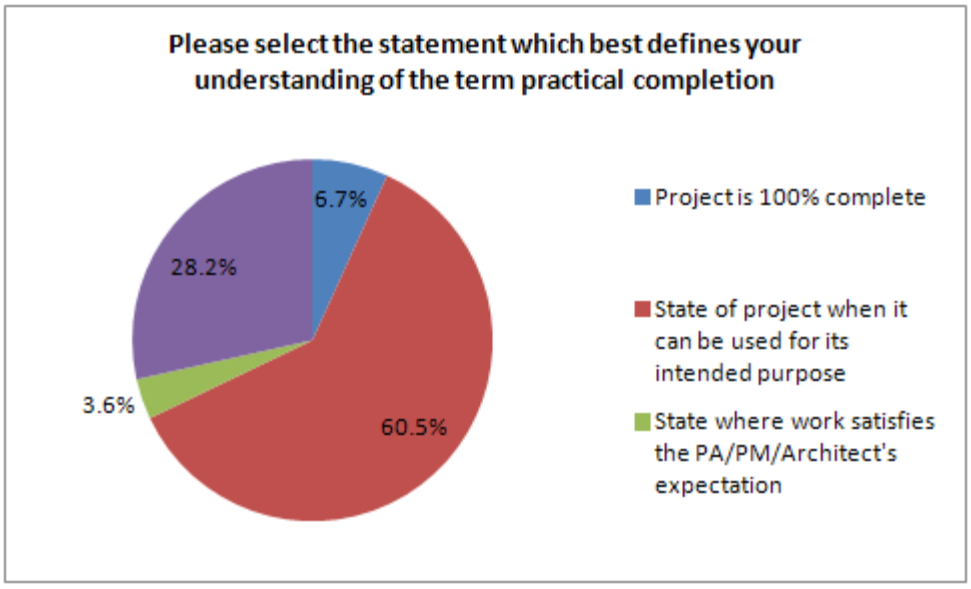

Figure 4: Statement that best defines understanding of PC

The findings indicate that there is no clear definition of PC although the majority (61.5%) supported the statement that PC is the state of the project when it can be used for its intended

purpose. (However, the response by the remaining 38.5% of the respondents still presents a difference in thinking and potential problems in terms of clearly defining PC). There is therefore clear a need for a universal definition for PC.

Sub-hypothesis 1 is therefore supported.

6.2 Sub-hypothesis 2

Sub-hypothesis 2 states that "… measurable assessment criteria such as aesthetics (architect), functionality (mechanical, electrical, structural and civil), cost–value (quantity surveyor), health and safety (health and safety agent) have to be used to determine PC". In order for the researcher to test the validity of this assertion respondents were requested to indicate how in their opinion PC 'could be best defined'. It was envisaged that if there was no need for measurable assessment criteria a common response would be selected.

Of the respondents the majority (66.7%) indicated that PC could be best defined by specifying the expected deliverables, 18.5% of the respondents indicated that PC could be best defined by assessing the client's expectations, whereas 14.9% of the respondents indicated that the PA/PM expectations are a better indication of how PC could be defined. Furthermore, respondents were asked whether they had experienced problems with the way PC is assessed and defined. More than half of the respondents (52.6%) indicated that they had encountered problems with the current process of determining PC.

Respondents where then asked how in their opinion, PC should be defined; that is either by using technical specifications as intimated in the hypothesis or whether contractual rights and obligations had to be clearly indicated to the assessors of PC. The majority of the respondents (61.8%) indicated that PC should be defined using technical specifications which can be used to determine or assess PC.

Respondents were then asked to rate their PC assessments to date as being fair, biased and/or having experienced client interference. Of the respondents, 65% indicated that their assessment had been fair to date, whereas 35% indicated that the assessments were either biased or affected by client interference. The 35% indication of bias and client interference justifies the need for assessment criteria although this sub-hypothesis was not fully supported by the findings of the survey.

It can however be surmised that the majority of the respondents (65%) was coerced due to lack of a sound alternative regarding the good professional standing of the respondents. In other words, respondents told the researcher what he or she wanted to hear rather than the truth (Leedy & Ormrod, 2005).

This assertion was further motivated by the respondents' opinion in response to the question about how the assessment criteria or method is to be defined. Of the respondents 52% indicated that the current assessment criteria are too concise, that it is, too brief and lacking detail, while 48% of the respondents indicated that it is vague or non-existent.

The respondents were then required to indicate what they considered to be the set back in the assessment of PC. Of the respondents, 45.8% indicated that there is a lack of clear deliverables, 32.7% of the respondents indicated that the lack of an assessment framework and documentation is a problem, whereas 21.4% indicated that there is a lack of common assessor skills in the determination of PC.

The respondents were then invited to suggest what they considered to be other setbacks in PC assessment. Of the total number of the open ended responses received, 47% indicated that the definition of PC needed to be clearly stated at the start of the project and that all team members have to be in agreement, so as to adequately assess PC at the end of the project. Issues relating to client interference, a lack of understanding relating to assessment of PC in construction contracts were also raised in the open ended responses.

As a result of the foregoing survey findings sub-hypothesis 2 is supported, which states that measurable assessment criteria have to be used to determine PC.

6.3 Sub-hypothesis 3

Sub-hypothesis 3 states that "… the determination of PC should be executed by means of a team approach using a criteria based score card". The respondents were asked whom to consider as the party who should assess PC. Of the respondents, 55% indicated that the determination of PC should be the PA or designated consultant's responsibility. This was almost twice the number of respondents who felt that there should be a team based approach to determine PC (28.3%). It is also worth noting that a fair portion of respondents (13, 9%) indicated that the client should determine PC.

Furthermore, respondents were asked to indicate the skills that are relevant for assessing PC. Figure 5 captures the survey findings on the skills that are considered relevant for assessing PC.

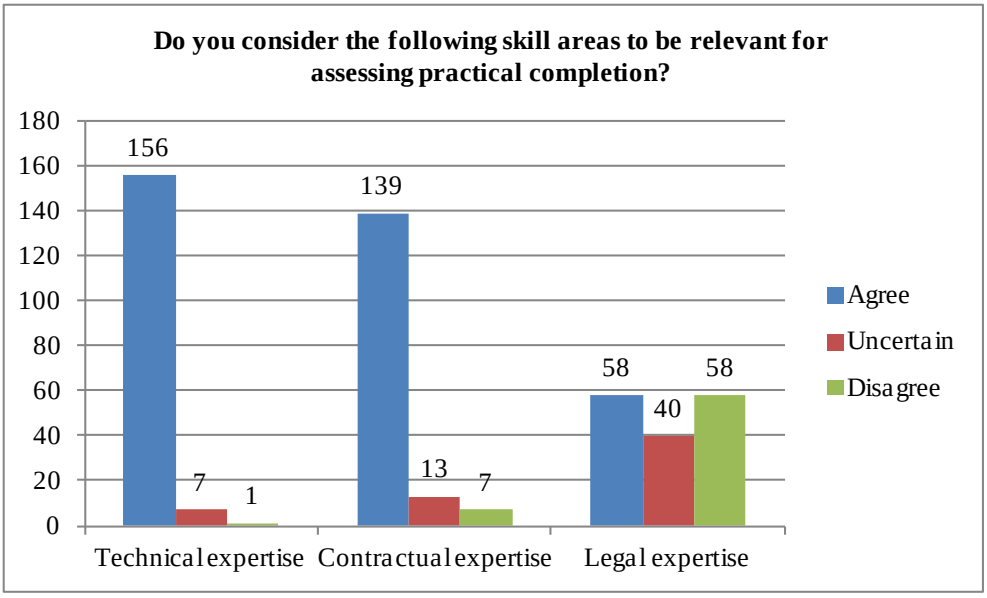

Figure 5: Skills relevant for assessing PC

Respondents were requested to rank the attributes that they considered to be desirable when assessing PC from an individual viewpoint. Respondents indicated that experience and fairness where the most fundamental factors in determining PC. Figure 6 captures the survey findings on desirable characteristics for assessing PC.

 ISBN: 978-1-84219-840-7 .

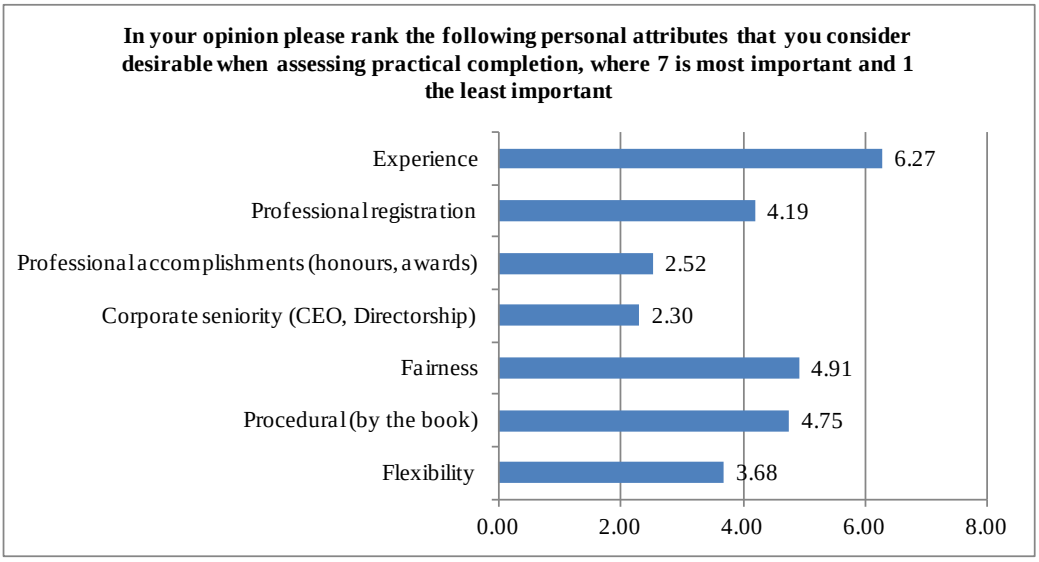

Figure 6: Desirables personal attributes for assessing PC

The findings themselves, however, indicate that the team approach as hypothesised in sub-hypothesis 3 is not supported.

7 CONCLUSION

PC of a construction project has been a source of contractual disputes for a prolonged period of time. Scholars attribute PC related disputes to the lack of a clear definition of PC and the lack of assessment criteria as well as deliverables to assess and determine PC of a project in an objective manner. As a result, the study sought to establish how PC is currently determined in order to determine whether there was a need for the establishment of a universal and clear definition for PC as well as to determine whether objective team based assessment criteria were required to determine PC in standard construction contracts.

A summary of the research findings is provided below:

Sub-hypothesis 1

- PC has to be defined clearly so that all the participants on the project understand exactly what is expected of them;
- PC can be defined per project in order to distinctly define the deliverables by their specifications; and
- A precise definition would assist in preventing or lessening the disputes encountered at PC stage.

Sub-hypothesis 2

- A PC assessment framework will set out the criteria that will be used to determine PC by specifying what is required or expected at PC and how it is going to be assessed by the professional team;
- Formal documentation has to form part of the determination of PC by the client's representative such as certificates of compliance and certificates of occupation; and
- The documentation to be issued at PC should be checked off on a deliverables checklist which can form part of the contract as a technical provision.

Sub-hypothesis 3

- The team approach to determining PC was not supported by the majority of the respondents as most shared the view that PC should remain as part of the duties of the PA/PM/engineer.

From the research findings PC as defined in the JBCC PBA (2007) seems to be the most applicable; this can be slightly modified as a generic definition for construction contracts to read:

> *the state of completion as certified by the PA/PM/engineer where the works, or a section thereof, is substantially complete notwithstanding the presence of minor defects and can effectively be used for the intended purpose as described in the contract data, or when the employer by agreement takes occupation of the works, or part of the works, before the intended or revised date of PC.*

It is envisaged that the use of such a standard definition will result in consistency and fairness vis-à-vis the determination of PC in the construction industry.

Recommendations

- The study has confirmed that the determination and assessment of PC is a subjective process, which, coupled with the ambiguous definition of PC in standard forms of contract, often has the result that the process of achieving PC ends in dispute. The researcher recommends that in the determination and assessment of PC the PA/PM/engineer adopts the principles of objectivity supported by specific assessment criteria to be agreed between the parties at the outset of the project (refer Annexure A for an example of such assessment criteria).
- A formal course on PC assessment (including the consequences thereof) as part of continuous professional development, should be made compulsory for all built environment professionals, who normally assume the role of PA/PM/engineer on projects.

In conclusion it may be stated that the main objective of this study has been achieved and that the development and adoption of a clear definition of PC as well as assessment criteria, coupled with the implementation of the recommendations made, where applicable, would go a long way towards reducing the number of PC related disputes in the construction industry.

ANNEXURE A: ASSESSMENT CRITERIA FOR PC

The state of completion where, in the opinion of the PA/PM/engineer:

1. Residential: Private dwelling

The works may be occupied by the owner/tenant with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

2. Residential: Block of flats/cluster home/townhouse/hostels

The works may be occupied by the owner/tenant after all remedial work has been completed;

3. Residential: Hotel and/or retirement home

The works may be occupied by the owner/tenant for the purpose of installing built in furniture, fittings and equipment (FF&E) and with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

4. Industrial buildings: Warehouse/factory/distribution centres

The works may be occupied by the owner/tenant for the purpose of installing built in fixtures, fittings, plant and equipment and where loading bays and parking areas are available for owner/tenant use and with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

5. Commercial: Office buildings

The works may be occupied by the owner/tenant with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

6. Commercial: Shopping centres

The works may be occupied by the owner/tenant for the purpose of installing built in fixtures, fittings, plant and equipment and where loading bays and parking areas are available for owner/tenant use and with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

 ISBN: 978-1-84219-840-7 .

7. Head office buildings for specific building owner/tenant

The works may be occupied by the owner/tenant with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

8. Buildings for education: Schools/universities/colleges

The works may be occupied by the owner/tenant with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

9. Correctional Services: Prisons

The works may be occupied by the owner/tenant and all remedial work as listed by the PA in a PC list has been completed;

10. Health care buildings: Hospitals/clinics

The works may be occupied by the owner/tenant and all remedial work as listed by the PA in a PC list has been completed;

11. Public buildings: Theatres/museums/libraries/fire stations

The works may be occupied by the owner/tenant for the purpose of installing built in fixtures, fittings, plant and equipment and where loading bays and parking areas are available for the owner/tenant use and with minor disruption to carry out remedial work during the defects liability period to achieve final completion;

12. Other

To be described by the PA in the contract data when preparing the tender enquiry document and should cover the specific building type if not listed.

New Disadvantaged Business Enterprise (DBE) Requirements for United States Federal Stimulus Funded Projects

Thomas M. Korman, Ph.D., P.E, P.LS[1] , Lonny Simonian, P.E., P.M.P.[1], and Hal A. Johnston, C.P.E.[1]

[1]Construction Management Department,
California Poythecnic State University, San Luis Luis Obispo, CA
United States

Email: tkorman@calpoly.edu; lsimonia@calpoly.edu; hjohnsto@calpoly.edu

Abstract:
It is policy of the United States Federal Highway Administration (FHWA) to promote increased participation of Disadvantaged Business Enterprises (DBEs), which are defined as for-profit small business that are at least 51% owned and controlled by one or more socially and economically disadvantaged individuals, for federally funded highway construction projects. Through the development and implementation of supportive services programs, the FHWA contributes to the growth and eventual self-sufficiency of DBEs so that they may achieve proficiency in competing for contracts and subcontracts, administered by State Transportation Agencies (STA). When the US Congress enacted the Surface Transportation Assistance Act (STAA) of 1982, it also directed that at least 10% of Federal-aid highway and transit funds be expended with small disadvantaged business firms. These regulations expanded upon the Minority Business Enterprise (MBE) program, which had been in effect since 1972. The American Recovery and Reinvestment Act (ARRA), enacted by the US Congress intended to provide an economic stimulus. When appropriated the ARRA funds brought new requirements for the DBE Program that include a Race Conscious component and apply to all project phases from engineering through project closeout. This paper reviews and provides an analysis the new DBE requirements and their application to ARRA Projects.

Keywords:
Disadvantaged, business, enterprises, effort. Highway.

1 Introduction

The recent American Recovery and Reinvestment Act (ARRA), enacted by the US Congress in February 2009, intended to provide a stimulus to the U.S. economy in the wake of the economic downturn. To date, over $30 billion of the ARRA funds have been allocated for transportation investments, which have been given to states and local agencies. With the appropriation of the ARRA funds, it is the policy of the Federal Highway Administration (FHWA) to promote increased participation of Disadvantaged Business Enterprises (DBE's). New requirements have now been implemented by the FHWA DBE Program that include a Race Conscious component.

The Federal Highway Administration (FHWA) policy was designed to promote increased participation of DBEs in federal-aid highway contracts through the development and implementation of supportive services programs, which contribute to the growth and eventual self-sufficiency of DBEs so that they may achieve proficiency in competing for contracts and subcontracts, administered by State Transportation Agencies (STA). Therefore, when the United States Congress enacted the Surface Transportation Assistance Act (STAA) of 1982, it also directed that, to the extent possible, at least 10 percent of Federal-aid highway and transit funds be expended with small disadvantaged business firms. These regulations expand upon the Minority Business Enterprise (MBE) program, which has been in effect since 1972.

2 Disadvantaged Business Enterprise (DBE) Defined

A DBE is a for-profit small business that is at least 51% owned and controlled by one or more socially and economically disadvantaged individuals, as defined in 49 Code of Federal Regulations (CFR) 26. There are citizens of the United States (or lawfully admitted permanent resident) Member of one of the following groups:

- Black American,
- Hispanic American,
- Native American,
- Asian-Pacific American,
- Subcontinent Asian Americans, and
- Women

In 2000 Western States Paving Co. (Washington State) submitted the lowest bids on two separate Washington State Department of Transportation (WSDOT) subcontracts. In each case, Western States' low bid was rejected in favor of a more expensive bid by a minority-owned contractor. (In one case their bid was actually $100,000 lower than that of the minority-owned firm which was awarded the subcontract.) This occurred because applicable federal and state laws demanded that a percentage of the federal highway money must go to minority-owned firms.

Western States sued in U.S. District Court, and they lost. Western States then appealed the District Court ruling to the 9th Circuit Court of Appeals, who ruled in favor of Western States. The three judge panel of the 9th Circuit Court ruled that WSDOT had failed to prove the existence of lingering effects of past discrimination - underutilization in quota-speak - in the local road building business which is legally required in order to justify the use of racial targets and goals (quotas).

The ruling applies only to recipients of Federal financial assistance from the

- Federal Highway Administration (FHWA)
- Federal Transit Administration (FTA)
- Federal Aviation Administration (FAA)

 ISBN: 978-1-84219-840-7 .

located in the states comprising the 9th Federal Judicial Circuit, which only includes the following states: Alaska, Arizona, California, Hawaii, Idaho, Washington, Oregon, Montana, ad Nevada. In addition, this ruling covers the U.S. territories, of Guam, and Northern Mariana Islands.

In 2005, the FHWA issued guidelines to all state DOT's to conduct Availability & Disparity Studies. Disparity Studies found the underutilization of four groups:

- Black American,
- Native American,
- Asian-Pacific American,
- Women

These four DBE groups are considered Underutilized DBEs (UDBEs). The findings determined that the DOT's should implement Race Conscious DBE Programs to address underutilization.

3 Calculating DBE Goals

The 9th Circuit Court stated that race conscious elements must be limited to those parts of the country where its race-based measures are demonstrably needed. Therefore, it is necessary to determine the market area (within an agency's geographic area), where contractors have historically bid on similar contracts. Two goals are now necessary: DBE % goal and the UDBE % goal. Only UDBE participation will count towards the Race/Gender Conscious UDBE goal. DBE participation by Hispanic Males and Subcontinent Asian Males will only count towards the Race/Gender Neutral DBE goal portion. Typical methodologies for calculating a DBE and UDBE Goal includes:

- Determining the Market Area (within an agency's geographic area, all counties where contractors have historically bid on similar contracts
- Obtaining the total number of business establishments listed in the market area using the County Business Patterns databases (U.S. Census Bureau)
- Obtaining the total number of DBE and UDBE business establishments located within the market area using a Unified Certification Program (state specific).

4 DBE Program Contract Administration

New Disadvantaged Business Enterprises (DBE's) Requirements affects the following project phases

- Engineering
- Bidding
- Good Faith Effort's
- Contract Award
- Construction
- Project Closeout

Engineering

Under federally funded projects DBE and UDBE goals apply to professional services. Agencies are required to set DBE and UDBE goals

Bidding

Agencies are required to unbundle contracts and set schedules to facilitate DBE participation. Provide information on contracting opportunities and procedures. Hold pre-bid meeting with primes and DBE's to explain program requirements and RC and RN goals. Implement supportive services program to improve business management. Distribute DBE directory to plan holders. Provide occasions for DBE's to network with primes

Good Faith Effort's

Bidders are required to submit Good Faith Efforts (GFE), which should include:

- Names and dates of publications used by bidder
- Items of work made available to UDBE's
- Names, address and phone number of rejected UDBE's and reasons other firms were selected
- Efforts made to assist UDBE
- Names of agencies contacted to provide assistance
- Any additional documentation to show GFE

Agency must determine if bidder has made a GFE, if the bidder does either of the following things:

- Documents that it has obtained enough DBE participation to meet the goal; or
- Documents that it made adequate GFE to meet the goal, even though it did not succeed in obtaining enough DBE participation to do so.
- Bidder required to submit solicitations of UDBE's
- Names and addresses of UDBE's participating
- Description of work each UDBE will perform
- Dollar amount of participation of each UDBE
- Written documentation of commitment to use UDBE
- Written confirmation from UDBE that is participating

Must ensure documents are complete, accurate and adequately document GFE. Agencies are burdened with making a fair/reasonable judgment, which includes evaluating the following:

- Quality, quantity, intensity of efforts
- Actively & aggressively trying to meet goal
- Efforts of other bidders

Contract Award

Contract award shall be made only to a bidder who makes good faith efforts to meet the UDBE goal. If bidder does document adequate GFE, award of the contract must not be denied on the basis that the bidder failed to meet the goal. (49 CFR Part 26.53). However, bid protests are likely to occur if second and third bidder meet the UDBE goal and low bidder did not.

Construction

During the construction phase of a project, agencies must maintain oversight of prime contractor's activities (subcontracts and goals) to ensure consistency with requirements. The prime contractor must not terminate a UDBE to self-perform the work. If a UDBE is terminated, the prime contractor is required to make substitution of GFE to obtain another UDBE if needed to reach contract goals. Furthermore, it is the responsibility of the local agencies Resident Engineer (RE) to report in their daily reports, the labor, equipment, and materials used by UDBE.

Project Closeout

At the end of a project, the local agencies are required to document and list all subcontractors who worked on the project. In addition, they are required to list materials and supplies obtained from a DBE/UDBE manufacturer which count as 100% of cost toward DBE/UDBE goals, and list all materials and supplies purchased from a DBE/UDBE regular dealer which count as 60% of cost toward DBE/UDBE goals.

5 Conclusions

The Disadvantaged Business Enterprise Program was created to ensure non-discrimination in the award and administration of federally assisted contracts and to create a level playing field on which DBEs can compete for federally assisted contracts. Benefits have included the remove barriers that affect participation of DBEs in federally assisted contracts; and have assisted in the development of firms that can compete successfully in the marketplace outside the DBE program.

Protecting Highway Construction Workers through Legislation

Thomas M. Korman, Ph.D., P.E, P.LS[1] , Lonny Simonian, P.E., P.M.P.[1], and Hal A. Johnston, C.P.E.[1]

[1]Construction Management Department,
California Poythecnic State University, San Luis Luis Obispo, CA
United States

Email: tkorman@calpoly.edu; lsimonia@calpoly.edu; hjohnsto@calpoly.edu

Abstract:
In recent years there have been numerous pieces legislation aimed at increasing safety for construction workers. Of particular interest are those relating to the protection of highway construction workers. These include the following, the "Move Over and Slow Down" law, Double Fine Zones, Anti-assault and Battery law. The paper reviews and provides an analysis of the new legislation and it impacts on the construction industry

Keywords:
Assault, construction, highway, protection, workers.

1 Introduction

The main body of all papers should commence with an introduction section which should explain the background and purpose of the paper. Formatting is described in section 2 below. In recent years, the California legislature passed and the governor approved 696 new bills, many of which impact the construction industry. Of particular interest are those relating to protecting the safety of highway construction workers. This includes the following:

- "Move Over and Slow Down" law
- Double Fine Zones
- Anti-assault and Battery law

About ten (10) years ago, the term "road rage" entered the common vocabulary in the United States. The California Driver handbook defines road rage by stating that "Road rage happens when one driver reacts angrily to another driver."[1] Road rage can take many forms, ranging from an extended middle finger and a loud stream of obscenities to actual physical violence. Other common examples of road rage-induced behaviors include tailgating another vehicle to intimidate the other drivers for going too slow, following other motorist who have committed a traffic offense, cutting other motorist

[1] California Drive Handbook

off, etc. The common thread between all of these acts is that they are committed with the intent of punishing or getting revenge on another driver.

Incidents of road rage have been increasing since the 1990's, the American Automobile Association (AAA) Foundation for Traffic Safety reported a 51% increase in road rage incidents from 1990 and 1996. There has been some dispute as to whether this dramatic increase was due solely to an increase in road rage incidents or whether increased reporting of these types of incidents might also have also played a role in the statistics. However, road rage soon became so much of a public concern that in 1997 Congressional hearings were held on the issue. In a recent report published by the National Highway Traffic Safety Administration (NHTSA)[2], the following is stated, "If it seems that there are more cases of rude and outrageous behavior on the road now than in the past, the observation is correct, if for no other reason than there are more drivers driving more miles on the same roads than ever before".

2 Construction Zones and Temporary Traffic Control

When construction work is performed on a highway, highway construction workers often become the target and/or victims of road rage acts. Temporary traffic control (TTC) measures include signs and message boards to warn drivers of workers, slow moving equipment, and closed lanes ahead. Through the use of cones, drums, and delineators, motorists are guided through a highway construction work zone. In addition, motorists are instructed to merge as soon as it is safe to do so and without crossing the cones or drums and reduce peed and be prepared to slow down or stop for highway equipment. In highway construction work zones, travel lanes are often narrowed and/or the highway shoulder is closed. Motorists are advised to watch for bicycles and "share the road" when they are present.

The most common cause of deaths and injuries in work zones are rear-end collisions. In fact, most of the people killed in work zones are drivers and passengers. Motorists are instructed, for their safety and the safety of their passengers, to slow down, allow extra following room between vehicles, merge early, expect sudden slowing or stopping, watch for other motorists changing lanes at the last minute, and to minimize distractions. Lastly, motorists are instructed not stop the vehicles to watch the highway construction work and obey special signs or instructions from workers.

There have been several high-profile cases of California road rage in recent years. In July of 2007, California Highway 138 had to be completely closed down due to road rage directed at construction workers. The highway, which is located near Wrightwood, California, was being widened due to an increase in population and vehicle traffic that had overwhelmed the highway's capacity. During construction of the highway widening project, motorist experienced significant travel delays. A construction worker was shot with BB's, threatened, cursed at, and it was even reported that highway construction workers had food thrown at them.

[2] National Highway Traffic Safety Administration

3 Move Over and Slow Down

In 2007, California, implemented a "move over" law requiring drivers to move over or slow down when they see emergency responder vehicles on the side of the road. A revision of the statute was effective January 1, 2010, which adds an additional category to the list of covered responders (DOT vehicles with flashing amber warning lights) and makes the law permanent. This revision to the existing law was introduced as Senate Bill (SB) 240 by Senator Roderick Wright, District 25 (Inglewood).

The law requires motorists to slow down and, if safe, move over to a lane not immediately adjacent to the stationary vehicle. The law does not apply when the vehicle with flashing warning lights is not adjacent to the freeway or is separated from the freeway by a protective physical barrier. The previous law required motorists to only yield to law enforcement, emergency responders, or tow truck operators who are working on the roadside. According to Caltrans Interim Director Malcolm Dougherty, “Motorists often automatically slow down when they see police or CHP officers…We also want them to slow down for Caltrans vehicles and equipment”.

The Move Over law, which took effect in 2007, requires drivers to move over one lane when emergency vehicles displaying flashing lights are present. It was amended in 2009 to add Caltrans vehicles displaying flashing amber lights. Drivers are required to move over and slow down when approaching a stationary emergency vehicle or tow truck that is displaying flashing amber warning lights, or a vehicle, marked DOT that is displaying emergency flashing or amber warning lights, while it is stopped on the side of a state highway or freeway. The law is designed to reduce the deaths of police officers, tow truck drivers, paramedics, DOT employees, and other emergency personnel who are aiding stranded or injured motorists or involved in road work. California law specifies a fine of not more than $50 per violation as the penalty for failure to comply

4 Double Fine Zones

Due to increased collision-related injuries and fatalities, certain roads are designated as "Safety Enhanced- Double Fine Zones." Fines for violations are doubled in these zones and also in highway construction or maintenance zones when workers are present (CVC §42010). Section 97 of the Streets and Highways Code, relating to highways allow for the provision to designate highway or road segment as a Safety Enhancement-Double Fine Zone. The provision requires the Director of Transportation, in consultation with the Commissioner of the California Highway Patrol, to certify that a segment of state highway meets specified criteria. It allows for the designation to remain valid for a minimum of two (2) years and authorizes the renewal and revocation of a designation, as specified. A state highway segment qualifies for a double fine zone designation by the department as a Safety Enhancement-Double Fine Zone if all of the following conditions have been satisfied:

- The Director of Transportation, in consultation with the Commissioner of the California Highway Patrol, certifies that the segment identified in subdivision meets the following criteria: first the highway segment is a conventional highway or expressway and is part of the state highway system, and second, the rate of total

collisions per mile per year on the segment under consideration has been at least 1.5 times the statewide average for similar roadway types during the most recent three-year period for which data are available, and third the rate of head-on collisions per mile per year on the segment under consideration has been at least 1.5 times the statewide average for similar roadway types during the most recent three-year period for which data are available.

- The Department of the California Highway Patrol or local agency having traffic enforcement jurisdiction, as the case may be, has concurred with the designation.
- The governing board of each city, or county with respect to an unincorporated area, in which the segment is located has by resolution indicated that it supports the designation.
- An active public awareness effort to change driving behavior is on-going either by the local agency with jurisdiction over the segment or by another state or local entity.
- Other traffic safety enhancements, including, but not limited to, increased enforcement and other roadway safety measures, are in place or are being implemented concurrent with the designation of the Safety Enhancement-Double Fine Zone.

5 Anti-Assault and Battery

Legislation has recently been established to protect highway workers against the offense of assault when engaged in the performance of their duties. Prior legislation defined a "highway worker" as an employee or contractor of the Department of Transportation (DOT) engaged in specified activities related to state highways. New legislation expands the definition of highway workers for that offense of assault to include employees of a city, county, or city and county, as well as employees of a contractor while working under contract with the DOT, contractors and employees of contractors while working under contract with a city, county, or city and county, and volunteers. This paper reviews and provides an analysis of the new legislation and its impact on the construction industry.

This piece of legislation began as Assembly Bill (AB) 561, proposed by Assembly Member Wilmer Amina Carter who represents California's 62nd Assembly District, which includes the City of Rialto, City of Colton, City of Fontana, California, and the City of San Bernardino in the County of San Bernardino.

When AB 561 was proposed, an existing law had already been established to protect highway workers against the offense of assault while engaged in the performance of his or her duties, where "highway worker" is defined as an employee or contractor of the Department of Transportation engaged in specified activities related to state highways. AB 561 expanded the definition of highway worker for that offense to include employees of a city, county, or city and county, as well as employees of a contractor while working under contract with the Department of Transportation, contractors and employees of contractors while working under contract with a city, county, or city and county, and volunteers, as defined, and to include additional specified activities related to local roads or streets.

As stated in the California Penal Code under Section 241.5. (a) and Section 1720.4 241.5. (a), when an assault is committed against a highway worker engaged in the performance of his or her duties and the person committing the offense knows or reasonably should know that the victim is a highway worker engaged in the performance of his or her duties, the offense shall be punishable by a fine not to exceed two thousand dollars ($2,000) or by imprisonment in a county jail up to one year or by both that fine and imprisonment. (b) As used in this section, "highway worker" means an employee of the Department of Transportation, a contractor or employee of a contractor while working under contract with the Department of Transportation, an employee of a city, county, or city and county, a contractor or employee of a contractor while working under contract with a city, county, or city and county, or a volunteer as defined in Section 1720.4 of the Labor Code who does one or more of the following:

- Performs maintenance, repair, or construction of state highway or local street or road infrastructures and associated rights-of-way in highway or local street or road work zones.
- Operates equipment on state highway or local street or road infrastructures and associated rights-of-way in highway or local street or road work zones.
- Performs any related maintenance work, as required, on state highway or local street or road infrastructures in highway or local street or road work zones.

6 Conclusions

Concern over the increase in highway worker deaths, the California Department of Transportation (Caltrans) has partnered with the California Highway Patrol (CHP) to provide enhanced speed and DUI enforcement in highway construction and maintenance zones across California. Four (4) Caltrans workers died in traffic-related incidents during the 2011 calendar year. Three (3) were killed within 48 days, during the months of May and June. The deaths reversed a steady trend of reduced fatalities, which is partially attributed to the "Slow for the Cone Zone" public awareness campaign, which was established in 1999. A total of 178 Caltrans workers have died on the job since 1924. The partnership between Caltans and the CHP has resulted in CHP officers parking their patrol vehicles within construction work zones. Caltrans hopes that the presence of the officers will help to slow traffic or encourage vehicles to move over at least one lane from a highway work zone, as required by the Move Over law described above.

The CHP now employs one or more additional enforcement vehicles at some construction work zones. The presences of the CHP officers are to enhance and ensure safety, and will ticket drivers traveling too fast in work zones.

"Adhering to this law can mean the difference between life and death," said CHP Commissioner Joe Farrow. "The only way to prevent tragedies from occurring on the side of the road is by giving emergency personnel, highway workers and the public some space."

In order for motorist to be motivated by the threat of fines, they must at least be aware that the fines exist. Warning signs should be consistently used on roadway construction

projects to increase public awareness. Through the Internet, public service announcements, billboards and other media further partnership is recommended between Caltrans, the CHP, the California Office of Traffic Safety, and the Department of Motor Vehicles to increase awareness of the aforementioned laws.

Abstract:
Public-Private Partnerships have been widely used to deliver public infrastructure and services. An enabling legal framework is essential for smooth PPP application. This paper is aimed at examining the legal constraints for PPPs and exploring possible solutions to remove the constraints. Comparative case studies of PPP practices in New Zealand and China were adopted with semi-structured interviews as main data collection method. The results show that the New Zealand's legal system generally allows the adoption of PPPs, although some Acts impose procedural requirements on obtaining approvals and land acquisition. The challenges with legal framework in China are multi-faceted and mainly reflected in: (1) uncertainty of the legitimacy of the government to enter into PPP contracts; (2) indirect constraints such as insufficient protection of property rights and potential risks of appropriateness, limitations on private asset and land ownership, and impediments for obtaining approvals by the private sector; and (3) fragmented and inconsistent legal base. The research suggests that to address the legal constraints, the public sector is required to set up effective governance structure, develop strong leadership, be consistent with its policy and commitment, promote standardised PPP legal or guideline document, and take on more risks.

Keywords:
China, legal constraints, New Zealand, Public-Private Partnerships (PPPs)

1 Introduction

Public-Private Partnerships (PPPs) have gained increasing popularity across various countries in the provision of public assets and associated services. The infrastructure sectors in which PPPs have been applied include roads, urban rail, water and wastewater, power station, hospital, schools and prisons (Grimsey and Lewis, 2005, Kwak et al., 2009). PPPs have captured much attention by governments due to the perceived benefits such as better risk allocation, improved quality of services, and alleviation of public budgetary constraints (Cheung et al., 2009, Li et al., 2005). International practices suggest that not all PPP projects have achieved equal success. A

number of researchers such as Zhang (2005), Mahalingam (2010) and Aziz (2007) identified that lack of enabling legislative framework is one of the main reasons impeding the fruition and successful implementation of PPPs. Issues in relation to legislation, such as restrictions on Direct Foreign Investment (DFI) and prohibitions on private sector participation in the long-term operation and management of public services, are likely to pose considerable constraints on the adoption and application of PPPs (Adams et al., 2006, Zhang and Kumaraswamy, 2001).

This research aims to investigate the possible legal constraints inhabiting the use of PPPs and suggest workable strategies to address the constraints and further facilitate PPP implementation. In order to achieve the objective, comparative studies of New Zealand and China PPP practices were conducted with a special focus on the legislative and regulatory aspects. Semi-structured interviews were used as the main data collection instrument to investigate whether the participants envisage problems in the development of PPP programmes that are caused by lacking of enabling legal framework. By drawing on similarities and differences on the legal regime of PPPs between the two countries, improvements to PPP-related legislation and regulative provisions are suggested.

2 Literature Review

2.1 Importance of enabling legal framework for PPPs

The legal framework regulates the limits in which the government and private entities work (Aziz, 2007). Adequate legal framework provides a foundation for public procuring authorities to structure a PPP procurement process and establish contractual relationship with the private sector partner that are pursuant to the host country's legislation (Zhang and Kumaraswamy, 2001).

Researchers such as Chan et al (2010) and Grimsey and Lewis (2004) stressed that the attraction of prospective PPP projects to the private sector entities largely depends on the environment where the projects are undertaken. Lacking of an enabling legal framework, the legitimate rights of the private sector cannot be guaranteed, resulting in potential risks, especially the political risks like expropriation and nationalisation (Wang et al., 1999). Without an adequate legal basis in place, the public interests are likely to be threatened as given the limited number of capable participants to finance and bid for PPPs, PPP procurement may create a non-competition situation, aggravating the risk that the right partner is not selected. Also, lack of sufficient legal provisions to protect the public interests, the quality of public services may be compromised as the private sector partner is likely to opt for sub-optimal service solutions in order to achieve excessive profits from participating in PPPs.

2.2 Legal constraints for PPPs

Despite the importance of an enabling legal framework for the adoption and application of PPPs, a wide range of legal constraints for PPPs have been identified from past global PPP experiences. Generally, the legal constraints primarily manifest in three main categories:

2.2.1 Direct restrictions on the adoption of PPPs

In some countries, there are explicit legal provisions that prohibit the use of PPPs in infrastructure development. The prohibitive provisions cover various aspects, including the restrictions on the private sector's involvement in the operation and management of public services, constraints of long-term leases or ownership of public assets or land, limitations on the private sector to exert third-party charge (e.g., tolls) for the usage of public services, and restraints on the private sector to wholly, or partly invest in the provision of public assets (Algarni et al., 2007, Grimsey and Lewis, 2004).

2.2.2 Indirect constraints for the smooth implementation of PPPs

Researchers such as Adams (2006), Li (2005) and Aziz (2007), found that in addition to clearly specified legislation precluding the private sector's participation, legal constraints exist that will indirectly impede the application of PPPs. For example, in Australia, some PPP models (e.g., full-service model, incorporating "core services") are excluded from the spectrum of PPPs when selecting the delivery method (Jefferies and McGeorge, 2009). In Europe, prior to the introduction of "Consolidated Directive on public procurement and concessions in 2004, the previous European Union (EU)'s public procurement rules could not sustain highly sophisticated procurement, like PPPs (Savvidese, 2011). In China, despite the release of laws concerning property rights, the private sector's concerns still exist that their rights specified in the PPP contract cannot be properly protected under the current legal system (Adams et al., 2006).

2.2.3 Inconsistencies of legal provisions between various levels of governments

Sometimes the legal and regulatory provisions or policies are not consistent among different levels of governments, as suggested by Chen (2009) and Yuan (2010). PPPs may be allowed under central government whilst the provincial or municipal government precludes the private sector's participation in public works. Also, the regulations in different sectors governing the capital asset management may vary regarding the permission of PPP use (De Jong et al., 2010).

2.3 Responses to the legal constraints for PPPs

Differing strategies have been adopted to respond to the legal constraints for PPPs. Competitive Dialogue procedure was introduced to the EU for complex procurements (e.g., PPPs) to provide policy, legal and institutional frameworks for PPPs (Savvidese, 2011). The use of Competitive Dialogue assists with maintaining competition between the private participants and ensuring the contracted party have the required capacity to fund and operate PPPs (KPMG, 2010). In the UK, Australia and Canada, a suite of PPP guidance and policies have been developed, detailing the PPP procurement processes, requirements for contract management and guidance on value for money assessments (Aziz, 2007). Carrillo (2008), Dixon (2005) and Zhang (2005) believed that such guidelines and policies offer a basis for structuring and implementing PPPs under a stable and enabling legal and regulatory framework. Chen (2009) and Wang (1999) maintained that for developing countries like China, large international organisations, such as the World Bank and the Asia Development Bank played an important role in identifying and resolving the emerging legal issues, ranging from ensuring a transparent and competitive tendering process, establishing appropriate payment mechanisms, and ensuring contract enforcement. For countries where the large international organisations

are not accessible, the appointment of highly-skilled legal advisors, under the conditions that the legal fees will not compromise the value for money outcomes, is claimed to be essential to guarantee that the possible legal constraints are sufficiently addressed along the procurement process (Akintoye et al., 2003, Carrillo et al., 2008).

3 Research Methodology

Comparative case studies were adopted in this research and interviews were used as the main data collection method. The main reason for choosing case studies strategy is that the legal aspects of PPPs are closely related to the country's policy, institutional, economic and social context and the case study approach is preferred in examining phenomenon within its real-life context (Yin, 2009). Comparative case studies of New Zealand and China's legal aspects associated with the adoption and implementation of PPPs provide opportunities to understand the variations arising from diversity across policy contexts, based on which recommendations can be made on removing the legal constraints for PPPs. A qualitative interview method was selected as it provides in-depth insights and perspectives on a subject matter, which is desirable in this research for seeking rich and insightful information on the key dimensions of legal issues of PPPs (Mcneill and Chapman, 2005). In addition, a qualitative approach is suitable when little is known on the topic as is the case with investigating the legal aspects surrounding PPPs.

Fieldtrips to Auckland, Wellington (from November 2010 to April 2011) and Beijing (from July 2010 to August 2010) enabled the data collection exercise. The participants of the interviews were selected via a purposeful sampling procedure as it allows the selection to be narrowed down to specific group of people who can provide rich information on the subject matter (Liamputtong and Ezzy, 2005). The research targeted practitioners with extensive PPP experiences (more than ten years), familiar with the PPP policy context in respective jurisdictions and knowledgeable about legal-related issues about PPPs. All the practitioners selected hold senior positions in their organizations (at executive level). In the China's case study, three interviews with academics with extensive PPP-related research experience were conducted to gain a more holistic understanding of China's evolving approach and context of PPPs. The profile of participants interviewed is presented in Table 1.

Table 1. Profile of participants interviewed

	New Zealand	China
Public sector	NP1-NP2	CP1-CP3
Private sector	NR1-NR4	CR1
Legal/commercial advisors)	NA1-NA4	NA
Academics	NA	CA1-CA3

Seventeen interviews were undertaken (ten for New Zealand and seven for China). The participants were approached through email or telephones. Semi-structured interviews were used to solicit reliable and comparable qualitative data whilst allowing a high

degree of flexibility during the interviews. The main themes explored in the interviews include:

- The effectiveness of current legal frameworks to sustain a PPP programme
- Possible legal constraints preventing the adoption of PPPs or impeding PPP implementation
- Measures that have been taken to address the emerging legal constraints
- Additional strategies proposed to remove the legal constraints and further facilitate the PPP development

The recorded interviews were transcribed, coded and analysed using with the assistance of qualitative analysis software – NVivo 9. The use of the software enabled the researcher to develop themes and patterns and sort through the data accordingly in order to compare, contrast, and synthesise. Pattern-matching techniques were adopted to link the findings based on case studies data to the conceptual framework (Platt, 2008).

4 Research Results

4.1 Case Study of New Zealand

4.1.1 PPP practices and policy context

In New Zealand, the private sector has been involved in the provision of public works and related services for many years. The experiences with PPPs were nonetheless limited (New Zealand Office of the Auditor-General, 2011). The main PPP projects were undertaken at local government level, including water and wastewater projects. (Grimsey and Lewis, 2005). The scarcity of PPP practices was partly due to the New Zealand government's sceptical view towards the adoption of PPPs (Ascari Partners Ltd, 2005). For example, the Treasury's discussion paper concluded that the benefits of using PPPs may also be achieved in traditional ways (Katz, 2006).

The New Zealand government's approach to PPPs has changed since the government announced its infrastructure policy and support for the development of PPP programmes in 2008. A PPP project will proceed as long as it can demonstrate value for money (National Infrastructure Unit, 2010). Proposals with whole of life costs more NZ$25 million are required to include a PPP option in the choice of procurement route (The New Zealand Treasury, 2011). Since 2008, two social infrastructure PPP projects– the new prison at Wiri and two new schools in Hobsonville have been brought into market.

Relevant policy settings have evolved around PPPs to facilitate the PPP implementation. A central coordinating authority – National Infrastructure Unit (NIU) was set up within the Treasury in 2009 acting as a centre of excellence for PPPs. A number of policies and guidelines that are specific to PPPs are available, including *Guidance for Public Private Partnerships (PPPs) in New Zealand* (National Infrastructure Unit, 2009), *Draft Public Private Partnership Standard Contract - Version 2* (National Infrastructure Unit, 2011).

4.1.2 Legal constraints for PPPs

When asked of the perceived legal constraints for PPPs, all New Zealand participants indicated that there are no substantial legal constraints preventing the adoption of PPPs. As a response to the government's infrastructure development policy, a legislative reform has been underway and a series of acts have been reviewed to remove the unnecessary barriers impeding the use of innovative delivery models for public infrastructure and services (e.g. PPPs). For instance, prohibitive provisions on PPPs, such as the restrictions on private sector management of prison services in Corrections Act (2004) and limitations on concession period of private sector operation of water projects specified in Local Government Act (2002), have been removed from legislation allowing the use of PPPs in prison and water sector (National Infrastructure Unit, 2010). In addition to the recent changes, the Land Transport Management Act (2003) allows for limited tolls and private sector involvement in the operation and management of roads (Ascari Partners Ltd, 2005).

All participants admitted that although PPPs are possible under the current legislative framework, legal constraints exist that will hinder the smooth implementation of PPPs. Eight participants emphasised the Resource Management Act (RMA) (1991) are likely to cause delays to the procurement process and compromise the innovative solutions by the private sector. For example, Participant NA1, NP1, NR1 and NR3 explained the ways in which the RMA impacts on New Zealand's PPPs,

In New Zealand, you have to design things to a very developed design stage before you will be able to get your designation under RMA, which means the procurement is likely to be delayed. You will get very little opportunity to innovate when it comes to the private sector participation (NA1).

Ensuring that you get the use of the site you need for the procurement you are undertaking and you can do it in a way that it doesn't constrain the solutions that the private sector might generate. So we have to go about developing a designation process under RMA that removes the constraint as possible (Synthesis of opinions of NP1,NR1 and NR3).

Participant NP2 and NR4 further pointed out that the effects of procedural requirements imposed by the RMA have been seen in New Zealand's current pilot PPP project – Wiri Prison and the previous PPP endeavour – Vector Arena. For example, in the case of Vector Arena, as mentioned by Participant NR4, the delegation process undertaken in accordance with the RMA was lengthy, causing delays to the project's overall timeline. After the appointment of the initial preferred bidder – Abigroup, the RMA delegation was obtained via a prolonged consultation process. However, the process was further delayed after the second preferred bidder – Quay Park Arena Management (QPAM) Ltd was selected as the private sector partner as another RMA delegation application was lodged followed by a similar protracted process. Participant NP4 and NR4 maintained that the prolonged delegation process was part of the reason the project experiencing time delay.

Five participants stressed the likely legal constraints arising from the Public Works Act (PWA) (1981) on the acquisition of land for PPPs. Although the PWA granted the

Crown with statutory authority to acquire land for a public work, it also requires a series of steps to acquire land, resulting in long transaction duration for potential PPP projects. As highlighted by Participant NP2 and NR4, in New Zealand, the issue with land acquisition is especially critical due to the country's special legal document – Treaty of Waitangi, which allows Iwi (regionally linked tribes) to institute compensatory claims of historic ownership of land. Participant NP1, NP2, NR4 and NA2 argued that for any New Zealand PPPs, the requirements by Treaty of Waitangi must be addressed and consultation with iwi is vital if the intended site is owned by them.

New Zealand's legal constraints for PPPs are also reflected in the evolving nature of legislation over time, as argued by six participants. They further elaborated that the unstable legislative terms regarding the use of PPPs is party as a result of New Zealand's short election cycle (3 years). The National Government explicitly signalled the encouragement of infrastructure spending and private sector participation, whereas the Labour Party appears to hold a negative view towards the value that PPPs could bring to New Zealand, as observed by the participants (NA1, NA2 and NR2). The participants' point can be confirmed by the case of Auckland Central Remand Prison (ACRP) project, which has undergone a process of "private management – hand back – private management". When the project first came to operation, the then National Government granted the prison operation and management to a private company – Australasian Corrections Management Pty Ltd (GEO Group, 2009). After a five-year's management by the private company and the Labour Government came to power, the control of the project was reverted back to the Public Prisons Service in 2005 due to the passing of the Corrections Act 2004 specifying that only the public sector authorities can provide correctional services (Department of Corrections, 2011a). In 2011, a new correctional facility named Mt Eden Corrections Facility (MECF) was completed and the ACRP was incorporated to the new facility (Department of Corrections, 2011b). The management of the project was again transferred to a private company – Serco as the Corrections (Contract Management of Prisons) Amendment Act, passed in 2009 (under the current National Government), allowing private sector entities to tender for contracts to manage the operation of prisons, on a case-by-case basis (New Zealand Parliament, 2009). As argued by Participant NP1, the change of legislation in terms of the permission of private sector's participation in contract management of prison services mirrors the New Zealand's unstable legislative base for the adoption of PPPs.

4.1.3 Strategies suggested to remove the identified legal constraints

In terms of the measures that have been taken to address the legal constraints for PPPs, eight participants emphasised the importance of having a clear and standardised approach towards the selection and implementation of PPPs and they added that the government has made great effort in achieving this. For example, the recently released guideline document *Better Business Cases for Capital Proposals Toolkit*, has explicitly specified the criteria under which PPP procurement option may be selected and a specific approach for seeking approval from Ministers and approaching the market. As indicated by Participant NP2 and NA3, the transparent selection criteria and approval process provides a legal and regulatory basis for the public agencies to proceed with a PPP. In addition to a clear and streamlined procedure for the selection of PPP candidate projects, the participants advocated a standardised and consistent approach towards the realisation of PPPs. Establishing, updating and consistently applying policies and

guideline documents were perceived effective to enable the institutionalisation of PPP procurement and transaction. Participant NP1, NP2, NA1, NA2 and NA3 stated that the New Zealand government has made a substantial progress in terms of publishing and applying PPP guidance. With respect to the two available PPP-specific guidance documents, the participants gave positive comments:

…The Guidance is a good first tier document although it is fairly high level and not detailed enough to guide people with the practical procurement. (Synthesis of views of NP2 and NA1)

…New Zealand documentation (the Standard Contract) is very clear and concise. And in vertical, it is very fair in the way which applies the obligations on the Crown and the contract. It is structured understanding the basic positions to be reached. It is the right balance. (NP1)

Six participants stressed that setting up effective governance structure is essential for ensuring that all possible legal and regulatory constraints are identified and the responding mitigating methods are in place. As stated by Participant NP2 and NA4, a steering committee is required to be formed at initial stage and meet on a regular basis (monthly is common). A core group comprising of the experts from NIU and the representatives from the agencies is necessary and they should be meeting on a more frequent basis (perhaps weekly). Through the contact of the core group and the steering committee, the public sector is able to reflect on the potential legal barriers (e.g., lengthy resource consenting process as required by RMA) and respond to problems raised on time.

Four participants argued that a committed and dedicated public procuring team, coupled with strong leadership are useful means to alleviate the negative effects of legal constraints on PPP implementation. Participant NP1 stated, “In practice, we need to stick to what we have said…We promise something in market sounding. The commitments need to be followed through…We should always follow the timeframes we set up in the beginning.” (NP1) The public sector’s strict adherence to their commitments and timelines helps to guarantee that any delays or problems arising from the requirements of RMA or land acquisition issues can be dealt with promptly. Strong leadership assisted by the central PPP unit – National Infrastructure Unit is beneficial to make sure that the required decisions are made and the necessary approvals are obtained in accordance with the pre-determined timeframes, maintaining the private sector players’ confidence in participating in New Zealand’s PPPs.

Six participants asserted that in order to address the private sector’s concerns in relation to legal and regulatory issues, the government should take on more risks in New Zealand PPPs. For example, Participant NP2 advised that the public sector could assist with obtaining the relating approvals and conducting site investigation. For example, “the RMA consenting process would have been done before the project goes to market to avoid delays…We might take site investigation and make those reports available to bidders to alleviate from having to do it themselves (the private sector).” (NP2) With respect to the legal constraints (e.g., prohibition on the private sector to be involved in long-term management and operation of public assets) arising from political risks, the participants suggested that the government should retain risks of this type. The ways to

address the risks include promise to compensate (to a capped amount) the bidders in competition if the PPP project was cancelled due to the change of government.

4.2 Case Study of China

4.2.1 PPP practices and policy context

In China, PPPs have been implemented in a variety of sectors such as water and wastewater, venues, land transport and power station, mainly in the form of build, operate, and transfer (BOT) (Wang et al., 1999). The initial initiative for the government to opt for BOT was mainly to relieve the public budgetary constraints, especially in the area of public infrastructure (Chen and Wang, 2009). The concept of Public-Private Partnerships was officially introduced by the Chinese government with the release of policy note *Suggestions to Promote and Guide Private Investments* (De Jong et al., 2010). A report *Suggestions to Advance Marketisation in Civil Infrastructure Industries* issued in 2002 introduced a dozen more PPP projects using diversified PPP models (e.g., the National Stadium for Beijing Olympic Games – the Bird's Nest) (Liu et al., 2009).

China's PPPs are initiated by both central and local government (Chen, 2009). However, compared to other countries in which PPPs are mainly promoted by central government, local governments in China have shown more interests in engaging with the private sector to advance the infrastructure. This is probably attributed to the institutional change in 1994 – tax sharing reform, under which the majority tax incomes are collected by central government whilst the capital expenditure responsibilities remaining with the local governments (Chen and Wang, 2009). Facing the funding gap to sustain infrastructure development, local governments tend to refer to the private sector investors to address the bottleneck via the adoption of PPPs.

In countries like the UK, Australia and Canada where relatively mature PPP markets have been established, a suite of policy and guideline documents have been developed ranging from the technical note on assessment of value for money, model risk allocation matrix, key commercial principles, to contract management guidance (Infrastructure Australia, 2008). However, in China, the guidelines for PPPs are very limited with few documents setting out specific legal directions for PPP project, such as the Method of Managing Urban Public Utilities Concessions (2004) (Chen and Wang, 2009).

In China, the informal personal connections between government officials and representatives from some State-owned enterprises or potential private companies gives rise to moral hazards, leading the market to cast doubt on the fairness and transparency of the tendering exercise (De Jong et al., 2010). The situation is worsened when negotiated selection procedures (common for PPPs) are used rather than open tendering as lacking of a transparent process and evaluation criteria, risk may arise that weaker proposals are chosen (Yescombe, 2007).

4.2.2 Legal constraints for PPPs

According to all participants, China has substantial legal and regulatory restrictions on the private sector involvement in public sector procurement. Despite the availability of a number of policies and status allowing the private sector participation in some

infrastructure sectors, uncertainties prevail concerning the legitimacy of the government to enter into PPP contracts. Participant CA1 and CA2 elaborated that in China, PPPs are mainly practised in sectors such as power generation, water and wastewater, land transport and public transport. However, the PPP application in some infrastructure areas, such as schools, hospitals and prisons is restricted in China under the current legislative system. There are also restrictions on the private investment in the public infrastructure and the associated services. For example, Participant CP1 and CP2 stated that in the case of Beijing Metro Line 4 project (in which PPPs were used), the government was only allowed to introduce private investment at the ratio of 7:3 (governmental investment: private funding), under the requirement of *Suggestions on Improving Financing Mechanism for Unban Infrastructure*, issued by the Beijing Municipal Commission of Development and Reform. Participation CP1 further added that the formation of the Joint Venture Company (also referred as "Project Company", acting as an investment vehicle) between the public sector and private investors, should follow the legislation concerning foreign capital injection: Chinese entities' shareholders' equity shall not be lower than 51%. As suggested by Participant CP1, CP2, CA1 and CA2, the restrictions on the government to enter into PPP contracts and limits on Direct Foreign Investment (DFI) in the public infrastructure regime help to ensure that public interests are protected. However, the relevant regulations would considerably limit the potential to utilise private financing and affect the private sector's interests and confidence in participating in China's PPPs.

In addition to direct restrictions on the adoption of PPPs, other legislation, regulations and government policies indirectly impose constraints on the implementation of PPPs in China. Although new legislation protecting private property was released, concerns still exist among the prospective private investors regarding asset ownership, as maintained by Participant CA3. Participant CR1 and CA1 mentioned that the commercial law in China also poses constraints to PPP formation as the Project Company is required to have a minimum registered capital of the total estimated investment. Moreover, the restrictions on private acquisition of land and the right of land development affect the adoption of PPPs, as pointed out by Participant CP1, CP2 and CA2. For example, commercial land exploitation surrounding urban rail links assists with enhancing private benefits, making the urban rail projects financially viable and sustainable, but the ability to achieve this is problematic in China due to the lack of stable legislation permitting private land exploitation. In the case of Extension of Shenzhen Subway Line 4, because the public land cannot be sold to the private entity, the private consortium is only allowed to undertake commercial development along the metro lines, leading to the reduction of the private investor's interest in this project (De Jong et al., 2010). Participant CP1 and CP2 highlighted this issue using the example of Beijing Metro Line 4 project, in which the Hong Kong Mass Transit Railway (MTR) was appointed as the private sector partner. In Hong Kong's metro business, MTR is involved in a variety of activities apart from railway operations, including the development of residential and commercial projects, property leasing and management. However, this mode cannot be replicated in this case because commercial land and property development is restricted by the government. Besides, in the Beijing project, MTR was not allowed to run any additional businesses in subway stations (e.g. bookstore, convenience store, etc.), which formed part of MTR's revenue sources in their business in Hong Kong. So ticket sales and advertising incomes were the main revenue sources for MTR. Without being

granted the rights to undertake commercial development and running subway station businesses, the private sector partner tended to take a cautious approach when stepping into China's PPPs and request for government subsidies to bridge the gap between expected return on investment and actual income from ticket sales.

All participants highlighted that in China, the legislation, regulations and policies in relation to private sector involvement are enacted at different levels of governments (central, provincial, and municipal), dealing with different aspects of PPPs. Sometimes conflicting policies exist. For example, Participant CA3 argued that the central government does not permit governments providing guarantees in attracting private investment. However, for some local governments, the officials tend to provide guarantees to PPP projects in order to attract prospective private investors to alleviate the financial burden to fund infrastructure projects. The discontinuity of legal base at different levels usually causes confusions to the prospective private sector players, hindering the PPP development in China. Participant CR1, CA1 and CA3 claimed that the fragmented legal and regulatory base for PPPs is likely to impede the PPP approval and subsequent procurement and implementation process. The approval process for PPPs normally involve various government departments at different level (central, provincial and municipal), who resort to different legislation, policies and statues to proceed their decision making, rendering the PPP approval process cumbersome and lengthy and discouraging the private sector players to bid for PPP projects in China.

4.2.3 Strategies suggested to remove the identified legal constraints

With respect to the substantial legal constraints for China's PPPs, all participants agreed that the fruition of PPP proposals requires a political champion and continuing political commitment. Participant CP2 and CP3 articulated the case of Beijing Metro Line 4 to illustrate the point. During the project development and procurement, the heads from government were involved in the project steering committee and well informed at various decision-making points. As stated by CP2 and CP3, the involvement of senior government officials and keeping them informed helped to ensure that the government was able to respond to tricky issues as a result of legal and regulatory constraints and take commensurate measures to address the issues promptly and in an efficient manner.

Five participants held a view that having a highly-skilled and experienced public procuring team with strong leadership is vital for resolving the emerging legal concerns when initiating, structuring and implementing PPPs. They generally acknowledged that lacking a central PPP unit acting as a centre of expertise and providing commercial advice to line agencies, it is difficult for public procuring authorities in China to apply a consistent approach to towards the execution of PPP projects. However, Participant CP1, CP2 and CA2 highlighted that it would be of great benefit to have a core team comprising of experienced experts who are familiar with the structure of PPPs and specialised in the financing and development of PPP projects. Again, Participant CP1 and CP2 cited the Beijing Metro Line 4 case, articulating the important role played by the project procuring team:

In Beijing project, the Beijing Infrastructure Investment Company Ltd. (BIIC, a state-owned enterprise), acting as both a contracting party and public procuring authority, provided a platform to carry out the project on behalf of the government.

As a part of the joint venture company, BIIC devoted 2% of the equity injection. As a public procuring authority, BIIC released the initial financing plan, completed the feasibility study, and planned and implemented the procurement. With sufficient empowerment from the government, the project team could effectively respond to the private sector partner's concern about profitability arising from the legal constraint prohibiting commercial land exploitation and running station businesses. By setting up adjustable charging approach via associated contract terms, both parties were able to reach agreement and enter into execution phase.

All participants agreed that in order to sustain a viable PPP in China, the government is required to share or retain more risks. The government needs to take on risks in relation to legislative, policy and regulatory change. The government is also recommended to take on or share risks associated with obtaining the approvals as they are better positioned to cope with the bureaucratic process required by various government departments. With regard to the demand and revenue risks, the government is suggested to share the risks with the private sector partner in order to ensure the economic viability of the intended project. It is especially the case when demands and the private sector's revenues are largely dependent upon the government's regulation (e.g., the regulated fare of metro lines, water pricing).

5 Comparative Analysis of Case Studies

An investigation of New Zealand and China's PPP practices finds that legal constraints exist in both countries, impeding the adoption and smooth execution of PPPs. New Zealand's current legal system generally allows the adoption of PPPs after a decade of debate on whether or not PPPs are suitable delivery models. Having witnessed the PPP development in countries such as the UK, Australia and Canada, the New Zealand government has included the PPP option in the pool of public sector procurement models and clearly indicated that a PPP will proceed as long as the value for money outcome is justified. By contrast, in China, the legitimacy of the government to enter into PPP contracts relies on enabling legislation, which in its current state, incomplete and fragmented. The involvement of private sector in long-term management and operation of public assets and private investment are restricted to specific infrastructure sectors or certain types of forms. The fragmented nature of PPP legislation in China is partly attributed to the fragmented PPP practices at different government levels, featured by three waves of PPP development in the 1980s, early 2000s and post-2005 after the release of *Opinion of the State Council* (Chen and Wang, 2009).

New Zealand's legal constraints for PPPs are mainly reflected in the procedural impediments and land acquisition restrictions imposed by Resource Management Act and Public Words Act. The indirect constraints for PPPs are partly originated in New Zealand's special historical events such as colonisation and the development of legal document – Treaty of Waitangi. In comparison, China's indirect legal restrictions on PPPs are multi-faceted, ranging from insufficient protection of property rights and potential risks of appropriateness, limitations on private asset and land ownership, prohibitions on land exploitation to impediments for obtaining approvals by the private sector. These legal constraints, to some extent, are due to the Chinese government's concern for wider public's interests. The lack of a mature PPP market, unclear criteria

for the selection of PPP models and inexperienced public procuring authorities may also be responsible for the indirect legal constraints for PPPs.

Inconsistent legislative provisions in relation to the permission of private sector involvement as a result of the change of government increase the risk of bidding for New Zealand's PPP projects, affecting the prospective private investors' interests in entry into New Zealand's PPP market. In China, the inconsistencies in legal framework surrounding the use of PPPs are primarily caused by the institutional arrangements for public sector procurement and the ambiguous role of governments (both as regulator and contracting party). Lacking of a coordinated approach towards the infrastructure planning and capital asset management and a thorough legal document specific to PPPs, various governments generally undertake infrastructure investment and development on an individual basis and therefore initiate a PPP for different reasons (mostly likely financing). The diversified government tend to establish policies or statues to accommodate the conditions of a specific project. The legal framework governing the execution of PPPs is therefore likely to vary between different governments or government departments, creating obstacles for the potential private investors to understand China's policy intent and directions of PPP.

6 Recommendations

With regard to the identified constraints, participants from New Zealand and China recommended associated remedies. A dedicated and experienced public procuring team with strong leadership is believed to be critical for ensuring that appropriate actions can be taken in face of emerging legal constraints. Involving government officials at different layers of the governance structure contributes to facilitating informed and prompt decisions to be made in a timely manner. Compared to New Zealand where a central PPP unit was set up within the Treasury to oversee and assist with PPP development, the PPP execution in China poses higher requirement on the public sector's capacity. As a developing country, China's first generation of PPP projects gained considerable supports from multi-lateral organisations such as World Bank and Asia Development, playing a leading role in scrutinising the PPP options and structuring the PPP transaction (Chen, 2009). However, in the absence of such organisations, China needs to develop its own capacity and skills in selecting and running PPP projects.

In addition to the requirement of capacity building, both New Zealand and Chinese government are suggested to take on more risks in PPP transaction. For both countries in which PPP markets remain relatively immature and lack of a required level of sophistication, the governments must be aware of, acknowledge and share or take on risks that are not best managed by the private sector. Risks that are related to legislative and regulatory change, or influenced by legal constraints should be retained by the governments.

New Zealand's attempts to promote a consistent and clear approach towards PPP selection and implementation have positive effects on the execution of the two pilot projects. The *Better Business Cases for Capital Proposals Toolkit* and the *Standard Contract* are perceived useful and effective in guiding the PPP practitioners. Consistent

application and continuous updates are necessary to capture the emerging trend of PPP development. In China, there has been a call for issuing a specific legal document dealing with PPPs, yet this is not conclusive. It would be of great benefit to have the document available and keep it updated as the experiences of PPPs grow. It is also important for the Chinese government to institute a well-established capital asset framework in which the criteria for PPP selection are clearly specified.

Standardisation of the Conditions of Contract in the Building and Civil Engineering Construction Industry in South Africa

Mahlomola Letsie[1] and JJP (Basie) Verster[1]

[1]Department of Quantity Surveying and Construction Management,
University of the Free State, Bloemfontein,
South Africa

Email: letsiem@ufs.ac.za; versterj@ufs.ac.za

Abstract:
The purpose of the study was to identify problems encountered as a result of using different types of conditions of contract in South Africa. The four types of conditions of contract recommended for use in the country are the NEC, JBCC, GCC and FIDIC. A literature review of publications on the subjects related to contractual disputes, the different conditions of contract used in South Africa, the CIDB and the challenges faced by contractors in South Africa was done. Interviews were conducted and questionnaires were also distributed to contractors, consultants, employers and other role players in the construction industry. Responses were received and analysed and the conclusion was that the current situation of using different types of conditions of contract is causing problems to role players and thereby affecting the growth and development of the industry and the economy of the country. It is therefore recommended that there should be one standard document of conditions of contract used for building and engineering contracts in the country.

Keywords:
Built Environment, Civil Engineering, Conditions of Contracts, Construction Contracts.

1. Introduction

The construction industry plays a major role in the economy and social development in South Africa. It provides the much need employment and physical infrastructure in the country. According to the Construction Industry Development Board (CIDB) (2012), which is a government body mandated to oversee the development of the construction industry, the legacy of apartheid has left the South African construction industry with a number of development and transformation challenges.

These include:

- Improving effectiveness of the public sector spending on physical infrastructure development and maintenance.
- Improving labour absorption, labour relations and job stability.

- Accelerating sustainable transformation through access to opportunity, finance and training.
- Reducing the impact of HIV and AIDS in construction
- Ensuring international competitiveness.

Part of the mandate of the CIDB is to support contractor development and emerging sector participation with more emphasis on the development of the previously disadvantaged contractors, by:

- Establishing an enabling environment for contractor development.
- Enhancing and strengthening contractor development mechanisms, including emerging contractor development programmes (ECDP's), joint ventures (JVs) and other appropriate mechanisms.
- Facilitating performance improvement of contractors.
- Supporting the creation of a pool of skilled artisans, supervisors, technicians and technologists for the construction industry (CIDB 2012).

In order for the construction industry in South Africa to fulfil its desired goal of development, there are certain challenges which have to be overcome. One of the major challenges is the use of different documents for conditions of contract, which result in challenges of disputes and inefficiency caused by lack of understanding of the terms and conditions. There are four types of conditions of contract recommended for use in South Africa. These are the New Engineering Contract (NEC), International Federation of Consulting Engineers (FIDIC – Conditions of Contract for Construction), General Conditions of Contract for Construction Works (GCC), and the Joint Building Contracts Committee (JBCC 2000) (Maritz and Schutte 2007).

2. Emerging Contractors

South Africa was ruled under apartheid from 1948 until 1994 when the country had its first democratic elections and a new democratic government came into power. People that were affected by the apartheid rule prior to 1994, being the less fortunate and least contributors in the countries' economy, are referred to in the new Constitution of the Republic of South Africa as Historically Disadvantaged Persons (HDP), and these racial groups generally comprise of Africans, Coloureds, Indians and Chinese.

The post apartheid transformation of the South African society was coupled with the economic transformation which resulted in emerging companies owned by the HDPs increasingly engaging in the formal economy (Martin and Root 2010, p.64). The construction industry, like in any other industry within the economy was also affected by the situation of an increasing number of new entrants into the industry. These new entrants are referred to as emerging contractors. The emergence of new contractors in the industry is associated with a number of challenges such as inadequate construction knowledge and lack of experience which tends to lead to limiting their growth (Martin and Root 2010, p.64). The South African government is fostering growth and development of entrepreneurs by creating an enabling environment for them to enter into the mainstream economy. This is done through various policies and institutions with specific mandates.

 ISBN: 978-1-84219-840-7 .

3. Problems Faced by Emerging Contractors

The South African construction industry is in the developing phase where there is a huge influx of emerging contractors entering the industry. The government, through the CIDB, the National and Provincial Public Works departments and other concerned government institutions are trying to address and manage the challenges faced by this introduction of new role players in the industry but however, much still needs to be done. According to the Member of Executive Council for Gauteng Province, Mr. Humphrey M.Z. Mmemezi:

> "The boom in the construction industry has mostly benefitted big companies at the expense of emerging contractors, who were struggling to grow due to various reasons in the sector, despite the boom in the industry that was brought about by the FIFA Soccer World Cup, through refurbishment of stadiums and the construction of new ones (Mmemezi, 2010)."

The introduction of the emerging contractors with CIDB grading of 2 to 6 GB and CE into the construction industry is associated with a number of challenges as access to finance, technical expertise and contracts administration, to name a few. The challenge of contracts administration is made worse by the following factors:

- The contractors enter into contracts with little or no knowledge of the type of conditions of contract in use and have to learn the contract on the job, which poses a risk.

- There are various types of conditions of contract recommended for use in South Africa, which puts even more pressure on the already overburden contractors to learn and mater then all.

The need for small and medium construction companies in the country's economy is evident. Small and medium companies have a potential for addressing the problem of unemployment and creating a sustainable economy, but however, emerging contractors still remain unsustainable and this can be attributed to the shortcomings of the current development opportunities which lack continuity and necessary planning (Lazarus 2005, p.18).

Small and medium contractors are also frustrated by problems beyond their control such as the reluctance by finance institutions to increase their risk appetite in as far as lending finance (Mmemezi 2010).

> "Many strategies for emerging contractor development that are based on instruments such as targeted procurement, have generally failed to empower emerging contractors because they are implemented without well-defined skills transfer frameworks. The sector continues to be regarded by construction clients and suppliers as a high commercial risk and this presents further barriers to meaningful participation. Related to this is the lack of clear policy targets against which to measure the effectiveness of contractor support programmes (Lazarus 2005, p.4)".

 ISBN: 978-1-84219-840-7 .

4. The Construction Industry Development Board

The Construction Industry Development Board (CIDB) is public entity established in 2000 with a mandate of promoting a regulatory and developmental framework that builds the construction delivery capability for South Africa's social and economic growth and also building a proudly South African construction industry that delivers to globally competitive standards (CIDB 2012). Part of the mandate of the CIDB is to regulate the construction industry in the whole country and also to support contractor development and the participation of emerging contractors. In order to achieve its mandate, the CIDB has implemented a grading system as illustrated in Table 1 below. The registered contractors are graded according to their type expertise, level of experience and availability of resources to complete different sizes and types of contracts. The CIDB has also entered into partnership with the National and Provincial Public Works Departments to form and implement the National Contractor Development Programme (NCDP), which is aimed at developing emerging contractors (CIDB 2012).

Table 1 shows the CIDB contractor grading system.

Table 1. The CIDB contractor grading system
(Source: CIDB 2012)

Works Capability		**Contractor Grading**				
Designation	**Maximum (ZAR) value of contracts that a contractor is considered capable of performing**	**General Building (GB)**	**Civil Engineering (CE)**	**Electrical Engineering (EB & EP)**	**Mechanical Engineering (ME)**	**Specialist Works (SP)**
1	200 000	X	X	X	X	X
2	650 000	X	X	X	X	X
3	2 000 000	X	X	X	X	X
4	4 000 000	X	X	X	X	X
5	6 500 000	X	X	X	X	X
6	13 000 000	X	X	X	X	X
7	40 000 000	X	X	X	X	X
8	130 000 000	X	X	X	X	X
9	No limit	X	X	X	X	X

The largest percentage of the total number of registrations with the CIDB consists of small and medium contractors of Grades 2 to 4 in General Building (GB) and Civil Engineering (CE) for the whole country. Tables 2a and 2b show the distribution of registration of contractors in the whole country from Grades 2 to 9. Overall, it is seen that the number of registrations in Grades 2 to 4 account for around 60% to 70% of the total registrations in Grades 2 to 9, whereas the number of registrations in Grades 7 to 9 account for around 8% of the total number of registrations (CIDB 2012, p.18).

From the above analysis it is evident that the larger percentage of the country's registered contractors consists of the small and medium contractors.

Table 2a. Supply registrations per Grade – General Building (GB)
(Source: CIDB 2012)

Contractor Grading (GB)	Number of Contractors	% Distribution
9	29	1%
7 & 8	305	6%
5 & 6	1284	24%

5. Conditions of Contract

The conditions of contract play a vital role in defining the roles and responsibilities of the parties in a contract. They serve as a guideline to define the expectations and obligations of each party in order to eliminate the risk of failure by the parties or disputes in the contract. It is of vital importance that both parties in a contract understand the terms and conditions of the contract as the contract determines the success or failure of the project.

(Finsen 1991, p.1) defines a contract as "an agreement between two or more persons which gives rise to personal rights and corresponding obligations. It is an agreement which is legally binding on the parties". The two parties in a contract bind themselves to an agreement. The contractor agrees to construct the structure for the agreed amount and the employer agrees to pay.

There is no clear guideline governing the choice of specific types of conditions of contract in the industry. Usually the common practice is that the employer alone or through the advice of his/her technical team will decide on the type that they prefer and understand better or one that they find suitable for the project with less or no consideration at all of the other party in the contract, the contractor. This situation leads to frustration amongst the contractor, technical team and sometimes even the employer as more time is spent in having to learn the contract instead of executing the project. This can further affect the ability of the contractor, members of the technical team and even the employer, to execute their responsibilities effectively and efficiently and therefore resulting in contractual disputes and project failure.

The industries preference of the conditions of contract is clearly illustrated in the quarterly report of the CIDB, "Construction Industry Indicators". The study of the distribution per project and employer category as illustrated in Table 3 shows that the largest group of responses received were from civil works (43%) and non-residential building projects (26%). Projects of the private sector (24%), provincial departments (18%) and metropolitan councils (35%) were best represented in the survey (CIDB 2012).

Table 3. Agent survey response distribution per project type and employer category 2010 (Source: CIDB 2012)

Project Type	**Total No. Of projects**	**24**	**11**	**6**	**18**	**35**	**5**	**1**	**0**	**% of Total Survey Results**
Residential Building	29	17	1	0	2	4	1	4	0	5%
Non-residential Building	145	37	17	10	65	12	2	2	0	26%
Civil Works	237	38	19	15	26	121	17	1	0	43%
Mechanical Works	16	4	1	2	0	7	1	1	0	3%
Electrical Works	100	28	22	5	6	38	1	0	0	18%
Special Works	28	7	2	1	2	13	3	0	0	5%
Not Specified	0	0	0	0	0	0	0	0	0	0%
Total No. Of Projects	555	131	62	33	101	195	25	8	0	
Employer Category		**Private Sector**	**Public Corporation e.g. ESKOM, ACSA**	**National Department**	**Provincial Department**	**Metropolitan Council**	**Regional / District Council**	**Public Private Partnership**	**Not Specified**	

A similar study of the type of contract document used for different project types in the year 2010 as shown in Table 4, shows that the JBCC form of contract was most popular for residential (69%) and non-residential (70%) building projects as well as for special works contracts (57%). The GCC form of contract was most popular for civil works (82%) and mechanical works (60%) contracts. For electrical works the GCC (27%), NEC (23%) and JBCC (25%) were all popular forms of contract. The GCC (60%) and FIDIC (26%) forms of contract were mostly used for mechanical work contracts. The study also shows that it was necessary to significantly amend the contracts to suit particular needs, especially when the NEC (36%) and FIDIC (39%) forms of contract were used. These were mainly used for mechanical and electrical works projects (CIDB 2012).

Table 4. Type of contract document used for different project types in 2010
(Source: CIDB 2012)

6. Contractual Disputes

Disputes are common in the construction industry. One of the main reasons for entering into a formal agreement with clearly defined term and conditions is to reduce or eliminate the risk of disputes. It is important for both parties in a contract to have a clear understanding of the conditions of contract that bind them in order to execute their duties and responsibilities without infringing into the rights of the other party.

Construction risks need to be identified and mitigated as early as possible, preferably at tender stage or contract signing stage. Failure to do so may pose a risk of possible disputes in the near future. Constructions disputes can be costly if not attended in a timely manner as valuable resources and time can be spend dealing with the dispute which may also result in causing delays in the completion date (American Bar 2012).

According to Mills (2006) the eruption of disputes on a construction site is usually as a result of several factors, including;

- A culture of under-competitive tendering, with contractors ready to tender, claim high;
- A project team assembled ad hoc without considering whether the team can work together;
- The function of the contract administrator, whose position as an independent certifying officer is considered at variance with being in the pay of the employer; and
- Poorly drafted contracts

From a South African perspective, one of the biggest risks that lead to contractual disputes is as a result of contractors commencing the construction works without proper contract documentation.

> "Contractors in South Africa often commence with construction following instructions contained in a letter of intent, also known as the memorandum of understanding in the mistaken belief that the letter of intent is equivalent to a letter of acceptance or employer's award (Muller and Welcome 2008)."

The letter of intent does not represent the employer's acceptance of the offer and the contractor has a right to not sign the contract agreement should he/she decide not to sign, the reason being that, according the South African law a contract only exists once the offer has been accepted and there is no contract prior to acceptance (Muller and Welcome 2008).

7. Objectives of the Study

The objective of the study is to establish the opinions and perceptions of the various stakeholders in the building and construction industry in South Africa in relation to the relationships and risks associated with the use of different types of conditions of contract.

8. Research Methodology

The research methodology included literature review of local and international publications on the subjects of contract disputes, the different conditions of contract used in South Africa, the CIDB and the challenges faced by contractors in South Africa. Two questionnaires were circulated around the different role players in the construction industry in Bloemfontein. The use of questionnaires was influenced by the following reasons:

- Time and budget constraints – it was more cost effective and quicker to reach the number of people sampled through questionnaires.

Interviews were also conducted with a small number of selected role players for the following reasons:

- A limited sample of senior project managers from various employers around Bloemfontein could be reached.
- The interviews also provided more flexibility to optimise the gathering of information.

8.1 Sample

The sample for questionnaires consisted of various stakeholders in the building and construction industry around Bloemfontein city of the Free State province and questionnaires were distributed as follows:

- Fifteen questionnaires were distributed to contractors,
- Eight questionnaires to consultants,
- Four questionnaires to employers and
- Four questionnaires to other individuals actively involved within the construction industry.

A 75% response rate was received.

Interviews were conducted with three officials from the project management departments of the each of the major employers in the Free State Province being the Mangaung Metropolitan Municipality and the National and Provincial Departments of Public Works. Three local contractors were also interviewed.

8.2 Research Methods

8.2.1 Interviews

The interviews comprised questions on the interviewees experience, their challenged in carrying out their day-to-day project management and construction duties, their level of understanding of the type of conditions of contract that they frequently use in their projects and also to establish whether they could easily switch from one form of conditions of contract to another without difficulty. The interviewees indicated their different views on their challenges and desired improvements on the types of general conditions of contracts to be used in South Africa.

8.2.2 Questionnaires

Two questionnaires targeting different groups were distributed. The first questionnaire was designed for contractors with the aim of establishing their various roles in the construction industry, the type of conditions of contract they have used in the past five years, their challenges with understanding the terms and conditions of their contract resulting in disputes, financial losses and finally, the conditions affecting their ability to execute their duties effectively. The second questionnaire was designed for the other group of role players such as professional consultants, employers and other professions involved in the construction industry. The respondents indicated their challenges and desired changes in construction contract. All participants were assured that their participation was voluntary and the information they provide would be treated confidentially.

8.3 Data Analysis

Microsoft® Office Excel® 2007 was used for data analysis with tables and graphs.

9. Findings

9.1 Interviews

The interviews conducted with the officials of the three main employers and contractors in the province show the following:

- The government makes use of a modified JBCC 2000 contract predominantly for building contracts and mostly the GCC for engineering contracts.
- Contractors do not always have a say in the choice of the form of conditions of contract for their contracts with the government.

 ISBN: 978-1-84219-840-7 .

- There is a common risk of small contractors within the CIDB Grades 1 to 4 in General Building (GB) and Civil Engineering (CE) of not meeting their contractual obligations as a result of them not understanding the contract well enough, which at time leads to contractors suffering losses due to penalties and delays.

- Small contractors are often disadvantaged in contracts as a result of them not being aware of their contractual rights and obligations.

- Employer/Client relations are often compromised as a result of contractual disputes which could be avoided.

9.2 Questionnaires

Twenty four questionnaires were completed and returned out of thirty one questionnaires that were distributed. Fourteen questionnaires were returned from consultants, employers and others and ten questionnaires were returned from contractors.

The data as illustrated in Table 5 indicates that the JBCC and GCC contracts were the most popular contracts used by the respondents in the past five years with each one used twelve times, which constitutes thirty eight percent (38%) each, the NEC is the second highest with nineteen (19%) and FIDIC is the lowest with six percent (6%).

Table 5 shows the distribution of the conditions of contracts used in the past five years.

Table 5. Contract document used in the past five years

Conditions of Contract Used	**Contracts used in the past 5 years**	**Percentage of usage**
JBCC	12	38%
NEC	6	19%
GCC	12	38%
FIDIC	2	6%
TOTAL	**32**	**100%**

The data as illustrated in Table 6 shows that of the four types of contracts used, the users understand the JBCC contract the most, followed by the GCC and NEC with FIDIC being the least understood.

Table 6. Level of understanding of the contracts used in the past five years

	LEVEL OF UNDERSTANDING		
Conditions of Contract	**High**	**Moderate**	**Low**

JBCC	6	9	2
NEC	2	4	3
GCC	2	6	2
FIDIC	1	1	2

Table 7 illustrates the challenges of the respondents and their desired changes. Thirty eight percent (38%) of the respondents have suffered a financial loss as a result of their lack of understanding of the conditions of contract. Fifty eight percent (58%) have had disputes in their previous contracts as a result of their lack of understanding of the conditions of contract. Sixty three percent (63%) recommend that the South African construction industry should make use of one form of contract document. Forty two percent (42%) believe that changing of the conditions of contract that they are familiar with can affect their ability to execute their duties effectively and over fifty percent (50%) say that using one form of contract for construction contracting in the country can improve efficiency, the use of different conditions of contracts discourages the government's efforts to train and develop small contractors and to address the imbalances in the industry. They also believe that the current system does not give the contractor mush say in the choice of the type of contract to be used.

Table 7. Challenges and desired changes

Question	**Answer**		**Percentage %**
	Yes	**No**	**Yes**
Have you suffered a financial loss as a result of lack of understanding of the conditions of contract?	9	15	38%
Disputes as a result of lack of understanding of the conditions of contract?	14	10	58%
Do you recommend the use of one form of conditions of contract in South Africa?	15	9	63%
Can changing of the conditions of contract affect your ability to execute your duties effectively?	10	14	42%
Can having one form of conditions of contract improve efficiency in the industry?	14	10	58%
Does the use of different conditions of contracts discourage the government's efforts to train and improve emerging contractors?	14	10	58%
Does the use of different forms of conditions of contracts discourage the government's efforts to correct the imbalances within the industry?	13	11	54%
Does the current system favour the employer over the contractor in the choice of the form of contract?	12	12	50%

 ISBN: 978-1-84219-840-7 .

10.Conclusions

According to the literature review and research findings, construction contracts play an important role in defining the roles and responsibilities of parties in an agreement and also in eliminating the risk of disputes and failure, therefore both parties should be able to understand the terms and conditions of the contract in order for the contract to achieve its intended purpose.

The use of different types of conditions of contract is creating problems for the intended users especially the small and emerging contractors who lack experience and resources to hire experts for their contracts administration. This problem does not only affect small contractors, but it also affects the other role players such as the consultants, who also go through the same trouble of having to learn and understand all types of contracts in use. This situation also has a potential to hamper the development of the construction industry and the economy of the country as it hampers the growth of small and medium employers.

11.Recommendations

There is a need for a concerted effort by all role players in the construction industry in South Africa to design one standard document of conditions of contract that can be used for both building and engineering contracts. This can be achieved by modifying the existing contracts to suit the local conditions and also to meet the requirements of the industry. The CIDB should also play a leading role is brining all concerned parties together and also regulating the construction procurement documentation for both government and private contracts.

AN ASSESSMENT OF THE ADOPTION OF PARTNERING IN THE NIGERIAN CONSTRUCTION INDUSTRY

Saka, Najimu[1]

[1]*School of Engineering and Built Environment, Glasgow Caledonian University, Scotland, United Kingdom G4 0BA*

ABSTRACT

Cooperative orientation among members of Construction Supply Chain (CSC) remains important to successful management of construction projects. However, in most developing economies of Africa the traditional adversarial system of construction procurement is yet to be fully substituted by the cooperative orientation of partnering. This paper investigates the level of adoption of partnering in Nigerian Construction Industry (NCI). Data on partnering adoption were obtained from project participants with the aid of structured questionnaire. The result indicates that only few out of the firms surveyed claim they have some form of partnering arrangement with their top suppliers/subcontractors. The study finds that the most important challenges to successful partnering are partner selection, communication gap and informal arrangement. Other challenges include trust, sharing of risk and reward, commitment and conflicts of interest etc. The study concludes that partnering remain at its infancy in the NCI. The study recommends for a clear partners selection and alliancing guidelines, efficient communication, proper sharing of risk and reward, commitment to CSC objectives, involvement from inception, legal backing and construction code of practice backing for a successful adoption of partnering in Nigeria.

Keywords: alliancing, construction supply chain, Nigerian construction industry, partnering, procurement, subcontractors, trust.

INTRODUCTION

The continual tension brought about by competitive procurement in the Construction Industry (CI) has created a culture akin to the 'law of the jungle', leading to communication gap and deficit of trust, poor relationships, adversarial attitudes and disputes among construction stakeholders (Stehbens, et al., 1999). In a move to change this situation the Latham (1994) and Egan (1998) reports on the UK Construction Industry (UKCI) and the Movement for Innovation (M4I) (2000) advocates the use of partnering , stressing that smooth relationships based on mutual trust benefit stakeholders

[1] saka.najimu@gcu.ac.uk

by improving project performance. Partnering has worked in the CI of several countries (Matthews, 1999) including the UK (Green, 1999), Hong Kong (Chan *et al*., 2004) and South Africa (Allen *et al*., 1999) Japan (Reading Construction Forum, 1998) Australia (Stehbens, et al., 1999). However, partnering is not widely practiced in developing countries due to low awareness and skepticism about its workability and benefit (Ng, 1997). In Nigeria the concept of partnering is new; awareness is low and the potential benefits not yet understood or explored by stakeholders. The study aims at investigating the level of application of partnering in the Nigerian Construction Industry (NCI).

LITERATURE REVIEW

Partnering can be defined by:(i) its 'attributes', such as trust, shared vision and long term commitments; and (ii) the 'process', including developing a mission statement, agreeing on goals, organizing and conducting workshops (Crowley and Karim, 1995 and Matthews, 1999). The concept of partnering emerged in the mid-1980s (Hancher, 1989) although partnering between contractors and private clients is not new (Godfrey, 1996). Partnering stresses the importance of developing a synergy of a 'win/win' relationships and forging trust based on principles of mutual trust, respect, commitment, cooperation, open communication and excellence for all stakeholders towards facilitating greater collaboration to the achievement of project objectives (Latham, 1994, Barlow, et al., 1997, Fellows, 1997, Scott 2001). Trust and teamwork prevent disputes and foster a cooperative bond among stakeholders. Generally trust is seen as the cornerstone of a successful partnering and improving procurement and contractual relations in the CI (Latham, 1994 and Hellard, 1995).

Through personal relationships and communication among stakeholder, risks and goals are better understood leading to trust and possibly a synergistic relationship (Fellows, 1997, Lau, 1999). Partnering encourages parties to re-design their business processes to facilitate improvements in the exchange of information, development of closer cooperative relationships and ultimately, mutually beneficial project collaboration through trust (Wong and Cheung, 2004). Partnering may be short-term and project-orientated or long-term and strategic in nature (Barlow and Jashaparar, 2000). In the latter case the partnering is typically concerned with optimising the partnership's resources through closer collaboration to maximise long-term benefits, whilst in the former, emphasis is more likely to be on agreeing on project governance issues to secure immediate project benefits rather than on developing advanced cooperative practices (Beach, et al., 2005).

More recently further advancement to partnering termed Alliancing has been successfully utilized in the CI. Besides including key factors contained in partnering, alliancing adds a clearly defined risk allocation with gain/pain share to manage the process. Alliancing is "where the arrangement is underpinned by an incentive scheme, whereby the rewards of the contractor and indeed, the owner are linked directly to actual performance during the execution phase of the project" (Scott, 2001).Parties contractually commit to their contribution levels and required profit and then place these at risk in undertaking the project. This provides incentive to achieve project goals (Walker and Hampson, 2003). Alliancing thus provide a legal base for partnering as a contractual requirement and uses clearly defined risk allocation with incentives to manage the process (Tang, et al. 2006).

There are five types of alliancing: *Transactional Relationship:* no formalized relationship; each transaction is made independently at arms length ; *Basic Alliance:* tactical relationship designed to establish basic level of trust and honest, open communication; *Operational Alliance:* frequent communication regarding capacity and demand with joint problem solving; *Business Alliance:* greater mutual dependence with specialized processes & unique products and services; And *Strategic Alliance:* long term trusting relationship involving shared commitment/resources that deals with strategic issues (Mentzer, et al., 2000)

Benefits of Partnering/Alliancing

Partnering lead to- improved ability to respond to changing project environment; improved quality and safety; reduced project cost and time; improved profit and value; and improve efficiency of resources utilization (McGeorge and Palmer, 1997). Partnering significantly result in ; expeditious work processes; elimination of redundant work; minimisation of surprises; cost savings for clients and profits for contractors; better time, quality and safety performance; reduce claims and variations; and reduced exposure to disputes and litigation(Matthews, 1999, Graijek, et al. 2000, Li *et al*. 2000, Prahalad and Hamel, 1990, Anumba et al. 2000b). Additionally, partnering offers opportunity for participants to develop a working atmosphere conducive for innovation, teamwork, trust and commitment (CII, 1991). Through partnering best practice such as Supply Chain Management (SCM), Total Quality Management (TQM) and Risk Management etc can be successfully transferred from the Manufacturing Industry to the CI (Anumba, et al. 2000a, Ngowi, 2000, Tang, et al. 2006). Partnering is effective in developing competitiveness (Errasti, et al., 2007). Similarly, alliancing like partnering significantly improve cost and time performance of construction projects (Ross, 2001, Voordijk, 2000, Clegg, 2001, Scott, 2001, Gallagher, 2002 and Olds, 2002). A comparative assessment of the performance of partnering and alliancing projects indicates that both partnering and alliancing reduce the incidences of cost and time overruns but alliancing have a greater impact on project cost than partnering (Tang, et al., 2006).

METHODOLOGY

Research Design; the study adopts a survey research design, which is a structured mean of collecting data on certain variables of interest from a representative proportion of the population. Survey may be use for exploratory, descriptive or correlational studies. Surveys remain very popular in research because they enable a research to quickly obtain quantitative and qualitative data on variables of interest from a proportion of a given population. The possibility of studying a sample of the population is a major advantage because of the savings in cost and time.

Sampling; the study involve the five subgroups of participants in the CI – which includes consultants, contractors, subcontractors, suppliers and plant hiring organizations. A sample size of 100 firms was adopted for the study. Purposive and convenience sampling approach were used to reach the respondents. The questionnaires were hand delivered to the respondents for filling and later collected through the same means. A total of 50 (50%) questionnaires were returned by the close of the survey , however, one of the questionnaires were not use due to error , hence, the total sample size is 49.

Method; the study used structured questionnaires which are divided into four sections. The questionnaire is composed of structured questions with various options to choose from i.e. closed form items and limited open questions. The study faced difficulties sourcing information via questionnaires from most construction firms' officials. This may be due to the relative newness of the concept of partnering and alliancing in the NCI.
Analysis; Descriptive statistical analysis of completed questionnaires was carried out including measurement of central tendency and frequency.

RESULT

Relationship with Top five suppliers / subcontracting firms

*Relationship with the largest Firm;*The result shows the type of relationship between construction firms and their topmost customers, 12.2% maintain a full partnership , 16.3% have some form of partnership arrangement , 40.8% were undecided while 30.6% said they have Traditional relationships with their number first customer.
Relationship with the Second Largest Firm ; For the type of relationship with the second largest customer, 6.1% of the firms held that they have full partnerships , 14.3% of the firms held that they have some forms of partnership , 59.2% are undecided while 20.4% have Traditional relationships with their second largest customer.
Relationship with the third Largest Firm ; For the third largest customer, 4.1% of the firm have a full scale partnership , 20.4% have some form of partnership , 61.2% are undecided and 14.3% claimed they Traditional relationship with third largest customer.
Relationship with the fourth Largest Firm ; for the fourth largest customer only 2% of the firms maintain full partnership, 20.4% have some of partnerships, 65.3% are undecided 12.2% claimed they have Traditional relationship with fourth largest customers.
Relationship with the fifth Largest Firm ; For the fifth customer just 2% have full partnership, 24.5% maintained some form of relationship, 59.2% are undecided and 14.3% have Traditional relationship with fifth largest customer (see table 1).

Table 1 Relationship with top most firms

Type of relationship	Largest firm	Second largest	Third largest	Fourth largest	Fifth largest
	Percent	Percent	Percent	Percent	Percent
Full partner	12.2	6.1	4.1	2.0	2.0
Partner	16.3	14.3	20.4	20.4	24.5
Undecided	40.8	59.2	61.2	65.3	59.2
Traditional	30.6	20.4	14.3	12.2	14.3
Total	100.0	100.0	100.0	100.0	100.0

Types of Supply Chain Alliancing

Consultant; Among the consultants surveyed 6.1% use strategic alliance, 10.2 used business alliance, 28.6% use operational alliance, 24.5% use basic alliance and 12.2% use the transactional alliance.

Contractors; Among the contractors surveyed 6.1% use strategic alliance, 30.6% used business alliance, 34.7% use operational alliance, 6.1% use basic alliance and 2% use the transactional alliance.

Sub Contractor; for the sub contractors surveyed no strategic alliance, 10.2% used business alliance, 42.9% use operational alliance, 10.2% use basic alliance and 16.3% use the transactional alliance.

Suppliers; Among the suppliers surveyed no use strategic alliance was recorded, 22.4% used business alliance, 30.6% use operational alliance, 22.4% use basic alliance and 4.1% use the transactional alliance.

Hiring Company; Among the hiring companies surveyed no strategic or business alliance was recorded , however, 16.3% use operational alliance , 20.4% use basic alliance and 42.9% use the transactional alliance(see tabel 2).

Table 2 level of usage of the types of supply chain alliancing

Types of alliancing	Consultant	Contractor	Subcontractors	Supplier	Plant hirer
	Percent	Percent	Percent	Percent	Percent
Strategic alliancing	6.1	6.1	-	-	-
Business alliancing	10.2	30.6	10.2	22.4	-
Operational alliancing	28.6	34.7	42.9	30.6	16.3
Basic alliancing	24.5	6.1	10.2	22.4	20.4
Transactional alliancing	12.2	2.0	16.3	4.1	42.9
Total	81.6	79.6	79.6	79.6	79.6
System	18.4	20.4	20.4	20.4	20.4
Total	100.0	100.0	100.0	100.0	100.0

*Benefits of Strategic Supply Chain Partnering ;*An assessment of the benefits derivable from alliance show that respondents rated quality improvement as the most important benefit M=4.47, followed by technology development M= 4.33, then risk shearing M=3.88 surprisingly reduction of material cost was rated the least M=3.53(see table 3).

Table 3 benefits of strategic supply chain Partnering

Benefits of partnering	Mean(M)	Rank
Quality improvement	4.47	1
Technology development	4.33	2
Risk shearing	3.88	3
Meeting production time	3.8	4
Meeting market demand	3.69	5
Reduction in prod cost	3.53	6
Reduction in material cost	3.49	7

Challenges to Successful Supply Chain Partnering; As for the challenges involve in the implementation of a successful supply chain alliance respondents rated partner selection M= 6.4, communication gap M=6.14 and informal arrangement M= 6.1 as the most important.

Table 4 challenges to successful supply chain Partnering

Challenges of partnering	Mean(M)	Rank
Partner selection	6.4	1
Communication gap	6.14	2
Informal arrangement	6.1	3
Trust	5.82	4
Risk sharing	5.47	5

Reward sharing	5.29	6
Commitment	5.1	7
Conflict of interest	4.89	8
Legal framework	4.86	9

*Corrective Measures for Successful Supply Chain Partnering ;*On measures necessary for a successful partnering/alliancing, respondents rated clear partners selection guideline M=6.04, clear alliance guideline M=5.94, bridging communication gap M=5.92 as the most important. A pre-defined approach to shearing risks and rewards was rated fourth (M= 5.2). Commitment to supply chain objectives was fifth (M=4.8). Involvement from inception (M= 4.67); Legal backing (M=4.27) and code of practice (M=3.92) were rated least as sixth, seventh and eight respectively.

Table 5 corrective measures for partnering

Measures	mean	rank
Clear partners selection guideline	6.04	1
Clear partnering /alliance guidelines	5.94	2
Bridging communication gaps	5.92	3
Proper sharing of risk and reward	5.2	4
Commitment to supply chain objectives	4.8	5
Involvement from inception	4.67	6
Legal backing	4.27	7
Construction code of practice backing	3.92	8

DISCUSSION

Most of the highly rated challenges in this study such as communication gap, informal arrangement, trust, risk and reward sharing, commitment, conflict of interest and legal framework are supported in the body of literature. For example Harback *et al.* (1994) identify five challenges of partnering: unfulfilled expectations; unfinished business in which some elements of the partnering arrangement are still in dispute; assumption that all parties involved in the partnering are willing to share personal beliefs /thoughts; and adoption of a one-size-fits-all approach to all projects. Hellard (1995) also highlights the potential challenges such as: the perceive risks in trusting; commitment of top management; and difficulty in changing myopic thinking and cultures. Akintoye and Black (1999) identify five risk factors: managers' unwillingness to relinquish control; partners becoming complacent; increasing dependence on a partner; pressure to perform; and a partner reverting to adversarial relationship. Similarly, Begg, (2003) asserts that the CI guidance on partnering is vague on the legal implications of relational concepts when expressed in construction contracts. The lack of trust inhibits the sharing sensitive information. The unwillingness to share information is an attitudinal barrier that arises from long-standing tensions that has been perpetrated among Construction Supply Chain (CSC) members.

CONCLUSION

The adoption of the concept of Partnering/Alliancing is at its infancy and thus facing several challenges. Some of these challenges includes: - Partner selection; Communication gap; Informal arrangement; Trust; Risk and Reward sharing; Commitment; Conflict of interest and Legal framework. Therefore for a successful

partnering there are needs for Clear partners' selection guideline; Clear alliance guidelines; efficient communication; improved risks and reward sharing; Commitment to CSC objectives; Involvement from inception; Legal backing and Construction code of practice. A formal guideline comprising of policies and procedure to guide who potential partnering and alliancing arrangement, how resources will be shared and investment will take place have to be established. Formulating a clear partner selection guideline will help in determining who to work with on a collaborative, alliance basis; and who has the potential advantage over others.

ABSTRACT

The probability of schedule overruns on construction projects can be ascertained using a 'best fit' probability distribution from an empirical distribution. The statistical characteristics of schedule overruns occurring in 276 Australian construction and engineering projects were analysed. Skewness and kurtosis values reveal that schedule overruns are non-Gaussian. Theoretical probability distributions are then fitted to the schedule overrun data; including the Kolmogorov-Smirnov, Anderson-Darling and Chi-Squared non-parametric tests to determine the 'Goodness of Fit.' A Four Parameter Burr (4P) probability function best describes the behaviour of schedule overruns, provides the best overall distribution fit and is used to calculate the probability of their occurrence. Implications for managing schedule risk are discussed.

Keywords: Australia, schedule overrun, distribution fitting, probability distribution

INTRODUCTION

Client demands for early completion to minimize finance costs and increase return on investment to satisfy investors and stakeholders can lead to over optimistic schedules being produced (Kog et al., 1999). As a consequence, the likelihood of schedule overruns being experienced increases. According to the Building Cost Information Service of the Royal Institute of Chartered Surveyors, 48% of projects experience schedule overruns (Kennett, 2009). Schedule overruns can adversely influence the organizational performance and profitability of clients, contractors and key stakeholders. Schedule and cost overruns often arise simultaneously, albeit projects can experience a cost overrun and be delivered ahead of schedule or vice versa (Love, 2002). A plethora of reasons are proffered within the extant literature to justify schedule overruns that arise including change orders, rework, unforeseen ground conditions, and delays in design information (Chan and Kumaraswamy, 1997). Yet despite the accumulation of knowledge pertaining to the causal nature of schedule overruns, there has been limited research that quantifies their empirical and statistical distributions. In addressing this identified shortcoming, this paper uses data from 276

[1] plove@iinet.net.au

Australian construction and engineering projects to determine the 'best fit' distribution to enable a realistic estimate of possible schedule overrun probabilities.

SCHEDULE OVERRUN

Schedule overruns are often referred to as 'delays', 'schedule growth' or 'time overruns'. A schedule overrun occurs when the original contract period specified at contract award is extended beyond what was agreed prior to the commencement of works on-site (Assaf and Al-Hejji, 2006). According to Bhargava et al. (2010) projects with longer planned durations experience higher cost overruns and similarly the converse is also true. Odeck's (2004) research, for example, demonstrated that larger cost overruns were experienced in smaller projects. Thus, it appears larger projects are better managed and that longer completion times provide an opportunity to make adjustments to facilitate better planning and scheduling to minimize delays that may be caused by factors such as inclement weather and change orders.

A study of 309 Australian construction projects undertaken by Bromilow (1969) revealed that 88% experienced a schedule overrun. Over forty years later, Ashan and Gunawan (2010) revealed almost identical findings and observed that 86% of development projects conducted experienced a schedule overrun. The amount by which a project experiences a schedule overrun was found to vary significantly. Assaf and Al-Hejji (2006) found that most contractors and consultants indicated that average schedule overruns range from 10% to 30% of original contract period. Ashan and Gunawan (2010) reported that the average schedule overrun was found to be 33.37%, though this varied between different countries. For example, the mean schedule overrun in Bangladesh was 34.41%, China, 13.63%, India 55.69%, and Thailand 32.71%. Projects experiencing a schedule underrun on average experienced a US$79 million cost underrun (19% of planned cost). Of the 86% of projects completed within budget or under budget, 29% experienced an average schedule overrun of 16 months.

RESEARCH APPROACH

The dataset presented in Love et al. (2009) for Australian construction and engineering projects is used to develop 'best fit' statistical distributions so that probabilities for cost overruns at contract award can be determined.

Questionnaire Survey

The questionnaire survey developed for the study reported in Love et al. (2009) was used to extract cost overrun information as well as that relating to rework costs and causes. Stratified random sampling was used to select the study sample from the telephone directory, Yellow Pages® for the various regions of Australia. Two main benefits can be derived from using a stratified sample: (1) It can ensure that adequate and representative respondents within each subgroup under study are acquired; (2) Stratification also ensures that respondents within the same group are homogeneous.

Before the sample size for the main study could be determined, a pilot survey was completed with 30 building and 20 civil engineering contractors. As the survey of building contractors was undertaken first, it was considered to be reliable, and then used to pilot the civil engineering sample. The firms sampled comprised of design and engineering consultants, project managers, and contractors. The rationale was to test the suitability, clarity, and comprehensibility of the questionnaire as well as measure the response rate. Participating firms were contacted by telephone and informed of the research aims and objectives and informed that all responses would remain strictly confidential; albeit, generalizations of the findings would be made available to all participants.

On participant consent, questionnaires were mailed to the sample, with a stamped addressed return envelope enclosed. Participants were invited to critically review the questionnaires' design and structure by annotating comments onto the document itself in order to provide constructive feedback. Comments received were positive and therefore the questionnaire remained largely unaltered for the main surveys; albeit a few minor layout changes were made to increase clarity. A total of 25 responses were received in the building project pilot survey, giving an 83% response rate. For the civil engineering project survey, a total of 17 responses were received, giving an 85% response rate. These high response rates were obtained because prior consent to support the work was obtained from all survey participants.

In the main survey, 420 and 300 questionnaires were distributed to design consultants, contractors and project managers for building and civil engineering projects, respectively. As there were no fundamental changes required to either of the pilot questionnaires they were added to the samples. For the building and civil engineering projects, 161 and 115 responses were received respectively, which represents a total consolidated response rate of 36% for both surveys, which is within an acceptable range for a survey with industry practitioners.

PROCEDURE

Descriptive statistics such as the mean (M), standard deviation (SD), and inter-quartile were calculated. A one-way Analysis of Variance (ANOVA) was used to determine if cost overruns significantly varied between construction and engineering projects and original contract value at a 0.05 significance level. Probability density functions were developed using *EastFit 5*. A PDF for a continuous distribution can be expressed in terms of an integral between two points:

$$\int_a^b f(x)dx = P(a \le X \le b) \qquad \text{[Eq.1]}$$

A cumulative distribution functions (CDF) was also produced. For theoretical continuous distributions the CDF is expressed as a curve and denoted by:

$$F(x) = \int_{-\infty}^{x} f(t)dt \qquad \text{[Eq.2]}$$

The empirical CDF, which is displayed as a stepped discontinuous line and dependent on the number of bins, is represented by:

$$F_n(x) = \frac{1}{n} \cdot [\text{Number of observations} \leq x] \quad \text{[Eq.3]}$$

The PDF, CDF and distribution parameters ($\alpha, \beta, \gamma, \mu, k, m, \sigma, \xi$) for continuous distributions such as *Beta*, *Burr*, *Cauchy*, *Error, Gumbel Max/Min*, *Johnson SB*, *Normal*, and *Wakeby* were examined using the estimation method Maximum Likelihood Estimates (MLE). Using StatAssist 5.5, the 'best fit' distribution was then determined using the following 'Goodness of Fit' tests, which measure the compatibility of a random sample with a theoretical probability distribution:

- *Kolmogorov-Smirnov statistic (D)*: Based on the largest vertical difference between the theoretical and empirical CDF:

$$D = \max_{1 \leq i \leq n} \left(F(x_i) - \frac{i-1}{n}, \frac{i}{n} - F(x_i) \right) \quad \text{[Eq.4]}$$

- *Anderson-Darling statistic (A^2)*: A general test to compare the fit of an observed CDF to an expected CDF. The test provides more weight to a distributions tails than the *Kolmogorov-Smirnov* test. The Anderson-Darling statistic is defined as:

$$A^2 = -n - \frac{1}{n} \sum_{i=1}^{n} (2i-1) \cdot \left[InF(x_i) + In\left(1 - F(x_{n-i+1})\right) \right] \quad \text{[Eq.5]}$$

- *Chi-squared statistic* (χ^2): Determines if a sample comes from a population with a specific distribution. The Chi-squared statistic is defined as:

$$\chi^2 = \sum_{i=1}^{k} \frac{(O_i - E_i)^2}{E_i} \quad \text{[Eq.6]}$$

where O_i is the observed frequency for bin *i*, and E_i is the expected frequency bin *i* calculated by:

$$E_i = F(x_2) - F(x_1) \quad \text{[Eq.7]}$$

Here *F* is the CDF of the probability distribution being tested, and x_1, x_2 the limits for the bin *i*.

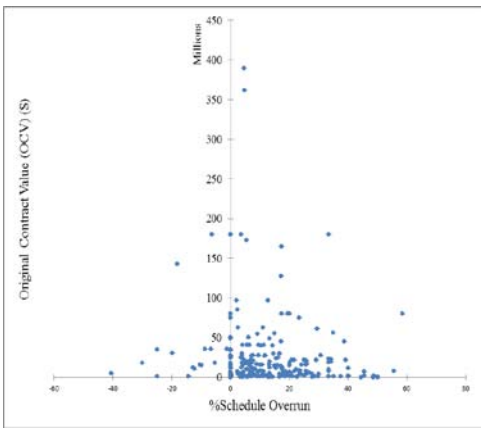
The above 'Goodness of Fit' tests were used to test the null (H_o) and alternative hypotheses (H_1) that the datasets: H_0 - follow the specified distribution; and H_1 - do not follow the specified distribution. The hypothesis regarding the distributional form is rejected at the chosen significance level (α) if the statistic *D*, A^2, χ^2 is greater than the critical value. For the purposes of this research, a 0.05 significance level was used to evaluate the null hypothesis. The *p*-value, in contrast to fixed α values is calculated based on the test statistic and denotes the threshold value of significance level in the

sense that H_o will be accepted for all values of α less than the *p*-value. Once the 'best fit' distribution was identified the probabilities for schedule overruns were calculated using the CDF. Then, to simulate the samples randomness and derive cost overrun probabilities, a *Mersenne Twister*, which is pseudorandom number generating algorithm, was used to generate a sequence of numbers that approximated the sample to 1000 (Matsumoto and Nishimura, 1998).

RESULTS

Data from a total of 276 construction (n=161) and civil engineering (n=115) projects was obtained. In the case of construction projects, these ranged from banks to hospitals and hotels. For the civil engineering sample, these ranged from tunneling to road construction and sewer treatment plants. The summary statistics reveal that the mean original contract value was AU$23,142,486 (SD=A$41,171,772; minimum=AU$132,347; maximum = A$390 million) and the mean actual contract value was AU$25,455,372 (SD= AU$45,090,928; minimum = AU$136,671; maximum = AU$420 million). The actual construction period was an average 4.7 years (SD=3.3 years), ranging from 15 weeks to 3.75 years.

To better understand the sample composition, an examination of respondents' stratification, geographical dispersion, and company turnover was completed for the construction and civil engineering samples. In terms of respondent stratification, 45% were design consultants (architects, quantity surveyors, and structural, mechanical, and electrical engineers), 31% were contractors, and 24% comprised project managers. With regards to geographical dispersion, organizations were situated across states: Victoria (45%), New South Wales (17%), Queensland (27%), South Australia (9%), and WA (2%). The analysis revealed that the average annual turnover of organizations sampled varied: < AU$1m=14%; AU$1 to AU$10m =37%; AU$11 to AU$50m=20%; AU$51 to AU$250m=13%; and > AU$250m=16%. The descriptive statistics for the schedule overruns that were incurred in the sampled projects are presented in Figure 1. The mean overall project schedule overrun for the sample was 11.42% (SD=14.24). Means schedule overruns were also determined for the two groupings of project types: (1) construction 13.07% (SD=16.89%) or 8.88 weeks (SD=24.22 weeks) and (2) civil engineering 11.13% (SD=11.96%) or 4.27weeks (SD=13.76 weeks). The spread of the schedule overruns incurred in each project is plotted against the original contract value (Figure 1).



Range	99
Mean	11.42
Variance	203
Std. Deviation	14.24
Coef. of Variation	1.247
Std.Error	0.857
Skewness	0.389
Excess Kurtosis	1.325

Figure 1. Distribution and descriptive statistics of schedule overruns

An ANOVA test was used to determine whether there were significant differences between the schedule overruns experienced in the construction and engineering projects (p = 0.05). The analysis revealed that there were no significant differences between the schedule overruns experienced between construction and civil engineering projects [F (1, 274) =.413, p = 0.21]..

Probability of Schedule Overruns

The construction and engineering datasets were combined and the 'best fit' probability distribution was examined using the 'Goodness of Fit' tests: *Kolmogorov-Smirnov* and *Anderson-Darling.* The results of the 'Goodness of Fit' tests revealed that Burr *Four Parameter (4P)* distribution provided the best fit for the dataset (Table 3). The Kolmogorov-Smirnov test revealed a *D* statistic of 0.08758 with a *P*-value of 0.2725 and the H_0 was accepted at α = 0.02 and α = 0.01 levels. The Anderson-Darling statistic A^2 was revealed to be 3.0801 and the H_0 was accepted at α = 0.02 and α = 0.01 levels. The Chi-squared (χ^2) statistic was found to be 1.8008 with a *P*-value of 0.0.87596 and the H_1 was accepted.

A Burr distribution is a continuous probability distribution for a non-negative random variable. It has a flexible shape and controllable scale and location and is sometimes considered as an alternative to a Normal distribution when data demonstrate positive skewness. The parameters of the Burr (4P) are all continuous: k is a shape parameter ($k > 0$), α is a shape parameter ($\alpha > 0$), β is scale parameter, and γ location parameter ($\gamma \equiv 0$ yields the 4P Burr distribution). The PDF is expressed as:

$$F(x) = \frac{\alpha k \left(\frac{x-y}{\beta} \right)^{\alpha-1}}{\beta \left(1 + \left(\frac{x-y}{\beta} \right)^{\alpha} \right)^{k+1}} \qquad \text{[Eq.8]}$$

The CDF is expressed as:

$$F(x) = 1 - \left(1 + \left(\frac{x-y}{\beta} \right)^{\alpha} \right)^{-k} \qquad \text{[Eq.9]}$$

The distribution parameters for the sampled construction and engineering projects were found to be: k = 0.19541, α = 2.1247E+8, β = 5.6456E+8, γ = -5.6456E+8. The calculated probabilities of a schedule overrun being experienced are presented in Table 1. The probability of experiencing a schedule overrun of >10% is 45% (P(X > X1), 0.45). Delimiters were also been used to provide probabilities of schedule overruns within ranges. The probability of a project experiencing between a 1% and 10% schedule overrun, for example, is 36%. For a mean schedule overrun of 15.91% the likelihood that a project's duration is extended by this amount is approximately 60% (P (X < X1) = .60)

Table 1. Probability of schedule overruns

Probability of a cost overrun between:	**P(X1 < X < X2)**	**Probability cost overrun**	**P(X < X1)**	**P(X > X1)**
1 and 5%	0.17	5%	0.36	0.64
6 and 10%	0.19	10%	0.55	0.45
11 and 15%	0.14	15%	0.60	0.40
16 and 20%	0.09	20%	0.78	0.22
21 and 25%	0.07	25%	0.85	0.15
26 and 30%	0.05	30%	0.9	0.10

IMPLICATIONS FOR MANAGING SCHEDULE RISK

Determining the likelihood of a project to experience a schedule overrun from contract award is a risk that clients and construction organizations generally fail to consider. Instead, emphasis has generally focused on the potential for cost increases by adding a contingency into the contract value. However, there is a proclivity for schedule contingency to be contained within a project's construction program as 'float' or 'slack'. This is the amount of time that a task in a project network can be delayed without causing a delay to subsequent tasks (free float) and/or its completion date (total float). Tasks are often delayed by rework, which can significantly contribute to schedule overruns being experienced and negatively impact construction-related tasks (e.g., productivity), completion dates, and resourcing (Love, 2002). While 'float' has been conventionally used as a risk management mechanism to accommodate for client initiated change orders, clients and construction organizations have tended to place emphasis on assessing risk they can control by establishing deterministic estimates of duration and cost. This approach invariably anchors project teams to early optimistic estimates. Assumptions, omissions, and qualifications, particularly for the determination of projects schedule duration, are made to establish as basis for the project from a tactical and operational perspective. It is often assumed that risks, particularly with delays and schedule overruns, will reduce with time and progress.

The volatility of strategic risks will invariably vary over time, particularly in the case of design errors, as they enter a period of incubation, and 'when' or 'if' discovered may have disastrous consequences on a project's schedule or a facility's structural integrity. Failure to recognize volatility may result in the uncertainty surrounding schedule risk being understated. For example, tactical risks such as those associated with errors in contract documentation, change orders and the procurement of materials significantly reduce as a project's schedule time reduces. It is frequently assumed by practitioners that any risks not considered in the deterministic estimate and covered by contingency during the design development process will not be taken into consideration at contract award.

CONCLUSION

To manage and control the risk of schedule overruns, its probability of occurrence must be determined. Using data obtained from 276 construction and engineering

projects, the statistical characteristics of schedule overruns were analyzed. Using the contract award as a reference point, schedule overruns from 276 construction and engineering projects were calculated. The mean schedule overrun was revealed to be 11.42% from contract award. No significant differences for schedule overruns were found between procurement method, project type and contract size. The empirical distributions for schedule overruns were found to be non-Gaussian and non-parametric 'Goodness of Fit' tests were used to select the best fit probability distribution. A 3-Parameter Burr probability function was found to provide the best overall distribution fit to calculate the probability of schedule overruns. It is suggested that distribution fitting of empirical distributions is necessary to produce reliable and realistic schedule overrun probabilities and as a result improve decision-making. The research has consequently provided an initial platform to examine the probability of schedule overruns. Determining the best fit distribution is pivotal to calculating realistic schedule overrun probabilities. Further research, however, is required to extend the dataset and test the reliability of probabilities that have been produced.

ABSTRACT

The construction industry in Nigeria is faced with challenges in the execution of construction projects involving labour -only contract and direct- labour contract. This study therefore compares the performance of labour only and directly employed labour contracts in southwest Nigeria. Qualitative data was obtained from the consultants and key management staff of the companies that are responsible for decision-making via in-depth interview. Quantitative data was obtained through administration of questionnaires using 5-point likert scale to measure the labour productivity and the performance of other project variables. Descriptive and inferential statistical techniques were used for the analysis. The study revealed that the productivity performance is higher in labour- only contract than direct- labour contract executed in the same context and working environment. It then concluded that the use of labour-only contract should be more embraced than the direct labour contract in Nigeria.

Keywords: construction, direct-labour, labour-only, performance, productivity.

INTRODUCTION

The construction industry is recognized as an independent and profitable sector of the national economy of a country in developed parts of the world. It is regarded as a significant source of direct employment and contributes through its wide range of operation and projects to the growth and development of virtually all other economic sectors (Chua, 1996). In developing country like Nigeria due to downward trend in economic situation of the country, the procurement methods prominently used are Labour

only contracting and Direct Labour (Ogunsanmi and Iyagba, 2003) others include Design and Build, and Traditional Contracting. Moreover, a construction project is a complex process that has defined level of periodic productivity that correlates with the overall goal of the project (Idoro, 2002). It is therefore important to compare the productivity performance of some procurement methods (such as Labour only and Direct labour contracting methods) with each other to determine which is better in meeting the overall goal of the project in terms of cost, quality and time (Loh and Ofori, 2000). The study therefore compared the performance of Labour only and Direct Labour contracts in South western Nigeria to determine whether the performance of Labour Only Contract is higher than Direct Labour Only Contract.

RELATED WORKS

Construction sector is one that values cost, time, and quality performance of any project undertaking in its highly competitive, global and open business environment, by effective utilization of different available resources to achieve maximum output with less input. The combined effect of the efficient and effectiveness of an economy in the utilization of resources leading to tremendous impacts in the form of competiveness employment, income and inflation, profitability, standard of living and balance of payment is productivity Chukumaobi (2002). In construction industry labour productivity is defined as the best way construction workers utilize efficiently and effectively the available resources in most economic manner to achieve a set goals and objectives Fagbenle (2006).

Labour Only and Direct labour Contracting Systems

Ogunde (2011) identified labour only contract as one of the project procurement methods used in the construction industry in Nigeria, which principally involves the client and the contractor. In the labour only contract the client provides all the materials required for the project while the contractor provides the labour force and he is equally paid for the cost of labour including his overhead and profit by the client (Ogunsanmi and Bamisile 1997). However, the client needs to institute some cost montoring controls on the contractor for better management of the project. Surveys of National law and practice on the use of labour only contract reveals that there are two consistent elements which must be present for a work arrangement to be a contract labour situation. Firstly, there should be contractual arrangement under which a worker under takes work for a person or organization other than under a contract of employment. Secondly, there should be some elements of economic or organizational subordination or dependency between the worker and the person for whom the work is performed (Adenuga, 2003).

Fagbenle (2005) refered to direct labour system as an arrangement where a client, organizes the various operations involved in the construction and use both the materials and manpower at his disposal towards the realisation of a successful project. It is also expressed as a system whereby a client uses his/her own in-house resources for the production of the design and the actual construction of a project (Odunlami, 1996). Oyefeko (1988) classified direct labour system into two which are direct labour approach by a client who is an individual; and direct labour approach by a client who is a partnership, corporate body or government. Seeley (1976) gave the merits of direct labour

system as allowing for full control of activities of operatives, thereby permitting reasonable flexibility and direct quality control. It also gives the operatives in-depth knowledge of the building process and becomes familiar with the user`s requirements and any constraints on the execution of the work. Fagbenle, (1999) emphasized that direct labour system however creates unnecessary idle time owing largely to administrative bottlenecks. It does not recognize the use of cost control analysis as fund control measure. Another essential feature of the direct labour system is that the nucleuses of the operatives are employees of the organization that is embarking on direct labour system. Again, the client does everything in direct labour approach whereas in labour-only contracting, construction risks are shared between the owner and the contractor. According to Omolemhamham (1990), equipment – based intensive and community based are some of the characteristics commoners/factors associated with the direct labour method of project execution.

Measurement of Project Performance

Seeley (1996) observed that the traditional project measure of cost, time, and quality are frequently used to measure contractor`s performance by clients. Hatush and Skitmore (1997) grouped the factors affecting the environment of construction projects under cultural, economic, political, social, physical, aesthetics, financial, legal, institutional, and technological and policy. Moreover, the neglect of quality has a detrimental effect upon time and cost performance. Other influencing factors identified include other non-traditional measures such as health, safety, material waste and management expertise (Smallwood, 2000). Maloney (1990) expatiated on the seven dimensions of performance to contractors, such variables as they apply to effectiveness, the degree to which the objective of an oganisation is met, efficiency -the ratio of the resources to be used on a project to the resources actually used. Quality which involves conformity to specification, productivity was defined as the ratio of output to input where output is the physical units of construction achieved and input is the man-hour used to achieve the output. Innovation refers to creativity, discovery of new and better materials and response to change. Lastly, profitability expressed as the ability of the contractor to generate adequate revenues in excess of the cost incurred.

Performance of Labour Only and Direct Labour Contracts

Ogunsanmi (2000) carried out comparative study of the performance of labour-only contracting and direct labour procurement systems in three states of Nigeria and concluded that labour only contracting performed better than the direct labour approach. Adenuga (2003) also investigated the labour only contracts in Nigeria and concluded that the system is becoming an increasing prominent feature of the construction labour market. Dada (2003) made a case study of Lagos state indigenous contractors` performance with contracting measures and concluded that there is no significant difference in the assessment and rating of the identified measures of contractor`s performance.

METHODOLOGY

A total of 100 questionnaires were distributed to selected Consultants, Clients, Contractors, Operatives based in the South Western part of Nigeria that had been

involved in projects with labour only and direct labour contracts across the nation. Twenty five questionnaires were distributed equally to the Consultants, Clients, Contractors and Operatives respectively. Qualitative data was obtained from the Consultants and key management staff of the companies that are responsible for decision-making via in-depth interview. Quantitative data was obtained through administration of questionnaires using 5-point likert scale to measure the labour productivity and the performance of other project variables. Descriptive and inferential statistical techniques were used for the analysis. The data computation was carried out using the Statistical Package for Social Scientists (SPSS) and the following presentation shows the background and characteristics of the respondents.

Out of the hundred (100) questionnaires administered on the respondents, only twenty (20) for the consultants, twenty three (23) for the contractors, fifteen (15) for the clients, and fourteen (14) for the operatives, a total of seventy two (72) completed set of questionnaires could be-retrieved. This represents a total of average of 72% of respondents which is good enough to draw inference on this study (See Table1).

Table1: Respondents` Characteristics

Respondent	Questionnaires served	Questionnaires received	Percentage (%) received
Contractors	25	20	80
Consultants	25	23	92
Clients	25	15	60
Operatives	25	14	56
Total	100	72	72

Table1 shows that 80% of the contractors returned the questionnaires, 92% and 60% responses from the consultants and clients respectively. The average total is 72%. This is a very high response.

Educational Attainment and Years of Experience of the Respondents

The analysis revealed that thirty (41.7%) respondents have at least HND/BSc, twenty two (30.6%) respondents have M.Sc and higher qualifications, thirteen (18%) respondents have NCE/OND while only seven (9.7%) of them possess Technical/WASC. It shows that most of the respondents are highly qualified educationally. Also, Table 2 shows that eighty percent (80%) of the respondents have more than ten years of working experience

Table 2: Years of Experience of the Respondent

Period	Number of Respondents	Percentage (%)
1 – 10 yrs	4	28
11 – 20 yrs	39	52
21 – 40 yrs	27	16
40 yrs and above	2	4
Total	72	100%

 ISBN: 978-1-84219-840-7 .

in the construction industry and twenty percent (20%) have more than twenty years of experience. It can therefore be assumed that the respondents have good understanding of construction processes.

Respondents Experience in Labour only and Direct labour Contracts

Tables 3 and 4 show the staff strength of the construction firms investigated and their involvements in labour only and direct labour contracts. Over seventy percent of the respondents have experience in labour only and direct labour contracts.

Table 3: Staff Strength of the Respondents Firms

Employed	Number of Respondents	Percentage (%)
1-50	43	59.7
51 – 100	22	30.6
101-200	4	5.5
>200	3	4.2
Total	72	100%

Table 4: Respondents Experience in Labour Only and Direct Labour Contracts

Labour only Contract	Direct Labour Contract
Yes 60 (83.3%)	Yes 57 (79.2%)
No 12 (16.7%)	No 15 (20.8%)
Total 72 (100%)	Total 72 (100%)

Variables Affecting Performance of Labour Only Contract

The variables affecting the performance of labour only contract were measured and ranked to determine how these variables affect performance in the delivery of labour only contract (See Table5).

Table 5: Variables Affecting Performance of Labour Only Contract

S/N	Variables affecting performance	Response Rate					Mean Score	Rank
		1	2	3	4	5		
1	Availability of Materials	2	6	7	15	42	4.24	1
2	Availability of funds	4	6	6	13	43	4.18	2
3	Availability of tools and equipment	3	6	7	32	24	3.94	3
4	Poor supervision	3	5	8	36	20	3.90	4
5	Poor communication	4	6	13	34	15	3.69	5
6	Skill of Workforce	1	6	34	23	8	3.43	6
7	Lack of information	4	10	41	12	5	3.06	7
8	Mode of Employment	8	43	10	5	6	2.42	8
9	Distrupted days	35	14	13	7	3	2.01	9
10	Construction method	41	15	8	5	3	1.81	10

11	Availability of labour	39	18	9	4	2	1.78	11

(The aggregate mean of the factors affecting performance of labour only contract is 3.17)

Table 5 shows that labour only contract is mostly affected by lack or in-availability of materials (4.24) at the required time, quality and quantity. The supply of materials is usually done by the client and any delay by the client in supplying the materials most often affects the performance of the contractors' involved in labour only contracts. Availability of labour (1.78) is the least factor affecting the performance of labour only contract because the supply of labour is the sole responsibility of the contractor and forms the basis of labour only contract. The Availability of funds (4.18), Tools and Equipment (3.94), Poor supervision (3.90) and the Skill of the workforce (3.43) are important variables that determine performance of labour only executed projects.

Variables Affecting Performance of Direct Labour Contract

The variables affecting the performance of labour only contract were measured and ranked to determine how these variables affect performance in the delivery of direct labour contract (See Table 6).

Table 6: Variables Affecting Performance of Direct Labour Contract

S/N	Variables affecting performance	Response Rate					Mean Score	Rank
		1	2	3	4	5		
1	Disrupted days	1	3	9	14	45	4.38	1
2	Poor communication	3	2	5	17	45	4.38	2
3	Availability of funds	1	3	6	21	41	4.36	3
4	Mode of Employment	2	4	8	20	38	4.33	4
5	Lack of information	3	3	6	15	45	4.33	5
6	Availability of labour	2	4	9	18	39	4.22	6
7	Availability of Materials	2	4	7	27	32	4.15	7
8	Availability of tools and Equipment	5	5	7	23	32	4.00	8
9	Skill of Workforce	8	23	34	6	1	2.57	9
10	Poor supervision	20	36	8	5	3	2.10	10
11	Construction method	34	24	8	4	2	1.83	11

(The aggregate mean of the factors affecting performance of direct labour contract is 3.70)

The result of the findings shown in Table 6 reveals that direct labour contract is mostly affected by disrupted days due to bureaucracy (4.38), poor communication among parties involved in the contract (4.38), lack of funds (4.36) and the mode of employment (4.33) which makes the employees to be paid salaries or wages at specific days whether or not the work has been done or not. Other equally important factors are Lack of availability of labour, materials tools and equipment. Construction method (1.83) is the least factor that affects performance in direct labour contract. It can thus be inferred from Tables 6 and 7 that labour only has more resistant (3.17 Aggregate mean) to the factors affecting

performance than direct labour (3.7 Aggregate mean) because of extra commitments on the part of the contractor.

Parameters for Measuring Performance in Labour Only Contract

The basic determinants for measuring the performance of delivery of projects in terms of time, cost, quality, health and safety and Overall performance of labour only contracts were analysed and ranked in Table7.

Table 7: Labour Only Contract Performance Measures

S/N	Performance Determinants/Parameters	Response Rate					Mean Score	Rank
		1	2	3	4	5		
1	Time	1	3	9	11	48	4.42	1
2	Cost	3	2	5	17	45	4.38	2
3	Overall performance	3	3	6	15	45	4.33	3
4	Quality	10	21	6	19	16	3.14	4
5	Health and Safety	38	26	12	4	2	2.49	5

(The aggregate mean of performance determinants of Labour only contract is 3.75)

The result shown in Table7 revealed that labour only contracts performed best in Time delivery (4.42) of projects and least in Health and Safety (2.49). Cost was ranked next by the respondents and closely followed by overall performance. The result is in agreement with the findings of Fagbenle (2006, Ogunsanmi and Iyagba, Ogunsanmi (2000), Loh and Ofori (2000), Wong (1990) and Choo (1986)

3.6 Parameters for Measuring Performance in Direct Labour Contract

The basic determinants for measuring the performance of delivery of projects in terms of time, cost, quality, health and safety and overall performance of labour only contracts were analysed and ranked in Table 8.

Table 8: Direct Labour Contract Performance Measures

S/N	Variables affecting performance	Response Rate					Mean Score	Rank
		1	2	3	4	5		
1	Health and Safety	2	4	6	22	44	4.41	1
2	Quality	15	21	6	19	49	3.6	2
3	Overall performance	5	25	16	13	15	3.11	3
4	Cost	47	12	4	4	2	1.58	4
5	Time	44	23	3	2	1	1.53	5

(The aggregate mean of performance determinants of Labour only contract is 2.85)

The result shown in Table 8 revealed that that direct labour contracts performed best in Health and Safety (4.41) of personnel involved in execution of the project and least in

Time delivery of the project (1.53), which often leads to cost overrun. Quality was ranked next by the respondents and closely followed by overall performance. The implications of this findings is that direct labour contract (2.85) is not as effective and efficient in time and cost delivery of projects which are paramount indicators of performance as labour only contract (3.75).

CONCLUSION

The study shows that the project variables that affect project performance are mode of employment, availability of materials, availability of labour, availability of tools and equipment, poor supervision, poor communication, disrupted days and skill of workforce. These variables affect labour only contract and direct labour contracts in varying degrees thereby leading to cost overrun, time overrun, poor quality and health and safety challenges.

However, when the study compared the performance of labour only and direct labour contracts in SouthWestern Nigeria to determine whether the performance of labour only contract is higher than directly employed contract, it revealed that the productivity performance is higher in labour- only contract than direct- labour contract executed in the same context and working environment. Also, direct labour contract is not as effective and efficient in time and cost delivery of projects as labour only contract which are paramount indicators of performance. Direct labour system however creates unnecessary idle time owing largely to administrative bottlenecks. It does not recognize the use of cost control analysis as fund control measure This is in agreement with the findings of Fagbenle (2006), Ogunsanmi and Iyagba, Ogunsanmi (2000), Loh and Ofori (2000), Wong (1990) and Choo (1986). It is therefore concluded that the use of labour-only contract should be more embraced than the direct labour contract for construction projects in Nigeria and also recommended that all efforts should be geared towards improving cost and quality performance of labour only contracts.

THE SOFT SYSTEMS APPROACH TO UNDERSTANDING TRUST IN ALLIANCES IN AUSTRALIA

Ling-Ye She[1], Hemanta Doloi [2] and Anthony Mills[3]

ABSTRACT

Alliances are complex projects with high levels of risk and uncertainty. Despite the pain share and gain share commercial arrangement in alliances, Trust is still an issue between the Alliancing Leadership Team (ALT) and Alliancing Management Team relationship (AMT). Although the concept and components of trust have been discussed by various researchers, the characteristic of trust under different situations has not been tested within the procurement research domain. Based on semi-structured interviews with the members of the ALT and AMT of an alliance project in Australia the underlying trust based relationships between the AMT and ALT were investigated using the Soft Systems Methodology (SSM). Results demonstrate that cognitive, affect, system and cognitive-affect based trust are mediated by common good, needs, sharing, breach temptation and mishap situations. This research demonstrates that the adversarial culture of the Australian construction industry cannot be changed by the implementation of trust principles alone. The culture of suspicion dominating the ideological view of the construction industry requires organizational learning between alliance parties to execute appropriate behaviours, aligned with the alliancing philosophy, to effectively achieve ideal collaboration.

Keywords**:** Alliances, adversarial culture, soft systems, trust

INTRODUCTION

Research on project alliancing in Australia has revealed that communication and trust between the Alliance Leadership Team (ALT) and Alliance Management Team (AMT) was a major issue that impacted on the effectiveness of the alliance (Mills and Harley 2010). The precondition for project alliancing to be successful is to develop a trust framework that allows the ALT and AMT to deliver superior project management coordination. The principle objective of Alliances is to align team

[1] lyshe@student.unimelb.edu.au
[2] hdoloi@unimelb.edu.au
[3] anthony.mills@deakin.edu.au

member expectations so that they work together for the benefit of the project (Mills et al. 2012).

The Construction Industry Institute Australia (CIIA 1996) and Larson and Drexler (1997) suggested that developing trust was pivotal to the success of partnering projects. Project alliancing in relational contracting is similar to partnering for the purpose of achieving mutual goals in the delivery of the project but this method is mainly used for infrastructure and large projects where there is high level of complexity as well as opportunity for innovation. More research is needed to explore how trust affects the AMT and ALT which are formed specifically for the purpose of project alliancing.

Project alliancing can be defined as a project delivery form in which "the owner collaborates with one or more service providers to share the risks and responsibilities in delivering the capital phase of a project (DTF Victoria 2006). In alliancing each alliance member places their profit margin and reward structure "at risk" so the entire alliance entity either benefits together or lose all (Walker et al. 2002). This then creates a motivation to collaborate and cooperate within the alliance relationship. Alliances operate on the principles of mutual trust, commitment and communication to reduce conflict and enhance productivity as well as overall performance (Lee and Cavusgil, 2006).

According to Mills et al (2012) an alliance is formed by the ALT and AMT. The ALT is in charge of the strategic decision making of the project as well as supporting the AMT team whilst the AMT is in charged with the operation of the project. The ALT team includes the client and determines the Target Turnout Cost (TOC), which is the agreed amount the building would cost to deliver (Walker et al. 2002). The AMT would include personnel from the contractor's side. Both AMT and ALT would have representatives from both the client and contactors' side to facilitate equity, knowledge as well as collaborative spirit in decision-making.

A normative frame is important for trust in a business relationship. It largely suspends opportunistic behaviour when interests are aligned. Legitimate mistrust is the perceived likelihood that a potential or actual transaction partner's interests are not aligned with one's own interests and that the partner's actions are driven by a salient gain frame such that relational and normative considerations are pushed into the background (Lindenberg 2000). Trust has been defined by different scholars over the years as predictability on human behavior (Cheung et al. 2003). For the nature of the construction industry,Robinson's (1996) definition of trust that "[it] is "one's *expectations, assumptions*, or *beliefs* about the *likelihood* that another's future actions will be beneficial, favorable, or at least *not detrimental to one's interest*" is most applicable to this research which is investigating the stability of trust between the ALT and AMT relationship within alliancing projects.

This definition of trust isn't the most optimistic in outlook but it implies that even if the parties are not absolutely considerate of each other's interests at least their actions will not be detrimental to the extent that it would break the partnership of shared

goals. This allows legitimate inherent mistrust to co-exist with trust and so it is the certainty of trust at any given point of time or situation that can be predicted to determine the intention of future behavior.

Distrust however is understood to be the "expecation that others will not act in one's best interests, even engaging in potentially injurious behaviour" (Govier 1994, Lewicki et al. 1998) and the "expectation that capable and responsible behaviour from specific individuals will not be forth coming" (Barber 1983; Lewicki et al. 1998). Mistrust is when there is lack of confidence or doubt as there may be a hidden agenda but not necessarily imply that there is serious malicious suspicion. Mistrust can occur in a positive state of a relationship and may even assist in the building of trust as parties communicate more openly regarding potential issues before the commencement of the partnership. Distrust is a negative attitude and signifies that there is an issue or conflict that needs to be resolved in a trustworthy manner or else all endeavors to build trust within a relationship would be rendered ineffective.

Mistrust can transform into distrust through miscommunication, misunderstandings and untimely resolution of issues both explicitly and implicitly known to one or both parties. In a highly adversarial construction industry, there are currently high levels of distrust beyond legitimate inherent mistrust. It is distrust which is hindering trust. Based on Lindenberg (2000) there are five situations affecting the conditions of trust in collaborative relationships. The five situations are namely *common situation*, *sharing situation, need situation, breach temptation and mishap situations.*

Trust has been identified as a driver of alliancing projects however it has also been identified as an issue between the ALT and AMT relationship. Although the concept and dynamics of trust has been defined and discussed by various researchers (Wong et al. 2008; Mayer et al. 1995; Rousseau et al. 1998) the situational impact of trust on the behavior of individuals between the ALT and AMT within alliancing projects has not been tested and is clearly a gap within the construction research domain. It can be hypothesized that in the culture of suspicion within the contemporary society, the adversarial attitude between construction professionals becomes entwined among individuals' past experiences, contractual obligations and confusion in the behavior expected within different procurement systems. It is important to understand trust from the perspective of its volatile nature in order to predict the likelihood of an individual's actions of either fostering trust or deviating towards distrust.

This research aims to capture the trust conditions affecting the AMT and ALT in the context of the Lindenberg's five situations as mentioned above. The objective of this research is to investigate under what conditions trust is facilitated and tarnished between the ALT and AMT relationship within alliancing projects.

METHODOLOGY

Soft Systems Methodology (SSM) is a powerful methodology for inquiring into complex situations (Checkland, 1981). It is a dynamic method that offers a people centred way to examine the problem areas and focuses to intervene in a messy situation in order to improve it in a structured way. SSM methodology comprises two

key steps in conceptualizing the real world picture into a structured outcome. Firstly, a rich picture is developed for careful assessment of the real world issues based on participants' responses. Secondly, a CATWOE (Customers, Actors, Transformation, Weltanschauung, Owners, Environmental Constraints) analysis is performed to demonstrate the various underlying elements affecting the measured phenomena. Finally a conceptual model is derived.

In this research, a total of nine participants selected from the Alliancing Association of Australia working in the ALT and AMT from a building alliance were interviewed. The building alliance was a refurbishment of an arts centre in Victoria. The risk and reward allocation was heavily placed on the non-owner participants in the event of a cost overrun or under run in the final TOC performance. From the ALT, there was a design representative, a construction representative and three client representatives. From the AMT, there was a design representative, a construction representative, and a client representative as well as an Alliance General Manager which chaired the AMT. Every respondent had more than 16 years of experience within the construction industry although only one of the participants had worked on more than one alliancing project in during their entire career within the construction industry. This demonstrates that alliancing contracting is not used as nearly as much compared to the Design and Construction procurement method for complex projects.

A university ethics clearance was obtained articulating the process of the interview. For the purpose of protecting their identity in the interviews, an agreement was signed between each participant and the researcher that the name of the alliance would be kept anonymous due to the commercial sensitivity of some of the information that was been given for this research. The participants were asked a set of questions on the conditions of trust between the ALT and AMT relationship within the alliancing projects that they had worked on. A set of questions were also asked to cross examine and confirm their position on their perception of their view points. The questions were semi-structured for the development of the rich picture to find out what the 'wicked' problems were from each participant's perception of the complicated trust issues that occurred within the alliance.

DATA ANALYSIS

Figure 1 depicts the rich pitcure of an effect of cost over runs on the trust conditions under different situations between alliance parties via the ALT and AMT in pain sharing mode. The black arrows represent the direction of the trust attitude between parties under a particular situation. The dotted lines show the functional links between the parties. As seen in both cost overrun and under run scenarios, clients, sponsors, non-owner participants (NoP; designers and contractors) and end-users are the key customers with the highest stake on the project decisions. The actors include Alliance General Managers, ALT and AMT members, consultants and wider project group who are perceived to have the critical roles in terms of achieving "Best for Project" outcomes.

The transformation is governed by the relevant knowledge, processes and technologies that allow the identification of the underlying causes of trust mistrust and distrust conditions associated with different situations between parties under cost overruns and under runs modes. Weltanschauung refers to the phrase "why brother"

and the root cause being bothered is the adversarial attitude between alliance parties which affects the trust between the ALT and AMT in achieving ”Best for Project” outcomes. The environmental constraints are the competition, legislative regulations, environmental sustainability, community perceptions and corporate objectives.

The rich picture demonstrates that under the pain share mode in the common good situations, cognitive-affect (communication related) and system based trust (contract related) are being affected. The reason is that in a pain share mode, the performance of one or more alliance parties has already created a conflict and therefore, the communication between the parties involved become a critical point to determine how the conflict is resolved. Figure 1 depicts a rich picture of the interviews with the ALT and AMT participants.

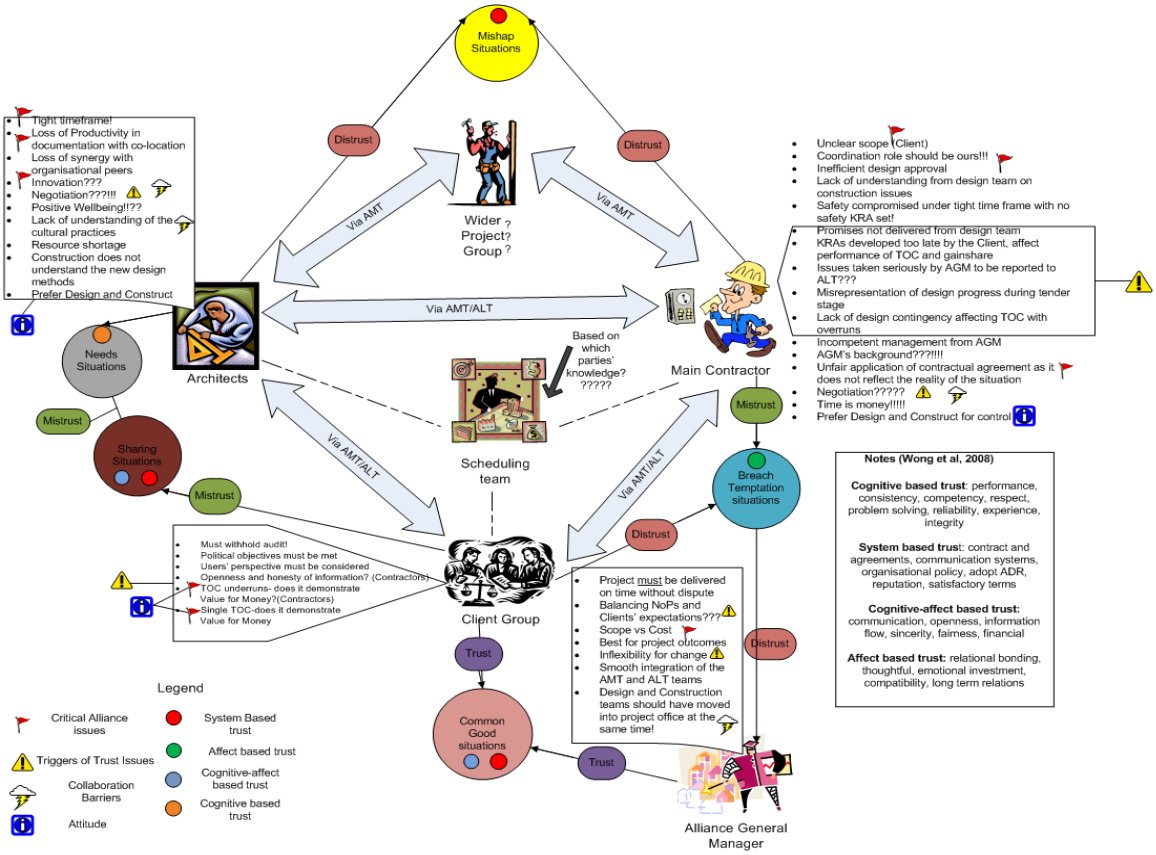

Figure 1. Trust conditions under pain share mode

In breach temptation situations, affect based trust (long term relations) is being affected under a pain sharing mode This is due to a ‘no sue’ clause within the Project Alliance Agreement. Under a pain sharing mode, system based trust determines the extent of distrust versus trust under mishap situations. In sharing situations cognitive-effect and system based trust are being affected under a pain sharing mode. In needs situation cognitive-affect based trust is being affected under a pain sharing mode, demonstrating that alliances are business relationships based on performance and common goals. This demonstrates that the contractual terms (i.e. KRAs, TOCs etc)

need to be proven by the performance of the project underpinned by strong communication between parties. Table 2 depicts root definition of rich picture in terms of the CATWOE analysis.

Table 2: Root definition under a pain sharing modes

Elements of CATWOE	**Description**	**Outcome**
Customers	Project management agency, sponsors, end users Non owner Participants (NoP), end users	The customers' expectations and how the expectations are understood and communicated are critical to building the trust foundations from the pretender to implementation and handover stages. If the expectations are not understood perfectly then it is the foundation for distrust to arise when conflicts occur.
Actors	Project owner, existing user, Project Management agency , ALT, AMT, wider project team (subcontractors), consultants, financiers,	The interaction and trust between the ALT and AMT is largely controlled and influenced by the leadership of the Alliance General Manager (AGM) who chairs the AMT and reports to the ALT any unresolved issues by the AMT. The perception of trust between the ALT and AMT is therefore highly influenced by the managerial capabilities of the AGM.
Transformation	Understanding the conditions of trust between the ALT and AMT within alliancing projects	There are two trust phenomenon in relation to the performance of TOC: When TOC is above and beyond 5% contingency, trust affects the relationship *among* alliance parties; owners and non-owner participants. The condition of trust *between* the ALT and AMT becomes a reflection of the trust among the alliance parties.
Weltanschauung	To improve the adversarial attitude between project participants so that a best for project outcome and value for money can be achieved	Under the pain sharing mode, the adversarial attitude has not changed although certain adversarial outcomes have been mitigated under the 'no sue' clause of the Project Alliance Agreement (PAA). Mishap situation has an impact on the system based trust under a pain sharing mode especially when there is distrust between the alliance members. Breach temptation has an impact on the affect based trust and is the initial intention of the alliance. Even in a pain sharing mode where there is distrust, there is no intention of breaching the contract.
Owners	Project owner	Perception of the existence and ability to negotiate must be maintained by the owners to foster trust with the non-owner participants. Negotiation is the most preferred method of conflict resolution in Australia within the construction industry. Although alliancing contracting restricts the ability to change the TOC once the PAA has been signed, significant miscalculations of latent conditions must not be ignored. Strict adherence to the PAA without fair consideration of the implication to the non-owner participants' profit margin and gain sharing outcome creates adversarial attitude between the relationships.
Environmental constraints	Political influences, TOC, alliancing best for project practices, culture, identity of individuals within the alliance in respect to their identity in their parent organisation, heritage issues, sustainability,	Under a tight scheduling timeframe, innovation requires the integration of team collaboration between the members of the AMT with the support of the ALT. when the scope of works is unclear problem solving requires cognitive-affect based trust. Unclear establishment of the KRAs have an impact on the cognitive-affect based trust as the KRAs affect the gain share aspect of the profit margin. Ambiguity

	Key Results Areas (KRA), KPI, safety requirements, quality, schedule, community, weather, approvals, unclear scope, emergence	creates ideas for innovation however it is also a catalyst for the perception of uncertainty and risk transfer which the behaviour required for risk sharing.

In the context of alliancing contracting, the 'Adversarial' Trust framework in Figure 2 takes a view that mistrust is an inevitable element of trust even in a "fair" gain share and pain share commercial arrangement within the PAA. Mistrust can develop into distrust in a mishap situation under a pain sharing mode. Mistrust can also facilitate cognitive-affect and system based trust through the understanding of the concerns of the alliance parties under breach temptation situations as the there is a 'no sue' and no blame culture written in the PAA. The contribution of this research demonstrates that the trust between the ALT and AMT is a reflection of inter-organizational trust among the alliance parties. Organizational learning is needed among all alliance parties before any effective trust strategies can be implemented to potentially reduce the culture of suspicion, currently dominating the ideological view of the construction industry.

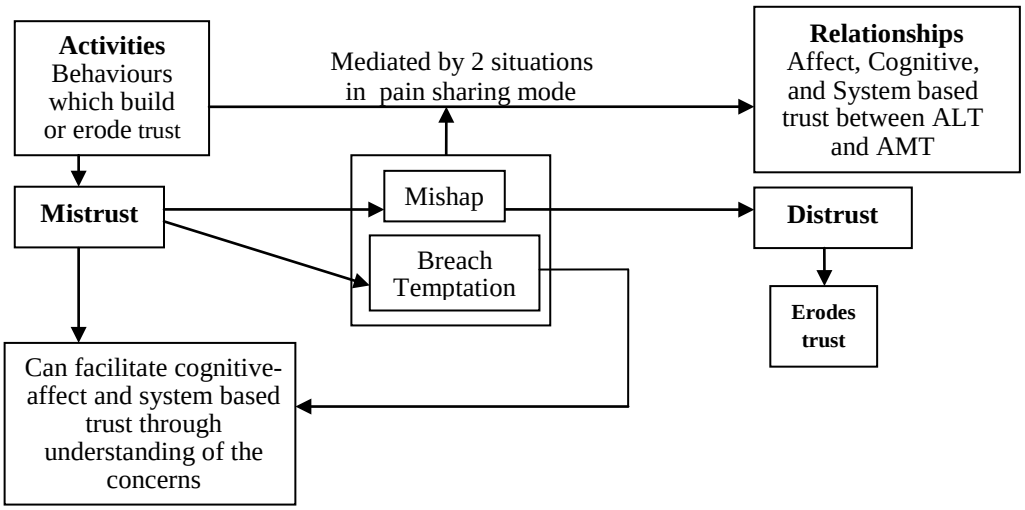

Figure 2: Adversarial' Trust framework developed from SSM

CONCLUSION

Trust conditions between ALT and AMT are volatile especially under a pain sharing mode with mishap and breach temptation situations. Cognitive, affect, system and cognitive-affect based trust are mediated by common good, needs, sharing, breach temptation and mishap situations. The distinction between mistrust and distrust also demonstrates that mistrust can co-exist with trust without detrimental effects on cooperation through the facilitation of cognitive-affect based trust. This is determined by the perception of risk sharing across the project life cycle depending on whether the TOC is in a gain share or pain share mode. Trust can only be facilitated in an alliance when Target Output Cost (TOC) has reached its gain share expectations In a pain share mode, distrust is the dominant attitude between all alliance members.

Mistrust can also develop into distrust if a mishap situation is not well handled in the process of negotiation and problem solving. The adversarial attitude between alliance participants under pain sharing mode demonstrates the influences of culture on the effectiveness of collaboration overriding contractual commercial alignment. More research is need in the integrated area of organizational learning and cultural practices to further understand the reality of trust in relational contracting rather than the representation of reality.

ABSTRACT

The management of large and complex civil infrastructure projects is often a challenge for the relationship between client and contractor. Many projects often end up in dissatisfaction or even in litigations for both parties. To change this situation, different partnering models and guidelines were established all over the world in the past years. One part of these models, or even a model on its own, is the Early Contractor Involvement. It is used in many countries around the world and comes up with several advantages in improving not only the whole planning, but also the actual situation between client and contractor. Nevertheless, this model is not applicable for public financed civil infrastructure projects in Germany. Until now, the strong regulations for public financed projects and public tendering hinder an adoption of the models from other countries. Hence, the knowledge of the contractors has to be used in other forms in the very end of the planning process or even during the construction phase.

Keywords: cooperative contracting, Early Contractor Involvement, Germany, infrastructure projects, partnering.

INTRODUCTION

The situation in large construction projects all over the world seems to be very similar. Many projects end up in a cost and time overflow whereby the relationship between client and contractor is not very cooperative (Black et al., 2000). Moreover, project participants often complain about too many disputes and litigations. Girmscheid (2005), Ingram and Bennet (1997) and Spang (2009) characterized the typical situation in the German and international construction and plant market by the following facts:

- Dissatisfied clients and distrust between client and contractor/s
- Decrease of Know-how due to “lowest price-principle”
- Increasing expenses for claim and anti claim management
- Growing number of disputes and litigations between clients and their contractors
- Low rate of return and high risk of business failure for contractors.

This situation is not satisfying for either clients or for contractors. Hence, both parties consent that new models for project delivery had to be found.

In the beginning of the nineties, Latham (1994) analyzed the reasons for the dissatisfying situation. He demands, inter alia, for a rethinking of the tendering system and to evaluate the contractor, not only by price criteria but also by quality criteria. Beyond this, he demands to establish preconditions to achieve a win-win situation between client and contractor, to be managed through a partnering approach. Some years later, Egan (1998) recommended that the construction industry should take a look at other industries and use their best practices by implementing them in their processes. Furthermore, clients and contractors should work together to achieve a common goal. To reach these goals, he also demanded for partnership between clients and contractors. Especially in complex projects, like for example big infrastructure projects with limited budget, the traditional way of project handling seems to be insufficient (Sakal, 2005).

During this time, a new concept was established with the Andrew Project of the Oil and Gas Company BP. The project had so many uncertainties that the project success was not certain. That led both parties, but especially the client, to look for a new way of contracting. In this project, contractors are chosen not only by price but also by quality criteria. This was necessary, because the contractors got involved earlier in the project to improve it by bringing in their knowledge. For this, the client needed strong and experienced contractors. The goals of the further project handling were fixed with a fair risk sharing between all parties, better and faster solution of conflicts without court processes and a pain and gain regulation for exceeding respectively failing the jointly fixed project targets. The result of this development was the first form of an alliance contract including an early involvement of the contractors, which leads to a satisfactory project for the client with savings of more than 20 % (Rooney, 2006).

This was the impulse for the Australian construction market to adopt and to develop this way of contracting. In the meantime, until today, alliance contracts including the early involvement of the contractors are used in Australia in the private and public sector more than anywhere else in the world (Ross, 2009).

Worldwide, especially in the private sector, fast changes towards more partnerships are applicable. In contrast, changes in the public sector are relatively slow, because of stricter regulations. However, international construction markets are rather different in matters of market conditions, legal situations and public authorizations.

EARLY CONTRACTOR INVOLVEMENT

Reasons for Early Contractor Involvement

Worldwide there are many forms of Early Contractor Involvement (ECI) in the construction industry. Originally ECI was established in the UK during the 1990s and has been introduced in Australia since 2005 (Swainston, 2006). Here it is not only used in the Alliance Contracting, a special form of contract for construction works, but also in the pure form of just involving the contractor earlier in the project. The big advantage of the early participation of the contractor during the design phase is the possibility to use his knowledge for improvements of the planning. In traditional contracts the client hires an architect or engineer for the design. During this period the architect/engineer and the client work together until the design is finished. One advantage of this execution model is that the designer is an independent person and just focuses on the demands of the client and not on the targets of a contractor’s company. On the other

hand the big disadvantage is that designers sometimes have just limited knowledge of the execution of the construction works because they are often not involved in the execution phase of the planned project. Thus he often gets no feedback for his design work and cannot improve it for example by "Lessons Learned". In contrast, the contractor has exactly this missing knowledge. If he can be involved in the planning phase, his Know-how can be used to improve the project (Gil et al., 2000).

Assaf & Al-Hejji (2006) proved the importance of good planning by a survey on time performance on projects in Saudi Arabia. In this survey 23 contractors, 19 consultants and 15 clients took part. Inter alia, Assaf and AL-Hejji found the following influencing factors on project duration which can be allocated to the planning phase:

- Mistakes and gaps in design documents
- Delays in producing design documents
- Unclear or inadequate drawings
- Complexity of project design
- Misunderstanding of owner's requirements by the design engineer
- Inadequate design-team experience.

Furthermore they state that by involving the contractor earlier in the project the impacts of these factors can be reduced or completely prevented. Moreover, through this early involvement the constructability can be enhanced (Proverbs and Holt, 2000), which may also lead, in most cases, to positive effects on time and cost performance.

In particular, changes in the scope of the project are much easier and cheaper during the design phase than during the execution phase. In Figure 1 the influence on project costs in the different stages during a construction project is shown. While in the conceptual design about 80 % of the costs can be influenced in the construction phase the amount decreases to c. 10 %. In contrast the costs of a change in the scope rise during the project duration. Even some changes will not be possible in the late project stages.

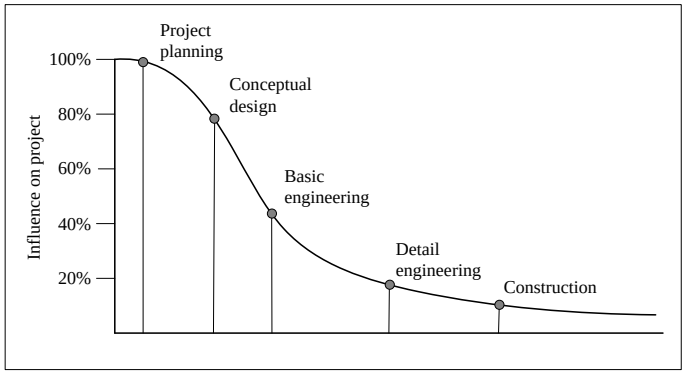

Figure 1 Influence on project costs (Scott, 2001)

Benefits also arise for the contractor by getting involved earlier in a project. In the traditional model, contractors get a comparatively short period of time to check and understand all documents and plans. On this basis they have to make an offer to the client. Until this point they have to understand the design work, have to think about how to build it and have to check if there are any (hidden) risks in the documents. By getting involved earlier, they have a longer time for the process and have more security that they did not miss something important. In a field study, conducted by the Chair of Project Management in 2006, 126 practitioners (57 clients, 54 contractors and 15 third parties involved) were asked about the applicability of risks in the tender documents (Figure 2).

 ISBN: 978-1-84219-840-7 .

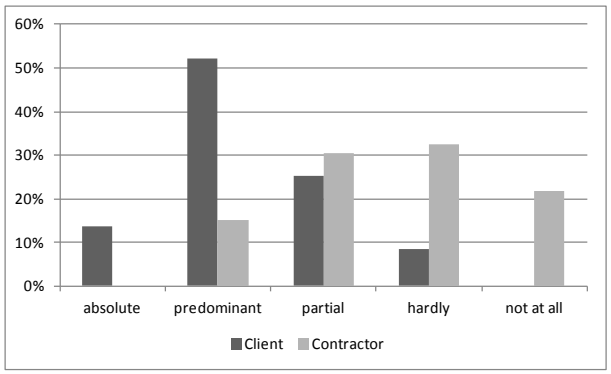

Figure 2 Risks are recognizable in the tendering documents (Spang et al., 2009)

More than 60 % of the clients stated that they are absolutely or predominantly applicable, while just 15 % of the contractors had the same opinion. The majority of the contractors, about 55 %, answered that the risks are hardly evident or even not applicable in the tender documents. In this point just 8 % of the clients agree with them. This different point of view on risks in tendering documents could be fixed by an earlier involvement of the contractors in the planning process. Hereby contractors get in touch with the project and thereby also with the risks, before they make an offer, which allows them to offer a risk adjusted price.

Another reason for an earlier involvement of the contractors could be found in the answers the practitioners gave on the question if the contractually agreed scope is clearly described in the tender documents (Figure 3).

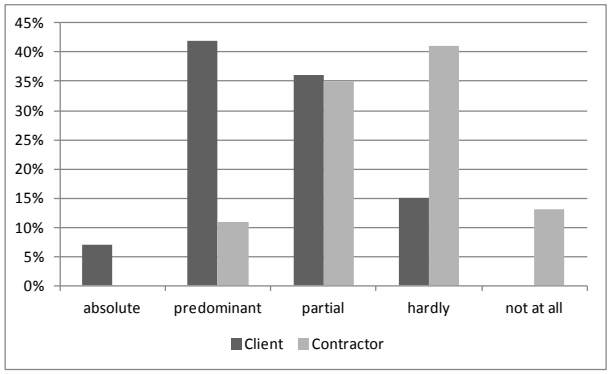

Figure 3 Clearness of the contractually agreed scope (Spang et al., 2009)

Nearly half of all participating clients (49 %) state that the contractually agreed scope is absolute or at least predominantly clearly described, while the majority of the contractors (54 %) stated the opposite. Clients are convinced to have described the scope perfectly based on a high design quality but contractors find shortcomings and space for interpretations. This is a possible reason for many disputes between client and contractor later during the construction phase. An earlier involvement of the contractors, using their knowledge, and the development of the plans together, could also help to solve this problem.

In short, the main benefits of ECI can be summarized as follows:

- Use of contractor's Know-how to improve the project
- Reduction of mistakes in design documents
- Better risk-understanding
- Enhanced constructability

- Better overall project performance (cost, time, quality, satisfaction)

Process of Early Contractor Involvement
In this chapter, the ECI-procedure will be described in a 'pure' ECI Model from Australia and the 'Bouwteam'-Model from the Netherlands.

Swainston (2006) describes the Australian ECI model as follows: In an ECI project the contractor will be involved right after the business case is finished. He will be chosen through non-price criteria. For this, interviews with the later onsite staff, the managers and the designers are conducted. When the right people, best for the job are found, a two stage process begins. But although it is divided into two parts, the contractor gets just one contract for the design and the execution phase. In the first stage, the contractor in collaboration with his designers and the client designs the project to a stage, that it can be priced exactly. Client, contractor and the contractor's designers work together in an alliance-style relationship with an open-book philosophy. This is necessary to prove that the public funds are spent efficiently and the price for the construction works is not too high.

On the basis of this design stadium, the contractor presents the client a risk-adjusted offer for the works. That means that the contractor includes a special 'risk-budget' for the risks found out during the design phase, which are allocated under his responsibility. If the client does not accept the offer, the contractor will be paid on a time basis for his design work and the project will be tendered like a traditional construction project. This is possible, because the contract includes this 'exit-point' for the client. In the event that the client accepts the offer, the contractor continues his work and the contract will be adjusted. The basis can be, for example, a lump sum contract for the final design, the execution and for the documentation. In this stage, client and contractor work together like in a D&C contract. The contractor finishes the design and builds the planned work. Benefits of this model found in Australia are: shorter time of delivery, lower tender costs, fewer changes during the construction period, better understanding of the project on both sides, higher flexibility and more innovation (Swainston, 2006).

Similar models exist in many other countries of the world, like for example in the Netherlands. The 'Bouwteam'-Model has very similar intentions like the ECI in Australia, although the process is not 100 % exactly the same. In some projects savings of about 20 % could be achieved by using this model (Weber et al., 2002).

Early Contractor Involvement in Infrastructure Projects in Germany
In Germany there exists actually no ECI in civil infrastructure projects like shown above. Till now, the strong public regulations hinder the adoption of these models for the use in Germany. These boundaries result from:

1. The plan approval process
2. The principle of open competition
3. The requirement of transparency
4. The principle of equal treatment

For civil infrastructure projects, the usual planning process is structured in five steps, the basic evaluation, the preplanning (including the route determination), the conceptual design, the plan approval and the execution planning. So, clients get the final approval very late in the planning process, which means a high uncertainty in the stages before. But as shown above, the influences on project costs are higher in the early stages, especially during the route determination. That's why contractors should be

integrated as early as possible – although there remains still a risk for both parties, namely the result of the plan approval which can lead to major changes.

Another obstacle is the principle of open competition in relation to the requirements of transparency and the equal treatment. Either clients have to choose a contractor very early and stay together till the construction is built, but then a price-competition is not possible, or, if they do the planning with one of the contractors and tender the construction works traditionally, they have to ensure an equal treatment of all of them. This means the clients have to make sure, that all of the potential bidders have the same, identical information, which will be hard to achieve. If the client makes a mistake and not all bidders have the same, identical information, any of the disadvantaged bidders could go to court and could make a new tendering of the project necessary.

One slight approach in Germany to use the contractor's knowledge in the very end of the planning phase of public financed infrastructure projects in Germany is the so called 'Funktionsbauvertrag' (Functional construction and maintenance contract). It allows the contractor to improve the design at limited points after the actual design phase is finished. It was developed in the 1990s and can be assigned to the Public Private Partnerships (PPP), because it has very similar regulations (Knoll et al., 1999). Most parts of the contract are tendered on the basis of a unit price without any use of the knowledge of the contractor (Racky & Altmueller, 2010). But some parts of the contract which contain the omitted construction works of the bound superstructure are tendered in a reference construction style. Here, the contractor has the chance to, perhaps, improve the design. This is the only point, where the contractor has very limited, involvement in contrast to the traditional design-bid-built method. After the construction works are finished, the contractor has to maintain the construction for a period of approximately 30 years like in 'normal' PPP-projects. Until today there is just a handful of projects contracted this way and there is no project where the time of maintenance is over. Because of this there are no wide and reliable experiences to evaluate this model. But the first findings are (Pauli, 2006):

- Quality incentives through life-cycle considerations of the contractor
- More innovation through functional description
- Less effort for the client for maintenance
- Better planning of financial resources for the public authorities.

The 'Funktionsbauvertrag' is, as mentioned above, the only way to use the knowledge of the contractor in the planning phase of public financed infrastructure projects.

However, not to leave the contractor's knowledge unused, at the Chair of Project Management of the University of Kassel, a guideline for partnership between client and contractor in public financed infrastructure projects (PPA-Model) was developed by researchers and practitioners from the client's and contractor's side. Moreover, lawyers also accompanied the development. Since 2009 this guideline is tested in Pilot-Projects. It consists of seven elements which aim for partnership between both parties. For the use of the contractor's knowledge especially the last element of the guideline is interesting. There are three cases for optimization in the construction phase given, while the process is always the same. The contractor makes a suggestion for an optimization to the client. If he accepts this, the contractor develops it and makes an offer to the client including all effects (e.g. on time, cost or quality). The three cases are:

1. Value engineering. When the client accepts this suggestion, both receive part of the saved money in a contractually fixed proportion, like 50/50.
2. Higher quality as demanded. If the client sees an advantage and accepts the suggestion, both should agree about a bonus for the contractor.
3. Faster project delivery. If the client sees an advantage, both parties have to agree about a bonus for the contractor.

During the development of the guideline in 2005 to 2008 it was the only way the participants saw to use the knowledge of the contractor in the boundaries of public regulations (Spang & Riemann, 2011).

The first findings in using this method are positive. Especially the first case, the value engineering, is well used. Through its application the client was able to save money by getting the same quality and the contractor could realize a bonus for bringing in his knowledge – the perfect win-win situation.

CONCLUSIONS

Early Contractor Involvement is used in many countries around the world. The ways of involving the contractor and the experiences are quite similar. With these models the time of delivery and the tender costs could be lowered, the changes during the construction period decreased and all of the parties involved got a better understanding of the whole project, which also leads to a higher flexibility and more innovation. All in all the quality of the whole project could be enhanced. These benefits are exactly the points which were criticized in the German construction industry by clients and contractors during the mentioned field study. But implementing the Early Contractor Involvement especially in public financed infrastructure projects in Germany like shown in the model from Australia is not applicable at the moment. Reasons are to be found for example in the strict policies of public funding and tendering. The only possibilities to use the knowledge of the contractor and to motivate him to look for innovation in public financed infrastructure projects are the ‘Funktionsbauvertrag’ and the PPA-Model. These are first steps, but involving the contractor much earlier during the design phase would lead to higher benefits because the costs can be better influenced in this stage of the project. Further research in this topic is in progress by a research project. Its aim is to find new ways to involve the contractor earlier in the planning phase of publicly financed infrastructure projects in Germany respecting the strong regulations for public projects. For this it is analyzed, whether one of the foreign models can be adopted with some changes in it, or if a new model by using the best practices from all of the investigated ones can be set up. Moreover, after finishing this research project, further research is necessary in collecting information concerning the usability and maybe further development of these models.

A FEASIBILITY STUDY OF BEST VALUE IN ITALY

Kristen C. Barlish[1] and Alberto De Marco [2]

[1]*Performance Based Studies Research Group (PBSRG), Arizona State University, PO Box 870204, Tempe, AZ 85287-0204, USA*

[2]*Department of Management and Production Engineering, Politecnico di Torino, Corso Duca degli Abruzzi 24, 10129 Turin, Italy*

ABSTRACT

A variety of business models for performance and quality are being proliferated in the construction and services industry. In Europe, specifically in the Netherlands, the Best Value (BV) business model is being applied and is having positive impacts, making it further attractive to countries that are new to BV and looking for improvements. A feasibility study of BV in Italy is conducted via: a brief synopsis of BV, a resource and environmental analysis, and presentation of the results of a survey carried out to determine the degree of achievability of BV in Italy are analyzed. The feasibility regarding the approach to implementation of BV is also discussed. The results of the industry survey are analysed to understand the overall contracting environment and hypothesize on the potential outcomes of the utilization of BV in the Italian construction and services industry. A list of recommendations to utilize BV is developed.

Keywords: Best Value, business models, feasibility study, Italy, performance

INTRODUCTION

Despite technical advancements such as Total Quality Management (TQM), Lean principles, Six Sigma, Building Information Modelling (BIM), and other Supply Chain Management (SCM) developments, the construction industry has continued to have performance issues. The main observed barriers to achieving increased performance via these models are individual and organizational resistance to change, unsustainable approaches to implementation, and poor economic times resulting in a realignment of expectations (Sullivan 2011). In Italy, the performance of the construction and services industry has not noticeably improved, with construction investments on the decline since 2009, and being hindered by factors such as excessive public debt and deficits, lack of flexibility, considerable corruption and conflict of interests in public procurement and administration (GI 2010), high taxes (World Bank 2010), and bureaucratic procedures (Bevini 2011 and USCS 2011). A new model, the Best Value (BV) business model is being proposed to the Italian

[1] kristen.barlish@asu.edu
[2] alberto.demarco@polito.it

construction and services industry to aid in the identification and achievement of performance improvement opportunities**.** After the USA, the Netherlands is the country where the BV process is being carried out on the largest scale. The process is being utilized in both private and public sectors, and in a variety of disciplines (Van de Rijt and Witteveen 2011). The application of BV in the Netherlands can provide many good lessons learned for the international application of BV beyond its original USA foundation. The main questions regarding the feasibility of the BV business model in Italy immerged as: 1) Could BV be beneficial to Italian projects? 2) What are the main barriers to BV implementation? 3) What is the most sustainable implementation approach of BV?

METHODOLOGY

A feasibility study aims to identify the following progression (Haramis 1992; Palvia and Palvia 1988): 1) needs analysis of the user; 2) relationship of proposed system to existing or similar systems; 3) environmental analysis; 4) resource analysis; and 5) evidence of the user's ability to react positively to the proposed system and associated impacts. The approach to measure the feasibility of the BV model in the Italian construction and service industry begins with a synopsis of BV, a resource and environmental analysis, followed by a presentation of survey results of Italian construction and service industry professionals designed to measure the industry's receptiveness to BV concepts, and finally an analysis of the results of the survey to determine BV's degree of achievability in Italy. The feasibility regarding the approach to implementation of BV is also discussed. A list of recommendations regarding future implementation of the BV model in Italy is further developed.

Proposed System

Based on the idea that the overall Italian market could benefit from a new, transparent performance model, the BV business model is proposed as a new way to deliver services, run organizations, and optimize supply chains (PBSRG 2012). While other trendy models such as Total Quality Management, LEAN, and Value for Money focus individually on quantitative assessment, design, and vendor-driven approaches, BV is more of a holistic management methodology and can also have quantifiable benefits via performance information measurement tools (NAO 2004 and Sullivan 2011). The BV model's basic tenants include transparency, accountability, and proper pre-planning (Kashiwagi 2011).

The BV model divides a project into three phases: 1) selection; 2) pre-planning; and 3) management by risk minimization. In the selection phase, the main purpose of the BV model is that vendors are given an opportunity to differentiate themselves from other vendors and clients are given the tools to properly select a vendor based upon their overall value of price and performance. Some of the important tools in this phase are the risk assessment and value added plans. In the pre-planning phase, vendors are required to create a pre-plan of their overall execution based upon their original proposal. The final phase of award and measurement is where the vendor tracks and reports all deviations to the contract in terms of cost, time, and overall satisfaction to the client. Lastly, the client completes a final satisfaction survey as part of the project's closeout (Kashiwagi 2011 and Sullivan 2008).

RESOURCE ANALYSIS

The Italian market is constrained in terms of cost, time, and satisfaction, similar to the global market. The barriers of BV implementation are not necessarily limited to one particular country's challenges; rather, challenges identified in the Netherlands' and

Botswana implementation are quite similar to Italy (Kashiwagi et al., 2008 and Van Leeuwen 2011). The challenges observed in Italy are not a result of legislation or technical capability; however, a clear understanding of the current legal environment is necessary to develop a complete feasibility study.

Legal Context

Selection methods and criteria in the European Union (EU) Public Procurement setting must take into consideration the EU legal directives and decrees of the member countries. The Italian Public Procurement Code, approved by Legislative Decree April 12, 2006, no. 163, brings together all the provisions governing contracts above and below the EU threshold with exceptions. The most pertinent are Directives 2004/17/EC and 2004/18/EC that establish selection and award criteria (PPN 2011).

BV Compliance with EU Directives and Italian Code

There are two selection criteria for Italian Public Procurements: lowest price and most economically advantageous tender (M.E.A.T.). The lowest price only criterion is in direct opposition to the BV business model, therefore the M.E.A.T. criterion is more compatible with the BV model. For 86.6% of works contracts the contracting authorities have used the lowest bidder criterion (AVCP 2011). It has been observed that contracting authorities have been struggling with determining award criteria that add value and at the same time meet all legal requirements of M.E.A.T. for many years. As a result these award criteria become minimum quality levels of performance and no dominant differences in quality levels are found between the tenders offered (Pietroforte and Tangerini 1999). The Netherlands' implementation of BV has uncovered some main conclusions about the application of BV tools in the European legal system (Van Leeuwen 2011). First, with regard to selection and award, past performance information can be used in a tender, but should in principle be used as a contractor selection criterion rather than an award criterion to avoid legal problems; risk assessment plans are commonly used as an award criterion; and interviews can also be used, while ensuring objectivity and equal treatment. Finally, if the pre-award period is used before awarding the tender, the main aspects of the contract, such as price and risk allocation should not be discussed.

SURVEY

A survey was designed for measuring Italian industry professionals' perceptions towards the current construction environment, and their receptivity towards BV concepts, to contribute to the feasibility study for BV implementation. The survey was composed of fifteen conceptual questions and was distributed to over 50 Italian construction industry professionals and organizations identified as having Project Management functions in Italy via social networking sites, conferences, and personal emails from March to May 2012. The survey received 389 respondents, which exceeded the required response rate according to Cochran's categorical method (margin of error 7% and 95% confidence level) (Bartlet et al. 2001). Respondents were asked some background information and to rate BV conceptual-based questions on a scale of (1-10) with "10" as strongly agreed and "1" as strongly disagreed. The criteria related to Information Measurement Theory concepts, the Kashiwagi Solution Model, industry perceptions, and BV overall as promoted by the Performance Based Studies Research Group (PBSRG) (Kashiwagi 2011).

Background Data

Survey respondents were primarily designated as Professional architect/ engineer/ technical services/ designer (89%), Consultant (6%), Vendor/Contractor (2%), with

the remaining in Owner/Investor, Government, and the University sectors. The average number of employees in the respective companies was 16 and the average number of projects per year was 336. The average overall reported satisfaction with the Italian construction and services industries was low, rated as 4 (on a scale with "1" being dissatisfied and "10" being highly satisfied).

Results

The survey measured a high degree of receptiveness of the BV model in the Italian construction and services industry (Table 1); however, more education is required prior to implementation. The most commonly contested concepts were: micro-management and control of the vendor by the client are not important to the success of the project, the reliance solely on minimum standards can lead to a lower realized quality outcome/product, and third-party involvement in a project is not necessary for clients to obtain their objectives. These concepts are important to the success of future implementation of BV in Italy. As survey participants were uneducated in BV concepts, future implementation should first begin with education to assist participants in understanding and target the identified areas of contention.

Table 1 – Survey Results

No.	Criteria	Optimal	Agree 10-8	Unsure 4-7	Disagree 1-3
1	An individual cannot control nor change the outcome of a project or an event.	10	15%	48%	38%
2	When an expectation does not match the outcome, not enough information was available and used.	10	45%	47%	8%
3	Management and inspection are very important to the success of a project.	1	49%	38%	12%
4	The person who has a high level of information makes fewer decisions and control.	10	17%	33%	50%
5	The person who has a low information level takes risks and uses management instead of leadership.	10	25%	52%	23%
6	The less control and management the owner does the more risks are shifted to vendors.	10	44%	38%	19%
7	Standards actually cap the highest possible quality an owner could achieve.	10	44%	44%	12%
8	Performance measurement is not beneficial	1	9%	41%	51%
9	Owners need to hire a separate party to represent their needs and to manage the vendor and ensure technical requirements are met.	1	51%	35%	15%
10	The owner should never give their budget to the vendors.	1	27%	33%	41%
11	A manager should feel comfortable minimizing the amount of control and inspection they perform.	10	10%	40%	50%
12	A manager should feel comfortable measuring themselves (in terms of performance).	10	41%	47%	12%
13	The current environment of construction industry is "win-win."	1	12%	70%	18%
14	Low bid is an environment of high competition, low performance, causing change orders, leading to higher prices.	10	81%	16%	4%

FEASIBILITY OF APPROACH

As previously discussed, BV is being successfully applied in an international industry environment by the original implementers, PBSRG; however, it has yet to be sustained in another academic environment, domestically or internationally. As the third and final question of feasibility, the approach to implementation must be

analysed. The approach taken by PBSRG at Arizona State University (ASU) has been described as "out of the box" (Kashiwagi et al., 2008) and requires further explanation.

Historical Barriers

Traditional construction management academic research funding does not have access to owners who are willing to turn over their delivery of services to academic researchers. PBSRG uses the deductive and dominant logic of BV to convince owners to adopt the BV model, and to become partners in the development of the process (Kashiwagi 2011). This type of approach is challenging to undertake given the observed barriers; however, these barriers are not only limited to Italy (Kashiwagi 2011 and Kashiwagi et al., 2008 and Mselle et al., 2009). The main areas of differentiation from other academic research groups and in PBSRG's approach and methodology have been uncovered as (Kashiwagi 2011 and Kashiwagi et al., 2009 and Kashiwagi et al., 2008):

- Application of the model is on active industry projects - PBSRG runs simultaneous theoretical research, prototype testing, and implementation testing, minimizing the time to see results, and having quick access to hypothesis and test results. The BV model has been tested on more than 975 procurements in $4.6 billion in procured services and construction.
- Logic is not pedagogical - PBSRG is using deductive logic (observations), common sense, and dominant information, instead of inductive logic (exploratory work and the heavy dependency/use of industry expert opinion). As needed refinement for dominant improvements are made.
- Results are impactful - PBSRG and the vendors measure the project results of cost, time, the project management/risk management effort, and satisfaction throughout the project, and record all deviations. Documented fewer vendor-caused deviations, increased client satisfaction, and continuing industry demand.

In previous BV implementations, it has been observed that most often academic research is struggling with a structure that can introduce change, and to provide solutions to the construction industry's problems (Kashiwagi et al., 2009). Similarly, research barriers have been observed in the areas of: the university system, resistance to change, and deficient planning (Van Noorden 2010 and Kashiwagi et al., 2008 and Kashiwagi et al., 2009). In the university system, the research drivers are to publish papers, not to test hypotheses, there is low industry involvement overall, and funding is based on this approach (alternative approaches are unsupported). Furthermore, large organizations (professional and academic) are resistant to change when there is no perceived problem or need. Lastly, the environment is reactive and follows industry "trends" and perceived new systems.

Observed Barriers

In order to promote the education of the BV model and to test its feasibility in Italy, over fifteen educational sessions were held and industry groups were approached, educated, and given proposals for the implementation of the BV model in their projects. Despite overall positive feedback, none of the industry groups responded to further communications or expressed desire to collaborate with the research group. In working with the Italian industry, the research group observed barriers in the areas of: operations/administration, lack of perceived benefit by the industry, language, and culture. Under the current operations and administration, research groups have difficulties approaching clients. Secondly, the notion is that the industry has no desire

to collaborate with research groups. Furthermore, at times private companies may not communicate adequately in English and tend to focus on translation differences. Culturally, it is perceived that models originated in America can be seen as only appropriate to American culture. Lastly, research groups have a different approach and mentality than the industry; industry professionals have more project experience.

CONCLUSIONS

The original research questions in the feasibility study can thus be addressed and the recommendations regarding future implementation of BV in Italy are given.

Question 1: Could BV be beneficial to Italian projects?
Yes, the background analysis of the Italian market revealed that the Italian market is experiencing challenges and Italy could benefit from a holistic model that promotes transparency, accountability, and pre-planning. As a current implementer of BV, the Netherlands is the closest comparison as a fellow EU member state.

Question 2: What are the main barriers to BV implementation?
The resource analysis proved that the BV model is not illegal or lacking applicability; rather, a lack of alignment with BV concepts at the organizational and individual levels would be a barrier. The survey uncovered the topics needing education in the future. Therefore, the main barriers to BV implementation are in the education of the model and the degree of sustainability of the implementation approach.

Question 3: What is the most sustainable implementation approach of BV?
The feasibility study regarding the approach uncovered individual and organizational barriers of the implementers (and academic), resistance to change, and deficient planning, presenting imminent challenges for the research group in this academic system. In order to work towards overcoming these challenges, any group seeking to implement BV must completely understand and measure these in the proposed strategic plan prior to implementation.

Recommendations
While BV has proven to be beneficial in international markets, the key to increasing implementation is utilizing the model on projects and documenting the results. In Italy, BV could provide benefits and has the potential to improve performance based upon the feasibility study. Proper strategic and implementation plans should first be devised prior to implementation and follow the subsequent sections.

Strategic Plan
Future collaborators (academic and professional) must have a desire to change the industry and research paradigm within their own means and adopt the concepts of transparency, accountability, and proper pre-planning in their operations. All interested parties must first recognize and map out the barriers and be committed to challenging their own operations. Following is a suggested action plan:

1. Analyze the environment and effects of aforementioned barriers: 1) university's (or organization's) system; 2) change resistance; and 3) difficulty to plan.
2. Create a plan with the research group (or organization) and review with PBSRG and document the areas that need the most attention
    a. Host educational sessions for research group (or organization) and industry
    b. Identify a client with pilot projects for BV utilization
    c. Run a BV project with PBSRG assistance, potential tools: risk assessment plan, value added, interviews, pre-award document, and weekly risk reports
    d. Document the deviations

e. Create a summary or case study
f. Create a plan with interested clients

3. Execute the plan and document the deviations

Implementation Plan

Over the past 17 years, BV testing has followed this progression for implementation (Kashiwagi, 2011):

1. Identify an owner/buyer who wants to increase their value and decrease their risk, cost and transactions on a delivered service.
2. Use the hypothesis of the deductive logic with the goals of minimizing client management/transactions, help the client do more with less, measure vendor performance (and deviations), and identify the source of any deviations.
3. Run a procurement test, using the "latest" BV structure.
4. Document the source of all project deviations.
5. Analyze the test results. Identify problems that could be further minimized.
6. Make the modifications in the BV system, and run another test.

The BV business model can be applied on Italian construction and service industry projects to provide benefits; however, it is dependent on identifying both an academic and an industry group that is able to surmount the challenges and barriers identified in this feasibility study. Additionally, it is suggested that potential implementers follow the list of recommendations, strategic, and implementation plans regarding future implementations of the BV model in Italy. At present, research is being carried out to continue to identify areas of potential implementation in Italy.

ACKNOWLEDGMENTS

With the goals of exploring the application of the BV business model internationally, a lead research assistant with PBSRG at ASU achieved a Fulbright Grant to investigate this opportunity through collaboration with the Department of Management and Production Engineering at the Politecnico di Torino in Turin, Italy, from September 2011 until June 2012.

A NEW APPROACH TO CONSTRUCTION ITEM PRICING

David Cattell[1]

[1]*Institute of Sustainable Development, Bond University, Gold Coast, Queensland, QLD 4229, Australia*

ABSTRACT

The competition for work between contractors is largely determined by lump sum prices for whole projects. However, most project contracts are instead governed by the unit prices for each of the project components. These item prices are more difficult for clients to assess. Translated, this means that contractors have considerable scope within which to decide their prices without effecting their competitiveness and without being noticeable by clients. Research on mathematically optimising these prices started 50 years ago but this has so-far failed to address the risks involved, despite widespread acknowledgement that these risks are considerable. A new component unit pricing (CUP) theory has now been developed that has identified and assessed these risks. This gives contractors prospect by which to decide prices that are in accord with the market – by which they can not only earn more profits but avoid risks as well.

Keywords**: b**idding, operational research, price, risk.

INTRODUCTION

Construction projects are typically competed for by way of project lump sum prices. These bids are easy to compare but they do not provide a basis by which these contracts can be administered. For this purpose, contractors are also typically having to submit sets of prices for each of the constituent items within the project. These will, in turn, add up to their overall project prices. The item prices provide a basis for determining (a) interim payments, (b) valuations for variations, and (c) any escalation compensation that might be offered for inflationary increases in costs. It is, however, very difficult for clients to assess and compare the sets of prices from different contractors (Skitmore and Cattell 2012). This affords contractors a fair amount of scope when pricing items (regardless that the composite project prices are, instead, heavily bound by competitive constraints on account of being so easily compared, at a superficial level).

Contractors can use this scope by which to deliberately price items such that they will enjoy (a) an improved cashflow, (b) more favourable valuations for anticipated variations, and (c) improved escalation pay-outs (if these are provided in the

[1] dcattell@bond.edu.au

 ISBN: 978-1-84219-840-7 .

contract). It is easy to envisage simple cases (such as those initially used by Gates 1967) in which contractors can accomplish any one of these objectives in isolation but more difficult to imagine (1) how the pursuit of any one of these objectives does not detract from the others, and (2) how they might optimise this, especially considering that contracts can comprise thousands of items. Furthermore, these prices are logically having to be governed in some manner and cannot be decided on without some form of constraint. At the extreme, it is obvious that negative prices would, for instance, be ridiculous! Similarly, to have exceptionally high prices on those items that are to be built in the early stages of the project and to price all other items at close to nil would be equally unacceptable.

This complexity should not distract from the importance of this process and the substantial incentive for "getting it right". A test on a hypothetical project (explained in Cattell 2012b) indicates that a contractor could improve their profit by around 150%, without substantially changing their risk. This analysis was done compared to the benchmark comparing a simple scenario of "balanced prices" in which the prices are, instead, decided on the basis of using the same mark-up applied to all of the items' estimated costs.

Some researchers (see, for instance, Arditi and Chotibhong 2009) are of the opinion that contractors are obliged to only submit "balanced bids" and that it is unethical if they do not. Cattell (1987) has, however, argued that there is no such ethical obligation and that it is instead reasonable to expect that contractors should not attempt "excessively abnormal" and "abusive" pricing but that this is not to be confused with "unbalanced" pricing. Contractors with unusual costs might, indeed, have need to unbalance their prices specifically in order so as to make these acceptable (rather than expose the client to their unusual costing aberrations).

Various attempts (starting with Gates 1967 and Stark 1968) have been made to optimise item prices, since Gates (1967) first suggested that this was possible almost 50 years ago, and these have become known as "unbalanced bidding models". These have suffered from some flaws that have caused them not to be used in practice and yet it has often been commented on (Green 1986) that unbalanced bidding has become the norm and is widely practiced, albeit without the benefit of any mathematical optimisation.

A new approach is now being suggested that overcomes the flaws prevalent in the prior models. This suggests a basis for a scientific method of maximising *utility*, taking account of both the pursuit of profits and the risk that these might not be realised.

THE FLAWS IN PRIOR UNBALANCED BIDDING MODELS

A comprehensive assessment of the prior models is provided by Cattell (2007). The greatest flaw in these models has been that they have not adequately taken account of the (substantial) risks involved. They have recognised that there are risks but they have not been defined, let alone quantified. Universally, they adopted only one mechanism to contain risk: imposing upper and lower limits on the prices of each item.

This approach suffers from two flaws. Firstly, none of this research suggests any method by which to decide these pricing limits. This becomes more significant in light of the second flaw: by way of the linear programming (LP) modelling typically

 ISBN: 978-1-84219-840-7 .

being advocated, all of the items barring one, are simply effectively assigned either of these imposed maximum or minimum prices. The models roles, in effect, do not help to identify optimum prices (as one might expect *within* these bounds) so much as rather to simply identify which items to price high and which to price low. These high and low prices play lead roles that are seemingly beyond that which was intended. The use of sophisticated LP modelling simply to split a project's items into two divisions appears inappropriate when there is nothing similar as scientific guidance being advocated by which to decide the pricing limits that play such a significant role.

THE RISKS IN ITEM PRICING

Item pricing has been found to induce three types of risks: the risks of *rejection*, of *reaction* and of *being wrong*.

Risk of rejection

Exceptionally extreme and unreasonable prices can likely be expected to induce criticism from the client, to the extent that this may lead to the client rejecting the contractor's participation overall. There can, for instance, be little doubt that clients would reject the pricing from a contractor in the event that it were so extreme that the contractor only priced one item and no other. If one is working within the scope of more likely scenarios, it is more difficult to predict the client's response but, nevertheless, one can do better than imagine that it is appropriate that there should be pencil-thin boundaries such as the previous style of upper and lower pricing limits. It appears more reasonable to assume that the odds of rejection will be worse as any single price becomes more extreme, without having to draw any single line of limitation.

It has been identified that this risk for any item resembles the 'tea-pot' shape shown in Figure 1. The skew of this curve is explained by way of the risk of low prices, as they get close to $0, being more easily assessed than the risk of high prices. Any single exceptionally low price will highlight to clients that the bid is, overall, an unbalanced one. The client will realise that, corresponding to this low price, other prices will likely be loaded high, even if these are less easy to detect. If a client is sensitive to unbalanced bidding, as suggested by Arditi and Chotibhong (2009) and others, they have as much cause to reject a bid with obviously low prices as they have to reject high prices.

 ISBN: 978-1-84219-840-7 .

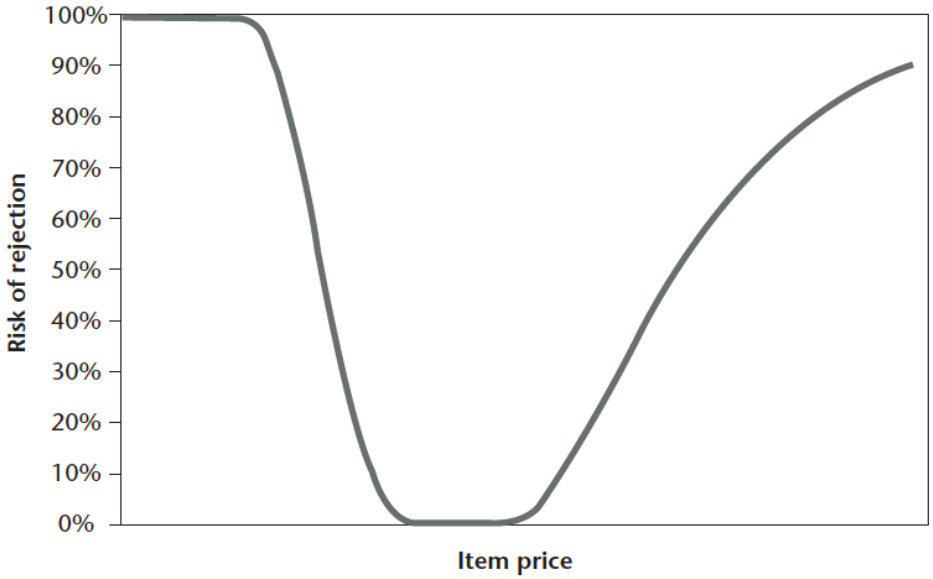

Figure 1 – The risk of rejection for a typical item (Cattell, 2012b)

In terms of quantifying this risk, note that the risk does not amount to the loss of the entire profit that the contractor is hoping to accomplish from this contract. Rather it is accountable to the delay before the contractor will be able to win the next one, and the differential in profits between the two, as well as the cost of having to invest in this additional bidding effort. Notice that if the contractor realises that they have made a mistake with their pricing of a project, especially once they become privy to the prices from other contractors, they might even have incentive to want to induce the client to reject their bid. Figure 2 shows the risk in dollar terms. The overall risk is not additive for all of the constituent items seeing as any one item's extreme price could be judged sufficiently abusive as to trigger an overall rejection. Thus, the overall risk is considered to be equal to the greatest of the risks resulting from each of the items.

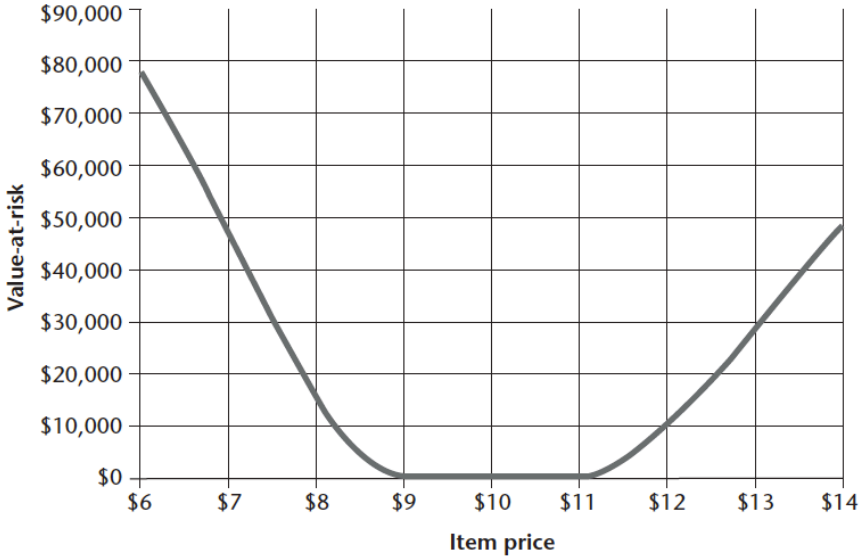

Figure 2 – The risk of rejection for a typical item (Cattell, 2012b).

 ISBN: 978-1-84219-840-7 .

Risk of reaction

Besides risk of an outright rejection, there is also a risk that clients may *react* to a contractor's prices. The client could accept the contractor's prices but then adjust the project accordingly. If, for instance, the contractor has priced a particular finish especially high, and if their prices for an alternative finish are attractively low, the client might take advantage of switching from the expensive finish and substituting it with the cheap one. Contractors are, therefore, taking a risk if their prices appear abnormal – to the extent that the client is able to grasp such situations. From the client's perspective they will only be able to assess prices relative to 'normality' prevalent across the industry, and not relative to any secret knowledge that the contractor has of their own costs and cost estimating methods.

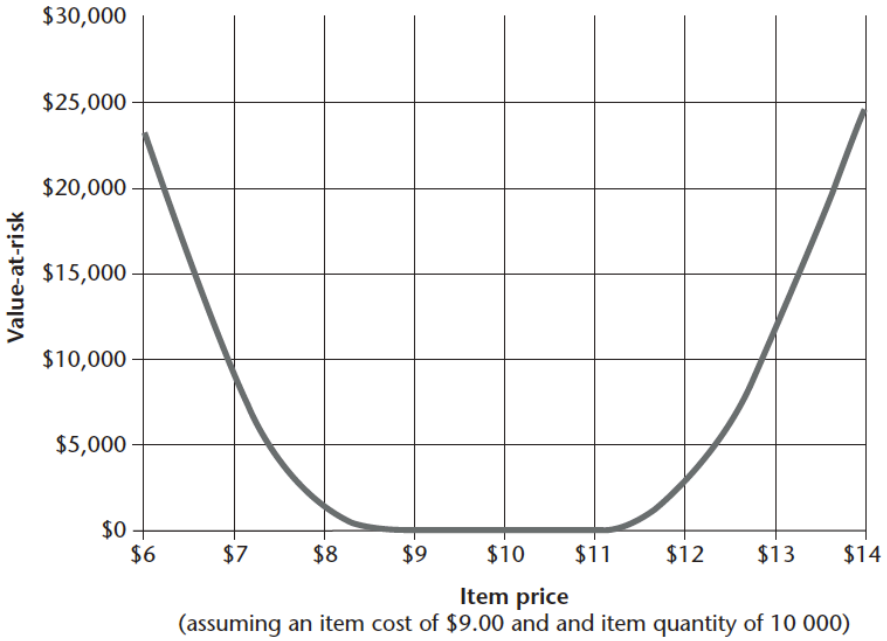

Figure 3 – The risk of reaction for a typical item (Cattell, 2012b)

The risk of reaction amounts to being a risk of erosion of the profits that would otherwise be enjoyed if the client were not to redesign the project.

Risk of being wrong

Cost estimating and item pricing are processes fraught with many unknowns. The contractor is having to decide their prices on the basis of their estimates and assumptions and many of the factors involved will finally be different from that which was anticipated upfront. This uncertainty amounts to being a risk: conceived as a 'risk of being wrong'. In some projects that are inherently of greater risk than others, or in which a contractor has invested less in the process of preparing their prices, the contractor may have great cause to be more conservative with their pricing. If a contractor instead prices an inherently risky project with extreme prices, they will accentuate their risk. If they, for instance, price excavation work extremely high or extremely low and the final quantities land up substantially different from the BQ, the contract will be subject to a more substantial adjustment (either in favour of the contractor or not) than if they had adopted more moderate pricing.

 ISBN: 978-1-84219-840-7 .

Value-at-risk metric

This analysis of risk shows that the risks are of two different forms: the one ('direct' form of risk) being induced by way of item prices, and the other ('indirect' form) not. In both cases though, a more conservative spread of prices will lead to less risk than will more abnormal prices. Such pricing though doesn't promise as much prospect of profits as more extreme pricing which therefore presents a classic economic decision: having to weigh up the merits of ambitiously striving for the hope of more profits or reining this in for reason of concern of the risks involved. If the contractor can be equipped with quantified assessments of their profits and risks across their full spectrum of pricing alternatives, they will be able to decide their item pricing with all the sophistication employed in the mainstream world of financial investments.

These two different forms are not easily additive: the indirectly risk being typically measured in terms of variance, and the direct risk not. However, the Value-at-Risk (VaR) method (see Benninga and Wiener 1998, and Kolman *et al.* 1998) of expressing risk provides a mechanism by which to accomplish common ground. Figure 4 shows how the risk of being wrong can be assessed at any particular price point: showing that there is a 100% chance of the possibility of a small loss and increasingly less chance of greater degrees of loss. With adequate data, similar charts could be established for each possible price. At higher prices, given the inherent uncertainty, the more that they will have at risk. Figure 5 shows how this can be made to translate across a spectrum of prices, given a particular probability.

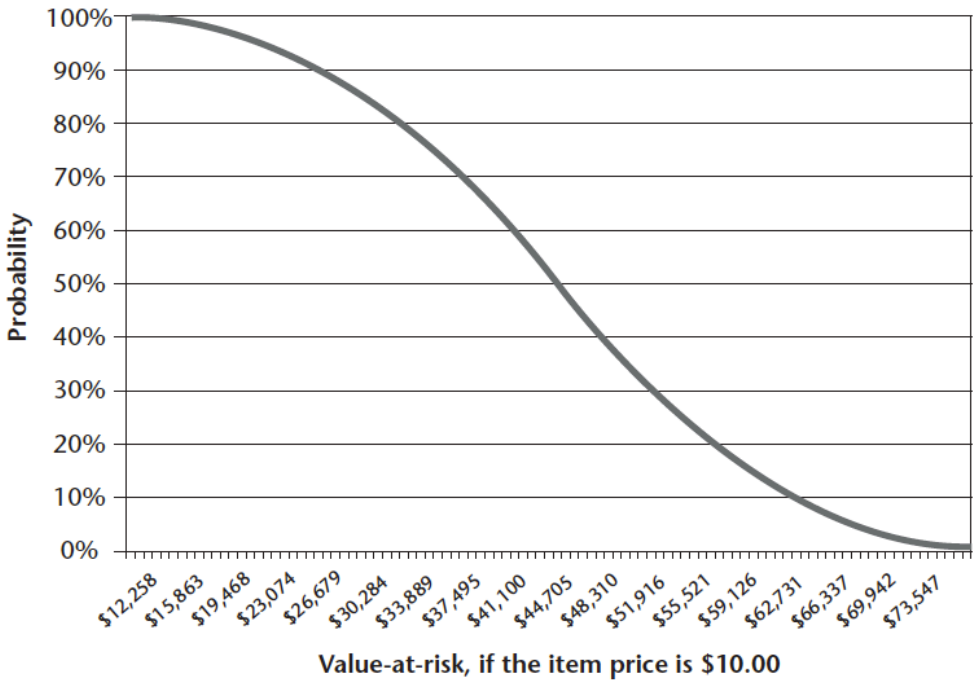

Figure 4 – The risk of being wrong, for an example item, showing that a contractor may be 100% confident of being at risk of making a small loss at a particular price, and increasingly less chance of losing higher amounts (Cattell, 2012b)

 ISBN: 978-1-84219-840-7 .

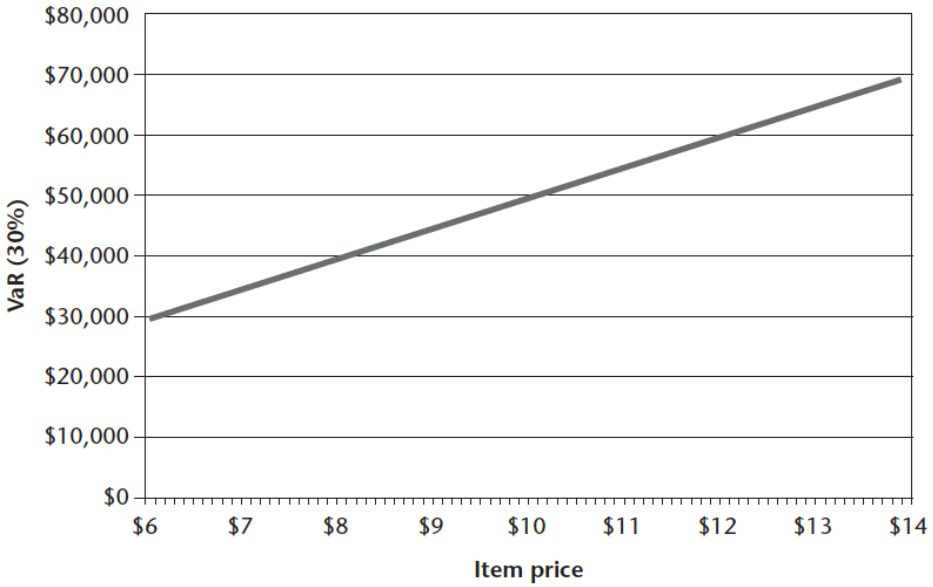

Figure 5 – The risk of being wrong, given a probability, across a spectrum of prices (Cattell, 2012b)

Combined risk

This analysis provides the mechanism by which to determine an overall combined assessment of risk for each item, across their pricing spectrum – see Figure 6 as an example. Furthermore, Component Unit Pricing (CUP) Theory provides the basis of assessing the profit benefits across this same spectrum of choice. Combined, the contractor then has a basis by which they can assess their *utility*, recognising the trade-off between profit and risk according to their personal attitude towards taking on risks.

However, the challenge is made more complex when one considers that these decisions cannot be made on items independently. All of a project's items are integral parts of a combined whole, and any high prices assigned to some items have to be met by low prices being decided for other prices, so that as a whole, the item prices equal the project price.

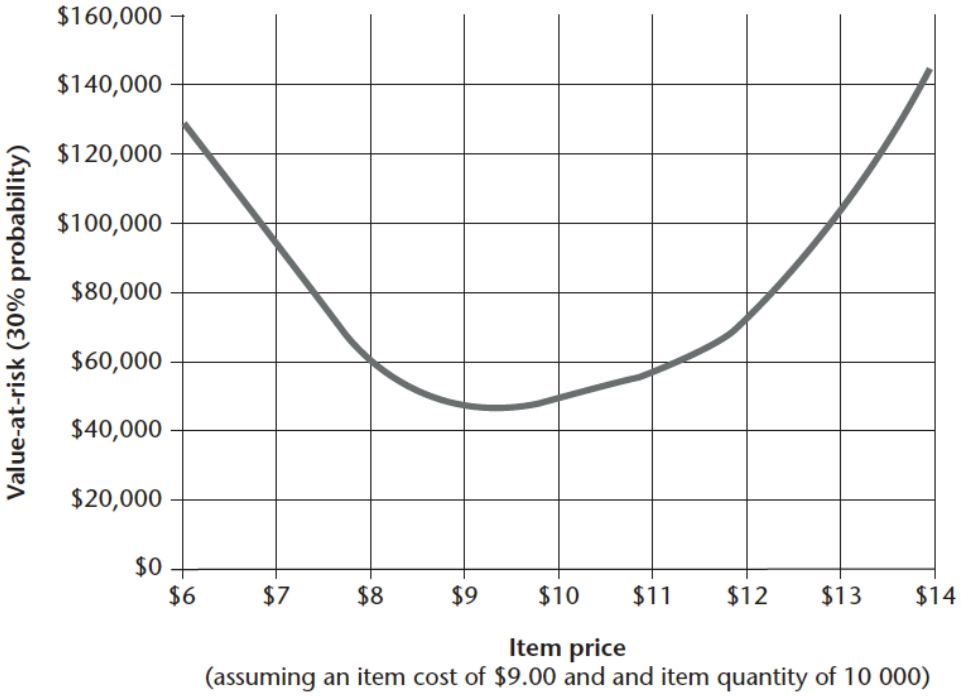

Figure 6 – An example of the combined risks across a spectrum of prices for an item (Cattell, 2012b)

A TEST OF CUP THEORY

A test has been done using hypothetical data for a small project (Cattell, 2012b). It has shown that the contractor's profit from a project could be increased by around 150%, without any appreciable change in risk, relative to a scenario of balanced prices. Interestingly, all the prices identified as being optimal all fall well within the ranges described as being considered normal for that nature of work within the industry. Specifically, the system is designed so as to accomplish pricing that is appreciably normal and not extreme. Furthermore, CUP Theory now provides a scientific basis by which contractors with a great appetite for risk can identify those prices that fall further away from the central norm (whether these are on the high or low end of the spectrum, depending on the nature of the items and what they have to contribute as benefits to the contractor). By contrast to the earlier models, this new theory ensures that the prices don't simply 'stick' to one or other of an extreme upper or lower limit, regardless of all settings.

CONCLUSIONS

Prior research acknowledged that there are considerable risks arising from the prices assigned to each item. Nevertheless, these efforts failed to identify the specific risks involved and hence also failed to incorporate these into the mathematical models that were identified. The only mechanism that was advocated to address risks was to constrain each of the prices within a range that was somehow to be decided. This approach has now been replaced by CUP Theory which identifies and takes account of the risks. This now provides a scientific basis by which to govern prices so as to not only pursue profits but also avoid risks. There is, however, further research and development required to make it practically available.

ADDING PRODUCTION VALUE THROUGH APPLICATION OF VALUE BASED SCHEDULING

Søren Lindhard[1] and Søren Wandahl[2]

ABSTRACT

Customer value is a key goal in the Lean philosophy, essentially only actions that adds value should be conducted. In a transformation view, the basic lean approach is to remove waste, which indirectly increases value (or withstand value lose). Lean Construction acknowledges two different types of value views. Product value, as stated above and value in relation to cooperation in the construction process. Process values are important when it comes to the comfort (physical and mental wellbeing) of the craftsmen cooperating aligned around the same goal of a smooth process and a great end product. By increasing the comfort of the craftsmen their productivity could increase. Furthermore, shared process values decrease the needs of managerial standards, structures, and systems. By means of a questionnaire survey this study investigates the connection between scheduling and the comfort achieved through process values of both engineers and foremen on site. The questionnaire identifies relevant process values, and these are compared to values observed in the scheduling process at three construction cases. The aim is to minimize time usage in the scheduling processes and to increase robustness of the schedule by securing an adherence of the schedule. The results show a lack of focus of the scheduling process' surrounding atmosphere. Process values such as sympathy, kindness, helpfulness, and equality had only minimal attention. In order to foster these "soft" values it was found that hierarchy should be minimized and management should seek towards democratic leadership.

Keywords: Last Planner System, Lean, Scheduling, Values, Waste.

INTRODUCTION

Ohno (1988), one of the fathers to Lean, stated that the total capacity of a production system equals the sum of work and waste. Therefore, in order to increase the work and streamline the production Lean has a partisan focus on removing waste. Lean emphasizes the production as a flow of materials where raw materials are undergoing moving, waiting, inspections, and transformations before it reach the intended shape and function as the final product or construction (Koskela 2000; Koskela 1992). Only transformations add value to the product. All other activities are only expenditures in cost and time and can be regarded as waste. The concept is then to eliminate or

[1] lindhard@m-tech.aau.dk
[2] swa@iha.dk

minimize waste by eliminating the non value-adding activities and streamlining the value-adding activities (Lindhard and Wandhal 2012; Koskela 1992). In order to remove waste you need to know and eliminate the root causes. In Lean theory 7 different sources to waste are identified: 1) Waste of overproduction, 2) Waste of stock on hand,3) Waste of transportation, 4) Waste of making defective products, 5) Waste of processing itself, 6) Waste of movement, and 7)Waste of time on hand.

Lean, which includes Lean Construction, only focuses on the hard and direct observable waste. I relation to Ohne's definition a production system consist of work and waste. Work is often considered to be only the transformation, because it is the output. But as an input, in order to complete the transformation, human production factors are needed. The motivation and skill of the employees are having a huge impact on the output both regarding quality and quantity. Thus humans can affect the capacity of the production system. This is especially the case in construction which is considered a labor intensive industry.

Improved human skills are expanding the capacity of the production system since new knowledge is added. Opposite does improved motivation not ad anything to the existing system. Therefore, improving motivation is an exploitation of capabilities already in the production system and a known approach to minimize waste. Capabilities and utilization is also important in relation to the machines in the productions system. Therefore, the phrase can be generalized to: Waste is not to fully utilize of the capabilities and possibilities in the production system.

As mentioned, Lean's primary focus is on removing waste to maximize the value creation. In fact the production outcome is the same, but value lose is evaded by reduced resource usage. Thus removal of waste does not extend the existing value creation in the production system. Extending the value creation can only be achieved by improving the work to increase the customer satisfaction, cf. Ohne's rule.

Crating value is a fulfillment of the customer demand and requirements. Johnson and Kaplan (1987) defined value this way: "value of any commodity, service, or condition, utilized in production, passed over into the object or product for which the original item was expended and attaches to the result, giving it its value." Creation of value in any production system is achieved by producing what the costumers wants to fulfill the customers' demands and requirements. In construction this value creation has two customers: the next trade and the end costumer (Wandahl 2004a). Value creation is measured in relation to cost which includes the consumption of both time and resources. Moreover, value is determined in relation to achieved benefits and compared to value and cost of substituting and competing products.

Creation of value comes through process, but the values in the process are important for maximizing the human input. Production process values are important when it comes to the comfort and motivation of the individual craftsman on site (Bejder et al. 2008). By increasing comfort and motivation of the craftsmen their dedication and accountability will increase resulting in increased productivity (Singh 1996; Olomolaiye 1988). Accountability is important in the scheduling process where the schedule is founded on commitment which needs to be obeyed. Due to interactions and interdependencies between the subcontractors, the flow of work is dependent on fulfillment of these commitments.

The production process values are a part of the corporate culture which dominates the construction site (Van den Steen 2010). Culture is the social and nominative glue that

holds the, in construction, temporary organization together (Siehl and Martin 1990). The main organization in construction is a joint of smaller organizations from the participating subcontractors. Thus, there is a hierarchy of culture where the individual subcontractor has its own subculture (Hunter and Tan 2006).

Culture is by Triandis (1972) defined as: "an individual's characteristic way of perceiving the man-made parts of one's environment. It involves the perception of rules, norms, roles, and values, is influenced by various levels of culture such as language, gender, race, religion, place of residence, and occupation, and it influences interpersonal behavior." According to Kroeber and Kluckholm (1952), culture is affecting behavior by determining patterned ways of thinking, feeling and reacting. Therefore, since behavior is determined by culture, culture needs to be managed. In construction the overall culture changes since organizations change. Every project consists of its unique composition of organizations and employees which together forms the projects culture. Thus, management of culture is important for ensuring optimal capacity utilization, i.e. optimal output of the production system.

Value Based Scheduling (VBS) is introduced in an attempt to affect behavior through changed culture. The concept is focusing on leadership and the connected process values. The objective is to increase motivation, collaboration, and output by establishing comfort and trust between individual craftsmen. An improved involvement when making commitments in the schedule makes the schedule more realistic. Together with increased accountability and dedication the likelihood for observing the schedule is increased. As mentioned every construction project consists of its own unique culture. Therefore, the values should be determined at project basis to fit the present project. Cultural changes are difficult to accomplish, hence it is important to ensure everyone's support in this change process. It is therefore critical that everyone is consulted and have a voice when the values are determined. This ensures alignment and observance of values from top management to each craftsman, on site.

VBS is a parallel to Value Based Management, where values constitute a supplementary scheduling, planning and management tool (Wandahl 2004b). VBS is a proactive approach to avoid or limit problems related to scheduling. The values form an ethical guideline supporting on site behavior and support and reduce the demands to the existing scheduling system, which at a Lean construction company would be Last Planner System (LPS). VBS increases the reliability of the schedule, because commitments increasingly are kept. Values affect behavior by increasing motivation, dedication and accountability, resulting in an increased probability of schedule observance. Thus the robustness of the schedule is increased.

It is important that the scheduling system supports the determined values. Therefore, the purpose of this research is to determine which values in general are preferred in such a system. Moreover, this research suggests which values a scheduling system is expected to deliver. By fulfilling the identified values and needs the scheduling processes can be improved. Identification of the values is achieved through the following research question:

Which values could be combined with existing scheduling procedures of onsite construction and how can these values support Last Planner System?

 ISBN: 978-1-84219-840-7 .

RESEARCH METHODOLOGY

To investigate which values that are preferred in a scheduling process an electronic survey was conducted. The samples in this survey were A) the members of leanconstruction.dk, comprising 16 contractors representing a large proportion of contractors in Denmark B) former students at the MSc in construction management programme at Aalborg University, who present is employed as contractors. The two samples were chosen because respondents, to a greater extent, were expected to know about and have experiences with Lean and LPS. Usage of LPS is important since it is based on Lean thoughts. This increases the quality of the replies and the validity of the survey. In total 192 persons were included in the survey. The questionnaire was completed by: 14 project managers, 17 construction managers, 16 site managers, and 7 foremen. The respondents represent varying opinions and contribute with different experience to scheduling. This secures an unbiased and valid survey.

The questionnaire process takes its outset in the strategy presented in Akintoye and MacLeod (1997). First, an initial invitation was sent out to every participant and after two weeks a reminder was sent out to those who had not yet completed the survey. In total 51 persons completed the survey resulting in a response rate of 27%. In the questionnaire the respondents were asked to rate a number of values in relation to the importance in the scheduling process. The values in the survey were found by reviewing the values represented at a number of partnering projects.

Additional three construction cases were followed see Table 1. At the construction cases LPS had to be applied. Data collection consisted participation in scheduling meetings and observations to capture the production process values. Onsite observations help capturing the context wherein the scheduling is conducted. Focus was on the atmosphere and values which were characteristic at the meetings.

Tabel 1 Data collection at the three case-studies.

	Case 1	**Case 2**	**Case 3**
Contract form	Turnkey contractor	Turnkey contractor	Prime contractor
Site observations	Once every forthnight in total 5 observations.	1-2 times every forthnight in total 8 observations.	1-3 times every forthnight in total 8 observations
Meetings partispated in	Subcontractor, foremen and safety meetings	Subcontractor and LPS meetings	Subcontractor, foremen, emergency and construction meetings
Observation length	10 weeks	10 weeks	10 weeks
Interviews of site-manager	Unstructured and semi-structured	Unstructured and semi-structured	Unstructured and semi-structured

The research presented is a part of an ongoing research project aiming to disclose new parameters to help and support scheduling in construction. The research is explorative and open minded, and is trying through creativity to avoid the limitations of a narrow-minded and traditional way of thinking.

RESULTS

A questionnaire was designed to capture and rate the importance of different values in relation to scheduling processes and the schedule itself. To capture a complete and

nuanced picture project managers, construction managers, site-managers and foremen has been included in the survey. The results from the questionnaire are afterwards compared with case observations from 3 construction sites. Focus has been on how and whether or not the values are supported, encourage, and fostered in LPS.

In the questionnaire the respondents were asked to rate the importance of certain values and to which extend they found it important that the given values would be supported by the scheduling process. The results, which are presented in Table 2, shows a tendency in the construction industry to rate the "hard" values such as responsibility and collaboration higher than the "soft" values such as helpfulness, kindness, and sympathy.

Table 2 "If scheduling should be combined with values to which extend do you think the schedule should encourage [Value]?" When calculating the weighted average: to a very high degree was valued 1000, a high degree 100, some degree 10, lesser degree 1, and not at all 0.

[Value]	**Respondents**	**Weighted average**
Responsibility		643
Respect		534
Cooperation (Willing to share)		530
Honesty		518
Trust		514
Equality		392
Helpfulness		255
Kindness		226
Sympathy		199
Total (N=)	51	

Responsibility turns out to be the highest rated value. Thus it is important that the involved contractors' respect and obey the mutual agreements and, as best as one can, seek to observe the commitments. Therefore, responsibility is a key issue in LPS in the search for increased robustness. Responsibility is together with trust the only values LPS directly seek to foster. In LPS trust lays the foundation to collaboration.

In LPS, responsibility is increased by involving foremen in the Phase scheduling. Participation and joint-responsibility increases the awareness of subcontractors regarding the importance of observing the schedule. Moreover, responsibility and awareness are fostered by the implemented PPC calculation. Basically, PPC is a measure illustrating the percentage of kept commitments, where also trust and honesty comes to a test in relation to the likelihood of commitments being obeyed. Furthermore, joint-responsibility in the scheduling and sequencing does unite the parties and encourages collaboration.

LPS puts only little attention to the atmosphere wherein the scheduling processes proceeds and to the comfort of the individual craftsmen. This was characteristic at the observed cases where no focus was on kindness, helpfulness, sympathy, equality, or respect. It is important to stress that the "soft" values increase comfort. It was therefore, no surprise that one of the three sites was dominated by a harsh tone. This rough behavior was promoted by the site-manager who had a very brutish appearance. Moreover, he used his hierarchical advantage to force through his own agenda and

opinions. His leadership did not at all seek towards equality and did not encourage collaboration, honesty, sympathy, etc. Hierarchy of power was observed at all three construction sites. But in the other two cases the hierarchy was not as direct visible and not used as a management tool.

DISCUSSION

Both the questionnaire and the studies show that scheduling in today's construction only has minimal focus on the values which foster comfort to the individual employee at site, and hence frames an effective working climate. Management should put more effort into ensuring this comfort because it is the breeding ground for motivation and mutual trust. All too often construction sites are plagued by internal competition among the participating trades. In the worst cases this leads the trades to a state of war where the only objective is to maximize own profit, and to sub-optimize in all aspects. Therefore, Lean could be improved by focusing not only on transformations but also at the leadership which guide and support the transformation process to increase comfort and motivations of project participants. The result will be increased efficiency and productivity as well as a more robust schedule.

Production process values should be identified to support the existing schedule system. Values need to be mutual developed and agreed. This will ensure all subcontractors commitment for observance. Common goals and values lay the foundation for the culture at site. It unites and glues the temporary organization together and makes them act as they were one company, cf. Siehl and Martin (1990). Additional long-term cooperation through partnering or joint ventures could form the setting for a united culture. This will improve the scheduling and the encouragement for collaboration will increase. The willingness to share resources to increase utilization and find common solutions will also be expected to rise.

Finally, it is important to minimize hierarchy of power in the scheduling process. Lean should seek towards a flat organizational structure. Here, it is important that all participants should be involved and have an influence in the development of the schedule. This increases the quality of the schedule (Ballard and Howell 1994). Moreover, it increases the motivation by fostering equality, sympathy, and mutual respect.

Construction sites are often dominated by autocratic leadership which, according to Cassel (2008), creates *"ego-centered"* individuals where competition and power drives the motivation. Mutual competition at construction sites is evident and composes a significant problem in today's construction. Mutual competition was observed multiple times during the case studies, and hindered collaboration. Thus is there a need to change this style of leadership. Construction sites should seek to be managed through democratic leadership. According to Cassel (2008) individuals under democratic leadership tend to be social- and group-centered. Moreover the extreme emphasis placed on competition is replaced by courtesy, honesty, and cooperation (Cassel 2008).

FUTURE RESEACH

This research is an initial part of an on-going research that emphasises the human aspect of construction production scheduling. Here, VBS is intended as a support to LPS to increase robustness of the schedule by increased motivation and dedication to the commitments. Additional further research is needed to support the research and to

form guidelines for selection and observance of values and how they can be supported by leadership style. Among others this involves pilot projects to test the theory.

CONCLUSION

Lean does not focus on the importance of humans in the production system and ignores their influence on capacity and quality. Humans do together with machinery and equipment compose the production system. Improving motivation is a utilization of the existing capabilities in the system. In Lean, there is no direct focus on utilization. Here, not fully utilization of the capabilities and possibilities in the production system should be regarded as the 8th source to waste.

If utilization is regarded as waste unnecessary waste could be removed if the motivation and comfort at the employees on site is improved. This can be achieved by focusing on the production process values. Moreover, values form an ethical guideline which influences culture and behavior. By fostering dedication and responsibility the likelihood for observing the commitment in the schedule is increased.

The atmosphere wherein the scheduling process proceeds is important to the comfort of the individual participant. Management should increase their effort of ensuring this comfort because it is the breeding ground for motivation and mutual trust. Therefore, leadership is important. Site management should seek towards democratic leadership because it encourages courtesy, honesty, and cooperation which are key elements in an attempt to improve the current scheduling system. In general Lean should seek towards minimal hierarchy because involvement and influence improves the quality of the schedule and it fosters equality, sympathy, and respect.

ABSTRACT

A roofing materials manufacturing company can evaluate performance of representatives, products and contractors by utilizing Arizona State University's Performance Based Studies Research Group, and their PIPS program,. Service life of the systems can be tracked and customer satisfaction measured. Facilities purchasing a new roof system, can benefit from the information gathered as a guide in making second, value based decisions. Creating a historical, concise and accurate documentation of roofing systems is a benefit to all involved. The procurement process, installation and longevity of the roofing systems can be tracked and graded.

Keywords: performance, procurement, purchasing, roof, value

INTRODUCTION

The task of selecting a roof, roofing products manufacturer and the contractor proves to be one of the most important, and daunting tasks, facing a facilities manager or architect. Aside from the aesthetic and architectural aspects, the decisions are numerous. The considerations are cost, product performance, warranty, professional installation, and project monitoring. This purpose of this paper is to examine the importance of performance information in the delivery of roofing needs in the built environment.

For the customer that is in charge of purchasing a roof, information and the experience of others can be invaluable. Sometimes the case is that the roofing decision maker has no prior experience in roof procurement. They lack information

[1] lgreenfeld@tremcoinc.com
[2] dgajjar@exchange.asu.edu
[3] Dean.Kashiwagi@asu.edu
[4] Kenneth.Sullivan@asu.edu

necessary about which is the most reputable company, and the best performing contractors. Armed with the understanding of what peers experience can reassure them that their decision is the best that can be made.

Selecting a roof system involves the consideration of numerous factors, including quality, warranty, service, responsiveness and, the biggest one, price. The process is somewhat overwhelming. Their final decision needs to take all the variables into consideration. When presenting to their superiors, the customer needs to have the background information to justify the choice.

Researchers and educators from the Performance Based Studies Research Group, at Arizona State University, administer a procurement process. Their Performance Information Procurement System, or PIPS, provides the research, survey administration and data analysis needed to evaluate a manufacturer or contractor. It gives clients information on which to base their decisions and gives them a solid performance rating of manufacturers and contractors. Their studies enable the executive to make decisions as to reliability of companies and the value they will receive.

As stated on ASU website, "best value procurement system provides an answer to measure output, and minimize risk." (www.pbsrg.com)

The Consideration of Price

Price can be defined as value, or worth, of a product or service. Too many purchasers rely solely on price. In many purchases, value can be sacrificed in the name of price. Be it a large or small roofing budget, the purchaser should expect value for the money spent. Just as the highest price does not guarantee higher value, lower prices do not mean financial savings. The highest price can be an inflated amount to achieve a higher profit margin for the supplying company. The lowest price most often means that there is a lower initial cost but the maintenance, lost time, property damage and delays can add dramatically to the low cost, resulting in an inversion of value.

Hiring a reputable roofing professional gives the buyer an advantage. The best professionals will gather information pertinent to the project. They will determine the needs of the customer as to the roof system usage. For example, the roofing expert can determine, What is the roof protecting? What are their energy savings priorities? What is the effect of the weather/climate in that geographical location? What roof mounted equipment is to be installed? Will the use of the roof be out of the ordinary (such as helipads, heavy equipment placement, venting of grease or chemical vapors)?

The Consideration of Warranties

"Today's commercial roof buyer usually relies on a low price and a warranty to procure their roof purchase" (Fricklas, 1995). These two factors are why roofing is the black eye of the construction trade. The client does not realize that the manufacturer's attorney has written the warranty to protect the manufacturer, not the customer. By accepting their warranty, they give up better protection that they would get through the Uniform Commercial Code (UCC).

The number of lawsuits involving low slope roof systems equals or exceeds the total number of lawsuits filed over all other building systems combined (The Manual Of Low-Slope Roof Systems - (Griffin & Fricklas, 1982). Roofs were the single factor most commonly involved in architects' claims. (D.P.I.C.).

According to the National Roofing Contractors Association (NRCA), "roofing consumers, with the assistance of roofing professionals, should focus their purchase decisions primarily on objective and comparative analysis of proven roof system options that best serve their specific roofing requirements, and not on warranty time frames."

The best measure with which to judge the worthiness of a service provider is to examine their past performance. In order to make an excellent choice in the roofing partnership, it needs to be verified that the servicing company delivers the services promised. The best way to resolve this is by an examination of the company's past projects. History can be an excellent predictor of the future and PBSRG's "PIPS" program can provide this information.

The concerns and key issues are entered and scored in the A.S.U. PBSRG Customer Service Satisfaction Survey. The results show the history and rating of the manufacturer and contractor. The data is confirmed, recorded and analyzed by educational professionals and researchers. This combination of personal experience and accredited certification bodies reinforce the business decision.

Performance Information Collection Tools

Surveys are a common tool in today's business environment. Consumers have begun seeing the advantage of having reviews from their peers on which to base their decisions. It aids them when buying products and services. In years past, consumers relied on publication such as Consumer Reports, The Better Business Bureau, or the experiences of friends and neighbors. Most online retail stores ask customers to fill out a survey form regarding the product that they have purchased. The grades and comments are then available on-line to consumers wanting to purchase these items. It aids in the decision making process by addressing an individual's needs and features desired in a product. The internet furnishes purchasers with reviews by their peers, on a specific product. People are accustomed to availing themselves of this valuable tool. Today's buyers then have comprehensive value expectations and can make informed decisions based on all of the information supplied to them by other people like themselves. They can compare cost, value and service based on real experiences. This demonstrates the confidence that consumers have come to place in the opinions of others. This demonstrates the strength of information used to determine product value.

The Customer Satisfaction Survey is a measurement tool designed to provide an assessment of performance. It strips off marketing while asking 5 questions that are rated on a 1 - 10 scale, and 4 questions that are yes/no. The purpose of this process is to determine the performance of roofing systems and contractors.

Surveys are only as reliable as the agency administering them. The interviewer must be educated and well trained. The information gathered needs to be properly

compiled in order to be of the most value. With the resources and expertise behind ASU's construction division and research group, it makes them especially qualified to provide a comprehensive, realistic and viable report. The beneficiaries of these reports can experience a high level of trust with this prestigious university conducting the nonbiased report.

The data collected from the surveys benefit the consumer. It also benefits the manufacturing company and the contractors. The use of ASU's Performance Based Procurement Model can direct a company's attention to areas in need of improvement. When used nationwide, this program can evaluate the performance by area, manufacturer's representative, or contractor. This allows the company to analyze, and develop a strategy for improvement. A survey will expose the cause of problems in specific geographical areas. It identifies the weak component whether it is the contractor, the rep or a combination. Problems and concerns can be narrowed in on, and measures can be taken correct deficiencies in performance of Company, reps, products and contractors. This can amount to enormous financial savings as the company can focus on problems such as call backs for leaks, rework and warranty claims. The biggest loss is when roofing manufacturers do not perform or respond, and lose a customer.

Case Study – Tremco Inc.

Tremco Inc., established in 1928, specializes in the manufacture and sales of roofing materials and related services. The company participates in the ASU Performance Based Procurement Program and benefits from the surveys.

How Is It Administered?

On a monthly basis, Tremco's Warranty Department provides a nationwide list of completed roof projects to ASU PBSRG with all pertinent contact information. Two demographic groups are used. One group is comprised of recent roof completions; the other group is older installations. The list assigned to undergraduate students who work for PBSRG. The client is contacted, results are tabulated, and a report made available to Tremco.

What Do The Measurements Mean?

The questionnaire focuses on measuring performance (example in Figure 1). Customer survey results are more significant with historical data rather than with only recent installations. A newly installed roof that is free of leaks could be fairly predictable. However, roof systems that are 14-22 years old, and performing leak-free is more impressive in the arena of value.

The customer rating system is based on a 1 to 10 scale, with 10 being the highest. There are 5 questions that require this numerical rating. There are four questions that are yes/no.

Customer Survey Responses

 ISBN: 978-1-84219-840-7 .

Based on 90 responses, totalling almost 3.5 million square feet of roof area, Larry Greenfeld, Tremco Sales Rep in the Phoenix, Arizona area, received the following ratings:

Table 1: Phoenix-area Roofing Performance

Criteria	Rating
Contractor's Performance	
Quality of workmanship	9.4
Professionalism	9.5
Level of honesty	9.8
Response time to emergencies	9.1
Overall customer satisfaction	9.3
Tremco's Overall Performance	
Ability to resolve issues	9.8
Responsiveness	9.8
Ability to coordinate with facility personnel	9.7
Overall customer satisfaction	9.7
Overall Roof Performance	
Customers that would purchase again	99%
Roofs that do not currently leak	99%
Oldest roof surveyed	22 years
Average age of roof	14 years
Largest roof area	260,000 SF
Average roof area	38,570 SF
Total roof areas surveyed	3,471,321 SF
Number of roofing surveys returned	90

Using The Survey As A Sales Tool

The most difficult part of selling a roof system is that the customer cannot see, taste, hear or hold the end product. The raw products do not give them the vision of how well their system will perform. They are in essence, buying "blue sky", and trust that they put in sales representative, the manufacturer and the contractor. Tremco only uses approved contractors that have earned the privilege through their years in the business & financial stability. The survey and their results serve to reassure the customer that they will be getting the quality and value that they anticipate and deserve. The strength and creditability of the results lies within the administration by an independent studies group that does not stand to gain financially by the outcome of the surveys. Administering the program are researchers and educators in ASU's Del E. Webb School of Construction Program, in the Performance Based Studies Research Group. The scores provided by such a prestigious university validates the buyer's decision, reassuring them of the value that they will receive. The survey results are an extraordinarily powerful tool to utilize when attempting to assure a customer to trust Tremco and their products. A presentation to facility personnel begins with a summary of performance results as collected by ASU. Clients are impressed with the excellent scores, and are more open to believing that they too will receive service and value. From this point on they are more convinced that what the manufacturer's rep tells them is factual, and not an empty sales pitch. Every Tremco representative should be availing themselves of this convincing data. The positive grades make their job easier when it comes to selling Tremco's service and products.

(Sales Group Description)

(Sales District)

The PBSRG, at Arizona State University, collects and documents past performance information on contractors and system manufacturers. Tremco is participating in a process identifying the performance of their roofing systems. You have been identified as a client for whom they have previously performed work. We would greatly appreciate your time in completing this survey.

Rate each of the criteria on a scale of 1 to 10, with 10 representing the best (i.e. extremely satisfied) in a particular area and 1 representing the worst, or Y or N, with Y representing Yes and N representing No. Please rate each of the criteria to the best of your knowledge. If you do not have sufficient knowledge of past performance in a particular area, please leave it blank. This is a university survey and your responses will remain confidential.

Figure 1. Performance Survey

CONCLUSIONS

The information provided by PBSRG provides an objective and viable tool for the consumer to choose a quality product and contractor without the distractions of marketing, promises, or a salesman's hype. The impact of this information is that it provides a non-proprietary conclusion that directs the decision maker to a high performance choice.

The surveys used nationally will provide information on who are the highest performers. The results of the study will publicly expose those geographic areas where contractors' installations were defective; it will also expose where manufactures have not met customer expectations.

The results provided by PBSRG help to minimize the risk in selecting a roof system. The fact that such information is available for the owner can reassure them that they are making the right decision. Manufacturers benefit from the information that they receive. It enables them to determine which areas are highest and which are lowest in areas of customer representatives, product, services and support service. With history, durability and life span of the roofing systems installed, value is factually charted. PBSRG is a benefit to consumers, manufacturers and contractors.

ABSTRACT

Cost management is a major discipline in delivering construction projects of different sizes and complexity. In existing cost management systems information is usually produced too late, and is often too aggregated and distorted for use in project management. A review of existing literature suggests that the main problems for the poor performance of traditional cost systems are related to flaws in estimating and cost control processes, inadequate information modelling, and more significantly, the lack of integration of cost management across the whole project. In addition, problem of measurements provided by traditional cost systems not sufficiently linked to the goals and objectives set for project. Traditional cost control processes are also criticized because they simply identify variances by monitoring actual performance against cost estimates. To address these inherent weaknesses in the current practice of cost management, a framework for an integrated system has been proposed which aims to cover the gaps of traditional methodology by integrating the stages in projects' whole life cycle. The current paper outlines the integration methodology that has been adopted in the proposed system. It covers the project stages from inception to operation stage. An alpha version of an applied model derived from the proposed integrated system is presented as a basis for future research.

Keywords: cost control, cost estimation, cost management, project delivery, project management.

INTRODUCTION

Existing traditional cost management systems are mostly based on the same principles conducted ages ago. Cost information is usually produced too late, and it is too aggregated and too distorted to be relevant for project management. (Kern & Formoso 2004). An accurate estimation of construction cost is crucial in construction projects for budgeting, planning, and monitoring for compliance with the client's available

[1] T.Theodorakopoulos@lboro.ac.uk
[2] F.T.Edum-fotwe@lboro.ac.uk
[3] christine.pasquire@ntu.ac.uk

budget, time and work outstanding. In cost estimation, the experience of the estimator and the project information are significant factors. Therefore, parametric cost estimation models are very useful in the early stage of a project's life cycle, when little information is known about the project's scope. Bottom up estimation technique provides total cost by preparing individual estimates based on the Work Breakdown Structure (WBS) of the project. Today is the most found estimation technique applied in projects because of high level of accuracy. Main disadvantage is the effort which increased together with levels and details in WBS analysis. (Rupen 2009)

As described various cost estimation methods are used today. These are considered as traditional estimation methods and include parametric, analogy and bottom up methods. When choosing a methodology the company or the manager may always consider that cost estimating is a forecast, a projection of future costs based on a logical extrapolation of available historical data. The method or the type of cost estimating method is used today depends on adequacy of project definition, level of detail required, available data and time constraints. (Long 2000)

Identifications of Drawbacks and Limitations

Implementation problems with cost estimation may also include that very often cost estimates are no longer reliable. The failings of the traditional cost management systems have three important consequences. Firstly, such systems cannot provide accurate project cost. Costs are distributed to project in a simplistic and arbitrary way that usually does not represent the real demand of the project itself. Secondly, they fail to stimulate decisions that can affect the overall project result. Finally, the cost management information provided by traditional systems is of little help to managers in their effort to improve project performance.

A review of existing literature clearly indicates that the main problems for the poor performance of traditional cost management systems are related to flaws in estimating and cost control processes, inadequate information modeling, and the lack of integration of cost management. In addition, there is the fact that measurements finally provided by traditional cost management systems are not linked to the goals and objectives set for each project. Ostrenga (1997) argue that cost estimates are not reliable due to oversimplifications made when costs are attributed to projects. By contrast, traditional cost control processes are also criticized because they simply identify variances by monitoring actual performance against cost estimates. Cost projection is usually not taken into consideration. (Kern & Formoso 2004)

The proposed integrated cost management system together with model development application which is investigated in following sections provides a proactive means for project control and seeks to make cost a driver for design, thereby reducing waste and increasing value. Under this new approach, estimation stage and Control stage are integrated and share the same goal of maximizing the performance and the value of the project.

Cost Management Process

The literature review regarding traditional cost management approaches highlights the need to define the process approach to managing beneficially the projects' cost. Horngren et al (1990) regards a costs management system is regarded as a framework for project cost information. Those systems consist of a set of principles, methods and tools whose main objectives are to estimate costs and to generate information in order

to support different managerial decisions during the distinct phases of project. Cost management systems must be dynamic, proactive and able to support different decision making processes, as well as to protect the business from the harmful effects of uncertainty. According to Kim (2002), particularly in the construction industry, cost management systems must include the processes required to ensure that the project is completed within the approved budget. These processes include integration between cost estimating, cost control and cost projection to meet the project targets. The integration system proposed is a complete managerial process, which aims to generate information to support decision making and to stimulate cost reduction, value improvement and continuous improvement in the organization. Cost management systems are understood as being composed of two main processes the cost estimating process and cost control process under an integrated environment (Kern et al 2004)

Cost Estimation Process

The objective of a cost estimating process is to estimate the cost of projects. This requires a thorough understanding of the design, contracts, procurements and construction in order to properly model the sequences and manage the resources of the estimation process. In construction, the cost estimating process usually starts by producing a budget, normally at the very early stages of the project. It is a very important cost document throughout the project's life cycle and is often part of the project main contract. This initial estimate also serves as a reference for cost planning and control. As project cost estimating is a very complex task due to the inherent uncertainty and variability of construction, the cost control process must provide feedback on the cost estimating process in order to improve the quality of information available in the cost database that will be used for other projects in the future.

Cost Planning and Cost Control Process

After costs have been estimated, the financial performance must be planned and controlled during the planning and procuring stage by means of a cycle composed by two sub-processes, cost planning and cost control. Cost planning involves refining the initial cost estimate and generating a project cash flow, based on additional information that is generated along the project, such as schedule of payments for the main material suppliers and subcontractors, which should be based on production plans. This sub-process may support decision making in an efficient way, so as to increase likelihood of achieving project plans and meet project's objectives.
In addition to cost estimating, the process relies heavily on feedback from the cost control process. Plans have to be changed whenever necessary and situations that need special attention must be highlighted. The aim of cost control sub-process is to monitor actual cost performance and identify improvement opportunities, which must be dealt by corrective actions. It should not be limited to comparing current and estimated performance but also focused on the value generation.

Cost Management processes described are used in the project delivery stages from inception to the use stage. Their integration process that this study analyzes will provide a complete integration cost management system with emphasis in the links of these processes and the feedbacks from one process to the other.
Table 1 provides an overview of the project cost management processes and their links integrated in one single system operating as a whole process.

Table 1: Proposed Project Cost Management process and integration linkages

Proposed Integrated Cost Management System and Applied Model-Alpha Version

It is important that the method used to develop the project budget is precise enough to provide a basis for controlling and monitoring the desired building throughout the detailed design process. A good budget should be supported by established design parameters and quality levels and then priced on a conceptual basis in enough detail to allow the control process to be effective. (Theodorakopoulos 2009). Since the integration has been applied in the proposed system an applied model has been developed which uses the proposed integrated system and its components. The time process of developing a prototype cost management model has been previously described and analyzed in Figure 1. The alpha version of the prototype model is the second step in the time process of the completion of integrated system. The IS development which is currently analysed provides all the necessary tools to parameterize the model into many project categories according to their needs and meeting their project targets

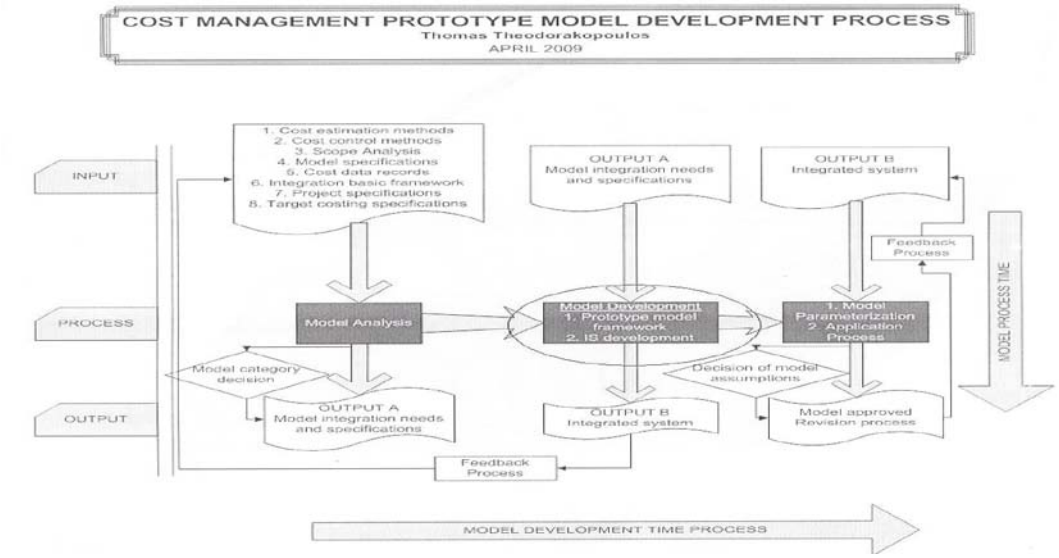

Figure 1: Model Development Time Process Step 2

Model Development Analysis

This analysis uses a generic algorithm which calculates the total project cost according to the cost estimation method chosen and the various project features. This project example describes an activity which is measurable in terms of cost (Theodorakopoulos 2009). The applied model consists of two main components, the budgeting cost database and the actual cost database, both presenting in Figure 2 and 3 accordingly. Both planning and control databases follow the same WBS structure in various levels in a unique ID coding system allowing full integration process between budgeting and control stage.

Figure 2 shows an example extracted from budgeting cost database referred to the budgeting of a bridge construction in phases. Participation weight factors are used in budgeting process depending on the nature of the structure. Hence is succeeded to gain a complete budget for all project activities.

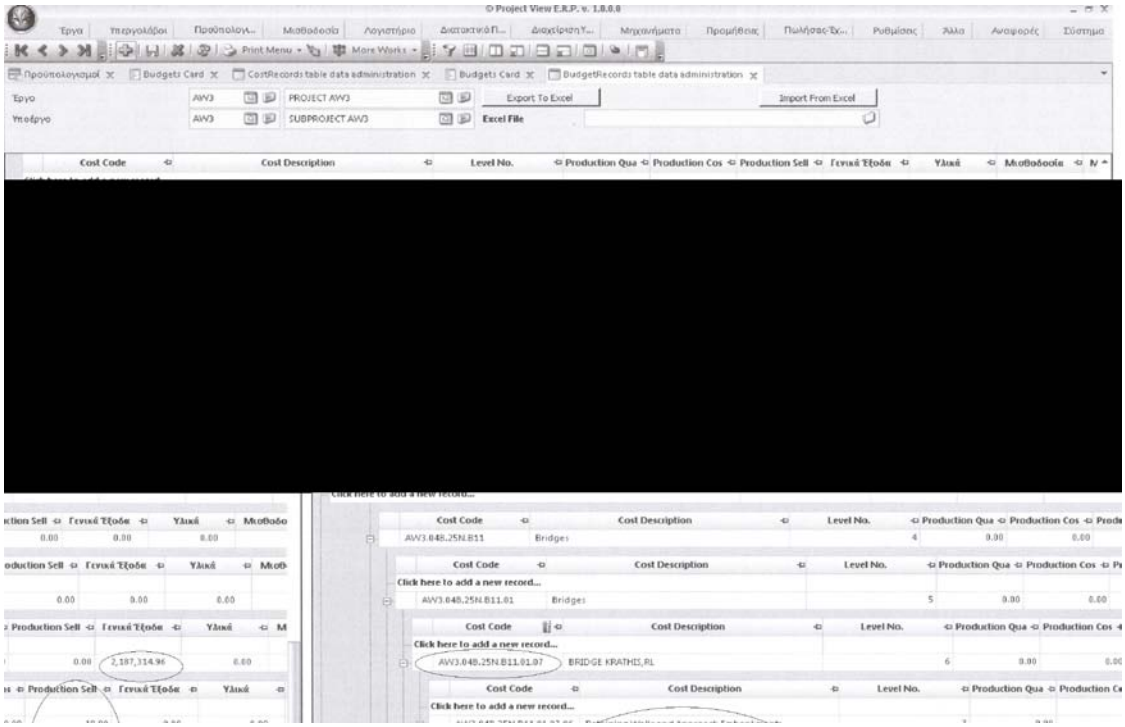

Figure 2: Budgeting WBS environment -Bridge Construction Budgeting Process

Following the procedure of integration of both budgeting and control stage, the actual cost database must be fill in throughout the project construction period as showing in Figure 3. In this database is clearly defined the identical WBS taken from budgeting procedure but filled in with actual cost information derived from the construction site. This actual cost is distributed in the five basic cost categories such as personnel, plant, materials, subcontractors and general expenses. All cost information is imported to the database by using simple excel files from project diary without the risk of operators' errors. Therefore the actual cost database provides a clear picture of the cost occurred in any level of the project.

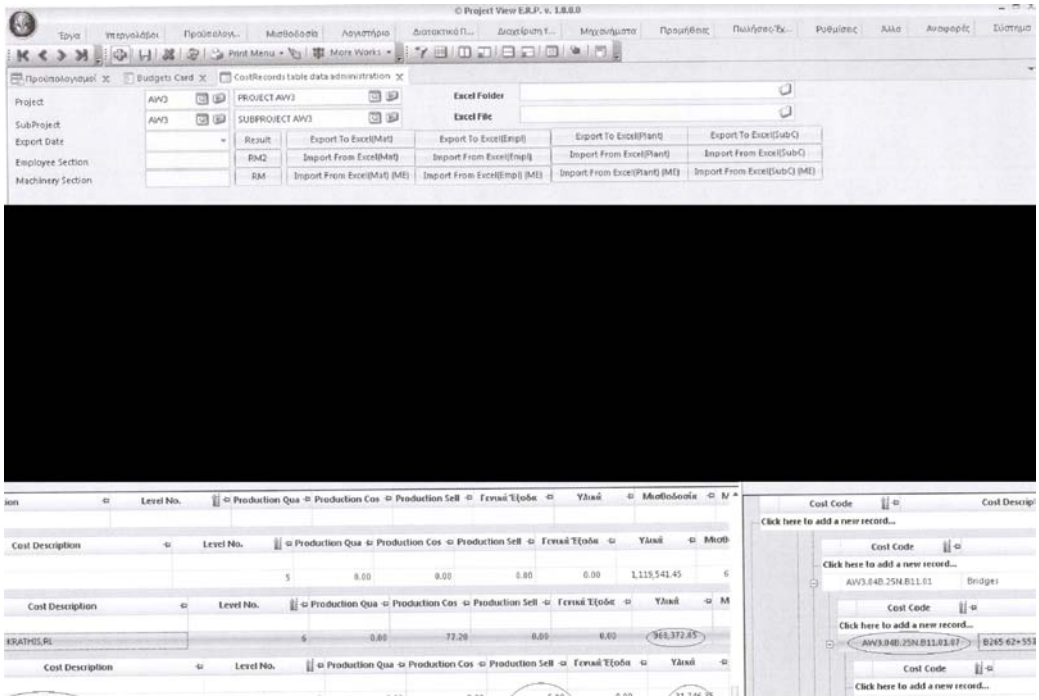

Figure 3: Actual Cost WBS environment-Bridge Construction Control Process

Since actual cost information is being imported to the system, the applied model is able now to calculate valuable reports supporting any decision making or actions to put project back on track.

IS application model data information is used to provide simple and reliable reports through a second analysis which has been described as Earned Value Analysis (EVA). EVA is a project control technique which integrates cost, schedule and technical performance. It proves the earn value of a completed work and compares it with actual cost and planned cost to determine the project performance and forecast its future trends. (Khamidi 2011). EVA provides consistent, numerical indicators with which projects can be evaluated and compared (Theodorakopoulos 2009). The EV analysis is an integrated remote monitoring technique for complex interaction of the time and cost parameters to provide the performance measurements of a whole project. It is an effective and useful tool assured that follows the integration analysis of budgeting and actual cost described previously.
Figures 4 & 5 are reports which extracted from the prototype integrated cost model, giving information. A real bridge construction has been chosen as an example to prepare these reports. Figure 4 presents all information regarding a bridge construction in process. By using the basic three variables, Budget Cost of Work Scheduled (BCWS), Budget Cost of Work Performed (BCWP) and Actual Cost of Work Performed (ACWP) it calculates the Schedule Variance (SV) and the Cost Variance (CV) and schedule and cost indices of this specific structure. EV analysis which is presenting in current report, showing itself as an objective and valuable tool to accurately compute cost Estimate At Completion (EAC) is the conventional Earned Value Management methodology with associated Cost Performance Index (CPI) and Schedule Performance Index (SPI). (Narbaev & Marco 2011)

CONCLUSIONS

This study is the implementation stage of a complete integrated cost management system development in a project delivery. A successful alpha version of an applied cost management model has been developed. Integration process between planning and control stages, through the IS model, is a helpful tool to derive valuable reports to the project managers and directors during the construction period, hence correction decisions may put the project back on track. The model will be tested in more

ongoing various projects and the results will be compared and used to prepare the final version of the integrated cost management system. The application model aims to maximize the performance of the proposed integrated system and used also as a feedback for further corrections. The integration process will be expanded in more components and more project factors by keeping WBS as a dominant factor of transferring information from planning process to control process.

ABSTRACT

Maintenance of buildings is dependent on budgetary fund allocations. Past studies have revealed that budgeting for maintenance of buildings relies heavily on historical data, is not guided by sound policies or strategies or adequate foresight. For university campuses with varieties of buildings, this may imply consequential chronic dysfunctions, public health hazard, negative impact on brand development and higher operational costs. Despite the underlying importance, few studies have been undertaken in South Africa to gain deeper understanding on this issue. Using an exploratory case approach, a study was designed focussing on processes, policies and dynamics in budget development for maintenance of university buildings. The study investigated two universities in Johannesburg. A combination of documentary review and in-depth interviews was used to gather findings which were then thematically analysed. Documents used were mainly archival from the universities in focus. Six in-depth interviews were conducted. The study revealed that lack of proper policy framework to guide maintenance budgeting greatly hampered the effectiveness of the generated budgets. In addition cross-departmental rivalries and tussles often prevented synergies in the development of budget for maintenance purposes. A number of minimal measures were suggested to improve functionality and effectiveness of budgeting for maintenance of university buildings.

Keywords: budgeting, effectiveness, Johannesburg, maintenance, university buildings.

INTRODUCTION

Universities are characterized by their open access to a significantly large number of people, enormous social and historical significance, public funding, and facilities which require incessant maintenance. The need for continuous maintenance for university facilities is related to prevalent heavy usage and the historical nature of the buildings. Consequentially, heavy funding often from public coffers is committed to ensure the required maintenance is undertaken. This underscores the importance of budgeting for maintenance of university buildings. It is noted that more often than not, the budgeting for maintenance of building facilities is characterised by over-reliance on historical budgets, improper policy and procedure implementation and

[1]Kennedy.Aduda@wits.ac.za

[3] rmabule@yahoo.com
[4] madonselal@yahoo.com

inaccurate maintenance information (Yik *et al.*, 2010; UNCHS, 1993). University facility managers encounter similar challenges when budgeting for maintenance. This paper undertakes a diagnostic analysis of budgeting process for maintenance of university buildings for two cases in Johannesburg. Consequentially the existing associated practices are analysed and recommendations made to improve budgeting process for maintenance of university buildings.

BUDGETING FOR MAINTENANCE OF UNIVERSITY BUILDINGS

The importance of periodical budgeting for maintenance of facilities cannot be ignored (Kelly, 2006 and Manganye *et. al.*, 2008). In particular, budgeting for maintenance of facilities is instrumental in efforts to attain desired functional efficiencies. Additionally, maintenance budgets are indicators of financial preparedness of facility owners or operators to invest in continued functionality of buildings. It is advised that budgeting for maintenance be informed and guided by sound maintenance strategies and policies to ensure greater effectiveness. However, this does not seem to be the case as reported by Westerkamp (1997) and later Boshoff (2009). Generally, Boshoff (2009) observes that budgeting for public asset maintenance in South Africa relies on an annual earmark of 10% of the operating budget for maintenance and takes historical perspective. It is argued that this method may be flawed as maintenance funding requirements are a function of the assets' needs and not total operating activity of an entity.

Despite the attached importance, maintenance of buildings in Universities is often poorly prioritized and misunderstood. Sherwin (2000) and Tsang (2002) report that built asset maintenance is perceived most Universities as a cost burden. This is perhaps related to the fact that in most cases demand for maintenance action, identified via an assessment of the condition of the building invariably exceeds the funds available (Pitt, 1997; Shen, 1997). Consequentially, Universities will always be reluctant to commit funds for asset maintenance (Chew *et. al*., 2004). This may be related to the fact that maintenance may be viewed as rivalling the core business function of the Universities. The linkage between maintenance expenditure and output production is often ignored. Maintenance budgeting then becomes an exercise based on last year's costs plus an allowance for inflation (Boshoff, 2009). Wireman (2004) reports that asset value based benchmarks forms the basis for best practice when preparing a maintenance budget. This is however disregarded in most cases (Kelly, 2006). This may be related to the fact that the senior management cadres rarely appreciate the link between facilities maintenance and profitability. It is therefore no wonder that Walker (2005) supports the need for Senior Management Staff at Universities to recognise facilities maintenance as a key business driver, and hence profitability in the institutions. This makes optimal maintenance of building facilities an operational prerequisite for Universities. Optimal maintenance is dependent on the efficiency of the maintenance budget (Grigg *et. al*, 2001). To achieve optimal maintenance, budgeting for maintenance must be periodical and should take into account the expected maintenance workload (Kelly, 2006: 42). For Universities, maintenance budgets must reflect the strategy of the maintenance function, define results to be achieved, plan the most economical use of resources, measure the magnitude and cause of variations and provide a plan of action and a basis for future policy (Wilson, 2002).

Yik *et al.* (2010) highlight various types of maintenance budgets. Of these, flexible, historical and zero-based budgets could be considered most appropriate for maintenance strategies used in University buildings. This is guided by considerations such as (1) the fact that flexible budget converts the University's maintenance strategies into operating plans (Khan *et al.*, 2007); (2) the need to consider historical performance data in building maintenance budgets for University buildings and as a way to improve operations (Zuzelo, 2010) and (3) using maintenance strategies to builds up a maintenance budget from scratch as advocated in *zero-based budget* formulation (Kelly, 2006). Each type of budget has practical distinguishable advantages and disadvantages.

The choice of budgeting framework for maintenance of university buildings must consider the three main issues. First, University buildings are largely aged and nearing physical and functional obsolescence; the accompanying decay can be controlled with sound maintenance (Flores-Colen *et al*., 2010). Second, the need for holistic evaluation of sustainability and costs issues when planning maintenance of each University building for (Gauzin-Müller and Favet, 2002). Lastly, formulation of a full works programme for each building and components detailing type of maintenance and maintenance strategy (Queensland Department of Public Works, 2010). The type of maintenance or maintenance strategy will therefore be chosen on the basis of maximizing the buildings functionality. However, it must not be forgotten that building maintenance planning must be accompanied by adequate funding (Flores-Colen *et al*., 2010). Technical and statutory factors need to be considered during the process of formulating the maintenance budget for University buildings (Wilson, 2002). Cognisance should be made of the fact that these factors differ across various stages of buildings life cycle. This is further complicated by the fact that university buildings are used for various purposes, are distributed across a wide age and are exposed to heavy usage. In line with a suggestion by Shim and Siegel (2008) the budgeting process must also take into account the short-term, intermediate-term and long-term goals of the University. Three essential elements for formulating the University buildings' maintenance policy exist. These are the choice of maintenance strategy, defining maintenance standard and allocation of maintenance resources. Building maintenance policy forms a critical aspect of university operations processes as it provides a management framework to determine appropriate maintenance strategy and standard (Lee and Scott, 2008). Maintenance strategy could be shaped by the need to adopt corrective, preventive or condition-based maintenance. El-Haram and Horner (2002) observe that adoption of standard for maintenance is dependent upon organisational resource level. This succinctly underlines the importance of maintenance budgeting process. Factors affecting maintenance budgeting process may be historical, endogenous, exogenous and economic according to Yik *et al.* (2010) or related to political influence, procurement, design and construction and maintenance and maintenance budgeting practices as outlined by Boshoff (2009:4).

An efficient maintenance budget is a natural performance assurance indicator. However, the budget preparation process is fraught with several challenges often related to difficulties in prediction of building performance and prioritisation of maintenance needs. For example, reliance on historical data may be limiting due to inability to successfully forecast maintenance expenditures (Langevine *et al*., 2002). Also, the development of effective maintenance budget for University buildings is

influenced by financial priorities set by the public patrons who fund academic activities (El-Haram and Horner, 1995). Additionally, the UN Centre for Human Settlements (1993) reports that inferior knowledge on actual cost of operations and maintenance for University buildings presents a great challenge. This betrays conflict in funds allocation often encouraged by the fact that budget preparation is often the task of finance departments that have little understanding of facilities operations and performance details. Furthermore it is difficult to separate operating costs from those dedicated to maintenance since they are often charged to one general budget of running costs. All these challenges suggest that maintenance budgeting process is bedevilled with uncertainties in decision making and inadequacies in regulations and standards. In South Africa, this is complicated by the fact that most funds allocated to institutions are used on staff salaries and that the unit value of funding and subsidies to universities from the public has been consistently reducing over the years (Buys and Nkado, 2006). Buys and Nkado (2006) emphasise the need for increased pro-active, rather than preventative maintenance management at these particular institutions as means of enhancing cost effectiveness. As part of this, it is also advised that the maintenance budget should be based on financial and maintenance requirements as set out in the maintenance plan that is informed by maintenance policies and strategies (Buys and Nkado, 2006). This forms the basis for pre-supposition explored in this paper that: '*Budgeting for maintenance of university buildings in Johannesburg is not guided by clear policies and strategies; consequentially, the process is hampered by poor decision making*'.

METHODOLOGICAL ISSUES

The study used a case based qualitative approach due to its "subjective" nature (Naoum, 1998: 38). Four universities existing in Johannesburg were contacted to participate in the study. However, two universities accepted to participate in the study. The study used a mixture of in-depth interviews and documentary reviews to gather information. In-depth interviews ensured that the respondents' professional experience, thoughts and opinions were well articulated. A total of seven respondents were interviewed from the participating two universities in Johannesburg. This population included facilities managers, supervisors, a financial manager and a director of operation. The criteria to select the respondents were based on the experience in facilities management, service duration, educational background and finance management. Documentary reviews were used to obtain information on best practices, organisational policy, regulations, planning and structure. The use of documents in institutional depository for research ensured some measure of authenticity. Bias, confirmability and authenticity in interpreting the professionals' opinions were addressed by the participation of three interviewers in all interview sessions. Emanating findings were analysed according to themes emanating from responses and documentary review. With regards to ethics, care was taken to adhere to the policies of the Universities studied, attainment of utmost confidentiality and non-disclosure of information uncovered during research.

FINDINGS AND DISCUSSIONS

The studied Universities each had diverse types of buildings ranging from: old and new buildings, difference in ages, sizes and uses. The following sections present summarized discussion of study findings. The discussion refers to the respective universities studied as A and B.

Management Structure

The management structures for both Universities were found to be hierarchical. Decision making for maintenance and maintenance budgeting was left to the divisional heads who could vertically delegate authority. This slowed down facilities operation as it took longer to make crucial decisions. This is further complicated by the fact that though maintenance budgeting was the preserve of finance department; it relied on information and plans from the facilities department. In such a set up, it would be logical to encourage greater horizontal rather than vertical communication across organisational structures (Daft, 2007). At University A, this was further worsened by the fact that the responsible departments for maintenance budgeting were involved in a turf wars as a result of lack of clarity in departmental roles. Thus maintenance budgeting at University A was fraught with poor information flow and communication. In comparison, information flow and communication at University B was considered more effective due to clearly articulated decision making structure and properly demarcated departmental roles.

Budgeting Methods

The study revealed that both universities used a combination of budgeting methods. The process of budgeting for maintenance of buildings was discovered to be highly flexible in terms of methods used. Whereas this is certainly desirable, it exposed the fact that budgetary control structures were lacking and as such decisions were largely ad-hoc and depended on the senior management at the finance departments. Furthermore, it also meant that budgetary needs were not benchmarked to asset value as recommended by Wireman (2004). In a hierarchical structure this could be open to abuse or bias by responsible individuals who had massive centralised powers and decision making responsibilities. This is worsened by the fact that both universities betrayed apparent lack of clear policies guiding maintenance and related budgeting. This subsequently works against optimal maintenance budgets alluded to earlier on by Grigg *et. al* (2001).

Maintenance Budgeting Guidelines, Processes and Procedures

Examination of the budgetary processes for maintenance at both universities failed to demonstrate any best practice. Processes were largely random and non-uniform. This could be related to the fact that processes are not well documented. However, the respondents all agreed that budgets for maintenance were generally submitted by maintenance or facilities departments to the Finance department in both Universities. It was also noted that lack of guidelines for maintenance budget preparation and unclear maintenance policies distorted the processes of development of budgets for maintenance. Finance department in University A however had some measure of guidelines on budgeting; however this had limited impact due to failure to specifically address maintenance issues or facilities context. University B did not follow any particular guidelines in budgeting for maintenance. Thus budgeting process was inclusive of all other institutional requirements. This automatically made maintenance of facilities vulnerable as immediate and highly visible needs such as staff salaries and direct learning requirements would be naturally preferred as alluded to by (Buys and Nkado, 2006). It is however laudable that limited positive measures were evident at both universities. For example, maintenance budget reviews were a norm at University A whereas maintenance performance evaluation existed at University B. These measures were not effective due to lack of supportive structures and culture.

Maintenance Strategies and Policies

Interview sessions revealed that both universities did not have clear maintenance policies but were guided by general policies on financial expenditure from the Finance department. Specifically, respondents at University A were categorical that no maintenance policies existed whereas respondents from University B were vaguely aware but unsure of any policies in this area. This is contrary to requirements for optimal performance of facilities alluded to by Lee and Scott (2008) and Wilson, 2002). Consequently, maintenance practices were haphazard, random and not indicative of desired optimal performance. It was however noted that both universities were guided by existing vision and mission in discharging maintenance of facilities. None the less, the vision and mission of the facilities department at University A was unspecific to the department and lacked clarity. However, University B's vision and mission of the facilities department was well documented, specific to the department and detailed. There are few and specific targets set for the maintenance budget which ignores the maintenance strategy. In addition, University B had pre-set annual targets for facilities maintenance; however, these were not based on maintenance objectives but on available funds. Once again this demonstrated that lack of adherence to best practices such as the need to base maintenance budgets on financial, maintenance requirements, maintenance policies and strategies as intimated by Buys and Nkado (2006), Yik *et al.* (2010) and Boshoff (2009). None withstanding this, University B's common targets complimented the institutional objectives, vision and mission statement. Also noted was the fact that both Universities relied on historical cost data to budget for their maintenance. This was then loaded with inflationary components without taking into account the evaluation of facilities maintenance need. This confirmed observation by Boshoff (2009) on banal and shallow use of historical data in budgeting for maintenance of facilities.

CONCLUSIONS

The focal issue emerging from the study was that budgeting for maintenance buildings at the two Universities was not well guided by any maintenance policies. This clouded the decision making process during budgeting with a lot of uncertainty thus making the process random and unreliable. Previous presupposition that *lack of maintenance policies results in poor decision making for maintenance budgeting for University buildings* was confirmed by the findings. In addition, the hierarchical management structure also made maintenance budgeting process highly susceptible to confusions and reduced effectiveness resulting from inadequate flow of information and inefficient communication.

RECOMMENDATIONS

Consequently, it is recommended that facilities managers ensure that proper guidelines are in place on budgeting for maintenance. Once formulated, the facilities' professionals should be duly educated on the policies and the policy implementation processes. Regarding the management structure and associated poor information flow, formation of a new maintenance budgeting framework is recommended (see Figure 1). The framework adopts a multi-professional management structure and reduces bureaucracy by ensuring that all respective stakeholders at the university are represented in an iterative maintenance budgeting process. This will ultimately ensure increased team and goal oriented efforts, heightened transparency, effective communication and shared responsibilities. The framework is envisioned as a complement to formulation of well-articulated maintenance and budgeting policies.

ABSTRACT

Lifecycle consideration in terms of environmental impact and total cost of buildings attract increased focus in construction. Here, total cost and environmental impact both involves: erection, operation, maintenance, demolition, and disposal of the building. The mindset of Lean Construction is focusing on eliminating waste and adding costumer value to both the design and build phases. But in this aspect waste and value is only viewed in the first generation owner perspective with fixed usage. Through theoretical considerations this research looks into the change of costumer value. Changes happen, so do changes in usage of buildings. Organisations and structures change, the result is often changed requirements or changed value perceptions. Costumer value is decreased since the owner has a building not fitting the present demands. Hence, there is a need of a construction redesign or in a worst case scenario the building end up unused. If, in the design process thoughts have been put into the *"value-lifecycle"* including second and even third generation usage, the transformability process of needs from generation to generation could be improved. This way value is kept in the building. Keywords in what could be called Flexible-Value-Design are multiple usage possibilities, flexibility and transformability.

Keywords: Flexibility, Lean Construction, Transformability, Value, Waste.

VALUE CREATION IN CONSTRUCTION

Value is an important element in Lean Construction and design. Here, the basic concept is to remove waste in order to increase the value creation (Freire and Alarcón 2002; Koskela 1996; Koskela 1992). According to the Lean philosophy value is to build what the customer wants or desires. Thus, it is a fulfillment of the customers' whishes, demands, and requirements. Johnson & Kaplan (1987) defined value this way: *"value of any commodity, service, or condition, utilized in production, passed over into the object or product for which the original item was expended and attaches to the result, giving it its value."*

[1] lindhard@m-tech.aau.dk
[2] swa@iha.dk

The question which needs to be asked is: who is then the customer? In Lean an activity is said to have two different customers (Wandahl 2004). Construction projects consist of multiple trades with interacting and interdependent activities (Bertelsen 2003; Salem *et al.* 2006). The first customer is the trade which have to follow up on the completed activity, i.e. the next link in the supply chain. The successor is dependent on the quality of the work and it being ready on time. If the previous activity is not completed or rework is necessary his own work cannot be conducted timely. If he has no buffered activities his productivity will decrease. Furthermore, because the construction is restricted by a tight sequence delays in one activity will easily be transmitted and therefore affect other subsequent activities (Lindhard and Wandahl 2012). The second customer is the end customer, user or the owner of the construction. Here, functionality, design, quality, cost, time, etc. are affecting the end customers' perception of value at the acquisition date.

Value creation is said to be a fulfilment of the customer's needs (Freire and Alarcón 2002). The Lean Construction philosophy seeks increased customer value. But value is only viewed in relation to the 1st generation owner and with fixed usage. Thus, focus is only on capturing and fulfilling the present needs of the owner (Freire and Alarcón 2002). Therefore, only the current needs are in the design process captured and transferred into design specifications (Ballard and Koskela 1998). The owner's present needs represent only a snapshot of the owner's value perception which over a period of time will change (Flint *et al.* 1997). Usage of buildings follows the changing needs of the owner and users and does therefore also changes with time. Therefore, the perception of the buildings value decreases when the building no longer fulfils the owner's needs.

More attention and new approaches is needed in order to overcome the owners changing value perception and preserve the value of the building. Moreover, when designing buildings it must be taken into consideration that the building at some point will change users and even owner. Here, the building now has to fulfill the needs of the new users or the 2nd generation owner. Furthermore, when the building is put up for sale the transferability is important, and together with the market value it composes a large share of the owner's value perception of the building.

In order to preserve the value of the building the buildings fulfillment of need has to be flexible making it possible to adjust for future needs. Therefore, when designing and constructing with multiple usage possibilities in mind much more value can be added to the building. Furthermore, to future proof the construction, 2nd and 3rd generation owner value should also be considered to increase the buildings value in the whole lifecycle.

A CHANGING ENVIRONMENT

The world is not static but dynamic and changing. Companies and cities develop through time and causing the surrounding environment to change. The developing companies have continuously to make organizational, infrastructural, and constructional changes to adjust and fit into the new reality (Simons 1994). Still constructions are when designed and constructed viewed as static monuments.

The companies changing constructional needs lead to redesigned, sold, or in worst case unused or demolished constructions. Thus, sold constructions do reflect the tendency of changes in the owners' value perception and needs. Historical evidence

 ISBN: 978-1-84219-840-7 .

show that the usage of constructions change. Therefore, in an attempt to picture the changes in usage of construction the national statistic of registered sales in Denmark is shown in Table 1. The figures have to be related to the number of inhabitants. Denmark is a small country with approximately 5.4 million residents.

Table 1 Registered Sales in Denmark (DST 2012)

Sales: Year	**2006**	**2007**	**2008**	**2009**	**2010**
Factories and warehouse buildings	1.756	1.617	1.219	705	1.240
Agricultural property	5.498	5.598	4.782	3.556	3.595
Business property	2.069	2.061	1.545	1.006	1.289
Mixed residential and business property	3.448	3.122	2.306	1.538	1.799
Apartment block	3.765	3.526	2.476	1.738	2.333
Single-family homes	58.950	58.270	46.138	40.551	46.504

From Table 1 the total business related sales can be calculated. This includes factories and warehouse buildings, agricultural property, business property, and mixed residential and business property. From 2006 to 2009 the total business related sales varied from 6.805 to 12.771 sales. During the financial crisis the sales dropped down.

Despite a concomitant changing effect which was expected to race sales the crises did moreover affect the companies' solidity and the propensity to invest. Furthermore, the crisis did make it difficult to receive mortgage loan. This made the property difficult to sell and the prices dropped (Brunnermeier 2008). Therefore, a lot of companies' have been forced to keep constructional facilities which do not fit the current needs. To keep the construction still useful transformability and flexibility has been extremely important.

Not only big financial crises affect the owners' constructional needs. Small changes or developments in the surrounding world continuously change the owner's value perception. Changes happen both inside and outside the company and forces changes to the constructional needs. Everything can change and affect the usage of the construction. Thus, changes are influenced by an infinite number of parameters which make the changes complex and impossible to forecast.

Changes in the organization will always induce changes in usage of the constructional facilities. The owner can chose to ignore these changes by accepting a reduced fulfillment of needs, he can chose to redesign the construction to fit current needs or he can chose to sell the constructions where after the 2nd generation owner has to redesign the construction to fulfill his needs. To fit the building to the new demands the building has to go through a transformation process.

Transformability is important. Multiple options promote the likelihood of a redesign of the constructions. If the construction is not transformable it is a risk that it

sometimes in its lifecycle will end up unused or demolished before necessary. The key is to design the building so the transformation has to be as little and as simple as possible. Thus should changes be as quick, easy, and cheep to complete as possible. To promote transformability the building needs to be designed for a changing environment. Thus, the design process should consider the whole *"value-lifecycle"* of the construction which has to fulfil the changing needs of both 1st 2nd and 3rd generation owners. The question which needs to be answered is:

How do we handle the changing needs of the customers and how can we increase the constructional transformability to make the constructions fit to current needs?

The research is explorative, open-minded, and visionary; it tries through creativity to avoid the limitations of a narrow-minded and traditional way of thinking. The reseach presented is grounded on theoretical considerations alone but will be followed and supported by further research. The future research will focus on the changing constructional needs of companies in Denmark.

HANDLING CHANGES IN USAGE

Companies are continuously affected by their surrounded environment which changes their needs and value perceptions. Often these changes are related in the marked and therefore difficult to forecast. The outcome is changed usage of the company's constructional facilities. It is important to secure that the building is fully utilized and still fulfil the company's needs. Therefore, to enable the company to respond to changes, constructions need to be adaptable.

Even though changes in general are difficult to forecast some changes might be predicted and should be considered already in the constructions design face. Many future problems can be caught before emerging by carefully contemplate the construction design. Tendencies in the surrounding environment and the existing marked can be analysed and predicted just as in real business life.

Foresight is important. Here, the company's plans and expectations to the future are in particular important. For instance, it would be stupid to build a construction with a non-expandable max capacity if the company is experiencing or expecting high growth. One way to capture the future needs could be by making the owner conduct a *"lifecycle"* plan of his expectations to the future usage of the building in its lifetime. Thus, the design face should proceed based on the owner's *"lifecycle"* plan. Predicting the future is difficult. Therefore, it is important to notice that the *"lifecycle"* plan is only expectations which thus are not necessarily fulfilled.

In order to optimize the value-fulfilment the *"lifecycle"* plan needs to cover all relevant focus areas. One example to a focus area to carefully consider is the location. A lot of factors have to be taken into consideration. For instance: Does the location fulfil potential future needs? Does the location make it possible to upgrade and expand the facilities? If a future expansion is considered should surrounding acreage be purchase? How do geographical changes in the marked and organizational changes in the company affect the location? How is the location in relation to transport options and logistics and can the location fulfill potential future needs with increased sales? Is it possible to attract a qualified labour force? If a future sale is necessary would the location promote a future sale? All relevant questions need to be answered and considered already when the construction is designed.

There are a lot of other relevant focus areas besides the location. Another example could for instance be environmental concerns including future environmental requirements, energy consumption, and the company's external appearance as an environmentally preferable company. It is important to state that the list is not considered exhausting. The number of questions and consideration continue almost infinitely. If all concerns have to be considered the design process will become very complex and cost full. Therefore, the purpose with the *"lifecycle"* plan is to let the company identify the relevant key issues. These key issues do then form the groundwork to the subsequent design of the construction.

Furthermore, since plans does not always become reality the contemplate design with relation to the owners *"lifecycle"* plan should be supplemented with an increased flexibility and transformability in the construction design.

Flexibility is understood as the ability to change the constructional usage without needing to make constructional changes. Thus, increased flexibility makes the construction agile because the ability to adapt to the changing environment is increased. The key to flexibility is design the construction with multiple applications in mind. This could for instance be by making the inner shape of the room flexible. This could be achieved by using walls or interior which are easy to displace.

Constructional flexibility would make it less cost full to change the design since it reduces the need of transformation in the adaption process. But instead will the creation of flexibility in the construction most likely induce increased cost to the erection of the construction. Therefore, both related expenses in cost and time and possible savings have to be taking into consideration in the design face. Therefore, every initiative, which purpose is to increase the flexibility of the construction, has to be considered individually with the owner as the decision-maker.

Transformability is the ability to change usage of the constructional facilities. Opposite flexibility the construction is transformed in the process. The constructions transformability is determined in relation to the cost, time, and the resources spend in the transformation process. Basically there are two different types of transformability. Here, one type of transformability is related to the ability to transform the existing structure in order to adapt to the changing environment.

One approach to achieve transformability in the existing structure could be by reducing the number of load-bearing wall which penetrate the inner structures. This increases the adaptability in the inner design of the construction where light wall easily can be broken down or dissembled.

The second type of transformability is related to the ability to ad structures to the existing structure. This form of transformability could for instance be related to the possibility to add an extra floor to an existing construction, building an expansion, or constructing an entire new structure. Since this transformation has to be completed without ruining the design of the constructions both design and structural concerns are critical. Since increasing the transformability of the constructional structures, likewise flexibility, is cost full a cost-benefit analysis needs to be preformed. Again the initiatives have to be considered individually where it in the end is the owner's call to make the final decision.

It is important to notice that the effects of value changes not are limited to be handled in design. Changed values and needs can have an impact already in the construction phase. Often the owner does, in collaboration with the architects, continuously make changes in the design. This is often small changes related to materials, textures, or colors but sometimes the changes are having a greater impact even at the structural design. Therefore, construction planning and scheduling does not only have to cope with the complexity and changing nature of a construction site it also has to be able to handle the owners changing needs satisfactorily. Changed design caused by changed owner values or needs bring uncertainty into the schedule. The scheduling tool needs to be able to handle this uncertainty and still keep a steady workflow to maintain high productivity.

Today most changes evolve unforeseen. Changes can happen at any time and therefore interrupts the making ready process. To minimize the impact changes has to be foreseen. One approach is to investigate the triggers which cause changes. This helps site-managers to understand and predict future changes. A second approach to foresee upcoming changes and react faster is to improve the communication between construction site and owner and architect. If structural changes are needed the flexibility and transformability of the construction is once again important to adjust the construction to fit current customer needs. Moreover, the flexibility and adaptability is important in the workforce and in construction process itself. Communication and collaboration are essential when handling changes. It takes teamwork to work around the changes to find and exploit new possibility and to optimize the process. Furthermore, communication and collaboration does minimize misunderstandings.

FUTURE RESEACH

This research is an initial part of an on-going research that emphasises Lean Construction and creation of customer value. The main focus is on how to coop with changes in the customer's value perception in relation to usage of the constructional facilities in the constructions lifetime. The purpose of this research is to create a broader understanding of values not as static but dynamic. Additional further research is needed to support the research and to form guidelines for achieving flexibility and transformability in the design face.

Future research areas include:

- What are the root causes to why companies replace or redesign the constructional facilities.
- Understanding the dynamics which drives and triggers changes.
- How constructions are adapted to the changing environment and which parameters do increase this transformability.
- How flexibility and transformability can be achieved in an constructions
- What are the key parameters which should be considered in order to future proof a construction.
- How and when foresight is achieved.
- Improving the schedule in handling unexpected changes

CONCLUSION

In relation to the Lean Construction philosophy value is achieved by fulfilling customer needs. To respond on a changing environment constructional usage needs to adapt to respond to the changing world and fit to the present needs. Even so constructional value is in design considered as static. Thus, the design process should consider the whole *"value-lifecycle"* of the construction which has to fulfil the changing needs of both 1st 2nd and 3rd generation owners.

In order to preserve the value in the construction the constructions fulfillment of needs have to be flexible making it possible to adjust for future needs. Changes are difficult to forecast but instead of ignoring the changes tendencies in the surrounding environment and the existing marked can be analysed and predicted. The company's plans and expectations to the future are in particular important. Therefore, it is suggested that the owner should conduct a *"lifecycle"* plan of his expectations to the future. Thus, the design face should proceed taking the owner's *"lifecycle"* plan into consideration.

Since forecast not always are reliable the construction still needs a flexible and transformable design to increase the adaptability to changes in usage. Flexibility is understood as the ability to change the constructional usage without needing to make constructional changes while transformability is understood as the ability to change usage of the constructional facilities by transforming the constructions. The constructions flexibility and transformability is determined in relation to the cost, time, and the resources spend in the adaption process.

Transformability can be categorized into the ability to transform the existing structure and the ability to ad structures to the existing structure. Since transformation has to be completed without ruining the design of the constructions both design and structural concerns are critical. Opposite is constructional flexibility achieved by designing the construction with multiple applications in mind.

Increasing constructional flexibility and transformability, to make the construction agile to changing usage, is cost full. Therefore, both related expenses in cost and time and possible savings have to be taking into consideration. Every initiative, which purpose is to increase the flexibility or transformability of the construction, has to be considered individually with the owner as the decision-maker.

The tendency of changes in customer needs is often already experienced during the construction phase where the schedule has to handle the unexpected changes in the design satisfactorily. If a change requires structural changes flexibility and transformability of the construction is once again important. The impact of changes can be reduced by understanding the triggers to predict future changes. Furthermore, the impact can be reduced by improved communication and collaboration at site.

EFFECTIVENESS OF DUE PROCESS UNIT OF NIGERIA-CONSTRUCTION PROFESSIONALS' VIEW

Aladeloba, Adesina E.[1]

[1]*School of Environmental Studies, Yaba college of Technology, Yaba, Lagos, Nigeria.*

ABSTRACT

The Budget monitoring and price intelligence (Due Process) policy reform initiative by Nigerian government is to develop criteria for assessing contractors' competences in periodic prequalification juxtaposed with the criteria for assessing project prequalification based on current data about contractors' capacities. The criteria are financial strength, past experience and adequate resources for periodic prequalification based on classification and qualification levels.
An improved contractor selection process is achieved in the public sector as barriers to entry are removed and protection of public and client's interests accomplished. The population of study covers stakeholders who expressed opinion on its effectiveness. Field trips were made. Secondary data were obtained from various materials relevant to the subject matter. The data is presented in a simple descriptive format using frequency tables. The outcome of this research work revealed all stakeholders are unified in belief that it will achieve desired objectives and call for renewed commitment and dedication to an improved contract procurement system free of sharp practices.

Keywords: Approval thresholds, Corruption, Due diligence, Financial bid, Prequalification.

INTRODUCTION

The establishment of this unit by President Olusegun Obasanjo in 2001 was an indication of obvious lapses in the country's procurement system over the years and abuse to rules and standard in the award and execution of public contracts in Nigeria. The consequences of these are a procurement system characterised by inflation of contracts cost, over-invoicing, diversion of funds, abandonment of government projects, denial of social amenities to the citizenry, proliferation of uncompleted projects, less quality of work and so on. Furthermore, the yardstick for measuring the veracity and effectiveness of a due process are sacrificed as competition, competence, integrity, transparent and value for money are non-existent. However, the establishment of the due process has brought about a total re-awakening in the process of award and execution of contract, so much that certain level of credibility has been restored to the process. The different stakeholders acknowledged this fact but expressed divergent views on its effectiveness as the system is still fraught with corruption. As a result of the retrogressive outlook of the subsisting method, due process became an emerging trend necessary to alert Nigerians that

 ISBN: 978-1-84219-840-7 .

corruption is no longer fashionable in the Project procurement Process. Previously, researchers like Donny M. Mangitung (2010) worked on Typical contractor prequalification characteristics of public procurement practices in Indonesia, Onukwube and Aladeloba (2011) examined Modelling the determinants of project development budget and the works of a host of other numerous researchers in their area of study were reviewed by the researcher, (but) it appears that little research has been done with regard to the effectiveness of Budget monitoring and price intelligence policy reform initiative geared towards project procurement in any government hence the need for this study. The aim of the study is to appraise the views of practitioners on the effectiveness of Due process as a way of encouraging the emergence of an enduring project procurement process. This will enhance the awareness level of professionals in Nigerian construction industry on the effectiveness of Due process thus encouraging the evolution of more enduring procurement system and serve as a useful perspective of professionals on the subject matter.

RESEARCH PROBLEM

According to Calvert et al [2003], Construction projects development involve a great number of people interacting to achieve set goals which is heavily dependent upon inflow and outflow of information. It is therefore imperative to adopt a medium of communication free of ambiguity and ambivalence which will leave no one in doubt as to what is being said. This no doubt encourages cross fertilisation of ideas; new thoughts, challenges and innovations necessary to improve and re-direct its operations. Therefore the research work will endeavour to answer questions bordering on what the due process is all about, who the participants are, how the due process operates; its requirements vis-a-vis what is expected of the participants while the following objectives are also considered: (1) to identify the factors inhibiting the operation of due process. (2) to determine the extent to which these factors affect the operation of due process and (3) to analyse the views of the practitioners with a view to determining the continued relevance of Due Process as a project procurement process. Entering the construction industry is relatively easier than entering the manufacturing industry, as illustrated by the number of construction companies being dominated by small and medium-sized companies. However, construction business failure is higher than in the other industry (Arditi etal. 2000; Kangari 1988). Thus, to protect public and client interests and reduce barriers to entry, complex mechanism is continuously being developed to avoid market failures or an individual contractor's failure in order to meet its contractual obligations (Mangitung 2005; Russell 1996; Schulman1982).

DEVELOPING PROCUREMENT STRATEGY

Obiegbu (2005) posited that procurement is the process that creates, manages and fulfils contracts; and as such forms an integral part of construction projects and occurs at any point in a project cycle whose external resources are required to provide supplies and services in any combination or in the disposal of surplus plants, equipment and materials and demolition of redundant building and infrastructure. Procurement starts immediately the need for it is identified and ends as soon as the transaction is completed. However, the strategy chosen is governed by certain parameters including available resources, nature of

job, risk sharing, Degree of complexity among others while the consideration of organizational methods including contractual arrangements, method of procurement, bidding procedure and conditions of contract remain very material.
The vehicle on which the objectives of the Budget monitoring and price intelligence (Due Process) unit are carried across remains its vision and mission stated as: to help move Nigeria to a level where public procurement is governed by principles of integrity, transparency, competence and competitiveness as national ethos and to use the due process mechanism to re-establish and sustain an open, transparent and competitive federal procurement system that is integrity driven, upholds spending within budgets and ensure speedy implementation of projects in other to achieve value for money outcomes without sacrificing quality and standards respectively. (BMPIU 2006)

These discussions have been tailored towards the six core requirements that the unit seeks compliance namely advertisement which allows for equal and effective communication to enable all participants in the contract market effective competition. Advert further spell out guidelines for both contracts below #10,000,000 and those above. Advert for the first categories of contract can be placed on the notice boards erected in conspicuous layout at the ministry, agency or department while the advert for the second categories must be placed in not less than two National Newspaper or Government Gazette. This is aimed at addressing the problem of transparency noticed in the old order which had led to the award of contract to ghost firms, sales of letters of awards; existence of proxies representing the interest of individuals and firms, certification of non-existing works for payments and so on; will encourage equal access to information by all prospective participants in the public contracting arrangements. There are specific standards expected to be observed in placing adverts and the details must include the project title, name of client, names of consultants, location of the project, general distribution of work, appropriate cost range, the form of contract, the likely date of commencement, anticipated completion date, tender documents to be issued, bond requirements and many more relevant information deemed necessary. The prospective contractors are also expected to respond by submitting a resume' of their company with the following basic information namely Name of company, location of head office, company's website, Email, Telephone ,fax of company, Names and addresses of the directors, types of ownership, class of registration with the federal ministry of works and company registration, organizational structure, Number of years in business, company's annual turnover, the list of current work loads, the list of completed projects including the titles of the works ,names of client, location of work and total contract sum. Others include the names of personnel; their qualification, experience, expertise, availability of operatives, available plants and equipments, types, condition and number, name of bankers and sources of funds.

CONTRACTOR PREQUALIFICATION: DEFINITIONS

Contractor prequalification is commonly found in the literature as a single definition, namely, a process of assessing contractors' competences required by regulations or by clients before a bidding stage using a set of main criteria in order to find responsible and eligible contractors that can perform the construction work completely and satisfactorily

 ISBN: 978-1-84219-840-7 .

if awarded the construction contract. Prequalification is a screening process applied to contractors before tendering; to reduce the risk of project failure (McCabe et al. 2005)

Periodic prequalification is a process of developing a standing list of contractors relevant for a certain periodic time frame, some project types and a certain range of project sizes, which can be used by a client for short-listing or inviting bid. This type is usually separated from project prequalification in terms of time and purpose of evaluation. Standing list, select list and approved list are commonly classified as this prequalification type. Sometimes a client develops the tender list from these lists without further qualification. By contrast, project prequalification is a process to develop a list of qualified contractors for a particular project, on a project-by-project basis, which can be combined with periodic prequalification, for short-listing or inviting bid.

Prequalification Process and Criteria

Prequalification is a process by which clients evaluate the competence level of a prospective contractor to perform a given task or responsibility to satisfaction. This is the very first elimination stage of would-be consultant/contractor who responded to an invitation for prequalification advertisements. It is usually a process that precedes the issuance of drawings and proposal. In a bid to ensuring quality performance, prospective contractors are subjected to screening by the client or its representatives in accordance with established criteria regarded as necessary ingredients for ensuring quality performance. The level attained by the prospective contractor on a score scale of 100 percent would determine whether or not a participant qualifies. The analysis is based on set of objective criteria which are technical and financial in nature. The two main objectives aimed at achieving are:
-Short listing and selecting competent respondents to the adverts.
-weeding out those who do not pass the competent test of the commercial or financial bid.

The criteria adopted are also categorized into two namely those that are regarded as sacrosanct; that is a-must-get for all the companies and those that are not depending on the nature of registration of such company-an enterprise or limited liability company. All the must-get criteria score zero on the weighing scale and are regarded as responsive-absence of anyone could automatically disqualifies an applicant from the exercise. These are sets of documents which qualifies a prospective contractor for participation in the Pre qualification exercises. They are:
-Evidence of incorporation of Business name-0%
-Company registration with federal ministry of works in relevant category-0%
-Audited account of company for three years-0%
-An evidence of tax payment/clearance certificate for three years-0%
While the non must-get criteria are graduated as:
-Evidence of financial capability and banking support-15%
-Experience/technical qualification of key personnel-25%
-Evidence of similar projects and knowledge of the industry-20%
-Capacity of company in terms of equipments and technology-20%
-Annual turnover-5%

The remaining 10% is allotted to respondents with evidence of local contents and community social responsibility in support of the local content policy of the federal government. Best practice in contracting establishes the benchmark score for prequalification acceptable for considering a respondents as competent as 70% and above (BMPIU,2006)

The issuance of an invitation-to-bid documents to a prospective contractor who had partaken in the prequalification process pre-supposes that he is successful and thus a ***Competent Bidder***. The Bid documents contain sufficient information to enable competition take place under strict fairness. The tender document comprising technical and financial parts is expected to be submitted within six weeks of issuance of Bid documents. At the close of bidding, the tenders are opened in the presence of the bidders or their representatives and the civil society group in order to demonstrate openness and fairness in the procurement process. Having gone through the above, a competent Bidder adjudged as having been technically and financially qualified is produced and offers the client the lowest cost for execution of the contract. It therefore requires that a check list for review and certification approval of the different stages of the procurement process be produced.

RESEARCH METHOD

Considering that Due process is a reform initiative by Nigerian government to accentuate the emergence of positive changes in the people's standard of living and it is expected to be achieved by meeting the client's quality requirement on a construction project. According to Oakland (1999), Conformance (doing things right) with regard to former requirement set by producer is of great importance. Experience shows that this often caused significant gaps between the clients' need and expectations and the requirements that the producer was striving to meet.(Sorgvist 1998). Consequently, medium of communication must be easily understood to encourage participation. The method of collecting information was necessarily crafted in such a way that respondents are encouraged to divulge information-an initial step was to consult a group of construction practitioners to identify a set of concrete measures for Budget monitoring. An inventory of items of Budget monitoring and price intelligence measures was undertaken for the present study. These items were randomly ordered in the instrument to discourage potential response bias, to engage participants in arms-length discussion and in some cases, orally interviewed to elicit information. In the application of questionnaire, the respondents were requested to rate each of the prequalification criteria and the objectives of due process in form of a priority scaling table with 6 options; 5=very, very important, 4=very important,3=just important,2=less important,1= negligibe, 0=not important. In order to test the effectiveness of the survey instrument, a pilot survey involving 10 professionals was conducted for clarifying and refining the questionnaire. This helped to facilitate the identification of inherent defect in the structure and rendition of the questionnaire thus prompting a redraft of same and the interview schedule. The sample size 25 is considered to be representative enough and cuts across all the professionals in the built environment. 16 of the 25 questionnaire were retrieved; 64 percent of the total given out. Data collected were analyzed using simple descriptive frequency table. Limited sample size is used in this research; nevertheless, the researcher hopes to achieve

greater sample size in subsequent works which can then be subjected to mean item score, spearman ranking, correlation matrix, linear regression analysis, chi-square and factor analysis for more insightful inferences on the subject where appropriate.

RESULTS AND SUMMARY OF FINDINGS:

Professional Qualifications of Respondents

The response to this question is as depicted below:.

Table: 1

Non corporate	11	44
MNIA	6	24
MNSE	3	12
MNIOB	4	16
MNIQS	1	4
Total	25	100

Respondent's involvement with Government project

The response on the involvement of respondents with Government projects is as depicted below:

Table: 2

Response	**Nos.of respondents**	**Percentage**
Yes	16	64
No	9	36
Total	25	100

Factors inhibiting the operation of the due process:

The first objective of this study is to identify the factors inhibiting the operation of the due process.

Documents considered important before bidding for government project.

The results are as presented.

Table: 3

Serial Nos.	**Criteria**	**Number**	**Percentage**
1	Evidence of incorporation	14	32
2	Registration with federal ministry of works	9	21
3	Company audited account for 3 years	6	14
4	Evidence of tax payment for 3 years	5	11
5	All the above	10	22
	Total	44	100

Level of importance respondents attached to the selection criteria

The third objective of this study is to analyse the views of the practitioners in order to determine the continued relevance of due process in project procurement. The results are as presented below:

Table: 4

Serial Number	Opinion Expressed	Responses	Percentage
1	It is straight forward and sincere	8	50
2	It is cumbersome and fraught with Abuses	8	50
	Total	16	100

Extent to which these factors affect the operation of due process

The second objective of this study is to determine the extent to which these factors affect the operation of due process (level of importance). The results are as presented below:

Table: 5

Serial nos.	Criteria	Level of importance						Nos.of respondents	Percentage
		5	4	3	2	1	0		
1	Evidence of incorporation of Business name-0%	8	4	4	5	4	-	25	100

CONCLUSIONS

This study sought to appraise the effectiveness of Budget monitoring and price intelligence unit of the Nigerian Government. This study has been able to establish that participants expressed divergent views on the operations of the Due process especially in areas of Documents considered to be necessary for bidding (must-get), its objectives and sincerity of the operatives. These objectives are carefully selected in order to encourage the evolution of a more enduring system that will not exclude a prospective contractor for flimsy reason. Based on this result, the following suggestions are offered to ensure improvements of the Due process: 1) contracting firm or companies should be encouraged to involve more registered members of professional bodies in their personnel team, 2) government should embarked on awareness campaign to encourage participation, 3) the prequalification criteria should be made public with available projects well advertised to create more awareness, 4) the due process should be made operational at all levels of governments in Nigeria rather than limit it to federal government projects and 5) any criteria that does not have direct linkage to the technical ability of the contractor should be dropped.

ESTABLISHING RELATIONSHIP BETWEEN CHARACTERISTICS OF PREVENTIVE MAINTENANCE AND COST PERFORMANCE

Au Yong Cheong Peng[1], Azlan Shah Ali[2] and Faizah Ahmad[3]

[1,2,3]*Faculty of Built Environment, University of Malaya, 50603 Kuala Lumpur, Malaysia*

ABSTRACT

The building maintenance costs are rising rapidly from time to time due to poor maintenance in the past. In UK, total spending on building maintenance had a dramatically increase of 66% in the past 10 years. In Malaysia, the development plan allocation for repair and maintenance works in building sector increased from RM296 million during the Eighth Malaysian Plan to RM1,079 million during the Ninth Malaysian Plan. However, the development plan allocation for repair and maintenance works in the Tenth Malaysian Plan has decreased to RM500 million. The decrease of resource allocation for building maintenance activities urges the professions to develop solutions on reducing the maintenance costs. Thus, it is vital to identify the cost characteristics of preventive maintenance, includes scheduled maintenance and condition-based maintenance through literature review. The characteristics of preventive maintenance always affect the maintenance cost performance. Therefore, relationship between characteristics of preventive maintenance and maintenance cost performance must be established to understand and take into consideration in the maintenance planning stage. At the end, the significant relationship will be able to help the industry practitioners in selecting appropriate maintenance strategy with optimal maintenance expenditure, yet improving the maintenance outcome.

Keywords: condition-based maintenance, cost characteristics, maintenance cost performance, Malaysia, scheduled maintenance.

INTRODUCTION

Building maintenance is the combination of technical and administrative actions to ensure the items and elements of a building in an acceptable standard to perform its required function. In order to implement or perform the tasks of building maintenance efficiently, a proper building maintenance management is a necessary tool for it.

Generally, building maintenance is subdivided into two main categories, which are planned maintenance and unplanned maintenance under BS3811 (Seeley, 1987).

[1] auyongcp@gmail.com

Planned maintenance is the predetermined tasks that are well organised and performed in advance. The maintenance actions reduce or prevent any damage of the components or items. On the other hand, unplanned maintenance is carried out in the event of emergency or contingency maintenance without any predetermined plan. The maintenance actions are carried out after failure or damage detected.

In fact, planned maintenance is supposed to be the major activity in building maintenance instead of unplanned maintenance. Otherwise, frequent breakdown or downtime could be occurred and high maintenance cost is required by unplanned maintenance for repair and replacement works (Chareonsuk et al., 1997). Thus, unplanned maintenance should be minimised to achieve optimal maintenance expenditure.

Since Horner et al. (1997) noted that there are several strategic options available to management and many alternative decisions to be considered for maintaining a building in proper aspect, the comparative study on the maintenance strategies is necessary to control the maintenance performance, especially the maintenance cost.

COST CHARACTERISTICS OF SCHEDULED MAINTENANCE

Hameed et al. (2010) pointed out that maintenance activities performed at fixed time interval are mean to reduce the probability of failures and breakdowns. However, some researchers argued that scheduled maintenance is not cost effective, which the replacement of components is often performed regardless of the condition. Literature indicated that the maintenance performance of scheduled maintenance relies on the criteria as stated below:

Skilled Labour

Since scheduled maintenance is carried out in a fixed time interval, it does require permanent maintenance personnel or technicians to perform the tasks. Commonly, the organisation allocates different amount of salary for the maintenance personnel based on their level of competency. Furthermore, Horner et al. (1997) claimed that the labour is highly demanded for scheduled maintenance activities. Thus, skilled labour is one of the main characteristics to be considered for implementation of scheduled maintenance.

Spare Part and Material

According to Horner et al. (1997), spare part and material is much required for scheduled maintenance compared to other maintenance strategies. Some parts of building systems or services need to be replaced with a new one in fixed interval as determined in the schedule maintenance program, no matter such items are damaged or not. In addition, the quality of spare part and material always has an impact towards maintenance performance (Ali et al., 2010). Thus, the selection of spare part and material should not only concern about cost saving, the quality of spare part and material is another essential aspect to be taken into consideration.

Predetermined Interval for Maintenance

The interval of maintenance activities is critically influencing the maintenance outcome. Narayan (2003) proven that unavailable or delay to perform maintenance task at the right time may cause further damages to the system components. Meanwhile, Yang (2004) argued that the scheduled maintenance programs might not

be able to avoid the risk of failure occurred on system components before the fixed replacement time. This problem occurs due to unknown condition of the system components. Hence, an adequate maintenance interval must be identified and performed to enhance the effectiveness of scheduled maintenance.

Maintenance and Failure Downtime
Since Yang (2004) had mentioned that the scheduled maintenance is not able to prevent the risk of failure, the downtime and cost allocation for maintenance and failure should be considered when planning the maintenance approach. According to Zuashkiani et al. (2011), breakdown may cause collateral damage in a particular system. Relatively, additional downtime and cost will be incurred for the failures occurred before the predetermined maintenance time. Hence, the amount of downtime for maintenance and failure must be taken into consideration for the planning and execution of scheduled maintenance activities.

COST CHARACTERISTICS OF CONDITION-BASED MAINTENANCE

Condition-based maintenance is aimed to minimise the total maintenance cost by collecting and gathering the condition data of the building systems, especially those critical components. However, the maintenance strategy might not be applicable to all building systems or assets in terms of the availability of such maintenance technology and cost effectiveness (Horner et al., 1997). The characteristics of condition-based maintenance toward maintenance performance are stated below:

Skilled Manager
This maintenance strategy requires vigorous analysis on the data and information of systems condition and reliability, as well as financial maintenance data. Meanwhile, building managers must have proper understanding on the failure modes and rates, asset criticality, and other significant factors while implementing condition-based maintenance (Ellis, 2008). Thus, a skilled manager is required to ensure the success of the maintenance strategy.

Monitoring Equipment and Technique
According to Edward et al. (1998), there is a wide range of techniques to examine the condition of specific items or assets, such as oil analysis, vibration monitoring, thermography and so on. Specific measuring and monitoring equipments are required by expertise to perform the maintenance tasks. The tools might be complicated and costly for an organisation (Carnero, 2006). Therefore, the availability of monitoring equipments and capability of the maintenance personnel to use the equipments should be taken into consideration for condition-based maintenance.

Acquisition of Data and Information
Bevilacqua and Braglia (2000) argued that the data and information acquisition systems are the necessary applications to perform condition-based maintenance. The documentation and record of information are essential to ensure the reliability of information about the conditions and remaining lifetime of system components. Ali (2009) further explained that the conditions of buildings and systems must be considered to allocate adequate maintenance cost. Thus, the maintenance personnel should acquire the data and information regarding the conditions of building system components.

Frequency of Monitoring and Inspection

Condition-based maintenance can only be implemented with proper system monitoring and inspection. Hameed et al. (2010) demonstrated that planning of appropriate maintenance activities prior to failure and maintenance cost is greatly influenced by the ability to monitor and inspect the condition of systems. Thus, it is necessary to identify the optimal frequency of monitoring and inspection, so that condition-based maintenance can improve the performance in term of cost-effectiveness.

RESEARCH METHODOLOGY

This research was conducted through literature review in early stage. The cost characteristics of scheduled and condition-based maintenance were identified by reviewing the journal articles and other reliable reference sources. Then, quantitative approach was adapted to study on the relationship between characteristics of maintenance strategies and maintenance cost performance. Questionnaires were sent out to the relevant expertise in Klang Valley, Malaysia to obtain the factual data for analysis, such as building or maintenance manager, building executive or supervisor, and other maintenance personnel. At the end of the research, Spearman's rank correlation analysis results were produced by using SPSS to show the relationship between characteristics of maintenance strategies and maintenance cost performance.

FINDING

In this research, the number of valid return questionnaires was 120, which is 30 per cent of the total research population. Thus, the results were able to represent the research population.

Table 1: Job title of respondents

Job Title	**Frequency**	**Percentage (N=120)**
Building Manager	57	47
Building Executive/ Supervisor	43	36
Building Technician	12	10
Others	8	7
Total	**120**	**100.0**

Table 1 indicated that the respondents of the questionnaire survey comprised building managers, building executives or supervisors, building technicians, and others. Based on the data obtained through the survey, some of the respondents, who selected the category of "others", were either managing directors of a property management firm or mechanical and electrical engineers.

Table 2: Correlation between characteristics of scheduled maintenance and maintenance cost performance

**. Correlation is significant at the 0.01 level (2-tailed)
*. Correlation is significant at the 0.05 level (2-tailed)

In schedule maintenance, the quality of work provided by the maintenance labour directly influences the maintenance performance outcomes (Groote, 1995). The statement was proven by the analysis result. According to the correlation analysis result obtained as shown in Table 2, the skill and knowledge of maintenance labour was found to be significantly correlated to the maintenance expenditure variance. The labour without proper skill and knowledge are more likely to misjudge and misinterpret the condition or problem of a system. The repair and replacement works done by such labour might not be appropriate. As a result, further damages will be occurred and additional repair works will be required. As such, the task spends additional maintenance cost and leads to the issue of over-budget.

Then, level of spare part and material stock is another aspect highly concerned in scheduled maintenance. Greater amount of spare parts are needed to replace the existing parts compared to other maintenance strategies. In this research, the level of spare part and material stock was found to be significantly correlated to the maintenance expenditure variance (see Table 2). The analysis result supported the statement of Tsang (1995) that accurate spare parts identification and stocking help to control and reduce the operation and maintenance cost. For example, the maintenance personnel will be urged to order small amount of spare parts to execute the maintenance works when there are no adequate spare part stock. It usually costs higher to order small amount of spare part instead of large amount. As a result, the variance of maintenance expenditure occurs.

Furthermore, the analysis result supported the statement of Ali et al. (2010) that the quality of spare part and material always has an impact towards maintenance performance. The result indicated that the quality of spare part and maintenance expenditure variance were significantly correlated (see Table 2). Hence, the statement of De Silva and Ranasinghe (2010) was supported, which revealed that good quality spare part and material can optimise the maintenance expenditure. Poor quality spare part and material is likely to damage and cause unwanted failure to the building systems. Thus, additional repair and replacement works are required. Extra maintenance expenditure is needed and variance of maintenance expenditure is happened.

Meanwhile, length of predetermined maintenance interval is vital aspect to be considered in scheduled maintenance. The length of fixed maintenance interval was significantly correlated to the maintenance expenditure variance (see Table 2). The correlation analysis result supported the statement of Narayan (2003), which proved that delay or unavailable to perform maintenance work at the right time may implicate further damages or defects to the system components. Thus, additional repair and replacement costs are required to restore the system back to its acceptable operation

standard. Nevertheless, optimal maintenance interval must be achieved. Although frequent maintenance is able to enhance the quality of a system, it is costly at the same time (Moghaddam and Usher, 2010).

Besides that, proper planning for the downtimes is necessary to retain and improve the maintenance performance. The amount of failure and maintenance downtimes was significantly correlated to the maintenance expenditure variance (see Table 2). The statement of Chareonsuk et al. (1997) was supported, which stated that the downtime might be very costly. The maintenance expenditure is likely to be varied as more downtimes occur in a building system. Therefore, the downtime for maintenance must be well managed to avoid unnecessary cost. Minimal failure and maintenance downtimes should be obtained in building maintenance.

Table 3: Correlation between characteristics of condition-based maintenance and maintenance performance

Characteristic	**Maintenance Expenditure Variance**
Skilled Manager-Skill and Knowledge	**-.276****
Equipment and Technique-Availability	**-.350****
Equipment and Technique-Capability to Adopt	**-.240***
Acquisition of Data-Reliability	**-.394****
Monitoring and Inspection-Frequency	-.138

**. Correlation is significant at the 0.01 level (2-tailed)
*. Correlation is significant at the 0.05 level (2-tailed)

In condition-based maintenance, skilful and knowledgeable maintenance manager is needed for allocating appropriate manpower, providing training, monitoring the system conditions, as well as supervising the execution of inspection and maintenance works. The analysis result as shown in Table 3 stated that the level of manager skill and knowledge was significantly correlated to the maintenance expenditure variance. Condition-based maintenance is meant to prevent system failure by monitoring the system condition and restoring the system to its required standard before failure occurs. When a manager does not have sufficient skill and knowledge to adopt the condition-based maintenance effectively, defects and failures are likely to occur. Thus, additional maintenance cost will be required for the repair works. As a result, the exact maintenance expenditure varies from the planned maintenance expenditure.

Additionally, the availability of condition monitoring technology may help to improve the maintenance outcome. It was found that the availability of equipment and technique significantly correlated to the maintenance expenditure variance (see Table 3). Since Tsang (1995) mentioned that the availability of reliable monitoring and inspection technology is one of the factors to be concerned in condition-based maintenance, the selection of monitoring equipment and technique must be suitable for the monitoring and inspection of building systems. Therefore, the probability of system failure is minimised. The maintenance expenditure variance is prevented as well because emergency repair cost is reduced.

Meanwhile, specific monitoring and inspection tools and equipment require the expertise to operate and use them in condition-based maintenance. The capability to

adopt equipment and technique was found to be significantly correlated to the maintenance expenditure variance (see Table 3). According to Carnero (2006), it is complicated and costly for an organisation to acquire the condition monitoring tools and technology. If yet, the maintenance personnel are not capable to utilise those tools and technology, more maintenance issues might be occurred. Additional maintenance cost will be needed to solve the problems. Therefore, the exact maintenance expenditure varies from the planned one.

Furthermore, system condition data and information is one of the most important aspects to be considered in condition-based maintenance. In this maintenance strategy, the maintenance tasks such as replacement works are implemented when the parts are almost end of their lifetime by referring to the condition data. The reliability of data and information was found to be significantly correlated to the maintenance expenditure variance (see Table 3). The primary aim of condition-based maintenance is to prevent failure occurs by monitoring the condition of building systems. Basically, emergency repair cost will not be allocated in planning stage of this maintenance strategy. However, when the obtained system condition data is not reliable and accurate, the occurrence of sudden breakdown may not able to be avoided. As a result, additional maintenance expenditure is required for the repair work and it varies from the planned maintenance expenditure.

CONCLUSION

The significance in selecting appropriate maintenance strategies to improve maintenance performance should be emphasised in maintenance management. Through examination of literature, the characteristics of scheduled maintenance and condition-based maintenance were found to be directly influencing the maintenance cost performance. Therefore, it is important to understand the influences of the characteristics in whole maintenance process, which is from planning to outcome of maintenance. In this research, the Spearman's rank correlation coefficient detected significant correlation between characteristics of maintenance strategies and maintenance cost performance. Thus, those significant characteristics as stated below should be taken into consideration in planning and execution of maintenance program:

Characteristics of scheduled maintenance:

(a) Level of skill and knowledge of labour
(b) Level of stock of spare part and material
(c) Quality of spare part and material
(d) Length of predetermined maintenance interval
(e) Amount of maintenance and failure downtime

Characteristics of condition-based maintenance:

(a) Level of skill and knowledge of manager
(b) Availability of equipment and technique
(c) Capability to adopt the equipment and technique
(d) Reliability of system condition and maintenance data

As a conclusion, the research result would allow the practitioners, such as maintenance personnel or organisation to be clear on which aspect of maintenance strategies they should concern in maintenance activities to improve the maintenance cost performance.

HOW TO MEASURE PRODUCTIVITY: A REAL POSSIBILITY

Luís Otavio Cocito de Araújo[1] and Paulo Eduardo Sampaio[2]

[1]*Department of Civil Construction, Federal University of Rio de Janeiro, Rio de Janeiro, 29949-900, CT, BL D, S207, Brazil*

[2]*Department of Civil Engineering, State University of Rio de Janeiro, Rio de Janeiro*

ABSTRACT

Although there are numerous ways to quantify loss of labor efficiency, they have failed in several aspects and disappointed expectations for not being rigorous. The quality of productivity measurement is directly associated with the quality of improvement actions. This paper presents an innovative tracking model of data on work hours and units of outputs in construction projects. The tool developed for that purpose is presented briefly. Its use offers new possibilities for productivity metrics, as productivity indices are determined according to the concept of stratification of productivity. The success of the proposed model is corroborated by the results of its implementation in the major oil and gas company of Brazil. The studies of construction gain a new perspective about productivity management.

Keywords: Labor Productivity, Measurement, tool

INTRODUCTION

Dealing with labor inefficiency is generally seen as a quite difficult task. Although there are numerous ways to quantify labor efficiency loss, they have failed in several aspects and disappointed expectations for not being rigorous.

As industries need to improve their productivity, measuring is necessary. However, the method of measurement needs to be carefully conceived and designed, so that the complexity of construction projects is considered. In accordance, Caldas et al. 2010 makes the following remark: “Therefore, to improve the productivity of any onsite operation, it is important to rapidly record relevant data on utilized resources and methods in the operations and the output quantities produced by the operations. Timely and accurate productivity information brings an immediate awareness of project specific issues to construction management, and empowers construction management to take prompt corrective actions, thus avoiding costly delays. There is sufficient evidence to suggest that onsite productivity measurement is the premise for making any productivity improvement decisions.”

[1] luis.otavio@poli.ufrj.br
[2] pauloasampaio@gmail.com

The choice for an appropriate method of measurement is a challenge, as "most of these methods are manually intensive, resulting in relatively outdated information and expensive data collection systems" (McCullouch 1997; Cheok et al. 2000). Gouett et al. 2011 argues that metrics – such as labor productivity - have been criticized because they are often calculated weeks or even months after the work has been completed, once reports from the superintendents are received. That kind of measurement does not enable the correction of problems while work is evolving. Results frequently come when the project is well off schedule and budget.

In general, delays in responding to claims, high operational costs and insufficient information are some of the criticisms made to most common metrics that address productivity, and this is the case of labor productivity as well.

Whenever labor productivity is measured in construction, variations are identified; so understanding those variations is fundamental for any process of productivity improvement. Nevertheless, all productivity methods are limited to the only purpose of releasing the productivity value. The clues to understand the variations are part of another information package, usually obtained by means of interviews, observation etc. Associating that information with productivity is a hard task.

It would be easier if the factors that influence productivity and, thus, cause variations were presented separately for identification and treatment. It would be even better if the impact of each level could be measured, as Caldas point out "in order to understand the factors that affect productivity, there must first be an effort to track it" (Caldas et al. 2010). The motto "get measured to get improved" applies in this case, as it suggests that every process of improvement necessarily requires a robust metrics system.

The present authors understand that measurement quality is directly associated with the quality of improvement actions. In this work, a robust measurement system is presented and discussed in light of a crucial concept: "Stratification of Productivity". This metrics system promises various new management perspectives, to be discussed in future works.

OBJECTIVE

The objective of this paper is to present an innovative model of tracking of work hours and units of outputs in construction projects. With this model, the present authors aim to respond to the criticisms made to obtaining of metrics.

Data collected by the model allow for the stratification of labor productivity (Araujo et al. 2012). This concept is the basis of the productivity management model (Araujo et al. 2011), developed by the authors of this article with the support and endorsement of a major Brazilian company.

In addition, this article is aimed at demonstrating the viability of this tool in construction sites, taking into account the figures that corroborate its dissemination in that major Brazilian company.

BACKGROUND

A considerable effort has been invested in the promotion of techniques for the evaluation of labor activity as tools for the productivity treatment. Work sampling techniques are an example of those efforts.

Lately, research work has been revisited (Picard and Seay Jr. 1996; Jenkins and Orth, 2003; Picard 2004), resulting in proposals to treat productivity improvement by applying work sampling. Even more recently, Gouett et al. 2011 presented the Activity Analysis model as a continuous productivity performance improvement process. Companies have made public the use of this model (Toon 2011) and their satisfaction with its results.

In general, there seems to be a movement of academia and companies towards adopting the model of activity analysis to support their programs of productivity improvement. The motivation for the use of this model is in part attributable to the difficulties of construction companies in executing metrics.

The present authors, however, having a 10-year experience with research about productivity in Brazil, agree with Thomas 1991 on what he proposes: "direct-work percentages from work sampling studies cannot be used to predict labor productivity measured as the work hours per unit of output."

New automated tracking systems (Chi and Caldas, 2012; Lee et. al. 2012; Caldas et. al, 2010; Bohn and Teizer 2009) are promising, but they still require a long trajectory of development to become an effective tool. Yet, they incur the risk of never being capable of tracking information with the desired level of detail, which could only be achieved with human intervention. The high complexity of construction sites, their big dimensions, the impossibility of limiting or restricting areas are some of the aspects that invalidate the use of automated tracking techniques.

The present authors adopted the premises of the Factor Model (Thomas and Yiakoumis 1987) to approach labor productivity in 2007 (in the beginning of this research) believing it was the most appropriate model to measure and improve productivity.

However, the model has one limitation, as Caldas et. al 2010 illustrates: "because of the manual efforts required in input and output quantity collection, the productivity information in the project level information systems is often slowly updated (every one to two weeks), leaving such systems only suitable for the purpose of macro project control, such as cost tracking, and impractical for supporting rapid response to problems that cause productivity loss in ongoing operations."

This article will demonstrate how that limitation was removed.

CONTEXT OF THE STUDY

In 2007, the authors of this article started to develop a tracking model guided by one critical premise for an appropriate management model: the productivity indicator must respond to stratification (Araujo et. al. 2012). The tracking of inputs and outputs must allow for an overall U.R. value as a sum of fractions, in accordance with the concept of "productivity stratification".

That concept responds to one of Thomas' questions: the difficulty to interpret the actual productivity curve (i.e. the one that considers the presence of all the factors at the same time).

The author argues that if those factors could be discounted from the actual curve, an ideal curve could be obtained, representing the reference productivity for a certain service (Thomas and Yiakoumis 1987).

Thus, a tracking model, inspired by that premise, was developed, applied and validated within three research projects. Those projects were established with the major oil and gas company in Brazil and had the purpose of measuring labor productivity in critical construction processes. Those projects were named IPOP I, IPOP II and IPOP III and took place from 2007 to 2009.

The results impressed the company not only for the figures, but also for the quality and potential of the information released.

For the two universities, State University of Rio de Janeiro and Federal University of Rio de Janeiro, involved in the research project, a new challenge was posed: systematize the tracking model so as to make it an effective productivity measurement tool. By 'effective', we mean that this tool would have an extended use, not limited to experimental purposes, which lead to slow response time and require a highly qualified team.

The present authors' extensive experience with tracking of field data motivated a new invitation for a new research project.

By the end of 2010, a powerful tracking model, previously validated through a pilot test, was presented to the partner company.

PRELIMINARY CONSIDERATIONS

The tracking model was developed to be used in all the steps of a construction project. The only condition for its effective implementation is that 'inputs' and 'outputs' be clearly identified and, therefore, be susceptible to tracking.

Inputs include the resources to be transformed (material) and the transforming resources (labor and equipment). Particularly, transforming resources are tracked by measuring the amount of resources by the period of time during when they are available. For example, for the labor resource, inputs are commonly measured by the number of men multiplied by the amount of hours during when they were available to work. Those inputs are conventionally identified as "Workers x hour", or simply "Wh".

Given the need to standardize the productivity indicator and to allow for its stratification, it is important that the tracking of "workers" and "hours" follows a set of definitions.

Regarding the tracking of Workers, the convention to determine the U.R. presented in the previous literature are respected (Thomas and Kramer, 1987; Thomas et. al. 1990). For instance, only Workers who belong to the direct production staff or "direct labor" are considered.

As for the tracking of hours, the only premise adopted from productivity management manuals is that the hours available to work be considered.

The tracking model advanced as it reviewed the procedure to track the hours available to work. Along the day, "Workers available to work" conduct diverse activities. Tracking the time spent in each of those activities then becomes the main premise for the tracking of hours in the proposed model.

Thus, instead of tracking just the available hours (h), the "Hours Spent by Activity" are tracked. That new proposal is the main driver for the application of the productivity stratification concept.

It is important to mention that activities must be previously defined. Thus, the observer will be able to register data respecting the existent classes of activity.

In order to structure and standardize the "Hours Spent by Activity" tracking, an "Activity Analytical Structure" – AAS – is generated. The AAS is a labor stratification tool that considers the activities identified by the observer. It is structured as a hierarchical tree (from the most general activity to the least one), taking into account the usual activities of a work day.

The AAS should be developed aiming at:

i. respecting the first level of occupations (ID1), composed of seven classes of activity, which are a standard for all and any production process to be monitored;
ii. decomposing each ID1 category hierarchically in secondary levels of activity, hereafter called ID2, ID3....IDn, with the purpose of identifying the termination activities (i.e. those that "reveal" the activity with which workers are involved at a painstaking level of detail).
iii. facilitating the understanding of the sequence of activities typical of a day of work, serving as a powerful communication tool.

First Level of Activities

The seven classes of standard activities were defined and delimited in a period of two years of work, involving exhaustive field applications, debates with specialists, etc. The seven categories of the ID1 are, therefore, fully validated. Figure 1 illustrates a hypothetical work day, with the tracking of hours by class of primary activity. This example shows the seven categories of ID1 as indicated by the tracking model.

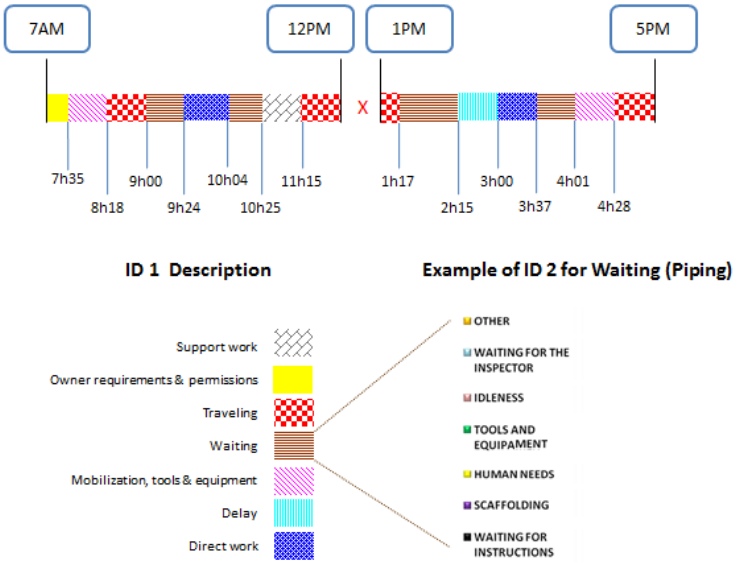

Figure 1. New proposal of work hours tracking.

Class of Secondary Activities

From the first level, the seven classes of activity are subdivided into secondary classes, which gain particular characteristics according to the construction process. The secondary classes can be subdivided until a "terminal activity" is reached, which provides a maximum level of details about the activity with which "Workers" are involved.

 ISBN: 978-1-84219-840-7 .

As each construction process has specific characteristics, its classes of secondary activities are unique. However, from the moment an AAS is defined for a certain process, it should not change, not to hamper future comparisons. The AAS should be documented and preserved by the company. Figure 1 shows an example of secondary class (ID2) for the ID1 "Waiting" – in this case for the assembly of piping.

PRESENTATION OF THE TRACKING MODEL

The Tracking Model is implemented by means of a software specifically developed for the purpose: "PRODCAT". This software was developed in Microsoft .NET and runs in mobile devices (PDAs) in the Windows Mobile operating system.

The tool is operated by professionals of a technical level, previously trained to deal with the following items: i) the functionalities of "PRODCAT"; ii) the characteristics of the process phase that will be monitored; ii) the corresponding analytical activity structure (AAS). The training of these technicians, including the implementation of a pilot tracking, takes three days.

After the construction process and phase to be measured are defined, the technicians start an intensive monitoring of the staff of workers involved.

The definition of the size of the sample (n) considers the following items: i) identification of the total amount of workers in the professional categories that will be monitored; ii) estimation of the number of days that will be tracked; iii) total hours of the amount of workers to be monitored – Population Size (N). The following statistical premises are considered: i) proportion of the occurrence of the event: 50% - p = 0.50; ii) proportion of the non-occurrence of the event: 50%: (1-p) = 0.50; confidence level (d) at 95%: d = 1.96; sampling error (e): 5%: e = 0.05, along the work day.

The focus of the tracking is on the staff of workers, which is chosen randomly (among the staffs that are suitable for the phase/process concerned) in the beginning of the day.

"PRODCAT" is used to collect the hours available to work of all the workers of the staff under monitoring (considering the activity with which workers are involved in each moment); the service accomplished by this staff; the content and context factors; and the daily disturbances. Figure 1 shows some of the main screens of "PRODCAT". The central screen is highlighted.

All and any change of activity of each component of the staff along the work day is registered (Figure 1-A). Whenever one or more components of the staff engage in the "service" activity, the observer identifies the type of work being executed, considering a pre-list of possible outputs (Figure 1-B). Whenever there is a modification of one or more context /content factors during the work day, the observer registers the change (Figure 1-C). All and any abnormality along the work day is registered in the observation field (Figure 1-D). New workers, who become components of the staff along the work day are added (Figure 1-E).

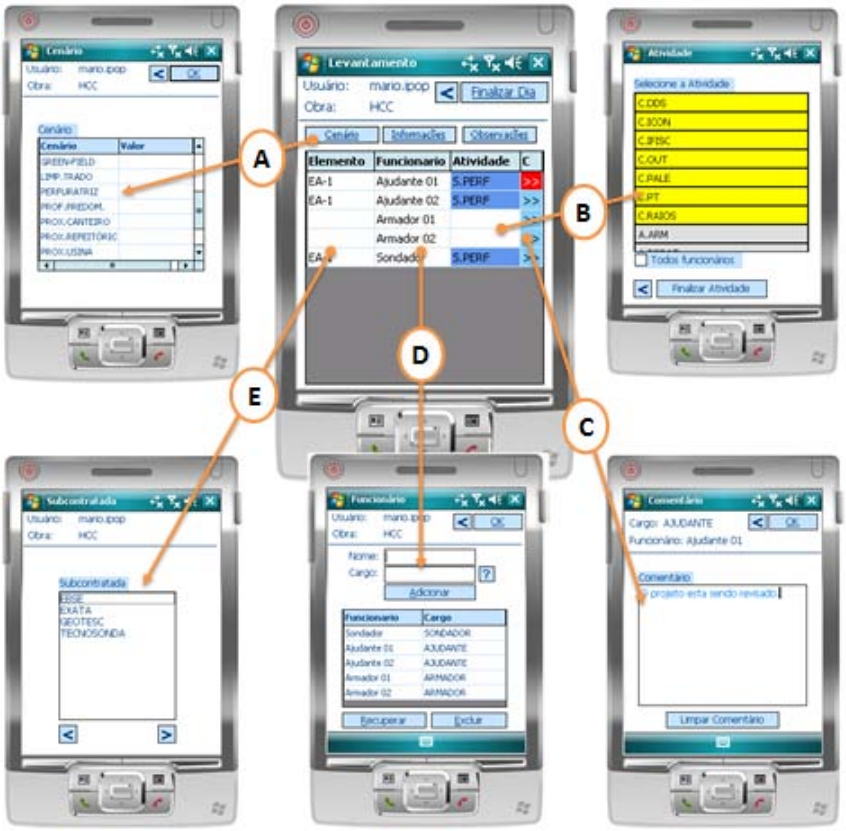

Figure 1 – Main screen of PRODCAT

At the end of the day, the technicians upload the file via a wi-fi network. Upon the completion of the upload process, the productivity of the day can be analyzed by means of reports automatically generated via a specific web system (to be examined in a future article). Some of the data from those reports are presented below.

EXAMPLES OF INFORMATION MADE AVAILABLE

In Figure 2, labor productivity (piping assembly) collected on the day "n" was 21 Wh/joint. The graph shows the labor productivity rate in further detail. Analyzing the metrics, one can see that 8 Wh were spent in service; 2, in delay; 3, in mobilization; 3, in tools & equipment; 10, in waiting; 3, in travelling; 1, in attending owner requirements and instructions; and 1 Wh in support to do one joint.

Caution with each activity seems to favor the improvement of productivity. It is import to highlight that the stratification of the productivity rate into further levels of activity can be obtained for any period of time monitored by means of the PRODCAT. The information is not limited to the first level of activities. For example, if the fraction corresponding to "waiting" is exerting a major impact on the composition of the indicator of productivity, the tracking model allows for the investigation of the most representatives reasons for the interruptions.

 ISBN: 978-1-84219-840-7 .

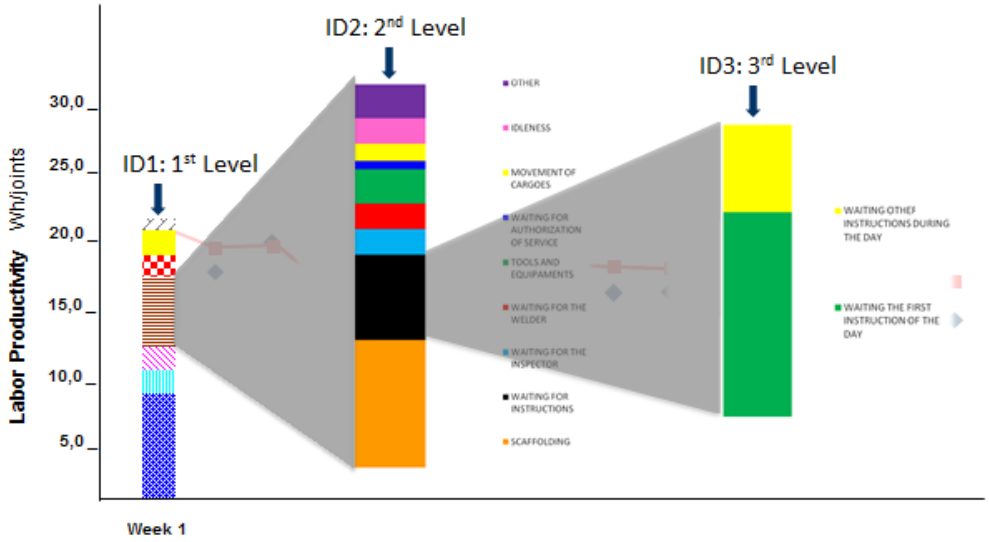

Figure 2 – Stratification of labor productivity

Each indicator of productivity brings a set of data pertaining to the work performed (Figure 3). It is the content factors - piping diameter, material and welding processes for piping assembly - and the context factors, as show in Figure 3, that will contribute to the understanding and interpretation of labor productivity.

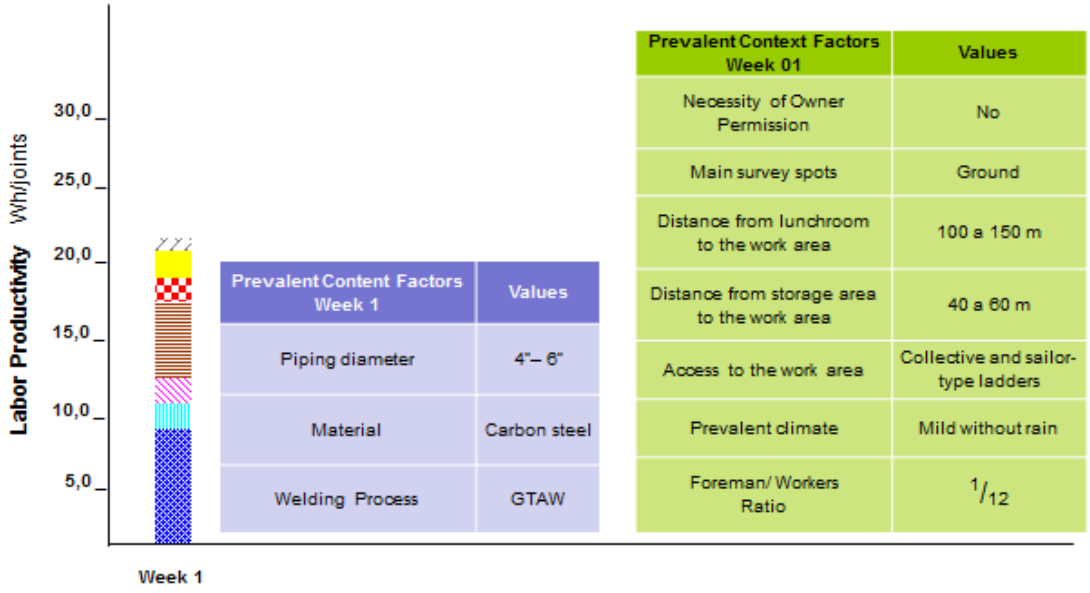

Figure 3 – Prevalent Content and Context Factors of week 1

CONCLUSIONS

It is important to mention that all the processing, as shown in Figures 2 and 3, is done in a system specially developed for this purpose. Thus, the period of time elapsed from the tracking of data in the field to the availability of information processed takes a few minutes. This makes productivity management more dynamic.

The tracking model presented in this article is an important tool for productivity management, because of the following characteristics: i) it adopts and respects the premises of the Factor Model as a methodological framework; ii) it facilitates the interpretation of productivity curves; iii) it enables the stratification of the

productivity indicator (a requirement for productivity management programs); iv) it endows the productivity indicator with the capacity of being "self-explanatory"; v) it automatically aggregates content and context factors to the productivity indicator, what is fundamental for the understanding of occasional variations; vi) it enables comparability and productivity analyses.

The PRODCAT has been used since January of 2010 by the Brazilian company that was a partner during its development. In May of 2012, more than 50 technicians used the tool daily. Up to May 2012, the company estimated more than 160 thousand work hours tracked in accordance with the model proposed in this article. In general, the tool has contributed for the understanding and improvement of productivity in the company's ongoing construction works.

ABSTRACT

Problems in making deadlines are frequently considered a case of lack of resources in Brazil rather than a case of inefficiency in the use of available resources. The present authors defend that unproductivity should be targeted in order to mitigate construction delays. A new model to manage labor inefficiency in construction sites is presented in this article in light of the new concept of productivity indicator stratification. This concept enables the demonstration and quantification of the causes of inefficiency in the use of labor. Two real cases, resulting from two research projects conducted with the largest company of Brazil, are analyzed in the article. They reveal that productivity management, if properly treated, contributes to the management of deadlines in construction projects and, therefore, to the minimization of schedule delay damages.

Keywords: Labor Productivity, Scheduling; Construction industry; Delay time.

INTRODUCTION

Schedule delays in construction work can cause considerable financial damage. For clients, delays in inaugurating industrial plants lead to major revenue losses. For contractors, schedule delay losses cause both financial damage and annoyance as a consequence of claims from clients. In general, delays lead to “late completion, lost productivity, acceleration, consequential damages, increased cost, and contract termination” (Ardit and Pattanakitchamroon, 2008).

In Brazil, problems in making deadlines are frequently considered a case of “lack of resources rather than a case of inefficiency in the use of available resources” (Araujo et al. 201, work presented in the CII Annual Conference). However, increasing the amount of resources has proved ineffective to respond to problems with deadlines in the Brazilian reality due to the lack of qualified and available labor and to the increase in costs and complaints.

Particularly, among the most relevant reasons for delays in construction – the lack of qualified labor, inefficient technology and poorly detailed execution projects – the matter of labor efficiency stands out. In recent studies, there has been some emphasis on the fact that "schedule delay damages and losses of labor efficiency go hand-in-hand" (Thomas 2010).

One of the most common metrics to describe labor efficiency is the "labor productivity" (the ratio of work hours to units of output). But this metric has been criticized because it is often calculated weeks after the work has been completed, when the reports from the superintendents are received. The problem of measuring productivity this way is that "areas of low productivity are identified in the site office well after the issue first occurred on-site". Gouett et al. 2011.

OBJECTIVE

Dealing with labor inefficiency is generally seen as the most difficult task in a productivity management program (i.e. a process of continuous improvement of labor productivity aimed at mitigating delays in the finalization of civil construction work). Although there are numerous ways to quantify labor efficiency loss, they have disappointing expectations.

The objective of this article is to present a new model to cope with labor inefficiency, capable of responding to the gaps shown by the literature. This model can determine the causes for inefficiency and quantify their impacts on productivity. It enables the comparability of productivity across projects and the correlation of factors with productivity metrics – crucial capacities for the effective study of labor productivity (Liao et al. 2011).

The article is introductory for it reveals the foundations of this new methodological proposal, already developed, validated and implemented by one of the biggest oil and gas companies of the world.

BACKGROUND

Gouett et al. 2011 presented the difficulties in establishing a robust methodology to measure labor efficiency loss in construction work. Regarding this aspect, Thomas (2010) pointed out that "one reason why it is difficult to recover for loss of efficiency claims is that there is no rigorous methodology for quantifying loss of inefficiency damages". In addition, the author argued that "an important point to remember is that a loss of efficiency study can be subjective and the expert needs time to develop the story of what happened".

Wambeke et al. (2011) discussed the causes of variations in the starting times and duration of construction project tasks and suggested that these variations result in disruptions to the schedule and/or decreased productivity. They argued that "there is a gap in knowledge in terms of identifying the root causes of variation and their magnitude". Through a nationwide survey, they identified the top eight causes of starting time variation and top nine causes of task duration variation. The authors' conclusions benefit managers, as they put forward a set of causes for variations in construction tasks. However, the occurrence and impact degree of those causes vary according to the construction work, processes and phases. It is more effective, then, to know the causes in association with the specific needs of the construction tasks.

Identifying and measuring the real impact of the causes of productivity loss is a gap this article takes into account.

 ISBN: 978-1-84219-840-7 .

PRELIMINARY CONSIDERATIONS

In the present days, two primary purposes for measuring productivity are usually taken into consideration (Thomas et al. 1986): (1) to control project cost and schedule; and (2) to obtain data for planning.

The first purpose (Thomas and Mathews 1986) can be easily understood by rewriting the equation that measures the labor productivity rate (U.R.) (Telles et al. 2011).

_____ _____

The U.R. equation can be rewritten as follows:

_____ (02)

Time can be measured by the number of hours spent on a day of work. Thus, the equation can be rewritten once more as follows:

_____ (03)

Or yet:

_____ ( )

For the same amount of service, there would be two ways for reducing task duration: increasing resources – more craftsmen, hours or both – or improving productivity – by reducing U.R. values. The first option has financial impacts and offers no guarantees, since human resources are hard to control. However, this is the common option adopted in Brazil.

In a different direction, the authors of this paper chose to measure labor efficiency to mitigate delays in construction. When challenged by one of the largest companies of the world, the present authors did not hesitate over whether to adopt the factor model as their methodological basis.

To develop a productivity management tool considering the factor model, the main challenge was to develop a tool that: i) could be understood by companies; ii) could be operated by professionals from these companies; iii) presented low operation and implementation costs; iv) provided very rapid and precise responses to construction work managers.

After over two decades of research to validate the factor model (Thomas et al. 1990), the authors start corroborating a possibility put forward by Thomas et al. 1990: “The factor model **is** the best tool currently available for studying the causes of productivity.”

Need for a New Approach

The literature on labor efficiency loss emphasizes that measuring the influence of productivity factors is equally important and difficult. The main difficulty is associated with the isolation of the factors and their separate treatment. Another difficulty lies in the identification of the impact of each factor, since the level of this impact is not constant. For instance, a contextual factor such as temperature in the

work environment is perceived differently by different people, exerting diverse influences on productivity.

Case 1 (see Figure 1) illustrates the fact that knowing and measuring the influence of factors could explain the unit rate (U.R.) variations.

In this case, labor productivity related to a certain service was measured in five different construction sites (Figure 1, represented by letters A, C, D G and H) with very similar characteristics - phase, size and typology. The construction projects were controlled by the same company, presenting identical execution procedures and similar quality, safety, environment and health demands.

The variation among the different construction sites (Figure 1) is substantial – representing 80%. It is not possible, however, to conclude for the worst productivity level based on the graph information. The highest value of UR is not necessarily associated with the worst productivity – a possible assumption in a first analysis.

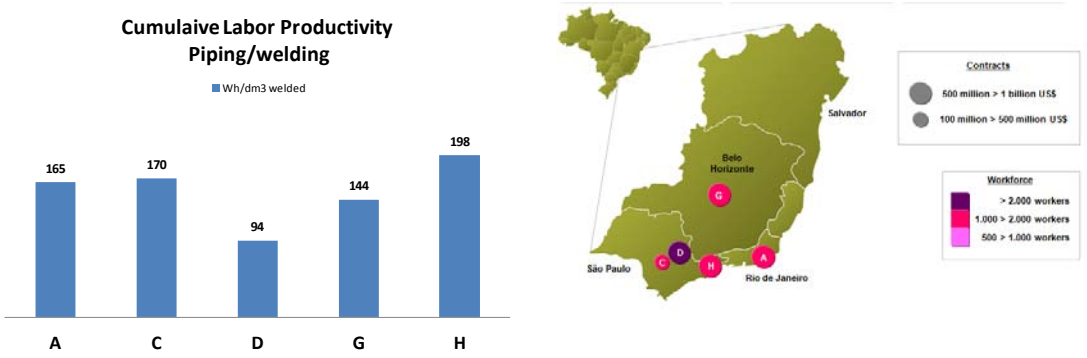

Figure 1. Case 01: U.R. variation in different construction works. Source: Telles et al. 2011

In Case 2 (see Figure 2), variations from potentially influencing factors are not significant. Nevertheless, there is a significant variation in U.R. values (Figure 2). This case illustrates that an important premise of productivity management is to consider labor in the estimation of productivity losses, when those losses occur in environments that were not influenced by content and context changes.

The productivity in the root pile execution process was measured by a group of properly prepared technicians for 65 days. The geological profile of the area presented minimum variation. The diameters of the piles did not change during the monitoring period. The group of workers remained constant; none of them were replaced in the period. The drilling equipment and the equipment for the injection of grout remained the same. Climate conditions did not change considerably.

In short words, the surrounding conditions, herein presented, remained unchanged from the beginning to the end of the period during which productivity was measured. Figure 2 presents the daily U.R. values determined in the period.

The U.R. variation along the days is dramatic – a difference of 300% between the lowest and the highest U.R. values. The inefficiency in the consumption of resources is clearly demonstrated.

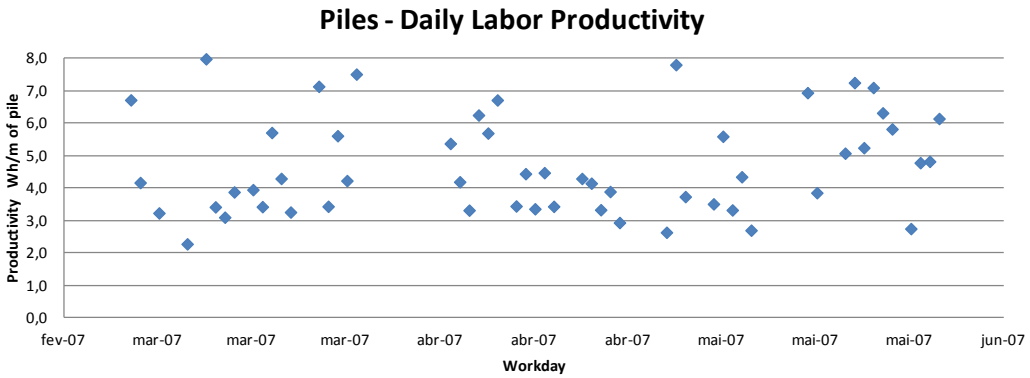

Figure 2. Case 02: daily U.R. variation in the same site with little variation in the surrounding conditions

The two cases demonstrate how necessary it is to understand the reasons why the productivity indicator value changes. Some questions should be particularly investigated: (1) Could the highest, and consequently worst, U.R. values, be mitigated? (2) What is necessary to obtain the best U.R values more frequently, provided that their obtaining has been proved feasible? (3) What is the path to obtain practical and rapid responses, avoiding an exhaustive search for explanations? (4) From what point could managers start addressing the U.R. variations reported in case 2, for example?

NEW APPROACH

The Construction Industry has specific characteristics when compared with the traditional Manufacturing Industry. In a factory, workers find a pre-prepared environment, with the inputs, equipment and instructions necessary for the task execution. Workers hardly ever leave their work post – just for physiological needs.

The environment of the Construction Industry is totally different. Inputs and equipment may not be available, and workers may leave their work post to obtain resources. In addition, interference from simultaneous activities may interrupt tasks temporarily.

The cases studied herein are examples of the following conclusion concerning the construction industry: the time converted in effective service - *the period when workers are found in their work post, putting in their efforts with the only purpose of executing the operation that characterizes the service concerned* - is just a part of the workers' time in a construction site during their work day.

When workers are not directly involved with their main work activities, they are involved with complementary and/or secondary activities or with no activity at all. Irrespective of the nature of these activities, all the hours spent are measured, considering they constitute the work availability period.

Productivity tracking techniques estimate available hours without distinguishing the type of use that is given to those hours – idleness, effective service, waiting, etc. Eventually, the obtained indicator reflects an overall productivity value, of which interpretation is quite difficult (c.f. cases 1 and 2).

Finding influencing factors, which may explain productivity variation, requires the identification and follow-up separation of productivity fractions not affected by those factors. In order to determine the productivity fractions, work hours (inputs) are tracked according to the nature of activity (Figure 3). This new tracking method,

namely "stratification of productivity" (to be discussed in another article), enables the treatment of productivity as a sum of identified and independently measured fractions, rather than as an overall "closed indicator".

The productivity stratification (see Araujo and Sampaio, 2012) facilitates the identification of influencing factors, and the presentation of U.R. in "fractions" enables the thorough examination of unproductivity, as its exceeding factors are revealed, identified and quantified all at once.

Influencing factors may be specific for each U.R. fraction concerned, or there may be U.R. portions that are not affected by content and/or context factors. For example, if the 'service UR' is isolated, it is possible to know which content factor is correlated with it, or yet, if no influencing factor is correlated with it.

Considering the U.R. presented in Figure 3, the quality of information made available (especially considering it is about the same data presented for case 1) is remarkable. The following readings can be obtained: i) the U.R. fraction potentially influenced by content factors – named service U.R. – presented low variation; except for D. This conclusion is corroborated by the analysis of the service content factors, which remain virtually unchanged among A, C, G and H; ii) the U.R. fractions corresponding to "waiting" are highly significant, surpassing the service U.R. – C and H; iii) the other fractions show the impact over the overall productivity caused by idleness, displacements, monitoring by inspectors, support services.

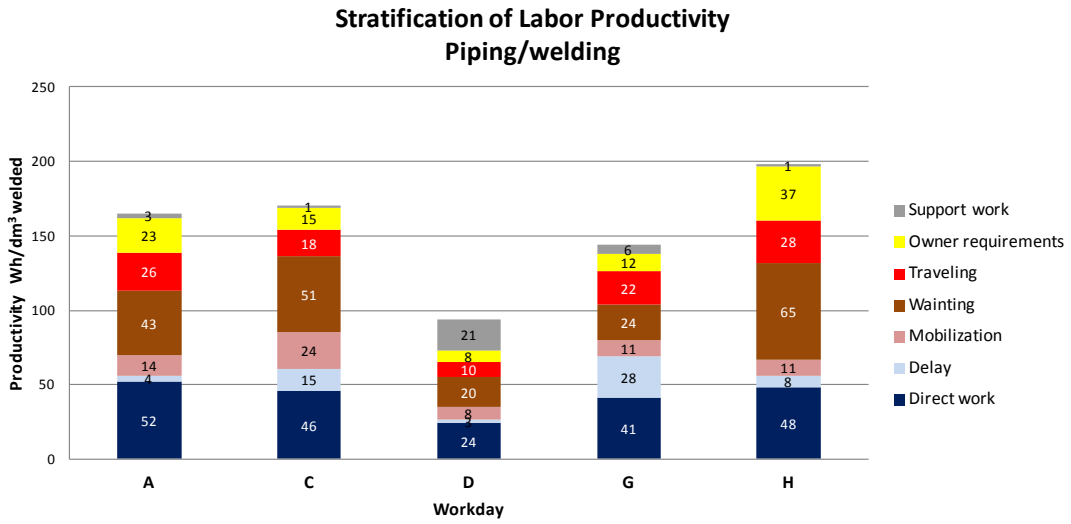

Figure 3. U.R. Stratification

In sum, the new model makes the exceeding factors explicit, favoring actions to reduce the overall UR. The challenges particularly posed by Case 2 can be addressed for each productivity value can be analyzed separately. For a daily value or for an overall value referring to any period of time, the stratification of the indicator enhances the analysis by providing the following possibilities: i) real knowledge of productivity; ii) identification and quantification of unproductivity; iii) identification of the causes and of the responsible areas for unproductivity, etc.

Figure 4 shows the stratification of the cumulative labor productivity presented in Case 2. The main causes of the "waiting U.R." are highlighted.

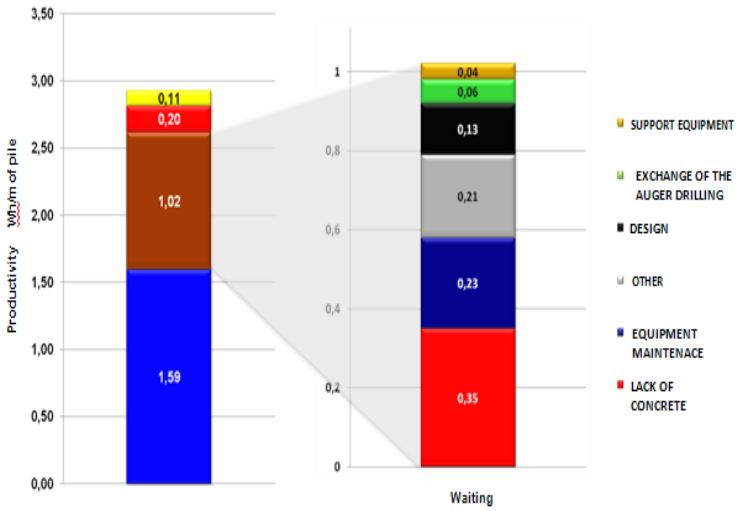

Figure 4. An example of productivity stratification for Case 2

CONCLUSIONS

The productivity stratification reveals virtues and faults of production processes with respect to the efficiency/inefficiency in the use of resources for the generation of goods and services. By doing so, it also reveals the responsibilities and the responsible areas for the rights and wrongs in construction processes.

The model presented in this article proves relevant for labor productivity management and, consequently, for schedule management for the following reasons:

i. It stratifies the productivity indicator – usually "closed" and difficult to be interpreted – in quantifying fractions, organized and structured according to a pre-conceived hierarchical model (analytical structure of activities).

ii. It points to two paths towards the improvement of productivity. One is focused on the treatment of the productivity fraction exceeding factors. The other focus on the identification of influencing factors – positive influences should be replicated and negative influences, mitigated, whenever possible.

iii. It determines and quantifies the impact of labor unproductivity. The productivity fractions, identified as "exceeding factors to be eliminated", that is, "unproductivity", can be analyzed in terms of frequency and relevance, favoring actions towards its reduction.

iv. It identifies those who are responsible for "unproductivity", favoring targeted claims that will result in faster and more efficient responses.

Finally, opinions, pseudo-paradigms, speculations are replaced by safe and exact information, which can be obtained by means of a rigorous and non-biased metrics and which is made available in a simple and objective way.

MISTAKE-PROOFING: PREVENTING QUALITY FAILURES IN THE UK CONSTRUCTION INDUSTRY

Prof. James Sommerville[1], Dr. Nigel Craig[2], Barbara Chomicka[3]

Glasgow Caledonian University, Cowcaddens Road, Glasgow G4 0BA, Scotland, UK

ABSTRACT

The continuity of fund flow into the UK office and luxury residential markets depends to a large extent on the supply of quality products. The delivery of prized and trophy assets for high-net-worth individuals, Insurers, Private Equity, Institutional and Sovereign Wealth Funds requires robust performance-based quality management processes to be implemented at both organisational and project level. An extensive review of the literature published in the last twenty years on quality management within the construction industry in the UK suggests, that quality management practices in the industry are deficient as a result of limited attention being given to design verification and review processes by design organisations and inadequate reflection after project completion. However, the continuous supply of prime assets suggests, that construction firms involved in their delivery developed robust processes which allow them to overcome the quality problems and achieve the required quality excellence. The applied performance-based quality management systems, which involve the extensive use of samples and mock ups, are linked to the widely implemented, in the manufacturing industry, mistake proofing (Poka Yoke) concept. However the considerable cost and programme implications of their deployment limit their application in the wider construction industry.

Keywords: defects, quality cost, quality management.

INTRODUCTION

The UK construction industry image and its reputation are still deeply rooted in the past (Chomicka 2012). The industry image is equated with the findings of a review of its procurement and contractual arrangements contained in the Latham Report (1994) together with the Egan Report (1998). These reports identified industry practices as being 'ineffective', 'adversarial', 'fragmented', 'incapable of delivering value for its customers', 'lacking respect for its employees' (Latham 1994) and found the industry to have low profitability, too little capital investment, insufficient research, development and training and that too many of its clients were dissatisfied (Egan 1998). Since publication of both these reports, they are widely being referred to in academic research and press reports.

[1] J.Sommerville@gcu.ac.uk
[2] Nigel.Craig@gcu.ac.uk
[3] bchomicka@gmail.com

 ISBN: 978-1-84219-840-7 .

In the 18 years since the Latham Report (1994), industry practices have changed in line with competitive dynamics and advances in technology (such as the arrival of the internet). There is a constant flow of funds into the UK office and luxury residential markets, which depends to a large extent on the supply of quality products. The UK construction industry successfully delivers prized and trophy assets for high-net-worth individuals, Insurers, Private Equity, Institutional and Sovereign Wealth Funds. This continuous supply of prime assets suggests that UK construction firms involved in their delivery developed robust quality management processes based on methods prevailing in the manufacturing sector.

The adoption of quality management practices used in manufacturing sector and further adopted within the construction industry is not a coincidence. The subcontractors involved in delivery of prestigious office and luxury residential schemes in the UK often come from various manufacturing industries and include, for example, yacht manufacturers. The majority of these companies operate internationally, are not UK-based businesses although some employ a UK-based workforce. On prime and super prime residential project, subsequent trades take possession and sign-off the works of their predecessor and it is not uncommon for example that a specialist painting firm would refuse to accept its predecessor's works (painters or plasterers) if the insufficient quality of preceding trades would compromise the quality of their own works.

The niche prestigious office and prime residential market sector in the UK influenced a shift in the UK construction industry from prevailing certification-based approach to quality towards complex performance-based systems. As part of this shift, a widely implemented mistake-proofing (Poka Yoke) system in the manufacturing industry found its endorsement in the construction industry. As indicated in Dos Santos and Powell (1999) observations, due to the one-off nature of construction industry's products and the specific manner of their assembly, the Poka Yoke approach could not be directly translated into construction. Instead, the concept has been adapted to reflect construction industry-specific circumstances and is commonly found in the extensive use of samples and mock ups on quality-driven projects.

RESEARCH METHODOLOGY

The following two research methods were selected: literature review and review of prestigious commercial office and prime residential case studies. In line with this approach, there are two phases in this study: 1) Investigation of existing research and 2) Exploration and interpretation of specific case studies to complement literature review. There were three commercial offices and four residential case studies (one 'affordable', one luxury, one prime and one super prime) used in this research.

A literature review was chosen as a staring point of this research to establish subject background, learn from other research, formulate research problems and synthesise the work of others. The findings of earlier research was used to analyse the introduced case studies, which were hand-picked by the researchers to best illustrate the link between quality management practices utilised in the manufacturing sector and UK construction industry. The findings of the literature review suggest that there are two main streams of Poka Yoke concept exploration: one focused on achievement of zero defects on completion and the second concerned with 'idiot proofing' of solutions against misuse by the end user. In the light of this presentation size constraints, the

 ISBN: 978-1-84219-840-7 .

Poka Yoke devices analysed in this research have been narrowed down to two methods of mistake-proofing to deliver a 'zero defects' product – samples and mock-ups.

QUALITY FAILURES IN THE CONSTRUCTION INDUSTRY

The problem with mistakes (quality failures) exists in every industry; nevertheless the construction industry is constantly being compared in an unfavourable light to the manufacturing industry, and car industry in particular. The construction industry's products are no different to products manufactured by other industries; however, they tend to be much more expensive. Unlike the periodic or temporary extensive editorial criticisms of car manufacturers during their product recall periods, the issue of quality failures in the construction industry is a constant subject of public debate. There are numerous blogs, websites, newspaper and magazine articles and television programmes dedicated to this issue, predominantly in the residential sector setting. The reason for this situation can be found in a number of high profile instances, in which there was a significant amount of quality failures identified in buildings (Sommerville 2007) and a slow response (or no response) from inadequate product providers (developers and contractors). In the UK, over a third of new build houses have between 100 and 200 defects, with the average number of quality failures per home being 62 and there is a suggestion, that 'the problem is getting worse' (NBI 2012).

The definition of a 'mistake' in the construction industry is not an easy task. A review of contemporary research surrounding quality failures within the general construction industry indicates, that there is a wealth of quality failure definitions and terms that are often used interchangeably (Sommerville, et al. 2004). The terms such as faults, repairs (Ashford 1992), quality failures and deviations (Burati, et al. 1992), non-conformance (Abdul Rahman 1993), rework (Love and Li 1999) and defects (Josephson and Hammerlund 1999) are most commonly used in construction literature. A 'mistake' or 'quality failure' in the construction sector does not necessarily mean that something fails to fulfil its function. For example, in one of the researched case studies, the use of a white paint with different reflectivity (20 per cent) on ceiling grill units which when installed were adjacent to ceiling tiles powder-coated with the same white colour (identical RAL) but with 10 per cent reflectivity, caused a perception of a colour difference between grilles and tiles for some of the end users. The perception of a different shade of white was deemed to be a quality failure that had to be rectified by a contractor.

In order to eliminate mistakes, there has to be a process or device that would make it impossible for them to occur. A prevention technique- Poka Yoke, which was developed by Shingo (1986) for a car manufacturer, provides a tool enabling the design and delivery teams in the construction sector to eliminate quality failures.

THE CONCEPT OF POKA YOKE IN CONSTRUCTION INDUSTRY

The car manufacturing industry is renowned for the robustness of its quality management systems and subsequent quality of its outputs, particularly the Toyota Motor Corporation, is often referred to as the exemplar of quality management excellence. Although the amount of Toyota's quality failures in the last three years was substantial (Haq 2010), nevertheless its contribution to the development of

quality management thought and a method of dealing with identified quality failures make it a world-renowned exemplar. One of the most influential contributions was introduction and application of the Poka Yoke idea (Shingo 1986), which translates as 'mistake-proofing', 'fail-safe' or 'avoiding inadvertent errors'.

A Poka Yoke device is any apparatus that either prevents a mistake from being made or makes the mistake obvious at a glance. There were several attempts to investigate prevention techniques such as Poka Yoke effectively implemented to construction tasks in the UK. For example, Spear and Bowen (1999) found Poka Yoke to be 'difficult' to transfer to the construction industry and according to Dos Santos and Powell (1999) 'construction still lacks investigation into the interpretation and adaptation of this common core to its own reality'. However, Pollet and Ryall (2010) have successfully undertaken an experimental case study to investigate the potential of Poka Yoke devices application at a second-tier (subcontractors') level. In their study, electrical contractors produced a device to be used as a guide and template for cutting out electrical back boxes in plasterboard walls to an exact size to ensure that they did not cut an opening larger than required (as historically, correcting such defects has been a very time consuming exercise and involved a number of different trades (Pollet and Ryall 2010).

It is proposed in this study that another practical applications of the Poka Yoke concept in construction: samples (specimens or small quantity of products) and mock-ups (usually full-sized scale model of a structure, used for demonstration, study, or testing) permit to review design functionality, identify any buildability issues, identify opportunities for pre-fabrication, sequencing strategy and the overall quality of the end result before the construction commences. These devices also provide quality standard benchmarks for subcontractors and suppliers and therefore these sub-contractors can be performance measured.

Poka Yoke also involves a change in the mindset of the organisation (Pollet and Ryall 2010), which is particularly important in the current business landscape following the economic downturn. Nowadays, everyone involved in project delivery needs to 'think and act quality' to gain competitive advantage, or even to survive. By demanding an excellent quality end products, clients expect to reduce costs not only in the building delivery processes, but also in building's performance, administration and white-collar services associated with the building management and use (ECH 2011).

MISTAKE-PROOFING IN THE CONSTRUCTION INDUSTRY

The primary purpose of mistake-proofing is delivery of a quality product. There are various definitions of quality in the construction industry and for the purpose of this study quality has been defined as the conformance of the finished product with the contractual documentation, its alignment with projects strategic objectives and exceeding client's expectations. The design and delivery processes in construction are mapped out to meet these requirements and the studied Poka Yoke devices – samples and mock-ups – form part of the wider quality management practice. The extensive use of samples and mock ups has become an increasingly common feature of all construction projects. Samples include, for example, external cladding panels, ceiling tiles, grilles, wall panels and carpet tiles. The examples of mock ups include floor and wall junctions, bulkhead details, blind boxes, shadow gaps, doors (with frame and architraves), toilet or a kitchen. The examples of fully operational mock ups

 ISBN: 978-1-84219-840-7 .

(sometimes referred to as exemplary units), which have working ventilation to test acoustics or water supply pressure, include a full radio studio or a fully fitted apartment (to understand spatial relationships, interfaces and performance).

However, the extent and application of these devices depends on the type of construction sector client and the nature of the project to be delivered. For example in the affordable housing sector case study, in line with the design and build procurement selection with an architect being 'novated' to the contractor, an architect designed the external lighting scheme and specified the light fittings. The specification was for a 'preferred product' or 'similar approved' for the contractor to provide. Upon receipt of drawings and specifications, the contractor, in line with prevailing approach, sourced a 'similar' light fitting sample from its supply chain for the architect's approval. The sample was presented to the architect during the weekly design review meeting, over the table, and approved via subsequent e-mail and recorded in meeting's minutes. In due course, the contractor procured the fittings and installed them broadly in line with the architect's drawings. The variation between the designed locations and actual ones was due to the required method of installation of the actual fitting which was not known at the design stage or reviewed beforehand, the location of the wiring 'pulled' by MEP subcontractor (for example 5 cm more to the right), location of the gas meter and many other reasons. On the researched prime residential scheme, the design, specification, procurement and installation of the external light fitting followed a different route. The lighting scheme was designed by a specialist lighting consultant (and in researched prime residential case study there were two separate lighting consultants: one renowned for its expertise in external lighting solutions and one 'guru' in internal lighting design). The external light fitting was selected by the lighting consultant in collaboration with an interior designer, landscape designer, MEP consultant and an architect. The lighting consultant specified a particular light fitting which was then sourced as a sample for review. Two of the proposed light fittings were then installed on the mock-up of the external façade to check, whether they do not create unforeseen issues when used with a particular type of stone, the overall 'feel' and aesthetics of the proposed combination of selected light fitting and type of stone used in façade cladding (which was specified by mineralogist employed by the façade engineer) was assessed. Following the review of a mock up, the façade trade contractor's designers, in collaboration with the architect and MEP consultant, developed production drawings for the façade which included marked up holes in panels to facilitate fittings' installation. The stone-clad façade panels arrived on site pre-drilled to ensure accuracy and achievement of design intent (e.g., the required level of quality).

As can be seen in the example explained above, the relationship between quality, cost and the final price of the finished product is a determining factor when it comes to the deployment of effective Poka Yoke devices. The cost of the exemplary unit assembly is significant, for example the provision of a mock-up for a development of under 80 prime market apartments of a realised average sale value of £2,400 per sq ft (£25.833 per sq m), which was erected in contractor's warehouse within the M25, came with the construction price tag of £184,000 (plus consultants' fees which are difficult to quantify in relation to this item). Although this translated to an average of £2390 per finished apartment, once the cost of all samples which were bought within each package and mock-ups erected on and off site for design review and testing purposes, this sum multiplied accordingly. If we estimate the approximate cost of samples and mock ups on this scheme and all additional mistake-proofing measures such as

appointment of specialist consultants who are not usually found on an average residential development scheme in the UK, the total cost of these product and market-specific measures (for prime residential) is approximately £70,000 per apartment, and accounts for 4.7 per cent of the average sale value of an apartment on this scheme (£1.5m). This amount doesn't take into consideration any uplifts for quality materials or other additional costs associated with prime properties (such as, for example, the provision of private lifts and separate staircases for staff).

If we review the use of the earlier described Poka Yoke devise – a template for cutting out electrical back boxes in plasterboard (Pollet and Ryall 2010) we find many large-scale examples of similar templates' application. For example, on a confidential luxury residential scheme in London, the contractor had to produce almost 140 number of templates (one for each bathroom) for cutting out holes for fixings and services in very large mirrors, which were located behind vanity units. These templates were made of plywood (following unsuccessful trials with cardboard) and their use included testing whether a particular, envisaged sheet of glass can be successfully transported into the bathroom for installation (the design intent called for one continuous sheet of glass with no intermediate joints to create a 'luxury' feel in the bathroom).

On every construction project, the design team is expected to identify mock-up and exemplary unit requirements early in the design process. There is usually a rigorous pre-contract and post-contract sample and mock up sign off process. An example of dashboard-formatted mock up requirements template is provided in Figure 1 below.

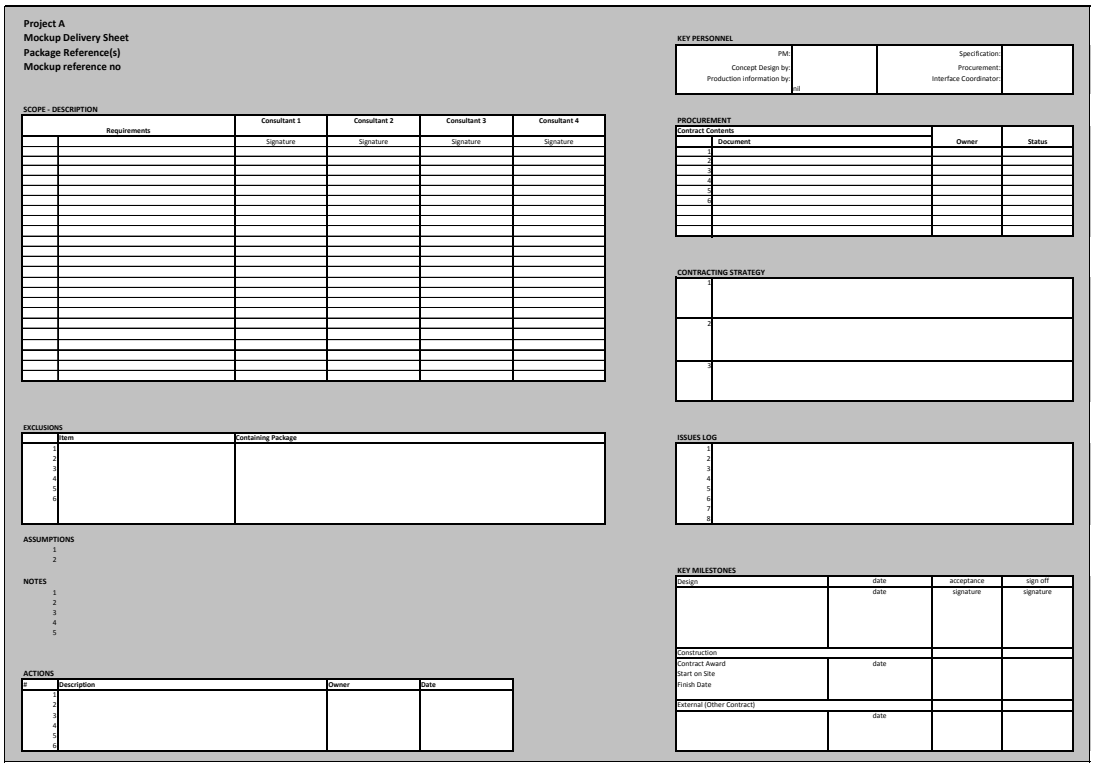

Figure 1 – Example of a mock-up requirement dashboard.

The accuracy of identifying, specifying, recording and tracking of samples and mock ups procurement and sign off processes is essential for the achievement of a 'zero defects' target and effective operation of these Poka Yoke devices.

CONCLUSIONS

Contrary to the prevailing image and reputation of the construction industry in the UK in the media and academic literature, the successful, continuous supply of quality products -- prized and trophy assets -- for high-net-worth individuals, Insurers, Private Equity, Institutional and Sovereign Wealth Funds suggests, that construction firms involved in their delivery developed robust processes which allow them to overcome the quality problems and achieve the required quality excellence. The applied performance-based quality management systems can be linked to the widely implemented, in the manufacturing industry, mistake proofing (Poka Yoke) concept and involve the extensive use of samples and mock ups.

Samples and mock-ups are used as the design development tool where the design functionality can be viewed and adjusted. In line with the findings of research in the field of quality failures in the construction industry, a great amount of workmanship quality failures can be attributable to people, design and construction. These mistakes can be avoided by the use of mistake-proofing devices such as samples and mock-ups. These measures permit identification of design mistakes, design scope gaps and to detect when the design team set the complexity bar too high, specifications does not highlight certain important issues to be observed by the contractor, the specification calls for a new material which contractor never came across before or an innovative way of materials' application which gave rise to unforeseen issues.

Samples and mock-ups are considered to be construction's best practice tool allowing the contractor to identify any buildability issues, identify opportunities for pre-fabrication, sequencing strategy, and to provide quality standard benchmark for subcontractors and suppliers to understand (and be measured against). However the considerable cost and programme implications of their deployment limit their application in the wider construction industry.

It is suggested in this research, that the extensive use of samples and mock ups is one of the most effective ways of managing quality in the construction industry and allows for less rework, fewer mistakes, fewer delays and better use of time and materials. The findings of this research create further opportunities for research on applications of Poka Yoke concept in the construction industry.

PROBABILITY DISTRIBUTION FITTING OF COST OVERRUN PROFILES

Peter ED Love[1], Chun-Pong Sing[1], Xiangyu Wang[1], and Ping Yung[1]

[1]*School of Built Environment, Curtin University, GPO Box U1987, 6845, WA, Australia*

ABSTRACT

The statistical characteristics of cost overruns experienced from contract award in 276 Australian construction and engineering projects were analysed. The skewness and kurtosis values of the cost overruns are computed to determine if the empirical distribution of the data follows a Normal distribution. The empirical distributions for the cost overruns are found to be non-Gaussian. Theoretical probability distributions are fitted to the cost overrun data. The Kolmogorov-Smirnov, Anderson-Darling and Chi-Squared non-parametric tests are used to determine the 'Goodness of Fit' of the selected probability distributions. A 3-Parameter *Frechet* probability function is found to describe the behaviour of cost overruns and provide the best overall distribution fit. The *Frechet* distribution is then used to calculate the probability of a cost overrun being experienced.

Keywords: Australia, cost, Frechet distribution, probability density function, overrun,

INTRODUCTION

A cost overrun can be classified as a 'random continuous variable' as it can take an infinite range of values. Typically, the probability density function (PDF) of the Normal distribution (otherwise known as Gaussian) has been used to determine project cost overruns (e.g., Flyvbjerg, 2007). A Normal distribution is symmetric about its mean value and therefore cannot be used to accurately model left or right skewed data. Even if cost overrun data is symmetric by nature, it is possible that it is best described using heavy tailed distribution models such as a *Cauchy*. Fitting an empirical distribution to data can be a difficult task considering the array of statistical distribution choices that are available. The selection of an inappropriate statistical distribution can produce incorrect probabilities, which can adversely affect decision-making and therefore lead to negative outcomes. In addressing this shortcoming, this paper uses data derived from 276 completed Australian construction and engineering projects to determine the 'best fit' distribution so that a realistic probability of project cost overruns from contract award can be determined**.**

COST OVERRUN

The term cost overrun is often referred to as 'budget increase', 'cost increase', or 'cost growth'. A cost overrun should, however, be distinguished from 'cost escalation', which is used to express an anticipated growth in a budgeted cost due to factors such as inflation. A lack of a standard definition juxtaposed with the inappropriate distributions models have contributed to inaccurate cost overrun probability forecasts being produced. Flyvbjerg et al. (2002) for example, defined a cost overrun as the difference between the forecasted and actual construction costs. In this instance, the budget at the decision to build is used as the reference for determining the overrun that may be incurred. Actual construction costs are defined as accounted construction costs at the time of completion. An alternative definition and reference point for determining a cost overrun have been provided by Zietoun and Oberlander (1993) who suggested that it is difference between the original contract value (i.e., contract award) and actual construction costs at practical completion. The dichotomy between definitions presented has contributed to significant variability in the cost overruns percentages that have been reported in the normative literature.

The Auditor General of Sweden (1994), for example, revealed that the average cost overrun for eight road projects was 86%, with a range from -2% to 182%. In contrast, Odeck and Skjeseth (1995) examined 12 toll projects and found the average cost overrun to be 5%, with a range of -10 to 170%. In a further study undertaken by Odeck (2004), a mean cost overrun of 7.9% and a range from -59% to 183% was reported for 420 road construction projects. For bridges and tunnels, Skamris and Flyvbjerg (1997) found the cost estimates from the decision to build to actual completion experienced a cost overrun of 50 to 100%. In a study of 258 transportation projects reported in Flyvbjerg et al. (2002), the following cost overruns were reported from the decision to build to actual completion:

- road construction (n=167), mean 20.4% with a range of 15% to 32%
- rail (n=58), mean 44.7% with a range of 24% to 60%
- bridges and tunnels (n=33), mean 33.8% with a range of -1% to 35%.

In contrast to the above findings, Vidalis and Najafi (2002) study of 708 road construction projects revealed a lower mean cost overrun of 10.52%. In building construction projects, for example, cost overruns have been reported to vary significantly for different project types. Ogunemi and Jaboro (2006) revealed the mean project cost overruns for residential were 40%, commercial 16%, and educational 28%. Similarly, Aibinu and Odeyinka (2006) found residential and commercial projects to experience mean cost overruns of 20.6% and 15.21%, respectively.

Issues relating to the project type and their influence on cost overruns have been examined and are subject to on-going debate. Flyvbjerg et al. (2002) revealed that there was a significant difference between the mean cost overruns for different project types but not for geographical location. Conversely, however, Odeck (2004) observed that project type did not influence the level of cost overrun incurred.

RESEARCH APPROACH

The dataset presented in Love et al. (2009) for Australian construction and engineering projects is used to develop 'best fit' statistical distributions so that probabilities for cost overruns at contract award can be determined.

Questionnaire Survey

The questionnaire survey developed for the study reported in Love et al. (2009) was used to extract cost overrun information as well as that relating to rework costs and causes. Stratified random sampling was used to select the study sample from the telephone directory, Yellow Pages® for the various regions of Australia. Two main benefits can be derived from using a stratified sample: (1) It can ensure that adequate and representative respondents within each subgroup under study are acquired; (2) Stratification also ensures that respondents within the same group are homogeneous.

Before the sample size for the main study could be determined, a pilot survey was completed with 30 building and 20 civil engineering contractors. As the survey of building contractors was undertaken first, it was considered to be reliable, and then used to pilot the civil engineering sample. The firms sampled comprised of design and engineering consultants, project managers, and contractors. The rationale was to test the suitability, clarity, and comprehensibility of the questionnaire as well as measure the response rate. Participating firms were contacted by telephone and informed of the research aims and objectives and informed that all responses would remain strictly confidential; albeit, generalizations of the findings would be made available to all participants.

On participant consent, questionnaires were mailed to the sample, with a stamped addressed return envelope enclosed. Participants were invited to critically review the questionnaires' design and structure by annotating comments onto the document itself in order to provide constructive feedback. Comments received were positive and therefore the questionnaire remained largely unaltered for the main surveys; albeit a few minor layout changes were made to increase clarity. A total of 25 responses were received in the building project pilot survey, giving an 83% response rate. For the civil engineering project survey, a total of 17 responses were received, giving an 85% response rate. These high response rates were obtained because prior consent to support the work was obtained from all survey participants.

In the main survey, 420 and 300 questionnaires were distributed to design consultants, contractors and project managers for building and civil engineering projects, respectively. As there were no fundamental changes required to either of the pilot questionnaires, they were added to the samples. For the building and civil engineering projects, 161 and 115 responses were received respectively, which represents a total consolidated response rate of 41% for both surveys, which is within an acceptable range for a survey with industry practitioners.

PROCEDURE

Descriptive statistics such as the mean (M), standard deviation (SD), and inter-quartile were calculated. A one-way Analysis of Variance (ANOVA) was used to determine if cost overruns significantly varied between construction and engineering projects and original contract value at a 0.05 significance level. Probability density

functions were developed using *EastFit 5*. A PDF for a continuous distribution can be expressed in terms of an integral between two points:

$$\int_a^b f(x)dx = P(a \le X \le b) \qquad \text{[Eq.1]}$$

A cumulative distribution functions (CDF) was also produced. For theoretical continuous distributions the CDF is expressed as a curve and denoted by:

$$F(x) = \int_{-\infty}^{x} f(t)dt \qquad \text{[Eq.2]}$$

The empirical CDF, which is displayed as a stepped discontinuous line and dependent on the number of bins, is represented by:

$$F_n(x) = \frac{1}{n} \cdot [\text{Number of observations} \le x] \qquad \text{[Eq.3]}$$

The PDF, CDF and distribution parameters ($\alpha, \beta, \gamma, \mu, k, m, \sigma, \xi$) for continuous distributions such as *Beta*, *Burr*, *Cauchy*, *Error, Gumbel Max/Min*, *Johnson SB*, *Normal*, and *Wakeby* were examined using the estimation method of Maximum Likelihood Estimates (MLE). Using StatAssist 5.5, the 'best fit' distribution was then determined using the following 'Goodness of Fit' tests, which measure the compatibility of a random sample with a theoretical probability distribution:

- *Kolmogorov-Smirnov statistic (D)*: Based on the largest vertical difference between the theoretical and empirical CDF:

$$D = \max_{1 \le i \le n} \left(F(x_i) - \frac{i-1}{n}, \frac{i}{n} - F(x_i) \right) \qquad \text{[Eq.4]}$$

- *Anderson-Darling statistic (A^2)*: A general test to compare the fit of an observed CDF to an expected CDF. The test provides more weight to a distributions tails than the *Kolmogorov-Smirnov* test. The Anderson-Darling statistic is defined as:

$$A^2 = -n - \frac{1}{n} \sum_{i=1}^{n} (2i-1) \cdot \left[InF(x_i) + In\left(1 - F(x_{n-i+1})\right) \right] \qquad \text{[Eq.5]}$$

- *Chi-squared statistic* (χ^2): Determines if a sample comes from a population with a specific distribution. The Chi-squared statistic is defined as:

$$\chi^2 = \sum_{i=1}^{k} \frac{(O_i - E_i)^2}{E_i} \qquad \text{[Eq.6]}$$

where O_i is the observed frequency for bin *i*, and E_i is the expected frequency bin *i* calculated by:

$$E_i = F(x_2) - F(x_1) \quad \text{[Eq.7]}$$

Here F is the CDF of the probability distribution being tested, and x_1, x_2 the limits for the bin *i*.

The above 'Goodness of Fit' tests were used to test the null (H_o) and alternative hypotheses (H_1) that the datasets: H_0 - follow the specified distribution; and H_1 - do not follow the specified distribution. The hypothesis regarding the distributional form is rejected at the chosen significance level (α) if the statistic D, A^2, χ^2 is greater than the critical value. For the purposes of this research, a 0.05 significance level was used to evaluate the null hypothesis. The *p*-value, in contrast to fixed α values is calculated based on the test statistic and denotes the threshold value of significance level in the sense that H_o will be accepted for all values of α less than the *p*-value. Once the 'best fit' distribution was identified the probabilities for cost overruns were calculated using the CDF. Then, to simulate the samples randomness and derive cost overrun probabilities, a *Mersenne Twister*, which is pseudorandom number generating algorithm, was used to generate a sequence of numbers that approximated the sample to 1000 (Matsumoto and Nishimura, 1998).

RESULTS

Data from a total of 276 construction (n=161) and civil engineering (n=115) projects was obtained. In the case of construction projects, these ranged from banks to hospitals and hotels. For the civil engineering sample, these ranged from tunneling to road construction and sewer treatment plants. The summary statistics reveal that the mean OCV was A$23,142,486 (SD=A$41,171,772; minimum=A$132,347; maximum = A$390 million) and the mean Acv was A$25,455,372 (SD= A$45,090,928; minimum = A$136,671; maximum = A$420 million). The actual construction period was an average 4.7 years (SD=3.3 years), ranging from 3 months to 3.75 years.

To better understand the composition of the sample, an examination of respondent stratification, geographical dispersion, and company turnover was completed for the civil engineering sample. In terms of respondent stratification, 45% were design consultants (architects, quantity surveyors, and structural, mechanical, and electrical engineers), 31% were contractors, and 24% comprised project managers. With regards to geographical dispersion, organizations were situated across states: Victoria (45%), New South Wales (17%), Queensland (27%), South Australia (9%), and WA (2%). The analysis revealed that the average annual turnover of organizations sampled varied: < A$1m=14%; A$1 to A$10m =37%; A$11 to A$50m=20%; A$51 to A$250m=13%; and > A$250m=16%.

The mean overall project cost overrun for the sample was 12.22% (SD=20.65) of Ocv. Means were also determined for the two groupings of project types, construction and civil engineering, and were found to be 12.22% (SD=24.22%) and 11.76% (SD=13.76%) respectively. For construction projects the maximum cost overrun was 244% and a minimum -84% (i.e. cost under-run), which results in a range of 328%. For the civil engineering projects sampled the maximum cost overrun was 109% and a minimum of 11%, which results in a range of 98%. An ANOVA test

was used to determine whether there were significant differences between the cost overruns experienced in the construction and engineering projects (p = 0.05). The analysis revealed that there were no significant differences between the cost overruns experienced between construction and civil engineering projects [F (1, 274) =.611, p = 0.41]. Previous analysis of this dataset revealed that project cost overruns did not vary with procurement and tendering methods and project types (Love et al., 2009). Therefore, generic probabilities for determining the occurrence project cost overruns based upon the 'best fit' probability distribution were calculated.

Probability of Cost Overruns

The construction and engineering datasets were combined and the 'best fit' probability distribution was examined using the 'Goodness of Fit' tests: *Kolmogorov-Smirnov* and *Anderson-Darling.* The results of the 'Goodness of Fit' tests revealed that *Three Parameter (3P) Frechet* distribution provided the best fit for the dataset. The Kolmogorov-Smirnov test revealed a D-statistic of 0.2451 with a P-value of 0.99508 for the sample of 276 construction and engineering projects. The Anderson-Darling statistic A^2 was revealed to be 1.5357. The Chi-squared (χ^2) statistic was found to be 4.7451 with a P-value of 0.78444. The 'Goodness of Fit' tests all accepted the H_0 for the sample distribution's 'best fit'.

A Frechet is a form of generalized extreme value distribution (GEV) that is used as an approximation to model the maxima of long (finite) sequences of random variables. The parameter α is a continuous shape parameter $\alpha > 0, \beta > 0, \gamma$ is a continuous location parameter where $\gamma \equiv 0$ yields the two parameter-Frechet distribution. The domain for the 3P Frechet distribution is $\gamma < x < +\infty$. The PDF is expressed as:

$$f(x) = \frac{\alpha}{\beta}\left(\frac{\beta}{x-\gamma}\right)^{\alpha+1} \exp\left(-\left(\frac{\beta}{x-\gamma}\right)^{\alpha}\right) \qquad \text{[Eq.8]}$$

The CDF is expressed as:

$$f(x) = \exp\left(\left(-\frac{\beta}{x-\gamma}\right)^{\alpha}\right) \qquad \text{[Eq.9]}$$

The parameters for the *Frechet (3P)* were found to be α = 10.158, β = 90.215, γ = -84.29. The calculated probabilities of a cost overrun being experienced are presented in Table 1. The probability of experiencing a cost overrun of >10% is 47%. Delimiters have also been used to provide probabilities of cost overruns within ranges. The probability of a project experiencing between a 1% and 5% cost overrun, for example, is 16%. For a mean cost overrun of 12.22%, the likelihood that a project's exceed this amount is 60% (P (X < X1) = .60).

 ISBN: 978-1-84219-840-7 .

Table 1. Cost overrun probabilities

Probability of a cost overrun between:	P(X1 < X < X2)	Probability	P(X < X1)	P(X > X1)
1 and 5%	0.16	5%	0.32	0.67
6 and 10%	0.2	10%	0.53	0.47
11 and 15%	0.16	15%	0.69	0.31
16 and 20%	0.11	20%	0.8	0.2
21 and 25%	0.07	25%	0.87	0.13
26 and 30%	0.05	30%	0.91	0.09

COST CONTINGENCY

A contingency can be defined as "the amount of funds, budget or time needed above the estimate to reduce the risk of overruns of project objectives to a level acceptable to the organization" (PMI, 2008). Most projects will experience cost increases between the decision to build and the contract award. A design contingency is typically allocated for changes during design for factors such as incomplete scope definition and estimating inaccuracy (Clark and Lorenzoni, 1985). As a project becomes more defined, the design contingency is absorbed into the budget for specific cost elements. Any unresolved design issues at the point of contract award should be incorporated into the construction contingency. At the initial budget stage a contingency of 30-50% should allowed for incomplete scope, and 5-10% for estimating inaccuracies (Clark and Lorenzoni, 1985). Thus, as a rule of thumb a 35-60% design contingency should be added to the initial budget estimate figure. Predicting the cost overrun from the decision to build to contract award relies exclusively on a large dataset so the empirical distribution of cost overruns can be used to determine the 'best fit' statistical distribution for probabilistic analysis.

A construction contingency is used for changes that may occur during the construction process. Under a traditional lump sum contract based on bills of quantities (BoQs), scope and design are supposed be fully defined and develop. As a result, Clark and Lorenzoni (1985) suggest a contingency value of 3-5% should be used. In practice complete drawings and BoQs are generally not available when a projects goes to tender. A similar situation arises when non-traditional methods are used to deliver projects. The analysis revealed that there was no statistical difference between the extent of cost overrun experienced and procurement method used. From the analysis presented above, it is suggested that a construction contingency value in excess of the average cost overrun of 12.22% should be used known unknowns (i.e. identifiable risks). For example, design errors and omission contained within contract documents have been found to contribute as much as 50% of a project's cost overrun (Love *et al*., 2009). From a client's perspective, design errors and omissions are identifiable risks and should be accommodated within a contingency. The probabilities derived from the statistical distributions provide the basis to monitor and reassess project costs. Identifying the key factors contributing cost overruns from contract award and assessing their likelihood of occurrence can enable clients and contractors to implement appropriate risk management strategies.

CONCLUSION

Using the contract award as a reference point, cost overruns from 276 construction and engineering projects were calculated. The research revealed that a mean cost overrun of 12.22%. No significant differences for cost overruns were found between procurement method, project type and contract size. The empirical distributions for the cost overruns were found to be non-Gaussian. Non-parametric 'Goodness of Fit' tests were used to select the best fit probability distribution. A *3-Parameter Frechet* probability function was found to provide the best overall distribution fit to calculate the probability of cost overruns. It is suggested that distribution fitting of empirical distributions is necessary to produce reliable and realistic cost overrun probabilities and as a result improve decision-making. Further research is required to determine if the probability distributions are applicable to wider populations.

REDUCING THE COST OF POOR QUALITY THROUGH KNOWLEDGE MANAGEMENT

Raymond Olayinka[1], Subashini Suresh and Ezekiel Chinyio[2]

[1,2] *School of Technology, University of Wolverhampton, WV1 1LY, UK*

ABSTRACT

The UK construction industry has been adversely affected by the current economic downturn, thereby creating a need to cut costs and improve efficiency, yet construction costs in the UK are higher when compared to other countries in the EU. A contributory factor to this high cost is poor quality in the project delivery process resulting in unnecessary expenditures of time, money, material and human resources and culminating into the 'cost of poor quality' (COPQ). COPQ has been linked to poor knowledge management (KM). While KM involves 'getting the right knowledge to the right people at the right time', the construction industry is recognised as being poor at learning, with organisations often 'reinventing the wheel', repeating mistakes and wasting knowledge resources. An on-going study from which this paper is developed therefore aims to investigate the impact of KM in reducing COPQ. Based on a thorough review of literature, the objectives are three-fold (i) to explore KM concepts and their applications within the construction industry (ii) to examine COPQ in construction (iii) to explore the impact of KM on COPQ. It is concluded that KM has neither been optimised nor fully exploited within construction management to reduce COPQ. The study contributes to efficiency improvement, quality improvement and cost reduction strategies within construction organisations.

Keywords: cost of poor quality, knowledge management, quality management.

INTRODUCTION

The construction sector is a major part of the UK economy. It represents some 7% of GDP or £110bn per annum of expenditure, some 40% of this being in the public sector, with central Government being the industry's biggest customer (ONS 2011). The industry has been affected adversely by the current economic crisis, therefore creating a huge need to reduce costs and improve efficiency. The Government's Plan for Growth Report (2011) particularly highlighted the critical importance of an efficient construction industry to the economy. Construction in the UK is relatively costly. The costs of infrastructure projects for example are excessively higher than in any other European country. Top-down analysis of benchmarks across sectors where comparative data are available, including high speed rail, roads, onshore wind and tunnelling all indicate higher relative outturn costs in the UK, ranging from a factor of 10% to over 100% difference. (Infrastructure Cost Review 2010). According to a

[1] R.Olayinka@wlv.ac.uk; S.Subashini@wlv.ac.uk; E.Chinyio@wlv.ac.uk

global research by EC Harris (2011) UK construction costs remains one of the highest in the world. A contributory factor to the high cost is attributed to poor quality in the project delivery process resulting in unnecessary expenditures of time, money and resources, both human and material and culminating into what is known at the cost of poor quality or COPQ (Juran 1989, Feigenbaum 1991). Studies have been undertaken to quantify COPQ on various construction projects, the results of which have varied from one study to the other. Abdul-Rahman (1996) and Hwang (2009) for example found COPQ to be roughly 5% of the original contract value. Burati et al (1992) however found it to be as high as 12.4%.

COPQ has been linked to poor knowledge management (KM). According to O'Dell and Grayson (1997), KM is a conscious strategy of getting the right knowledge to the right people at the right time, and helping them to share and put the information into action in ways that improve their organisational performance. The construction industry however has been recognised as consistently being poor at learning. Organisations often reinvent the wheel, thereby repeating mistakes and wasting resources (Egan 1998, Grimaldi and Rippa 2011). Specialist and technical knowledge is lost from one project to the next stifling an organisation's ability to develop knowledge and generate new ideas (Egbu and Robinson 2005). While the link between KM and COPQ has been established, it is unclear what precise relationship exist between the two neither is there empirical evidence to suggest that the implementation of KM has been optimised within the construction management domain to reduce COPQ. This study therefore aims to investigate the impact of KM in reducing COPQ. Based on a thorough review of extensive literature of an on-going doctoral study, the objectives are three-fold (i) to explore KM concepts and their applications within the construction industry (ii) to examine COPQ in construction (iii) to explore the impact of KM on COPQ. The study contributes to the body of knowledge in the area of efficiency improvement, quality improvement and cost reduction strategies within construction management.

RESEARCH METHODOLOGY

The study is part of an ongoing doctoral study consisting of three phases namely: the critical review of literature; research methods; and research output. This paper focuses on aspects of the first phase and is therefore a theoretical study presenting critical discussions around KM and COPQ and their connection to practice. The output from the study contributes towards the first phase and the analysis, especially the conclusions in conjunction with other theoretical outputs move the research into stage two. As such the research is extensive in nature, leading to more intensive research at a subsequent stage and comparing and contrasting the findings with those from other conceptual and empirical work. The first phase is exploratory and accomplishes several purposes including gaining insight into previous work being done in the area whilst also filling the gaps and extending prior studies. Information sources utilised include printed journals, online gateways and databases, industry regulatory body publications, online journals, reference texts, conference papers and various books on the subject matters of KM and COPQ.

KM CONCEPTS AND APPLICATION

KM has been defined by several authors in several ways. Newell et al. (2009) defined it from a strategic perspective as '…improving the ways in which firms facing highly

turbulent environments can mobilise their knowledge base in order to ensure continuous innovation'. As a tool and technique, Bounfour (2003) defined it as a set of procedures, infrastructures, technical and managerial tools, designed towards creating, sharing and leveraging information and knowledge within and around organisation. The most common definitions of KM are those involving processes. Fischer (2001) for example, defined KM as a cyclic process involving, creation, integration and dissemination of knowledge. Skyrme (2002) presented the KM process as a continuous cyclic diagram showing how knowledge is identified, collected, classified, stored, shared, accessed, used, and new knowledge is created. It can be summarised from most definitions that KM involves some form of knowledge acquisition, exploitation and evaluation.

Two main types of knowledge that are widely recognised within academia and industry are: tacit knowledge and explicit knowledge (Nonaka and Takeuchi 1995, Nonaka and von Krogh 2009). Tacit knowledge is highly personal, developed from experience, and hard to formalise, therefore it is difficult to communicate. Explicit knowledge on the other and is formal and systematic. It is therefore easy to communicate and share. Much of the effort in KM has been focused on converting knowledge from one type to the other e.g. tacit to explicit utilising two approaches namely codification and personalisation. Codified knowledge is stored in an organisation's databases where it can be accessed and re-used. Personalised knowledge is closely tied to the person who developed it and is shared mainly through person-to person contacts as supported by an organisation's cultural environment. KM utilises a wide range of tools and techniques some of which are technology based (e.g. intranets, collaborative technologies) while others rely less on technology (e.g. communities of practice, story telling).

KM plays an important role within construction management in improving efficiency, increasing quality and reducing costs (Al-Ghassani et al. 2004, Anumba et al. 2005, Robinson et al. 2001). It is particularly important due to the arguably unique characteristics of construction projects such as the complicated nature of operations, multitude of occupations, professions and organisations, temporary team members and heavy reliance on experience, the one-off nature of the projects, tight schedules and limited budgets (Mohd Zin and Egbu 2010). The industry is also people-intensive, characterised by a wealth of experiential knowledge, yet staff retire or leave organisations regularly, taking a great deal of tacit knowledge with them (Suresh et al. 2008). There is therefore need to strategically manage employee-owned tacit knowledge within construction organisations (Carrillo and Chinowsky 2006) and need for knowledge integration across organisational boundaries (Ruan et al. 2012) leading to measurable outcomes such as retained knowledge, innovation, improved performance and client satisfaction (Armbrecht et al. 2001, Liebowitz 2002, Chua 2004, Boyd and Chinyio 2006).

Much effort has been made within academia to develop effective strategies for managing knowledge within construction organisations and on projects. The areas addressed include knowledge accumulation, knowledge capture, knowledge storing, knowledge sharing and knowledge transfer. In practice, an industry-wide KM effort, particularly in the UK where this study is focused, can be traced back to the Egan Report (1998). The report identified KM as means of driving efficiency improvements, and recommended strategies by which they could be achieved. These included execution of demonstration or innovative pilot projects across the country to showcase best practice so that knowledge can be transferred to other projects

(Olayinka and Smyth 2007, Smyth 2010). Demonstration project case studies were published and disseminated or diffused via a central knowledge base accessible to construction organisations. Best Practice Clubs were set up as avenues of personalised knowledge sharing among industry experts. Annual industry key performance indicators (KPIs) were generated based on data from thousands of projects completed each year and collated from surveys of construction clients, contractors, consultants and M&E Specialists for purpose of knowledge assessment and benchmarking (Constructing Excellence 2007). In spite of these KM initiatives the construction industry remains criticised for inefficiency, poor quality and high cost (Wolstenholme 2009). This brings about the question of what impact KM has made on the construction industry especially in reducing costs and improving quality.

COPQ IN CONSTRUCTION

COPQ can be defined as costs that would disappear if systems, processes, and products were perfect, in other words, these costs will be non-existence if there are no quality issues (Juran 1989). COPQ concept has found a variety of applications in several industries such as manufacturing and business. The study focuses on COPQ within the construction industry as it has become a major contributory factor to inefficiency and wastage leading to higher cost of construction. COPQ is a segment of Cost of Quality (COQ). COQ consists of the Cost of Good Quality (COGQ) and COPQ. While COGQ affects costs for investing in the prevention of non-conformance to requirements and for appraising a product or service for conformance to requirements, COPQ affects internal and external costs resulting from failure to meet requirements (Crosby 1979, Feigenbaum, 1991, Juran and Godfrey, 1998). Internal failure costs are those incurred when rectifying an error or defect before a product is handed over to the construction client. These include the cost of rework, cost of delays, cost of wastage and the cost of investigating non-conformances (Fayek et al. 2004, Love et al. 2004). Conversely, external failure costs are those incurred due to errors or defects in the product after it has been handed over to the client. Examples are the cost of handling client complaints, cost of repairing defects, legal and compensation costs among others.

Studies have been carried out on the causes of COPQ which include design changes, poor skills, errors and omissions occurring during the design, construction or handover stages of a project. While attempts have been made to quantify COPQ on various construction projects, results have varied from one study to the other. Burati et al (1992) investigated 9 major engineering projects to determine the cost associated with correcting deviations to meet specified requirements and found that it amounts to an average of 12.4% of the contract value. Abdul-Rahman (1995) found nonconformance costs excluding material wastage and head office overheads in a highway project to be 5% of original contract value. Love (2002) analysed data from 161 construction projects of various types and found that the mean direct and indirect rework costs were found to be 6.4 and 5.6% of the original contract value respectively, nevertheless, rework costs were found not to vary significantly with project type and procurement method used. Hwang (2009) using data obtained from a database of 359 construction projects assessed the impacts of different sources of rework on construction cost performance where the direct costs alone tallied to 5% of the total construction costs on many instances. COPQ has proven to be greater than the investment for managing quality (Juran and Gryna, 1988; Sorqvist, 1998),

therefore creating a need to investigate cost reduction strategies and identify potential cost savings.

IMPACT OF KM ON COPQ

Several initiatives have been adopted within organisations to improve quality and reduce cost. Quality management systems such as TQM, ISO9000 and Six Sigma have elaborated on the effects which a team-based improvement system can have on production. In conjunction with the systems, organisations have used quality management tools and techniques such as Benchmarking tools, Pareto charts, Cause and Effect diagrams, Kano analysis among many others. Despite these initiatives the construction industry is still recognised as being poor at learning on a consistent basis thereby repeating mistakes and therefore requiring a conscious strategy of getting the right knowledge to the right people at the right time, and helping people to share and put the information into action in ways that strive to improve the organisational performance. KM is therefore crucial in quality improvement and cost reduction strategies within construction management. It is important to identify KM and other components of COPQ in order to devise a strategy for its reduction. According to Juran and Godfrey (1998), two of the primary objectives of establishing COPQ are: to quantify the size of the quality problem; and to identify major opportunities for cost reductions. A major by-product of an evaluation of cost is the identification of costs of specific segments, each traceable to some specific cause. For example internal failure costs, constitute four segments: the cost of rework (e.g. cost of redesign, redoing construction processes, re-inspection); the cost of delays (e.g. cost of down time, shortages, change to non-conformances); the cost of wastage (e.g. inefficient use of plant, labour and materials); and other costs associated with investigation, and penalties for rework, delays and wastage.

There exist several causes of internal failure cost. According to Fayek et al. (2004), these can be grouped under five headings namely: 1) leadership issues (e.g. incompetent project leadership, poor communication); 2) human resource issues (e.g. insufficient skills, lack of personnel); 3) engineering review issues (e.g. late design changes, poor document control, errors and omissions); 4) planning and scheduling (e.g. space constraints, unrealistic scheduling); and 5) materials and equipment supply (e.g. non-conformance to specification, double handling). Since failure costs are indirect costs usually arising as a result of internal failure costs, external failure costs will disappear if there were no internal failure costs. The current study therefore focuses on internal failure costs which usually occur within the design and construction stages of the project life cycle before handover to the construction client or customer. Having identified internal failure costs and their traceable causes, the next step is to investigate the impact of KM processes on each cause. For example, what is the impact of knowledge codification on the project leadership issue of poor communication?' or 'what is the impact of knowledge access on the engineering review issue of late design changes?' The output from the investigation is an understanding of the current impact of KM on COPQ, identification of potential impact of KM on COPQ leading to the design of a KM model for reducing COPQ. .

CONCLUSIONS

A review of literature on the impact of KM in reducing COPQ has been reported in this paper as part of an on-going doctoral study. The review explored KM concepts

and their applications within the construction industry, examined COPQ within construction management, and explored the impact of KM in reducing COPQ. It was identified that construction cost in the UK is generally higher than in most countries within the EU. Part of the cost is attributed to poor quality in the project delivery process particularly the unnecessary effort in re-doing construction processes which culminates into the COPQ. However COPQ is avoidable and has proven to be greater than the investment for managing quality. COPQ has been linked to poor KM due to evidence that the construction industry is poor at learning, thereby repeating mistakes and 're-inventing the wheel'. The arguably unique nature of projects which are usually people-intensive and involving temporary team members and fragmented operations leads to significant knowledge loss from project to project. Retirement, redundancies and transfer of highly skilled personnel also lead to significant knowledge loss. Evidence suggests that KM has neither been optimised nor fully exploited within construction management. The impact of KM in reducing COPQ therefore involves the optimal management of employee-owned tacit knowledge and the strategy of getting the right knowledge to the right people at the right time in order to minimise rework, delays, wastage, and all associated costs. Measurable outcomes of KM optimisation include retained knowledge within an organisation, innovation through the creation of new knowledge, improved efficiency, improved quality of the processes, and personnel and end-products ultimately leading to reduction on costs. Empirical work on the impact of KM in reducing COPQ in construction will be presented in a subsequent paper.

STANDARD FORMS OF ELEMENTAL COST ANALYSIS FOR CIVIL ENGINEERING

Joe Martin[1]

[1]*Executive Director, Building Cost Information Service (BCIS), RICS, Parliament Square, London, SW1P 3AD, UK*

ABSTRACT

Elemental classification differs from traditional trade based classification as it relates to parts of a construction Entity defined by their function without reference to their specification, design or construction, i.e. what they do rather than how they are built. The application of elemental classification for buildings to cost planning, cost management, cost analysis and cost benchmarking is standard in the UK and common in other countries. It has allowed the construction cost professional to provide elemental cost models from the earliest stages of a project and the design team to design to a cost rather than costing a design. The use of elemental classifications and their application to cost modelling is not common practice in civil engineering. An elemental data structure for civil engineering was developed by BCIS for the UK Defence Infrastructure Organisation and has been proposed for wider application; in the US ASTM Uniformat have also proposed elemental classification for civil engineering entities. The principles and applications of elemental classification are discussed and progress on developing standards in the UK and USA is reported.

Key words: Civil engineering, Cost analysis, Classification, Elements, Entities.

INTRODUCTION

This paper reports on current work being undertaken by the Building Cost Information Service (BCIS) of the Royal Institution of Chartered Surveyors (RICS) to produce a standard elemental structure for use in capturing and reporting cost information on Civil Engineering projects. The initial research and proposals were reported in detail to a previous COBRA conference (Martin 2010). This paper reports on the proposed Standard Form of Civil Engineering Cost Analysis (SFCECA) data structure that was published in November 2011 and the issues raised by the consultation with client bodies and the relationship to similar work in the USA being carried out by ASTM Uniformat II committees. This is a report on ongoing work and the tables and definitions set out in this paper are therefore liable to change. We would welcome comments and suggestions

[1] jmartin@bcis.co.uk

Background

The purpose of an Elemental cost analysis is to provide data that allows comparisons to be made between the costs of achieving various functions in a project, with those of achieving equivalent functions in other projects, so that information from existing projects can inform the budgeting and benchmarking of future projects.

The use of Elements and Elemental cost analyses is a well-established practice for buildings where the BCIS Elemental Standard Form of Cost Analysis (BCIS 2012) provides the rules for consistent analysis. This cost information is used for early cost advice, cost planning and cost benchmarking, while the Elemental classification is also used for client briefing, performance specifications, value engineering and life cycle costing[2].

No such common standard form of cost analysis exists for civil engineering. This makes benchmarking of civil engineering difficult and, where it is possible, a costly exercise. The purpose of this current work is to propose rules for analysing civil engineering projects into Entities and Elements.

Initial Research

BCIS undertook to develop a cost data structure for the UK Defence Infrastructure Organisation (DIO) to analyse the costs of their civil engineering projects in a consistent manner that would facilitate benchmarking and the provision of data for early cost advice. The DIO manages the Ministry of Defence's property infrastructure and ensures strategic management of the Defence estate as a whole. It has responsibility for most MOD expenditure on infrastructure management and delivery activities.

The initial phase was desk research to establish what classification system existed for civil engineering structures. The classification systems that offered something that looked like 'Entities' and 'Elements' as defined for our purpose were Uniclass (CPIC 1997) Omniclass (OCCS) and some unpublished proposal for specific Entities from the American Society for Testing and Materials (ASTM).

Both Uniclass and Omniclass are structured in a similar way to ISO 12006-2 Building Construction - Framework for classification of information.

The BCIS proposed structure was based on defining a standard list of 'Entities' and lists of 'Elements' for each Entity.

DATA STRUCTURE AND PRINCIPLES OF ANALYSIS

Entities

'Construction Entity' is listed as a table in ISO 12006-2, where it is defined as:

> *Construction entity:* Independent material construction result of significant scale serving at least one user activity or function. Examples building, bridge, road, dam, tower, sewer, museum (if a single structure), sports field, sewage settlement tank'.

The ISO recommends the use of two classification tables for Construction entities 'Entities by Form' and 'Entities by Function or user activity'.

[2] BCIS, *Principles of elemental classification for buildings (International),* provides a general introduction to elemental classification and its uses.

In Uniclass, which predated the ISO, the table for 'user activity/purpose' is called 'Facilities'. The Entity table uses the following definition:

> *Construction Entity* is an independent construction of significant scale. This table classifies construction entities according to their physical form/basic function. Examples include buildings, bridges, roads, dams, towers, retaining walls, pipelines, etc.

The concept that we require is structures defined by what they do, i.e. their object function. However, in trying to define the individual entities it was found necessary to refer also to physical form, e.g. quay as a 'vertical face with contiguous horizontal, usable surface for loading/unloading'. We have therefore used the Uniclass definition:

> *Entity* is 'an independent construction of significant scale defined by its physical form/basic function, e.g. Pavements, Pipelines, Buildings.'

We have expanded on the, rather sketchy, table in Uniclass and a list of entities defined in the Standard Form of Civil Engineering Cost Analysis – Outline Data Structure is attached is given in Table 1.

Table 1 BCIS and ASTM Entity structures

BCIS SFCECA	*ASTM UNIFORMAT II*
Pavements and landscaping	Transportation surfaces
Railways	Bridges
Platforms, quays, jetties and the like	Waterfront
Retaining structures	Dam and Canal
Dividing structures	Pipelines
Containers	Water and Sewerage
Support structures	Underground – Tunnel
Pipelines and ducts	Storage Tanks
Open conduits	Communications
Cables	Power
Wells	Manufacturing and Processing
Ground contouring	
Bridges	
Tunnels	
Ornamental structures	
Miscellaneous/unclassified projects	

Entity Types

Each entity will have a range of 'Entity Types' that define their user function, e.g. 'Pavements' may be used for runways, taxiways as well as various types of road, etc. It is proposed that the entity types will be defined based on Uniclass Table D – Facilities, where possible.

Elements

We have used the BCIS SFCA definition of an element:

> Element is a major physical part of an entity that fulfils a specific function, or functions, irrespective of its design, specification or construction.

 ISBN: 978-1-84219-840-7 .

BCIS STANDARD FORM OF CIVIL ENGINEERING COST ANALYSIS

For each Entity BCIS proposed a single set of elements with generic definitions, but these may need to be separately defined for different Entity Types. For example, roads and runways have the same element 'communications' but highway signalling is different, and is described differently, from air guidance lighting.

Example: The proposed Elements for the Entity 'Pavements' are:

Pavements

1 Substructure
- **1A** Subgrade

2 Pavement
- **2A** Preparation (for resurfacing)
- **2B** Pavement structure
- **2C** Pavement surface
- **2E** Edge treatment

3 Pavement completion
- **3A** Drainage
- **3B** Electrical power installation
- **3C** Lighting installation
- **3D** Heating installation
- **3E** Water installation
- **3F** Communications
- **3G** Protection and security
- **3H** Special installation
- **3I** Ancillary (structures and equipment)
- **3J** BWIC

Costs that are not attributable to the physical parts of the building should be analysed in to:

- Preliminaries
- Main contractor's overheads and profit
- Contingencies and risks
- Contractors design fees on design and build contracts.

For benchmarking rules are required for allocating the non-elemental costs to ensure consistence of the data.

Analysing a project

A project (i.e. a contract that is being analysed) may be made up of one or more Entities together with External Works and Facilitating works.
Broadly speaking 'Facilitating works' are things that are required before the entity can be constructed and 'External works' are things that are included to complete the contract in addition to entities analysed.

Ancillary information required

The context in which an Entity is built is probably the biggest factor in determining its cost. Therefore it is essential that the cost information is accompanied by information to put the costs of a project in its context. This should include, for example, details of site conditions, such as ground conditions, access, water table, tidal range, etc.

 ISBN: 978-1-84219-840-7 .

Elements for Specific Entities
Elements have been defined for each Entity. The published proposals provide the following information for Elements for each Entity.

- Definition: setting out a broad description of the element.
- Functional definition: describing what the element is intended to do.
- Measurement rules, suggested measurements that will help to define the scope of the works and aid in interpreting the costs. Where more than one measurement is given, the first is the Element Unit Quantity for that element.
- Design criteria: suggested design criteria that will help to define the scope of the works and aid in interpreting the costs.
- Includes/Excludes: illustrative list of items included in each element and list of exclusions cross referenced to another element to augment and clarify the definition.

An outline data structure has been proposed for all Entities and detailed definitions proposed for:

- Pavements
- Airfield Pavements
- Quays, Piers, Jetties, Platforms and the like
- Support structures (Masts, Towers and the like

ASTM UNIFORMAT II CLASSIFICATION OF HEAVY (CIVIL) ENTITIES

ASTM International, formerly known as the American Society for Testing and Materials publish an Elemental classification for building called Uniformat II. They also publish an outline for preparing Element classification for a range of Entities. A list of ASTM Entities is given in Table 1.

They have recently published, through the US Department of Commerce National Institute of Standards and Technology (NIST), a proposed UNIFORMAT II Classification of Bridge Elements (Kasi and Chapman 2011), and are working on element classifications for Dam and Canal, Waterfront, Highway Transportation and Road Tunnels.
The interest in this endeavour is the same as that of BCIS, i.e. the need for consistent analysis of costs for benchmarking and early cost advice.

BCIS is corresponding with ASTM and, while there are some differences in detail, the element structures that are emerging on both sides of the Atlantic are similar enough to suggest that analysing civil engineering projects into entities and elements will provide the useful benchmark data required by funders and clients.

UK GOVERNMENT DEMAND FOR CIVIL ENGINEERING BENCHMARKING

In 2010, Infrastructure UK, part of HM Treasury, published a Cost Review a report of an investigation into how to reduce the costs of delivery of civil engineering works for major infrastructure projects. The report identified a number of drivers for the higher cost of construction in the UK compared to other EU countries and supports the view

that higher costs for UK infrastructure are mainly generated in the early project formulation and pre-construction phases.

The cost international comparisons made in the report highlighted the lack of standard cost data reporting. However, it also concludes that if minimising outturn cost were considered at every stage of a project by all participants then projects would be cheaper. IUK found a tendency, particularly in the public sector, to concentrate on building within client's budget rather than aiming at lowest cost for the required performance. This has lead to a general Government strategy to implement cost lead procurement and the need for benchmark data. IUK has set up a data and benchmarking task group to work with departments to provide benchmarks.

The Ministry of Defence benchmarks are being developed around the data collected by BCIS for Defence Infrastructure Organisation using the SFCECA classification.

BCIS analysed six runway resurfacing schemes. It indicated a significant difference between schemes which included some new work in extending the runway as well as resurfacing. While the sample size is small, it does provide a benchmark figure of £68/m2 of pavement for resurfacing schemes and £250/m2 of pavement for the extension and resurfacing schemes (Costs at 2q2011, UK mean location).

The SFCECA for Airfield Pavements defines both the measurement of the Pavement area and the costs to be included in the benchmark.

CONSULTATION WITH CLIENT ORGANISATIONS

In discussions with client organisations, it has become clear that any standard structure needs to be agreed sector by sector with the major clients. Most clients have some level of cost reporting requirement on their projects and need to be convinced that a standard approach across their sector, and with other sectors where appropriate, will warrant their changing their requirements.

For example in the UK there are two major clients for railway work, Network Rail (NR) and London Underground (LU). Table 2 shows a comparison of their cost breakdown structure for track.

Table 2 London Underground and Network Rail cost structures for Rail track works.

LU Cost Feedback Structure		**NR Analysis of Costs**	
100	Trackwork	**1.01**	Permanent way
		1.03	Level crossings
200	Buildings		
300	Power supply	**1.05**	Electrification Contact systems
		1.06	Electric power and plant
400-405	Bridges	**1.08**	Civil engineering works (05 Bridges and viaducts)
406-408	Retaining structures (cuttings, embankments, retaining walls)	**1.08**	Civil engineering works (02 Earthworks, 06 Retaining walls)
409-410	Drainage	**1.08**	Civil engineering works (02 Earthworks, 08 General drainage)
412	Dividing structures	**1.08**	Civil engineering works (07 Fencing and enclosures)
414-415	Tunnels	**1.08**	Civil engineering works (0.4 Tunnelling)
500	Signalling	**1.02**	Signalling equipment and systems
600	Communication	**1.04**	Telecommunications

We have now proposed a revised structure for the SFCECA for railways which could present costs from both the London Underground and Network Rail structures. See Table 3.

Table 3 Possible SFCECA for Railways

Entity Railway

Trackwork
Level Crossings
Power supply
Electrification
Signalling
Communication

Other Entities

Pipelines (Drainage)
Dividing structures (fences and walls)
Bridges
Retaining structures (cuttings, embankments, retaining walls)
Tunnels
Buildings

CONCLUSION

The key to identifying standard elements for civil engineering structures is identifying entities with a definable object function.

Disaggregating the object functions of these entities identifies the elements.

BCIS has proposed a set of entities that will cover most projects and is developing elements for them.

It has become clear that for some entities, elements need to be defined differently for different entity types.

Some data has been collected on behalf of a client and the proposed data structures have already proved useful in providing benchmarks for future cost.

Similar proposals are being made by standards organisations in USA.

The advantages of having cost information available that relates to the functions of an entity are the ability to provide early cost advice and set robust budgets before design commences, to design to a cost rather than cost a design. However, it remains to be seen if consistent data collection of elemental cost information of civil engineering entities will be as useful as it has been over the past 50 years for buildings.

ACADEMIC INTEGRITY; ACHIEVING BEST PRACTICE IN BUILT ENVIRONMENT DEGREE PROGRAMS

Clive M J Warren[1], Ann Peterson[2], David Neil[2]

[1] *Business School University of Queensland, Brisbane, Australia*

[2]*School of Geography, Planning and Environmental Management, University of Queensland, Brisbane, Australia*

ABSTRACT

Educational institutions globally are grappling with the rising incidence of academic misconduct, in part fuelled by the ever increasing access to online information. Recent audits of universities in Australia (AUQA 2009) indicated that students believed that their institutions did not have the necessary strategies in place to dispel students' perceptions that plagiarism may be tolerated. This paper reports on the development of teaching tools within Built Environment degree programmes at the University of Queensland. The objective of an online tutorial tool was to improve students' understanding of academic integrity and good academic practice and to do so in a supportive teaching and learning environment, through the development of an online interactive tutorial. The aims of the tutorial were to: develop learners' skills in knowing when to reference information and thus avoid plagiarising in their academic work; provide accurate information in an interesting, relevant and interactive way; ensure relevance to the institution's diverse student body; incorporate the ability to assess students' understanding of good academic practice; and ensure that the tool would be accessible as a learning resource for students throughout their programs of study. Through pre and post implementation surveys the changes in student perceptions of good practice were identified and used to refine the tutorial tool. Finally the paper reports on the adoption of the teaching tool on a university wide basis and its compulsory application to over 20,000 students.

Keywords; Academic Integrity, Australia, On-line education, Plagiarism

INTRODUCTION

Plagiarism and poor academic practice are a fact of life. It is not disputed that students both inadvertently and deliberately plagiarise (Curtis et al. 2011; James et al. 2002; Park 2003; Sutherland-Smith 2008). This culture of plagiarism is then frequently carried forward into the workplace and professional life (Roberts 2008). These findings have particular relevance in programs that prepare students to enter into fields of professional practice, which uphold high levels of ethical practice. This paper investigates issues of academic integrity within the property and real estate degree courses in Australia and in particular the steps taken at The University of Queensland

[1] c.warren@uq.edu.au

(UQ) to address the perceived increase in the incidence of poor academic conduct among both undergraduate and graduate students. Universities offer a wide range of educational programs, many of which are vocational, leading graduates into careers which invariably require membership of professional institutions. Many of these courses seek accreditation of their programs by professional bodies in order to ensure that students can seek to attain membership after graduating. The property and real estate professions including the Australian Property Institute (API) and the Royal Institution of Chartered Surveyors (RICS) are among those which accredit many of the programs in Australia including those offered at UQ. Each of these professional bodies seeks to maintain high ethical standards among its members and each publishes a code of ethics by which members are required to abide (API 2008; RICS 2008). These ethical codes require that members 'practise their vocation with integrity, honour and professionalism' (API 2008). The relationship between student ethics and those in the profession has been highlighted on a number of occasions (Hefferan et al. 2010; Oladokun 2012; Wilkinson et al. 2008). In a recent UK study of property employers seeking to employ graduates, the key attributes were found to be professional practice and ethical standards (Poon et al. 2011).

Academic integrity and good practice are central to student learning and to professional life after graduation. The ability to apply critical reasoning to issues through independent thought and informed judgement are key attributes that universities seek to instil in their students, however poor ethical judgement is certainly not an attribute which should be reinforced by acceptance in education. Academic misconduct is a problem that seems to be on the rise in most countries (Carroll, Jude 2004; Carroll, J et al. 2001; Larkham et al. 2002; Park 2004; Roberts 2008). The Australian Universities Teaching Committee (AUTC 2008) indicated that while it is impossible to determine trends in the incidence of plagiarism in higher education institutions, it appears to be widespread, and occurs across a range of disciplines (Peterson et al., 2009a,b). Studies by McCabe and Trevino (1996) reported on a longitudinal study of university students in the USA which showed a marked increase in the reported occurrence of plagiarism over the 20 year study period. A staggering 54% reported copying material without proper citation and 26% deliberately plagiarised the work of others.

The apparent prevalence of plagiarism and the perception that the level of poor conduct is rising have been attributed to a number of factors including: the availability of on-line information and the resultant ease with which students can 'cut and paste' information from numerous web sources; the ability to easily download academic papers for free or at a small cost together with dedicated sources which actively sell assignments on a range of subjects (Evans 2000; Thompson et al. 2002); time pressures students face in meeting assignment deadlines; the use of group work to reduce faculty time pressures and large classes may lead to an increase in students' plagiarism of each other's work; reduced access to staff; and increased reliance on past student work (James, McInnis & Devlin, 2008).

The incidence of plagiarism and the perception among students that poor academic practice and plagiarism are tolerated in universities has been an issue raised by the Australian Universities Quality Agency (AUQA) in a number of its audits of Australian Universities. In an audit of UQ the agency observed that: 'The University also needs to address a concern held by students in some schools that plagiarism or copying is tolerated, a matter that AUQA recommends be addressed in the University's forthcoming review of its policy on plagiarism' (AUQA 2009). It is

 ISBN: 978-1-84219-840-7 .

recognised that a contributing factor to student perceptions of university tolerance of plagiarism can be attributed to a lack of clear understanding among students as to what constitutes plagiarism. Many cases of alleged misconduct can be attributed to misunderstanding and ignorance among students about why they should avoid plagiarism and how they can do so (AUTC, 2008).

This paper describes the steps taken to reduce poor academic conduct within the property and real estate programs at UQ. Many universities have developed policies and procedures to deal with plagiarism. These are largely punitive measures that address the consequences of poor practices resulting in loss of grades or a fail grade for the course. A more pedagogically sound approach is based on a proactive intervention which raises awareness and knowledge of good academic practices, and provides the necessary tools to avoid unintentional poor practice allowing students to demonstrate academic integrity. Our research indicates a significant improvement in the level of students understanding of academic integrity and resultant reduction in the incidence of reported cases of plagiarism following completion of the student intervention.

DEVELOPING A RESPONSE

Prior to the AUQA Audit in 2009 the incidence of poor academic conduct had been recognised within students undertaking property and real estate degrees at UQ. A major contributor to the identification of this problem was the widespread adoption of plagiarism detection software within a number of courses. Tools such as TurnItIn automated the detection of poor academic writing, collusion and of blatant plagiarism. Like many institutions the response to this increasing awareness of poor academic practice was the development of an enhanced School Protocol for dealing with individual cases of plagiarism with clear guidelines for escalation of disciplinary action based on the level of seriousness of the act of cheating. In reviewing individual cases of poor academic practice it became readily apparent that in many cases students were not deliberately seeking to cheat but rather, were inadvertently falling foul of plagiarism detection efforts due to poor or inadequate understanding of good academic writing practices. It was also apparent that there was some considerable variation among students in their understanding of good academic practise based on their education to date, with many overseas trained students in particular, appearing to have a much less developed understanding of the process of academic writing within Australian universities.

In order to address the lack of understanding among students a training module was developed. The rationale behind development of this tool was to ensure that all students entering the property programs would be required to undertake a training tutorial and to record a minimum pass mark to demonstrate understanding of the concepts. On completion of the training module all students should have a sound understanding of good academic practices and as a consequence any detected misconduct after completion of the module could more readily be attributed as a deliberate attempt to gain advantage rather than be blamed on a lack of understanding.

A comprehensive online training module was developed over a two year period with assistance from professional programmers and experts in instructional design. The intent was to create a user friendly format which engaged students in various online exercises aimed at developing their understanding of issues of copyright, academic referencing, collaboration and collusion in preparing academic assignments (Peterson et al. 2009, 2010). The module provided for interactive engagement, with students

using a number of response tools from simple radio buttons or yes/no responses through to requiring input of full bibliographic references in either Harvard or Chicago styles. Each section of the tutorial responses was evaluated and students were unable to proceed until an adequate score was attained. The student's final score was recorded as a record of completion of the tutorial. The module was initially implemented as a pilot in selected first year courses. Following a number of software design enhancements the module was implemented for all students within the School of Geography Planning and Architecture and for students entering the Business School program in property and real estate development (Peterson, Neil, et al. 2009).

EVALUATION OF INTERVENTION OUTCOMES

In order to evaluate the development of the training module a number of student surveys were developed and administered in order to gain an understanding of student attitudes and knowledge of good academic practice. Initial surveys of students focus on the early stages of developing the online tutorial tool and have been previously reported in (Warren et al. 2012). These early surveys of students were conducted both before and after the educational intervention with the objective of investigating any change in student understanding and attitudes toward plagiarism and poor academic practice. The questionnaires were administered online and provided an anonymous vehicle by which to obtain frank and honest feedback from a large cohort of students in their first semester at university. The survey was distributed to a group of 447 students initially with follow up surveys sent to 260 students who completed the tutorial.

Analysis of the initial survey data provided a basis on which to start to understand the main issues relating to good academic practice and was used to develop the online tutorial response. All first year students entering the program were required to undertake the tutorial and were later invited to participate in a post-evaluation survey. These post tutorial surveys clearly show that students' understanding of what constitutes plagiarism had significantly changed (Warren et al. 2012).

The success of the training tutorial as both a tool for enhanced student learning and as a means of ensuring that all students are aware of the Universities' policy on plagiarism has been recognised. This along with the attention brought to the issue by the AUQA audit of the university led to further refinement of the teaching tool and its introduction on a university wide basis. From 2012 all students commencing study at UQ are required to undertake the online-tutorial. With a total student cohort of around 20,000 students this represents a significant increase in the number of students undertaking the training module and has afforded the opportunity to develop a greater understanding of student attitudes across the whole university. As part of the implementation of the tutorial all students are invited to participate in an online survey prior to commencing the tutorial.

The results of this wider survey conducted in semester one 2012 will be used in conjunction with a follow up evaluation to be conducted at the commencement of semester two with the objective of identifying any changes in student understanding. Once again the completion of the training module will enable teaching staff to more clearly differentiate blatant plagiarism, as the students will no longer be able to claim they did not understand that what they were doing was wrong.

The university wide pre-tutorial survey was undertaken by a total of 1343 students with just 109 Students opting not to participate in the evaluation survey. The results

of this survey reveal a significant lack of understanding among students of what constitutes poor academic practice. Using the same survey format adopted for the earlier surveys and reported in Warren et al. (2012), the larger survey bears out those earlier results. The survey instrument used Likert scale questions to gauge student attitudes to a number of issues related to plagiarism and poor academic practice. The survey adopted a five point scale ranging from strongly agree to strongly disagree together with a "don't know' option. Analysing the survey results and combining those agreeing or strongly agreeing with what constitutes plagiarism, only 83% of students thought paraphrasing or summarising others' work without citation was plagiarism Table 1. This result alone shows that there is a serious issue to be addressed.

Conversely, directly quoting others' work and correctly citing the source was still seen as plagiarism by 20% of students once again demonstrating a lack of understanding. It has long been understood that while many students recognise that copying text is plagiarism they frequently fail to recognise that copying images is also plagiarism. The survey showed that copying a diagram or table and citing the source was still thought to be plagiarism by 21%, while only 73% understood that this was acceptable practice, with the remainder unable to decide.

Although in a related question, while plagiarism was thought to be a serious issue in academic writing with 97% of respondents agreeing that it was a serious matter only 70% thought that copying images and maps from the internet was serious. It thus seems that students apply a different standard to images than written text. Students were particularly unsure when it came to taking a paragraph of text and altering several words. Only 50% thought this was wrong, while 35% believed this to be acceptable practice.

Table 1 Student Responses: Plagiarism Includes:

	Agree	Neutral	Disagrees
Paraphrasing or summarising someone else's work and not citing them as the source.	83%	5%	12%
Quoting information in your essay and correctly citing the source.	20%	5%	75%
Working with a group to produce a final report and claiming you contributed equally when you did less work than the other members of the group.	50%	19%	24%
Submitting an assignment for assessment that you have previously submitted for another course.	54%	15%	26%
Inserting an image, map or diagram into your assignment and correctly citing the source.	21%	5%	73%
Not citing the original source when you use someone else's idea, but you express it completely in your own words.	63%	16%	18%
Creating an informal study group to brainstorm your assignment topic	18%	14%	64%
Observing a design and incorporating the key ideas into your design and acknowledging the designer.	21%	10%	66%
Copying a paragraph and replacing several words so it's not exactly the same as the original, and citing the source of the information.	50%	12%	34%
Copying and pasting information from the Internet and incorporating it into an assessment item without acknowledgement.	83%	4%	13%
Copying information from several sources due to the demands of the course and other time constraints.	75%	10%	11%

The results of this survey reinforce the need for students to be given specific guidance in good academic practice. This is particularly so when 61% of respondents acknowledged that they had never received any formal training in academic integrity and plagiarism. With this finding it is little wonder that many students fall into bad habits and unwittingly plagiarise in their academic writing. The need for training in good academic practice is further reinforced when nearly 12% of students consider cheating to be part of the real world and that 25% think that copying is a way to speed up assignment preparation.

CONCLUSIONS

The incidence of cheating and poor academic conduct among university students has been increasing in recent years. The increase in cases of plagiarism is variously attributed to the ease which material can be copied from web sources through to the increasing time pressures placed on students. Recognition of this growing problem among students studying to enter professions where honesty and integrity are fundamental values required in professional practice is of concern to both the academic community and to the broader profession. The results of a study among students seeking to enter the property professions has demonstrated a lack of clear understanding as to what constitutes good academic practice. This finding matches the observation among academics that much of the plagiarism detected in students' academic writing is a result of poor understanding or practice rather than a deliberate attempt to deceive. The educational intervention developed as part of the property and real estate programs at UQ has been successful in raising student awareness of the issues related to poor academic practice. However, as the results show there is still a need to increase student skills further in the use of proper citation. This research has validated the development of the teaching tool and led to its adoption on a university wide basis in 2012. Subsequent data from a university wide survey has validated the earlier findings that students lack a clear understanding of what constitutes poor academic practice. Most students recognise that plagiarism is a serious issue, yet many of them are unable to recognise what is or is not plagiarism in all but the simplest of incidences.

There is a need for much more in-depth research into the reasons for poor academic practice among students and in particular further evaluation of the benefits of a program such as that implemented in our courses. Further analysis across a more diverse group of students and subject disciplines is currently underway and will be evaluated against the increasing use of plagiarism detection software which is increasingly becoming a compulsory element in university assignment evaluation.

ASSESSMENTS FOR QUANTITY SURVEYING COURSES

Sean Ostrowski[1]

[1]*University of Glamorgan, Faculty of Advanced Technology, Wales, CF37 1DL*

ABSTRACT

A series of assessment schemes working from first principles to incorporate the appropriate objectives, competencies and outcomes. The need for contemporaneous feedback is incorporated into the various schemes. Using self and peer assessment is shown to be time saving, accurate and popular. The problems of failure and plagiarism are reviewed. A more rigorous system using minimum standards rather than percentages is demonstrated.

Key words : Criteria, definitions, minimum standards, percentages, principles.

INTRODUCTION

This paper examines assessment from first principles, proposes suitable criteria for assessing quantity surveying (QS) work and then provides practical examples. It is a further contribution towards a synoptic pedagogy for QS.

PRINCIPLES AND DEFINITIONS

The principles of teaching technical competencies like QS and their assessment have been elaborated in Ostrowski (2010, 2011) and are summarized below.

Table 1 Principles for a synoptic pedagogy for QS technical competencies.

EPISTEMOLOGICAL	COGNITIVE	PSYCHOLOGICAL	ENVIRONMENTAL	EMOTIONAL	TEACHING
Procedural Knowledge	Knowledge	Behaviourism	Facilities	Personal	Training
Contingent Instruction	Understanding	Cognitive Psychology	Collaboration	Motivation	Outcomes
Contemporaneous Feedback	Learning	Constructivism	Groups	Risk Free	Assessments

CRITERIA

Formative and summative assessments

*"…**formative assessment** is that undertaking the assessment constitutes a learning experience in its own right...**summative assessment** is not traditionally regarded as having any intrinsic learning value." www.heacademy.ac.uk 24.7.08.* It is often the case in technical competencies like measurement for assessments to be exercises for submission at the end of term. Although nominally a formative assessment, because they appear to demonstrate the progressive acquisition of knowledge, they are in fact a summative assessment because they do not provide any opportunity for feedback. To be formative assessments the feedback, which consists of marking the work and providing annotations on the scripts, needs to be

available before the next piece of coursework is undertaken, i.e. contemporaneous feedback. Summative assessments rely on a demonstration of the extent of the acquisition of technical competence and are normally closed book examinations with no feedback.

Criterion referenced and norm referenced assessments

Criterion Referenced Assessments (CRA) is marking to a standard. A judgement is made about performance. Norm Referenced Assessments (NRA) is competitive marking. They make comparative judgements about people. Technical competencies are an arbitrary positivist paradigm (Cohen, Mannion and Morrison, 2007) and there is either a right or a wrong answer. The objective is an active, authentic demonstration of capability, not talking or writing about it. The analogy is trying to use a written examination to establish the technical expertise of a bricklayer. What is required is a practical test of competence. Biggs (2003) describes it as the extent to which functional knowledge can be "…*put to work*…" (p. 206). The assessment is convergent, solving problems that have a particular unique answer. To reach an appropriate level to be able to demonstrate that the right answer has been achieved is a CRA of professional competence. NRM is not appropriate where the objective is a particular standard that has to be achieved.

Multiple choice tests

The attraction of multiple choice tests (MCT) is the speed of the process which reduces the marking burden of large classess. However there is a fundamental problem with using MCT. Technical competencies are a particular kind of knowledge, procedural knowledge and this requires a particular kind of teaching and a particular kind of assessment. This is aligned teaching. Biggs (2009) states *" Use an assessment task that directly addresses the outcome and enables you to directly judge if and how well the student's performance meets the criteria."* Shavelson, Ruiz-Primo & Wiley (2005, p.415) provides the direction " *And to measure procedural knowledge, performance assessments, not paper and pencil, are necessary."*

To emphasise the importance of ensuring that the right kind of test is provided Biggs (1996) is insistent that MCT is inappropriate. The following series of quotations leaves little room for doubt. *"However when the modes of assessment go no deeper than acquaintance, as is likely with MCT..."* (p. 46) and *"students saw MCT as requiring low cognitive level processes; indeed using deep approaches was negatively related to MCT test performance."* (pps.172-3) and *"MCT assesses declarative* (propositional) *knowledge, usually in terms of the least demanding process, recognition. MCT reflects the extent of (declarative) knowledge.* (p.180)

There are examples of MCT that have been devised for technical competencies that try to overcome this. For example the test is set up in the normal MCT manner but the answer can only be provided when the student has completed a calculation on a separate document. This means that the answer needs marking using the MCT format but also the calculation needs collecting and marking also. The additional marking reduces the advantage of using MCT and still does not provide an adequate assessment of the acquisition of the technical competence. The dangers of using inappropriate assessment procedures is pointed out by Gjestland, Blanton & Lerouge (2004, p.18) who state that "*The results indicate a significant difference in the performance of students between the questions testing declarative knowledge and those testing procedural knowledge* (Abstract) and *"...there is a significant difference in the performance of the students between declarative and*

procedural questions... those students with more experience...performed better at the procedural questions...".

MCTs are designed for a different kind of knowledge, cannot demonstrate the acquisition of procedural knowledge and cannot be adapted to do so.

Failure

The price of increased class sizes, reduced thresholds, increased diversity with little increase in teaching staff who are able to provide technical competencies is an increased failure rate. This failure rate, euphemistically called the retention rate, has also become the target for penalties to try to ensure that the most marginal of the students are retained in the system. This is a particular problem with technical competencies where there is a right and wrong answer with few marks available for interpretation and context.

Peelo and Wareham have reviewed failing students and have stated *"...this tension between the widest possible access to universities & the need to maintain standards has been with us for years..."* (2002, p.4). They have indicated that between 1992-1998 the rate of non-completions was 17-19%. The reasons for this are given as poor quality of experience, inability to cope with course demands, unhappy with social environment, wrong course, finance, dissatisfaction with some part. The *'inability to cope with course demands'* is likely to include academic ability and the time demands of students who also have to work or care for a family. They have used the phrase non-completions rather than failure or retention and they take the view that progression includes a significant amount of adjustment *"...For many failing is not an event but a series of hesitations..."* (2002, p.3) and *"... in educational terms, failing can be part of a developmental process and a means of learning..."* (2002, p.3). Work in South Africa on foundation years for disadvantaged students has indicated that the range of problems encountered required a high level of resources and personal attention. This comes mainly from the perceived inequalities of a substantial minority whose diverse backgrounds require individual attention. (Grayson, 1996 & 1997 and Miabila, Maladje & Addo-Bedialo, 2006).

Peelo and Wareham make a strong plea not to consider a low retention rate, i.e. a high failure rate, to be an indication of fault or failure. They state *" ...the key to dealing with failure in HE is to accept it as a normal and desirable part of the learning experience....Failure itself is unlikely to harm...a constructive acceptance of it is highly desirable..."* (2002, pg 123).

The solution is to reduce the standard or the application of a large amount of resources to achieve lower failure rates. The former is unacceptable and the latter impossible. An appropriate response might be that the increased failure rate is a natural consequence of increased diversity and numbers.

Bonuses

Hertzberg (1959) and Maslow (1970) identified significant motivating factors as achievement and recognition. Positive and negative motivation have been developed by McGregor (1960). Positive motivation is a reward for success, achievement and recognition is provided in the form of marks and bonuses. Negative motivation is just as important in a positivistic paradigm such as measurement where failure is recognised as incomplete and inaccurate work. For technical competencies negative motivation is an important educational tool. For high achievers a bonus mark for exceptional contribution is a useful positive

motivator. For low achievers the negative motivator of fear of failure is also effective. The public recognition of achievement is a proven positive motivator and the apparent suppression of published lists of results by the Data Protection Act (1998) is a retrograde step.

Minimum Standards

Another criterion for assessment is the need to set out and maintain a minimum standard that is acceptable. Perera, Pearson and Ekundayo (2011) have pointed out that there is no standard way to interpret the actual achievement of competencies. The use of minimum standards addresses this difficulty. The problem with percentages and Pass/Merit/Distinction as performance indicators is that undue emphasis can be given to the 'soft' options of managerial and moral competencies. A pass can be obtained despite a poor performance on the technical competencies because a large proportion of the marks are provided for other competencies. The pass rate or retention level, can also be increased by reducing the tariff for a pass. A pass rate of 35% is not unusual and a substantial proportion of this can be in non-technical competencies. Borderline cases at 25-35% are often favourably reviewed with an eye on a large tail of failures that is looming. This is the inevitable consequence of large and diverse student numbers and limited teaching resources. The result is that standards are compromised and the results are diluted to the point that students pass through the system and emerge with little technical competence. The system has been prejudiced and its value is questioned. It may not be possible to maintain technical competencies standards in the light of the relentless pressure on resources.

One solution has been described by Bouriscot and Roberts (2006, pgs 74-96) using a more rigorous approach. A performance based method of establishing if technical competencies have been acquired is described whereby medical students who are practicing various components of expertise do a circuit of 'stations' "*…and perform a particular task at each…"* A panel of experts *"…describe a minimally competent/borderline student to establish a level of competence for the particular examination…"* at each station. This removes the ubiquitous percentage system of marking and imposes a practical appraisal of technical expertise. Minimum standards is part of a marking scheme currently in use at London South Bank University (LSBU) by Helen Ward for assessing minimum clinical technical competence of nurses. It is described by Ward and Barratt (2009, p.5) who have provided a practical scheme for assessing the minimum clinical (technical) competence of nurses at LSBU using assessment stations of 10 minutes each. *"…final year 10-station OSCE session which comprises three physical examination stations (technical competence); three history taking stations; three stations that cover communication skills (managerial competencies)…"* Conversation with Helen Ward indicate that these schemes have been in place for 20 years. They are a benchmark for the whole industry for both the assessment process and the content.

The use of minimum standards at particular 'stations' for the assessment of QS technical competences provides a standard that will reassure the profession and students. Teachers will have to teach to this standard which is a more rigorous appraisal rather than to a sliding scale of percentages. The marking burden is also much reduced.

Plagiarism

Copy and paste is now the normal method of preparing work. If information is extensively and freely available restricting its use becomes counterproductive to

 ISBN: 978-1-84219-840-7 .

education and training. Plagiarism/copy and paste has a limited value in enhancing the knowledge of those participating in it. To provide specific guidance the emphasis should change from restriction to encouragement. For example indicate that the level of personal work should be 75%. This would limit plagiarism/cut & paste to 25% without providing a restrictive covenant. Bonus marks for no plagiarism/cut & paste would be a positive motivation for cognitive development. To date electronic surveillance, eg Turnitin, is not effective for technical competencies.

PRACTICAL APPLICATION AND EXAMPLES

The following table provides a comprehensive marking regime:-

Outcomes as percentages

The objectives are set out as percentages. They are the primary functions of technical, managerial and moral competencies. The key functions are the specific outcomes for that discipline. The proportions that are assigned emphasise the need to acquire technical competence. Failure to reach the necessary level of technical competence is a powerful negative motivator for low achievers. A bonus is a powerful positive motivator for high achievers.

Self and peer assessments

The group exercises carried out and marked by the students in collaborative groups in class, which encourages participation and provides empowerment. Self and peer marking is characterised by the self-marking students awarding marks according to the effort involved. The peers mark the quality of the work. The marking is best administered by asking the peers to mark the work first. This allows the self-markers to see a relatively objective assessment before they mark their own work. The emphasis changes from marking the effort to marking the quality. The work should be moderated by the examiner to indicate the gap between the marks provided by the students and that of the teacher. The marks of the students and the teachers will become closer with practice. My own experience is that this takes one academic year.

Formative Assessments

The courseworks are undertaken outside the classroom and are marked by the lecturers. Formative assessments help the acquisition of technical competencies and allows students to develop insights into their strengths and weaknesses. They have a primary objective of performance and comprise progressive problem solving coursework exercises. The annotation of the submissions and marking sheet is provided within 10 days on the Gradebook on Blackboard and provides the contemporaneous feedback which Biggs (2003) emphasises as probably the most important factor of all in assessments.

Summative Assessments

The principles of using both formative and summative assessments allows the growth of practice to be checked during the term and then tested and graded at the end. The summative assessment has a clear objective of demonstrating functioning knowledge and a suitable assessment task is problem solving. Closed book examinations demonstrate the extent of the acquisition of technical competence. The summative assessment of a formal three hour closed-book examination of solving problems that have a unique answer remains a challenge for some of the students. There remains a significant failure rate that is usually repeated at the

 ISBN: 978-1-84219-840-7 .

resits and this is because the realisation that shallow learning will not succeed in these technical competencies has not been achieved. Moderation of coursework and examination marking by other members of staff and external examiners ameliorates variable quality. These criteria are demonstrated on an assessment marking sheet below.

 ISBN: 978-1-84219-840-7 .

Table 2 Prescriptive marking using percentages

ASSESSMENT CRITERIA OBJECTIVES & OUTCOMES				**FORMATIVE**							**SUMMATIVE**	**UNIT MARK**

Minimum standards

This assessment programme provides an opportunity to demonstrate to all the stakeholders that the teaching has achieved a suitable minimum standard. The following table provides a recent example of a minimum standards assessment marking sheet for a technical question. The equivalent percentage mark is also shown. Many of the border line successes using the percentage method did not in fact meet the minimum standards because they were unable to demonstrate accuracy or comprehensiveness in some of the fundamental areas. Overall the percentage failure using percentages was 14%. Using minimum standards the percentage failure was 31%. This can provide a benchmark for students, staff, employers and professional institutions for acquisition of the necessary technical competencies at progressively higher levels.

Table 3 Minimum standards: working example

CONCLUSIONS

Despite the frailties of the various forms of assessments they are necessary to demonstrate levels of technical competencies. The development of an effective assessment scheme is part of a synoptic pedagogy for QS teaching. The requirements of teaching a complex technical subject based mainly on procedural knowledge are extensive. The same is the case for the assessment process. The pressure of increased numbers and limited resources provide an opportunity for innovative assessment systems that improve the standards and reduce the burden of marking. The prescriptive marking scheme provide an alternative which reduce the marking load, improve quality, removes bias and empowers students. The minimum standards system ensures a transparent threshold for students, staff and employers.

BINDER LEACHING OF NATURALLY HYDRAULIC LIME MORTARS

Alan M Forster[1] and Ewan Szadurski[2]

[1]*School of the Built Environment, Heriot-Watt University, Edinburgh, Scotland, EH144AS*

[2]*School of the Built Environment, Heriot-Watt University, Edinburgh, Scotland, EH144AS*

ABSTRACT

Masonry built in lime mortar is one of the principle building materials used in traditional construction. This form of construction can convey the appearance of strength and stability and could be argued to epitomise built homogeneity. This may however not reflect reality due to deterioration of the wall core resulting in an alteration in the effective thickness. Predicted future climate change models for northern regions, indicate more instances of heavy rainfall. This will undoubtedly result in materials used in mass masonry structures becoming saturated for extended periods, increasing instances of binder migration (binder leaching). The leaching process involves the deterioration of binder structure via dissolution and removal of calcium into the pore fluid. This can, in many cases, result in reprecipitation of calcium on the external skin of the structure. The effect of this phenomenon on the physical properties and performance of lime mortar has not yet been fully investigated but early stage results indicate a reduction in mechanical strength and an alteration of the materials moisture handling characteristics. The current EPSRC funded research project (EP/G064865/1) aims to ascertain the extent of binder leaching by inducing an artificially accelerated leaching environment. Leaching trials have been carried out on a variety of natural hydraulic limes (NHL), both carbonated and uncarbonated, representing those potentially found on mass masonry structures. The present work aids our collective understanding of this fundamental deterioration process enabling prediction of mortar condition and performance to be achieved. Determining traditional building resilience has never been as important, especially given the broader context of climate change.

Keywords: binder, dissolution, leaching, lime, mortar

INTRODUCTION

An estimated 446,000 pre 1919 dwellings, totalling 20% of the building stock, exist in Scotland today. The vast majority of these are believed (McKinney, 2007, Urquhart, 2006) to be constructed of stone. More specifically, it has been estimated that there are some 24,000 traditional built stone facades in Glasgow alone, requiring approx £500M to repair (Urquhart, 2006). Of course, structures constructed in traditional mass masonry are not restricted to Scotland or to tenement forms, with innumerable

[1] a.m.forster@hw.ac.uk
[2] ems5@hw.ac.uk

low rise domestic buildings, historic bridges, viaducts, infrastructural masonry (i.e. retaining walls), castles and palaces existing within the UK and across the world. Mass masonry construction is generally composed of an internal and external skin of masonry bedded in lime mortar with a lime built rubble core. The structural performance of these walls relies upon the effective thickness and homogeneity to create stability.

Anecdotal evidence from building professionals is that situations have arisen in which the mortars have been found to be binder deficient (Forster, 2007). In many situations, voids have been found in wall cores behind the apparently sound masonry pointing and bedding mortar, and this has been subsequently associated with progressive collapse in many traditional buildings (Kent, 2005). Beckman, (1995:86) indicates that '*if the skins are thin compared to their height and if they are not well connected to the core, they may buckle*'. It is therefore clear that the condition of the core is critical for stability.

McKibbins *et al* (2006:78) believes that '*Contributory mechanisms for deterioration of masonry in all types of structures include, moisture saturation and leaching of mortar…. Leaching results in physical loss of strength and adhesion. Mortar that has undergone severe leaching can become weak and friable, and is easily lost from joints by washing-out or compressive extrusion in areas of high stress, resulting in local stress concentrations and loosening masonry units.*' Beckman (1995:86) reinforces this view highlighting the implications of long term saturation, indicating '*rainwater enters the core and dissolves or leaches out the lime and loosens the fine particles. These are then washed down, leaving behind cavities, which grow until the rubble collapses into them*'. Binder leaching is clearly a function of moisture content and it is evident that due to increased rainfall associated with climate change (Hume, 2002; Cassar & Hawkins, 2007) masonry fabric will be wetter, for longer. Certain components within the mortar may dissolve and move from the body of the material and be re-deposited within the pores, construction voids, or may be left simply upon the wall faces of the building (see plate 1).

Plate 1: Lime leachate to piers

The most vulnerable binder components to dissolution are (Hewlett, 1998, Taylor, 1990) calcium hydroxide ($Ca(OH_2)$ and calcite (calcium carbonate, $CaCO_3$). The hydraulicity of the original mortars will have a significant influence upon the set characteristics of the material. Non-hydraulic and feebly hydraulic limes require a high degree of carbonation for their set propagation and have a correspondingly low

proportion of hydraulic components within their composition. Intuitively, these forms of lime binders are the most susceptible to dissolution, when placed in saturated, cold conditions and is a function of the relative proportion of $Ca(OH)_2$.

The extent to which binder dissolution occurs has yet to be fully undertaken. It is however, assumed that the rate of deterioration will be extremely slow and may take decades rather than years. Although these time frames may be very slow, it must be emphasised that many of the structures that we are dealing with may already be many decades old, and those that are considered historic in nature may be centuries old. Those buildings that are ruinous may have been roofless for several hundred years, further exacerbating the problem. This Engineering & Physical Science Research Council (EPSRC) funded project (EP/G064865/1) has undertaken to evaluate this phenomenon and this work establishes some of the preliminary findings.

RESEARCH OBJECTIVES

The aim of the research is to establish the rate and consequence of soluble binder leaching from various lime mortar types commonly used in traditional mass masonry construction. It determines the effect on physical and chemical properties of the mortars, and specifically the work investigates the changes to the macro and micro pore structure and its effect on moisture transfer mechanisms. The project objectives are:

1) Determine the rate of free lime binder leaching ($Ca(OH)_2$) in a range of hydraulic lime mortars, using ammonium nitrate accelerated deterioration method.
2) Assess the changes in moisture handling characteristics of the samples via sorptivity testing.
3) Assess the effect of binder loss upon the compressive and flexural strength characteristics of the lime mortars.
4) Characterise the change in the composition of the mortars.
5) Develop a predictive model for assessing the influence of binder depletion on compressive and flexural strength of the mortars to give building professionals and engineers a rational basis for of in-service performance prediction.

EXPERIMENTAL PROCEDURE

Sample manufacture and curing

A range of lime binders adopting a constant binder to aggregate ratio for all samples of 1:3 (by weight) was used. This regime was a modification of BS EN 459-2 (2010) and BS EN 1015 (2002). Well graded silicaceous sand (Cloddach concrete sand) ensured isolation of variables as it does not contain calcinitic mineral components. This aggregate is representative of materials commonly used for the repair of traditional masonry structures in Scotland. St Astier natural hydraulic lime (NHL) was used as it is the most commonly adopted binder for conservation works in the UK. NHL2 (feebly hydraulic), NHL3.5 (moderately hydraulic) and NHL5 (eminently hydraulic) samples were manufactured and cast into 160 x 40 x 40mm prisms moulds, following BS 459:2 (2010). These samples were cured in a TAS series 3 environmental cabinet under two different regimes in order to modify the physical and chemical characteristics of the mortar; one ensured a full carbonation set (60% RH at 20°C) whilst the other un-carbonated (100% RH at 20°C). This was an attempt to simulate conditions that may be encountered in existing structures, namely, fully carbonated mortars located in the outer masonry and partially carbonated or

uncarbonated material within the wall cores and inner sections of bridge construction. The carbonation regime followed that established by Lawrence (2006).

Accelerated leaching

A chemical extraction process using ammonium nitrate (NH_4NO_3) was utilised to accelerate the leaching of calcium (Ca^{2+}) ions from the NHL samples. Nguyen *et al*, (2007) formerly used this technique to evaluate deterioration in cements and concretes and indicated an accelerated leaching of Ca^{2+} ions in the region of 200-300 times that that of the natural phenomena. Modification of Nguyen *et al*, (2007), experimental procedure was undertaken to take account of the different characteristics of naturally hydraulic lime mortar compared to the relatively more durable concretes and ordinary Portland cements. This resulted in a dilution of the ammonium nitrate concentration reducing the solutions aggressivity. Samples were immersed in a solution of 1 mol/l (1M) concentration of ammonium nitrate in deionised water. The volume of the solution was kept constant and monitoring of the pH and temperature was continuously logged via a data acquisition system (see fig. 1).

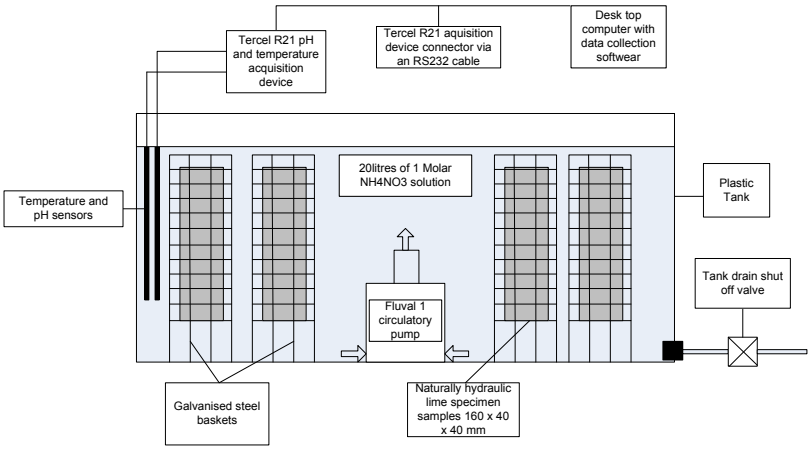

Fig 1: Ammonium nitrate extraction apparatus (after Nguyen, 2007)

A pump ensured that the ammonium nitrate solution was circulating, thereby preventing non uniform solution concentration. The samples were immersed for 1, 4, 9, 16, 25, 36, 100 and 169 days. Additional samples were ran in parallel for the initial 36 days. These were kept in vats of de-ionised water in an attempt to establish a datum for the natural dissolution rate.

Physical and chemical investigation of pre and post accelerated samples

A range of tests were established to determine the physical and chemical characteristics of the materials. Control samples were used to provide a baseline for pre deteriorated properties. Samples that had been subjected to accelerated deterioration were tested at various intervals (as previously outlined) adopting the following techniques:

i) Phenolphthalein testing: In order to measure the speed of dissolution the samples that were subject to the ammonium nitrate and deionised water were fractured and surfaces were sprayed with phenolphthalein solution. This was undertaken to measure, and ultimately calculate the leaching depth of the $Ca(OH)_2$ from the samples (see plate 2). **ii) Sorptivity testing:** The sorptivity of the mortar samples were evaluated using the '*sharp front theory*' established by Hall & Hoff, (2002:97). The sorptivity of each prism sample type was determined by immersing the bottom surface

of the samples in water and measuring weight gain / over-time following the basic function $t^{1/2}$ (see fig.4). This gave an indication of the change in pore structure and subsequently the moisture transfer characteristics. **iii) Flexural and compressive strength:** Each sample type was tested in a Lloyds universal testing machine (model M5K) at specific intervals. This enabled an assessment of the influence of loss of $Ca(OH)_2$ on the physical characteristics of the mortar samples. **iv) Petrograhic analysis:** A selected range of mortar samples were assessed under polarised light microscopy, enabling the pore structure and mineral composition of the binder to be determined by point counting. This was undertaken to identify the influence of leaching of $Ca(OH)_2$ and to evaluate the remaining components, such as calcite and calcium silicate hydrates (C-S-H). **v) ESEM analysis and EDAX:** The freshly fractured surfaces were studied adopting the Philips XL30 ESEM, whilst simultaneously undertaking Energy Dispersive X-Ray Micro-analysis (EDAX) techniques to determine the chemical composition of the products of hydration of the binders used, and the surface characteristics of the material.

Preliminary results and discussion

Provisional experimental results for the ammonium nitrate (NH_4NO_3) extraction tests will be discussed. It must be emphasised that the project is still ongoing and these results simply establish early stage findings of the physical properties, and more specifically the compressive, flexural and sorptivity values. The results focus on the NHL5 and NHL2, carbonated and un-carbonated mortar samples as they are representative of the extremes in material composition and more specifically the relative quantity of calcium hydroxide ($Ca(OH)_2$) and calcite ($CaCO_3$) if carbonated.

Compressive and flexural results

The test results indicate a clear difference between the samples subjected to the NH_4NO_3 and the de-ionised water (see fig 2 & 3). The samples generally correlate with perceived wisdom, in so much as, the samples with a higher proportion of hydraulic set and therefore a reduced carbonation requirement (such as an NHL5 samples) have a smaller decline in strength.

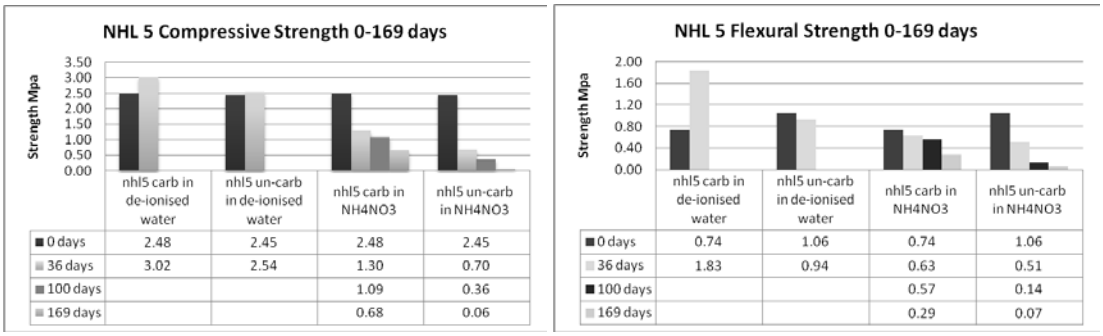

Fig. 2. Compressive and flexural strength changes over time NHL5

The NHL5 carbonated samples in the de-ionised water increased in compressive and flexural strength over the 36 day period while the un-carbonated samples showed an increase in compressive strength and a marginal decline in their flexural strength (See fig. 2). This may be associated with favourable hydration curing environment (i.e. submerged in water). The NHL5 samples in the NH_4NO_3, both carbonated and un-carbonated samples exhibited a large decrease in their compressive and flexural strength over the same time frame, with compressive strength being more effected.

 ISBN: 978-1-84219-840-7 .

After this initial 36 day period the NHL5 carbonated samples did not exhibit a large decline in compressive and flexural strength (100 and 169 day testing period). In comparison the un-carbonated sample continued to decline in strength, with the result that there was negligible strength left at the 169 day period (See fig. 2).

The NHL2 samples in comparison to the NHL5 reflect a different pattern. All the NHL2 samples decreased in both compressive and flexural strength when subjected to the de-ionised water and the NH_4NO_3. The small loss of strength in the carbonated NHL2 relative to the NHL5 samples subjected to the NH_4NO_3 could potentially be attributed to the high proportion of calcite formation. Conversely, the slow hydration of belite (C_2S) [the main hydraulic component in hydraulic limes] and its subsequent conversion into C-S-H in the NHL5 samples would make the carbonation formation disproportionately important in terms of strength development. The un-carbonated NHL2 samples in the NH_4NO_3 had insignificant strength left after the initial 36 day period (See fig. 3). This would generally be associated with higher proportions of $Ca(OH)_2$ and calcite leaching from the samples.

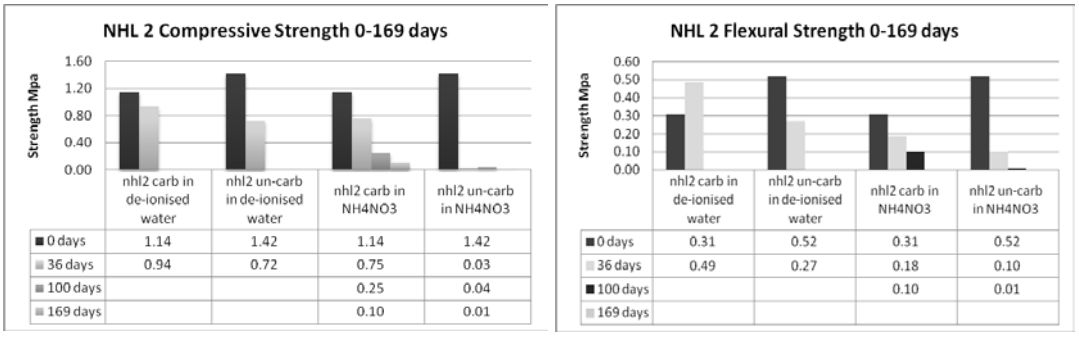

Fig. 3. Compressive and flexural strength changes over time NHL2

Sorptivity: The sorptivity values for the un-carbonated samples were lower than the carbonated ones. This was unexpected with the NHL5 carbonated samples attaining the highest values of all. The NHL5 samples, subjected to the de-ionised water exhibited the highest reductions in their sorptivity values (see fig 4). The carbonated NHL5 also exhibited a reduction after 36 days in the NH_4NO_3 whereas the un-carbonated samples increased. (See fig.4)

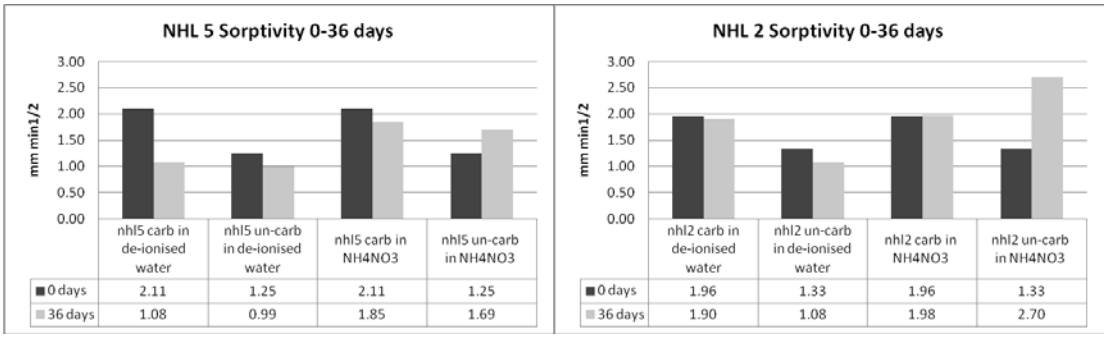

Fig. 4. Change in sorptivity value of NHL2 and NHL5

The carbonated NHL2 sorptivity values were not greatly affected over the course of the 36 days test runs, whereas the un-carbonated NHL2 samples reduced significantly in strength and exhibited a 50% increase in their sorptivity value. This is indicative of

 ISBN: 978-1-84219-840-7 .

washout of the $Ca(OH)_2$ and is visually represented in the phenolphthalein staining test results seen in plate 2.

Dissolution front assessment (phenolphthalein staining): It was observed during the first experimental run that all the un-carbonated [$Ca(OH)_2$] lime material had leached out within the first 36 days. As such it was not possible to track this dissolution front. Attempts to ascertain the extent to which the NH_4NO_3 accelerates the process and subsequently effects the materials physical and chemical properties were undertaken.

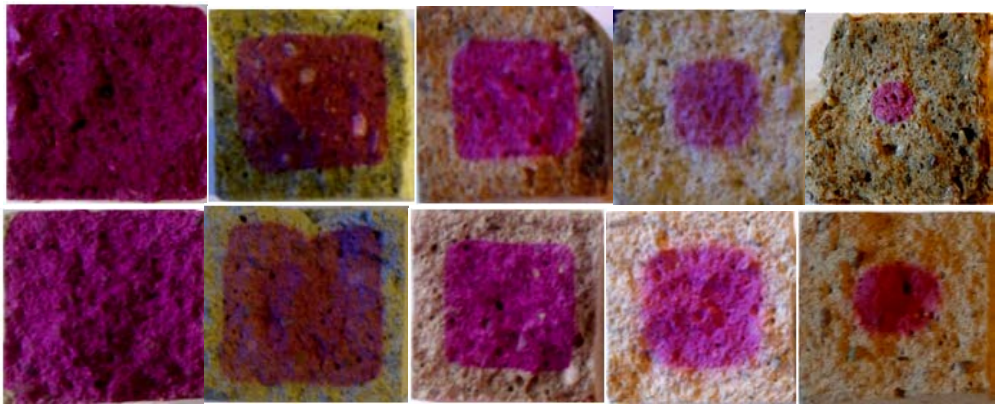

Plate 2: Phenolphthalein test results on uncarbonated samples subjected to NA_4NO_3 at 0-4-9-16-25 days (top NHL2, bottom NHL5)

The second test run measured the dissolution front by spraying the samples with phenolphthalein solution at designated time intervals, measuring the distance from the outside, to where the boundary of $Ca(OH)_2$ material remained. This is shown as the dark regions in plate 2 and reflects an alkalinity pH 8.6-12. The un-carbonated NHL2 samples leached $Ca(OH)_2$ at an accelerated rate compared to the un-carbonated NHL5. The advancing dissolution front correlates with the physical testing results attained over the initial 36 days. The increase in the depth of dissolution front of the $Ca(OH)_2$ can be directly related to an increase in sorptivity, and a decrease in the compressive and flexural strengths. The increased rate with which the NHL2 samples leached can be attributed to the quantity of $Ca(OH)_2$ contained within the material. It is reasonable to assume that this situation leads to a greater proportion of the composition of the material being lost via dissolution as the front advances through the sample; increasing the pore size, and pore interconnectivity.

CONCLUSIONS

These results confirm that the ammonium nitrate extraction method accelerates the leaching of $Ca(OH)_2$, or un-carbonated components of the mortar samples. This is evident by the phenolphthalein test results that clearly show the leaching front of the un-carbonated components and complete $Ca(OH)_2$ loss was noted by 36 days. This is important as it highlights the vulnerability of un-carbonated lime to saturated environments especially over longer time frames.

This information has practical implications for the performance of lime mortars and will have the greatest influence on binders containing a higher proportion of $Ca(OH)_2$, such as NHL2. Freshly placed lime mortars have been shown to have a greater resistance to $Ca(OH)_2$ loss than would have been initially expected. This will go some

way to alleviate performance fears of lime mortars that are inadvertently saturated. Practically, this preliminary study illustrates the significant alteration in the materials properties. It is evident that long term saturation of masonry and associated mortars should be considered when evaluating traditional and mass masonry structures. The loss of binder results in a reduction in both compressive and flexural strength and can also be correlated with an alteration in the moisture transfer properties of the samples. These characteristics are important to attain a better understanding of mortar performance but should be seen within the context of an early stage development of a wider range of tests. When combined these should enable a rigorous method for predicting the impact of the physical performance of binder loss to be achieved.

ABSTRACT

To develop a BIM course for construction programs, a systematic course development approach should be used. The approach presented in this paper has three stages, including preparation, development, and improvement. During the preparation stage, a syllabus review needs to be conducted to identify and evaluate the BIM courses currently offered by construction programs; an extensive literature review needs to be performed to identify current trends in the industry; and the survey needs to be implemented with professional BIM experts to prioritize the essential and necessary areas in BIM education. The development stage consists of framing a BIM course, setting goals and objectives, choosing and organizing the course contents, and planning the course schedule. At the improvement stage, the proposed course is improved, reviewed, and evaluated by BIM experts from the industry and academia through a detailed feedback process. From this systematically developed BIM course, students in construction programs will learn basic knowledge of BIM; the importance and applicability of BIM to the project; the basic BIM software skills; and the future direction of BIM in the construction industry. Furthermore, students will be able to understand the importance of collaboration among project stakeholders and the advantages and pitfalls of BIM.

Keywords: building information modeling, BIM education, construction education, course development, undergraduate curriculum

INTRODUCTION

BIM has quickly gained momentum in the construction industry. This momentum is shared by professional and industry organizations including the American Institute of Architects (AIA), the Associated General Contractors (AGC), and the American Institute of Steel Construction (AISC), as well as public sector bodies such as the U.S. General Service Administration (GSA). Many of these organizations have issued BIM guides and appropriate contract forms, such as the Consensus DCCS 301 BIM Addendum and the GSA BIM guide (Young, et al. 2009). Even though BIM has been

[1] ahny@ecu.edu, leenam@ecu.edu
[2] ccho3@uncc.edu

widely adopted in the construction industry, one of the key constraints limiting those companies seeking to utilize BIM is the lack of personnel with BIM skills. Many panel participants in the AISC and ACLL eConstruction Roundtable identified the lack of knowledge among practitioners who were otherwise ready to move the industry into the BIM age as a major bottleneck (Harmann and Fischer 2008). Young, et al. (2008) agreed, pointing out that the lack of adequate training is the greatest challenge to adopting BIM in the construction industry. Furthermore, the *SmartMarket Report* (Young, et al. 2009) suggested that to maximize the values and benefits to be gained by fully utilizing it, the process of adopting BIM goes far beyond simply creating a group of users within a company. In short, the construction industry needs to focus on BIM education and training to improve the business value of BIM.

Construction programs in higher education have a vital role in BIM education. Offering BIM education for construction graduates can lower the burden of construction companies on BIM training. Many educators have been interested in BIM education in construction programs. Sabongi (2009) studied how BIM was being implemented in the undergraduate construction curriculum. Becerik-Geber, et al. (2011) also studied the level of BIM integration into the current AEC curricula and identified the reasons for not incorporated BIM into the curriculum.

Multiple scholars have emphasized the importance of BIM education in construction related programs (Sacks and Barack 2010, Sylvester and Dietrich 2010, Peterson, et al. 2011, Wong, et al. 2011). Clevenger, et al. (2010) described the approach taken by Colorado State University's Construction Management Department to promote BIM-enabled learning. The effectiveness of BIM instruction was examined in studies conducted by Azhar, et al. (2010). All these scholars asserted that the students graduating from construction programs should be fully equipped with the BIM knowledge and skills they will need in their future careers.

BIM education in the construction program is still in the early adoption stage, even though several construction programs have offered BIM courses to their students. It is clearly necessary to develop BIM courses in all construction programs, which ultimately produces future leaders of the construction community who will change the industry paradigm during the course of their careers. This study adopted the Tyler Model (Tyler 1969) to develop a BIM course and therefore followed this model's three stages of development: curriculum preparation, curriculum development, and curriculum improvement (Ornstein and Hunkins 1998).

RESEARCH OBJECTIVES, PROCEDURES, AND SCOPE

The goal of this study was to develop a course entitled "BIM in Construction Management" for undergraduate construction students using Tyler's course development model. To accomplish this goal, three research stages consisting of *preparation*, *development*, and *improvement* were created. The course "BIM in Construction Management" developed as a result of this study is designed specifically for undergraduate students in construction programs. This course planned an introductory course that introduces students to fundamental BIM principles and skills over the course of one semester and will benefit undergraduate construction management students who are preparing for future careers in the construction industry.

PREPARATION STAGE OF BIM COURSE DEVELOPMENT

The course development began by identifying the precise needs of the construction students for whom the curriculum was intended. To identify the purposes, benefits, and challenges of BIM implementation in the construction industry, the authors interviewed BIM directors or managers in construction companies. Through the interviews, the authors also identified their general expectations regarding the level of BIM knowledge and skills from construction graduates when making new hires. The authors also developed a survey instrument to probe BIM practice and needs in the construction industry, prioritize the areas of BIM implementation considered important by BIM professionals, measure the relative importance of BIM knowledge and skills required for construction graduates, and identify the types of BIM software they expected their graduate recruits to be able to use. The survey was then distributed to BIM directors or managers at ten construction companies via a web survey tool. The survey results provided valuable guidance on how to organize the content of the BIM course being developed.

Through all these steps mentioned above, it was possible to develop learning goals and objectives, learning topics, instruction methods, and assessment content in the development stage for the course development.

DEVELOPMENT STAGE FOR BIM COURSE DEVELOPMENT

The development stage for course development was composed of five sub-stages which are the most important procedures in the systematic course development process. First, the *basic framework* for the BIM course was created (see Table 1 and Figure 1) based on the inputs from BIM professionals.

Table 1. Characterization of the Course

Course Name	BIM in Construction Management
Target	Junior or senior students in an undergraduate program
Prerequisites	Fundamental construction courses such as construction methods and materials, building structures, plan analysis, electrical and mechanical construction, construction estimating, construction planning and scheduling, and contracting
Course Description	This course will introduce fundamental BIM knowledge and skills involved in the construction process. Topics include visualization, communication, MEP coordination, practical BIM implementation, and relationship between GC/CM and other stakeholders. In addition, this course will utilize several basic software packages including Navisworks, Revit, and Google SketchUp with case-based instruction. A variety of activities and instruction sessions will familiarize students with the use of BIM software.
Learning Outcomes	Upon successful completion of the course, students will be able to describe BIM applications in the construction industry, explain how they are implemented in construction projects, apply their BIM knowledge and skills to actual construction operations, and analyze how BIM can improve a number of different construction processes.

Second, the *learning goals and objectives* were developed (see Table 2), considering BIM practice in the construction industry and the industry expectations of the new course. In addition, the authors reviewed existing BIM related courses in construction programs to analyze how the BIM education is currently offered. When necessary, the authors then contacted the instructors of those courses to request more information on the course.

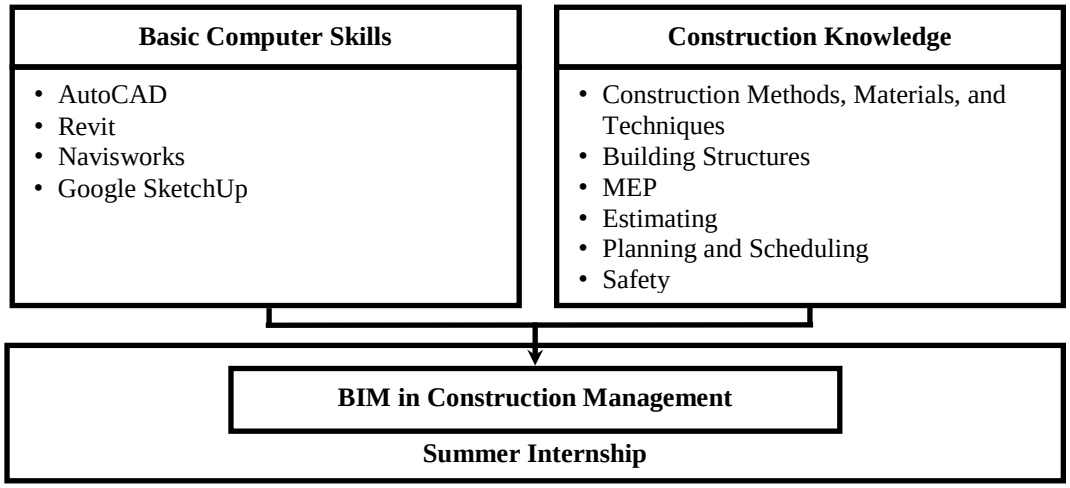

Figure 1. Framework of the Course

Third, appropriate *learning topics* were chosen by considering their relevance to the learning goals and objectives identified (see Table 3).

Table 2. Learning Goals and Objectives for the Course

Learning Goals	Learning Objectives
1. Have a general understanding of BIM knowledge and skills	1.1 State the definition and concept of BIM 1.2 Identify current trends for BIM in construction 1.3 Outline the importance of BIM implementation 1.4 Recognize the history and trends of computer-based modeling 1.5 Describe terminology of BIM
2. Comprehend the concept of BIM as applied in construction	2.1 Explain BIM practices in the construction industry 2.2 Distinguish stakeholders and their roles in BIM 2.3 Summarize how an Integrated Project Delivery System and Lean construction function in a construction project 2.4 Discuss why BIM is important in construction management 2.5 Indicate the benefits and its costs associated with implementing BIM in construction
3. Analyze BIM implementation in construction process	3.1 Compare BIM processes with conventional construction processes 3.2 Breakdown the areas of BIM implementation in construction 3.3 Appreciate the importance of a collaborative environment 3.4 Analyze a BIM implementation plan and contract 3.5 Identify and criticize collaborative work 3.6 Select the strategies of communication and collaboration in a project
4. Apply BIM knowledge to case situations	4.1 Demonstrate basic computer drafting skills 4.2 Manipulate multiple object models to create a single model 4.3 Relate schedule or estimating to BIM models 4.4 Discover the difference and difficulty of different BIM software use
5. Evaluate the future direction and application	5.1 Predict future trends for BIM in construction 5.2 Assess new opportunities for BIM, IPD, and learn construction 5.3 Explain new opportunities for using BIM for facility management and energy modeling 5.4 Support or judge the industry using BIM

Fourth, *content and instructional strategies* were developed (see Table 4), considering that (1) the total time given to each element of the course and the balance between theory and practice should be appropriate and (2) the content should be pitched at an appropriate level for students. In addition, the authors concentrated on matching the selected learning topics with appropriate instructional strategies. However, the choice of the instructional methods considered most appropriate to the subject and intended learning is totally up to the instructor.

Table 3. Learning Topics for the Course

Learning Topics	Sub-Topics	Related Objective
Background knowledge of BIM	• Definition and significance of BIM	1.1 / 1.3 / 2.4
	• Basic background of BIM and computer modeling	1.4 / 4.1 /4.2
	• Terminology of BIM	1.5
	• Practical approaches to BIM	2.1
	• Issues and opportunities for BIM implementation	1.2 / 2.5
BIM in Construction	• Stakeholders and their roles in BIM	2.2
	• Collaboration among stakeholders	2.1 / 2.2 / 3.5 / 3.6
	• BIM applications in construction projects	3.1 / 3.2
	• BIM standard and implementation plan	3.4
	• Rationale and value of BIM in construction	2.4 / 2.5 / 3.3
	• Contemporary trend in BIM research and practices	1.2 / 2.3 / 2.4
	• BIM software for construction	4.1 / 4.2 / 4.3 / 4.4
	• Future trends for BIM and new opportunities in construction	5.1 / 5.2 / 5.3
Analytic Assessment for BIM	• Critical analysis of current BIM cases	3.2
	• BIM analysis for construction process	3.1 / 3.3
	• Analysis strategies for BIM	3.4 / 3.6
BIM Implementation	• BIM practices and process	2.3 / 3.1 / 3.2
	• Case study related to BIM	3.2 / 3.3 / 4.3
	• Course projects using BIM	3.2 / 3.3 / 4.3 / 4.4
	• Internship or practicum field trip	1.2 / 5.4

Table 4. Course Content, Description, and Instructional Strategies

Course Content	Description	Instructional Strategies
1. Class Orientation	• Explanation of course syllabus • Introduction to assignments • Assigning groups for activities • Describing the field trip and guest lectures	Instructor's lectures
2. Instructor's presentation on BIM	• Explanation of BIM issues in construction • Definition and trends in BIM • Stakeholders and their collaboration • Value and opportunities of BIM • Main causes of BIM issues • Reading articles and cases on the use of BIM in construction	Instructor's lectures Assignment # 1 Group discussion # 1 Group discussion # 2 Assignment # 2
3. Learning about BIM practices and processes	• Explanation of BIM construction practices and processes • BIM standard and implementation plan • Roles and responsibilities of project stakeholders (Contract) • Issues and concerns of BIM application and adoption of the process • Areas of BIM application	Instructor's lectures Guest lectures Assignment #3 Assignment # 4 Group discussion #3
6 Learning BIM software (visualization tool)	• Google Sketchup • Revit • Navisworks • Introduction of other BIM tools	Instructor's lectures Guest lectures Assignment #4 Assignment #5 Assignment #6

7 BIM Implementation Case Study	• Analyzing the building elements of BIM in actual cases • Identify issues of construction operations • Developing alternative solutions and recommendations	Instructor's lecture Guest lectures Group project report Group work & presentation Peer evaluation
8 Field Trip and/or Guest Lectures	• Observation of practical BIM operations in a construction company • Application of actual BIM practices and processes • Issues and concerns related to BIM implementations in the industry	Guest lectures Group discussion # 4 Assignment #7 Field trip report
9 Future Direction of BIM Use	• Extensions of BIM use in construction • Future directions of BIM use	Assignment #8 Group discussion # 5

Finally, *assessment plan* was organized (see Table 5) to measure students' performance from a pedagogical perspective. Assessments must confirm that students have achieved the learning outcomes in various contexts and that the content has indeed been covered (McKimm 2007).

Table 5. Assessment content for the Course

Assessment Content	Percentage (%)
1. Assignments • Summarize practical BIM definitions • Review different journal articles related to BIM implementation in the construction industry • Summarize BIM practices and process • Develop, modify, and update BIM models with BIM Software • Write a field trip report • Describe future directions for BIM	50%
2. Presentations • Group presentations on approaches to implementing BIM analysis and identifying issues in actual BIM models • Group presentations on possible solutions and recommendations for construction operations	15%
3. Group project reports • Conceptual design model • More complete design model • Estimating and pricing using BIM • Spatial coordination and clash detection • As-built model for facility management	30%
4. Participation • In-class activities and a field trip • Group discussion	5%

IMPROVEMENT STAGE OF BIM COURSE DEVELOPMENT

Since curriculum development is a process that continuously strives to find new, better and more efficient ways to accomplish the task of education, it is extremely significant to actively engage in curriculum improvement (Oliva 2008). Thus, an evaluation and improvement exercise was performed with a BIM expert group in construction to improve the proposed course. Four industry BIM experts and four academic professors who teach BIM courses in construction programs provided their

own inputs of the course. Based on their comments and suggestions, the first draft model of the course plan for 'BIM in Construction Management' was improved and modified prior to its implementation in construction program. This improvement process will be iterative to improve and modify the course if there are opportunities to improve students' learning, new software and tools associated with BIM and new trends in the construction industry.

CONCLUSIONS

Based on the BIM education needs identified, the new course of "BIM in Construction Management" was created for undergraduate construction students, following the steps in the systematic course development process. The new course can be offered in the second semester of their junior year in the construction program to teach BIM related knowledge and skills. By taking this course, construction students will become familiar with BIM and its practice and thus will be ready to play a full role in their future careers as BIM managers in the construction industry. The major contribution of this study is to guide construction educators and programs seeking to develop a BIM related course for their construction curriculum. Through this study, construction educators can benchmark the outcome of this study to efficiently develop BIM courses for their students. Thereby, the construction industry will be able to recruit construction graduates who have BIM knowledge and its implementation skills in construction projects.

ABSTRACT

Research across academic undergraduate majors has indicated that college students of today, known as the Net Generation, learn in ways very different from previous scholars. In 2009, McWhorter School of Building Science at Auburn Universityused focus groups to evaluate how construction management (CM) students learn best. Significant differences were noted between content and delivery issues provided and the user-centered, student perceived needs and wants. Specifically, Auburn University realized key needs in areas of online learning, applied lab environments, and the variety of curriculum offerings. This study recalls student responses and provides Auburn University actions to each of those areas. Key actions include the development of an online learning academy and the construction of a field laboratory. Responding to Net Generation preferences represents a significant departure from standard practices of finding students to fit an existing curriculum; instead, this model seeks to find educational delivery and assessment methods that most appeal to students and allow them to learn best.

Keywords: curriculum, millennials, net generation, student preferences, teaching strategy

INTRODUCTION

In 2009, the McWhorter School of Building Science at Auburn University conducted a study to determine how construction management students of the current generation learn best. This study included background research across all curriculums and specific focus group studies on students enrolled in the construction management program. Results indicated that students of the Net Generation wanted less rote lecture, less textbooks, and more active, hands-on learning. In response to this, the McWhorter School of Building Science has

[1] farrocb@auburn.edu
[2] rab0011@author.edu

started the development of an online learning academy and a field laboratory. This position paper presents a discussion of these two initiatives. It is hoped that by disseminating this information, the University can initiate a discussion on active learning within the construction context and receive feedback to improve these initiatives.

The authors believe that the classroom of the future will be very different from the traditional model of the "wise professor" on stage. Specifically, a successful future classroom will offer applied, problem-based learning strategies while allowing time and facilities for "hands-on", applied experiences. This approach essentially matches the research data provided by students on how they perceive they learn best. The balance of this paper describes the research that led the authors to pursue new delivery strategies, considers the pros and cons of such an approach, describes what the program has done to date and what is planned, and presents preliminary responses by students and industry.

BACKGROUND RESEARCH

As part of a curriculum review that examined "what" was taught in the classroom, faculty at McWhorter School of Building Science at Auburn Universityalso researched "how" material should be delivered and assessed. Should classes continue to be delivered "lecture" style, or should new ways of delivering the material be considered?

What works best for typical undergraduate students

The "Millennial" or "Net" generation, born between 1980 and 2000, is today's undergraduate student. Their expectations have been shaped by today's culture which identifies with iPods®, cell phones, web surfing, and text-messaging. The needs of this student have been addressed by several authors to include ten themes (Brown, 2002; Frand, 2000; Howe & Strauss, 2000; Merritt, 2002; Oblinger, 2003; Skiba, 2005; Tapscott, 1998):

- Fierce independence
- Emotional and intellectual openness
- Inclusion
- Free expression and strong view
- Innovation
- Preoccupation with maturity
- Investigations
- Immediacy
- Sensitivity to corporate interest
- Authentication and trust

None of the above themes resonate with the typical authoritarian, fact-based learning of a typical lecture environment. Based on studies from the Department of Education and employers, Dr. Dee Fink (2007) argues that there is evidence that today's students are not having "significant learning experiences" in a lecture environment. Evidence exists that indicates delivering material based on student desires could lead to more significant learning experiences. These learning experiences include:

- Want material available 24/7/365 (Fraud, 2000)

- Desire open, one-on-one connection with faculty who take personal interests (Teaching the Millennial Generation, 2006)
- Desire immediate feedback (Carlson, 2005)
- Have a fascination with new technology (Howe and Strauss, 2000)
- Has a bias toward action wanting to apply knowledge gained (Brown, 2002)
- Want experiential and hands-on learning (Rogers and Freiberg, 1994)
- Enjoys working in groups (Howe and Strauss, 2000)
- Want interaction with students and faculty (Oblinger and Oblinger, 2005)
- Demand learning in a variety of ways (Oblinger and Oblinger, 2005)

What works best for Auburn Universityconstruction management students
Student focus groups met over a three month period in 2009. All students were enrolled in the Construction Management program at Auburn University. Key conclusions from the study included the following:

- Students want experiential learning activities.
- Multiple, smaller handouts are preferred over textbooks.
- Students demand easy contact with professors through a variety of means.
- Students like team work but do not want to work with those outside their major.
- Flexibility in all aspects of delivery and assessment is important to students.

SHOULD STUDENT PREFERENCES CONTROL TEACHING METHODS?

Do not abandon what has worked for years.
Not all agree that a customer driven approach to delivering education is best. One linguistics professor at American University said she felt pressure to "shorten lectures, increase group-discussion time, and ignore the 'multitasking' student who is e-mailing his friends in the back of the room" (Carlson, 2005). Some faculty report that listening in such an environment is distant, and faculty can be easily distracted. Others argue that lecture based education has served the industry well and moving away could discount the educational experience.

The student is the customer.
In the age of information technology, universities must reinvent themselves to continue being relevant in modern society. Curriculums must include project-based learning and address real-world questions that matter. Textbooks and a lecture style approach to delivering education will not work with this generation. A new way of delivering the curriculum is required. Professors must become conductors of groups that turn information, gained from a variety of sources, into knowledge. There must be a clear connection with what they are learning and how it prepares them for life in the real world. Professors must continue to instill curiosity, and they must be flexible in how they teach.

Finally, faculty must excite students to be lifelong learners so they may respond in a world that is changing so rapidly around them.

THE ONLINE ACADEMY

Traditionally, higher education has been based on the premise that knowledge and teachers are in short supply. With modern technology and expansion of higher education providers, knowledge is available on demand. Knowledge can now be transferred at any time and at a pace convenient to the student. This evolving trend has been the subject of much discussion within the McWhorter School of Building Science. The summation of those discussions is that the school seeks to leverage emerging technologies and practices to enhance existing delivery of undergraduate and graduate classes.

One particular approach to deliver material is to expose knowledge in small segments, through such entities as the "Khan Academy". The academy (www.khanacademy.org) is the use of 7-10 minute videos that provide information about a specific topic. The New England Journal of Medicine is a good example of a discipline specific resource for instructional videos in clinical medicine (http://www.nejm.org/multimedia/ medical-videos). These videos are vetted through a peer review process to validate content. The McWhorter School of Building Science plans to use this format coupled with online delivery to build brand, enhance student learning, and provide additional class time for applied learning experiences. These videos may be used as an initial entry into online educational programs for the school. These teaching tools could also be vetted through a peer review process.

What we have done to date…

Approximately 20 videos have been created to date by a combination of students and faculty. These videos are available at http://www.auburnccic.org/ and at itunesU (Figure 1). An initial evaluation ruberic to measure quality of videos has been developed. Currently, videos are being reviewed in-house only. These videos will serve as the anchor for the online academy.

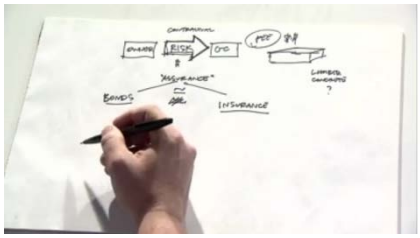

Figure 1: Sample screen-shot of video of insurance vs. bonds.

The target audience for each of the videos is our undergraduate student with little or no experience in the construction environment. Typically, this student is 18-22 years of age and has at least one year of college experience. Currently, we are serving our target audience using classroom lectures and textbooks. This project seeks to partially replace that mode of delivery with some short videos.

The target audience needs a fundamental vocabulary in construction terms and practices. Specific skills needed by the students include the need to interpret contract documents, estimate the cost of work, schedule a typical construction project, and manage risk. From a broader perspective, the McWhorter School of Building Science wishes to create students that are lifelong learners, solve problems effectively, and have an appreciation for the greater society in which they work.

The videos will be academically inspired but will focus on relatively simple individual concepts. Information in the video will not assume previous knowledge but will not be so simple that they do not appear professional.

Informal initial surveys of online videos of this nature have helped establish our frame of reference. Students specifically like RSA Animate (http://comment.rsablogs.org.uk/videos/). Specifically, they like the graphical nature of the presentation and believe the voice is excellent. Students do not appreciate so many "clever remarks" in many of these videos. Students appreciate some of the Khan videos. They especially like the ones where the reason for understanding the topic is clearly explained and the ones that take the complex and make it simple. Special care will be required to avoid videos that could become an extenuation of the "lecturer" at the front of the classroom. Videos must engage the learner.

Student reviews have been positive on the first set of videos responding that they liked the ability to watch the sessions multiple times, and they appreciated the additional class time to apply the concept.

What we plan to do…

By the end of calendar year 2012, the authors hope to have 100 videos online available free to the public. Viewers will have the opportunity to comment on the videos and offer feedback as part of a continuous improvement process. It is hoped that this will create a "critical mass" of videos that will allow for sufficient user-feedback and response.

If successful, other universities and professional practice could contribute to the online academy providing an easily accessible, free resource for learning in construction education. The academy could also provide an excellent resource for faculty to disseminate and receive tangible feedback on issues critical to construction.

THE FIELD LABORATORY

A recently completed curriculum review involving participation from faculty, students and industry stakeholders identified a need to expand the practical component of Auburn University curriculum. The new curriculum which comes into effect in the fall of 2012 has dedicated practical lab sessions in four classes per semester. Two classes are 3-hour structures labs where methods and materials of construction will be the focus. Two classes are 2-hour mechanical,

 ISBN: 978-1-84219-840-7 .

electrical, and plumbing labs where systems will be the focal point of application. This increase in practical lab sessions will increase the demand for space in our demonstration lab which is already over used. Some lab sessions are conducted outside our current lab space; however, that area is confined and not suitable to activities of scale.

Other construction programs (University of Florida, Wentworth Institute) have established external construction demonstration areas close to where their instructional activities occur. Such an approach would be best; however, it would require significant development not in keeping with the university master plan for the central campus. Thus, a site was located on University property approximately one kilometer from the main CM classroom building that would serve as a field laboratory. The site is approximately one acre in size and is located on a flat site with available on-site parking near a campus bus route (Figure 2).

Figure 2: Field laboratory with job site trailer in background.

What we have done to date…

Work to date has focused on developing a safe, usable site. The site has been fenced, and water as well as electrical supply have been provided to the site. A job site trailer with meeting space for up to thirty students has been added complete with internet access. A steel shipping container has been placed on the site for tool and material storage.

Some preliminary student and faculty activities have been held at the site. It was decided that some activities would require a concrete slab as a flat working area. The slab could be used for wall framing, form work, masonry work, and various demonstrations.

A working slab of approximately 30'x40' was placed by a concrete class. Students planned, managed, and executed the work of placing the slab. This slab has already been used for "brick day" where masonry professionals work with groups of students to lay brick walls. In this class the bricks are reused, but there is the possibility for the construction of permanent structures.

A faculty research project is also ongoing on site where a pervious concrete slab has been placed along with stormwater collection devices. This project will measure the thermal effects of pervious concrete on stormwater pollution.

A project by a graduate student involves the installation of a field bed for a geothermal HVAC system to test the heat dissipation properties of three subsoil mediums. The system will be permanent to allow further testing of geo-thermal HVAC systems to find ways to make residential systems more efficient.

What we plan to do…

Opportunities at the site abound. Immediately, we plan to use the site for some specific exercises:

- Erection of a small, two-story steel frame as part of a steel design class
- Erection of an elevated pan form system as part of a temporary structures class
- Installation of wood trusses to demonstrate bracing requirements
- Construction of wood framed wall forming system as part of temporary structures class
- Demonstrations of safety devices and safety training
- Demonstration of equipment

Longer term, the school would like to develop a few minor structures on the site. These structures will be designed and constructed as part of the curriculum and will be privately funded. Some of these may include:

- Construction of aggregate bins and mixing area to allow the building of concrete projects
- Erection of a wind turbine
- Stormwater protection devices
- Mock-ups for building systems

Over time new uses for the facility will be found including the following:

- New labs for the existing classes
- New elective classes developed around the field lab
- Graduate students expand vision on possible capstone projects
- Faculty pursue new research activities
- Industry can partner with the students and faculty to solve problems

The program's construction industry council visited the field lab, and the response was very positive. Not only did the industry professionals see the value of the field lab, several members offered resources to elevate the capabilities of the lab.

AUTHOR'S ANALYSIS AND CONCLUSIONS

In an effort to meet Net Generation desires for how the curriculum is delivered, Auburn University's Building Science School has developed an online academy consisting of 7 ½ minute videos that provide answers to tangible questions in construction management and a field laboratory. These developments are in direct response to student focus group surveys (Table 1).

Net student desires….	**Response by CM Program**
Experiential learning activities	Field Laboratory
Multiple, smaller handouts over textbooks	Short online videos may replace pre-class textbook assignments
Easy contact with professors	NA
Team work within the major	Use videos to make time available in class

	for applied group work; use teams in field lab
Flexibility in all aspects of delivery	Online videos available 24/7/365

Table 1: How the field lab and online video program respond to student desires

Faculty training is needed to assure that both the field laboratory and online learning academy are implemented in a way that will enhance student learning. The field lab must be used regularly on meaningful, applied problems critical to construction management. These problems must be relevant to the students. The online learning academy will provide additional class time for applied, experiential learning endeavors. Faculty must move away from designing rote lectures toward the design of engaging student discussions and case studies.

Much research has been published on "flipping the classroom" where online material is used to convey understanding, and the concept is applied in the classroom (Berrett, 2012). This paper proposes "flipping the classroom" and providing meaningful, "real world", applied labs. In combination, this approach has the potential to "hand spring" construction management forward and produce the future leaders of construction.

Future research is needed to assess the two initiatives. Student focus groups should be developed that provide feedback on both online videos and the field lab. A ruberic to measure student learning outcomes was developed and implemented prior to changes in the way the curriculum is delivered. The researchers believe that such a ruberic may help measure how effective the field laboratory and the online videos are as delivery vehicles.

DEVELOPING A GRADUATE COMPETENCY MAPPING BENCHMARK FOR QUANTITY SURVEYING COMPETENCIES

Srinath Perera[1], John Pearson[2], Lei Zhou[3] and Damilola Ekundayo[4]

[1,2,3,4]*School of the Built and Natural Environment, Northumbria University, Newcastle upon Tyne, NE1 8ST, UK*

ABSTRACT

An investigation into the views of industry and academia on Quantity Surveying (QS) education revealed that there is a considerable gap in the expectation of graduate competency and the achievement of it. It identified the need for deeper investigation into the root causes of this gap between expectation and provision of QS competencies. This paper presents an in-depth analysis of Royal Institution of Chartered Surveyors (RICS) QS competencies and their mapping to four RICS accredited QS programme specifications taken as case studies. The mapping is detailed and carried out in a dual vector scale matrix encompassing the breadth and depth of achievement of competencies. The mapping case studies form the basis for the development of a conceptual benchmark for achievement of graduate competencies. The detailed mapping exercise analyses the level of mapping of individual module specifications of RICS accredited programmes to the three levels of achievement of competencies specified by the RICS. The research purports to use an industry –academia industry forum to evaluate the conceptual benchmark in order to adjust and ratify the final benchmark values. The benchmark will define the threshold levels at which all competencies need to be achieved by graduate quantity surveyors.

Keywords: competency mapping, conceptual benchmark, graduate quantity surveyors, QS degree programmes, RICS Competencies.

INTRODUCTION

In the knowledge society, higher education has an important role to play in the development of the professional. To remain industry relevant, Higher Education providers in the design and delivery of study programmes need to understand industry expectations while complying with professional body requirements. The influence of industry upon curriculum development is becoming ever more significant in the fast changing world (Mekenzie, 2010). However, research revealed that current curriculum design and development do not always reflect industrial practice and

[1] srinath.perera@northumbria.ac.uk
[2] john.pearson@northumbria.ac.uk
[3] lei.zhou@northumbria.ac.uk
[4] damilola.ekundayo@northumbria.ac.uk

workplace reality (Perera and Pearson, 2011). There are a series of gaps between university education and industrial demand such as; over education and skills mismatch, etc. (Korka, 2010). Furthermore, Korka (2010) argues the insufficient involvement of professional associations and of employer representatives in the shared responsibility for higher education learning contents and learning outcomes.

The recent RICS report indicated that a similar scenario exists in construction and specifically in RICS accredited QS degree programmes (Perera and Pearson, 2011). The report revealed that there is a considerable gap between the industry's expected competency of graduate QS and what is actually attained. As a result, RICS degree programmes often produce graduates who are not fit for purpose hence there is confusion and dissatisfaction in the industry as to graduate QS competency. Perhaps those in academic circles are not aware of what the industry really wants because of misinterpretation and lack of proper attention, or the industry has unrealistic expectations. This is increasingly debatable. In fact, these two appear to be the case according to Perera and Pearson (2011). The current research is thus a further investigation and development of the initial RICS report which revealed these incongruities. The aim of this paper is to present the development process of a minimum benchmark for achieving competency in Quantity Surveying graduate education.

RESEARCH METHOD

Previous research established that there is indeed a gap between actual academic attainment and industry expectations of graduate QS from RICS accredited institutions. The current research sought to develop a benchmark that satisfies the aspirations of the various industry stakeholders. The main research instruments to be used to achieve this include case studies and expert forum interviews (see Figure 1). Detailed case studies were used to generate a conceptual benchmark to be later refined using the views of an expert forum comprising of academics and industry to finally produce the minimum benchmark. The current paper reports the results of the case studies resulting in the conceptual benchmark. The development of the final benchmark is currently underway and hence not reported here.

The case studies include examination of four RICS accredited QS degree programmes. The curricular of these programmes (module specifications) were mapped against RICS QS competencies at detailed level using coverage (as a breadth measurement) and amount of time spent i.e. module credits (as a depth measurement). The ensuing mapping was then verified for accuracy and consistency with programme directors responsible for delivery of these programmes.

Breadth measure

RICS QS competencies are analysed at a detailed level using the QS Study Checklist (RICS, 2008). This checklist is used as the framework for developing the conceptual benchmark where 1 and 0 is used to indicate coverage of a topic under a competency.

1 - Reflects that the topic is dealt with by the degree programme concerned.

0 - Reflects that it is not dealt with by the degree programme concerned.

These are analysed against the three level classification of level of achievement by the RICS (RICS, 2009). These are as follows:

Level 1 - Knowledge and understanding

Level 2 - Application of knowledge and understanding

Level 3 - Reasoned advice and depth of technical knowledge

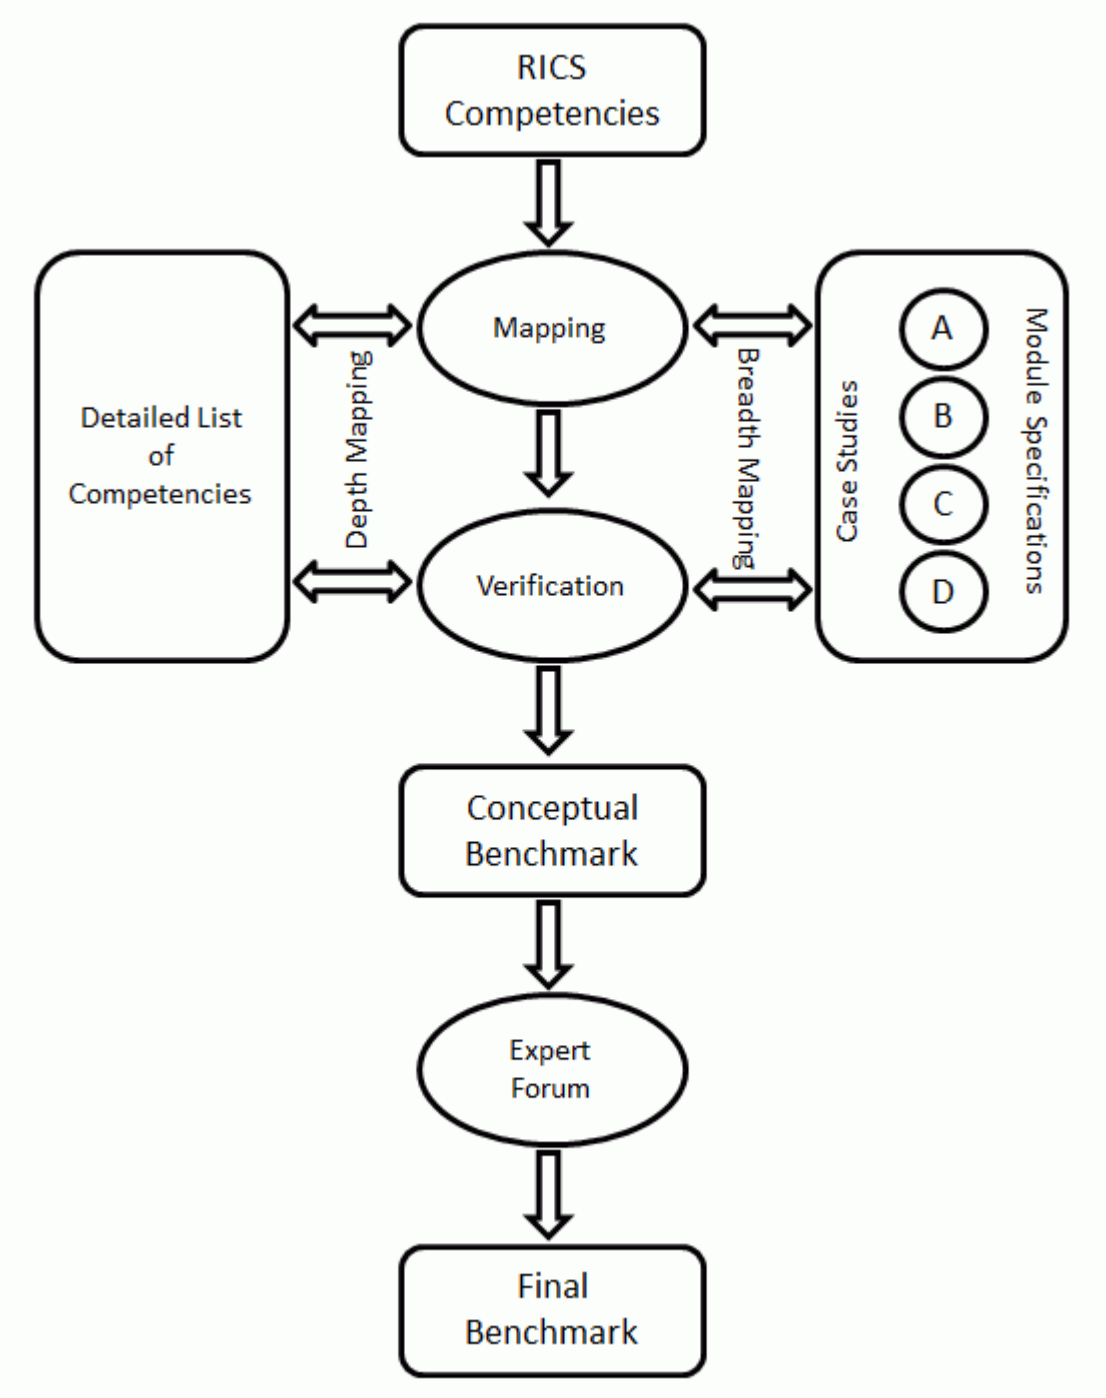

Figure 1 Research Method

A specific topic may be covered at both Level 1 and 2. In this case, there is a value 1 against both Level 1 and 2 columns. In another topic, if the topic is dealt with at Level 1 only then values 1 and 0 were placed against columns Level 1 and Level 2 respectively. Level 3 achievements are not covered in degree programmes as it is not practical to expect a graduate to cover a competency at Level 3. However, as the outcome of these case studies reflects a minimum conceptual benchmark, it will not prevent anyone achieving a competency at Level 3.

 ISBN: 978-1-84219-840-7 .

Depth measure
This reflects the amount of time spent on achieving a competency. In degree programmes, time spent on achieving module outcome is stipulated as Credits. Where 10 hours spent is considered as 1 Credit, a typical 20 Credits point module reflects 200 hours of learning by the student. This constitutes direct contact with formal teaching; lectures, seminars, tutorials as well as students' expected study time on the module content (time spent on their own). The depth measure is only indicated at competency level and not at topic level as it is impractical to stipulate expected number of study hours spent at a detailed topic level. A percentage score is used to indicate the proportion of time spent on each competency. This will provide valuable measure to understand relative time spent for each competency.

Both breadth and depth vector scale mappings of the four case studies were initially carried out using the respective module specifications of programmes. The results were then sent out to the programme leaders of the degree programmes concerned for necessary adjustments and ratifications. Descriptive statistics such as mean and percentage scores were used to analyse the results of the case studies as conceptual benchmark.

COMPETENCY MAPPING CASE STUDIES

The four case studies selected were leading QS honours degree programmes in the UK all accredited by the RICS. The dual vector scale representing breadth and depth of coverage of competencies informs the current practice in academia. There are a total of 360 Credits (3600 hours) of learning in a degree programme. Therefore typically there will be less than 3600 hours available to map against RICS competencies. The breadth mapping case studies (an excel spreadsheet with over 400 rows) cannot be presented here because of limited space. However, the depth mapping case studies (see Table 1) were based on and influenced by the breadth mapping outcomes. It reveals that competency coverage utilises 73-85% of the credit hours available on achieving RICS competencies.

CONCEPTUAL BENCHMARK FOR GRADUATE COMPETENCIES

The conceptual benchmark (see Table 1) is a dual vector matrix reflecting overall coverage and depth of coverage of the four case studies. The conceptual benchmark values reflect average levels of achievement of competencies by graduates completing a degree from any of the four case study QS programmes. It reveals under **Level 1 and Level 2** columns the topics covered in all the 4 RICS accredited degree programmes examined. A value of 1 against a particular topic implies that at least one of the case study degree programmes covers this. The **Credits hours'** column, which is the average of the four case study values, indicates typical expected times (in hours) devoted to each competency whilst the **Percentage** column shows the relative time proportion. Only a brief extract of the conceptual benchmark is shown in Table 2 due to paper limit restriction. However, the detailed conceptual benchmark follows a similar pattern to the brief presented in this paper.

CONCLUSIONS

It is admissible that Teamworking (M010) under Mandatory competencies received high rating in both depth and breadth mapping as there are many project type modules in all the degree programmes examined, where students can learn this skill. On the

other hand, Corporate recovery and insolvency (T020) and Due diligence (T025) under Optional competencies have zero value against both measures. It can be argued that in modern times and recession prone graduate QS should at least have a basic understanding of some topics covered under these competencies especially; types of insolvency and the role of the QS if this occurs. One main finding under Core competencies that needs further analysis is the scope of coverage not proportionate to the devoted credits hours. This is revealed in competencies such as Construction technology and environmental services (T013) and Quantification and costing of construction works (T074).

In addition, it is supposedly good practice to have a minimum benchmark which gives proper flexibility to programme leaders to include new topics in their curricula as may be required from time to time. Such flexibility is a good idea especially in the current and dynamic business environment where innovation is encouraged. However, this minimum benchmark needs to be effectively moderated to ensure that degree programmes do indeed cover the competencies which the industry expects of graduate QSs. An expert forum comprised of 15 industry and academic experts will be used in further research to moderate the conceptual benchmark. Diverse views of the experts will be harmonised using Delphi methodology to produce the final benchmark. This will provide a minimum benchmark and a useful instrument to aid RICS accreditation of QS degree programmes. It will be a useful part in the RICS partnership deliberations to assess compatibility of RICS accredited programmes. Whilst also providing room for flexibility and innovation in curriculum development, the final benchmark will help to maintain programmes that are representative. Eventually, this will help to produce graduate QSs that meet industry expectations and stakeholder satisfaction.

EFFECT OF PRACTICE TESTS ON OVERALL STUDENT PERFORMANCE IN A CONSTRUCTION SCIENCE COURSE

Ifte Choudhury[1]

[1]*Department of Construction Science, Texas A&M University, College Station, TX 77843, USA*

ABSTRACT

Literature indicates that when students who take optional practice tests, they perform better in mandatory course exams than those who do not take advantage of the practice tests. The purpose of this study is to find out whether this variable makes a difference in overall student performance in an Environmental Control Systems course in Construction Science offered by the author. The idea of optional practice tests had been introduced by the author in Fall 2011. There are 105 students in two sections of the course. Data was collected throughout the semester. The variable was tested along with other factors that may have an effect on overall student performance in a course, such as home work performance, quiz performance, and gender. Multiple linear regression technique was used to perform the analysis. The findings of the study indicate that optional practice tests do have a positive effect on student performance in formal course assessment.

Keywords: Construction Science, Environmental Control Systems, Practice Tests, Student Engagement.

INTRODUCTION

Student engagement is an important aspect of learning process in an academic setting. It occurs when the learners take responsibility for their learning rather than continuing to be passive and waiting to be spoon-fed by the instructor. Increasing student engagement in classroom setting is gradually becoming important (Deeter, 2008). Student engagement with the course material is of utmost importance irrespective of the method of delivery of instruction (Lockyer et al. 2001).

In order to enhance student engagement with course materials, the author introduced online practice tests for a course in an Environmental Control Systems at an undergraduate level. The tests were voluntary. The students who took these tests received immediate feedback. The purpose of this study was to determine whether student performance at an undergraduate level is affected by the optional practice tests. The measure of student performance was the sum of a student's scores in mandatory tests.

[1] i-choudhury@tamu.edu

It was attempted to determine whether the practice tests had an effect on cumulative test grade of a student on an Environmental Control Systems course. It was also critical to find out whether this relationship, if any, existed in the presence of other possible determinants of student performance.

REVIEW OF THE LITERATURE

Student Engagement

Institutes of learning are constantly striving for improving the student learning processes through use of advanced instructional technologies. They include, among others, interactive learning methods to foster student engagement.

Effective student engagement even in classes that are of medium size is a challenging undertaking. On one hand, students have minimal opportunities to interact with the instructor and one another to construct their own understandings of the course concept in a short period of time and, on the other hand, the instructor has also difficulty in providing feedback to the students on their understanding of the concepts.

Walker et al. (2008) argue that even with large-format classes it is possible to foster student engagement through integration of active learning techniques. It can be achieved outside the boundaries and confinements of classroom settings by making materials available online. Such a format may provide pedagogically constructive opportunities such as interaction among students, active student engagement, and feedback by the instructor. Feedback is particularly important, because it gives the student an opportunity to process the materials and retain them for a longer period of time (Semb & Ellis, 1994). Students need to grasp the course materials so that they can apply the concepts correctly. Quite a number of studies indicate that apt and constructive feedback is an important factor of improved student performance (Fink, 2003; Higgins et al. 2002; Bransford et al., 1999).

Other Factors of Student Performance

Even though the purpose of this study was to find out the effect of practice tests on student performance, it was necessary to explore other predictors that may have significant relationship with this dependent variable. Class attendance is considered by many researchers as one such predictor. There is a wide body of literature that indicates an inverse relationship between academic achievement and class attendance. Student absenteeism is an important issue in institutes of higher learning in the United States. Class attendances, at least in practice, are optional in most schools. Although instructors have different outlooks and policies toward attendance, most of them would like them to attend the classes to maintain a vibrant teaching-learning atmosphere; most instructors also associate class attendance with academic achievement (Cohn & Johnson, 2006; Devadoss & Foltz, 1996; Brocato, 1989). It is generally accepted that attending classes is an important aspect of college experience (Cohn & Johnson, 2006).

Studies reveal that there is a relationship between absenteeism and student performance in courses (Brocato, 1989). The hypothesis that there is a strong relationship between class attendance and student learning has been investigated empirically in journals of

 ISBN: 978-1-84219-840-7 .

higher education. It is not surprising that most studies have found an inverse relationship between being absent from the class and course performance (Cohn & Johnson, 2006; Murberger, 2001; Devadoss & Foltz, 1996; Brocato, 1989).

Studies have been conducted on the inverse relationship between absenteeism and student performance in different courses at college level. As long back as in the 1970's, Jenne (1973) found that attendance played a major role in a health science course. Jones (1984) reported that there is a negative correlation between absences from class and grades in a psychology course, irrespective of ethnicity or gender of the students. Romer (1993) reports a similar finding on a study related to intermediate microeconomic theory.

Devadoss and Foltz (1996) conducted a study on the effect of a number of predictor variables on performance in agricultural economics. They conclude that the study "provides strong empirical evidence of the positive influence of class attendance on student performance" (p. 506). Findings of another study on course in principles of economics show evidence of an inverse relationship between absenteeism and performance is statistically significant when students miss a sizeable number of classes (Durden & Ellis, 1995).

Investigations on relationship between absenteeism and student performance in construction science courses are negligible. However, there is on recent study by Senior (2008) that explores such relationship for course in construction management. The results of the study indicate a statistically significant correlation between missed classes and final student grade in the course.

Many courses in construction management comprise of concepts or ideas that students need to comprehend in order to succeed in follow-on courses. An in-depth understanding of the fundamentals of a course helps them transfer knowledge to from one course to another. Bransford et al. (1999) argue that it necessary for students to evaluate their learning current level of understanding continuously. In order to do that, they require constant feedback from instructors. Different methods are used by faculty at college level to enhance and improve such understanding by providing instant feedback (Freeman & McKenzie, 2001). Most widely adopted methods are giving short tests and assigning problem-solving home works.

There are, of course, few studies that report no relationship between attendance and performance. Browne et al. (1991) did not find any positive effect on attending lectures and student grades on tests in an economics course. Similarly, findings by Buckles and McMahon (1971) do not suggest any significant effect of class attendance on student performance.

Homeworks may also have a significant role to play in enhancing a student's in-depth understanding of course materials (Douglas & Sulock, 1995). Apart from being considered as tools for enhancing student learning, home works have been found to have a positive relationship with overall student performance (David et al., 2001).

The effect of one other variable on performance that has been tested by many researchers is gender. Some studies indicate that men have more positive attitude toward education in engineering and science than women (Lawson et al., 2006; Jones, 1984). It is reflected by their performance in relevant courses. However, there are other studies that do not report any correlation between gender and student performance (Lawson et al., 2006; Bond, 1998; Kreiner, 1997).

In view of the findings from this review of the literature, it was decided to include a few other variables in the model for analysis of the relationship between video-viewing and student performance. These variables include: absenteeism, home-works, and gender.

METHODOLOGY

Study Population

The study population consists of students who registered for an Environmental Control Systems course at an undergraduate level in a state university for Fall semester in 2010. There were two sections, 501 and 502, in which the students were enrolled; one section had 65 students and the other had 39. The sample size includes the total population of 104 students, 9 female and 95 male.

Data Collection

Data related to the study was collected from the instructor's own database. The same instructor taught the course in all three semesters under the study. The unit of analysis was the student.

Variables and their Operationalization

Test Grade (TEST). It is the sum of all the scores made by a student in three tests given during the semester. It was measured by the numerical grades obtained by the student in the tests.

Absent (ABSENT). It is the record indicating the complete absence of the student from class meetings. It was measured in number of class meetings missed by the student.

Gender (GENDER). It indicates the gender of a student. It was a dummy variable, operationalized by assigning a value of 1 when the gender was female and 0 when the gender was male.

Home work (HW). It is the performance by the student for a particular assignment related to a topic covered by the course and done at home. It was measured by the cumulative numerical grade obtained by the student in all home works.

Section (SEC). It indicates in which the student was enrolled. It was a dummy variable, operationalized by assigning a value of 1 if the student was enrolled in section 501 and 0 otherwise.

Quiz (QUIZ). It is the performance by a student in a short, previously unannounced, test held in the class related a particular course topic. It was measured by the cumulative numerical grade obtained by the student in all quizzes.

Practice (PRAC). It is the performance by the student for a particular assignment related to a topic covered by the course and done at home. It was measured by the cumulative numerical grade obtained by the student in all home works.

ANALYSIS

A stepwise regression analysis was performed to explore the data. This is an automatic procedure for statistical model selection in cases where there are a large number of potential explanatory variables. Forward selection procedure was used. The procedure involves selection of variables that are statistically significant. Following model was used for the purpose:

$$TEST = \beta_0+\beta_1 ABSENT+\beta_2 HW+\beta_3 GENDER+\beta_4 SEC+\beta_5 QUIZ+\beta_6 PRAC+\varepsilon \quad (1)$$

where β_0 = intercept, β_1 = the coefficient of ABSENT, β_2 = the coefficient of HW, β_3 = the coefficient of GENDER, β_4 = the coefficient of SEC, β_4 = the coefficient of QUIZ, β_4 = the coefficient of PRAC, and ε = error term.

Results

The results of the analysis are shown in Table 1.

Table 1. Statistical Analysis for TEST

Variable	Intercept	Regression Coefficient	T	p<|T|
Intercept	31.92		3.68	<0.001
HW		1.10	5.37	<0.001
QUIZ		0.89	4.12	<0.001
PRAC		0.004	3.12	0.002
F-value of the Model: 29.76	p>Model F = <0.001	Model R^2 = 0.47	Adjusted model R^2 = 0.46	

The results indicate that only HW, QUIZ, and PRAC were retained in the model. The excluded variables were ABSENT, GENDER, and SEC.

The F statistic of a model basically tests how well the model, as a whole, accounts for the dependent variable's behavior. The F-value of this particular model was found to be statistically significant at less than the 0.001 level.

An important aspect of a statistical procedure that derives model from empirical data is to indicate how well the model predicts results. A widely used measure of the predictive efficacy of a model is its coefficient of determination or R^2-value. If there is a perfect relationship between dependent and predictor variables, R^2 is 1. In case of no relationship

 ISBN: 978-1-84219-840-7 .

between dependent and predictor variables, R^2 is 0. Predictive efficacy of this particular model was not found to be very high with an adjusted value of 0.46. But such values are considered to be satisfactory related to empirical studies in social sciences (Freund & Wilson, 1991). The independent variables included in the model explained about 46 percent of the variance.

The results indicated that overall test grade of a student in an Environmental Control Systems course offered at a state university is positively correlated with taking optional practice tests in a at the level of significance of 0.002. This relationship exists in the presence of quiz and homework performance, which are known to have some effect on overall student performance. Overall test grade is directly related to all the three variables retained in the model. The results implied that when an optional practice testis taken, the overall test grade of the student increases by 0.004 point. The overall test grade would increase by 0.89 point and 1.10 points for every point earned in a home work and quiz respectively.

DISCUSSIONS

The results of the statistical analysis are meaningful in the sense that they support the importance of effective student engagement with course materials. The study shows that student performance enhances significantly when a proper environment in developed to foster student engagement for a course on Environmental Control Systems course at an undergraduate level.

A surprising aspect of the study was the exclusion of absenteeism as a predictor of student performance. The author has conducted a number studies that indicated that students having a higher number of absences from class tend to perform poorly in an Environmental Control Systems course. One possible explanation could be that a student, without attending the classes, could have good grasp of the course contents only by studying the online materials uploaded by the instructor and taking the series of online practice tests.

A poor performance in the home works and quizzes indicate an inadequate understanding of the materials discussed in the class. They eventually affected a student's overall performance in the course.

CONCLUSIONS

The study provides a moderate support to the positive influence of optional practice tests on student performance at an undergraduate level. It is evident online practice tests have the potential of being successful instructional tools, if they are properly integrated with traditional teaching tools. Immediate constructive feedback seems to be benefit of online practice tests. In most cases, it results in fostering effective student engagement, which, in turn, enhances student performance. The study will hopefully generate enough interest

to do further research for deriving models for predicting student performance in other courses.

FROM APPRENTICE TO MASTER OF SCIENCE IN ENGINEERING – AN EDUCATIONAL EXPERIMENT

Søren Wandahl[1] and Lene Faber Ussing[2]

[1]*Department of Engineering, Aarhus University, Aarhus School of Engineering, Denmark*

[2]*Department of Mechanical and Manufacturing Engineering, Aalborg University, Denmark*

ABSTRACT

As a consequence of the Bologna Process Danish higher educational system has fully adopted the 3+2 system. Access to Master of Science programmes is now granted to either Bachelor of Science or Professional Bachelor degree holders. The latter is known for admitting people with vocational qualifications. Hence, it is now possible for a person to go through apprenticeship, and later entering an Architectural Technology and Construction Management education, and finally, ending with a Master of science degree. Now in its fourth year of allowing MSc students with such background, it is possible to share some of the collected experience. So far it has been a success, but there have been hurdles. Students with vocational background combined with a professional bachelor degree are different from students with a Bachelor of Science background. This applies to the areas of among others: Mathematical skills and practical knowledge. The main success is that candidates have entered the job market with high success. Data has been collected through interviews and surveys with graduates, teachers and coordinators within the new master programme in construction management at Aalborg University in Denmark. This exercise has given insight what distinguishes traditional Master of sciences graduates and these new graduates.

Keywords: construction management, education, master degree, vocational training

INTRODUCTION

The construction industry is naturally interested in the educational system as customer to our candidates. This research limits focuses to only higher educations. On one hand, the industry often asks for well-educated candidates, especially with managerial skills. On the other hand, the industry asks for candidates with practical knowledge. Often these two requests are not to match in one education. Students with vocational training or an apprenticeship certificate is a seldom at our universities. This because these people often lack the requested admission requirements achieved in upper secondary educations. So if they were to enter the university they either have to restart their education and pass through upper secondary grades or take access course. People with vocational training can instead of a university degree obtain a professional bachelor degree. Until recently there existed no continuation of a professional

[1] swa@iha.dk
[2] lf@m-tech.aau.dk

bachelor degree. This could be seen as not fully implementation of the 3+2 system of the Bologna declaration, stating that a 3 year bachelor should grant access to a 2 year master.

This research reports on a Danish attempt to fully implement the Bologna declaration, and allowing students with a 3 year professional bachelor degree access to a 2 year master programme at Aalborg University. The programme is a Cand.Scient.Techn. programme in Construction Management, hereafter referred to as CST. The aim of this paper is to share knowledge of this process and to point out challenges in allowing submission to university from students with a professional bachelor degree and apprenticeship certificate.

The Bologna process

29 European countries signed the Bologna Declaration in year 1999 (EU 1999). Today the Bologna Process embraces 47 countries in the European Cultural Convention. The focus of this declaration is the higher educational system in Europe, vocational educations, and lifelong education. There are several aims of the Bologna process, where the most known is the development of the ECTS grade scale, comparable diplomas, mobility for students and a comparable grade structure. The main purpose could be shortened down to achieve comparable academic degrees in terms of quality and grading throughout Europe.

In this research the focus is on the comparable grade structure, known as the 3+2 system. The purpose is to grade the higher educational area in 3 year bachelor (both Bachelor of Science and Professional Bachelor), and a 2 year Master of Science (Dahlgren et al. 2009).

The current status is that the work is still in progress, and that the progression is different from country to country. The process has also had severe impact on the Danish higher education area. It is not within the scoop of this paper to describe the changes and impact thoroughly, instead a short “as is” description of the system is described in the following paragraph.

Short background on the educational framework

In general the educational level is high in Denmark (EACEA 2009). EHEA, a Bologna follow-up group secretariat, is leading the continuous change toward transparency in the higher education area. They also keep track on each country’s progress in the Bologna Scorecard. In the report from 2009 (Rauhvargers et al. 2009) Denmark is placed second, right after Scotland. Only implementation of the National Qualification Framework is not yet 100% in the Danish rating.

As mentioned, the implementation of the Bologna Process has created new ways of “moving around” in the Danish educational system, now allowing professional bachelor degree holders admission to Master of Science programs.

Brief introduction to the Cand.Scient.Techn. program

The students start at the the Cand.Scient.Techn. program at Aalborg University the 1st of February every year. The program is build-up of 4 semesters with four different topics. All 4 semesters are based on Problem-Based Learning principles, which implies: group work with real life construction cases, students identify and solve

problems in groups, teacher facilitates this process, interdisciplinary and practice based and students are active in class (Wandahl et al. 2008).

First semester has a 15 ECTS project where the topic is Project Design and design of construction sites. In addition 3 separate courses of 5 ECTS is mandatory. The courses are; Stressed concrete structures, Project management and economic, and Soil engineering. In addition students have to take a 2 week brush up course in applied mathematics.

Second semester has a project where the topic is Project management and production in the building sector and the three courses are: Building processes, Construction law and frameworks, and Development of quality and project management systems.

Third semester has a project where the topic is Management systems in construction companies and the three courses are; Development of advanced quality and project management systems, Strategy and performance measurements, and BIM.

The fourth and last semester has a 30 ECTS master thesis. Normally the students are working 2 or 3 students together on their thesis.

METHODOLOGY

With the purpose of evaluating the CST program, an electronic survey was conducted. The questionnaire was devised with outset in Forza's (2002) designing theory. The samples in this survey were past and current CST students, and in total 75 respondents were invited. 43 Answered, which results in a response rate of 57% which according to Malhotra and Grover (1998) is acceptable. The questionnaire was composed of four sections. First section entailed basic data such as age, gender, last educational, practical experience, and apprentice diploma. Second section concerned the enrolment process and asked why respondents applied, if they had enough information available for taking the decision, and what worries they might had prior to enrolment. Third section focused on structural, pedagogical and academic challenges because universities are another scale in all aspects compared to university colleges. Questions in this section were all open end questions, providing room for respondents to elaborate. The final section was only a single question, where respondents on a Likert scale should rate how well the education matched their expectations. A single question in section one was also based on the Likert scale. Questions in section two, on basic data, was factual information. All other questions were open end questions.

Data analysis was conducted in correspondence with the question type. When possible, correlation test are carried out, in some cases by converting answers to binary variables. Open end questions were analyzed by spotting trends. The preferred method was clouding, i.e. grouping of post-it on whit boards. Some answers can be hard to interpret because they were a bit off topic, but no answers were rejected.

To increase validity by means of triangulation, unstructured interviews with teachers were carried out. In total 6 unstructured interviews were conducted.

FINDINGS

Findings are grouped in three sections relative to the first three section of the questionnaire. Result of the fourth section of the questionnaire is described in the conclusion.

Background before enrolment

CST students seem to have a different background compare to MSc Students. Their age at enrolment is normal distributed with an average of 25,6 years, compared to MSC students average enrolment age of 24. 85% of the CST students are male and 15% are female. This is very similar to all technical programmes at Aalborg University.

98% of the respondents have a professional bachelor degree in form of an Architectural Technology and Construction Management diploma. This is very positive, since the purpose of the program was to enable exact this target group to obtain a master degree. It is also possible to enter the CST programme with a scientific bachelor, and with a variety of more or less relevant professional bachelor degree.

26% of the students have had relevant work experience in between their professional bachelor and entering the master programme. The amount of work experience is limited, approximately ½ to 1½ year. Employees have mainly been architects and consulting engineers. Moreover, only 30% of the students have had vocational training, i.e. an apprenticeship certificate. The remaining 70% have had upper secondary education before entering the professional bachelor. This is a little surprise, but reflects general society very well, i.e. high focus on young people getting a proper education. These 70% could probably have entered directly at the university (if achieved right qualifications in mathematics and physics), but choose not to. There are three reasons for not entering university directly. Firstly, the requested level in mathematics and physics is a barrier. This barrier also embraces the lack of interest in mathematics and logical analysis. Secondly, some students cannot oversee 5 years of study. It is simply too long, and does not reflect their current view on life. Thirdly, the social heritage is hard to overcome (Munk & Thomsen 2011). The main part of this group is grown up in non-academic homes. Hence they should be the first in the family to enter a university.

On their background it can be concluded, that the variance is high in terms of knowledge, competences, and skills. It is a large challenge for the university to take this variance into account. The university has no tradition in carrying out differential learning. What the teachers experience is that the university model with group work is essential for the students. They help each other, and together they manage to solve a "bigger" case than they could as individuals. The first semester of the CST program is specifically designed very flexible to cope with this variety in skills. For example students begin with a brush up course in applied mathematics. This course has no specific curriculum. The teacher only know what students must be able to do when finishing this course, and the teacher then aims at lifting the students as individuals to the target level independent on their starting point.

Several teachers have indicated that they have observed the abovementioned challenges, but they also mentioned that they are impressed of the students' practical knowledge in relation to construction. On teacher mentioned "*I contrast to most of our MSc students these CST do in fact know how to build a house.*"

Motivation for enrolment

When directly asked "Why did you enroll to the CST program?" the main answers are illustrated in table 1.

Why did you enroll to the program?	n	in % of N= 43
Own ambition of a master degree	22	51%
Hard to find job in economic down times	19	44%
Obtain management competencies	14	33%
The education looks interesting	11	26%
Differentiation from other when applying for jobs	10	23%

Table 1: Authors' interpretation of respondents' answers. The sum of n is higher than N because each respondent put forward several arguments.

There are three key points to observe. Firstly, more than 50% stated that they had a general quest for continuing their education. This CST program is one of the first, direct and most visible opportunities for professional bachelors with a degree in Architectural Technology and Construction Management. Secondly, the financial crisis is still slowing construction activity down, and therefore, fewer jobs are available. Several of the respondents answered that their first choice was to get a job, and the second choice was to get a master degree. This is confirmed by observations from the teachers, where it is noticed that approximately 20% of newly enrolled students quit the program within the first semester. Many of them due to job opportunities. Thirdly, 33% of the students aimed specifically at increasing their management knowledge. This is very positive, partly because the program was designed to give students construction management competencies, and partly because the construction industry often request labor with enhanced managerial skills.

Students did have different worries before enrolling. 28% of students had concerns about the mathematical level. Students with vocational training often have a low mathematical level, hence a chi-square test on these two binary variables is performed to find the probability of correlation between vocational diploma and concerns of mathematics. The calculation of chi-square, X^2, is 2.437, which with a freedom of 1 give gives a probability, p, for correlation of 0.11. This is not significant. In general students are worried about the overall level of a master degree compared to a professional bachelor degree. 26% expressed exact this worry. Several of the students had to move to a new city. Several of these expressed their concerns in terms of finding a place to live, moving away from girlfriend, find new friends, etc. Hence the social impact of enrolling is quite high. Since this is a new education 14% of the respondents expressed thoughts on how well the education is known by industry when they graduate. University strategy for meeting these worries was threefold. A website and brochures was created to inform about both content and social impact of studying at the university. Contacts to tutors were offered, both physical meetings and email and phone conversations. Finally, two of the teachers from the program were on a road trip visiting all of the Danish professional bachelor schools, hosting information meetings. This effort seems valuable, since 81% of the students found that they had plenty of information available to base their choice of enrolment on. Several of the respondents however comment upon that they found that the program was over sold in terms of management learning and indicates that information regarding the technical and mathematical level was restrained in brochures and at information meetings.

 ISBN: 978-1-84219-840-7 .

Structural, pedagogical and scholarly challenges

Students were asked to respond to their perception of structural, pedagogical and scholarly challenges due to students' transition from professional bachelor to master program. Questions were developed as open end questions, which allowed respondents to elaborate their answers. In the data analysis, answers has been interpreted and grouped into observed tendencies. Most dominant is the students' evaluation of structural aspects of now being a university student. Several of the students respond that they find the auditorium teaching challenging. They were used to have class based teaching with around 20 to 30 students, which they all were familiar to. A large amount of the university courses is conducted in large auditoriums because 50-100 students follow a course. More over there is students at different level from different programs following a single course. A key challenge for many of the students in such an environment is the lack of opportunity to raise questions and discussion technical matters. This one-way teaching with afterwards assignments needs habituation. It also challenges the way these CST students is used to prepare and do homework. Many of the teachers point out that the have a perception of CST students not preparing satisfactory. In some courses this is validated through a very biased exam score. For instance, the average fail rate in project management and economics is around 10%, but for CST students the rate has raised to around 50%. CST students are also astonished of the effort put into written work and assignments, and the need level for passing. This paramount focus on the writing abilities is new for the CST students. Finally, Aalborg University practices problem based group work, and many of these new students have trouble coping with group dynamics. It is new that they themselves have to found groups and also handle conflicts within a group. Some points out that this raises a kind of competition among groups, which is not the intention. Groups should foster mutual sharing of knowledge and resources which is found natural among other MSc students, but seems not to foster among the CST groups. It is also pointed out that several of the respondents find groups to be more isolating. They were used to have 20 to 30 "friends" in a class, now they only have 4 to 5 "friends" in their group.

Combining these three structural challenges several of the respondents rate the study environment as less attractive here at university than at their professional bachelor programs. This is a surprise for the university in general, because Aalborg University often promotes the great study environment (though comparable to other universities). Hence, there is room for easing transfer issues for these CST students, both regards to what the university can expect from prospect students and regards to how to better inform and prepare prospect students prior to enrolment. In general the transition process can be improved. Several helping guidelines were suggested by respondents. The information flow up to and during the beginning of the first semester should be more intense. Even though there is assigned a coordinator to each enrolment class, this seems to be insufficient. Some respondents write that they have a feeling of being misunderstood by "the university system" and that too little effort is put into knowing and understanding the basis that these students bring into the university. A few respondents describe situations among other students and teachers where they have felt condescending comments aimed at their workman background. This is inappropriate and unnecessary. A teacher stated that now after supervising more than 5 CST students during their final thesis he is convinced that these CST students is equal to traditional MSc engineering students, in terms of analytic and academic skills as well as in their ability to foresee new and improved construction management

solutions. In relation to the poor study environment the foundation for improving this lies in transition process.

Academic challenges in general are also commented upon, and a few general trends are observed. Teaching as well as project work is much more theoretical than the main part of the respondents is used to. Now students must know not only know how to do e.g. scheduling, but also why. This forces another challenges of homework. The workload is much higher than what they are used to. When textbook and sometimes classes is in English language some of these CST students find it very hard and time consuming.

Respondents were asked to point out what have been the most challenging in relation to their education. 36% pointed at the course in soil engineering on 1. semester. 20% thought the course in stressed concrete structures, also on 1. Semester, were the toughest. An obvious trend that the 1. Semester in general is the most challenging is evident. The remaining respondents pointed at a variety of courses, and only one respondent did not point out a course, but instead mentioned report writing as the most challenging of the program. As mentioned earlier, teachers have a perception of that student entering through vocational training have more trouble with mathematics than their peers. Correlation between vocational training and pointing out mathematics as the most challenging is calculated with a chi-square test. The calculation of chi-square, X^2, is 8.66, which with a freedom of 1 give gives a probability, p, for correlation of 0.0035. This is significant.

Finally, the academic level was also assessed by the respondents. The assessment should cover all semesters and all courses. 22% answered low, 34% medium and 27% high, and finally 17% very high. This results in a slightly right skew normal distribution.

FUTURE DEVELOPMENT

Due to among others this research some changes has been implemented in the CST program. It is in general the 1. semester that have changed. The course in soil engineering has been eased and given a slightly different focus. Now this course is named Foundations and soil loads. The course in stressed concrete structures is deleted along with the brush up course in applied mathematics. Instead a new course in fundamental statistics and Problem-Based Learning is offered. In total this is lowering the request for mathematical skills and increases the focus on structural changes and conditions for now doing academic work at universities.

CONCLUSION

When concluding on the success of developing a master education that enables holders of apprenticeship certificate, two important elements surfaces. Firstly, only one third of enrolled students have in fact an apprenticeship certificate. Two third enters with an upper secondary education. Secondly, data analysis clearly show that the one third are slightly more satisfied with the education with an average score of 8,25 on a scale from 1 to 10 (best). The lowest score appointed is 7. The remaining two third has an average score of 7,3 ranging from 2 to 10. It is clear that some of these students are in fact disappointed with the education. Now to classes has entered the job market, and this in times where construction activity still is low. Nonetheless, 80% of the first class were in job after 6 months. This is a great success, but still a bit

below average seen over the last 10 years of MScs entering the job market. Hence, it seems that the construction industry not is 'afraid' of the new Cand.Scient.Techn. title.

ACKNOWLEDGEMENT

We would like to acknowledge teachers, colleges, students and graduates participating in surveys and interviews. Without their willingness to evaluate and share, we would not have had any data.

INTEGRATING STUDY ABROAD OPPORTUNITIES INTO A CONSTRUCTION MANAGEMENT CURRICULUM

Scott W. Kramer, Ph.D.[1]

[1]*McWhorter School of Building Science, 118 M. Miller Gorrie Center, Auburn University, 36849, USA*

ABSTRACT

Many universities in the United States have recently emphasized international education as part of their core education mission, recognizing that increasing the global competence among the next generation is a national priority and an academic responsibility. One way to achieve this goal is to implement study abroad education into the construction curriculum. Therefore, in 2001, a few faculty members proposed the unconventional idea of a senior-level Study Abroad Thesis class for the Building Science undergraduate program. This idea became the first faculty-led study abroad class, among the 130 accredited construction programs in the Associated Schools of Construction, that involved an undergraduate research thesis. This class has been offered 10 times since 2002 and students have travelled throughout Western Europe and China as part of the 5-week data gathering component of the class. All students completed their Thesis research and graduated on time or ahead of schedule. Over a dozen student Theses have been co-authored with faculty and published in International conference proceedings or journals.

Keywords: construction education, experiential-learning, service-learning, study abroad,

INTRODUCTION

Evolving world-wide construction markets dictate that American building science students should possess an awareness of the built environment and cultural issues in a more *global* context. One way to achieve this goal is to implement study abroad education into the construction curriculum. Many academic disciplines outside of construction education (e.g. foreign languages, art, music, architecture, etc.) have successfully used study abroad programs as an effective means of broadening university students' academic, personal, professional, and cultural views of the world (NAFSA, 2012; Rebholz, 2000). Therefore, in 2001, a few faculty members proposed the unconventional idea of a senior-level *Study Abroad Thesis* class for the Building Science undergraduate program. This idea became the first faculty-led study abroad class, among the 130 accredited construction programs in the Associated Schools of Construction, that involved an undergraduate research thesis. This class is unique in construction education because of: (1) the multi-city traveling component, (2) the student's written research-based thesis with faculty jury presentation, (3) the required

[1] kramesw@auburn.edu

cultural events, and (4) the implementation of *experiential learning* through student-initiated research visits to foreign design and construction firms. The course design and implementation has evolved during the past 10 years and may be of interest to other construction faculty. Also, two additional study abroad opportunities for building science students will be discussed, along with their respective course design and learning outcomes.

UNDERGRADUATE RESEARCH THESIS CLASS ABROAD

The summer Study Abroad class consists of two parts: (1) a 5-week data gathering component while students travel throughout Western Europe or China, (2) a 5-week in-residence class work component, in Auburn, writing and defending the Thesis. Also, the summer Study Abroad class actually consists of two separate required Building Science (BSCI) classes. The first is the research-based *Study Abroad Thesis* class (4 credits) and the second is the *Temporary Structures in Construction* class (2 credits). By offering these two courses together, the senior students can graduate 1 semester early and complete their required senior capstone project during the 10-week summer semester, rather than the following fall semester as the cohort-based curriculum dictates. Typically the class size is between 10 to 20 students and is usually comprised of undergraduate Thesis students, but often graduate students participate and enroll in electives classes that satisfy their coursework requirements. Auburn University requires that two faculty members travel with the class and all students and faculty maintain medical insurance through MedEX.

Class Itinerary and Preparation

In addition to the summer study abroad class, all students are required to participate in a 2-credit study abroad preparation class offered during the preceding spring semester. The preparation class is designed to be interactive on many levels. The students participate in developing the course itinerary for the summer and select their thesis research topics to compliment the scheduled events in each of the cities visited. During the course itinerary phase, students are responsible for contacting the construction firms, material suppliers, and equipment manufacturers in cities that will support their research topics. Through this process, the itinerary is continuously revised to include construction visits that the students arrange. Other scheduled construction-related visits are arranged by the professor in charge of the class, in addition to arranging the cultural events for each city.

A high priority is placed on relating the students' research topics with the study abroad construction visits. This enables the students to collect data for their thesis research topics (e.g. sustainable design, green construction, project delivery methods, and craft worker training) as part of the visit (see Figure 1).

Sustainable Design, Shanghai

Study Abroad Cost

In an effort to promote study abroad at Auburn University, new administration guidelines concerning faculty-led classes have allowed the Building Science program costs to be much more attractive to prospective students. Effective 1/1/04, Auburn University students **DO NOT** have to pay university tuition in addition to the study abroad program costs. The students are required to pay only the $540 Office of International Programs fee, in addition to the direct costs of the study abroad class. This new policy helps defray the cost of the class for in-state students, but for out-of-state students paying triple in-state tuition, the cost of the study abroad class is typically the same as staying in Auburn, Alabama.

Learning Objectives and Class Organization

The overall learning objective of the class is *to expose students to construction-specific companies, projects, practices, and project management professionals that they would never be exposed to otherwise*. There are typically three construction-related visits per city (e.g. construction projects, material suppliers, construction firms, equipment manufacturers, etc.). Some of the past visits include: marble quarries in Carrara, Italy, concrete pump manufacturers in southern Germany, curtainwall manufacturers in Munich, renovation of the U.S. embassy in Rome, and renovation of the War Cabinet Rooms in London (see Figure 2).

Figure 2.

London – Skanska project

London – Bovis Lend Lease project

Students with U.K. War Cabinet Secretary – Bovis Lend Lease

Putzmeister PUMI, concrete ready mix truck & pump combined, Munich

The students collect original source documents (e.g. transcribed interviews with key executives, photos, company brochures, company training material, videos of visits, etc.) during the 5-week traveling half of the 10-week summer semester. Also, there is typically one cultural event per city (e.g. ballet, opera, concert, musical, etc.).

After returning from Europe or China, the second 5 weeks of the summer semester is dedicated to organizing and synthesizing the data acquired while travelling and writing the research Thesis. Students are required to write an original research paper, using the ASC Journal style guidelines (ASC, 2012), in the range of 40 – 60 pages excluding copies of original source documents, appendices, and references. In addition, the students are required to create a 30-minute PowerPoint presentation that

is presented and defended to a jury of Building Science faculty. The student's grade is typically based 75% on the written paper and 25% on the PowerPoint presentation.

Travel Blogs

In recent years, family members and friends have been concerned about staying in touch and following the groups' travels abroad during the summer semester. While email and cell phones are an important way of staying in touch, it does not offer a shared discussion environment that would serve as a travel journal or blog for the students' experiences. After exploring options of web blogs, travel blogs, newsgroups and Wikis, a WebCT™ (WebCT, 2004) site was developed in 2004 and other travel blogs have been used since 2008. See www.aubsci.org (Europe) and www.bsci2012sadu.blogspot.com (Australia/New Zealand) as examples of recent class blogs for 2012.

Students are typically assigned the task of posting a thoughtful and substantive reflection of some aspect of their visit to each city. They are also required to post a response to a classmate's posting for each city. These reflections are accompanied by digital photos uploaded and attached to the discussion posting. This provides for an online exchange of concepts learned among faculty and students while traveling, which is also shared with others back home.

Faculty Involvement

In order to ensure the future success of the class, in 2003 Professor Kramer developed a mentoring program where he acted as the lead-faculty mentor and Professor Hein was the faculty-in-training. This allowed Professor Hein to gain knowledge of the study abroad planning aspects and understand the academic requirements for the thesis research. During the summer 2005 class, Professor Hein graduated to faculty mentor and Professor Murphy was the faculty-in-training. This mentoring process has been very successful and has allowed different Building Science faculty to participate in the study abroad thesis class and to ensure its continuation (see Table 1).

SHORT TERM SERVICE-LEARNING CLASS ABROAD

As the Chinese proverb explains, "I hear and I forget. I see and I remember. I do and I understand" (Stewart et al., 1994). Service-learning favors *engagement* over *exposure* in order to make the trip a more rich experience instead of a nondescript field trip. It helps students retain the knowledge garnered from the educational investment (Tinker and Tramel, 2002). Service-learning trips are an opportunity for students who are inexperienced in the field to gain much-needed hands-on practice in a low pressure situation (Stewart et al., 1994). In addition, successfully using their skills to provide for an immediate need bolsters students' self-perception of their capability (Layer and Gwaltney, 2009).

The experience also enhances students' ability to communicate effectively — particularly with the client who is at hand in most service-learning situations (Aidoo and Sexton, 2008). Researchers at one institution noted that they had not anticipated the outcome of a strong camaraderie and collaboration as a result of the trip. Students developed their leadership and teamwork abilities and were able to synthesize information and solve problems with their peers (Stewart et al., 1994). Finally, service-learning trips foster a unique dynamic between faculty and students that typically does not occur in a traditional classroom setting. Working alongside one another, students develop a greater respect for professors and professors a friendship with the students (Tinker and Tramel, 2002).

Quito, Ecuador – Collaboration between SIFAT, Building Science and Nursing

Building on the school's previous study abroad experiences, two Building Science (BSCI) faculty members planned and implemented a 10-day service-learning trip to Quito, Ecuador during the spring semesters of 2010 and 2012. They offered the trip in hopes that it would appeal to students who would not have otherwise been able to study abroad. In order to minimize a common barrier to study abroad participation – cost, they limited the fee to $2,200 and traveled during Spring Break. Class credit was not offered in 2010, but in 2012 the trip was included in a required 2-credit BSCI class, *Temporary Structures in Construction*.

The 2010 group of 6 students and 2 faculty, consisted of undergraduate and graduate students from the McWhorter School of Building Science as well as 17 senior-level School of Nursing (SON) students and 4 nursing faculty. The nursing students set up a temporary women's clinic as part of their required 120-hour preceptorship class. In 2012, there were 8 BSCI students and 12 SON students plus 2 BSCI faculty and 3 SON faculty.

Both collaborative trips were coordinated through Servants in Faith and Appropriate Technology (SIFAT) a non-profit organization headquartered in Lineville, Alabama. SIFAT is a faith-based group that promotes holistic development in South America and Africa. They maintain offices and full-time staff of nationals in both Bolivia and Ecuador and seek to support sustainable self-help among needy populations.

Class Construction Project

The BSCI students worked on an on-going construction project called Dulce Refúgio, an after school care center for underprivileged children. The project will be built in two phases over the course of several years as funds and volunteer labor become available. The first phase involves the construction of a 4-story, 30,000-sf children's center which is being built on an urban site adjacent to an existing church building. The concrete structure will serve approximately 300 children. The second phase calls for the eventual demolition and re-construction of the church building.

The BSCI students and faculty members worked Monday – Friday, 8:00 am – 4:00 pm at the construction site. During this time, they formed and placed a grade beam (Figure 3) and four round columns (Figure 4). The group practiced many means and methods foreign to the students which included building round column forms from scrap tongue-and-grove floor boards (Figure 5), hand tying all rebar cages, and mixing concrete by hand directly on a flat concrete slab (Figure 6) with shovels. The team had the opportunity to work alongside the Ecuadorian nationals. Two craftsmen, an engineer, and the pastor of the church directed the construction process, and though they were initially skeptical of the North Americans' ability, they formed strong working relationships of mutual respect by the end of the week.

Figure 3: Grade Beam

Figure 4: Column Rebar

Figure 5: Column Forms

Figure 6: Mixing Concrete

Exhausted from the laborious tasks and the extreme altitude (9,500 ft.), the BSCI team typically ended their day late in the afternoon and embarked on numerous cultural excursions throughout the city. Students had the opportunity to stand on the equator at the *Middle of the Earth* and to climb the highest spires of the Basilica del Voto Nacional which has been under construction for 123 years. The group also rode the Teleferico, a gondola which transverses 3,000 feet to an altitude of 13,000 feet above sea level and offers an unparalleled view of the city. For another side trip, students traveled to a nearby rainforest for a zip-line ecology tour. Additionally, they experienced Ecuadorian culture by touring various open air markets, local hardware stores, and eating traditional Ecuadorian dishes. Perhaps the most rewarding experience, however, was interacting with the center's children in a North Americans vs. South Americans soccer match, which the children won handedly. All of the

activities provided invaluable insight to the lives of the construction project's future occupants and owners.

STUDENT EXCHANGE SEMESTER ABROAD

Even though the McWhorter School of Building Science has been a leader among the Associated Schools of Construction (ASC) in the area of faculty-led study abroad classes, the school does not currently have any semester-length student exchange programs with universities outside the United States. This deficiency will soon be corrected with the establishment of an exchange program between Auburn University and Hong Kong Polytechnic University.

This study abroad student exchange program will be designed to explore the built environment in Hong Kong and other Asian cities. Students will be exposed to some of the world's most modern and advanced works of Architecture, Engineering and Construction. Our aim is to allow Building Science (BSCI) students to study, in an academic residence, a variety of construction materials, methods, and technologies commonly used in Asia within the cultural context of living and studying in Hong Kong. This program will be offered once every year starting in 2014. The duration of the student exchange program will be one semester, preferably spring semester January – May and the target date for implementation is scheduled for spring, 2014.

BSCI students are accepted into the professional program as a cohort of 30 students at the beginning of their junior year of study (5th semester). Each semester, (Summer, Fall, Spring) only 30 students are admitted into the program. However, a double section of 30 students (60 total) are admitted into the spring semester every year. Therefore, the optimal time for BSCI students to study in residence at Hong Kong Polytechnic University (HK Poly) will be the 7th semester of their plan of study. The initial exchange program will be marketed to the 60-student spring semester cohort class. In this way, the students' 7th semester of study (shown in Table 2) will be a spring semester which aligns with the academic calendar of HK Poly.

Table 2.
